We note further, that out of the 100 illustrative cases, as presented by Dr. Roosa, 45 had hypermetropia of 1 D., 39 of 2 D., and 7 over 2 D., while relatively few had astigmatism of low degree (.25 D.—.50 D.), while in only four cases did the astigmatism reach 1 D. or over, which present just the class of cases that are capable of performing ordinary eye work without appreciable difficulty. Now, would the writer of the editorial, if he found a patient with a perceptible degree of ametropia, even though he experienced no difficulty, consider it good form to tell him to wait until his eyes bothered him before resorting to a glass? We infer that such would be his advice. But in view of the light that modern research has thrown upon the principles of physiologic optics, as first scientifically established by Donders, are we justified in ignoring scientific facts and basing our advice upon empiricism? The finger of scorn has been pointed at medicine sufficiently long to impress us with the urgency of resorting to scientific principles whenever applicable, and if there is in all medicine a department more worthy of the term science than ophthalmology, we are at a loss to appreciate it. Exact work in this line may be justly dated from the invention of the ophthalmoscope by Helmholtz in 1851, and we have but to glance at the ophthalmologic literature of to-day to demonstrate that its strides have been phenomenal as well as productive of great good—surgery, alone, in all her modern phases vying with ophthalmology. Yet your correspondent with one fell swoop would obliterate all of the modern teachings of ophthalmology. And again, does your correspondent believe for an instant that a highly ametropic eye can without correction of the existing error perform the same amount of eye work that the normal or emmetropic eye is capable of performing without disastrous effects? If so, we would invite his attention to the results of pathologic investigation, showing as it has such a difference in the character and arrangement of the ciliary muscular fibers, in eyes possessing different types of refractive error, as well as to the apparent intimate connection between the refractive state of the eye and glaucomatous changes.

In conclusion, we desire to array ourselves upon the side of ophthalmologic teaching, which advises the application of a glass timely enough to militate against the establishment of pronounced nervous impressions known to be sequelæ of uncorrected eyestrain consequent upon uncorrected refractive errors, and we believe in all cases of refractive error of moderate and high degrees in applying the requisite correction, whether it takes a cylinder of high or low degree, and can but point to our cases which show benefit in all instances, and we do not feel that by so doing we are losing sight of the fact that the eye is part and parcel of the general economy.

Very respectfully,

JAMES A. LYDSTON, PH. G. M.D.

"Superfluous Glasses."

BURLINGTON, IOWA, Feb. 13, 1894.

To the Editor:—At the meeting of the Iowa State Medical Society held in this city last May, I had the privilege of reading a paper entitled: "The Broader View of the Etiology and Therapeutics of Asthenopia." In this paper I took the ground that we were undoubtedly expecting too much from spectacles as a means of relief. My position was strongly

indorsed by Dr. C. M. Hobby at that time in the discussion which followed; and is again set forth by him in his letter in connection with your remarks under the above caption.

A serious obstacle in the way of reform or greater conservatism may be found, however, in the ideas which patients before seeking medical advice, have obtained upon the subject through reading (or hearing) about the wonderful cures of obstinate headaches and other maladies by the wearing of properly selected spectacles. They almost demand spectacles.

It is hardly possible to prevent, or even exercise censorship upon, the appearance of medical articles in the public prints; but if medical journals would sift exaggerations more carefully from the articles of enthusiasts in the profession, it might be spared some reproach.

Truly yours, H. B. YOUNG.

Fluid Drinks in Laparotomy Cases.

YOUNGSTOWN, OHIO, Feb. 13, 1894.

To the Editor:—I have just finished reading the excellent article entitled, "Fluid Drinks after Laparotomy," by F. Byron Robinson, in current issue of the JOURNAL.

Although I agree with him, that fluids are called for by the system with a special intensity after laparotomy; and that the patient is in the same condition as Tantalus, with even a greater burden to bear—that of a surgical condition is superadded; yet I think we can supply the fluid to the system in a better manner than by giving it by the mouth and stomach.

For some time I have been conducting experiments upon myself, regarding the absorption and elimination of water from the bowel.

We all know that a large enema, by distending the bowel will bring on increased peristalsis, and thus cause it to be expelled within a few moments. I have found by experimenting upon my patients and myself that if a small quantity, say eight ounces, be thrown into the bowel, it will not be expelled, but will be absorbed and eliminated through the kidneys. Not only this, but it seems to so stimulate the kidneys that not only the quantity thrown into the bowel, but a much increased amount is eliminated.

To-day at 12 M. I used in this manner eight ounces of water, and rested in a reclining position half an hour. At 2, 3:30 and 5 P.M., I urinated freely, the total amount being thirty ounces. This without any variation in my ordinary food supply, and no diuretics. Yesterday, kidneys acted in the usual manner, and I expect the same conditions to-morrow unless I repeat the experiment. I have tortured my patients just as Dr. Robinson says Tait does. I also have given fluids by the mouth, but more often with bad than good results.

Since using the above method, I have never heard the cry: "Water, water! For God's sake give me water!" so often heard by all operators who give no fluids. I usually have the nurse give an enema of eight ounces of water as soon as patient asks for a drink, and that ends the trouble for some time. In the course of an hour or so, the kidneys act freely, also the skin, thus eliminating from the system the effects of the anesthetic, and the effete matters of the blood. By this method a large quantity of water may be restored to the circulation at once, thus replacing the amount removed by depleting salines.

Although it is a supposed physiologic fact, that the seat of thirst is in the throat, yet I know by experience and expressions of gratitude from patients that the sensation of thirst is fully and freely gratified. I do not know that I ever saw this subject brought out in journals or text-books, and although I may have seen the idea at some time elsewhere, I think it worthy of consideration.

Very respectfully, J. A. DICKSON.

The Hyposulphites in Infectious Diseases.

NEW ORLEANS, LA., Feb. 12, 1894.

To the Editor:—My article upon the value of the sulphites and hyposulphites in the treatment of zymotic diseases, pub-

lished in the JOURNAL of February 3, has already elicited testimony of their value in the treatment of yellow fever, scarlet fever and diphtheria, as will be shown by the letters of Dr. T. O. Summers of Waukesha, Wis., and Dr. Elisha Cheney of Boston, Mass.

I shall take pleasure in sending you for our valuable JOURNAL, dear Doctor, from time to time, any additional testimony which I may receive upon this important subject.

With great respect and high esteem, I remain, truly your friend,

JOSEPH JONES, M.D., LL.D.
Professor of Chemistry and Medical Jurisprudence, Tulane University of Louisiana.

WAUKESHA, WIS., Feb. 4, 1894.

Dr. Joseph Jones, New Orleans, La.

Dear Sir:—I confess to no little ebagrín, as well as surprise, at your statement in a paper on the value of the hyposulphites, that you had "no facts with which to prove" the efficacy of their use in yellow fever, and your regret that your suggestion of their use was not put to the test in the late epidemic at Brunswick. No doubt you have forgotten that in 1879, after the terrible epidemic in Memphis, I called upon you and laid before you for inspection my little work on yellow fever just then issued in which, in the chapters on prophylaxis and treatment, the use of the hyposulphites was strenuously advocated and supported by the report of hundreds of cases. This was also confirmed by my work in 1888 in Jacksonville, and extensively reported at that time. When I wrote the work on yellow fever I was Professor of Anatomy in the Vanderbilt University of Nashville, where you once held the chair of Physiology, and for this reason I thought it strange that you should have so completely ignored my work. Respectfully,

T. O. SUMMERS, M.D.

BOSTON, Feb. 5, 1894.

Joseph Jones, M.D., LL.D.:

Dear Sir:—I have just received the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of February 3, containing your article on the sulphites and hyposulphites of sodium in relation to some of the zymotic diseases. I was to lecture to-day on diphtheria and had only a moment to run over your points, and so was not so prepared to use your statements as I should have gladly done.

I saw Professor Polli's statement as early as 1862 or '3, I think, and began the use of the hyposulphite of sodium as early as 1863 in diphtheria. I had an urgent case in an only daughter who was scrofulous, her tonsils quite meeting together. I was at my wits' end for a remedy and resolved to try the bisulphite and sent for it but could not obtain it. The apothecary, however, sent me the hyposulphite, saying that he thought I could use it. I did so and saved my frantically delirious little girl.

Now if you can get at the files of the *Boston Medical and Surgical Journal* for June 8, 1876, you will find an article I wrote which I think will interest you. It is on page 657 and is entitled: "Diphtheria Successfully Treated."

There are some cases it does not appear to act so well in, and I suspect it may be owing to too old hyposulphite which has changed to the sulphate, or to the lack of stomach action on it to eliminate its sulphurous acid. I wish you could make some experiments to determine these points.

While isolation is a sure preventive, I regard the use of the hyposulphite invaluable in cases which can not be isolated.

I have used the medicine also in scarlet fever with remarkable success. In one family of two children one came down with scarlet fever and the other took the hyposulphite and escaped the disease. I have used it in the early stage of typhoid fever and thought it very useful in mitigating the disease. In some cases of small children I have relied

almost wholly on the salt and do not swab their throats. I think the medicine should be given pretty strong and frequently, moderating treatment in both respects if the bowels are much affected. During the course of the case or afterwards, iron and the bitter tonics should be given.

Now it has never occurred to me to have a case where I began early, where the patch afterward traveled into the larynx. It seems to me that the vigorous early treatment with the hyposulphite is as near a specific for both diphtheria and scarlet fever as we have yet found. I hope you will be able to produce more evidence in its favor, and you are at liberty to use this communication any way you see fit.

I hope the profession will soon be able to discriminate between diphtheria and its sequela, the septicemia. They run so closely into each other most physicians are still regarding the latter as a real part of the former. I do not so consider them and believe if we properly treat and timely treat diphtheria we shall save from the latter and so save the patients. I think few cases treated energetically at first with the hyposulphite will ever be followed by paralysis. The hyposulphite has done so well for me I have not been disposed to try the other forms. Since that article my experience has confirmed my former confidence in the medicine. I think I was the first one to use it in these cases.

Very truly, E. CHENERY.

Care of the Vaccinated.

MT. PLEASANT, IOWA, Feb. 16, 1894.

To the Editor:—Smallpox being now so prevalent and vaccination the order of the day, may it not be well to consider at this time a seemingly little matter in connection with the latter subject? Those vaccinated go about and mingle freely with others in the usual way. The latter do not know the former are vaccinated, and subject them to roughness which they would not do if they knew they had a vaccine spot on their arm or body. They seize them, grasp or stroke them at this very spot, ignorant of the damage they are doing, and having no means of knowing it until the person cries out, and then the pain and damage has been done—most frequently, perhaps, among school children and other young persons.

Something to distinguish and forewarn, and protect the vaccinated person from this pain and unpleasantness, and the spot from damage, should be adopted; something to be universally understood as indicating the person, and spot of vaccination. For instance, a band of colored cloth or a square piece of the same sewed on the sleeve of the coat or dress, or other index to be adopted by common consent. This would keep off many strokes and pinches which, besides the discomfort to the patient, disturb the inflammatory processes and proper formation of the pustules, and invite other results such as ulceration and sloughing where otherwise a possible good result might have been reached.

Thus might also be avoided the occurrence of doubt as to the value of the vaccination, and expense and other adverse contingencies of a renewal of the vaccination.

Very truly, H. L. GREEN.

Johns Hopkins Hospital Reports.

KASOTA, MINN., Feb. 17, 1894.

To the Editor:—I see in Book Notices of JOURNAL of February 17, the notice of the Johns Hopkins Hospital Reports, but it does not state the name of the publishers.

If published by the JOURNAL send it to me with bill, or kindly inform me where it is published.

Yours respectfully, W. R. HAND.

The book is published by the Johns Hopkins University. Please address them direct.—[EDITOR.]

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Denver & Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville,

Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland, thence east by way of the Northern Pacific R. R. to St. Paul. A stop over at Yellowstone National Park for those who desire it has been arranged, and it is understood that at several places on the journey there will be short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentration on this train should be effected at Chicago and St. Louis.

Section of Neurology and Medical Jurisprudence, American Medical Association.—The AMERICAN MEDICAL ASSOCIATION will meet at San Francisco, Cal., during the first week in June, 1894, and as it is desired to make the meeting of the Section on Neurology and Medical Jurisprudence of the ASSOCIATION one of unusual interest and value, you are earnestly requested to contribute to this end by the presentation of a written communication on some neurologic or medico-legal subject, or by bringing for exhibition and discussion anatomic or pathologic specimens.

If you have not yet chosen a subject, but are willing to take part in the work of the Section, please notify the Secretary at once of this intention, and as soon as possible forward the title of your contribution. It will facilitate the work of the Section to send an outline of your paper. A preliminary program will be published during March.

FRANK P. NORBURY, Secretary,
Jacksonville, Ill.

Officers of the Section.—James G. Kiernan, M.D., Chairman, 910, 103 State Street, Chicago, Ill.; Frank P. Norbury, M.D., Secretary, Jacksonville, Ill.

Executive Committee.—O. Everts, M.D., Cincinnati, Ohio; H. N. Moyer, M.D., Chicago, Ill.; C. K. Mills, M.D., Philadelphia, Pa.

SOCIETY NEWS.

Bucks County, Pa., Medical Society.—The Bucks County Medical Society held its midwinter meeting in Quakertown on January 31. Dr. Estes, Surgeon-in-Chief of St. Luke's Hospital, Bethlehem, addressed the meeting.

The Tri-State Medical Society of Iowa, Illinois and Missouri, will meet at Kansas City, April 3 and 4. All reputable members of the medical profession in the three States are eligible to membership, and are cordially invited to be present and participate in the deliberations.

Grand Rapids Academy of Medicine.—At the annual meeting of the Grand Rapids Academy of Medicine of Michigan, held in Grand Rapids Feb 5, 1894, the following named officers were chosen to serve the ensuing year: President, Austin J. Pressey, M.D.; Vice-President, Frances A. Rutherford, M.D.; Secretary, Louis A. Roller, M.D.; Treasurer, Samuel R. Wooster, M.D.

The Fiftieth Anniversary of the Lancaster County, (Pa.), Medical Society.—The proceedings of the fiftieth annual meeting of the Medical Society of the city and county of Lancaster. This was an occasion of more than ordinary interest, owing to various causes, one of them being the fact that it is the oldest in the United States, with the exception of four in cities on the Atlantic sea-board. Another interesting fact is that John L. Atlee and D. Hayes Agnew, names which have shed as much luster on American medicine as any that have adorned the profession, were among its founders. The only one of the founders present at this meeting was the venerable J. Augustus Ehler.

The writer knew nearly all of the original members and for many of them entertained the highest veneration and respect. The present membership worthily sustains the reputation of its founders, the Society being one of the most active in the State of Pennsylvania and taking a deep inter-

est in upholding the dignity and honor and promoting the advancement of the profession. The memorial address of Dr. Ziegler was interesting, well-timed and appropriate. The banquet was well attended, and with the menu and the speeches together proved a very enjoyable affair.

Those outside of Lancaster County are: Drs. Judson Deland, W. W. Keen, John H. Packard, James Wallace, Joseph Price, W. B. Atkinson, A. R. Craig, T. S. K. Morton, A. K. Minnich, William Zeigler, Samuel Latta, John H. Musser, B. F. Bear, Mordecai Price, De Forrest Willard, B. A. Randall, Clinton Foltz, and Profs. C. K. Mills, Hobart A. Hare of Philadelphia; Dr. J. W. C. O'Neal, Gettysburg; Drs. Wm. Bacon, Fry, Gotwald, Rense, Gable and Wentz, York; Dr. H. H. Whitcombe, Norristown; Dr. Detwiler, Williamsport; Dr. Alrich, Chester; Dr. Putt, Harrisburg; Dr. Guilford, Lebanon; Prof. John H. Rauch, Chicago.

At 1:30 o'clock February 14, a business meeting of the Medical Society was held at Grand Army Hall, Dr. Oliver Roland presiding, and here was read the history of the Society by Dr. J. L. Ziegler of Mt. Joy. After the transaction of some general business the members of the Society and their guests repaired to Martin's Hall, where a dinner was served. The tables were arranged in a manner to foster sociability by bringing the guests as close together as possible, three wings shooting off from one long table, one at either end and the third wing in the middle. The decorations of the table were superb, ninety covers being laid.

Dr. Alex Craig of Columbia, presided over the table as Toast Master, and the following were the toasts responded to: "Our Guests," Dr. Hobart A. Hare, Philadelphia; "Origin of Our Society," Dr. J. Aug. Ehler; "Medical Organization," Dr. W. B. Atkinson, Philadelphia; "Medical Education," Prof. John H. Rauch, Chicago; "Offspring of Lancaster County Abroad," Dr. John H. Musser, Philadelphia; "The Press," Robert B. Risk, Lancaster.

The committee having in charge the arrangements of the jubilee was composed of Drs. George R. Welchans, Geo. R. Rohrer, M. L. Davis, Lancaster; Dr. A. M. Miller, Bird-in-Hand, and Dr. J. R. Leaman, Mountville. They did their work well, and their efforts were attended by a degree of success that can not but be highly gratifying to the members of the Society. We will print Dr. Ziegler's very interesting address in an early issue.

BOOK NOTICES.

Announcement. Messrs. J. B. LIPPINCOTT & Co., of Philadelphia, announce the seventeenth edition of the United States Dispensatory as in the bindery. The work will be ready for delivery in a few days.

The Physician's Wife; and the Things that Pertain to Her Life. By ELLEN M. FIREBAUGH. With portrait of author and 44 photo engravings of original sketches. In one crown octavo volume of 200 pages. Extra cloth, \$1.25 net. Special limited edition, first 500 copies, numbered, and printed in photogravure ink on extra fine enameled paper; bound in half-leather and vellum cloth, \$3.00 net. Philadelphia: The F. A. Davis Co., Publishers, 1914 and 1916 Cherry Street.

This little book is the outcome of a paper on the "Physician's Wife," read by the authoress, by invitation, before the Esculapian Society of the Wabash Valley at its meeting held in October, 1893. She subsequently enlarged the paper, and this book is the result.

A Treatise on Headache and Neuralgia, including Spinal Irritation and a Disquisition on Normal and Morbid Sleep. By J. LEONARD CORNING, M.A., M.D., Consultant in Nervous Diseases to St. Francis Hospital, New York. With an appendix. Eye Strain a Cause of Headache. By DAVID WEBSTER, M.D. Illustrated. Third edition. Pp. 275. New York: E. B. Treat. 1894. Price, \$2.75.

This book is a good companion to the work on "Neurasthenia" by the late Dr. Geo. M. Beard and published by the same house, and is worthy of the very favorable reception it has heretofore received at the hands of the profession. In this edition the author has added a chapter on the "Localization of the Action of Remedies upon the Brain," Dr. Webster confines his remarks "to those headaches which are dependent upon: 1, errors of refraction; 2, impaired accom-

modation; and 3, insufficiency of the extrinsic ocular muscles."

A Practical Treatise on the Diseases of the Hair and Scalp. By GEORGE THOMAS JACKSON, M.D., Professor of Dermatology, Woman's Medical College, New York, Infirmary, etc. New, revised and enlarged edition. Pp. 414. New York: E. B. Treat. 1894. Price, \$2.75.

The first edition of this book appeared in 1887, and the studies that have been made since that time have made a new edition necessary. The bibliography has been brought down to January, 1893. The work is divided in four parts. Part 1 treats of the anatomy, physiology and hygiene of the hair; part 2 of the essential diseases of the hair, which includes grayness and other changes in color, alopecia, alopecia areata, atrophia pilorum propria, hypertrophia pilorum, trichitasis and distichiasis, and sycosis; part 3 treats of the parasitic diseases of the hair, and contains seven chapters; part 4 treats of diseases of the hair secondary to diseases of the skin, and also contains seven chapters, and the work concludes with an appendix giving the bibliography and journal literature of the subject from 1860 to 1893.

MISCELLANY.

Indian Medical Congress.—The proposal to hold an Indian Medical Congress has, it appears, every prospect of being realized. It seems to be generally agreed that Calcutta will be the most suitable place for the first meeting, and another element which augurs well for the success of the scheme is the warm interest taken in it by Surgeon Colonel R. Harvey, Inspector General of Civil Hospitals, Bengal.—*British Medical Journal*.

A Deceitful Dutch Doctor.—The old cry that the Dutch have taken Holland, was repeated in Chicago last week when a "Dr." Van Noppen began to receive Dutch diplomas in response to the following which, according to the daily press, appeared in excellent Dutch in certain Holland papers:

WANTED.—A physician who has graduated from a Holland medical college to locate in Pennsylvania, U. S. A. Free transportation will be furnished, free house and stable rent, and an income of \$5,000 per annum guaranteed by the Government. In answering please send your diploma. Mr. Zuidema, No. 190 Ferdinand Street, Chicago, Illinois, U. S. A.

The Netherlands Consul, according to an interview published in the *Tribune* of the 17th, said:

"Yes, unfortunately, it is true. Thirty answers, in round numbers, have been received up to date, and more are coming every day. Only yesterday one physician sent a cablegram which must have cost at least \$20. Most of these letters contain all the papers which give the sender a right to practice medicine, and in many instances they could not be replaced should they have been lost. I am returning them as rapidly as possible, with an explanation which will probably make them more careful about parting with these documents in the future."

This is one of the worst swindles that has been perpetrated for many a day. It is supposed that Van Noppen wished to sell the diplomas, but his exact purpose is as yet shrouded in mystery, as he has not been prosecuted. It is quite probable that if the aforesaid Van Noppen should be caught in Holland, he would be dropped over a dyke and drowned in a ditch.

"Antipyrin," is manufactured exclusively under the Knorr patents by the Farbwerke at Hoechst. It is estimated that not less than seventy-five tons of this preparation are manufactured and sold annually, representing, according to one authority, a value of \$1,452,000, the greater part of which is clear profit.—*U. S. Consular Reports*.

House-to-House Inspection.—The Health Officer of Chicago has been urged to have a house-to-house inspection of the houses in Chicago to find out if possible, the number of cases of smallpox actually in the city at the present time. The disease is steadily, but slowly, being diffused throughout the city.

Actinomycosis.—The Chicago *Inter-Ocean* has started a crusade against meat dealers who kill "lumpy-jaw" cattle. Alderman Campbell introduced the following order at the City Council, February 19, which was passed by a unanimous vote:

Whereas, It is charged by the press that many thousand lumpy-jaw cattle are slaughtered yearly at the Stock Yards and placed upon the market for food, therefore be it

Ordered, that the Corporation Counsel be and he is hereby directed to prepare and present to this Council an ordinance providing for the killing by shooting of all lumpy-jaw cattle in the yards and turning them over to the Union Rendering Company.

The Late Professor Billroth.—Sir William MacCormac in the *British Medical Journal* for February 10, thus gives a personal reminiscence of the lamented Billroth:

"Few men more than Professor Billroth could inspire one with a greater sense of combined power and modesty. In manner and appearance he was most winning and sympathetic. His pupils and friends alike admired and loved him. I met him after the war in 1870-71, when he had already left Switzerland for Vienna, and several times in company with Langenbeck, his former master and fast friend. At that time it was thought by some in Vienna that he was still German in feeling, and would return sooner or later to take Langenbeck's succession; but this was not so, and he became in all his work and sympathy completely identified with the people among whom he lived. He was prominent amongst all his contemporaries in Austria, and sent his pupils to fill the chairs of surgery, not in the Austrian universities alone, but, as in the case of Czerny and others, to many German universities as well.

As an operator his knowledge and boldness were only equalled by his brilliant execution and skill; and what he did and the reasons for doing it were explained to his overflowing class with a rare talent for exposition. His patients, attracted by his great fame, came from very distant parts—not rich only, but poor also, to fill his hospital beds. He loved his science and art, but he also loved other arts as well, and painting and music were his favorites, while the great masters of both were amongst his most intimate friends.

One personal reminiscence may be interesting as showing his princely hospitality. During the great International Exhibition in Vienna he entertained a party of about one hundred military and civil surgeons who had come to attend a conference on the subject of medical aid in time of war, at a banquet at Vöslan, a well-known suburban resort of the Viennese. There were the choicest wines, from the Imperial Tokay downwards; native oysters from Colchester; sturgeon from the Volga and, last and best, Strauss' band. I shall not easily forget the magical effect produced when, after dinner, Johann Strauss, one of Billroth's great friends, mounted the orchestra and, waving his baton, the band played the "Beautiful Blue Danube." The music was beautiful before, but it seemed transformed when Strauss led it. Immediately afterwards Billroth gave the only toast proposed on this memorable occasion. He said: "*Ein Oestericher grüsse ich Sie, in Oesterich, mit Oesterich.*" The response did not want in enthusiasm. This dinner took place in a restaurant on the slope of a vine-clad hill covered with ripening grapes, which were to make wine such as we were drinking.

Our journey to this beautiful spot was by special train composed of carriages fitted up for the transport of wounded during war, a lazarette train, with everything of the most complete description for the purpose in view. It was, in fact, a large hospital on wheels.

Hospital Notes.

New Emergency Hospital.—South Omaha organized an Emergency Hospital Association February 12.

Hospital Fire.—The New Mercy Hospital on Prairie Avenue near Twenty-sixth Street, Chicago, was slightly damaged by fire February 16.

St. Joseph's Hospital, in Kansas City, has just completed an addition containing one hundred beds for surgical cases, with every modern facility, including a new laparotomy room with the finest equipment.

Must be Enlarged.—The pressure for admission to the New Lowell, Mass., General Hospital was so great that at a meeting of the Hospital authorities February 10, it was decided

to take up the question of enlargement as soon as practicable.

Deaconess' Hospital.—The Deaconess' Society of Dayton, Ohio, held their annual meeting January 23. The following officers of the Hospital were elected: President, Capt. A. A. Simonds; Vice-President, Rev. H. J. Colby, D.D.; Recording Secretary, Rev. Benj. S. Stern; Corresponding Secretary, Rev. R. T. Wegener; Financial Secretary and Treasurer, Louis H. Pook, Esq. Rev. C. Mueller is the Superintendent. The completion of the new building is being urged as much as possible, but more money will be needed to pay the entire cost.

Altoona, Pa., Hospital.—The annual meeting of the Altoona, Pa., Hospital was held February 7. Mr. McKiernan was chosen chairman and made a brief address. Messrs. W. J. Denning, W. W. Murray and L. R. Levan were sworn as judges of election, and the following gentlemen were elected trustees without opposition: John P. Levan, John M. Wallis, George W. Stratton, H. J. Cornman, H. C. Dern, David K. Ramey, F. L. Sheppard, A. J. Anderson, William Stoke, Benjamin F. Custer, William Murray, Theodore H. Wigton, Albert F. Heess.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from February 10, 1894, to February 16, 1894.

Capt. REUBEN L. ROBERTSON, Asst. Surgeon U. S. A., is granted leave of absence for one month, with permission to apply for an extension of one month.

Col. JOSEPH R. SMITH, Asst. Surgeon General, is granted leave of absence for one month and ten days, to take effect upon the adjournment of the Eleventh International Medical Congress, to be held at Rome, Italy, March 29 to April 5, 1894.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending February 17, 1894.

Surgeon A. F. PRICE, ordered to the torpedo station, Newport, R. I. Surgeon H. E. AMES, detached from torpedo station, and to the "Richmond."

Asst. Surgeon M. W. BARNUM, ordered to temporary duty on the "Ranger."

Asst. Surgeon M. W. BARNUM, upon the reporting of relief, detached from the "Ranger," ordered home and wait orders.

P. A. Surgeon G. T. SMITH, detached from Naval Hospital, Chelsea, and ordered to the "Ranger."

Asst. Surgeon M. R. PIGOTT, detached from the "Richmond," and to Naval Hospital, Chelsea.

P. A. Surgeon T. B. BAYLEY, detached from the "Machias," and to the "Richmond."

P. A. Surgeon JAS. F. KEENEY, died on board the U. S. S. "Anger," Feb. 10, 1894.

CHICAGO, MARCH 3, 1894.

No. 9.

ADDRESSES.

HISTORICAL ADDRESS.

Read before the Lancaster City and County Medical Society, on the occasion of the celebration of its semi-centennial, Feb. 14, 1894.

BY J. L. ZIEGLER, A.M., M.D.

MOUNT JOY, PA.

Time—noiseless, ceaseless, swift-winged time, has brought us to the fiftieth anniversary of our existence as a Society. It seems but yesterday that the venerable Dr. Samuel Humes first occupied the honorable position of President of the Lancaster City and County Medical Society.

On Feb. 14, 1844, the Society was organized by the adoption of a constitution and by-laws and the election of officers. There had been several preliminary meetings of the city physicians held at the house of Dr. Eli Parry, the first of which was held Jan. 18, 1844, at which meeting a sketch of a constitution and by-laws was submitted and a call issued to the physicians of the county to assemble on Feb. 14, 1844. This, the first meeting, will be best understood by reading the minutes:

“At a meeting of the medical gentlemen of the city and county of Lancaster, held this day pursuant to notice in the public papers, the following gentlemen were present: Drs. Samuel Humes, F. A. Muhlenberg, A. M. Cassidy, P. Cassidy, C. L. Baker, J. Leonard, J. S. Clarkson, J. B. Stubbs, Henry Carpenter, W. B. Fahnestock, J. A. Ehler, M. R. Gryder, Ely Parry, F. S. Burrows, N. W. Sample, Jr., J. L. Atlee, D. Hayes Agnew, A. Bitner, G. B. Kerfoot, S. Duffield, Jno. Leaman and W. L. Atlee.

“Dr. Samuel Humes was called to the chair and Dr. W. L. Atlee appointed Secretary.

“The object of the meeting having been stated by Dr. Eli Parry, the prime mover of this Association, it was, on motion,

“Resolved, That the minutes of the proceedings of the city meetings be read for the edification of the country members.

“After reading the minutes it was, on the motion of Drs. Burrows and Muhlenberg,

“Resolved, That the constitution and by-laws be read, and that after their reading a joint committee of three members from the city and three from the county be appointed to take them into consideration and present them to the meeting in the afternoon for final adoption.

“Committee: Drs. J. L. Atlee, Burrows and Parry, of the city; and Drs. Stubbs, Duffield and Sample, Jr., of the country. The meeting then adjourned to meet at 2 o'clock P.M.

“At 2 o'clock P.M., the meeting being called to order, the minutes were read and adopted. Dr. H. E. Muhlenberg was present in addition to the gentlemen above named.

“The committee appointed in the morning presented the constitution and by-laws, which were considered by sections, and after some slight amendments

the whole constitution and by-laws were, on motion of Drs. Parry and J. L. Atlee, adopted.

“On motion of Drs. J. L. Atlee and Parry:

Resolved, That a committee be appointed to nominate the officers recognized by the constitution.

“Committee: Drs. J. L. Atlee, Clarkson, Bitner, Duffield and Humes. After a short absence the committee reported the following nominations: For President, Samuel Humes, M.D.; Vice-Presidents, F. A. Muhlenberg, M.D., Samuel Duffield, M.D.; Recording Secretary, Henry Carpenter, M.D.; Corresponding Secretary, Washington L. Atlee, M.D.; Treasurer and Librarian, Eli Parry, M.D. On motion of Drs. Burrows and F. A. Muhlenberg:

“Resolved, That the nominations close.

“Resolved, That the gentlemen nominated be considered the officers of this Society until the stated meeting in January next.

“Dr. J. L. Atlee now nominated for membership the following gentlemen: Wm. E. Maxwell, M.D., Marietta; John Myers, M.D., Marietta; Jacob Glatz, M.D., Marietta; Richard E. Cochran, M.D., Columbia; Wm. S. McCorkle, M.D., Columbia; Geo. Moore, M.D., Columbia, who were elected.

“Letters signed H. Shoenfeld, M.D., and Daniel E. Shirk were received, read and ordered to be laid on the table.

“On motion of Drs. Parry and Carpenter:

“Resolved, That a committee be appointed to transcribe the preamble and constitution on parchment and present it to the Supreme Court for an act of incorporation.

“Committee: Drs. Parry, H. E. Muhlenberg and W. L. Atlee.

On motion of Drs. J. L. Atlee and F. A. Muhlenberg:

“Resolved, That a committee of three be appointed to make a selection of medical journals, which shall be subscribed for by the Librarian.

“Committee, Drs. J. L. Atlee, F. A. Muhlenberg and Burrows.

“On motion of Drs. Parry and Carpenter:

“Resolved, That the officers of the Society be authorized to procure such books as their duties require.

“On motion of Drs. Parry and Carpenter:

“Resolved, That a committee be appointed to procure a suitable room for the meetings of the Society.

“Committee, Drs. Parry, F. A. Muhlenberg and Humes.

“On motion, adjourned.

“SAMUEL HUMES, Chairman.

“WASHINGTON L. ATLEE, Secretary of meeting.”

We point with pride to the distinguished originators of our Association, and we hold in grateful remembrance the men eminent in their profession whose labors shed a luster on our Society.

Of those whose names stand upon the records at its organization, all have gone to their rest with one exception, Dr. J. Augustus Ehler, who is still engaged in the active duties of the profession with such vigor

and energy, that were it not for the "flourishing almond tree" one could not realize the possibility of his participation in the organization of our Society.

The Lancaster City and County Medical Society, if not the first organized in the country, may be said to be the pioneer. It was the first to aim at the general organization of the medical fraternity of the country. It antedates both the National and our own State Society. Its members took an active part in their organization, and its principles are engrafted upon their government.

In 1848, fifty-nine physicians, representing twelve counties, including delegates from medical colleges, hospitals and local societies, met in our city of Lancaster and organized the Medical Society of the State of Pennsylvania. The Lancaster City and County Medical Society had nine representatives in this body, six of whom were participants in the organization of the Lancaster City and County Medical Society, which with a beginning of twenty-three members, has increased to ninety-five.

The State Society with a representation of 12 counties and 59 members has increased to a representation of 54 counties, embracing an enrolled membership of 2,500, with a representation of 500 delegates.

Our Society has been honored by the choice of six Presidents of the State Medical Society, and once by the highest honors of the profession, the President of the AMERICAN MEDICAL ASSOCIATION.

Your historian, forty-six years a member of the Lancaster City and County Medical Society, has a distinct recollection of all the originators of the Society, with many of whom he enjoys pleasant social and professional memories.

Dr. Samuel Humes, our first President—tall dignified and precise—"his lyart hafets wearin' thin and bare"—illustrious vestige of the old-time physician, eminent in council, widely known, highly respected, honored by the fifth reëlection as President of our Society, and the first President of the Medical Society of the State of Pennsylvania.

Dr. F. A. Muhlenberg, a man of fine physique, dignified and clerical in aspect, well stocked with scientific and medical lore, an accurate diagnostician, popular and often called upon in council, his presence gentle and soothing in the sick room, and paternal toward the younger members of the profession.

Dr. Francis S. Burrows, a graduate of Edinburgh, an Irishman "without guile," brimful of wit and good humor, the center of the social circle, a distinguished surgeon, kind, gentle and encouraging in the sick room.

Dr. John L. Atlee, whom all of you knew, whose presence gave such zest to our proceedings, whose energetic and active participation in everything pertaining to the profession he loved ended only at death, whose distinguished achievements and his elevation to the highest honors of the profession adds another star to the crown of our rejoicing. I can not forego the opportunity of again referring to his successful revival of the operation of ovariectomy under circumstances so unfavorable. When the opposition of the most distinguished surgeons was such that none but the bravest would dare to venture on such an untried field, yet in the face of such opposition, of contumely, and denunciation of pen and press as barbarous and cruel murder, he performed his first ovariectomy June 29, 1843, antedating the existence

of our Society almost a year. The patient is still living in her eighty-third year.

Dr. Henry Carpenter, a descendant of physicians, the first and for many years the Secretary of our Society, a successful, extensive obstetrician, surgeon and general practitioner—with his cordial and social presence many of you are familiar.

I might mention many others, distinguished in the ranks of the profession, who retained their connection with our Society until their demise, but time does not permit, as a few of those who withdrew from the Society and sought other fields of labor demand a passing note.

Washington L. Atlee removed from Lancaster to Philadelphia, where he occupied the chair of Chemistry in the Pennsylvania Medical College. He became famous as a gynecologist and ovariectomist. He performed the operation more frequently than his brother, John L. Atlee, and in the beginning of his career shared with him the reproaches of those opposed to the operation. His first operation was performed March 29, 1844, nearly a year after his brother's first operation. The patient was Mrs. G. S. —, residing near Mount Joy. His third operation was performed March 15, 1849, and was the first ovariectomy he performed under the influence of an anesthetic—a mixture of one part chloroform and two parts ether. He was noted for his kindness and affability. I shall ever remember with gratitude my first professional intercourse with him in the first year of my practice.

The name of Dr. D. Hayes Agnew stands out in bold relief among the galaxy of peerless exemplars. His eminence as a surgeon, a teacher, a writer and a Christian gentleman is so well and so extensively known that it needs no commendation. Our Society deems itself highly honored by having his name inscribed upon the roll of its membership.

Dr. John Leaman, after practicing medicine very extensively and successfully for a number of years, entered the ministry of the Presbyterian Church, and was also elected Professor of Anatomy and Physiology in Lafayette College, a position he faithfully and satisfactorily filled until his death.

Of the members of our Society who joined subsequent to its organization, and who have closed their earthly career, much might be said in remembrance of their labor and virtues, would time permit, but I can not refrain from the mention of one who was so recently in our midst, whose high attainments and whose presence added so much to the pleasure of our meetings, whose advice and counsel was so acceptable, whose interest in the welfare and progress of the profession was always sincere, as was his detestation of dishonorable practice and quackery—the father of physicians—Dr. Joshua M. Deaver.

But the old familiar faces greet us no more. The voice, hushed in death, no more is heard expressing the kindly welcome or the sage advice; their lifework is done. "And like one who wraps the drapery of his couch about him and lies down to pleasant dreams" they have passed away; their hopes and fears, their trials and triumphs, their deeds of love and charity will only be known when the Book of Life shall reveal the records of eternity.

"There is no death; what seems so is transition;
This life of mortal breath
Is but a suburb of the life elysian
Whose portal we call death."

How many changes have been wrought during this

half century, the changes of many colored life. Old landmarks have passed away; the landscape, ever changing, ever new, has been transformed, teeming with busy life, nature and art vying with each other to add new beauties to the scene. The lightning drawn from Heaven, becoming an obedient servant, has been made to transport us from place to place and light us on our way; made to carry our messages of love and sorrow, trade and triumph, success and failure, annihilating time and space. Days have been changed to hours, minutes to seconds.

The progress in the arts and sciences and every department of human industry has been unprecedented.

The mind is lost in wonder and amazement when comparing the present with the past. And yet our present advancement must not be attributed alone to the genius of the present generation. The agencies bringing about these results are but the outgrowth of the patient, and oftentimes unrequited, labors of those whose names are almost forgotten.

Lancaster County is second to none in the world's history for its influence on human progress. He who shortened the pathway of the ocean, brought the continents into closer proximity and revolutionized commerce, was born in Lancaster County. Robert Fulton, by his application of steam to navigation, did more towards the spread of the arts of civilization than any other agency. Though despised and derided in his first feeble attempt, to-day the rivers, lakes and oceans of the world teem with the evidences of his success.

So, too, in our own profession, Dr. A. Kuhn, an almost forgotten citizen of Columbia, who was elected Professor of Botany and *Materia Medica* in the University of Pennsylvania and one of the physicians of the Pennsylvania Hospital. It is said he was remarkable for his carefulness, precision and punctuality.

Dr. Benjamin Smith Barton was born in Lancaster—a distinguished medical teacher, writer and physician. He was early in life, chosen Professor of Botany and *Materia Medica* in the University of Pennsylvania, and after the death of the distinguished Dr. Rush he was appointed to the chair of Practice of Medicine. "Natural history and botany were his favorite studies, and in his investigations of these branches of science he made a conspicuous figure."

Dr. Jno. Eberle, a native of Lancaster County and a citizen of the village of Manheim, was a Professor of *Materia Medica* and Obstetrics in Jefferson Medical College, and a writer of distinguished merit. His treatise on "The Practice of Medicine" was considered at the time of its publication one of the most valuable works on this subject that was ever issued, from the American or English press.

The labors of these distinguished men, with others in the profession, laid the foundation for the advent of a galaxy of bright stars in our professional world—whose names and influence were ever foremost in the advancement of the best interests of our profession, by advocating a wider and more thorough system of education, and by their labors in the organization of the profession, in commemoration of which we are this day assembled. One can not properly appreciate the immense advantage derived from the organization of the profession into county, State and National associations.

Just here allow me to digress, by reminding those who are not yet members of the National Association that it is their duty to show their appre-

ciation of the labors of our predecessors by uniting their influence with the AMERICAN MEDICAL ASSOCIATION. This can so easily be done by simply sending the credentials of membership of the county society, together with the annual fee, to the treasurer; your name will be enrolled on the list of membership, and you will receive in return the weekly visits of the best medical journal published in the land.

Contemplate for a moment the character of the profession before medical societies existed. Then every man's hand was against his neighbor; envy, jealousy, fault-finding and traducing injured the whole profession in the estimation of the public. Now the science has been so much enlarged and advanced in the various departments, and so rapid is the progress, and it requires so close an application to study in order to keep abreast with the times that one finds little time to quarrel with his neighbor. At the same time these gatherings make us better acquainted with each other and round off the sharp corners of asperity, uniting us, and helping each other as brothers engaged in the arduous labors of a noble and honorable profession.

A retrospect of the history of our science for the past fifty years will bring to our attention a vast change and a permanent advance toward its establishment as a true science.

Then, anesthetics were unknown; now, the greatest boon ever conferred upon suffering humanity. Contemplate for a moment the courage required of a patient about to submit to some fearful operation, conscious of the agony to be endured while submitting the quivering flesh to the knife. Contrast this with the calm, happy and undisturbed oblivion of all pain, and you will realize the blessing conferred upon thousands daily who are compelled to submit to the surgeon's art.

The discovery of pathogenic microorganisms and their rôle in the production of disease is one of these triumphs of science which has enabled the surgeon to secure favorable results to an extent never thought of by our predecessors; and to the physician it is a field of wide extent and inestimable value; although much remains to be explored, yet the results already obtained demonstrate the possibilities in store for the careful observer and earnest worker in the domain of preventive medicine.

The microscope (which within the recollection of your historian was simply considered a philosophical toy) has thrown a flood of light upon this subject, for without it we would still be groping in the darkness of conjecture, and to it we owe the knowledge obtained by the bacteriologist; and I may add that it has become indispensable to the physician as an aid to diagnosis. What the microscope has revealed as the cause—asepsis and antisepsis—enables the surgeon to prevent or counteract.

The hypodermic syringe has enabled us to defy nausea, and almost instantly to relieve suffering, and it has removed all doubts concerning the effects of drugs upon the system.

By the aid of the thermometer in diagnosis we can be more certain of the character of disease, and be directed as to the nature of our remedies.

The laryngoscope and the ophthalmoscope have enabled us to inspect living organs, and the aid furnished by these instruments has qualified us to treat diseases with an exactness hitherto unattainable.

Indeed, there have been so many additions and

helps by instruments of precision that their mere enumeration would prove irksome. In the department of materia medica it is simply impossible to enumerate, in the time allotted to our subject, the changes and progress that have been made. There has been probably no greater advance in practical medicine than in antipyretic medication. Chemistry, especially organic chemistry, has added a long list of those substances derived from the hydrocarbon series, many of which possess decided antipyretic properties. A few only have been generally used, such as antipyrin-acetanilid and phenacetin—their number is so great, their composition so complex and their therapeutic application so undetermined that any further notice of them will readily be excused.

This progress in medical science we chiefly owe to the advancement made in the science of chemistry and physiology, and in which our predecessors exercised a conspicuous influence. The annals of our organizations bear testimony of their urgent demands for a wider field of scientific research and a more thorough training in professional studies. Fifty years ago, chemistry and physiology was a mere side show to the student of medicine; indeed, most of our medical colleges did not have a chair of physiology, and the lecture hour occupied by the professor of chemistry was generally devoted by the tired student to worship of Morpheus.

To-day, chemistry and physiology have become the chief corner stone of the science of medicine, and he who would rank as an educated physician must cultivate these sciences. In view of what has been said, and the many subjects of interest and profit necessarily omitted, we need not be surprised that the efforts made for a more thorough education and a more prolonged course of instruction are so urgently demanded by the profession; and as we have to a limited extent obtained legal protection we may, with brighter hope, look forward to the time when sectarian medicine with its pompous arrogance and ignorant self-conceit will be relegated to that oblivion to which it is justly entitled.

Let me say to those who have recently entered, and to those who are about to enter the profession, that by the general diffusion of knowledge and the impetus of our public system of education, the future generations will be much more competent to judge of your ability, and will demand a higher standard and a more thorough knowledge of your profession; although great has been the advance and rapid the accumulation of facts elicited by our modern appliances and agencies for the prosecution of research, so that the neophyte might think there is nothing left for him to do but simply follow in the footsteps of his predecessor. Let him not be deceived. We are only on the threshold of the temple of medical science, and the possibilities in store for the earnest worker will amaze the laggard and leave him stranded in the bogs of hesitancy and irresolution.

Let me urge our young men to arouse, and imitate our great predecessors in untiring application, earnest prosecution and unflinching determination. If Agnew or an Atlee had not possessed these qualifications we could not point to them to-day with the pride and rejoicing in the honor which their membership confers upon our Society.

It is upon the young men of to-day that the duty devolves of continuing this work so nobly pursued

by the men whose memories we this day recall, and whose patient endurance has erected for them monuments that shall endure when the physician's art shall no longer be a necessity.

To the younger members of our Association we look for a continuance of the advances already made, the exploration of new fields and new agencies, for the amelioration of suffering humanity, for aid in extending and uniting in compact legions the co-workers in our noble profession; laying aside selfishness, jealousy and bickerings with an ardent desire and just emulation to excel in every good work, so that when our centennial shall have come, the historian may point with pride to a galaxy of brighter stars in the crown of their rejoicing.

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA.

[From the WASHINGTON STAR, February 15.]

The celebration of the seventy-fifth anniversary of the Medical Society of the District of Columbia was marked by the delivery of several addresses which, inspired by the occasion, have more than a passing interest.

The President of the Society, Dr. Samuel C. Busey, in his address dwelt upon some of the notable facts in the history of the Society of which he is the honored head. He said:

"Inasmuch as the occasion which has brought us together tonight is one of those historic events which emphasize the permanency of this city as the capital of a great and powerful nation, and following so quickly the commemoration of the centennial anniversary of the laying of the corner stone of the Capitol, identifies the history of medicine with that of the city from its foundation to the present time, I will venture to recall your attention to such historic data as will establish the coincident relation of the medical profession in this city with its early history, development and present prosperous condition.

"On July 9, 1790, Congress passed and on the 16th of the same month Washington approved the Act 'establishing the temporary and permanent seat of the Government of the United States on the River Potomac.' In March, 1791, Washington issued a proclamation defining the limits of the new federal territory and directing the commissioners and engineer to proceed with the preparation of the plan of the Government city. On Sept. 18, 1793, the corner stone of the Capitol was laid by Washington, and on the first Monday of December, 1800, the Congress of the United States began its first session in the Capitol in this city.

THE EARLY PRACTITIONERS.

"When Drs. Samuel Brown and John Crocker settled here, 'the territory was inhabited by a few farmers, their servants, and, perhaps, some tradesmen and fishermen.' With the settlement of Frederick May, a native of Boston and a graduate of Harvard University, in 1795, medicine as a science had its beginning in the city of Washington. Others followed and in 1815 there were 'nine physicians and two practicing apothecaries.' The first associate assemblage of the physicians of this city took place in 1813, called by public advertisement 'to take suitable notice of the death of Dr. Benjamin Rush,' the

father of American medicine, and to appropriately commemorate his life and professional services.'

"Perhaps prior, but certainly during several years succeeding this date, the influx of charlatans and pretenders was so extraordinary, and such injuries and wrongs were perpetrated by them upon citizens, that the qualified physicians began to consider and discuss methods of procedure and organization by which the community could be protected from such wrongs and informed of the qualifications of those fitted to practice the healing art. Those efforts culminated in a petition to Congress in 1818, signed by twenty-one physicians, for the charter, which was granted, and approved by President Monroe on the 16th of February, 1819.

"We have invited you here tonight to unite with us in commemoration of that event. And, now that you know those noble founders were animated by the highest inspiration of Christian philanthropy and beneficence in the foundation of a medical society, which has lived through a period of seventy-five years, contemporaneous in history with the federal city and the Government, you will appreciate and honor the pride we take in giving expression to our praise and gratitude in memory of those noble men on this anniversary night. From 21 it has grown to an active resident membership of 214, of whom but two have passed the age of allotted lifetime, and its senior in membership is a decade younger than it. I need not, then, tell you that in physical vigor and intellectual alertness it is now in the very prime of mature life.

DECREASE IN AVERAGE AGE.

"Such youth and vigorous manhood have not always characterized its membership. The average age has diminished with time and the increase of numbers. Among the honored dead twenty-seven lived beyond three score and ten, of whom six were founders; nineteen died at ages between 50 and 63 years, after the date of graduation, and seven held continuous membership in this Society for periods of fifty to sixty-three years.

"The average age of these venerable decedents was seventy-six and one-half years, the youngest of whom died at 70, in 1874, and the last at 89, in 1893.

In the primitive era of medicine in this city and during the early history of this Society the life of the general practitioner could not have been less arduous than since. Many of them began life when the practice of medicine was primitive and unremunerative in a community struggling with poverty in the development of a new city. It is true that the average lifetime of the medical is much less than that of either the legal or clerical professions, but this general law of vital statistics fails to explain the average youth of the present membership, which represents five of the eight decades of the life history of this Society. These data are somewhat phenomenal, and, perhaps, without special significance; nevertheless, they emphasize the fact that the pursuit of the art of healing is not conducive to longevity, and, while the average life of men in general is increasing, that of the medical profession is decreasing. With an average of forty-three and one-half years, and a prospective death rate of 57 per cent. under 65, the problem of life and longevity is of sufficient magnitude to command your attention. It will not do to ascribe

this high death rate during the prime of life and manhood wholly to mental worry, sleepless time and inadequate remuneration, for these find compensation in the assured livelihood, conscious pleasure and consolation of duty well done. Whether referable to such esthetic or to graver consideration, the time has surely come when the causes of the comparatively low average life of men engaged in the science of saving and prolonging life should be intelligently and definitely ascertained. Those few, thirteen in all, who have reached and passed the age of highest death rate are equally sure of the inevitable, but can offer their juniors the consolation of their good wishes.

CONTINUED IN ONE FAMILY.

"The elder May came here in 1795, five years before the transfer of the Government to this city. He was a pioneer who prepared the way for others, and the founder through whose professional life the history of medicine in this city during the years antedating the organization of this Society can be traced through membership to and before the establishment of the Government here, and continuously with its growth and development down to the present time. His son, John Frederick, was born and began the practice of medicine in this city and died a member of this Society at the age of 80, leaving a son now an active resident member. In this family the continuity of membership has been unbroken from its organization to the completion of its seventy-fifth anniversary. This Society, then, claims a life-time beginning before the Government at Washington and coeval with the foundation of the city on the River Potomac.

"The Medical Society of the District of Columbia is the youngest of twelve medical societies in this country, now in existence, which have reached and passed the seventy-fifth year of continuous active life, and is the oldest, if not the first, scientific body chartered by an act of the Congress of the United States. Ten of its founders were natives of Maryland, four of Virginia, two of Massachusetts, two were born within the present limits of the District of Columbia and of three the nativities are unknown. In personal lineage it is confined to three of the original thirteen States, but as a scientific body it claims ancestral descent from eleven progenitors, who are present by representation with us tonight. It is, however, the natural and direct heir of the medico-chirurgical faculty of Maryland.

"With such an ancestry dating back to 1766, during the period of colonial discontent and strife; a foundation springing from the noble impulses of humanity and inspired by motives of high professional responsibility; fulfilling in its corporate capacity, throughout its long life, the charter declaration to promote and disseminate medical and surgical knowledge, and keeping abreast with the progress of science which has made medicine the handmaid of religion, do you wonder that the successors of those who gave birth to this Society, now living in a community representing the intelligence, civilization, progress and power of a nation of sixty-five millions of free people, should invite you to this reunion to tell you how faithfully they have kept the promise of its founders, and to unite with them in giving thanks and praise to that Providence which rules the universe?

THE GLORY OF THE PRESENT.

"The period comprising the years from 1819 to 1894 has been one of marvelous progress in science, literature, art and in all that pertains to Christian civilization. The village city, with its domain of farms, scattered homes, graphic streets and avenues, 'squares in morasses' and 'obelisks in trees,' has become the metropolis of a munificent nation, under whose supervision it has grown into a city surpassing in beauty and rivaling in attractiveness the more favored cities of both the old and new world, and holding together in one compact community a cosmopolitan population where education and culture need neither the blazonry of titular insignia, the heraldry of ancestral distinction nor the glamor of wealth to command position and influence.

"During the same period medicine, here and elsewhere, advancing along the lines of pathologic research and physiologic therapeutics, has escaped the era of hypothesis and speculation and now, as a science of precision and demonstration, commands the respect and homage of the civilized world. Now, as heretofore and everywhere, it is foremost in charity, unselfish in devotion to the welfare of public health, magnanimous under public and private wrongs and generous to a fault in unremunerative perils and responsibilities. But even this is not the full measure of its philanthropy. The mission of preventive medicine and sanitary science will not be attained until the causes of disease are eradicated and death is limited to the ailments to which flesh is necessarily heir and the process of natural waste and decay. How soon, if ever, this may be accomplished remains with the laity. Medicine will continue the pursuit with the zeal and courage of a science which seeks the welfare of mankind rather than place and fortune. The medical is the only profession, trade or occupation which seeks, by its progressive attainment of its ultimate object, the continuous decrease of emolument."

THE SENIOR TO THE JUNIOR.

"One of the most pleasing incidents of this occasion is the presence of representatives of the eleven ancestral societies, the oldest of which was organized in 1766 in the State of New Jersey. This exhibition of fraternity is an exemplification of that beneficent spirit which dominates the medical profession and makes kindred of us all. Honored colleagues who will follow me will tell you of its achievements in science and of its educational and charitable foundations. I have only to conclude with a few words addressed to my colleagues and juniors.

"It could not have occurred before, and can never occur again, that the senior member will be unanimously reelected to the Presidency on the forty-fifth anniversary of his membership and preside at the seventy-fifth anniversary of this Society. Such a unique compliment can not be acknowledged in words which will completely and fittingly convey the gratitude I feel for such expression of personal and professional regard. At the centennial reunion some one of you will stand where I now stand, upon whom will devolve the duty which thrills me with pleasure to-night. In the enforced retirement which must come soon, I will cherish the hope that each one and all of you may live to celebrate the golden wedding day of professional life. And in communion with the Savior of man, who was first to heal the sick, the lame, the halt and the blind."

Dr. Busey stated that it gave him great pleasure to make the statement that he is indebted to Dr. J. M. Toner, a distinguished member of the Society, for many of the historical data cited in this address.

THE ADDRESS OF W. W. JOHNSTON, M. D.

The address of Dr. W. W. Johnston was an interesting and valuable sketch of the Society from its early origin down to the present. He said: "Twenty-five years ago the first anniversary of the Society was celebrated as we are celebrating the seventy-fifth now. Then, as now, the present was forgotten in the greater interest of the past, and the history of the origin and early progress of the organization was told with a fullness and detail which will make the address of Dr. J. M. Toner a valued record for all time to come. I wish that he were standing in my place to-night and that you were listening to the story of that olden time which he has made so full of freshness and of life. I feel more than an ordinary emotion in speaking of the anniversary oration of twenty-five years ago, when I remember that my father introduced Dr. Toner to the audience on that occasion, and that with unaffected pleasure born of a life-long devotion to the interest of the profession and the Society, he heard the story of early struggles in which he had borne his part, and ultimate triumph in which he so much rejoiced.

"It is peculiarly fitting on this night of jubilee that we should have as presiding officer the oldest and one of the most honored of our members, and that he should be, at the same time, one of the most active workers in the present as in the past, giving his constant presence and his aid to all that means progress. In our efforts now to make the past a living reality, we will be much aided by the thought that he has shaken hands with every President of the Society except the first two, Worthington and Sim. And if you will but take our President by the hand you will be reaching back and touching that time which we wish to bring as near us as possible in our felicitations to-night. That he may long live to extend his counsel to the coming years, that he may add many links to the chain which binds him to those far-off days, and that the distant future may yet be as his past, is, I am sure your sincere wish, as it is mine.

"I can not restrain my voice from associating with the President's on this anniversary the name of Lovejoy, who is the second oldest member on our list. His familiar face and figure form a part of my earliest recollections of the Society, and his conservative wisdom is stamped upon every judicial and ethical decision of the last thirty years. The Society delights to honor him and to thank him to-night for years of honorable and faithful service."

IN THE EARLY DAYS.

The speaker prefaced his story of the early origin of the Society by a graphic picture of the city in the early days of the present century, when a few scattered houses occupied the present site. "The founders of our Society," he said, "were active, hard working men, too, some of them; 'Sim, the second President of the Society, would start out in the morning on a bob-tailed horse,' the chronicler says, 'and visit twenty to thirty families during the day.' A sharp critic of the times avers that he gave but two medicines—calomel and Dover's powder—to all his pa-

tients, whatever the nature of their diseases." Entertaining sketches were given of Dr. Charles Worthington, the first President, and Dr. Frederick May, the third President.

Reference was made to the activity of the Society, in all matters pertaining to public health. Action in regard to vaccination was recorded in 1846. Cholera claimed the attention of the medical men of this city in 1832, when 459 deaths were caused by this disease. "With every year some question of importance affecting the health of the city has been the subject of animated discussion; sewerage, the drainage of the flats, the public abattoir, the ventilation of public buildings, the nature and prevention of prevailing fevers, and numberless questions of similar import have been discussed, to the great edification of the members and the benefit of the public.

"Mention can only be made of the effort to secure a permanent home for the Society, an effort abandoned in 1869, by the sale of what would have been a most valuable investment—the property at the southwest corner of F and 10th Streets. This result was due to the failure to secure the sustained coöperation of the members in its purchase, and the few enthusiastic supporters of the movement were not able to carry it through without the assistance of all. But that the Society was able to go as far as it did in 1868, with a membership of 140, promises well for the ultimate success of the project, which is delayed, not abandoned. The Medical Society is not a rich body, or we would have had a home of our own before this. The successive balances in the treasury were, in 1851, \$10; 1854, \$20; 1863, \$83; 1873, \$374; 1884, \$516; 1893, \$1,919. For the excellent administration of its finances the Society is indebted to its Treasurer, Dr. Franzoni.

"The Society record is not without its humor, although fun is not always intended. In March, 1873, the Society was invited to participate in the inaugural honors to President Grant, and to appear in the procession on foot, on horseback, or in carriages, as they might see fit. The picture of the staid members of our Society riding on prancing steeds along Pennsylvania Avenue, bedecked with bright scarfs, and the Society banner of Hygeia waving in advance, would, without doubt, have created a sensation, and added greatly to the beauty of the pageant. On May 16, 1866, the case of Dr. Gudgeon, a veterinary surgeon of great weight and prominence, was reported to the Society, the doctor having succumbed to excess of fat. This individual weighed at the time of his death upward of 500 pounds. I can remember him as one of the sights of Washington for many years.

THE ROMANCE OF LIEBERMANN.

"The history of the Society is not without its romance. If I could extract from the lives of our members all the moving stories and incidents of heroism, of dangers met and overcome, all the numberless acts of chivalrous valor, when there was no martial music to incite to bravery, but only the sense of duty and humanity, I could fill pages and volumes. I would like to tell the romance of one who was presiding officer at the anniversary twenty-five years ago, who was a member for forty-eight years, a doctor for fifty years, coming to Washington in 1840, and dying at the age of 74. The story was

told me by word of mouth, and is told here as I heard it.

"Liebermann was a Russian, the son of a banker of Riga; his education was carefully conducted, and in time he was sent to the University of Dorpat. Here he shared in the political sentiment of the period, and, like most other Russian students, then and since, adopted the revolutionary doctrines to which his age, his hatred of oppression and his love of freedom attracted him. While pursuing his studies at the University the fire of revolution broke out in down-trodden Poland, and Liebermann, burning with revolutionary ardor, joined a band of students with the object of assisting this oppressed people. Armed with scythes, old muskets, and whatever weapons could be found, the students marched rapidly to the Polish frontier, and crossing it, advanced toward a town which afforded to their ardent courage, the opportunity wanted. With cries of triumph, waving their weapons in the air, they impetuously rushed through the gates, which seemed open to receive and welcome them. But once within, the gates were suddenly closed; they found themselves caught, trapped; the town was already in possession of the Russians, and the young patriots were prisoners. Liebermann was hurried into Russia and flung into prison, preparatory to being sent to Siberia. Here he gave himself up to despair; his life seemed ended, and he saw a banishment worse than death before him. He could not eat nor sleep. In the same prison was a Polish woman of rank, much older than Liebermann. She took pity upon his youth and misfortune, and did all she could to comfort him. One day, calling him to climb a ladder in the cell so as to command a view from a window of the courtyard in the prison, she pointed out to him, in the midst of a convoy of prisoners on their way to Siberia, a man dressed in rags, covered with dirt and chained to the axle of a wagon; he was crouching on the ground, eating with apparent relish, a piece of black bread.

"That man," she said, "is a Polish nobleman of high rank. His misfortunes are greater than yours; he has lost everything, property, family and liberty; he is going to perpetual banishment, and yet he lives and endures. You are young; you may escape; you should be hopeful and brave." This lesson had its effect, and from this time he bore his imprisonment with more content. It was not long before he received the happy news that through the solicitation of influential friends he would be granted permission to go to Berlin and study medicine, under surveillance. He went to Berlin, profited well by the excellent teaching there, and in time received his degree. A passport was then given him to return to Russia by one of three ways. He chose to go by way of Hamburg, to take ship there and thus have an opportunity to visit this important city.

COMES TO THIS COUNTRY.

"On reaching Hamburg he saw an American clipper ship just about to sail for America. The adventurous spirit was strong within him, and, having money, he determined suddenly to visit the land of liberty before returning home. This plan, which could not have been formed by any one not of strong and bold character, was carried out. After a month's voyage he reached Boston. The city was then in the throes of a presidential election, and Liebermann's description of his first impressions of the processions,

flags, firing of cannons, and general din and excitement, was very amusing. From Boston he thought he would visit New York, and once there he could not return to Europe without seeing the capital of the country. In Washington he received the visit of a Russian acquaintance, who, learning of his education under Laugenbeck, and of the new operation for strabismus (cross-eye), brought to him a big butcher, whose eyes were looking in every direction but the right one. Liebermann operated so successfully that another case of the same kind was soon sent to him, and so rapidly did his fame spread as a corrector of deformities of eyes and limbs by tenotomy, that in a little while, without the wish or effort, he found himself engaged in active surgical practice. His departure, deferred from day to day, was, in time, indefinitely postponed, and it was not long before his marriage, his growing popularity, and his new associations, made him a permanent citizen of Washington, and a member of this Society, to whose welfare he was devoted for nearly fifty years.

"His characteristics were strong self-reliance, readiness of resources, much surgical and operative skill, and industry and energy. His manner was brusque, but his heart was warm, and his friendships and affections firm and fixed. It was one of his peculiarities that he would never attend any one professionally who lived on the same block, or in his immediate neighborhood, and when one of his old patients moved opposite to his residence on 13th street, between E and F Streets, he positively refused to continue to be his physician. Up to the very last his strength of spirit triumphed over his weakness of the body, and an hour before his death he rose from his bed, tottered to a chair and signed an important paper. He died lamented; he will live in our hearts honored and loved."

HOSPITALS IN WASHINGTON.

BY J. FORD THOMPSON, M.D.

The history of the hospitals of the District of Columbia was given in an address by J. Ford Thompson, who prefaced the purely historical portion by saying that "nearly everything that has been done to give our profession the high position it to-day occupies in the estimation of appreciative minds, professional or non-professional, has been the outcome of hospital teaching, for it is there, and only there, that those crucial tests of accuracy in judgment which our calling requires can be properly applied and verified. It may be considered as particularly fortunate that, as a rule, no objections are made, as no hardships are entailed to this using of the indigent sick for scientific purposes, and they may have some consolation in the thought that, as some recompense to the community for the often liberal expenditure of time and money, they offer themselves as a means of advancing the science upon whose success their own welfare depends.

"It is to be lamented that, at least in our own country, there is often a lack of harmony and good feeling in the ranks of those whose interests can only be subserved by an intelligent administration and a high standard of excellence in all that concerns the welfare and success of our hospital government; and this friction is generally most pronounced, as it is most frequent, between the medical staff, individually, or as a whole, and the governing body, however it may be constituted; and it inevitably

leads to a condition of things which has often retarded the growth and limited the sphere of usefulness of many an institution whose promise was as bright as charity could wish or science expect. Perhaps it is not always easy to place the responsibility for such misunderstanding, but it seems to be due in the great majority of cases to a misconception of the bounds and limits of the respective fields of duty and management of the two responsible bodies. I should say that encroachments are too often made upon strictly professional domain, and that its rights, at times, are ruthlessly infringed upon, and its dignity and self-respect assailed, without any justifiable or reasonable excuse for the action.

"It would seem to be apparent to minds of ordinary intelligence, as a self-evident necessity, that the medical boards should be fairly and sufficiently represented in the directing body, and that their opinions and counsels should be sought, and duly weighed in all questions involving the interests they have so largely in charge, and their advice should be unhesitatingly accepted upon many subjects, of which they alone are capable of passing judgment, such, for instance, as the choice of physicians to fill vacancies in the medical staff, selection of assistants and general supervision of internal arrangement and management, that can only be intelligently performed by men whose scientific training and knowledge fit them for the duty.

THE IDEAL HOSPITAL.

"The ideal hospital, and fortunately there are some such, to my mind is one which forms a part of one great whole of a thoroughly equipped medical college, of which the faculty should constitute the staff, all being under the control and supervision of a board of governors of the university, of which the college should be a branch. As the selection for faculty appointments is always made with great care and discrimination in order to procure the best available teaching material, the hospital would be, in the same way, provided with a corps of co-workers of unquestioned ability and fitness for clinical work, which is the highest and most exacting of our duties. In addition to this there would be the advantage of an unending supply of new life and energy in the young men who are now connected with all medical schools as special lecturers and teachers upon subjects to which they contemplate devoting their life work. They would be thoroughly trained to the duties of their new position and ever ready and willing to supplant their seniors whenever the exigencies required.

"A system with the main features resembling this, which has already proved the best, must eventually be adopted by all schools which hope to retain their reputation or existence, for all recognize the fact that hospital treatment is rapidly replacing the old method of didactic instruction, and every year we feel more and more the necessity pressing upon us of making provision for the new demands, and nowhere, perhaps, is this want more keenly felt than in our own city. But the difficulties to be encountered before such an arrangement can be accomplished to our satisfaction are unquestionably great, if not entirely beyond any probabilities that are now apparent.

"Those who are familiar with the great hospitals of Europe and America can compare their relative merits, and they must experience a feeling of national, as well as professional, pride at the rapid develop-

ment and present efficiency of many institutions in our largest cities. Indeed, it will be admitted that in construction, equipment and management they are unsurpassed by any others in the world, for which, almost without exception, thanks are due to the thoughtful generosity of private citizens. Such an one should be here in the capital of the nation, and a model of its kind in architectural proportions to harmonize with its palatial surroundings and rich in all the appliances and furnishings commensurate with the great nation's wealth and power."

Dr. Thompson remarked that it was evident to those who had examined the records that this was a very healthy community when this country was young, or that those in authority were sadly indifferent to the physical welfare of the resident population. It seems rather remarkable that here, at the seat of government and a rapidly growing city, there was no provision made for the care of the impoverished sick before the year 1844, except the few beds furnished by the old almshouse, on M Street northwest between 6th and 7th Streets. It is gratifying to know that the leading physicians and many prominent citizens were active and zealous for many years in their efforts to procure the necessary legislation for the establishment of such an institution as the city sorely needed, but their labors had been all in vain down to the date mentioned, when a sudden and accidental turn of fortune enabled them to carry out their design.

THE FIRST GENERAL HOSPITAL.

Congress was induced by a pressing necessity to make an appropriation of \$10,000 for the conversion of an old jail in Judiciary Square into an insane asylum, but after the necessary changes were completed it was found unsuited, particularly on account of its central location, for the purposes intended; and it was at this propitious moment that the Medical Faculty of the Columbian University appealed to Congress for the transfer to them of the building for hospital and other purposes, which being granted, they opened to the public without delay, our first general hospital.

In the year 1861 the Government took possession of the building for the use of the army, shortly after which it was entirely destroyed by fire. "The decade from 1861 to 1871," he said, "was an era in our national history, rich in momentous events, whose influences were felt in every nook and corner of the land. Our city was the heart and center of the great struggle and the theater in which was enacted the drama of war, and in its performance the medical profession played a conspicuous rôle. Hospitals in great number and of great proportions were hastily erected in various parts of the city, and our medical men became intensely absorbed in the field of duty most congenial to their tastes and capabilities.

"But in the decade mentioned there is much that more nearly concerns us than the trials and glories of the past, for during that period were organized and established upon an enduring basis almost all the institutions that are now in active operation, whose histories are interesting, but must be briefly told. Providence, Columbia, Children's, Freedman's and the Emergency, all fall within the ten years, the Garfield appearing upon the scene a little later."

The speaker alluded to St. Elizabeth's or the Government Hospital for the Insane, as in magnitude

and all that pertains to the welfare of the special class of patients, one of the model establishments of the world.

"Of those mentioned in the list," he said, "as of importance to the present generation, the Providence Hospital comes first as to time and is second to none in the position it has so long occupied in this community. Its origin was in 1862, and was due to the helpless condition, as regards civil hospitals, of the city after the loss of the Infirmary the year previous, there not being one to take its place or meet the emergency, which was most keenly felt. The Sisters of Charity, then in charge of St. Vincent's Asylum, taking advantage of the opportune moment, decided to open a general hospital of their own and lost no time in carrying out their design. They at first occupied the old Nicholson mansion on Capitol Hill for a couple of years, and then secured by purchase the present site, to which they soon afterward moved, after erecting a frame building to the east of the old three-story house which stood at the southeast corner of 2d and D Streets southeast. This ground, and much more than the original purchase, is now covered by the large and handsome building of the present time.

"I have not the time, I think my allowance is about already expired, to give here a detailed account of this Hospital or any others, for I am now struck by the truth of the remark of a friend, when I told him I was expected to give the histories of the hospitals of Washington in twenty minutes. 'Why,' he said, 'with your best team you couldn't drive around and look at them in that time.'

OUR HOSPITALS COMPARE FAVORABLY.

"I shall have to close with some remarks applicable to them all, although the genesis and development of each are well worth study as illustrating the kindness of human nature and the untiring zeal ever manifested by our doctors for their permanent success. Without doubt the essential question is as to the amount and character of the work done as compared to that of other cities more favored, in some respects, than ours; and to meet this question authoritatively is certainly very difficult, for our early records, and, indeed, it may be said, our later ones, also, are far from being satisfactory in detail and thoroughness, so that personal observation and opinion must be relied upon to a considerable extent in forming a judgment as to our relative standing, past and present.

"An experience, beginning with the old Infirmary and extending through all the hospitals of the city, with one exception, to the present time, with many opportunities of studying the methods and practice of those at a distance may be some excuse for the confidence with which the assertion is made that in every material respect and in all that concerns the true progress of medicine the work of our hospitals compares favorably with that of others, and quite abreast with the best in appreciation of the modern advances of science. It will scarcely be claimed by the most enthusiastic that their careers reveal much, if anything, in the epoch-making and record-breaking line, but they do show capability and conscientious performance of duty, which always come out well in the end.

"Claims are often made of priority in the introduction of some new operation or method of treat-

ment of disease, for some particular institution or member of its staff; but few, I think none, have been made here, at least none well substantiated, with the probable exception of that made for Dr. McWilliams, of having first used adhesive plaster many years ago at the Almshouse Hospital for making extension in fractures."

OUR MEDICAL COLLEGES.

The theme of address by Dr. Thomas C. Smith was "The History of the Medical Colleges of the District of Columbia." Beginning with the first organized of these institutions, the Columbian Medical College, which started in 1821, the speaker traced the history of the schools that have flourished in the District. At this time, he said, there is in successful operation in this city four medical schools. A brief history was given of the medical departments of Columbian, Georgetown, Howard and the National Universities.

"The Columbian Medical College," the speaker said, "has had its ups and downs. While its second course of lectures was in progress some physicians attempted to secure authority from Congress to open a medical school. They entirely ignored the existence of this College, and it was in evidence that their purpose was to cripple this, the only medical college in the District of Columbia. The faculty defeated the scheme. In 1840 the College was burnt out; in 1856 it nearly went out; in 1861 it was put out. In 1856 the lectures were suspended for the season because of lack of support, the dean having reported a balance of \$8.25 to show for the winter's work. In 1866 the medical school moved into its present quarters, which had been provided through the generosity of Mr. W. W. Corcoran. Prosperity has been the order of the day since then."

"The medical department of the Georgetown University," the speaker said, "if the paradox be permitted, was born with a silver spoon in its mouth, and has held on to it ever since, for its progress and success have been uninterrupted. The organization of this splendid institution is due to Drs. Noble, Young, Johnson, Eliot, Flodoardo Howard and Charles H. Liebermann, who conceived the idea and developed the plan of organization. They met in Dr. Young's office, Oct. 25, 1849, and, after deliberation, resolved to establish a medical college in this city. And they did it, and it remains, and will remain, a monument of glory to their names while medical science is taught in the District of Columbia."

The first session was held in 1851, and of the first faculty only one remains, Dr. James W. H. Lovejoy, who is still doing service as a Professor and President of the Faculty.

"The Howard University was chartered," he stated, "by act of Congress, approved March 2, 1867. The lectures in the medical department commenced Nov. 5, 1868. Two students attended the first course of lectures; scores attend more recent courses. It was the first college here to adopt the three years' course of study, and has now, with other progressive schools of medicine, adopted the four years' plan.

"The National University is the junior medical school, and was opened in 1884. It has a corps of active, ambitious professors, who are doing good work." Dr. Smith then spoke of the character of the work done by medical schools and their influence upon the advancement of medical science.

THE ASSOCIATION OF DISEASES AND MORBID PROCESSES.

BY H. A. WEST, M.D.

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE IN THE UNIVERSITY OF TEXAS, GALVESTON; SECRETARY OF THE TEXAS STATE MEDICAL ASSOCIATION, ETC.

Any one who has had the opportunity of observation in the clinical wards or dead-house of a general hospital, must have been struck, as I have been, with the multiform and complex pathologic conditions frequently met with; and with the further fact that even with the patient upon the postmortem table, in the hands of a skilful pathologist, with the viscera laid open to inspection, and with the aid of the microscope, it is oftentimes difficult to discover the primary condition, the connection between the different morbid processes, or to allege with certainty the cause of death.

I have thought, therefore, that it would be a subject of interest and perhaps of profit to collate some of the more important facts concerning the etiologic and functional relations of different diseases and pathologic conditions. I can not, in the short time at my disposal upon this occasion, do more than to very briefly discuss some of the more salient points. A volume could be written upon this theme without exhausting it.

Before proceeding in detail, and to illustrate the nature of the complications referred to, let me cite a few cases taken from the record of autopsies made upon patients from my wards in the John Sealy Hospital during the past few months:

Case 1.—John Miller, 53 years of age, laborer; admitted Jan. 23, 1893. Diagnosis, croupous pneumonia. Died February 9. Cause of death, acute pericarditis. Pathologic diagnosis: Croupous pneumonia in posterior part of lower lobe of right lung; passive hyperemia and brown induration of both lungs; right-sided hypertrophy of heart; chronic myocarditis; aorta atheromatous above the aortic valves; posterior coronary artery almost obliterated by atheromatous plaques; the anterior coronary artery converted into a firm calcified tube for at least one inch; the aorta presented calcareous plates at different points throughout its extent; the liver was mottled from fatty infiltration and congestion; the kidneys and other organs showed no positive evidence of disease.

This case presented the history and clinical picture of an ordinary uncomplicated croupous pneumonia; the pulse, however, giving from the beginning evidence of cardiac weakness. The crisis took place about the seventh day, was followed by rapid resolution and amelioration of all of the symptoms, until about February 5 when increased dyspnea, pain, a sense of oppression over the cardiac area, increased weakness and rapidity of the pulse, and well-marked pericardial friction râles, indicated an acute pericarditis.

Reviewing this case, several interesting questions are suggested: 1, did the passive pulmonary hyperemia, resulting from a dilated and weakened right ventricle, predispose to the occurrence of pneumonia? 2, what was the connection between the chronic myocarditis and the acute pericarditis? 3, what was the relation, etiologically, between the croupous pneumonia and the pericarditis? Did the latter result from an invasion of the pericardium by the diplococcus pneumoniae, or did it result from continuity of structure? 4, to what extent did the chronic myocarditis and the antecedent arterio-sclerosis contribute as the immediate cause of death by weakening the action of the heart? 5, does not arterio-sclerosis, with its frequent

accompanying contracted kidney, largely account for the heavy mortality in the croupous pneumonia of old age and chronic alcoholism?

Case 2.—A. Bolston, age 21, native of France; admitted Nov. 15, 1892; died Jan. 23, 1893. Clinical diagnosis, ulcerative endocarditis and gall-stones. Pathologic findings: Intestinal ulceration; gall-stones; glandular suppuration in mesentery; infarctions of spleen; hepatic cirrhosis and fatty degeneration; fatty kidneys; chronic pleurisy; edema of lungs; chronic myocarditis; splenification of bone marrow.

Here was presented a series of morbid processes as perplexing and incomprehensible as were the clinical phenomena shown during life. When the patient entered the Hospital the symptoms pointed to cholelithiasis of which there were several attacks. The skin, however, remained jaundiced showing the discoloration due to a mixture of icterus and excessive anemia. A slow pulse supervened, and an aortic diastolic murmur became audible, followed by edema of the legs and lungs. There was extreme dyspnea, and during the last few weeks there had occurred several attacks of partial hemiplegia with aphasia.

I shall not dwell upon the reasons which led me to believe that there was an ulcerative endocarditis; suffice it to say that my diagnosis was based chiefly on the development of a heart murmur, dyspnea, dropsy, irregular fever, excessive anemia and cerebral symptoms apparently due to embolism. Was this a case of typhoid fever? Was pernicious anemia the original trouble? The autopsy failed to answer these questions or explain many of the phenomena present during life. Careful section of the brain showed no causes for the hemiplegic attacks.

Case 3.—Old colored woman. At the postmortem the following lesions were found: Chronic interstitial nephritis; cardiac hypertrophy, with right-sided dilatation; induration and edema of the lungs; cirrhosis and venous engorgement of the liver; cirrhosis of the spleen; elongated cervix uteri; fibroids of uterus; pelvic peritonitis.

The pathologic sequences are here more explicable. Undoubtedly the kidney was primarily involved, the cardiac hypertrophy following as is usually the case. The other viscera, excepting the pelvic ones, became affected in consequence of circulatory disturbances.

The citation of these cases is sufficient to warrant a discussion of my subject. The association of diseases and morbid processes may admit of the following classification under which the subject may be presented:

1. Those diseases associated as a result of a common predisposing cause, e.g., famine, filth and other unhygienic conditions.
2. Diseases arising from the localization of specific infectious agents.
3. Diseased conditions resulting from disturbances of one function interfering with the performance of another.
4. Disorders arising from impairment of function promoting extraneous causes.
5. Morbid local conditions favoring the lodgment of infectious agents.
6. Morbid general conditions acquired, which act by affording a suitable soil for the development of diseased processes.
7. Inherited constitutional predisposition to different diseases having a similar character.
8. Certain extrinsic agents productive of inflammatory and degenerative processes in different organs and tissues.
9. Toxic products originating in the body and pro-

ducing similar effects and association of morbid processes as the above.

10. Uncertain associations not included above.

This classification, though incomplete, will answer the purpose of the present discussion.

In the frequent concurrence of epidemics of typhus and relapsing fevers we have an illustration of the effects of a common predisposing cause. The reduction of individual and community vitality resulting from famine, filth, destitution and overcrowding added to intemperance, overwork and depressing emotions, diminishes the resisting power of the system and largely contributes to the spread of these diseases. Although each one of these affections has its specific microorganism which is essential to its production, yet the above mentioned factors, predisposing to both, will account for mixed epidemics.

With regard to typhoid fever, such influences do not seem to exert any special predisposing effect, and hence we find this malady affecting all classes of a community, invading with impartiality the hovel of the poor and the palace of the rich.

In the occasional simultaneous prevalence of cholera and yellow fever, in the frequent association of yellow fever, dysentery and malarial fever, we have other illustrations of the influence of a common predisposing cause, and an explanation of the fact that many prominent writers forty years ago strongly contended against the specific nature of each disease and in favor of their common origin and convertibility.

Now we know that such association is dependent upon a widespread disobedience of sanitary laws. The following are instances of the association of morbid processes from the localization of infectious agents: 1, croupous pneumonia in typhoid fever; 2, croupous and catarrhal pneumonia and nephritis in typhus fever; 3, diphtheroid angina, meningitis, pleurisy and arthritis in scarlet fever; 4, croupous pneumonia in cerebro-spinal fever; 5, bronchitis and catarrhal pneumonia in measles; 6, croupous and catarrhal pneumonia in epidemic influenza; 7, orchitis in mumps; 8, catarrhal pneumonia in whooping-cough; 9, catarrhal pneumonia and nephritis in diphtheria; 10, diffuse bronchitis, lobular and croupous pneumonia and pleurisy in smallpox; 11, abscess of the liver in amœbic dysentery; 13, diffuse nephritis in yellow fever.

It is difficult in many cases to determine the cause and the relations of complications, as for example the croupous pneumonia occurring in typhoid fever. Generally, pulmonary affections, diffuse bronchitis, catarrhal and croupous pneumonia are not a direct result of the typhoid infection but are due to other causes, as hypostatic congestion, imperfect expectoration, inhalation of irritants, cardiac weakness, etc. But we do have a pneumonia taking place as a localized infection. As is clearly stated by Pepper¹ in his recent article upon typhoid fever: "Occasionally the disease (typhoid fever) begins with a chill and the symptoms of croupous pneumonia, and there may be nothing to justify the diagnosis of any other disease than this until after a week or more, when the failure of a crisis to occur, the development of rose-colored spots, and of intestinal symptoms, and the general typhoid condition of the patient, may show that the pneumonia was but an early complication of a general infectious disease. In some cases, it may re-

¹ An American Text-Book of the Theory and Practice of Medicine, Vol. 1, p. 98. 1893.

main throughout impossible to determine whether we have to do with a typhoid pneumonia, i.e., with a pneumonia with typhoid symptoms, or with a true typhoid fever with initial and predominating pneumonic symptoms and localization."

The above list is illustrative only, but is sufficient to show that an important part in pathology is played by the localization of infectious agents, especially upon the lungs and kidneys, and how important it is to watch these organs in all of the acute infectious diseases.

Let us turn now to diseased conditions from disturbances of one function interfering with the performance of another. Embraced in this category are many morbid conditions whose connections are clearly defined. I can only enumerate here the most common: 1, disturbances of the circulation depending upon organic heart disease resulting in passive hyperemia, impaired function and inflammation of the viscera. Here is an explanation of the fact frequently observed, that cardiac disease is usually announced by symptoms indicative of disease of some other organ: dyspnea, cough, profuse expectoration, possibly hemoptysis, diffuse bronchitis, brown induration of the lungs, depending upon long continued pulmonary venous congestion; 2, disturbances of digestion from passive hyperemia of the stomach, intestines and liver; 3, diminished amount of urine, dark in color, concentrated, highly acid, of a high specific gravity, slightly albuminous, depending upon passive congestion of the kidneys; 4, mental disturbances, impaired intellectual activity, stupor, drowsiness from cerebral hyperemia; these varied phenomena depending upon one central cause, viz., a valvular disease of the heart. Further illustrations of the interaction of deranged function are observed in diseases of the stomach. "Absorption, movement and secretion of this organ have an interchangeable connection, and are, moreover, closely related with disordered conditions of the intestines and liver. And *vice versa*, every disorder of the latter is reflected upon the former, as for example when the stomach contents are abnormally acid, or the organ contains much undigested food. In the latter instance, the chyme will act upon the intestines as an irritant, especially upon the upper part of the duodenum, swelling the orifice of the common bile duct, as a consequence of which the flow of bile is retarded, and the portal blood contaminated with the products of an incomplete digestion slows the hepatic circulation and, on the other hand, the biliary secretion is interfered with. A similar sequence of events occurs when the liver or the intestinal tract is primarily involved. Under such circumstances, we have to deal, not only with the resistance to the expulsion of chyme from the stomach by an overloaded intestine, and the backward peristaltic wave affecting the peristalsis of the stomach, but still farther reaching are the results of venous stasis affecting the entire portal system including the stomach." Thus we have so frequently associated gastric catarrh, jaundice, intestinal catarrh, constipation and diarrhea. Various other illustrations could be given of the mutual interaction of deranged functions, but these, I think, are sufficient.

Now as to the impairment of function promotive of extraneous causes: illustrating the mechanism of such influences tending to produce serious complications, we have the frequent occurrence of diffuse bronchitis, catarrhal and croupous pneumonia from

imperfect respiration, expectoration and deglutition. The conditions favorable to the imperfect performance of these functions are present to a greater or less degree in every disease characterized by that *ensemble* of symptoms known as the typhoid state. The circulation in the blood of fever toxins obtunding the sensibility of the brain, causes the patient to lie stupidly upon his back, with feeble inspiratory efforts and imperfect expectoration; to inhale inflammatory agents from the mouth and throat; and to swallow the wrong way irritants of various kinds, particles of food, foul and decomposing secretions, etc. And when to these factors we add an impaired pulmonary circulation from a weakened heart, and hypostatic congestion from a continuous dorsal decubitus, is it any wonder that in typhus, typhoid fever, remittent, cerebro-spinal fever, smallpox, and other diseases of like character, we have serious pulmonary complications taking place as a natural and, in many instances, unavoidable sequence?

In regard to morbid local conditions favoring lodgment of infectious agents, such conditions are chiefly inflammatory and affect mainly mucous membranes. These catarrhal inflammations are of special interest from the fact that by timely curative and preventive measures the onset of a much more serious malady may often be obviated. The association of tuberculous and catarrhal processes of the air passages was for a long time incorrectly interpreted; it was thought that such diseases as measles and whooping-cough were converted into tuberculous. We now know that the inflammatory conditions of the mucous membranes of the air passages, occurring in these two infectious disorders as well as in laryngitis, pharyngitis, bronchitis, tonsillitis, catarrhal and croupous pneumonia, act as predisposing causes of tuberculosis by affording a suitable place for the lodgment and development of the tubercle bacillus. In this way gastrointestinal catarrh favors the action of the specific causes of typhoid fever, cholera and dysentery. In a similar manner catarrhal processes about the throat, tonsillitis, laryngitis and pharyngitis, favor the likelihood of diphtheritic infection. Such instances could be multiplied, but let these suffice.

Concerning morbid general conditions acting by reducing the resisting power and affording a suitable soil, we have an impairment of vitality resulting from some severe acute diseases such as pneumonia, epidemic influenza, typhoid fever, and also from various unhygienic influences, insufficient food, overcrowding, uncleanness, alcoholism. Individuals who have been subjected to such influences, easily become the victims of tuberculosis, simply because a suitable soil has been provided for the lodgment and development of the infectious agent.

In regard to inherited constitutional predisposition to different diseases having a similar character, we have an illustration of how an inherited and constitutional weakness may predispose to the association of diverse disorders as, for example, in connection with syphilitic, scrofulous and tubercular processes. Thus a child with inherited syphilis becomes from the resulting cachexia, as well as from the local inflammatory conditions, a favorable subject for the development of tuberculosis. Again, a child, the subject of scrofula or tubercular adenitis, is liable to develop an intestinal, meningeal, or pulmonary tuberculosis. We have a similar illustration shown in the children of gouty parents, who instead of inheriting gout may

have an inherent predisposition to lithemia, weak digestive powers, and possibly diabetes. In certain nervous disorders we observe similar connections. Instead of inheriting the particular nervous malady from which his parent suffered, the child inherits a neuropathic constitution; and hence we notice the association of insanity, epilepsy, hysteria, migraine, alcoholism and the like.

As to extrinsic agents productive of inflammatory and degenerative processes in different organs and tissues, we have certain chemico-toxic and infectious agents which, though differing entirely in chemic constitution, produce similar pathologic results, acting either in the process of elimination on certain organs, or having an affinity for certain tissues, in which case they produce their effects through the circulation. Familiar examples of such agents are lead, alcohol and the syphilitic poison. Thus we find these three lethal substances playing an important rôle in the etiology of a large class of chronic inflammatory and degenerative processes, as for example chronic endocarditis, arterio-sclerosis, chronic parenchymatous nephritis, contracted kidney, cirrhosis of the liver, gout, multiple neuritis and chronic system degenerations, and inflammations of the spinal cord such as chronic myelitis and locomotor ataxia. From the common origin of such diseases we often see them associated, as arterio-sclerosis with chronic endocarditis and interstitial nephritis, contracted kidney with cirrhosis of the liver, gout with interstitial nephritis, cirrhosis of the liver with multiple neuritis, valvular heart disease with locomotor ataxia. In many instances several of these etiologic factors unite to produce a given disease, and it is often difficult to assign to each its proportionate share.

There are certain irritative substances produced within the body which act in a similar way, and produce morbid changes of like character as those mentioned in the last clause. We have, for example, frequently associated a chronic endocarditis and Bright's disease, or contracted kidney with cirrhosis of the liver, etc., where we can exclude any of the extrinsic agents above mentioned, and must assume the presence in the blood of some irritant which in the process of excretion or otherwise will produce inflammatory and degenerative changes. Our knowledge of the ultimate phases of digestion and assimilation is as yet too imperfect for us to say with certainty what is the chemic constitution of such agents in all cases; but of this fact we are assured, that is, that some derangement in the metabolism of nutrition, depending upon an excess of certain articles of food, especially the albuminoids, plays an important rôle in the etiology and association of diseases such as gout, diabetes mellitus, interstitial and chronic parenchymatous nephritis, chronic endocarditis and cirrhosis of the liver.

There are, again, certain diseases frequently found to coexist, not explicable in the before mentioned categories. I refer especially to cardiac and kidney disease. The association of heart and kidney disorders has been a matter of common observation for a long time. It did not escape the notice of Richard Bright who commented upon its causes more than half a century ago. The connection between morbid conditions of these two organs is manifest in many instances; for example, where the heart is primarily affected, and we have then the kidney of passive congestion, or where we have embolic processes in the

kidney originating from an endocarditis, or further yet, when we have disease of both organs resulting from a common cause as arterio-sclerosis; where a hypertrophy of the left ventricle occurs as a sequence of obstruction offered by diseased arterial walls, and, still further, where the kidneys suffer from impaired nutrition, affecting primarily the secreting cells. The pathologic sequences in such cases are readily understood, but what is the explanation of the large number of cases where the kidneys are the organs primarily involved and where there is no arterio-capillary fibrosis?

I can not here enter into details concerning the various theories which have been advanced to account for this connection; the truth is found probably in no exclusive theory, but rather in a combination of them all. Thus we can conceive how an altered constitution of the blood depending not only upon an accumulation in it of excrementitious products, but from the loss of albumen also, would offer an obstruction to the circulation and be followed by a compensatory hypertrophy. And we can understand that there is an element of truth in Traube's mechanical theory; for in many cases in consequence of deficient elimination of water there is an overfullness of the vascular system which might occasion a hypertrophy. The two would not exclude the theory offered by Dr. Tyson, viz., that the process is compensating and another instance of nature's method of supplying the deficiencies of one function by increased action of another. In this case a certain number of the secreting cells of the kidney having been destroyed, the heart, by increased action and consequent hypertrophy, sends the blood coursing through the kidneys under stronger pressure with the effect of increasing the amount of urine, and thus compensating for the loss of renal tissue.

In conclusion, let me mention briefly the principal facts relating to the connection between arterio-sclerosis, cardiac and kidney disease with cerebral hemorrhage and embolism. In almost every instance hemorrhage of the brain is due to the rupture of miliary aneurisms, and later investigations go to show that this disease of the vessel wall is identical with arterio-sclerosis. The etiologic factors also predisposing to cerebral hemorrhage are those which are contributory to atheromatous degeneration of the arterial walls. We have several other factors explaining the frequent association of cardiac and renal disease with rupture of blood vessels in the brain, as, for example, passive congestion from valvular disturbances of the circulation and weakened heart action impairing nutrition of the arterial walls, to which must be added the increased liability to rupture from strain due to a general arterial tension, the latter being an almost invariable accompaniment of interstitial nephritis and the hypertrophied heart connected with it. Hence we find hemorrhages of the brain productive of either mild or severe hemiplegic attacks or directly causing death in many cases of contracted kidney.

The *rationale* of cerebral embolism and thrombosis in connection with heart disease admits of easy explanation. We have frequently occurring thrombotic deposits upon the mitral or aortic valves, from chronic or ulcerative endocarditis, which are often washed off and lodge as emboli in one of the cerebral arteries; thrombosis is favored also by arterio-sclerosis through the roughening of the inner coat, inelasticity and occasional narrowing of the arteries. We may thus

have clots forming in the aorta or arteries at the base of the brain from whence they are carried into the smaller arteries as emboli.

WHY GENERAL PRACTITIONERS SEND CASES TO THE HOSPITAL.

BY S. S. TOWLER, M.D.

MARIENVILLE, PA.

I have adopted the above title simply because I could find no other for this brief paper, and yet it does not express all I want to get at. In an excellent article in the *JOURNAL* of January 27, Dr. Keister says that, "in nine cases out of ten, it is sheer stinginess on the part of the physician, that he is not properly equipped with instruments. This point, and one other, are the only exceptions—that I see—to take to that practical paper. The "one other" is this: "Conservative surgery is yielding better results every day, and I believe the time is not far distant, when women's ovaries will be let as severely alone by the abdominal surgeon as the Holy Bible." All I want to suggest on that point is that perhaps if "the abdominal surgeon did *not* let the Holy Bible," so "*severely alone*," he might operate less on "the women's ovaries." However, there are abdominal surgeons, and surgeons abominable. Stinginess will, to a great extent, cover a class of doctors without instruments, but there is a large number who will not purchase a full office outfit for the same reasons that they and others send cases to the city, or call a specialist.

There are first, the class of practitioners who know that they have not the nerve or skill to be good operators, and yet many of them are *good* physicians. These men send their patients, not because they know so little, but because they have arrived at that point where they know *what* they know. A man may be a most excellent physician and yet a very poor surgeon, and the physician who knows *that*, is to be commended for sending elsewhere. He is away ahead of the fellow who, thinking he knows it all, blunders away at all hazards.

But there is another reason why special cases go to the hospitals and experts: That is, because the general practitioner, especially in the country, has a very different environment from that of the man in the city. Every one knows the successes and failures—so to put it—of the country doctor, and unless he has attained an age and experience that protects him, his fatal cases are fatal to him.

To illustrate: In 1868 I had my first thigh amputation. About the same time Dr. Joseph Pancoast performed exactly the same operation on a wealthy lumberman a few miles away. Dr. Pancoast came and went the same day, and received for his work, \$1,000. I got the county fee bill of \$125, and had to take care of my patient until well. Some four weeks after this, Prof. Pancoast was up in my section on non-professional business. Meeting me, he said: "How is your patient?" "All right," I replied; "come and see him." Arriving at the house he looked the stump over, and said very kindly: "Good job; good as mine; it's all right." "Not exactly, Professor," I replied; "not exactly. It looks to me all wrong. Now here am I, a young fellow having all the no good, no pay patients shoved on him, and glad to get cash enough to pay my salt. When I do get a good case I have to take the county fee bill; you,

said to be wealthy, get \$1,000 for less work. In the equity of the thing I ought to have the thousand, and you the one hundred and twenty-five." He laughed for a moment, and then with a kindly sympathy and grave face, as he put his arm over my shoulder, said: "That is not the worst of it, my boy. I could have killed my patient, and it would have been all right; your patient might have died under the best treatment in your hands, and it would have killed you." That was years ago, and while I have safely passed that sort of fear, yet there are a great many practitioners subject to that same risk.

The country (and I include in this, town and country practice outside of larger places) surgeon may know that he can do an operation, and do it well. But no matter how well done, so far as skill is concerned, if the patient dies in the operation it takes years to live the effect down. If a patient goes to a hospital, with a fatal result, or dies in the hands of a specialist, it is, "Divine Providence that removed," and *not* "the great hospital doctors we had when Ann died."

The bickering jealousy in the profession is largely responsible for this. All the colleges in the world will not take meanness out of a man if it is born in him, and in the recent years when M.D.'s were made in "job lots," the profession got its share of the mean men in the world. A country doctor's patient dies in the operation. The next country doctor says: "I am sorry, very sorry, but why didn't the fool send her to a hospital? He never ought to have attempted such a thing." The next country doctor says: "I was afraid of that; I almost felt certain he could not carry that case through. He is too risky, too risky." Perhaps one out of the lot comes out like a man, saying: "He was all right. That same result would have happened any way, or in any one's hands. No one could foresee it." But mark you, every old woman in "the country-side," takes up the woeful tale, and spreads it around until harrowing stories of how "Dr. Smith grubbed in her belly with his hands and tore all her insides out," are told at every fireside. Poor Smith, who was perhaps the brightest doctor in that whole section, comes to be looked upon as a "butcher." Next time Smith gets a chance he sends the patient to the city, and goes along himself to take a hand in the business. Result: "Ah! Why didn't he do that with poor Mrs. Jones that he butchered to death?" Then if Mrs. Brown comes back cured, or partially relieved for the time being, she becomes at once a sort of heroine. Every woman in the town or country for miles, who has either a real or fancied pelvic trouble, and whose husband can raise the "ducats," wants to follow suit, and the family doctor must help the scheme, or take the consequences. Away goes the procession, and the general practitioner gets his pay in the taffy that the specialist sends to him through the patient.

Again, the country surgeon has constantly before him the possibility of a malpractice suit. Even in the line of general surgery this is a continual menace. A badly fractured leg or mangled arm, no matter how skilfully treated may get him into untold trouble. Much more is an unfortunate result of an operation of his own proposing, in special surgery, liable to do so. Furthermore, the more charity in his soul, and the poorer the patient, the more likely he is to be persecuted as well as prosecuted.

Again, the profession itself is largely to blame for this. Dr. B. sees a fellow with a limping leg. He squeezes it a time or two, and says, in a tone of righteous indignation and assumed great knowledge: "Who set that leg? The man who did that job ought to be prosecuted." With no thought or care of how good a job Dr. A. had made of a very bad leg, he spits out his professional venom. Away goes the fellow limping worse than ever—indeed, now he can hardly get along at all, and has a little groan for every step—and sees a lawyer. Result: "Certainly, sue Dr. A. He has inflicted great damage on you. Ten thousand dollars is what we want from him." Sue he does. Dr. A. comes out triumphant, but it has cost him hundreds of dollars, and weeks of time for himself, and lost days for his medical friends, to gain his victory. Result again: In that section the most risky cases are sent to the hospital. That is no overdrawn picture. In this and adjoining counties the best medical men in them—and I use the expression advisedly, have been subject to just that sort of treatment. In one case the claim was for damages for a ruptured perineum. At the trial the evidence showed that the very doctor who urged the suit had used the forceps in delivery, and that the defendant had had no opportunity to rupture the patient at all. In another case the prosecuted doctors had gone so far in their interest in the case, as to procure without cost, the services of the late and great surgeon, Dr. Hays Agnew, for their patient, but that did not save them from suit, though they won the case before the jury.

Another case after weary months was won by the defendant at a cost of over three hundred dollars. Another doctor, not very far from me, had a verdict rendered against him which was so unjust that the court granted a new trial. The next jury decided against the doctor, and again a new trial was granted. A third jury and a third new trial followed, and then the case was compromised.

In another case the plaintiff demanded \$20,000. Inside of time of trial he offered to settle for \$35, and on being told he could not have 35 cents, proceeded to postpone the case from court to court, until the defendant got hot and put the case on the trial list himself. The plaintiff never appeared. The defendant got a non-suit and full allowance of costs. The plaintiff, as usual, was not worth a copper, and the defendant was at a great loss. In every one of these cases the instigator was one of the profession. In addition to this form of affliction, the country surgeon is aware of the unfortunate fact that in his community one fatal result in surgery outweighs a dozen successful cases. The good cases are soon forgotten; the bad ones never.

Again, the country physician is at a disadvantage in special cases, especially those that require rest. If his patient is fairly well off, and has good common sense, he will succeed in having his orders carried out. But if he says to a patient, with a large family, and whose "hired girl" has skipped out without notice: "Madame, one thing you must have, and that is absolute rest"—the patient looks at him despairingly, and says: "Doctor, how can I have that with my family cares?" Result: She takes lots of medicine, washes, douches, battery treatment and so on, and gets no better. In despair, the husband raises some cash and sends her to a hospital where she gets the rest she so much needed—and perhaps

what she got besides she didn't need. As in the surgery case, she sets the pace for other women and away they go, one after the other. All these elements combine to put the country doctor at a disadvantage, and to lessen his desire to treat special cases.

It is admitted, certainly, that this state of affairs is very largely wrong. More special cases ought to be treated in the town and country than are treated there now. The only remedy I can see is this: 1, the country doctor ought to have his trained nurses, the same as the city man; 2, County, State and National societies ought to be made so strong and so well organized as to form a practical defensive and—so far as the caviling, sneaking, backbiting doctors are concerned—offensive alliance, that will not only afford ample protection to the honest practitioner, but silence the croakers and educate the public. These societies are of more use to the general practitioner than any one else, and are the best means of elevating the tone and dignity of the profession. Besides this, one meets through them some of the best fellows in the world. I have never known the "weakest vessel" present at such meetings, to be rudely repelled by the "biggest guns," but kind and courteous consideration is the rule.

The last points are mentioned to show the value of organization, and not to encourage needless bother of busy men, because they are good-hearted. Dickens said once, that Americans when not clear as to what should be done would hold a meeting and "resolute." It is more to the purpose to build up the County, State and National organizations. The highest possible motives sanction it, and even the rather mean motive of "policy," if a man has no higher, encourages it. So, having come to lastly, in my effort to give a reason why hospitals are never short of "clinical material," and to suggest a remedy for the troubles of the country brethren, I pronounce my benediction on the JOURNAL, and go to bed.

MY EXPERIENCES AS A SPECIALIST.—A DREAM.

BY J. L. TRACY, M.D.
TOLEDO, OHIO.

Psychologists have never satisfactorily explained the process by which we unconsciously and yet seemingly voluntarily permit ourselves to give audience to the acts and sayings of the peoples of dreamland. The ego of our dream has never been accounted for either. His relationship to ourselves, however, seems as we recall him, to be in many instances a very close one. He is like us and still is decidedly unlike us.

He appears upon the mystical stage which borders hard upon life's pathway, acts his part and retires behind the scenes. We awake to think, study, wonder and theorize concerning him, and we tire, cerebral anemia presumably, obtains, we nod in our chair and find him bowing to us. Evidently he follows us when we are awake, and we follow him when we are asleep. We call ourself the substance, him the shadow. This ego, our other self, takes possession of our quiescent physical body, divests it of tangibility and sensation, and with this etherialized body starts off, without effort, to travel long distances, and without a feeling of shame parades it naked through the

streets. He makes the body live consecutive days, weeks and months, without the expenditure of what we call time, and with no thought of incongruity places it in a saddle, to ride its best friend for a horse. The different stages in the dissolution of self are noted with interested indifference, our other self even in some instances watching his own burial, expecting and experiencing his own resurrection, and then going on to live lengthy periods in the spirit world. Psychologists have never been able to explain these things to us, because any one else knows as much about dreams as the psychologist does.

Psychologists doubtless dream according to psychologic law, but all dreamists do not dream that way. I do not. A biographer of Napoleon Bonaparte says of him, that he was a medley of contradictions, an incomprehensible self. My dream self in those respects, is much like Napoleon Bonaparte. If a man were responsible for what he dreamed, a dream like one of mine would load him up with responsibility pretty fast, and if any reader of this JOURNAL ever attempts to write a dream, he will feel the necessity of prefacing the narration of his experience while in dreamland, with such a statement of facts regarding dreams in general, as will shift all responsibility for the dream-thoughts upon his incomprehensible self.

The thought of irresponsibility for having dreamed a dream, is to me a great relief. My dream-self never pays any attention to me, and never talks about me to my back, as I do about him, so that I do not know what he thinks of my way of doing things. Judging though by the friends that I seem to make while in dreamland, my dream actions and sayings are quite as much in harmony with the opinions of the inhabitants of dreamland, as are my waking thoughts and practices with the things which are more unquestionably mundane.

I would not tire you with what the French people call a résumé upon the subject of dreams, yet, somehow, it seems to me that I will feel freer to relate the incidents of my dream, when I have called your attention afresh to some of the freaks which dreams may play; but, I feel safe even now, to go so far as to assert that I dreamed that I was a specialist.

I would have you bear in mind that in my dreams, incoherency, grotesqueness, improbability, inconsistency and absurdity, are always to a lesser or greater degree innate. To my dream-self, however, there is no thought of absurdity, but, on the contrary there is a logical working out of the laws of cause and effect, and desired results appear to be attained by the use of the phantasmal means at hand. Dreams as ordinarily dreamed, have been classified as air-castles, novel-reading, hair-invigorators, theosophy and plain dreams. This classification shows the evasiveness of dreams. At first sight I thought it an exceedingly unscientific one, but after a studious effort of some length to improve upon it, there came to me the old adage, that it is easier to discover a fault than it is to correct it, and I decided to let the classification alone.

Notwithstanding alienists teach that the longest dream is scarcely longer than a few minutes in duration, there is a good deal of time wasted in dreaming. A dream, as I have said, annihilates time, distance, and the material. It ignores our best waking thoughts, and puts two bodies into the same space at the same time. A dream mocks at reverence, and

makes us reverence mockery. We see as regular order, retrospection preceding perspection. A dream laughs at a difficulty, recognizes no such thing as a problem, but on the other hand presents you with the solution which balances without the shadow of a doubt. My dreams to my dream-self are realities. A dream must have its conception in some wakeful thought. For instance I could never have dreamed that I studied and worried over the selection of a specialty, if I had never heard of such a field of practice, any more than one who had never heard of the conflict, could have dreamed of the battle of Waterloo. Sometimes in dreams, the hobby of the dreamer comes to the surface, and in this instance, I recollect that I examined each specialty which presented itself to me, from the point of view of its probable money value to me. How I came to think of reflexes I do not now recall. I do remember distinctly though, that I threw out of consideration everything which did not have within it a good reflex center.

I dreamed that I finally selected habitual constipation as my specialty. The very general prevalence of the affliction, and the possible reflexes which could be made to radiate from it, struck me as being very valuable features. I examined it carefully, in my dreamy sort of a way, and could scarcely think of a disease which could not be accounted for as a reflex of habitual constipation. I was known in my town as the habitual constipationist.

To get my specialty before the public, I thought out what seemed to me then to be an original idea, of searching the records of the past for evidences of its earliest existence. The result of my investigations was a collection of curious instances wherein it seemed to me that habitual constipation had been, in some incomprehensible manner, overlooked as being the exciting factor in the arena of life. I issued reprints of my article, and in my dream it was not long until I had an extensive practice among paying patients. Since my dream, I have recalled the fact that years ago, when I was a medical student, I had visions of such a patronage. If I had a free clinic I can not recall it. Memory is one of the most treacherous and untrustworthy things upon which we place reliance, and so it may be that during my dream my mind recalled impressions which earnest efforts afterwards failed to bring to memory. At any rate, to the best of my recollection I had never, until in my dream, associated the instances which came to me then, with habitual constipation. The symptoms of my visionary patients were always the verbal expressions of themselves, or of others. Why that was so, is just as unanswerable as some other mysterious things connected with dreams.

The cases which I particularly recall, or which I can recall with sufficient distinctness to enable me to present to you, show another peculiarity of dream thought, which is that a trivial incident of early childhood may seem to be of the same importance as are questions which affect the welfare of a nation. Lack of detail is an ever present characteristic of my dreams, and in this dream how I got to my patients, or how I was sent for are shadowy facts which were left out of the dreamy make-up. I have numbered my cases, but whether in the order in which I dreamed them, I do not know. I never dream consecutively.

Case 1.—Mary, aged 7. History negative. Blonde. Curly hair; eyes blue, fairly nourished, temperature, pulse and respiration normal. I had been sent for by her teacher. I

found her at school, in a little schoolhouse at a country cross roads. I noticed a lamb with a ribbon around its neck, nibbling grass in the schoolhouse yard, as I went in. I found the teacher surrounded by the pupils, who were crying, and asking her: "What makes the lamb love Mary so?" Mary sat in the corner by herself, apparently studying her lesson. I dreamed that I thought as I looked at her, that no one but a specialist would think for a moment that there was any serious thing the matter with Mary, but when I left my office to go to see the patient, I had very little doubt as to what condition I would find her in. In a dream diagnosis, I think that a preconceived opinion like that, very largely shapes one's conclusions. I diagnosed habitual constipation, very much to the teacher's surprise. The steps to my diagnosis were, tender age of patient, great susceptibility to impressions, and long companionship of playmate. A mimetic, habitual constipation. I advised as the only possible relief, an operation, which was declined, and the patient passed from my observation.

Case 2.—Male, aged 40; married; a citizen of Indiana. Tall and slim; long bony arms; heavy whiskers and eyebrows; hair long, and combed straight back over his ears. Teeth discolored by tobacco, which he continuously chewed. Extreme nervous temperament. Heart and lungs were not examined; cerebral symptoms were not looked for. His landlady said that when he first came to Washington he had a ravenous appetite; lately though, he had eaten less and drank more. He was having one of his attacks when I came into the room. The first thing which I heard him say, was: "He who doubts he is a dastard; he who dallies is damned."

The puzzled expression upon the faces of those around him plainly showed the want of a satisfactory diagnosis. To me in the dream, his condition seemed to perfectly illustrate the baneful results which follow lack of confidence, and the putting off from time to time, attention to those calls, whose strict observance is the price of physical health.

Another symptom which I noted, was an inflated ambition to be known as a reformer. At the time I saw him he was presenting a bill, entitled, "An Act Regulating the Formation of Funeral Processions, Labor Day Parades, and all Street Displays whatsoever." I do not remember the detailed workings of the proposed Act, and if I could recall them they would hardly add anything to the importance of the symptom. I do remember, however, that the change or reform which the Act proposed, was to have the two-wheeled carts, one-horse rigs, and the poorer turnouts placed at the head of the procession; the silver-plated harness, bangles, and liveried footmen to bring up the rear. A few minutes spent with the physicians in attendance, was sufficient to convince them that it was a case of habitual constipation. An operation was decided upon, and the next morning set for making it, but whether it was done, and if done whether I regarded the operation as a successful one or not, I can not recollect.

Cases 3 and 4.—J. and G., boys aged 9, twins. Parents dead; cause of death not known. Scarcely of average height, illy nourished, and because of their remarkable resemblance J's hair was allowed to remain long while G's was clipped. Just before I arrived, they had both

"Gone up the hill to draw a pail of water."

I was told that they usually did so about four times a day. Owing to the commotion among the grief-stricken friends, I could not learn the exact size of the pail. There appeared though to be no doubt but that there had been quite marked polyuria. I remember calling the attention of the physician to the fact that one pail to two boys, meant one-half pail to one boy, and that the amount was not as he had calculated, four pails each, a day. He had been content with finding the diabetes, and had so diagnosed the cases. No post-mortem examination was allowed, but I was convinced, and so expressed myself, that the diabetes was reflexly the result of irritation caused by habitual constipation.

Case 5.—Male, aged 46. United States. Does not know anything about his parents. Brothers and sisters, if living are, he says, younger than he is. Weight 230 pounds; red face; eyes half closed. Temperature $101\frac{1}{2}$; respiration a little hurried. There is a good deal of excitement—though singularly enough, the excitement seems to be mixed with a considerable degree of obtuseness. Appetite for food, nil; mouth dry; breath emits a very strong odor. I found him in spite of the well-meant solicitations of his friends leaning against his desk, and demanding that the presiding officer tell him "where he was at." The real underlying cause of the mental condition of this patient was so obscure as to have greatly perplexed the physicians who had been in attendance.

As this condition of clouded excitement passed off, he would, so to speak, become poetically melancholy. There were two stanzas which seemed to occupy his mind most of the time. One of these was,

"The mill will never grind again
With water that has passed."

The other, very much like it in sentiment, was,

"Full many a flower will bloom and blush unseen,
And waste its fragrance on the desert air."

One of his physicians who was a very matter-of-fact kind of a man, had tried to arouse him from his melancholy thoughts by telling him that it would be a new kind of a desert which had flowers in it, and the patient discharged the entire corps of physicians on the spot.

I very soon became convinced that it was a case of habitual constipation. In all of my cases I remember that I always advised an operation, but I can not recollect the nature of the operation. How I came to associate an operation with habitual constipation I can not conceive and still whenever I could get consent to operate I remember that I always made an operation of some kind, and did remove something. This case was under observation for a year or so, and his most intimate friends regarded him as cured. I felt safer though in recording the case as improved, which I did.

In one of my dreams a century or two makes a very little difference. The past, present and future, all seem to be of the same tense. One of my Ireland dreams is just as sensible, and just as systematically gotten up, as is one that was located in Ohio. When I dream a foreign dream, I do not always imagine myself to be in a foreign country. I have the peculiar faculty of Europeanizing American scenery so as to bring it into harmony with the citizen of any other country whom I have happened to run across. Sometimes, and the next case is an instance of that kind, I do not remember anything regarding the residence of the principal actors in my dream.

Case 6.—H., male, aged 21. Height five feet nine inches. Weight 170 pounds. Black hair, black mustache, black eyes, dark complexion. Body muscular. Father died a few months before of some external trouble. Only sick an hour. Mother living, of fickle disposition, if not positively depraved. I did not arrive until an hour after his death. Not much could be learned of his childhood, but at his maturity he was of more than average intelligence. He was, too, impulsive and inclined to be sentimental, and so when a year or so previous to his death those about him noticed that he was in love with a girl of the neighborhood, they were not surprised to find that he was in love with all his might. I had been asked to see him on account of the development of symptoms which threatened insanity. I was told that he had never located his trouble in any particular part of the body, but that his symptoms had been of that vague, undefinable character, such as is common to nervous trouble of reflex origin. To friends who had tried to comfort and encourage him, he had complainingly asked:

"Who would these fardels bear,
To groan and sweat under a weary load?"

He expressed himself as "tired of the load" and said that to be rid of it

"Was a consummation devoutly to be desired."

The dominating theme of his erratic, though purposeful delineation of his trouble, was contained in the introductory phrase, "To be or not to be, that is the question."

I dreamed that this case was an exceedingly difficult one for diagnosis to the physicians in charge of it. I went at

the case with the thought in my mind that it was probably a case of habitual constipation. I recalled the sudden death of his father, the estrangement from him of his mother's affections which followed close upon her somewhat hasty acceptance of new hed and board, his love affairs, in which had been currents which had not run smoothly, and the condition of unrest which pervaded society generally. These were all of a disquieting, dispiriting tendency, exactly such circumstances as are likely to produce irregularity in the habits of life. After viewing the probable effect upon the patient of all these forces, I had little difficulty in convincing the physician that the trouble had been habitual constipation.

I considered myself very fortunate that I was permitted to make an autopsy, and was much pleased when the examination confirmed the diagnosis. I secured what I looked upon at the time as a very beautiful specimen, but just what the part which I brought away was, I do not recollect. I dreamed that I put the case down as one which illustrated the foolishness, if not indeed, the criminality of trusting in such cases to medication.

Case 7.—Male, aged 50, United States. Medium height; weight 250 pounds. Dark hair, mustache and eyes. Florid complexion, body well developed, and inclined to corpulence. Large head and larger neck. Temperature 97; pulse 76, respiration 22. Appetite good, digestion perfect, sleeps well at night. Marriage relations not inquired into. Family history excellent. His physician noticed nothing in particular wrong with him, until one day the patient began to insist that he was "confronted with a condition, and not a theory." Of itself, this symptom did not seem to the physician alarming, but there was such a positiveness in his manner of describing his trouble, as to cause some uneasiness to the physician, and so I was sent for.

I dreamed that I found the patient seated in a fishing boat, waiting for his helper to adjust a new bait. I thought that there was something so peculiar about his malady as to have attracted wide attention. I dreamed that there were many conflicting opinions among physicians as to the nature of the trouble, and, in consequence, many different plans of treatment had been proposed and tried, but without benefit. I dreamed that I studied and tried to analyze a great mass of symptoms without reaching a definite conclusion. I do not now see why it should have been so, but in my dream thoughts the word, "confront" seemed to be an insuperable obstacle to making the diagnosis of habitual constipation. His persistent statement that a condition confronted him, was in my way for a long time, and I had nearly despaired of making the diagnosis, when I chanced to stumble upon the symptoms of "innocuous desuetude." This symptom, to my mind, cleared up the diagnosis at once, in which diagnosis the physicians in attendance readily concurred. They joined me in advising an operation, to which the patient consented. While the preparations for the operation were being made, the patient related to me an incident which happened a few days before:

He said that some kind of a parade or celebration had taken place in some inland towns and, as part of the display many balloons, profusely decorated with small flags had been sent up. He said that in floating off, the balloons would collapse, the little flags would become disengaged from the balloons, and dart to the ground. He said that he had been lazily watching these flags fall for some time, when he happened to fix his eye upon one which was about to strike the ground near him. The flags fell staff downward, and as this one struck the earth he saw it sever from the body the tail of the common swift or newt, a little animal of the lizard group, the *spelerpes longicauda*. I dreamed that he said the staff of the flag was sharpened flatwise, which made it cut more smoothly than it otherwise would have done. The animal ran off and hid itself among the rocks, but the tail lay where it fell. I dreamed that my patient said that as he sat watching the tail wiggle about, as such tails will, that he could but think of the accident to the lizard as one of the purest chance occurrences which had ever come under his notice. Hours before, in a distant city the little flag had borne its humble part in the display, had floated away through space, had fallen to the ground and injured the little *spelerpes longicauda*. To physicians the most interesting part of the story is in what followed after the tail had been severed from the body. He said that while he was musing upon the accident, he noticed the animal emerge from its hiding place, slyly steal up to where the tail was, grasp it under one of its fore legs, and carry it to the water's edge. The lizard then carefully washed the wounded end of the tail, and the stump end of the tail upon its own body;

this done it laid the tail upon a stone, and, backing up to it, laid the wounded ends carefully in coaptation. After remaining perfectly quiet for a few minutes, the lizard slowly moved away to its hiding place again, taking the tail which had adhered to the stump, with it. My patient told me that he saw the lizard the next day, and there was only a dimly perceptible scar at the point where the amputation had taken place.

I was a little more incredulous about some parts of the story than I cared to express to my patient, and so made an excuse for consulting his library, which I dreamed he had with him in the boat, and I found in an encyclopedia mention made of the alleged recuperative powers of this animal under like circumstances. The manner in which the accident to the lizard had happened, I had not doubted.

I now learned that my patient had been, a year or so previously, operated upon by an habitual constipation specialist, but as there was a difference of opinion among those who witnessed the operation as to whether all of the parts had been removed, I decided to make an exploratory operation and clear up the uncertainty. If nothing to remove were found, the operation would stop with the exploration.

From this on, I only remember that I felt satisfied with the operation, and considered it a success. I recall also that I thought I kept watch of my patient for a number of years, and as no positive symptoms of the trouble showed themselves up to that time, I recorded the case as recovered.

APPENDICITIS WITH ORIGINAL REPORT, HISTORIES AND ANALYSIS OF ONE HUNDRED AND FORTY-ONE LAPAROTOMIES FOR THAT DISEASE UNDER PERSONAL OBSERVATION.

Read before the Pan-American Medical Congress.

BY J. B. MURPHY, M.D.

CHICAGO.

PROFESSOR OF SURGERY, AND CLINIC SURGERY, COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO; PROFESSOR OF SURGERY, POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; ATTENDING SURGEON TO COOK COUNTY HOSPITAL; ATTENDING SURGEON TO ALEXIAN BROTHERS' HOSPITAL; CONSULTING SURGEON TO HOSPITAL FOR CRIPPLED CHILDREN, ETC.

It might seem necessary to offer an apology for presenting a subject that has been so thoroughly discussed at medical associations and so voluminously considered in medical literature in the past four years. But I will offer none for presenting this subject, as many of its important relations to the physician and patient are still moot questions. There is probably no subject in abdominal surgery on which the profession is so divided and on which such opposite views are entertained. Gynecologists are fairly well agreed on what the procedure should be in cases of pyosalpinx, ovarian cysts, and even now on fibroid tumors, but at every medical meeting in which the subject of appendicitis is discussed we find the physicians almost equally divided for and against operative procedure. The question presents itself, Why are they thus divided? The answer is, They are divided because they have different views, or better, because they are not informed on: 1, the pathologic conditions that exist; 2, on the probable course or clinical history of the patients suffering from these pathologic conditions unaided by the surgeon; 3, on the comparative results to the patient by the aided and unaided methods. I will not consider

the anatomy of the appendix, nor treat of the various positions in which it may be found. The excellent paper by Dr. Joseph D. Bryant fully elucidates that subject.

Pathologic Conditions.—Let us first consider the pathologic conditions that exist. The inflammatory or infective lesions of the appendix for a scientific discussion of their relations to the comfort and life of the patient should be divided into the following classes, because each class has advantages and disadvantages peculiar to itself, and in considering the effects of these lesions upon the patient a fair idea of the percentages can not be obtained unless the classification is carefully carried out, so that the degree of jeopardy may be uniform. The lesions of the appendix and their effects on the surrounding organs and peritoneum should be divided into:

1. Simple catarrhal appendicitis.
2. Ulceration of the mucous membrane without perforation; *a*, pressure atrophy with infection; *b*, simple ulceration with purulent accumulation; *c*, typhoid ulcer; and *d*, tubercular ulcer.
3. Ulceration of the mucous membrane or ulceration of the appendix with perforation.
4. Gangrene of mucous membrane of appendix; *a*, local; *b*, general.
5. Gangrene of appendix complete; *a*, with perforation; *b*, without perforation.
6. Infection of peritoneal cavity; *a*, without perforation local and general; *b*, with perforation local and general.
7. Peritonitis; *a*, local peritonitis without limiting adhesion; *b*, circumscribed abscess; *c*, diffuse general.

The scope of this paper does not include the neoplasms, traumatism, nor herniæ of the appendix. I include in this paper the cases occurring in the practice of my partners, Drs. E. W. Lee, F. S. Hartman, and H. R. Wittwer, as the cases were all treated on the same basis, and had equal chances of recovery. Though the actual operations were performed by

Dr. E. W. Lee	20 cases with 5 deaths.
Dr. H. R. Wittwer	4 cases with 0 death.
Dr. F. S. Hartman	9 cases with 1 death.
Dr. J. B. Murphy	108 cases with 10 deaths.
Total	141 16

Mortality with my own cases, 9.2 per cent.

Etiology.—The pathologic lesions above mentioned are produced by certain causes which we will classify as:

1. Simple pus-infection, producing the catarrhal variety.
2. Extensive infection of wall by the amœba coli or pyogenic microphytes, producing gangrene of a greater or lesser portion of the appendix.
3. Pressure atrophy with infection of appendix; *a*, fecal concretment; *b*, foreign body.
4. Specific infections, as typhoid, tubercular, etc.
5. Retention accumulations; *a*, from cicatricial contraction; *b*, from occlusion with enterolith or foreign body.

Perforations of the appendix from various causes, I have found in the report of 465 autopsies of this disease occurred 324 times; of the appendices removed by us, there were perforations 39 times, and 58 removed during attack, or 70 per cent.

The simple catarrhal variety of appendicitis without retention is seldom brought to the surgeon's at-

tention; more frequently, and still not often, to that of the physician, as it usually accompanies a catarrhal enteritis, and has no symptom peculiar to itself except a slight excessive tenderness in the right iliac region. Of this class, we have not operated on or seen a single case. Catarrhal inflammation with retention is a very different condition; it presents a serious train of symptoms, producing a pulse as high as 130, temperature of 105 degrees, as can be seen by Cases 65 and 118.

This form is frequently brought to the surgeon's attention. It is accompanied by a train of severe symptoms both local and general, and endangers the life of the patient much more than the preceding one. There were three cases of this variety operated on, all recovered. Of the 141 cases operated on, the appendix was found completely gangrenous and not perforated in 4 cases, with 4 recoveries, no deaths. In this form of appendicitis the appendix is usually surrounded by bowel or omentum without a pus infection of the peritoneum.

Pressure atrophy of the appendix with perforation was considered in former times to be due in the majority of cases to foreign bodies that had passed into it from the alimentary canal. This was erroneous. Later observations show that only a very small percentage is due to foreign bodies, such as seeds, cherry stones, etc., passing into the appendix in that manner, but the great majority of pressure atrophy perforation is produced by fecal concretions (enteroliths). Number of foreign bodies in our cases, five, 3.5 per cent.; number of fecal stones, forty-three; percentage of fecal stones, about 30 per cent. This does not represent all, as many of the appendices allowed to remain undoubtedly contained them.

The specific infections seldom produce obstruction of the appendix or special symptoms. Of our cases, we had one of the typhoid variety. Mrs. B., Case No. 46, operated; recovered. Of the tubercular variety we had one case, and the patient recovered from the immediate effects of the operation, and died of a general tuberculosis eighteen months later.

Retention accumulations in the appendix from cicatricial contraction occur where an ulcer has previously existed in the appendix, and the contraction so occludes the caliber of the base of the appendix that the secretions in the cavity of the appendix accumulate, produce distension, bring on attacks of pain, fever, and local tenderness, and finally rupture. The only cases of this kind were Case 101, twelve attacks in two and one-half years, and Case 126, five attacks in eight months. The effects of the obstruction of a foreign body or concretment at the base of the appendix is the production of a gangrene of the appendix: 1, by infection and gangrene, not by restriction of circulation, as the appendix receives its blood supply from the side, not from the end; 2, by retention of contents; and 3, by strangulation from swelling of mucosa. The cases of this kind will be considered under the head of gangrene of the appendix.

Pathologic Lesions.—Simple recurrent catarrhal appendicitis is considered by physicians to be a frequent disease. The course of this disease is supposed to be an inflammation of the appendix and an accumulation within the appendix of the products of inflammation with the subsequent escape through the opening of the appendix into the cecum. That recurrent appendicitis is not of this variety, I am convinced.

Recurrent appendicitis in the cases that we have operated upon is due most frequently to a foreign body in the appendix, and next in frequency is due to cicatricial contraction, and these recover not by the passage of the products of inflammation through the neck of the appendix into the cecum, but by ulceration from without inwards in wall of cecum from a circumscribed suppuration about the appendix at the seat of the foreign body. These cases are misnamed by some authors, cecitis or pericecitis. Matterstock, in 146 autopsies for perityphlitic abscess, found the cecum perforated from within out only twice. Number of cases of this class diagnosed recurrent catarrhal appendicitis, and operated on by us, 3; of these, all showed rupture of wall and opening into cecum, and all recovered.

A simple ulcer of the appendix produces symptoms in two ways: 1, by occlusion of the appendix from a swelling of the mucous membrane, and the tension produced on the serous coat; 2, by an infection of the peritoneum through the wall of the appendix, or along its mesentery. In the literature on this subject we are led to believe that a pus infection of the peritoneum only occurs with perforation. This is erroneous, as in a number of our cases with simple ulcers of the appendix we had: 1, an infection of the mesentery and peritoneum, and yellow flakes of purulent material (see Case 67); 2, accumulations of a quantity of pus in the peritoneal cavity without perforation (see Case 143). This is very important, for in ulcerations of other portions of the alimentary canal such pathologic conditions are reported as occurring; and why should the mesentery of the appendix not be infected, or why should the peritoneum not be infected without perforation of the appendix, that is, by simple ulceration, as in other portions of the alimentary canal? There is no reason, and while it has not been previously noted, I have found it nevertheless a common pathologic condition.

That simple ulceration of the appendix with perforation should produce a serious, if not fatal, peritonitis, is to be expected the same as perforating ulcers of other portions of the alimentary canal. When a perforation first takes place, to which there are many exceptions, the rule is that adhesions are formed about the appendix, but as the accumulation outside of the appendix increases, these adhesions are ruptured and the contents of the abscess cavity escape into the peritoneum with the results to be considered under general septic peritonitis.

Partial gangrene of the appendix is produced in three ways: 1, mechanical compression by foreign bodies; 2, by accumulated fluid; 3, by, and most frequently, by infection of wall; *a*, biotic; *b*, toxic. The latter was the most frequent condition.

Complete gangrene of the appendix; *a*, with perforation; *b*, without perforation. In complete gangrene of the appendix, either from compression at its base by a foreign body or by infection of its wall, destroying the vitality of the tissue, or by contortion, shutting off its circulation, if an early operation is performed the appendix will be found black, non-adherent, surrounded by omentum, which is adherent to the wall of the bowel, and without pus infection of the peritoneum. It looks as though it were a miniature gall-bladder with extremely thin walls; The dangers of this variety with early operation before it has perforated, one can readily see would

be small, as the cecum can be lifted into the wound, the appendix ligated, excised in the absence of pus in the peritoneal cavity, and with very little danger of subsequent infection. When the appendix has perforated, as in subdivision *a*, the contrary is the case. We have a greater or lesser accumulation of the products of infection and gangrene of the appendix, the microphytes, pus, etc., liberated in the peritoneum with or without adhesions. In this variety, perforation can take place directly into the peritoneal cavity and a general peritonitis be produced, in which there is no effort at limiting adhesions, the same as you find following gangrenous destruction of other portions of the body from infection in which there is an absence of the effort of limitation and a non-restricted advancement of infection.

Peritoneal Infections.—The first variety of infections without perforation I have mentioned under the head of ulceration of the mucous membrane. The second variety is the most common in disease of the appendix, a small circumscribed abscess as a result of perforation. The effect of this abscess in its subsequent course depends: 1, on whether there follows necrosis of the wall of the adherent intestine which protects the peritoneal cavity and the admission of the contents of the abscess into the intestine; or 2, whether the abscess is retained within the constantly dilating sac, producing a large accumulation always separated from the general peritoneum, and which can be treated surgically by a lateral incision without opening the unaffected portion of the peritoneal cavity; or 3, whether the abscess suddenly ruptures into the peritoneal cavity; or 4, whether the abscess opens into other of the neighboring viscera or cavities, as kidney, bladder (Case 82) or pleura.

The local, circumscribed peritoneal abscess is a source of danger: 1, from absorption; 2, from necrosis of the tissues forming its wall, that is, wall of the bowel, followed by hemorrhage and death (Case 54); 3, danger of rupture into the general peritoneal cavity; 4, thrombo-phlebitis, secondary abscess. (See Cases 10 and 26.)

General Suppurative Peritonitis—as a result of disease of the appendix is produced: *a*, by a direct perforation and emptying of contents of the appendix into the peritoneal cavity (many cases); *b*, by a rupture of a small circumscribed abscess that had previously formed around the appendix (Case 108); *c*, by infection through wall of appendix (many cases), and also abscess (Case 86); *d*, by a rupture of gangrenous appendix into peritoneal cavity. The result of the infections of the peritoneum, or general suppurative peritonitis, depends upon the pathologic changes produced by the infection on the surface of the peritoneum. We have, 1, a dry septic variety of peritonitis with more or less complete exfoliation of the endothelium of the peritoneum, which terminates fatally in a very short period of time, as in Cases 25 and 43. We have, 2, where the quantity of pus is considerable, a ptomaine poisoning from the immediate absorption of the quantity of pus poured into the peritoneal cavity, where the patient at the end of four to twelve hours after the rupture will die with the most profound symptoms of collapse from toxins. (See Cases 102 and 104.) We have, 3, an escape of a quantity of pus into the peritoneal cavity, generating a suppurative peritonitis. Of this variety there were thirty-six cases, with twelve deaths. In all of these the patient had no immediate manifes-

tations of collapse; in many the pulse was not above 90, temperature not above 100 degrees at the time of the operation, even in cases in which the surface of the bowel in one-half or three-quarters of the entire abdomen was covered with pus. This condition can exist four, five, six, or even seven days without producing the symptoms of collapse which are recorded in our text-books as occurring *immediately* from *infections* or *ruptures* into the peritoneal cavity. The symptoms of collapse come on in these cases *only after an absorption of the products of inflammation*, never primarily, and when they do come on the patients die within a very few hours after their onset. The symptoms of collapse in these cases always surprise the attending physician, as his patient before their onset is considered to be very far advanced in convalescence—indeed, if not cured, and this explosion surprises him like a thunderclap from a clear sky.

I will not go into the details of the clinical history of the many varieties of lesions and their sequences which I have now related, as you can readily understand how the course in the various pathologic conditions would differ. There is probably no disease in the abdominal cavity that produces such a multiplicity of manifestations, pathologic conditions, and variety of dangers as that of lesions of the appendix. In comparing the operative with the non-operative treatment all these pathologic conditions must be considered separately, otherwise we can draw no reliable conclusions as to the merits of various procedures. In order to do this, the symptoms of each lesion must be so distinctly and separately outlined that the lesion can be recognized by the medical man without operating, as well as by the surgeon operating. We will, therefore, now consider the symptomatology of appendicitis.

SYMPTOMATOLOGY.

Can we recognize the various pathologic conditions by the symptoms? Can we say from the symptoms, this is catarrhal appendicitis; this is peritonitis? *Emphatically, no.* What are the symptoms of acute catarrhal non-obstructive appendicitis? They are the symptoms of enteritis, usually accompany enteritis, with a slight increase in the local tenderness over the appendix. What are the symptoms of suppurative appendicitis with obstruction, that is, with retention products of infection within the appendix? Sudden attacks of pain in the abdomen, either localized to the right iliac region, or general, shortly followed by nausea and very frequently vomiting. Local tenderness most frequent, occasionally general, extreme tympanites, a pulse of from 120 to 130; temperature of from 104 to 105½ degrees; in fact, the classical symptoms of peritonitis, and still no peritonitis present. (See Cases 83 and 116.) The symptoms of ulceration of the mucous membrane without perforation are just the opposite to the preceding ones in intensity, being as a rule the same symptoms, but very mild and with specific ulceration, as typhoid and tubercular; they are also practically the same as the latter. (See Cases 46 and 30.)

In ulceration with perforation, we have, 1, a sudden attack of pain; 2, followed always by nausea and frequently vomiting; 3, increased localized tenderness in right ileus; and 4, a temperature of 102–103 degrees. These symptoms continue for three days. They may be accompanied by extensive tympanites

and general tenderness. If the abscess remains circumscribed they will gradually subside, and at the end of a week the temperature will be 99½ to 100 degrees, pulse 90, absence of general tenderness, absence of tympanites, and only local tenderness present. But still there may be an abscess in the peritoneal cavity.

Gangrene of the mucous membrane has no special symptoms different from those just mentioned with ulcerative perforation, and can not be determined until the abdomen is opened and the appendix examined. There are following a perforation of the appendix no special symptoms, except a possible exacerbation of pain and an increased area of tenderness.

We have now considered the leading symptoms of the varieties of appendicitis, per se, without its complications, and we recognize four cardinal symptoms within the first forty-eight hours in every case: 1, sudden pain; 2, nausea and vomiting; 3, increased local tenderness over the appendix; and 4, elevation of temperature. These symptoms occurring in a healthy individual are pathognomonic of this disease and all that is necessary for its recognition. They are most marked and characteristic within the first forty-eight hours; therefore the diagnosis is most readily and positively made at that time.

Special care should be exercised in excluding females with history of genito-urinary infections.

The infections of the peritoneal cavity without perforation have no additional immediate symptoms to those of appendicitis without infection of peritoneum. *Infection of the peritoneum with perforation has immediately following the perforation no special symptoms above a circumscribed peritonitis, or a simple lesion of the appendix without perforation.*

The constitutional symptoms of a circumscribed abscess in the neighborhood of the appendix immediately on its formation are usually pain and vomiting, and elevation of temperature approximating 103 degrees. This continues for four or five days, subsides to 99½, or even 99 degrees, as long as the abscess remains circumscribed and does not open into the peritoneal cavity, or into the retro-peritoneal cellular tissue. Induration, increased local tenderness.

Diffuse General Peritonitis.—What are the symptoms of diffuse general peritonitis? If the members of this Congress were to answer that question from our text-books, or cases reported in our journals, they would say, *immediately*, that is, within a few hours after the infection—symptoms of tympanites, intense pain, collapse, particularly the latter would be present. I desire to call your attention to the symptom of collapse as a manifestation of peritonitis because it is misleading. We are taught in our text-books that the patient has *immediately* following a rupture into the peritoneal cavity of one of the viscera, or an abscess, particularly the latter, the manifestation of collapse. *I will state now that that symptom does not occur except under special conditions*, and I would warn the doctor who relies on the symptom of collapse as an immediate manifestation of perforation, that he is in error, except in cases of sapremia, as before mentioned, and that his erroneous idea on this subject will cost him the lives of many of his patients. The manifestations of rupture into the peritoneal cavity depend upon: 1, the character of the material entering the peritoneal cavity; 2, the quantity of

material; 3, the pathologic changes produced within the peritoneum by various substances; and 4, resistance offered by peritoneum. Examples of the first, when the substance admitted into the peritoneum is chemically irritating or poisonous, as gastric juice, fluid from hydatid cysts, cysts of the kidney, etc. As a result of these admissions into the peritoneal cavity, we have immediate manifestations; pain, tenderness, collapse. Examples of the second, where the quantity of material cuts an important figure. If the quantity of material be small, as of the substances mentioned in No. 1, as well as the admission of pus or the rupture of small abscesses into the peritoneal cavity, which we see in everyday practice, the immediate manifestations of their presence may be very limited and transitory. While if a large quantity be admitted, the rapid absorption, by the peritoneum of their toxins or ptomaines, produces rapid collapse and death without waiting for inflammatory reaction, the same as if a poisonous alkaloid were injected into the peritoneal cavity, as in Case 102. Examples of the third, where substances, small in quantity, but particularly septic in their nature, cause a peritonitis of greater or lesser severity, which peritonitis may assume the fulminating dry form so dreaded by all laparotomists, fortunately a form of rare occurrence and not amenable to treatment. Or the slow variety in which there is an accumulation of sero-purulent material which gradually increases in quantity and spreads over the surface of the bowel, producing but slight disturbance for a number of days until such time as the rapid absorption of the products of inflammation takes place, and the patient suddenly collapses and dies. The pus is guided in its advancement on the surface of the intestine by the position of the coil, as shown by formation of secondary abscesses on the opposite side of the abdomen and in the neighborhood of the kidney.

Errors in diagnosis occurred four times.

1. A perforating round ulcer of the stomach caused the peritonitis.
2. An extra nephritic renal calculus on right side.
3. Rupture of a psoas abscess.
4. Gangrene of entire mucous membrane of colon (diphtheritic colitis).

All cases, except the last, demanded immediate operation. It will be further noted that in every one of these four cases there was an absence of some of the cardinal symptoms.

In order to determine the advisability of operative interference, we must ascertain as near as possible: 1, what percentage of the cases terminate fatally that are not interfered with surgically? 2, what percentage of the same class of cases terminate fatally that are operated upon? 3, what are the additional dangers of the operation per se? It is estimated on good authority that from 27 to 30 per cent. of all cases treated medicinally terminate fatally sooner or later, if not operated. On that point I can not furnish statistics of my own as I operate on all cases. The percentage of deaths in our cases was 11 per cent., or 16 deaths in 141 cases.

In the first 100 cases we had a mortality of only 7 per cent. Since that, I lost three consecutive cases in as many days. The causes of death in our cases were:

1. Pyemia.
2. Septic pneumonia.
3. Septic phlebitis.
4. Multiple infarcts.

2. Ptomaine poisoning. } Rupture of large abscess into peritoneal cavity at time of operation.

3. Septic peritonitis. Thirteen existed before operation; *Thirty-six cases of general septic peritonitis operated.* I consider the dangers of the operation comparatively nil in competent hands.

What operation should be performed? In early cases the lateral incision over the most common seat of the appendix, in the right iliac fossa, should be given the preference. In late cases the incision should always be over the most prominent portion of the induration. In this class of cases the appendix is removed only when it presents itself palpably in the wall of the abscess and can be removed without rupturing the adhesions which separate the abscess from the uninfected portion of the abdomen. In early cases always remove the appendix, as it is the only certain means of preventing recurrence. I had eleven cases of recurrence in which the appendix was not removed at the primary operation; six of these were re-operated upon early in their first recurrence, appendices removed, all recovered. We never use fluid of any kind in the peritoneal cavity, pus or no pus.

When should we operate? On every case of appendicitis, or better, on every case where we have present the four cardinal symptoms:

1. Sudden attack of pain over appendix.
2. Always nausea, frequently vomiting.
3. Elevation of temperature.
4. Exaggerated local tenderness in various positions occupied by the appendix.

In every case in which the above symptoms were present, including every case on which we operated, except those mentioned as errors, we found pus, gangrene, or proof that it had previously existed within or about the appendix. In one case, in which elevation of the temperature was absent, the mucous membrane of the appendix was ecchymotic. The operation should be performed at the earliest possible moment after the onset of the symptoms: 1, because, at that time, the inflammation is limited; 2, the appendix is easily located and removed; 3, the time for rupture into the general peritoneal cavity has not occurred; 4, the gangrene of the bowel in the neighborhood has not taken place; 5, Matterstock states that upwards of 50 per cent. of the mortality from disease of the appendix occurs before the sixth day. It is therefore evident that the operator who waits to operate as late as the sixth day will lose 50 per cent. of all the cases that would terminate fatally without operation. I desire to urge upon you: 1, that you operate on all cases; 2, that you operate early, so as to prevent the disastrous effects of a rapidly spreading disease in the peritoneal cavity, and save yourself the humiliation of performing an antemortem operation.

Case 1.—Date of operation, Nov. 9, 1885. Operator, Dr. J. B. Murphy. L. E., aged 24 years; male. Cook County Hospital. History: Two weeks before operation, patient began to feel pain in right iliac region and in lower part of abdomen; nausea, vomiting and elevation of temperature. He noticed a swelling in right iliac region which gradually increased in size up to the time of operation. Operation: Incision over highest point of induration; drainage of abscess cavity; general peritoneal cavity not opened. Appendix was not removed. About twelve ounces of pus escaped. Patient made a rapid recovery.

Case 2.—Date of operation, March 2, 1889. Operator, Dr. Murphy. L. Z., aged 19 years; male, Cook County Hospital.

History: Patient has been sick for three weeks with the usual symptoms of appendicitis, at the time of entrance into Hospital. Some induration present. Temperature 99 degrees. Diagnosis: Appendicitis with perityphlitic abscess. Lateral incision directly into the abscess. General peritoneal cavity not opened. A fecal stone the size of a bean escaped in the pus. The appendix firmly imbedded in a mass of induration was not removed. Recovery.

Case 3.—Date of operation, March 22, 1889. Operator, Dr. Murphy. Mrs. O. D., aged 35 years; female. History: Typical attack began March 1. Severe symptoms of peritonitis were manifested on the 7th. Patient had fever, sweats and evening elevation of temperature until time of operation. Abdomen greatly distended; induration extended from right side beyond the median line to the left. Abdomen tympanitic over induration which was explained by presence of gas in the abscess cavity. Operation: March 22, three weeks after onset of attack. Lateral incision; about two quarts of very offensive pus escaped. The bowels were covered with a thick layer of fibrin. Drainage (rubber tube); recovery.

Case 4.—Date of operation March 25, 1889. Operator, Dr. Murphy. L. G., aged 14 years; female. History: On the 13th patient complained of pain in the right iliac region followed by vomiting. Temperature 102 degrees. March 19 temperature 99½ degrees, pulse 90. Tenderness increased in right iliac region vesical tenesmus. These symptoms continued without an elevation of temperature above 99½ degrees until time of operation. The induration was about the size of a hen's egg. Operation: Lateral incision into abscess. General peritoneal cavity not opened. Appendix not removed. Drainage; recovery.

Case 5.—Date of operation April 10, 1889. Operator, Dr. Murphy. Mr. X., aged 55 years; male. Case occurred in practice of Dr. Hicks of Burlington, Wis. Patient had a typical attack of appendicitis six weeks ago. Since then has been confined to bed with fever, sweats, pain and tenderness in right iliac region. Dr. Hicks pronounced the case one of perityphlitic abscess, and on the following day Dr. Murphy assisted by Dr. Hicks performed the operation. Operation: Lateral incision; general peritoneal cavity not opened; large quantity of very offensive pus escaped. The abscess extended down into the pelvis. No foreign body, no fecal stone. Drainage; recovery.

Case 6.—Date of operation May 3, 1889. Operator, Dr. Murphy. T. B., aged 13 years; male. History: April 25, 1889, patient came to my office complaining of pain in right iliac region. Examination: On examination no swelling could be detected; no elevation of temperature. He presented himself again May 3, with pinched anxious expression of countenance; pain, swelling and tenderness in right iliac region. No fluctuation, no symptoms of phlegmon in the abdominal wall. Temperature 102.5-10 degrees, pulse 128. Diagnosis: Perforated, perityphlitic abscess. Operation: Lateral incision; the induration had lost its resistance under the anesthetic; peritoneal cavity opened; an abscess found in the retro-cecal region. Fecal stone size of a Lima bean. The appendix had been amputated at its base by an ulcer; the body of the appendix retained its vitality by adhesions to the cecum; removed, drained. May 4, temperature 99 degrees, pulse 120, vomiting constantly. May 5, temperature 101.4 degrees, pulse 136. Still vomiting, countenance pinched and anxious, delirious; very tympanitic over entire abdomen. Died same day. General septic peritonitis.

Case 7.—Date of operation May 16, 1889. Operator, Dr. Lee. D. L., aged 19 years; male. Patient's attack began May 10 with severe pain in right iliac region accompanied by nausea and vomiting; these symptoms continued and constantly increased until May 13, when the pain extended all over the abdomen, but the greatest sensitiveness was in the right iliac fossa. Induration could be felt there without the signs of fluctuation or phlegmon, May 16. General amelioration of symptoms, pulse 84, temperature 99 degrees. Operation: Lateral incision, no infiltration of sub-peritoneal tissue. Intra-peritoneal abscess opened, drained; appendix adherent its entire length along the wall of cecum. Drainage; recovery.

Case 8.—Date of operation June 23, 1889. Operator, Dr. Murphy. H. R., aged 26 years; male. On June 18 patient was seized with pain in right iliac region, nausea, vomiting and constipation. At the end of twenty-four hours the symptoms became those of general peritonitis. Examination: On the third day distinct induration could be felt in right iliac region extending half way to umbilicus. No induration from rectum. Operation consented to on fifth day.

Operation: Lateral incision. When the peritoneal cavity was opened, to my great surprise it appeared perfectly healthy. No adhesions to anterior abdominal wall. The large induration which before operation seemed to extend to the umbilicus had disappeared. A careful examination revealed an induration mass close to the spinal column to the left just below the level of the umbilicus. The adhesions were gently separated, and an abscess opened; inserted drainage tube, packed about with iodoform gauze; recovery. This case illustrates how deceptive the sign of induration may be in the acute stage. It appeared to be in this case close to the abdominal wall in front and when the peritoneal cavity was opened it was found located at the posterior wall. The induration always appears larger than it actually is. This difference being most marked in the first few days of the attack.

Case 9.—Date of operation Aug. 9, 1889. Operator, Dr. Murphy. Mrs. N., aged 56 years. History: Patient had complained of pain and discomfort in right iliac region two weeks previous to Aug. 4, 1889. At this time pain became very intense, and a doctor was called at midnight to relieve her. Nausea, vomiting, great abdominal pain and tenderness and depression. These symptoms continued for four days. A consultation was called and an operation decided upon. The patient was extremely obese; no induration could be detected either from without or from the rectum. Operation: Lateral incision, directly into abscess; about an ounce of pus (very offensive) escaped and with it a small fragment of bone. General peritoneal cavity not opened. Rapid recovery.

Case 10.—Date of operation Aug. 16, 1889. Operator, Dr. Murphy. F. F., aged 56 years; male. Case occurred in practice of Dr. Volini. History: On August 16 patient was seen in consultation with Dr. Volini who had made a diagnosis of perityphlitic abscess and gave the following history: Three weeks ago patient was attacked with severe pain in abdomen followed by nausea, vomiting and high fever. Pain rapidly extended over entire abdomen and the patient became very tympanitic. The tympanites and general abdominal pain subsided in four or five days, but the sensitiveness and induration remained in the right iliac region up to time of operation. The patient's temperature was then 99 degrees (in the morning), but the attending physician stated that in the evening the temperature was very high and followed by sweats. The patient was very much emaciated and presented all the appearance of a typhoid in the third week. Diagnosis: Peri-appendicitis (circumscribed abscess). Operation: Lateral incision, general peritoneal cavity opened, circumscribed abscess evacuated; drainage,

Sept. 3—3 P. M. died.				

A second abscess was opened posteriorly on the 29th of August. Patient had chill Sept. 1, with pulmonary symptoms; from that time he continued to sink and died Sept. 3. Autopsy revealed embolic pneumonia of lower lobe of right lung. Sero-purulent fluid in right pleural cavity. Lungs otherwise normal, heart and liver normal. Remains of primary abscess in neighborhood of vermiform appendix which was opened in the first operation. Down in the retro-peritoneal cellular tissue a second abscess cavity was found which had been opened in the second operation; from this abscess he received his fatal pyemia. No peritonitis; no infarcts in any of the other organs. Head not examined.

Case 11.—Date of operation Oct. 1, 1889. Operator, Dr. Hartman. S. W., aged 10 years; male. History: Patient was taken sick with a typical attack many months before; the abscess was aspirated and finally external fistula formed. The patient improved, was up and about, but a mucus dis-

charge continued from the sinus. Operation: A laparotomy was performed; peritoneal cavity opened; fecal stone at the base of the sinus was removed from the appendix which was adherent to the abdominal wall and cecum; the appendix was not removed but its mucous membrane was curetted. Uneventful recovery.

Case 12.—Date of operation, Dec. 17, 1889. Operator, Dr. Lee. I. D., aged 22 years; male. History: About Dec. 3, 1889, patient was taken suddenly ill with pain in right iliac region accompanied by faintness and vomiting. These symptoms continued for two weeks together with fever and sweats. Examination: On examination was found a large circumscribed induration in right iliac region. Temperature 102 degrees, pulse 120. Operation: Fourteen days after onset. Lateral incision. Peritoneal cavity opened, contained a serous fluid and was very much congested. Large mass of adherent intestines could be seen. On separating these, a pus cavity was opened and drained. Pulse and temperature rapidly fell to normal and patient made a speedy recovery.

Case 13.—Date of operation, Jan. 16, 1890. Operator, Dr. Murphy. D. L., aged 20 years; male. History: Had an operation in May, 1889, for drainage of a perityphlitic abscess. Present attack typical; local pain, vomiting, fever, tenderness and induration. Operation: Fourth day after onset. Drainage of a circumscribed abscess. Appendicectomy. Recovery. (See history Case 7, May 16, 1889).

Case 14.—Date of operation, Jan. 26, 1890. Operator, Dr. Murphy. R. W., male; aged 26 years. Occurred in practice of Dr. Devlin. History: Patient's sickness commenced with a typical attack January 19. January 20, temperature 101 degrees; symptoms continued. January 21, temperature 102 degrees; induration detected in right iliac region. Operation advised. From January 22 to 24, temperature ranged from 101 degrees to 102½ degrees; pain and tenderness increased and induration extended to above the crest of the ileum. January 25, temperature 103½ degrees. January 26, operation: Lateral incision into pus cavity; general peritoneal cavity not opened. Appendix not removed. Half a pint of pus evacuated; drained. January 27, temperature normal and remained there; recovery.

Case 15.—Date of operation Feb. 28, 1890. Operator, Dr. Murphy. T. McC., aged 29 years; male. Patient had had twenty attacks previous to this. History: One week prior to operation patient had a typical attack of appendicitis. Symptoms continued accompanied by a temperature of 103 degrees up to the time of operation. Pulse 120. Operation: Lateral incision; a large pus cavity opened, without opening the general peritoneal cavity: About twenty ounces of pus escaped. Appendix not removed. Second day after operation fever had permanently disappeared. This case recurred but was not operated.

Case 16.—Date of operation, March 27, 1890. N. La B., male; aged 26 years. Operator, Dr. Murphy. Cook County Hospital. When patient was admitted to Hospital a slight induration could be felt in right inguinal region. There was great tenderness in the region of induration. Patient says he had a similar attack about three years ago. Temperature at time of operation 100 degrees. Operation: Five days after beginning of attack. Usual incision. Appendix found encircled and adherent to omentum. Appendix loosened from adhesions and amputated; it was large and swollen, the size of a man's little finger. The stump was canterized and top sewed. No pus in peritoneum. Iodoform gauze packing. Pus was found in appendix; recovery.

Case 17.—Date of operation June 11, 1890. Operator, Dr. Murphy. Wm. H., aged 20 years; male. Cook County Hospital. Patient was transferred from medical side of Cook County Hospital to surgical side for operation.

Operation: Typical incision. The appendix was located, ligated and amputated; the stump top-sewed with silk. The abdominal cavity was closed without drainage. The appendix contained enterolith and pus. Patient made a rapid recovery.

Case 18.—Date of operation June 25, 1890. Operator, Dr. Murphy. Miss W. Richmond, aged 27 years. Presbyterian Hospital. History: For the past four years the patient has had recurrent attacks of severe pain in abdomen which came on suddenly, continued for several days and was followed by a soreness of some days' duration. Present illness, patient was taken sick on May 12, 1890, with an attack far more persistent.

Case 19.—Date of operation June 26, 1890, Operator, Dr. J. B. Murphy. Rev. G., aged 40 years; male. On June 23 patient was seized with griping pains in right iliac region which gradually increased, accompanied by vomiting.

Pulse that evening 120; temperature 102 degrees. Localized tenderness; induration; general tympanites.

Operation: Appendicectomy. Appendix non-adherent, gangrenous, not perforated. The serous coat of the appendix was stretched over the gangrene debris of the mucous membrane and pus; it was not protected by adhesions except by omentum at base, and rupture was imminent. There was no infection of peritoneum. How different the condition would have been twenty-four hours later; the appendix would have been ruptured, a septic peritonitis developed as there was no protecting adhesions, and the patient's life would have been greatly jeopardized if not sacrificed. Rapid recovery.

Case 20.—Date of operation July 15, 1890. Operator, Dr. F. S. Hartman. Mrs. B. Typical attack; pain, vomiting, temperature and slight induration over crest of ileum, posteriorly. Operation: The operation was performed two weeks after onset of attack. Incision over crest of ileum, posteriorly; drainage of a circumscribed abscess. Appendix not removed. General peritoneal cavity not opened; recovery rapid.

(To be continued.)

A SUGGESTION AS TO THE CARE OF SILK SUTURES DURING OPERATIONS.

BY GEORGE F. KEIPER, A.M., M.D.

EYE AND EAR SURGEON TO ST. ELIZABETH HOSPITAL. LA FAYETTE, IND.

The ordinary method of sterilizing silk sutures is to put needles and silk in boiling water. Result, tangling of the different sutures and vexation in their separation. To overcome this, manufacturers

have put before us reels of silk in bottles containing an antiseptic solution. The ends are brought out through rubber corks. They are thus always kept sterilized. The needle is supposed to be threaded by this sterilized silk, but it would be hazardous to use it in living tissues unless both are sterilized after threading. This puts us where we usually begin, and the result is, to be safe, we must again sterilize the silk.

The accompanying photograph explains a method of caring for sutures; this I have used for two years. It is impossible for them to tangle. The needles are threaded and wound on an ordinary card, which is nicked the better to receive and hold the sutures.

They can thus be prepared and kept on hand ready for any operation. At the time of operation as many as may be necessary may be cut off and thrown into the sterilizer. When the surgeon is ready for one, it is simply unwound. Another advantage presented by this suggestion is that a separate receptacle for sutures is unnecessary.

SOCIETY PROCEEDINGS.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 273).

THIRD DAY—SEPTEMBER 14—MORNING SESSION.

Discussion of yesterday concluded.

THE GRAPHIC STUDY OF ELECTRICAL CURRENTS IN RELATION TO THERAPEUTICS.

By J. H. KELLOGG, M.D. of Battle Creek, Mich.

Something more than a year ago M. D'Arsonval, assistant to Prof. Brown-Sequard, the eminent Parisian physiologist,

by means of a special device constructed by him for the purpose. These curves he presented with his paper, and I presented a reproduction of them in connection with a paper which I read before this Association at its last session.

I was very forcibly struck by the description given by D'Arsonval of the physiologic effects of this current, as they seemed to tally so exactly with the effects which I had first obtained a number of years previous with a magneto-electric machine with which I was led to experiment in the course of a series of investigations which I was making with a large variety of electrical appliances of various descriptions. I first described this current in a paper read before the AMERICAN MEDICAL ASSOCIATION in 1888. The peculiarity of this current to which I then called attention was that it was capable of producing energetic and painless muscular contractions, and that it was also a most effective means of stimulating the nutrition of the parts to which it was applied. In concluding my description of the current, I stated as follows: "The therapeutic results following the use of this current justified me in claiming for it a decided superiority over any other form of electrical current for this purpose (that of exciting muscular action). I have used this current for medical purposes for the last five years." In the following year I described the current again in a paper read before the American Association of Obstetricians and Gynecologists.

The publication of D'Arsonval's graphic representations

Fig. 1. The Electograph.

presented at a Conference of the French Society of Physics, a paper in which he described an alternating magneto-electric current to which he applied the term "sinusoidal." This current he obtained from a small magneto-electric machine modeled after that of Clarke, which consists of a vertical electro-magnet and another electro-magnet so placed as to revolve upon a horizontal axis in such a manner that the extremities of the electro-magnet move in a plane parallel to the branches of the vertical magnet. This machine, and others of its type, as originally constructed, were furnished with an interrupting arrangement which reversed the current at the moment of highest potential. By a suitable modification in the mode of construction, D'Arsonval secured from the machine a current in which the rise and fall of potential was uniform from zero to the maximum and back to zero again, and in both directions. This fact he learned by a study of tracings obtained

of currents of regular and irregular variation led me to undertake a similar study of the current produced by the electro-magnet apparatus to which I have referred. Although recognizing the peculiarity of the current which I had discovered, and which had led me to utilize its therapeutic properties for a number of years and with excellent advantage, I was quite at a loss to understand its peculiar qualities. I showed the machine to Dr. E. Betton Massey of Philadelphia, and other medical electricians, who, like myself, were struck with its peculiar properties, but were unable to explain the reason of its peculiarities.

In order to obtain a tracing of the current, I improvised an electograph by attaching a writing lever to the solenoid of a large and very delicate galvanometer. The curve which I obtained by this means encouraged me to persevere. I accordingly undertook to make a more delicate machine, the construction of which, although different from that of

D'Arsonval's, was suggested to me by the description of his apparatus. (See Fig. 1.) The construction is as follows:

A, B, C, and D, Fig. 2, represent the several portions of a soft iron frame. On the two arms, D and E, are mounted two solenoids (E, E), each wound with 106 feet of copper wire of the diameter .032 inches. The two solenoids are connected, and the terminals (K, K), when the instrument is in use, are connected with the poles of the battery, thus producing an electro-magnet, of which A constitutes one pole, and B, B, the other. The arm A is cylindrical in form, and the terminals B, B, are semicircular at their ends, so as almost completely to embrace the arm A, thus producing an annular magnetic field. A small solenoid composed of 10.5 feet of very fine copper wire (.005 inches in diameter) is placed at F. The current to be tested is passed through this solenoid by making proper connections with the terminals (L, L). When a current is passing through the coils E, E, thus producing a magnetic field about the solenoid F, a current flowing in one direction through F, will cause it to be lifted up, while a current passing in the opposite direction will cause it to drop down below the level to which it is held by the spring I. The writing arm G, is attached at one end to the brass post H, the other end being free. A small standard connects it with the solenoid F, which, acting upon the short arm of the lever, produces even with a very slight movement of the solenoid, a considerable movement of the long bamboo lever, the free end of which rests against the smoked surface of a revolving cylinder.

Fig. 2. Section of Electrograph.

By means of this device, the most delicate variations in an electrical current may be instantly recognized and recorded by means of a kymographion, in the same way in which tracings are taken from a recording tambour.

By means of this instrument, I have taken a large number of tracings of different forms of electrical currents. Being especially interested in the sinusoidal current, I naturally first gave my attention to this, and obtained the beautiful tracing shown in Fig. 3.

The physiologic effects produced by the sinusoidal current which are most characteristic of it, are 1, its painlessness; 2, its great penetrating power. D'Arsonval has shown that the intensity of the motor, or sensory reaction produced by a given current is proportional to the variation of potential at the point excited. The constant alternation of the current prevents polarization of the tissues acted upon, and hence maintains the maximum exciting effect.

That important physiologic significance must attach to the mode of variation in potential, as well as to the amount of variation is clearly evidenced by the difference in the effects occasioned by the gradual or sudden withdrawal of the current in making an application of galvanic electricity, which is familiar to all medical electricians.

In the use of the sinusoidal current from my apparatus, different effects are observed, according as the machine is rotated slowly or at a high rate of speed. When rotated slowly and connected with sponge electrodes held one in each hand, vigorous contractions are produced in each arm, and in alternation, nearly all the muscles of the arm seem to participate in the contractions. When one electrode is placed in contact with the feet and the other held between the two hands, the muscles of both extremities are made to

contract vigorously. The contraction is spasmodic rather than tetanic in character. By proper adjustment of the current, strong muscular contractions may be induced without producing the slightest sensation in the skin, and without any pain sensation whatever. With one electrode placed in the rectum, or the vagina, and the other upon the abdomen, strong contractions of the abdominal muscles may be produced, and even of the muscles of the upper thigh, without any sensation other than that of motion. I have frequently seen patients, while taking this current, shaking so vigorously under its influence that the office table was made to tremble quite violently with the movement.

With rapid rotation of the machine, the current obtained is capable of producing strong tetanic contractions similar to those of the faradic machine. This difference is noticeable, however: with the electrodes held in the hands, and the muscles of the forearm thrown into violent tetanic contractions by running the machine at a high rate of speed, the patient can, if he desires, release the sponges at any moment; the only skin sensation produced by an application sufficiently strong to induce tetanic contractions, is a slight prickling, very much less intense than that produced

Fig. 3. Graphic representation of the sinusoidal current obtained from magneto electric apparatus employed by the author since 1883.

by a faradic current capable of exciting equally strong motor effects.

The sensory effects produced by the current are exceedingly interesting. As has been already stated, applications of the current sufficiently strong to produce vigorous muscular contraction are attended by no sensory effects whatever. The sensory effects are best obtained by giving the machine a high velocity. Adjusting the apparatus for high velocity, and applying the sponge electrodes, well moistened, to the temples with a gradually increasing current, and with the eyes closed, one seems to see rotating waves of light, resembling a luminous whirlpool, in the region of each electrode.

It is a curious fact that the position of this luminous field is not stationary; it moves with the electrode which seems to be the center of the illuminated area. As the current is increased in strength, the display of light increases in brilliancy, finally becoming so extended and intense that the whole front portion of the head seems to be brightly illuminated. At this point, one begins to experience very slight prickling sensations in the skin, which increase as

the intensity of the current is increased. A remarkable characteristic of the current is, that so strong impressions are made upon the optic nerves, or their centers, by a current too delicate to be recognized by the nerves of the skin. This effect must be due to the great penetrability of the current.

Duchenne showed, in his masterly work published during the siege of Paris, that there is a decided difference in the physiologic properties of the currents obtained from the first and the second helix, and that these currents have very different clinical applications. The current of the second helix was found to possess much greater penetrating power than that of the first helix. The currents of the two helices differed, according to Duchenne, just "as water that is warm differs from water that is boiling, or as iron slightly warmed differs from iron that is white hot," as regards their influence upon sensibility. This fact is only cited as an analogous observation, since the sinusoidal current possesses properties very different from those of any induced current with which I have ever experimented.

The therapeutic indications for which I have employed the sinusoidal current have been based upon the peculiar motor and sensory effects which I first observed ten years ago, and some of which have since been observed and described by D'Arsonval and Apostoli.

Within the last ten years I have made more than twenty thousand applications of the sinusoidal current, having used the machine exhibited with the paper since 1883. Twelve thousand of these applications have been made within the last two years. The greater number of the applications have been made in gynecologic cases, although hundreds of applications have been made in cases not belonging to this class. The uses for which I have found the current most valuable are:

As a means of exercising the muscles, particularly muscular groups which can not be easily brought into isolated action by voluntary effort, and in cases in which, through injury of the nerves or nerve centers, or through disability of some other organ, exercise by voluntary effort has been impracticable.

I have found this current available as a means of producing muscular contraction in cases in which degenerative changes had advanced so far as to destroy the reaction to the faradic current. I have also found the current of great value as a means of securing passive exercise in connection with the rest-cure, in which respect its superiority over faradism applied as prescribed by S. Weir Mitchell is incontestable. I have used for many years, and still use, the faradic current, applying it to the various motor points of the body in such a manner as to secure vigorous muscular contraction as a means of exercise in feeble patients, but I have found the sinusoidal current very greatly superior to the faradic current for this purpose, by reason of the painlessness of the applications and the greater vigor of the contractions which are obtainable. With the faradic current it is often difficult to obtain strong contractions, especially in fleshy persons, and in many cases almost no contraction at all can be obtained without the application of a current of such strength as to be almost unbearable in consequence of the pain produced; and the services of a person skilled in locating the motor points are necessary for its special application in a majority of cases. With the employment of the sinusoidal current, these difficulties disappear entirely. It is only necessary for the patient to grasp the sponge electrodes in his two hands, to secure vigorous contraction of all the muscles of the arm, or with the patient holding an electrode in one hand, the attendant may apply the other sponge to the upper part of the arm, or the shoulder, and thereby secure the most vigorous contractions of all the muscles of the arm operated upon. By a similar application of one sponge upon one side of the abdomen, and the other upon the other side, or one sponge at the lower extremity of the back, and the other at the upper extremity, vigorous contraction of all the intervening muscles is easily secured without taking the trouble to seek out the motor points, and no matter how great the quantity of overlying fat.

I find this current exceedingly valuable as an alternate treatment to be employed in connection with massage. It is not a substitute for massage, but it secures an activity of the muscular structures which can not be accomplished by any form of passive exercise.

The special use for which I have found the slowly alternating sinusoidal current of greatest advantage, has been, as a means of strengthening relaxed or undeveloped abdominal muscles in gynecologic cases. I long ago learned that a great share of the long category of symptoms complained of

by women suffering from so-called female weakness, such as "backache," "dragging sensations," "weakness," etc., are due, not to primary pelvic disorders, but to a relaxed condition of the abdominal walls resulting in what Trastour terms "desequilibrium," or disturbance in the static relations of the abdominal viscera. Relaxed abdominal walls allow the stomach, bowels, liver, kidneys, spleen and other viscera to become pendant; and a constant drag upon the branches of the great sympathetic which are distributed to these organs results in congestion and irritation of the great abdominal brain, as the semilunar and associated ganglia of the great sympathetic have been aptly termed, and through the morbid reflexes thus set up, give rise to a multitude of painful and neurasthenic symptoms, which render miserable the lives of thousands of women who are really not suffering from any disorder of the pelvic organs whatever, although perpetually under treatment for some imaginary prolapsus, or anteversion, or ovarian irritation, or other pathologic myth.

By strengthening the abdominal muscles, and thus replacing the prolapsed abdominal viscera and restoring the normal abdominal tension, so that the portal circulation recovers its normal tone, I have succeeded in curing hundreds of invalid women who had previously sought relief in vain at the hands of many gynecologists, and in the accomplishment of this, I am certain that the sinusoidal current has played a very important rôle. I find this current especially valuable at the beginning of the treatment of these cases, before the patient has acquired sufficient strength, or sufficient confidence to engage in active gymnastic exercises, or to be subjected to active or active passive exercises of the Swedish movement system, which I always utilize as a means of accomplishing a thorough-going and permanent cure.

I also find the sinusoidal current of great value as a means of after treatment in cases in which I have found it necessary to shorten the round ligaments, or to perform other gynecologic operations for the correction of displacements of the pelvic viscera not curable by non-surgical means. The neglect to employ these and other measures for developing the normal supports of the uterus and ovaries is, I am satisfied, one of the causes which has led to the general failure of the operation for shortening the round ligaments, in the hands of American gynecologists. I have performed this operation more than three hundred times, and with less than 5 per cent. of failures—scarcely a single failure in fact within the last four years since I have perfected the technique of my own method of operation. By the employment of a slowly alternating sinusoidal current for a few weeks after the operation, the abdominal muscles are developed so that they are able to hold the small intestines out of the pelvis, and thus relieve the pelvic viscera.

In cases of facial paralysis, this current affords an admirable means of exercising the muscles and stimulating the nutrition of the paralyzed structures, as one can pick out the affected muscles and put them into rhythmical action with very great facility. In the treatment of spinal curvatures due to weakness of the muscles of one side, or irregularities of muscular development, this current is also invaluable. With one pole applied to the feet and the other to the two hands, vigorous movements affecting nearly all the muscles of both extremities, are easily produced. The current affects involuntary as well as voluntary muscles. It is of great service in a case of constipation, one pole being applied to the rectum and the other to the abdominal muscles. It serves a double purpose in cases of this kind, awakening the vital activities of the rectum, and at the same time rapidly increasing the strength and efficiency of the abdominal muscles.

I have also found it of great service in cases of dilatation of the stomach. By means of a stomach electrode, which I have had constructed for the purpose, with one pole applied internally, the other externally, vigorous contractions are readily produced. I have verified this in several ways. After the current is turned on, one can easily detect the active peristaltic movement by listening over the region of the stomach with a stethoscope. The most positive evidence is afforded, however, by the fact that the stomach diminishes in size. I have sometimes noted an upward movement of the lower border of the stomach during a single treatment, amounting to fully two inches. No painful sensation is produced by the current, even when quite strong. I have, in some instances, increased the strength of the current sufficiently to enable me to obtain the most indubitable evidence of contraction of the organ in the forcing out of the stomach contents through the tube, or along the side of the

tube containing the electrode. This effect is always produced when the current is made sufficiently great. The ejection of the stomach contents is not accompanied by nausea, and ceases the instant the strength of the current is lessened, beginning again when the current is increased. I have used this current to the most excellent advantage in many cases of motor insufficiency of the stomach, with and without dilatation.

The fact that such profound motor and sensory effects can be produced without the ordinary shocking, pricking, and other sensations, is a grateful surprise to the patient, and certainly enhances its value as a therapeutic means.

I have found no electrical application so valuable as a means of relieving a hyperesthetic condition of the abdominal sympathetic ganglia, especially the semilunar ganglia, the lumbar ganglia, and the lumbo-aortic plexus of the sympathetic. It is equally efficacious in relieving pains beneath the shoulder blade and in the back, which are, often erroneously attributed by patients to a diseased liver, but which are due, in a great majority of cases to a congested and irritated condition of the abdominal sympathetic ganglia.

Fig. 4. Current from Faradic apparatus. (McIntosh). A, make; B, break.

Fig. 5. Fluctuating current (intervals indicated by time marking represent 1-250 seconds each).

A rapidly alternating sinusoidal current is one of the most efficacious means with which I am acquainted for the relief of the peculiar sensation known as "heaviness," of which dyspeptic patients often complain. This sensation is due to a perverted condition of the sensory nerves of the stomach. Its relief by a rapidly interrupted current is an evidence of the penetrating power of this current.

The rapidly interrupted current may be applied to the stomach either externally by means of a flat sponge electrode, one over the stomach and the other over the spine opposite, or internally by means of a properly formed electrode placed inside a stomach tube, with a flat sponge electrode either over the stomach or the spine opposite the stomach. I have applied the sinusoidal current in this manner in a large number of cases for the relief of stomach symptoms, especially in cases in which examination of the stomach fluid by the method of quantitative analysis, which I have elsewhere described, showed deficiency in that form of stomach work which consists in the combination of free chlorin with albumen as shown by the diminished amount of the combined albumen.

The physiologic laws which govern the various chemo-

vital processes of stomach digestion are certainly not fully understood, but that they are under more or less direct control of the nervous system, and especially of the sympathetic nervous system, particularly that portion known as the solar plexus, will probably not be disputed. The sinusoidal current seems to act by promoting a normal condition of the sympathetic, and its relations to the stomach thus facilitates the combination of the chlorin with albumen in the conversion of albumen into peptone.

Fig. 6. Improved sinusoidal apparatus designed by the author, giving two distinct currents.

An equally interesting fact, which has been observed in a number of cases, is the action of the current in promoting an improved value in the quality of the digestive product. In the method of examining stomach fluid referred to, an inferior quality in the product of peptic digestion is shown by the diminished value of coefficient *a*. An application of the sinusoidal current seems not only to promote the quantity of combined albumen, but to improve its quality.

In the employment of the sinusoidal current for its effects upon the nervous system, I have found a current of high velocity most useful. The potential of this current is so

Fig. 7. Arrangement of Leyden jars for producing alternating currents of great frequency (d'Arsonval-Hertz).

great it can be used only by the aid of a very excellent and well graduated rheostat of large resistance. When judiciously employed, I find it more effective than any other form of electrical current in the relief of pain and all other symptoms arising from a hyperesthetic state of the nerves or nerve centers. I have found it especially serviceable in the relief of pelvic pains and the various forms of headaches. It is also especially valuable in the relief of various disorders of sensation included under the general term, paresthesia. The pe-

cular numb, tickling, crawling and other sensations of which neurasthenic patients often complain, are almost certainly relieved by it. The same is true of the great variety of peculiar head symptoms complained of by neurasthenic patients—and women suffering from pelvic disease. Most of these symptoms, I am satisfied, are the result of reflex disturbance of the abdominal sympathetic, which I believe is especially favorably influenced by the sinusoidal current.

By careful management the electrodes may be applied to the head, and a current capable of producing decided effects passed through the brain in different directions without the slightest pain or other than the most agreeable sensations. I have never seen the slightest unpleasant effect from the application of this current, while it is not an uncommon thing to find patients who seem to possess an idiosyncrasy against the faradic, and in some instances, although much less frequently, against the galvanic current. In a good many thousand applications I have never yet found a patient who has experienced any ill effects from the application of the sinusoidal current. The only inconvenience I have ever observed, has been an occasional muscular soreness when a too vigorous or too prolonged application of the slowly alternating current had been employed, but this is only the effect of the gymnastics, and should not be attributed to the electrical current *per se*.

Fig. 8. Solenoid and coil for use in connection with condensers.

A very important advantage of this sinusoidal current, is the fact that in its employment one may deal with elements as accurately known and capable of being as accurately dosed as in the use of the constant current. My apparatus is provided with a permanent magnet, so that the only element which it is necessary to determine is the rate of motion, which is easily ascertained by means of the indicator commonly employed for this purpose. In the apparatus employed by D'Arsonval the source of induction is an electro-magnet and requires accordingly, a determination of the amount of current used to excite the magnet as well as the velocity of the apparatus. In this respect the sinusoidal current possesses an immense advantage over any form of faradic current.

The current produced by a faradic machine is subject to continual modifications from variation in the strength of the actuating battery, and in the adjustments of the rheotome, as is well shown by the tracings which I present with this paper. (Figs. 6 and 7.) I have made a large number of tracings of the currents produced by various forms of faradic apparatus and under various conditions, and have made some experimental attempts with a view of securing an improvement upon the ordinary form of induction appa-

ratus, but I have thus far met with little encouragement of success. I believe the faradic machine is inherently faulty as a scientific electrical apparatus for medical purposes. The rheotome is a fatal element of weakness, changing the character of the current with the slightest modification and often, as every medical electrician knows, in a manner which, if the thing were intelligent, must be regarded as purely whimsical.

The invention of Faraday answered an excellent purpose during the embryonic period of electro-therapeutics, but now that we have learned the value of the milliampèremeter, the voltmeter, and the coulombmeter, and have acquired methods of precision in our electro-therapeutic procedures, the faradic battery, like the shocking machines of a half century ago, must give place to a more precise and more reliable instrument. The effort to overcome the weaknesses of the induction coil by the provision of some means of measuring the current obtained from it, is a task as useless as it is difficult, since nothing else than a graphic representation of the curves produced by it could enable a practitioner to regulate the machine twice alike, and such a method of regulation would be altogether too cumbersome and dangerous for practical use.

In the group of tracings shown herewith, which are intended to illustrate the effects of changes in the rheotome, no change whatever was made in the apparatus, except such as results from turning slightly in or out the adjusting screw of the rheotome. The increased or diminished amplitude of the curves produced are an indication of the changes in the potential current resulting from the changes referred to. There seems to be no method by which fluctuation in the character of the current can be remedied, and consequently the faradic machine, in the opinion of the writer must sooner or later be recognized as too rude an appliance to be of value in scientific electro-therapeutics, or, at least, to be of use only in a limited class of cases in which mere excitation is the object to be accomplished.

I do not profess to have yet made an exhaustive study of the subject to which this paper is devoted. My time is very fully occupied with professional duties, and it is only now and then that I can spend a few midnight hours in scientific researches. I shall continue the study of the subject, however, and from the indications obtained from some experiments which are not yet completed, I feel justified in promising some further, and perhaps more interesting results at some future time.

I present, in connection with this paper, a number of tracings which I have selected as typical, from a great number of tracings which I have made with my electrograph, and which I hope to have the pleasure of exhibiting in operation before the members of the Society at a convenient season.

(To be Continued.)

NECROLOGY.

R. S. Addison, M.D., of Chicago, February 21.

Austin Peggs, M.D. of Ossian, Iowa, January 29.

Jacob A. Fink, M.D. of Commerce, Mich., February 12, at Pontiac.

B. Brown Williams, M.D. of Meadville, Pa., February 15, aged 79 years.

J. M. Lathrop, M.D. of Dover, Ohio, February 9, of pneumonia.

H. C. Roberts, M.D. of Nashville, Tenn., February 17. Dr. Roberts was four years in the Confederate service during the war of the Rebellion.

Geo. W. Weeks, M.D. of New York City, February 15, aged 29. He was a native of Norwalk, Conn., and was graduated at Bellevue Hospital Medical College.

Frederick K. Sprang, M.D., of Reading, Pa., died February 17, aged 57 years. He was a graduate of Jefferson Medical College of Philadelphia, in the class of 1860, and was a native of Oley, Berks County. He was a member of the Board of Medical Examiners of Berks County.

Amasa F. Kinne, M.D., who was born in Vermont in 1813, and moved to Ypsilanti in 1850, died in that town Feb. 14.

Oliver P. James, M.D., of Doylestown, Pa., died at that place Feb. 19. Dr. James served one term in the State Senate and was once nominated for Congress. He was president of Doylestown Borough Council for a number of years and treasurer of the Bucks County Fair. He was treasurer also of the local Masonic Lodge.

Benjamin S. Codman, M.D., of Boston, senior member of the firm of Codman, Shurtleff & Co., dealers in dental and surgical instruments, died Feb. 22, aged 78 years. He was graduated from the Harvard Medical School with honors. After leaving he practiced dentistry for some years, but about 1855 he, with A. M. Shurtleff and F. O. Whitney, established the firm which exists to-day.

Deaths of Eminent Medical Men.—Dr. John Burnley Walker, medical officer of health, to the combined districts of the Colne Valley, Yorkshire, England—Dr. Edward Strobl, Professor of Pharmacology and Hygiene in the University of Strassburg, aged 79.—Dr. Nebinger, Chief Surgeon to the Municipal Hospital, Bamberg—Dr. Arthur Ravara, Surgeon to the St. José Hospital, Lisbon, and to the King of Portugal, from the bursting of an aortic aneurism while he was examining a patient before performing ovariectomy; and Dr. Pierre Joseph von Benedan, who was Professor of Comparative Anatomy and Zoology, for more than sixty years in the University of Louvain, and one of the leading scientific lights of Belgium, aged 85 years.

Toland Jones, M.D., of London, Ohio, died February 18. Dr. Jones was born Jan. 10, 1820, being at the time of his decease a little over 74 years of age. He was educated at the Granville College and at the Ohio Medical College, Cincinnati. In 1862 he enlisted in Company A, One Hundred and Thirteenth O. V. I., of which he was made Captain. In 1864 at the battle of Kenesaw Mountain he was promoted to the colonelcy of his regiment, which belonged to the Second Brigade of the Second Division, Fourteenth Army Corps. He represented this district in the Ohio Senate in 1866-68. He has also been President of the Madison County Medical Society and in 1888 was President of the Central Ohio Medical Society. In the same year he was also presidential elector and was chosen to carry the Ohio returns to Washington. In 1889 he was appointed Surgeon General, with the rank of Brigadier, on the staff of Governor Foraker, to fill out the unexpired term of Adolphus E. Jones, deceased, of Cincinnati.

Martin Luther, M.D., one of the most eminent physicians in Pennsylvania, died at Reading, February 22, after an illness of three months with influenza and complications, aged 68 years. Dr. Luther was born March 16, 1826, at New Holland, Lancaster County, Pa. He was a son of Dr. John Luther of New Holland, for many years a prominent citizen and influential member of the Masonic fraternity. His grandfather was also a physician. Dr. Luther was educated in the best academies of Chester and Berks Counties, began the study of medicine in the office of his brother in New Holland, and was graduated from the Jefferson Medical College in 1848. For two years succeeding his graduation he practiced with his brother. In 1850 he removed to Reading, and soon after his location there he became one of its leading physicians. He served as physician to the Berks County Almshouse from 1853 to 1855, and the two succeeding years was physician to the county prison. In 1862 he was appointed Surgeon-in-Charge of the United States Army Hospital at Reading, and remained in that position until the Hospital was discontinued. In 1864 he served as Surgeon to the Board of Enrollment of the Eighth Congressional District,

and acted in that capacity until the close of the war. He took a prominent part in establishing the Reading Dispensary in 1868, and was an influential member of the Berks County Medical Society, was for several years its President, and a number of times its delegate to the State and AMERICAN MEDICAL ASSOCIATION. Dr. Luther was a member of the Academy of Sciences of Philadelphia, and of the Reading Board of Health. He had an extensive practice and was a good surgeon. His ability was at all times recognized by the local courts, and his testimony in questions pertaining to his profession was always received with the most profound respect. He was a kind and careful physician, and to those who had his confidence he was the most companionable of men—a man of extensive reading, and a keen observer of men and affairs.

Dr. Luther was the youngest of three sons, all of whom had been noted for skill and ability, and in his death the genealogy of the family ceases—a family of doctors who had been prominent in Pennsylvania for over one hundred years.

Obed Harvey, M.D. of Galt, Sacramento County, Cal., died of apoplexy Jan. 17, 1894. He was born in Wayne County, N. Y., Sept. 7, 1825. He commenced the study of medicine with private tutors, attended lectures at Rush Medical College, Chicago, and at the Rock Island Medical College, Ill., from which he graduated in 1849. In 1850 he went to California, settling in Placerville, Eldorado County. For some years, in company with Dr. Asa Clark, he had charge of the county hospital there, and the two were the leading physicians of the county. In 1857 he went East, and was on the steamer, *Central America*, when she was wrecked in a gale and sank September 12, off Cape Hatteras. The Doctor was in the water from 8 o'clock at night until early morning, when a sailing vessel chancing to come upon the scene, he was rescued with the few who had survived. On reaching New York he was highly praised for the courage he had shown, and for the professional services and assistance he had given the passengers. In that city he continued the pursuit of the object of his visit, which was to improve his professional knowledge under the superior facilities to be found in a large city. For this purpose he connected himself with the Medical Department of the University of the City of New York, from which he received an honorary degree in March, 1858. He attended the annual meeting of the AMERICAN MEDICAL ASSOCIATION in 1858, as a delegate from the California State Medical Society, and is said to be its first representative in the National body. Returning to California, he resumed his practice at Placerville, investing his gains with sagacious forecast. About 1869 he removed to Sacramento County and laid out the town of Galt, where, and in the vicinity of which, he became the owner of a large estate, covering an area of between five and six square miles. He had a very extensive acquaintance with the distinguished men of the State; and his coöperation was frequently sought in projecting important public improvements and providing charitable institutions. He was many years ago a member of the Board of Directors of the State Insane Asylum at Stockton and was President of the Board at the time of his decease.

Dr. Harvey was a noticeable person among his fellow men. A figure of standard height and proportions, graceful and dignified in his bearing, a pleasing face, his was a comely and fitting physique for the intellectual strength, moral purity, and the humane disposition which characterized him. He was married in May, 1863, to Miss Susan M. Hall, an estimable lady of varied accomplishments and high social standing, who survives him. He leaves a son and daughter who are admired examples of a faultless heredity and innate refinement, crowned with a liberal education, recently completed in Eastern institutions.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, MARCH 3, 1894.

THE PHONOGRAPH IN AUSCULTATION.

In that charming address written by the late AUSTIN FLINT, which, alas! he did not live to deliver ("Medicine of the Future") in writing of the increase of knowledge of the normal and abnormal actions taking place within the body, writes:

"It seems to me certain that the principles of the telephone will, by-and-by, be applied to intra-thoracic respiratory and heart sounds, so that they will be transmitted to the ear with more distinctness than they now are with the binaural stethoscope. The healthy and morbid sounds will then be so easily observed as to render the physical diagnosis of pulmonary affections in all cases a very simple problem. More than this, the clinical teacher may be able to demonstrate auscultatory signs to a class of medical students seated in the lecture room or hospital amphitheater. The same is to be said of the auscultation of the heart. . . . I will go further, and say that intra-thoracic sounds may be transmitted from the patient to the physician. . . . Again, and still further, the sounds from the chest of a patient may be phonographically registered, transported never so far, and made available after an indefinite period."

The distinguished author then mentions the bellows murmur over the fontanelles; those of the arteries and veins; the fetal sounds; the intestinal borborygmi; the noises of gall stones; the musical tone of certain hydatids, to point out that there are more extended fields of auscultation than that of the thorax, and concludes:

"It can hardly seem an extravagance to predict, then, of the future development of auscultation to one who has listened with the aid of the microphone, to the footsteps of a fly."

The words of PROFESSOR FLINT are rapidly being realized through the marvelous developments of electricity, by the great EDISON. That wonderful man, whom the electric fluid seems almost to obey, as the

genii of the lamp obeyed ALADDIN, has already developed the phonograph so that its resources are being utilized, and we have no doubt that fuller practice and experiment will diminish its defects, and fully establish its place as a valuable aid to diagnosis.

THE OLD-TIME TREATMENT OF STRICTURE OF
THE URETHRA BY CAUSTICS.

Nowhere are the revolutionary possibilities of surgical practice more strikingly illustrated than in the comparison of bygone with present methods of treating urethral stricture. While in an old book store we recently found a book descriptive of a method of treating strictures by caustic applications entitled, "An Improved Method of Treating Strictures in the Urethra," by THOMAS WHATELY, M.R.C.S., etc., published in 1804. In view of the comment on the treatment of stricture by caustics appearing in the latest work on urethral stricture, in which the method is mentioned as a relic of surgical barbarity unworthy of serious attention, the pretensions of MR. WHATELY'S book are worthy of notice.

It would seem that this author had a long standing feud with the celebrated EVERARD HOME—the English surgeon—on the subject of the proper treatment of urethral stricture. MR. HOME argued that there was but one treatment for this condition, viz: Burning through the obstruction with lunar caustic, which *lapis infernalis* he fixed on the end of a bougie.¹ MR. WHATELY, on the other hand, put forward the application of pure caustic potash, "kali purum," as the ideal method. The champion of the "kali purum" naively insinuated that the only cases in which his method failed were such as had been through a course of HOME'S treatment. In speaking of cases in which he had attempted to perform a preliminary dilatation with small bougies he says: "Sometimes, indeed, there has been great difficulty; but the only cases where I have not been able to succeed or have met with uncommon difficulty, have been almost exclusively those which had previously been treated with caustic according to MR. HOME'S method."

To moderns the criticisms passed upon MR. HOME'S method would seem to be well founded, although savoring of a pot and kettle argument.

WHATELY'S method was as follows: Having moderately dilated the stricture by bougies, as a preliminary measure, a wax bougie was selected which would just pass the stricture. In the extremity of this soft bougie a bit of "kali purum" the size of a pin's head or smaller was embedded; the instrument was now greased with "hog's lard" and passed quickly down to the face of the stricture. By steady, intermittent and moderately firm pressure the formidable bougie was carried through the obstruction. This process was repeated every seven days, larger

¹ Mr. Home's book, published in 1795, was translated into the German in 1800.

and larger bougies being used, until the stricture was "cured." The operation was said to be quite innocuous. "In the greater number of cases in which the caustic is thus applied, even in the first instance it gives but little pain at the time of its application. A slight scalding in making water, and a trifling discharge during the first day or two, are, however, commonly produced by it."

WHATELY bases his opinion of the necessity for caustic applications largely upon the important observation that the urethra is not merely contracted, but is actually diseased at the point of stricture.

"I have observed in several cases of stricture that when the point of a bougie touches, though in a most gentle manner, the anterior part of the contraction, some drops of blood have immediately issued from the part. This circumstance favors the opinion that a stricture is not merely a contracted, but also a diseased portion of the urethra. A stricture being likewise according to MR. HUNTER, the hardest part of the urethra, and according to MR. HOME, a thickened contraction of the inner membrane, is another circumstance which corroborates the opinion above mentioned. Such an alteration from the natural state of the membrane could not be produced by a mere contraction of its fibers; the change must therefore be occasioned by disease."

One of the objections urged against lunar caustic is that the sloughs which it produces "not infrequently plug up the strictured orifice and produce suppression of the urine." HOME is quoted by WHATELY as observing a slough an inch in length in one of his own cases. WHATELY attributes bleeding during his operation "entirely to the bougie, and not to the caustic."

WHATELY'S own comments upon his method are quite sufficient to impress one with its barbarity. The modern surgeon will have difficulty in comprehending how men of ordinary intelligence and knowledge of pathology could fail to appreciate the barbarity of the caustic treatment of stricture. How WHATELY and HOME—both of whom were surgeons of repute and vast experience—could fail to do so is a mystery, yet at the same time a forcible illustration of the absurdity of the dogma of infallibility which makes us slaves to authorities. It will be remembered that that master mind, HUNTER, evolved a theory of "the venereal disease"—which embraced all forms of venereal infection,—based upon a single ill-starred clinical observation of the effects of inoculation of syphilis on his own person.

WHATELY says that, "by strictly observing these rules respecting the interval between each application of the caustic, we give time for the separation of the slough and the cicatrization of the sore (!) occasioned by the action of the kali, and hereby the danger of hemorrhage is in a great degree prevented; a consequence, however, which we could not guard against, were the caustic to be applied upon a slough formed by a previous application of this powerful agent."

After thus blandly forgetting the mischievous

effects of putting true cicatricial tissue where none previously existed in the urethra, and having confessed the grossest kind of malpractice, our author goes on to say that bougies should not be introduced between seances lest hemorrhage be caused thereby. According to WHATELY, the only way to curb the death dealing bougie and inhibit its properties of evil, was to arm it with a piece of caustic. He quotes MR. HOME as having had a case of perineal fistula in which the urine came away partly by the perineum and partly through the rectum. "In this case the caustic bougie passed into the rectum." He neglects to state what happened to the patient's rectum, but the bougie was rendered harmless by being tipped with caustic.

Our author, however, redeems himself somewhat by concluding his chapter on operative manipulations, by taking "some notice of the means to be employed for relieving suppression of urine should this occur from the use of caustic or any other cause."

A very interesting observation was made by WHATELY, viz.: Epididymitis occurred oftener after the passage of the ordinary bougie than after that armed with kali. The modern surgeon, with an appreciation of the antiseptic properties of caustic potash, can readily understand this observation. Like many others of his time, WHATELY came against the principles of wound-infection without understanding them.

In common with every hobbyist, WHATELY marshals a formidable array of successful cases in support of his method; these cases would look well if paralleled with some of our modern reports of "electrolysis in urethral stricture." On reflection we are glad that urethral defects due to malpractice can not be transmitted by heredity. A large portion of mankind might otherwise be compelled to seek methods of micturating other than *per vias naturales*. Taking one consideration with another, the lot of the urethra of a hundred years ago "was not a happy one." But after all, the errors of the old-time surgeons had a ring of honesty and true conviction that made their faults quite tolerable as compared with the mysterious ways of some modern surgical hobby riders. One can see at a glance what they intended and can judge of the merits of their methods by their published statistics. The modern originator of surgical procedures, however, has too often a way of reserving just enough of the details of his methods to necessitate referring our cases to him. He has a custom also of reporting a large number of cases of patients who live in the next county or just over the State line out of reach. Verily, the errors of the past generation of surgeons are of more value to surgical science than many of the alleged achievements of to-day.

THE LAW CREATING A MEDICAL COUNCIL AND
MEDICAL EXAMINING BOARDS IN PENN-
SYLVANIA.

After ten years continuous agitation the Legislature of Pennsylvania passed a law establishing a Medical Council and three State Boards of Medical Examiners, May 18, 1893. Pennsylvania was behind many of her sister States, as far as medical legislation was concerned, but the law just enacted contains provisions which, if judiciously and energetically carried out, will exercise a greater influence on medical education in the United States than any legislation which has yet been accomplished. While it is true there are minor defects in the law, these can be overcome by intelligent administration. The Governor has recently appointed the members of the three State Boards of Medical Examiners as the law takes effect March 1, 1894.

The Act under which the appointments are made provides for the establishment of a Medical Council, consisting of the Lieutenant Governor, the Attorney General, the Secretary of Internal Affairs, the Superintendent of Public Instruction, the President of the State Board of Health and the Presidents of the three State Boards of Medical Examiners. The Boards of Examiners are appointed from physicians of ten years practice, seven from each of the following named Societies, viz: the State Medical Society, the "Homeopathic" State Medical Society, and the "Eclectic" State Medical Society. Each of the Boards must hold two or more stated or special meetings every year for the examination of all persons who from the first of next March propose to enter upon the practice of medicine in that State. The Boards are required to submit the questions proposed to be asked applicants to the Medical Council, and from these questions the Council will select the queries for each examination, except that in the departments of therapeutics, practice of medicine and materia medica, the questions shall be based upon the doctrines and teachings of the "school" selected by the candidate. After passing the examination before the proper Board the results are submitted to the Council, which having satisfied itself that the applicant is duly qualified for the practice of medicine, issues a license to practice, to the candidate, and a record is made. This record is open to inspection in the office of the Council, and, on presentation of the license to the Prothonotary of the county in which the physician desires to practice, he or she is entitled to registration in accordance with the provisions of the law regulating medical practice already in force.

Applicants who have received their medical degrees after July 1, 1894, must have studied medicine for at least three years in some legally incorporated medical college, and after July 1, 1895, must have pursued medical studies for at least four years, in-

cluding three years attendance upon some legally constituted medical college.

Several of the States, as a qualification for examination, require attendance on three annual courses. These are Minnesota, North Dakota, Washington and New York. Therefore this requirement of four years' study goes farther than any direct legislative enactment that has yet been passed and sustains the position taken by the Illinois State Board of Health in July, 1887, in refusing to recognize the diplomas of any medical college, after the session of 1891 and 1892, which did not require three annual courses of lectures and four years of study.

A number of the leading schools have already required four annual courses of lectures; and with this additional incentive it is safe to assume that all the medical colleges in the United States, by the year 1900, then in existence will require four annual courses and thus remove, to a great extent, the stigma heretofore resting on medical education in the United States.

If the applicant fails in his first examination, he may be re-examined after six months have elapsed and within two years. Physicians licensed after examination by State Boards of Examiners or State Boards of Health of other States, where the standard of acquirements is substantially the same as that required in Pennsylvania shall receive a license from the authorities without further examination. This feature is now introduced for the first time in medical legislation in this country, and is eminently just and wise. The requirement of a fresh examination each time that a practitioner desires to take up his residence in another State would necessarily become oppressive and onerous.

The Act does not affect physicians now registered in their respective counties under the Act of 1881, who thus register before March 1, 1894, nor does it apply to physicians from other States or counties called to consult with registered physicians. This latter provision is also broader and more liberal than that which obtains in nearly all the other States.

It will be observed that the distinctive features of this law as compared with those of other States are the establishment of the Medical Council, which, however, corresponds in part to the Board of Regents of the University of the State of New York, and the recognition of licenses granted by similar bodies in other States. This legislation is sufficiently comprehensive to protect the public from professional incompetence, and encourage the attainment of the knowledge requisite, without being open to the criticism of being illiberal and exclusive.

DEAD DRUNK.

The death of JOHN MARKEY a few days ago in Chicago from a fractured skull, he having been run into

by a street car, and booked for drunkenness by the police, is another evidence of the stupidity of the average policeman; and the careless disregard for life that obtains in this country among police officers. An inquest was held. "The intelligent coroner's jury heard the testimony of the intelligent officers, and rendered the intelligent verdict that the death was the result of acute alcoholism." His wife was not satisfied, as she knew her husband was not a drinking man, and she induced the coroner to have a post-mortem made, when it was found that his skull was fractured. A second inquest was held, which resulted in a verdict in accordance with the facts.

A man is found in the streets unconscious, no matter whether it is due to apoplexy, fracture of the skull or any lesion of the brain; he is thrust into a cell to sleep off his supposed drunk (often to be found dead in the morning) or for the same reason not received at a hospital, when if he had been properly cared for his life might have been saved. In some cases, no doubt, there may have been evidence that the party had been drinking, and probably had received his injury while intoxicated, but this is no reason why he should be neglected. The police should be instructed, so that at least when in doubt a medical man be called to see the case. The judgment, "dead drunk," is too often literally true. Instances of this character have often occurred, and within the last six months twelve cases have been noted in different cities, and it is high time that something should be done to stop it. Unfortunately, the police are not alone in this disregard for life, as two months ago two ambulance surgeons of New York committed the same mistake—we might almost say the same crime.

CONSTITUTIONAL RIGHTS OF PERSONS CHARGED WITH INSANITY.

Attention has already several times been called, through the columns of the JOURNAL, to the fact that the Supreme Court of Minnesota has held to be unconstitutional certain sections of that State's insanity law enacted in 1893. There is, however, a very important principle involved in this decision which merits further notice, as being of universal application.

Every one has either known, or read, of cases where the greatest wrongs have been, intentionally or unintentionally, perpetrated, by the unscrupulous and wickedly designing, or criminally indifferent, upon persons charged with insanity. History is full of instances where it would seem as if any person was perfectly defenseless against the most manifestly trumped-up charges of insanity.

This Minnesota case, of *State v. BILLINGS*, better known as the "BLAISDELL Case," is not one of this sort, but it furnishes the opportunity for the court to declare that, while the State should take charge of

such unfortunates as are dangerous to themselves and to others, not only for the safety of the public, but for their own amelioration, due regard must be had to the forms of law and to personal rights. To the person charged with being insane to a degree requiring the interposition of the authorities and the restraint provided for, there must be given notice of the proceeding, and also an opportunity to be heard in the tribunal which is to pass judgment upon his right to his personal liberty in the future. There must be a trial before judgment can be pronounced, and there can be no proper trial unless there is guaranteed the right to produce witnesses and to submit evidence.

Any method of procedure, which a legislature may, in the uncontrolled exercise of its power, see fit to enact, having for its purpose the deprivation of a person of his life, liberty or property, is in no sense the process of law designated and imperatively required by the Constitution. Any statute having for its object the deprivation of the liberty of a person can not be upheld, unless it absolutely secures to the person the right to have the tribunal proceed by "due process of law," which, as above intimated, requires notice, hearing and judgment.

Of the Minnesota statute held to be invalid, it is not necessary to say more than that it was so constructed that the opportunity to be heard in defense was not guaranteed to the person charged, and was not so framed as to compel a hearing before condemnation, or a trial, under the general forms of law, before judgment might be pronounced.

Another very remarkable thing about this BLAISDELL case, is that it was not until upon the rehearing of it, which was decided Jan. 25, 1894, that the court, or the parties, seemed to know of the existence of this now condemned law. On the first hearing, which culminated in an opinion handed down Dec. 13, 1893, the commitment of MRS. BLAISDELL was considered wholly with reference to the old law, and held illegal.

BASES FOR EXPERT OPINIONS.

The Supreme Court of Nebraska holds in the case of the Omaha & Republican Valley Railway Company v. Brady, decided Jan. 16, 1894, that the opinion of a medical expert may be based: 1, on his acquaintance with the party whose condition is under investigation; 2, upon a medical examination of him which he has made; or 3, upon a hypothetical case stated to the expert in court. Some latitude must necessarily be given in an examination of medical experts and in the propounding of hypothetical questions, the better to enable the jury to pass upon the question submitted to them. It is the privilege of counsel in such cases to assume, within the limits of the evidence, any state of facts which he claims the evidence justifies, and have the opinion of experts upon the facts thus assumed.

CORRESPONDENCE.

LETTER FROM EUROPE.

Major Girard, Surgeon U. S. Army, to Professor Senn.

No. I.

SEA VOYAGE—BREMEN—GÖTTINGEN—DR. HILDEBRANDT—PROFESSOR KOENIG AND THE GÖTTINGEN CLINIC—PROFESSOR ORTH.

GÖTTINGEN, Feb. 9, 1894.

Dear Dr. Senn:—In compliance with your request and the invitation of Dr. Hamilton, I will commence a series of letters, relating what, in my travels, I may find of interest to the profession. Owing to my appointment as delegate from the War Department to the International Congress at Rome, my professional tour in Germany has to be somewhat curtailed, but I hope to supplement this loss by an account of my experiences in the "Eternal City."

As a preface I desire to say that I do not expect or hope to compete with your inimitable style in the "Four Months Among the Surgeons of Europe." My account will also not be in chronological form, hence the dates of my visits and their durations will be omitted.

The passage in the steamer gave me an opportunity to test the efficacy of the treatment of naupathy recommended by Dr. Skinner in his excellent article in the *New York Medical Journal* of last December. I had provided myself with the necessary solutions of atropin and strychnia, and that of caffein. Unfortunately, I met a ship's surgeon who either was not, or did not want to be, a believer in any treatment for seasickness, and consequently I was not given the privilege of experimenting on the steerage passengers, but I had a number of personal friends in the first cabin, who gladly availed themselves of any means of escape from the horrible malady. Among them I noted particularly three very distinct cases: One where a lady, by means of the injections, was enabled to go to table, while she had before suffered from violent headache and intense nausea. The passage being very stormy, the treatment had to be continued almost daily. The other, a lady who had suffered from endless vomiting day and night for four days, was almost miraculously relieved by one injection of half a dose, and although she was not able to appear on deck until near the end of the voyage, could partake of her meals in her stateroom.

The third case, an elderly lady suffering from excruciating headache and vomiting up to hematemesis, after one injection was at once relieved.

I am sorry that I did not have a better opportunity of testing more fully this treatment, but with pleasure add this testimony to that of Dr. Skinner, holding out some hope to the sufferers on the sea.

Your introduction to Dr. D. Kulenkampff of Bremen, led to a very cordial reception. The Doctor took great pains to exhibit to me the various hospitals, many of them the outcome of private charity, of which Bremen may well be proud. The "Städtische Krankenhaus" especially is almost perfect in its appointments—great cubic capacity of beds, floors laid with linoleum or cement, direct and indirect heating, ventilation by expiration, wide porches, two detached disinfecting rooms—one by dry heat, the other by steam—detached, well ventilated and well appointed kitchen and storerooms, electric dynamos, etc. The operating room is tiled on the walls, the floors marble terrazo, such as the surgeons deemed a necessity a few years ago. This is by the surgeons themselves now considered a not indispensable luxury, which is replaced by thorough individual asepsis. The appliances for sterilization are complete.

In the other hospitals, the old methods of heating by

means of large stoves and natural ventilation are mainly relied on.

On my arrival in Göttingen I was very kindly received by Dr. Hildebrandt, formerly first assistant to Prof. Koenig, and now one of the teachers of surgery in the University. He introduced me to the great surgeon (Koenig), whose name in Northern Germany is mentioned in the same breath with von Bergmann and von Billroth. Speaking of the latter, I learned yesterday with great regret that, after a brief illness, he had passed to the unknown country—a loss to surgery which you no doubt greatly regret.

A few notes from Prof. Koenig's clinic may be of interest. He presented a young man of anemic countenance suffering from tubercular synovitis of the knee-joint. The limb was somewhat atrophied. The circumference of the knee slightly enlarged, motion fair to about 35 degrees. I had learned in Bremen that a reaction had taken place in Germany with regard to operative procedures in tubercular joint diseases, and that the knife was rarely resorted to. I expected to see an injection of iodiform emulsion, but found that a reaction of the reaction had taken place in Prof. Koenig's clinic. He said, that while in children or wealthy people non-operative treatment might be justifiable, until indications for operation were absolute, in the working class, who expected to be fitted for bread-earning in the shortest possible time, such a procedure was not justifiable. He predicted that he would probably not even find affection of the cartilage, but expected from the thickening of the synovial sac, extensive tubercular deposits in the same. As to the method of operation, flaps, etc., he said that as to eventual success they made no difference whatever. He chose Hahnemann's method of incision across the patella and division of it by the saw after application of the elastic bandage and Esmarch's tourniquet. He then very carefully dissected off the synovial sac, including the mucous bursa, removed with the saw the epiphyses, trimming off the edges with a small sharp knife, united the patella by means of a shoemaker's awl and catgut, and periosteal continued catgut suture, placed a drainage tube in either side of the joint and beside the extensor tendon, enveloped the whole in a wood wool dressing and then placed it on a posterior splint. After this the constricting band was removed. The operation took an hour.

The next operation was an amputation of the thigh for recurring tubercular disease, which originally appeared to have been started by an injury to the foot with eventual development of tubercular foci in the bones of the tarsus, then in both elbows, finally in the knee joint. The operation was performed after the clinic by one of the senior students under the direction of the Professor. Elevation of limb, elastic bandage and constrictor (which, by the way broke during the operation and had to be replaced without perceptible increase of flow of blood, owing to rapid pressure on femoral), flap. The periosteum was retracted, but no flap made or fastened. Single ligatures. One of these slipped off toward the end of the proceedings, showing the wisdom of your method of double ligatures.

The next operation was for epispadias, made by the Professor himself,—the second step in the procedure, the first having brought about closure of the canal. A circular flap around the opening, liberated to the bottom of the urethra was folded over a catheter and united in the fashion of the Lembert suture. The defect was covered by a flap brought down from above the urethra, presumably not encroaching upon the parts eventually covered with hair and the whole held in place with catgut stitches.

The operations were performed under chloroform, although since the last Congress of Surgeons, ether more and more takes its place, not with great willingness, how-

ever, on the part of the German surgeons. In the last case ether was used at first, but owing to spasmodic action of the abdomen, flooding the field of operation with urine, abandoned and replaced by chloroform, which speedily brought about an even narcosis.

A resection of the hip-joint—without chain saw—was done with great dispatch and knowledge of the landmarks used and was carried into the interior of the pelvis through the acetabulum to remove tubercular deposits.

As to Prof. Koenig, he is a man apparently of 60, with a determined face, but generally kindly manner.

The buildings of the clinics are all new, and in every respect up to modern views in such matters. None but cases useful for instruction are admitted, and the chiefs of the several clinics are autocrats in this question. Prof. Erb has charge of the internal clinic; Prof. Orth of the Pathological Institute, which is the roomiest, best adapted building of its kind I have ever seen. A new work by Prof. Orth's pen has just appeared on "Diagnostics based on Pathologic Changes." It fills a want. Prof. Rosenbach, a very urbane gentleman, the discoverer of staphylococcus and streptococcus, has charge of the Surgical Polyclinic. I believe that the facilities of Göttingen for either study or post-graduate investigations are equal to any university, and the absence of distractions in the town should, it appears, lead to studious habits. I regretted, however, to find that the native students did not avail themselves as they should of the splendid opportunities offered them, and that so many empty seats must have a depressing effect on the enthusiasm of the teacher.

My next will be devoted to Wurzburg.

Sincerely yours, A. C. GIRARD.

"Superfluous Spectacles."

KEOKUK, IOWA, Feb. 24, 1894.

To the Editor:—Superfluous spectacles are those prescribed by incompetent persons. Who are they? Surely not the educated physician who, after years of preparation, drops into ophthalmology by a sort of natural affinity; surely not the man or woman, who, when examining the eye, sees not only an optical apparatus but a living being behind it. No. The incompetents are those half-hatched and abortive products ground out by the so-called "ophthalmic colleges." These "colleges" are engaged in manufacturing opticians out of jewelers and oculists out of jays. Six weeks' time suffices in either case to produce a diploma-bearing individual who goes forth to prey upon the credulity of the populace. These are the persons who are to blame for "superfluous spectacles."

Every educated physician engaged in ophthalmic practice, knows that many cases of asthenopia in which refractive error exists, are not cured by glasses. The glasses are blamed, the oculist denounced, and regular medicine is brought into disrepute, all because too much confidence has been placed in the curative power of the lenses. In these very cases, glasses are needed because of the existence of error. The fact that asthenopic symptoms are not relieved by lenses should not lead us to regard such lenses as "superfluous spectacles." Glasses will cure many strange symptoms—but they are not omnipotent. Often change of air, of occupation or the treatment of nasal disease; often the use of tonics and other constitutional treatment will be necessary. It is in such cases that the "eye oculist" of six weeks' preparation will fail.

What is the remedy? *Abolish the "Ophthalmic Colleges."* If they are valuable, why not establish rectal, genito-urinary, hepatic, stomachic and pancreatic colleges? Specialism in medicine has gone mad.

JAMES MOORES BALL, M.D.

A Suggestion.

INDIANAPOLIS, IND., Feb. 15, 1894.

To the Editor:—Permit your correspondent to express the opinion that our JOURNAL might be more useful, more generally read and kept closer in touch with the general profession by having a department for "Gleanings From the Reports of Medical Societies."

To utilize this suggestion each society should elect or appoint a competent reporter or corresponding secretary, whose duty it should be to give a brief report of each paper read and case reported that the society deemed of sufficient importance to interest the general profession.

These short reports should be sent to the JOURNAL for the consideration of its editors who would doubtless be glad to give them to their readers, or such parts of them as they might think proper.

This plan would identify every society with the JOURNAL, and make the members of the different societies anxious to read what might be reported from their own organization, and the comments thereon, as well as the reports from other societies.

I hope this plan or some other, for the above reasons, will meet the approval of the JOURNAL and of the many intelligent and hard working local societies throughout the United States.

JAMES W. HERVEY, M.D.

Idaho State Medical Society.

MOSCOW, IDAHO, Feb. 18, 1894.

To the Editor:—I notice in your roster of "State Medical Societies of America," that Idaho is omitted. We organized in September, 1893, *strictly in line* with the AMERICAN MEDICAL ASSOCIATION, as the Idaho State Medical Society. Our annual meeting is at Boise City September 5.

Officered as follows: W. W. Watkins, M.D., President, Moscow; C. L. Sweet, M.D., Boise City.

Very truly yours, W. W. WATKINS, M.D.

Medical Department University of Wooster.

CLEVELAND, OHIO, Feb. 19, 1894.

To the Editor:—Will you kindly correct a statement made in a recent issue of your JOURNAL, to the effect that Dr. F. C. Taylor was elected to the position of Secretary of our Faculty. Such is not the case. The writer is holding the position at the present time and has for some time previously.

Very truly yours, H. W. ROGERS, M.D., Sec'y.

From Professor Osler.

BALTIMORE, MD., Feb. 20, 1894.

To the Editor:—For one, I fail to see anything *undignified* in the letter of Dr. S. Solis-Cohen, of which "Constancy" complains. It seemed to me admirable in every respect—frank, straightforward and to the point.

Yours truly, WM. OSLER.

Hay Fever.

ST. LOUIS, MO., February, 1894.

To the Editor:—I am specially interested in hay fever. Please inform me where I can get a list of resorts in the United States frequented by victims of that malady?

Respectfully, F. C. EWING, M.D.

Hypnotized.—Sandow, the strong man, whose muscular development was recently made the subject of an article in this JOURNAL by Dr. Lydston, has been successfully hypnotized in New York. While in that state it is said that he lifted a two-pound dumb bell with the utmost difficulty.

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Denver & Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville, Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland, thence east by way of the Northern Pacific R. R. to St. Paul. A stop over at Yellowstone National Park for those who desire it has been arranged, and it is understood that at several places on the journey there will be short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentration on this train should be effected at Chicago and St. Louis.

Announcement.—The Committee of Arrangements has secured Odd Fellows Hall Building, corner Market and Seventh Streets for the ASSOCIATION meeting June 5, 1894. Assembly Hall, for the general meeting, has a seating capacity of 1,500; the twelve smaller halls, for Section work, range in capacity from 500 downward, with committee rooms adjacent.

The engagement carries three of these rooms on Monday for accommodation of associate organizations, as that of the editors, colleges, etc.

The banquet room on the ground floor 65x95 feet, will be devoted to exhibition purposes for which it is admirably adapted, and has been secured for the entire week, that exhibitors may have Monday in which to place their goods, and Saturday in which to remove them. Nearly half of the space is already taken, and others who desire to make a display of their goods under the most auspicious circumstances ever presented on the Pacific Coast, should lose no time in applying to the chairman for space.

Headquarters for the ASSOCIATION have been located at the Palace Hotel corner Market and New Montgomery Streets, only four blocks from the place of meeting. Here we have "Marble Hall," 36x40 feet as a registration room where work will begin on Monday, and "Parlor A" for Committee work.

R. H. PLUMMER, Chairman.

San Francisco, Feb. 21, 1894.

Nebraska Excursion.—We observe that our Omaha brethren are being posted on the coming meeting of the ASSOCIATION. An excursion has been arranged from Omaha, by the editor of the *Clinic*, Dr. Wilkinson, who will speak of it in the next issue of his journal as follows. We hope that his party will join the regular train at Denver, so all may enter the Golden State together:

"The rates for the excursion will probably be made very low. They now are those of the Midwinter Fair, which will also then be in progress, and until July 1, and the special train of Pullman coaches to be directed at the will of the profession, whether desiring to go by way of Salt Lake City and return by way of a trip on the Pacific Ocean from San Francisco to Portland and from Portland back to the starting point, or vice versa is a consideration that a glance at the map will show compasses, in a general way, all points of interest, as only the Union Pacific can offer, in those expansive countries known as the 'Far West' and the 'Pacific Slope.'

"Arrangements will be effected by which many details of the trip may be made most convenient and interesting. The editor, who is to take charge of the excursion, will make use to this end of all suggestions sent to him.

"It is proposed that the train be directed first to Denver, in order that those desirous may see the city and also that this train may accommodate those having on other lines transportation as far as Colorado. The rates will be made proportionately less at this point.

"Concerning the AMERICAN MEDICAL ASSOCIATION: It is America's representative body of medical men. It is that society to which, practically, all the societies of the Union can and do center, because its voice is thoroughly democratic.

"This voice is the Nominating Committee, composed of one member from each State represented at the yearly meeting; this member of each State is chosen at the meeting by the members of his State present. This is the balance-wheel of the democracy of the AMERICAN MEDICAL ASSOCIATION.

"As to the meetings they are thoroughly cosmopolitan, from the immaculate and more formal evening dress, after the going down of the sun, of the men who hail from the 'cities,' to the conventional garment of the physician everywhere, all are on the same footing at all times, whether at the receptions—in banquet halls or at work through the days of the four-days session in the many different sections.

"To become a member of the AMERICAN MEDICAL ASSOCIATION is a very simple matter. Have the indorsement of the president or secretary of any society of which you are a member in good standing (State, district, etc.), and which considers itself in affiliation with your State Medical Society or for that matter, with the AMERICAN MEDICAL ASSOCIATION. (This affiliation means to have subscribed to the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION.)

"Send this indorsement together with \$5 to Dr. Richard J. Dunglison, Treasurer, box 1274, Philadelphia, Pa. In this way you become privileged in all the functions of the ASSOCIATION, together with becoming a subscriber to the JOURNAL of the ASSOCIATION, which is to-day in the front rank of American medical weeklies.

"One more suggestion. If you desire a vote on the important issues (the Code is one of them) at the next meeting, it is as well at this time that you join a State medical society and go as a delegate.

"Full particulars are given in this issue of the *Clinic* as to membership of the Nebraska State Medical Society and we hope next issue to present the routine in full of the Iowa State Medical Society.

"You will be given official papers as a delegate to the AMERICAN MEDICAL ASSOCIATION at and after the time of meeting of the State societies in May, if you will furnish the respective secretaries of these societies with the request at any time between now and the time of the annual meeting.

"So far as we know the following societies in Iowa and Nebraska are in affiliation with the AMERICAN MEDICAL ASSOCIATION:

"Nebraska State Medical Society, Iowa State Medical Society, Medical Society of the Missouri Valley, Tri-State Medical Society, Omaha Medical Society, Richardson County (Neb.) Medical Society, Northwestern Medical Society, Loup Valley (Neb.) District Medical Association, Central Nebraska Medical Society, Lincoln (Neb.) Medical Society, Otoe County (Neb.) Medical Association, Cherokee (Ia.) Medical Association, Sioux City (Ia.) Medical Society, Johnson County (Neb.) Medical Society, Western Association of Gynecologists and Obstetricians, State Line Medical Society, Cedar Valley (Ia.) Medical Society, Des Moines County (Ia.) Medical Society, Dubuque (Ia.) Medical Society, Washington County (Ia.) Medical Society, Warren County (Ia.) Medical Society, Wapello County (Ia.) Medical Society, Society of Physicians and Surgeons of Muscatine County (Ia.), Shelby County (Ia.) Medical Society, Scott County (Ia.) Medical Society, Ringgold County (Ia.) Medical Society, Polk County (Ia.) Medical Society, North Iowa Medical Society, Muscatine (Ia.) Medical Society, Mitchen County (Ia.) Medical Society, Medical Association of Northwestern Iowa, Austin Flint Medical Society (Ia.), Botna Valley (Ia.) Medical Society, Bremer County (Ia.) Medical Society, Buchanan County (Ia.) Medical Society, Capital District Medical Society (Ia.), Central District Medical Association (Ia.), Clinton County (Ia.) Medical Society, Dallas County (Ia.) Medical Society, Delaware County (Ia.) Medical Society, Des Moines Valley Medical Association (Ia.), Eastern Iowa Medical Association, Fayette (Ia.) Medical Society, Fort Dodge (Ia.) District Medical Society, Guthrie (Ia.) Medical Society, Jackson County (Ia.) Medical Society, Jefferson County (Ia.) Medical Society, Johnson County (Ia.) Medical Society, Keokuk County (Ia.) Medical Society, Louisa County (Ia.) Medical Society, Madison County (Ia.) Medical Society, Marion County (Ia.) Medical Society, Julien Medical and Surgical Society, (Ia.) Maple Valley Medical Association (Ia.)."—*Omaha Clinic*.

SOCIETY NEWS.

The Cheshire County (N. H.) Medical Society met at Hinsdale February 9. Dr. Herbert K. Faulkner read a paper on "Intestinal Obstruction," and Dr. Gardner C. Hill read a paper on "Hematuria."

The Orange Mountain (N. J.) Medical Society held a regular meeting February 16, on invitation of Dr. W. D. Robinson. About forty members were present. The paper of the evening was read by the retiring President, Dr. Carl Buttner, his subject being "Home Treatment for Consumption."

New York State Medical Society.—At the last annual meeting of the New York State Medical Society, the following officers were elected: President, George H. Fox, M.D., New York City; Vice-President, Frank Low, M.D., Pulaski; Secretary, Frederick C. Curtis, Albany; Treasurer, Chas. H. Porter, Albany.

Rockford, Ill., Medical Society.—The Rockford, Ill., Medical Society was formed Feb. 12, 1894, and the following officers were elected for the first year: President, G. S. Wing; Vice-President, T. N. Miller; Secretary, J. E. Allaben.

The regular meetings of the Society will be on the second Tuesday evening of each month. Those present at the first meeting were Drs. Henry Richings, A. N. Comings, T. H. Culhane, F. M. Hill, Starke, Fringer, Miller, Allaben, Tibbets and Winn.

The Northampton County, (Pa.) Medical Society held its bi-monthly meeting at Bethlehem, Pa., February 16. These members attended: Dr. C. H. Ott of Chapman's; Dr. W. H. Seip of Bath; Drs. Chas. McIntire, David Engleman, Amos Seip, E. M. Green and W. B. Erdman of Easton; Drs. B. P. Breinig, E. H. Schnabel, W. L. Estes, John H. Wilson, H. C. Masland and H. Threlkeld-Edwards of the Bethlehems. Two papers were read at the session: Dr. McIntire on "How to Prevent Blindness," and Dr. Edwards on "Serum Therapeutics." The annual meeting will be held at the United States Hotel in Easton, in April.

The Monthly Meeting of the London, Ont., Medical Association was held on February 19, in the Medical School. A large number of members were present, and the proceedings were of much interest to the profession. The Association recognize the great evil that has wounded the practice of medicine in the way of lodge and contract practice, and propose to invoke the aid of the Ontario Medical Council to remedy the evil. Dr. Butler read a valuable paper on "Acute Inflammation of the Middle Ear," which is prevalent as a result of la grippe. Dr. Drake presented the notes of a very unusual and interesting case of rupture of the heart, and exhibited the specimen. The papers were discussed at length by many of the members.

Medical Club of Philadelphia.—The Medical Club of Philadelphia held its annual meeting at the Hotel Metropole February 15. Dr. H. G. McCormick, President of the State Medical Society, was the special guest of the Club at the banquet which followed the business meeting.

The following officers were elected: President, J. H. W. Chestnut; First Vice-President, Prof. Peter D. Keyser; Second Vice-President, Prof. Hobart A. Hare; Secretary, Lemuel J. Deal; Treasurer, Roland G. Curtin.

Board of Governors: J. M. Barton, Frank Fisher, Prof. William Pepper, Prof. Charles K. Mills, A. H. Hulshizer. Additional Members of the Executive Committee: James VanBuskirk, Prof. E. E. Montgomery, M.D., Prof. James C. Wilson, M.D., L. Webster Fox and T. Chalmers Fulton.

The addresses referred principally to the new law creating a State Medical Council and Boards of Medical Examiners, towards the passage of which the untiring efforts of Dr. McCormick largely contributed. Among those who spoke were Dr. John H. Rauch of Chicago, who for so many years was President and Secretary of the State Board of Health of Illinois, which is in fact the Medical Examining Board of that State; Dr. William B. Newell of the New Jersey State Medical Examining Board; Dr. Hobart Hare of the Jefferson Medical School; Dr. Ernest L. Laplace of the Medico-Chirurgical College; Dr. Charles K. Mills of the Policlinic; Dr. Horatio C. Wood of the University of Pennsylvania, and Dr. John B. Roberts of Woman's Medical College. The

speakers were introduced by the President, Dr. J. H. W. Chestnut, to whose indefatigable efforts the Club owes its existence. There were present about one hundred of the most prominent physicians of Philadelphia and other parts of the State, among whom may be named as members of the newly created Board of Examiners, Dr. W. S. Foster of Pittsburgh, and Drs. Henry Beates and A. H. Hulshizer of Philadelphia. The affair passed off with much éclat and was greatly enjoyed by the participants.

Medical Society of the State of Pennsylvania.—Committee on Scientific Business. At its last meeting the Medical Society of the State of Pennsylvania appointed—under the provisions of a by-law proposed at Harrisburg and adopted at Williamsport—a Committee on Scientific Business, "to secure scientific papers and to provide scientific discussions for each annual meeting, and to cooperate with the Committee of Arrangements and Credentials in arranging the program." The members of this Committee are Drs. Dulles of Philadelphia; Gorgas of Harrisburg; LeMoyné of Pittsburgh; Tyson of Philadelphia; and Towler of Marienville. The object of this change in the law is to have a permanent Committee which, becoming familiar with the subject, shall find it easier to secure good scientific work than is possible for a committee that is appointed new every year.

This Committee on Scientific Business is working in conjunction with the Committee of Arrangements, of which Dr. E. E. Montgomery is Chairman, and will cooperate with it in arranging the program.

The Committee hopes that each member of the State Society will aid it in attempting to make the meetings of the Society of greater scientific importance than they have been in the past. To this end the Committee will welcome suggestions from any member of the Society and especially, at this time, offers of contributions to the work of the next meeting at Gettysburg, May 15 to 18. It is desired that there should be as many brief, concise, practical papers as possible, and it is proposed to have a discussion on tuberculosis, devoting the morning to "Medical Tuberculosis," and the afternoon to "Surgical Tuberculosis."

Any communication from members of the Society in regard to the work of the Committee will be welcomed by it.

Members of the Society desiring to read papers, or to take part in the discussion on tuberculosis, will please notify the Chairman of the Committee, Dr. Charles W. Dulles, 4101 Walnut Street, Philadelphia.

BOOK NOTICES.

Antiseptic Therapeutics. By E. TROUËSSART, M.D. Translated from the French by E. P. HURD, M.D. Two Vols. Paper. Detroit: Geo. S. Davis. 1893. Price, 50 cents.

This is one of the most timely books of the year, and will be welcomed by all who wish to practice medicine according to the modern theories of bacteriology. Whether this newer practice will stand the test of time or not, it must be confessed that our therapeutics has not, up to this time, kept pace with the histologic knowledge.

We give, as a sample, the therapeutics of typhoid fever, which, according to our author (pages 234 and 235) is probably produced by the bacillus typhosus of Eberth:

"There are few diseases in which vigorous intestinal antiseptics is more plainly suggested by reason of the ulcerations which are seated in the walls of the intestine.

"According to Bouchard, there are four indications to fulfill: General antiseptics; intestinal antiseptics; antipyretic medication; and lastly, regimen. He begins by a saline purgative; then gives calomel in the dose of 40 centigrams (6 grains) a day in twenty doses, for four days, taking care to avoid salivation. He gives quinin only when the temperature exceeds 104 degrees F. in the morning and 105 degrees in the evening; then he gives 2 grams (30 grains) daily during the first and second week, then 1½ grams during the third; then 1 gram only, taking care not to give another dose until after seventy-two hours. General baths at 38 degrees C. (100 degrees F.), cooled by degrees down to 30

degrees C. (86 degrees F.) and repeated eight times in the twenty-four hours, are only contra-indicated when there is intestinal hemorrhage or pulmonary hepatization. Beef peptonos for nourishment, and glycerin (six to seven ounces a day). Vegetable acids under the form of lemon-juice.

For intestinal antiseptis, Bouchard prefers naphthol, α , which he administers under the following form:

"R. Naphthol α
Salicylate of bismuth aa 5 gm.

"M. Div. in chart No. X. Sig: Take one powder every hour.

"Benzo-naphthol, recently introduced into therapeutics, may be substituted with advantage for naphthol, especially if the kidneys functionate badly. In the latter case it is well to avoid the salicylate of bismuth."

While there are yet many vacant places, enough is given in this book to show the great advances made in therapeutics based on antiseptic medication.

Atlas of Clinical Medicine. By BYRON BRAMWELL, M.D., Assistant Physician to the Edinburgh Royal Infirmary. Volume II. Part III. Edinburgh: T. and A. Constable. University Press. 1893.

The third part of Volume II of this valuable clinical periodical, with finely executed plates illustrative of the text, has just been issued. The articles are: Exophthalmic Goitre: the clinical investigation of cases of exophthalmic goitre; Acromegaly: case of acromegaly in a giantess; the clinical investigation of cases of acromegaly; General Exfoliate Epidemic Dermatitis; Unilateral Hypertrophy of the Face.

There is an extra plate entitled "Old Age," which shows senile changes in the head and face in a very natural manner.

The number contains an index, title-pages and table of contents of the second volume. The high standard of this excellent work continues to be maintained.

MISCELLANY.

Dr. J. H. Cleaver, of Council Bluffs, Iowa, has been nominated for Mayor by the republicans of that city.

The Medical Department of Laval University, Montreal, has received a donation of \$3,000 from Rev. Abbe Colin. The sum named is to provide certain necessary scientific apparatus.

Dr. Adolph Dnsterhoff, has left to the Berlin University 100,000 marks, the interest of which will be awarded twice a year to the most diligent student in the Medical Department.

New York Academy of Medicine.—Dr. Mary Putnam Jacobi has been elected chairman of the section on nervous diseases by the New York Academy of Medicine.

Lewis Balch, M.D., who for the last seven years has been Secretary of the New York State Board of Health, has announced his intention to resign at the next meeting of the Board.

Dr. Livingston of Bennettsville, N. Y., has built up an extensive practice, notwithstanding that he has been deaf and dumb from the age of three years up to three years ago.

Died from Glanders.—Mrs. Sophie Bersford, died at San Francisco, February 20, from glanders, which she took from a horse purchased from a dealer, who it is said knew that the animal was diseased at the time of sale.

Savannah Medical Journal.—The Savannah Medical Journal Publishing Company announce a new monthly medical journal to be especially devoted to the interests of the medical profession of the Gulf States.

Veterinary Surgeons.—The annual meeting of the Illinois State Veterinary Association was held at Springfield, February 21, with a full attendance. Papers upon important subjects were read by prominent members of the Association.

Typhoid Fever.—We have several letters in regard to the paper of Dr. Woodbridge which recently appeared in the JOURNAL on the abortive treatment of typhoid fever. The writers animadvert on the fact that the treatment has not been given in detail. We have in hand a supplementary article from Dr. Woodbridge, which will appear next week and give his treatment in full.

The Practitioners' Club of Chicago met at the Great Northern February 26. Professor N. Senn presided. The topic for discussion was the "Medical Department of the Newberry Library." Dr. Ephraim Ingals gave an account of the beginnings of the Library. Dr. Wire gave a detailed statement of its present condition, and Dr. Senn told the story of the procurement and development of the Senn collection. Dr. George W. Webster spoke of the library of the AMERICAN MEDICAL ASSOCIATION. Short speeches were made by Drs. Hollister, Andrews and Hamilton.

Quarantine at Fernandina.—A meeting of the State Board of Health was held in Jacksonville February 23. The meeting was called for the purpose of considering the erection of a quarantine station at Fernandina. The members of the Board are: William B. Henderson, President, Tampa; Dr. Joseph Y. Porter, Secretary and Health Officer, Key West; James P. Taliaferro of Jacksonville and Dr. Warren R. Anderson of Pensacola.

St. Louis Medical College Changes.—The Faculty of the College of Physicians and Surgeons has accepted the resignation of Dr. Barnes, who for many years has been Dean of the College, and the vacancy has been filled by the appointment of Dr. J. A. Close. Dr. George H. Thompson has been elected Secretary to fill the vacancy caused by the resignation of Dr. G. W. Cole several weeks ago. Changes in the staff of the College were recently made, when Dr. J. W. Smith, Assistant to the Professor of Surgery, was dismissed by the Dean and Dr. J. D. Nifong appointed in his place.

Consumption an Infectious Disease.—A committee of the Philadelphia Pathological Society, consisting of Drs. John Packard, W. E. Hughes, G. G. Davis, F. Eshner, W. L. Coplin, John H. Musser and Drs. Ball and Allyn, appeared before the Board of Health February 20, and presented the following action taken by the Society relative to the infectious nature of tuberculosis:

"WHEREAS, In the opinion of the Pathological Society tuberculosis is an infectious disease, and the Society recognizes the fact that the most frequent source of infection is the human subject affected with the disease, and that there are many practical obstacles to be overcome before a generally accepted system of preventive measures can be established; therefore, be it

"Resolved, That in the opinion of this Society the line of action to be followed by the health authorities should be one of education and preparation of the people for future action, and that the first step in this direction should take the form of frequent and well propagated announcements to the effect that the health authorities are prepared to undertake, upon request of the attending physician, with the sanction of the family, the disinfection of premises vacated by tuberculous patients."

After the subject had been discussed by the committee, and the members of the Board, the matter was referred to the Sanitary Committee.

The Medical Editors Travel.—February 15 the medical editors who are traveling through the South, passed through Raleigh. They stopped last night at Southern Pines and will then proceed to Charlotte. From Charlotte

they will return to Monroe and go to Atlanta. From Atlanta they will return to Wilmington, arriving there on the morning of the 20th. That evening at 6 o'clock they will arrive here and spend the night, leaving at 11.25 A.M. the morning of the 21st for Portsmouth, en route northward.

The party is composed of the following persons:

Dr. W. C. Wile, *New England Medical Monthly*, Mrs. Wile and daughter, Danbury, Conn.; Dr. E. C. Angell, of the *Sanitarian*, Brooklyn, N. Y.; Dr. Ferdinand King, *Polyclinic*, New York City; Clark Bell, Esq., *Medico-Legal Journal*, New York City; Dr. T. D. Crothers, *Journal of Inebriety*, Hartford, Conn.; Dr. T. D. Wood, *Brooklyn Medical and Surgical Journal*, Brooklyn, N. Y.; Dr. Howard Van Rensselaer, *Medical Annals*, Albany, N. Y.; Dr. W. Blair Stewart, *Medical Bulletin*, Philadelphia, Pa.; Mr. Griffing and wife, representing the *Connecticut Press*; Mr. R. G. S. McNeille, *Bridgeport Standard*; Dr. Geo. L. Porter, the *Times and Reporter*, Philadelphia; Dr. S. G. S. Stewart and wife, *New York Medical Times*.

The party is under the care of Mr. Geo. W. Taylor, passenger agent of the Seaboard Air Line, and of Captain Whistnant and Mr. Patrick.

Dr. Cheatham and Miss Cheatham of Henderson, N. C., are at present with the party.—*Raleigh, N. C., Chronicle*, February 16.

Hospital Notes.

New Hospital.—Ottumwa, Iowa, is to have a hospital.

The N. Y. State Hospital at Rochester was damaged by fire February 20. The loss is about \$15,000.

Dubuque, Iowa, is to have an Emergency and Contagious Disease Hospital. It will be managed by the City Board of Health and the county authorities.

St. Mary's Hospital at Evansville.—The new St. Mary's Hospital at Evansville, Ind., was formally opened February 15. The new building occupies an entire block, and it is said that nearly 10,000 visitors inspected it at the opening.

The Missouri, Kansas and Texas Railroad Company are to build a branch hospital "somewhere in Texas." The good people of Fort Worth are bestirring themselves to secure its establishment in that place.

C. E. Riggs, M.D., Inspector of the Fergus Falls (Minn.) Hospital for the Insane has submitted his report to the Board, which among other recommendations includes one for the erection of a separate building for the confinement of the criminal insane.

Dr. B. G. Maercklein, a Milwaukee dentist, has purchased from Drs. William H. Earles and Walter H. Neilson a third interest in Trinity Hospital, with a view to establishing a medical and dental school. A new building will be erected at a cost of \$75,000.

Mr. Guthman of Youngstown, Ohio, has devised a plan to endow the hospital of that city with \$100,000. The plan is for one hundred men to take out insurance policies in the sum of \$1,000 each, on the twenty years endowment plan. In this way, the \$100,000 endowment can be obtained for the hospital and the donors not miss it. Only persons who can well afford to do so will be asked to contribute to the success of the scheme by taking policies.

Woman's Charity Club Hospital.—In 1893 the Woman's Charity Club of Boston, organized a hospital at Roxbury on Parker Hill. Matters have gone smoothly until recently when somebody proposed that medical students should be allowed admission to the hospital for purposes of instruction. Then the trouble commenced, and the new regulation was the subject of many ups and downs, but finally the Club voted, no, with such emphasis that the statues of Molly Pitcher and Priscilla Alden that ought to be over the door of the Council Chamber were observed to turn pale with fright.

Hospital Saturday and Sunday Association.—The thirteenth annual meeting of the Hospital Saturday and Sunday Association of Brooklyn was held last night at the residence of the President, William G. Low.

The most interesting report was that from the collections of Hospital Saturday and Sunday which came on the last Saturday and Sunday of the year. Despite the hard

times, the collections this year are over five hundred dollars more than last year. The total amounts to \$6,468. The following officers were unanimously re-elected for the ensuing year: William G. Low, President; David M. Stone, Vice-President; the Rev. Dr. C. Cuthbert Hall, Secretary; R. J. Kimball, Treasurer.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from February 17, 1894, to February 23, 1894.

First Lieut. BENJAMIN L. TEN EYCK, Asst. Surgeon U. S. A., will report in person to Col. JOSEPH C. BAILY, Asst. Surgeon General, President of the examining board appointed to meet at Ft. Sam Houston, Texas, at such time as he may be required by the board, for examination as to his fitness for promotion.

A board of medical officers, to consist of: Col. CHARLES H. ALDEN, Asst. Surgeon General; Lieut. Col. WILLIAM H. FORWOOD, Deputy Surgeon General; Major CHARLES SMART, Surgeon; Major WALTER REED, Surgeon; Capt. JAMES C. MERRILL, Asst. Surgeon, is constituted to meet at the Army Medical Museum Building, Washington, D. C., on the 12th day of March, 1894, at 10 A.M., for the examination of candidates for admission to the Medical Corps of the Army.

The National Guard.—The Eighth Regiment Ohio National Guards Hospital Corps will be located at Canton, Ohio. Surgeon A. V. Smith is in command of the new corps.

Marine Hospital Changes. Official list of changes of stations and duties of medical officers of the U. S. Marine Hospital Service, for the four weeks ended February 17, 1894.

Surgeon R. D. MURRAY, to proceed to Key West, Fla., for special duty, Jan. 26, 1894.

Surgeon P. H. BAILHACHE, granted leave of absence for twenty days, Feb. 5, 1894.

Surgeon GEORGE PURVIANCE, detailed as chairman, Board of Examiners, Feb. 12, 1894.

Surgeon G. W. STONER, detailed as member, Board of Examiners, Feb. 12, 1894.

Surgeon H. R. CARTER, to report at Bureau for temporary duty, Feb. 2, 1894. To proceed to Brunswick, Ga., Quarantine as Inspector, Feb. 6, 1894. Detailed as recorder, Board of Examiners, Feb. 12, 1894.

P. A. Surgeon J. H. WHITE, granted leave of absence for seven days, Feb. 17, 1894.

P. A. Surgeon P. M. CARRINGTON, granted leave of absence for thirty days, Feb. 19, 1894.

P. A. Surgeon W. D. BRATTON, granted leave of absence for thirty days, Jan. 20, 1894.

P. A. Surgeon W. J. PETTUS, granted leave of absence for thirty days, Jan. 30, 1894.

P. A. Surgeon G. T. VAUGHAN, to report to the Secretary of the Treasury for special duty, Jan. 26, 1894.

Asst. Surgeon G. B. YOUNG, ordered to examination for promotion, Feb. 14, 1894.

Asst. Surgeon W. G. STIMPSON, ordered to examination for promotion, Feb. 14, 1894.

Asst. Surgeon B. W. BROWN, ordered to examination for promotion, Feb. 14, 1894.

Asst. Surgeon M. J. ROSENAU, granted leave of absence for thirty days, Feb. 26, 1894.

Asst. Surgeon L. E. COFER, to proceed to Mobile, Ala., for duty, Jan. 30, 1894.

Asst. Surgeon J. M. EAGER, granted leave of absence for four days, Jan. 30, 1894.

Asst. Surgeon RUPERT BLUE, granted leave of absence for eight days, Jan. 26, 1894.

Asst. Surgeon SEATON NORMAN, ordered to examination for promotion, Feb. 14, 1894.

Asst. Surgeon EMIL PROCHAZKA, to proceed to New York City for duty, Jan. 24, 1894. To proceed to Buffalo, N. Y., for temporary duty, Feb. 2, 1894.

ORIGINAL ARTICLES.

SLEEP, SLEEPLESSNESS AND HYPNOTICS.

BY S. V. CLEVENGER, M.D.

CHICAGO.

A theory of sleep phenomena, to be complete, must have data for its construction drawn from wider sources than we find have been surveyed in the average physiologic essay on the subject.

Notwithstanding the strides made by biology, more particularly in its morphologic aspects, the past quarter century has added but little to Wm. B. Carpenter's summary of "Sleep and Somnambulism," in his famous "Physiology," or what is contained in J. G. McKendrick's article in the *Encyclopædia Britannica*. A full bibliography is given in the *Dictionnaire Encyclopédique des Sciences Médicales*; McNish, Durham, Kohlschütter, Pflüger and Mosso afforded the main discussions, which have been added to but little by later writers.

Herbert Spencer (*Principles of Biology*, Vol. I., Chap. IV.) on "Waste and Repair," summarizes much that could be more directly applied to a satisfactory consideration of the study than was required in his "Synthetic Philosophy."

Spencer notes that reptiles maintaining no great temperature and passing their lives mostly in a state of torpor, suffer but little diminution of mass by waste, but with the higher order of animals which are active and hot-blooded we see that waste is rapid, and when unchecked, bulk and weight decrease, ending very shortly in death. From these and allied considerations, he formulates the dictum that in the same creatures there is most waste when most motion is generated. Valentin computes the carbonic acid exhaled by the waking marmot as seventy-five times more than when it was hibernating, and the oxygen inhaled was forty-one times greater in the waking state. Invalids who are able to take scarcely any nutriment, by being kept warm and still, are able to lessen waste by thus reducing force expenditure.

Experimental comparison between the hibernating marmot and starving pigeon shows the latter loses forty times more muscular substance than the torpid marmot, eleven times more fat, thirty-three times more alimentary canal tissue, eighteen and three-tenth times more liver, fifteen times more lung, five times more skin, so that the parts least consumed in hibernation are the hydro-carbonaceous deposits which serve as a store of force, while in the awake and active pigeon, equally unsupplied with food, the greatest loss takes place in the motor organs. The diminished ability of bodily organs to perform their functions after activity, is noted. That legs, arms and eyes become enfeebled, and that concentrated attention prostrates the brain, are familiar truths.

Repair is everywhere and always making up for

waste. While awake, waste is in excess and repair is going on, but not to the same extent as when asleep; though repair is at this time in excess, still some waste is necessitated by the carrying on of never-ceasing functions.

"During activity, the reintegration falls in arrears of the disintegration, until, as a consequence, there presently comes a general state of functional languor, ending at length in a quiescence which permits the reintegration to exceed the disintegration and restore the parts to their state of integrity."

Extending these considerations of Spencer and those who had previously written to the same effect, we are confronted with the fact that tissue restoration is undeniably a chemic process, and the queries arise, why, in such states as cerebral congestion, with its surplusage of blood, the brain may not rest, and why should sleep occur at all if there is proximity of food to the tissues undergoing waste?

Surveying the physiologic accompaniments of sleep in all animal life, we find that in the simplest forms, surfeit and extreme privation arrest motions, and the rational explanation of this would be that the majority of molecules that compose such simple forms are relieved of tension, either by the completion of molecular construction or by their not having within combining reach, atoms with which combinations are possible.

Nutritive processes are certainly carried on during sleep, and the quiescence of sleep facilitates this action by staying the waste of such tissues as are most in need of such reparation and, obviously, nourishment is transferred from such parts as can spare it best to those that are deficient in this regard. If repair were instant and incessant upon waste, then sleep would not be needed to transfer nutrition about the body, and one of the best evidences of this is that, often, massage may so redistribute blood and feed the jaded tissues as to largely take the place of sleep, at times rendering it unnecessary. At other times, massage or a warm bath may induce sleep more rapidly by starting a redistribution such as takes place normally during profound sleep.

If we look upon sleep as merely an *effect*, or an accompaniment of a nutritive process, and as not in every case even a necessary one, we substitute a regard for the real instead of the apparent phenomenon.

In *æstivation*, *amœbic encystment*, *hibernation*, the absence of food requires quietude that will conserve what little there is present in the animal itself. In *plethora*, *apnœa*, etc., this quietude is enforced by the surcharged molecules being incapable of further assimilation, which drops the activity of the entire animal towards the lowest expression.

A parallel is afforded by the action of soil which at times agriculturists claim "needs a rest." It is conceivable that time may be necessary to effect certain chemic combinations even in the presence of

the requisite elements for the soil restoration. Fertilizers of appropriate sorts may cover the exhausted soil, but time is needed for the assimilation of such fertilizers and the ground must lie fallow until its productive capacity is regained, however long this may require; and very likely this necessity for a greater or less loss of time in building up complex cerebral or sarcodal structures explains why sleep occurs, and shuts off further decomposition until reconstruction can take place. The limit of comfortable activity having been reached, sleep takes place because further drain through waste may be distressing, and this discomfort becomes agonizing when prolonged, a fact taken advantage of by the Chinese as a method of torturing criminals.

Less heat and carbonic acid being produced during sleep further indicates the reduction in chemic decomposition that then occurs. Helmholtz estimates 40 calories produced during sleep and 112 when awake. "He who sleeps, dines," is an old saying, and much sleep favors obesity.

Mass motion being suppressed in sleep enables molecular rebuilding the better, as the molecules are not then engaged in the major activities but eat, so to speak, themselves, while the body rests, just as workmen take an hour off to dine, and discontinue the work upon which they are aggregatedly engaged.

Whenever supply is constant to the animal or to its tissues, the necessity for sleep diminishes in proportion to the ability of such animal or tissues to rapidly reintegrate the compounds destroyed. The differences between the sleeping habits of animals are thus at once explained. It is conceivable that animals may exist whose nearly every cell is so constantly bathed in absorbable food as to place it comparatively beyond the need of sleep, but such animal, as a rule, could not be very highly organized, or, like the sloth, could not be very active, and the rete mirabile in the axilla of the sloth shows how part of the muscular strain is provided for while the animal hangs to the tree.

A still further important factor in this connection I communicated to *Science*, New York, Nov. 11, 1892, in an article entitled, "Preliminary Note on Sleep."

"That there is a relative anemia of the brain during sleep is well established, but the hypotheses advanced to account for this or any other of the sleep phenomena are unsatisfactory. In "Comparative Physiology and Psychology," 1884, I treated the subject briefly, and since then have been gradually accumulating and arranging data for a theory which I have finally adopted, and which appears to me to be fairly complete as enabling the major phenomena to be accounted for.

"Briefly stated, where there is physiologic waste there is, normally, repair, and the activities of the brain demonstrably are kept up by renewed nutrition derived from a blood supply adjusted to the ordinary needs. When there is cerebral anemia, as in chlorosis, then there is increased desire to sleep, the brain does not receive the necessary quantity to compensate waste, and it rests, just as any commercial activity will cease with withdrawal of means to continue it. Those who are familiar with my nutrient reflex theory, mentioned in the book referred to (Professor C. K. Mills of the Pennsylvania University, and Professor C. L. Herrick of the Dennison, Ohio, University, have written approvingly thereon), will under-

stand that with the cessation of sensory stimulation there will be less blood attracted to the brain and other nerve centers, the heart-beats lessen in vigor and number, and, with the pulse-rate fall there is ordinarily less blood in the brain.

"Now, it is evident that the anemia of sleep is not caused by constricted blood vessels, else there would be the facial pallor seen during an attack of epilepsy, or paroxysm of anger or fright; and with this quieting of the brain processes by stimuli withdrawal, such as is afforded by darkness, silence and absence of irritation generally, a further lessening of molecular interchange in the brain occurs; and I claim that *it is the molecular activity in the brain that attracts the blood there chemically and mechanically*, and the sympathetic, or vaso motor system has evolved to facilitate this regulation of demand and supply. Then, granting this, there will be, during sleep, a passive condition of the blood vessels, and the blood supply will fall to a minimum.

"An extension of these considerations will enable all that pertains to sleep to be accounted for, such as aestivation, hibernation, insomnia, dreams, and all derangements of sleep."

At this stage we may conveniently condense what otherwise could easily fill a volume, in reviewing as much of sleep phenomena as may be necessary to test the consistency of this mainly chemic theory. Larval and fetal inactivity or sleep, the prolonged sleep of infants and the drowsiness of pregnant females can be understood as demands for lessened activity during constructive processes. An army is recruited and accoutered before it fights, and the molecular cell building is the process of getting ready for the major life activities.

The suspension of consciousness during sleep is apparently due to the lessening of function of organs generally. Consciousness, being a function of the gray matter, or central nervous system, is in abeyance because the gray matter is undergoing reconstructive rest as well as other portions of the organism. Imperfect sleep and dreams are caused by this rest not being complete, the circulation in these centers being irregular.

Worry notoriously exhausts more than many kinds and degrees of work, and sleep overcomes the exhaustion produced by this as well as other excessive brain taxation. In such instances we have a painful cerebral activity, and the molecular breakdown is greater than in simple mental application.

Stimuli withdrawal ordinarily lessens the nutrient reflexes, less blood is forced to the head, and the fall of blood pressure in the medulla drops the heart beats to a lesser number through pneumogastric action. Closing the eye reduces optic excitation, noises are heard and the blood does not immediately fall to a minimum in the brain, hence sleep may not appear until time has passed. As the vaso-motor reflexes are less and less called upon, an ebb of blood finally admits of obtuseness to noises, etc., when they do occur. With the restoration of general cell nutrition, the desire for activity increases and general reflexes are easier provoked. The nutrient reflexes of the brain now begin to send blood there upon stimulation, and the person awakes with the noises and light of day, or upon slighter provocation, if these are absent. The instance is often cited of a boy who was blind and anesthetic, who fell asleep when his ears were closed to sounds.

But stimulation is a relative matter, for many who are accustomed to continuous noises become adjusted thereto, as does the miller who is awakened by the machinery stopping. In Arctic regions, also, the exclusion of light is not necessary to induce profound sleep.

Somnambulists have been separately classed as the speaking, the acting, the speaking and acting, and the hearing, seeing, speaking and acting. In all these, consciousness is absent, hence somnambulism is more or less automatism of important organs; dream acting. Sleep, to be complete, must overtake all portions of the body, and if from any cause irritation persists in any part, as during pain, then imperfect sleep results. It is conceivable that a speech center, centers for arm and leg movements, etc., may be hyperesthetic independently of the adjacent parts. Dr. George W. Jacoby, in a paper read before the New York Metropolitan Medical Society, Feb. 15, 1893, ably surveys the matter of "periodical sleep seizures of an epileptic nature," in which this sort of unconscious automatism is mentioned, and he believes that there is a relationship between the corpulence in some of these cases, such as that of Dickens' fat boy, Joe, and perverted nutrition due to a pathologic condition in the psychic centers. Dr. Jacoby concludes that "sleeping attacks, occurring alone or in combination with other symptoms, if of brief duration and followed by amnesia, are probably epileptic in character. If somnambulism, particularly of a noisy kind, is present, this probability becomes a certainty."

In narcolepsy, he claims that there is consciousness of what is going on during the attacks, the patient is not obtuse when awakened and he at once has full possession of his intellectual faculties. In this instance it would seem as though consciousness was the only faculty that was not asleep. Hysterical lethargy is associated with other evidences of the disease, such as more or less hemianesthesia. Hysterical sleep, in my opinion, is directly due to partial brain ischemia through contracted blood vessels to one or more parts. The amblyopia, deafness, aphonia, etc., could be also thus accounted for, as well as the fact that sudden impressions, or the cerebral suffusion produced by nitrite of amyl, cut short the attack.

The prolonged somnolence of cerebral syphilis, Buzzard (*Diseases of the Nervous System*, p. 288) assigns to the remarkably thickened walls of the arteries at the brain base—usually of a nodular character—diminishing the caliber of the vessels. Huebner, in Ziemssen's *Cyclopædia*, also has important observations upon this subject: "The consequence would appear to be that the cortical substance of the hemispheres must be starved of blood to a considerable extent."

The great sleeplessness of mania for long periods and the supervening emaciation, show that not only cerebral but general rehabilitation is interfered with; waste is not only in excess of repair but the latter is seriously impeded by disease. Hence the necessity for sustaining treatment in this disorder. I have occasionally known stimulants to secure an abatement of the furor and produce sleep, when other routine measures merely added to the trouble. The hot bath, while temporarily beneficial, too often is followed by collapse, additionally going to show the necessity for sustentation in many of the cases that are frequently overdosed with depressants.

Warmth, judiciously used, however, is attended

with good results. The fact that so many of the insane sleep best on hot nights should not be lost sight of. In Griesinger's "*Mental Pathology and Therapeutics*," page 75, et seq., sleep, in connection with insanity is well considered, and he particularly compares insanity to dreaming.

Preyer originated the blunder that sleep was caused by a toxic substance in the blood, upon the inference that as fatigue was associated with sarcolactic acid in the muscles, the latter was the cause of the former. Pflüger regarded sleep as cerebral asphyxiation from excess of carbonic acid accumulation. On the other hand, recent experiments point to increased consumption of oxygen during sleep. Evidently, as a definite amount of nitrogenized hydro-carbonaceous matter is consumed in all waking effort, cessation of activity lessens this consumption, but not to the extent of arresting it altogether, for the inevitable result would be a disintegration of the tissues.

The complex albumen molecule, $C_{72} H_{112} N_{18} SO_{22}$, with its 225 atoms, in undergoing metabolic changes, adds to and subtracts from its number of atoms within a certain range, and maintains its life and potencies. Let us say that twenty-five of its atoms are used up, exploded in exertion, and its limit of exhaustion has been reached. Plainly, these twenty-five atoms should be regained during comparative quiescence by other than toxic or asphyxiating means. In short, the cell eats while the colonial activity ceases, and this is the meaning, the end and aim of sleep. If, in addition, twenty-five more atoms enter into the combination, making it a still more complex molecule, a margin of fifty atoms may thus be imagined as enabling extra exertion within safe limits. Destructive metabolism could be supposed to ensue from several hundred of these atoms being parted with.

The chemic composition of the hypnotics affords no clue to their modus operandi. The mere presence of nitrogen in many is negatived by this element also occurring in ammonia and thousands of compounds with varying properties. Chlorin also appears as a food constituent in salt, as part of the anesthetic chloroform, and as a suffocant in its gaseous form. Neither the number nor the position of the atoms of carbon, hydrogen, nitrogen and oxygen in morphin explain why it differs from quinin which also contains these elements in other proportions.

Neither complexity nor simplicity of atomic combinations guarantees any explanation of the molecular rationale, but in a general way the more useful drugs have a constitution admitting of more or less direct conversion into animal constituents, and yet this is far from being a safe universal guide, for some of the deadliest poisons, even in small quantities resemble foods in their chemic structure.

In some instances, solubility modifies actions materially for better or worse, in others the looseness of the atomic make-up explains some effects, and the resistance to atomic splitting up, or the temperature necessary for decomposition, explains other effects. With what knowledge we possess we can formulate something in general from specific instances:

Alcohol, $C_2 H_6 O$, is rapidly assimilated and in a certain sense is a food. This rapid assimilation by reconstructing the tissue could account for its stimulant effect, and when there had previously been cell waste upon which the insomnia depended, the sleep-inducing properties of alcohol are accounted for.

The stupidity that follows over-indulgence is precisely what would occur from cerebral tissue surfeit.

Morphin, $C_{17}H_{19}NO_3$, upon thorough consideration also falls into this dangerous food category. It, with alcohol, though less rapidly, enters into molecular combinations with nerve tissues and induces a certain exhilaration and subsequent dulling of the senses.

The exhilaration caused by oxygen and the stimulant effects and later anesthesia of nitrous oxid gas, without doubt are owing to the rapid assimilation of these articles by the blood and nerve centers. The stimulant effects of all these agents could be ascribed to rapid atomic interchanges, such as occur with less swiftness and danger in the ordinary course of nutritive supply.

The warmer blooded birds take up oxygen more rapidly than mammals, and far more so than reptiles. The acidity of muscle and nerve substance in connection with blood alkalinity renders possible the conveyance of alkaloids, and make it likely that soluble alkaloidal hydrocarbons of the neurotic group, assimilable by the organism, have sufficiently close molecular resemblances to the acid protagon as to account for their mutual affinities and bio-chemistry.

In the constitution of protoplasm, as well as that of any compound whatever, there is a necessity for the absence of certain molecular groupings which would destroy the combinations if integrity is to be preserved. The cell environment is reached by adaptability, and in the differentiation of cells it is easily seen that what would be nutrient to one may easily poison another by combustion conversion, as with sulphuric acid, or affinities in lesser degree existing between the toxicant and molecule.

The life of the cell depends upon the absence of these deleterious molecules for which there are affinities, precisely as animals must avoid fire. Prussic acid, HCN , presents the simplest example. The nitrogen therein is in a dangerously assimilable form, and its sudden surcharging of the nerve centers with carbonized blood paralyzes the body. Even though the venous blood occurs after prussic acid has first caused the blood to appear to be arterialized, at least destructive chemic changes are instantly induced by this simply constructed poison. The action of nitroglycerin and amyl nitrite exhibit the swiftness of union between the nitrogen and important structures. Nitrogen has a persistent tendency towards its free inert state, and this very disposition confers upon it great physiologic importance. On the other hand, oxygen has a great antipathy to uncombined existence. These two mechanically mixed ingredients of the air play complementary parts in biologic phenomena.

Certain drugs have special affinities for certain groups of nerves, and white pigs and sheep are said to be differently affected by vegetable poisons from colored individuals, a fact accounted for, doubtless, by the presence or absence of pigment compounds which have affinities for or resist the influence of certain poisons.

The antidotal action of chlorin gas in prussic acid poisoning may be due to the former directly lessening the surfeit (so to speak) imparted by the hydrocyanic acid. The sedative property of small doses of the latter show that it has a nutritive value which larger doses exaggerated poisonously.

The theory that chloral, C_2HCl_3O , liberates chloroform in the blood is tenable notwithstanding the definite urochloralic and other urinary excretion after chloral ingestion, but how does chloroform, $CHCl_3$, cause anesthesia? Its solvent power over sulphur, phosphorus and fatty bodies, conjoined with its primarily intoxicating properties, might make it appear to combine slight nutrient with destructive effects, the latter acting later but more powerfully.

The greater safety of ether (sulphuric ether, $C_2H_5_2SO_4$) and its readily decomposing into alcohol, sulphurous acid and olefiant gas, together with its stimulating property in small doses, point to the nutrient action outweighing its toxic or to the relative proportion of each being within safer amounts in ether.

It is doubtful if the bromids become substitution compounds in any of the animal tissues, further than to pervade the secretions and lessen activity by taking the place of nutrient materials. About as free nitrogen dilutes the air and lessens the quantity of oxygen respired, so may the inert bromid salts saturate the circulation in place of other materials that could enter into combination. If bromid salt ingestion passes a certain point, distressing insomnia may result, probably from the anemia exceeding what ordinarily occurs in sleep. Chloral, also, in large doses may utterly fail to do anything but cause distressing wakefulness and gastric irritability, especially in senile debility associated with heart disease. The significance of this being that waste is but increased by the chloral. Alcoholics in such instances act promptly and beneficially for easily understood reasons.

Ergot has an indirect hypnotic effect through its contraction of the blood vessels, upon the muscles of which it acts directly. Winckler's discovery of a coloring matter in secale closely resembling hematin might mean that oxygenation of the involuntary muscles is accomplished by ergot, and the contractility is thereby induced.

Though, strictly speaking, phenacetin and phenocoll can not be classed as hypnotics, their effects as sedatives and certain chemic considerations make them specially interesting as neurotics.

The antipyretic effects of acetanilid and phenacetin when combined with acids are destroyed; the earliest discovery of the kind being that of Ehrlich, that the acid sulphone group abolished the affinities of certain substances which they previously possessed for the nervous system. The existence of so many alkaloids having this affinity, taken in that connection, afford hints that some of the combining efficacy of neurotics depend upon the union of a base and radical in the nerve tissues, notwithstanding the fact that these alkaloids may be introduced into the system combined with sulphuric or other acids; such acidulation being looser than in the coal tar series.

An ingenious introduction of the basic glycocoll into the group whence phenacetin is derived rendered it much more soluble, and to this extent increased its ease of administration without altering the antipyretic and analgesic properties of phenacetin when thus converted into phenocoll.

Unlike the majority of synthetical antipyretics, phenocoll, according to Kober of Dorpat, is not poisonous to animals and does not affect the blood. It has a slight stimulant effect upon the circulatory system. Phenacetin is closely allied chemically to acetanilid

and physiologically both phenacetin and phenocoll act as a modified acetanilid or antipyrin. What particular change in the construction accounts for this modification only great advances in bio-chemic knowledge will reveal, but it can be conjectured that differences in the closeness with which nitrogen, as well as other atoms are held in a compound, may unlock a molecule quicker or retard its entering into new combinations.

Considering the derivation of paraldehyde, its somnifacient influence might be regarded as similar to that caused by alcohol. The ordinary ethyl or acetic aldehyde being alcohol, minus two atoms of hydrogen, and paraldehyde is formed by the condensation of three molecules of aldehyde into one molecule. It is so easily split up, so sensitive to oxidizing agents, and so much care is required in securing a pure article, that with safer and better hypnotics in the field paraldehyde is not likely to come into general favor. Not only has the pungent aldehyde been found in it as an admixture but the poisonous amyloaldehyde also.

Urethane and its derivative, somnal, have been pretty well abandoned by physicians. "Antikamnia" owes its present popularity to advertising, and being but a mixture of acetanilid, bicarbonate of soda and caffeine, according to Helbing (*Modern Materia Medica*, p. 3), it needs no further mention.

Were it not for chloralamid, which is rapidly superseding all modern synthetically constructed hypnotics, sulphonal would have remained in high esteem. In treating the insane, sulphonal has the advantage of solubility in hot tea or coffee and can therefore be given without the patient's knowledge. The common practice of administering the dry sulphonal leads to undesired effects, such as a prolonged but unsatisfactory drowsiness or stupidity usually the day after it is taken. The action of sulphonal has apparent reference to its alcoholic derivation through mercaptan. The derivatives, trional and tetronal, possess few if any advantages over the original drug, while it is claimed that the latter sometimes caused vomiting.

The substitution of chloral for opium created an epoch in therapeutics, notwithstanding the fact that chloral was found to have very disagreeable after effects and some dangers in its use. The advent of sulphonal enabled chloral to be largely superseded, but finally the discovery of chloralamid affords us all the advantages of chloral in the absence of its disadvantages.

The poisonous dose of chloral hydrate is not established; small doses have caused death and large doses have been tolerated. Idiosyncrasies cause wide variance in effects.

Chloralamid requires a slightly larger dose than chloral, but the former causes what resembles ordinary physiologic sleep to a far greater degree than is induced by chloral. In other respects the drugs are closely allied, except that the deleterious properties of chloral appear to be absent from the newer compound. Particularly the gastric irritation induced by chloral frequently destroys its usefulness, and chloralamid has no such influence upon the stomach, nor is it an irritant to any mucous membrane.

Some laboratory experiments of Kny of Strassburg, demonstrated that chloralamid was free from action upon the heart and digestive tract, nor did it cause congestion and the other unpleasant after effects of chloral, though he inferred that the latter

was slowly released in the circulation from chloralamid, and its depressant effects were counteracted by the formamid which acted as a stimulant.

Thirty years ago, formiate of ammonium was used by Ramskill in the London Hospital for the Epileptic and Paralytic. He considered it useful in chronic paralytic diseases with general torpor, and he thought that it had a special tendency to the nervous centers. Formic acid is a circulatory stimulant, but too energetic to be useful except when chemically combined. It is one of the fatty acid series and has been found to exist in small quantities in the spleen, pancreas, thymus, muscle and brain, and in leucocythemia in the blood, urine, sweat and marrow.

An important group of animal constituents, called the amido-acids, is derived from the fatty acids by replacing one or more hydrogen atoms by the radicle amidogen NH₂. This includes leucin, tyrosin, glycocin, taurin, creatin.

As the amines, amides and amido-acids are nitrogenous organic compounds among the simpler organic proximate principles, it is a safe assertion to make that the union of the formamid with the chloral in chloralamid justifies the classing of this new preparation among the *nutrient hypnotics*; that is, among those like alcohol, which, when properly administered, supplies material that has been exhausted in the nervous centers, notwithstanding the superficial objection that some of these organic compounds are decomposition products.

Reasonably, much of the toxic influence of chloroform may be ascribed to the solvent power of that anesthetic over sulphur, phosphorus and fatty bodies, as these substances are important ingredients of nerve tissue. Now if this toxic effect is obtunded or prevented by the union of chloral with formamid through the former expending this deleterious solvent propensity upon the latter, and the formamid being so closely allied to the normal nitrogenous proximate principles as to act practically like a food, which we can all the readier assume from its slight stimulant effect upon the circulation, the combined nutrient and toxic effect of chloral in that drug and chloroform is replaced by an *almost wholly nutrient hypnotic in the compounding of chloralamid*.

Glycocoll (also known as glycocin, and amido-acetic acid) is the base which united with the phenetidine group forms phenocoll and renders it soluble. This base being an amido-acid, on the principle enunciated above, phenocoll should be a safer and more effective antipyretic and sedative than phenacetin.

The published attestations of physicians as to the usefulness of chloralamid are so numerous, but at the same time so uniform, that brief mention of most of the references would swell this article unduly.

There has been a notable absence of any disposition to decry the drug in any quarter worth attention. In the use of every hypnotic, as well as any other therapeutic agent, bungling administration occurs but this should not discredit rational exhibition. We may as well inveigh against water, because it drowns.

Briscoe of Chicago, accounts for a few failures through some practitioners using hot liquids as a vehicle, when chloralamid should never be offered in any other than cold solution.

In my experience, the elixir has a delayed action as compared to the powder dissolved just before use, an effect for which I have not tried to account.

The facts that chloralamid is about one-half as expensive as sulphonal, and superior to it, one would imagine were inducements for hospitals to purchase it in preference to the older and costlier hypnotic, but in certain quarters the error prevails that chloralamid is only soluble in alcohol. This arises from the fact that in twenty parts of water, chloralamid dissolves very slowly at ordinary temperatures, between 60 and 70 degrees F. Where, for any reason, it is not desirable or convenient to use the small amount of alcohol, about a minim and a half to the grain, in preparing it for use, the aqueous solution can be prepared beforehand, half a day, or kept in the dispensary stock in that form.

Brandy or raspberry syrup are the most used vehicles; a drop or two of dilute hydrochloric acid to the ordinary dose facilitating solution.

It is to be hoped that the mistake so often made in giving sulphonal dry, will not be made in chloralamid administration, as its action may be delayed until the next day and cause a stupid half wakefulness not at all desirable.

Dr. Joseph Collins contributed to the July, 1892, *Journal of Nervous and Mental Diseases*, an excellent review of his experience with chloralamid in insomnia associated with various troubles, such as phthisis, pneumonia, neurasthenia, alcoholic delirium, senility, chorea, sciatica, lithemic headache, overwork, opium habituation, meningitis, and reports that he was particularly struck with its efficacy in two conditions, viz.: pain and excessive irritable activity of the brain.

An important feature he notes, in the treatment of certain cases, is to beware of giving drugs which will in any way militate against the excretion of deleterious matters from the system and lower the condition of vascularity, such as the preparations of opium and the bromids.

"In conditions where chloral is indicated," states Dr. Collins, "but some intervening symptoms contraindicate its use, such as weak heart and respiration, as in the asthenic stage of acute disease, or in diseases of the heart and lungs, chloralamid can be substituted with safety and with good results."

He sums up in favor of its safety and reliability, its absence of after effects such as headaches and its value as a hypnotic where pain or cerebral activity are prominent factors.

Taking other authors at random, we find that as to the time of action, personal idiosyncrasy determines differences, but to no greater degree than was observed with chloral, the average limit being from one-half to three hours intervening between the dose and its effect, the duration of sleep varying from two to nine hours.

In many forms of mental disease, chloralamid acted beneficially in relieving insomnia; regular sleep was induced in chronic alcoholics and in patients suffering from locomotor ataxia, even when they had been taking large doses of morphin. Other ailments in which sleeplessness occurred were alleviated to the extent of sleep procured by chloralamid as follows: Cardiac asthma, chorea, neuralgia, rectal carcinoma, hysteria, spinal disease, delirium of cerebral hemorrhage, rheumatic fever, thoracic aneurism, gastric carcinoma, hepatic carcinoma, bronchitis, cephalalgia, chlorosis with mitral insufficiency, endocarditis and renal colic.

It has been effectively used as a sedative in sea-

sickness, neuralgias and the sufferings of gastric ulcer.

The United States Dispensary designated chloral as the most efficient soporific and the one most often used, and claimed that for producing sleep no medicine equaled it except opium, and to this it was preferable as wanting the properties which render opium inapplicable in certain cases, as in active congestion and acute inflammation of the brain and to a certain degree in constipation of the bowels.

In the rapidly accumulating literature of the subject, we begin to note that where chloralamid appeared to be ineffective in a certain disorder, in the experience of one author, other physicians obtained good results from its administration in the same ailment. In short, the history of chloral discussion is repeating itself in some of the contradictory experiences, but with the advantage for the later drug, that, wherever chloral has been established as of use, chloralamid proves not only more satisfactory, but where through deleterious properties contraindications for chloral using forbid its use in a large list of diseases, chloralamid has been proven to be perfectly safe. No hypnotic has won so universal favor in as short a period and without the arraignment against it of occasional unfortunate episodes.

The largest dose on record used at one time is reported by Dr. Lackersteen, *Medical News*, Nov. 25, 1893. A patient swallowed a mixture containing 140 grains of chloralamid with about 40 grains of bromids and fully recovered from the stupor which followed.

Personally, I have found it useful in facial neuralgia in small doses, and often sleep was induced by from fifteen to thirty grains when pain had previously prevented rest, showing that chloralamid has sedative or analgesic effects.

The restlessness of anemic states has been allayed by small doses, and in a few cases I have substituted chloralamid for the bromids in treating epilepsy with apparent benefit, alternating the drugs or using them conjointly so as to diminish the dose of each. It would require at least a year's experimentation in this disease with chloralamid to enable a more conclusive statement than that it has been satisfactory as far as used by me; but I have not excluded other medicines at these times except for such short periods in treating epileptics that not only will a lengthened period be required to determine how far chloralamid is useful in this ailment, but I would prefer to hear from numerous other physicians who may make similar trials before pronouncing unqualifiedly in favor of its continued use in epilepsy.

Against the distressing activity of hemichorea in adults, which destroys rest and prevents sleep for so long as to imperil life, I hope much from chloralamid as I had previously found that chloral was absolutely the only remedy that would afford the required sleep for a few hours at a time; had chloralamid been then known it could have been continuously used where the chloral had to be withdrawn owing to the stomach irritability it induced, substituting a source of danger equally grave. Dr. Barrs of Leeds, reports good effects from chloralamid in ordinary chorea. Some reports from psychiatric institutes venture statements to the effect that chloralamid is good in one psychosis and not in another. Now the trials have been far too few to enable such assertions to be extended generally.

There is a strong probability that a large percentage of all cases of insomnia in the insane can be relieved by judicious chloralamid exhibition, particularly if attention is paid to accompanying conditions and general physiologic treatment is adopted at the same time. To merely impute the sleeplessness to brain disorder and give a hypnotic without reference to the condition of the heart, liver, kidneys, or emunctories generally, would be extremely irrational, and would fully account for failures in some instances. At times I have found that the insane patient would be affected differently by the same dose from no discoverable cause, but where proper attention has been paid to the general bodily condition, as a rule, good results were secured with chloralamid.

In delirium tremens, it is only common sense to see that elimination is carried on properly, and often eliminants alone will end the furor of alcoholism.

In some of the congestive attacks of parietic dementia, ergot if anything, would prove more useful, but parietics will secure sleep from chloralamid ordinarily, as well as other patients.

I have found it useful in the sleeplessness and painful cerebral states of melancholia, and particularly so in the case of one recurrent melancholiac whose relapses were cut short by the prompt action of the drug.

In cerebral and spinal syphilis, pain is assuaged markedly by chloralamid, but of course it should not be given where there is a stuporous tendency, nor with expectation of anything but amelioration.

In the traumatic neuroses it is particularly valuable. Several cases of Erichsen's disease from concussion of the spine were enabled to secure sleep from chloralamid when ergot, massage and hot water applications which had previously been helpful had failed.

If the small doses of chloralamid, when substituted for bromid of potassium, are found to be generally applicable, I do not believe that ill effects can follow from the abuse of the chloralamid in this way, at all comparable to what has been experienced in the wretched overdosing of the bromids. At least the anemia and mental hebetude produced by bromids will be escaped from by the substitution. And how far these small doses of chloralamid can be properly used remains to be ascertained, but my experience has been satisfactory enough to lead me to continue their use in many of the nervous affections where irritability or pain are prominent.

There is such a thing as the chloral habit, which is much more readily stopped than the opium addiction, but whether it is too early to assert that there is or is not a chloralamid habit, certainly nothing denoting any liability to habituation has been prominently mentioned, though so far as that is concerned any drug that proves serviceable in continued suffering may be used too long, and the only question of concern is what undesirable consequences may come from such prolonged use. If chloralamid is a reconstituent hypnotic there can be no such bad effects following its over-indulgence as are recorded against opium and chloral.

It would be folly to expect that any single remedy for insomnia would be available in all instances, for just as sleepless states may be caused by any of the multitude of maladies to which the body is liable, so must there be numerous appropriate measures of relief,

when relief is at all possible. The advice to seek and remove the cause of the sleeplessness is sensible enough, though in too many instances the cause is only conjecturable. Nevertheless, a rational system of hypnotic use can be secured on a physiologic basis, and with far more satisfactory results if we duly regard the cause of the loss of sleep and existing bodily conditions. For example, a dose of ergot in some hyperemic states may relieve pain or cause sleep by lessening the vascular tension upon which these disabilities depended. A hot bath may distribute the circulation and act derivatively upon organs which, when congested, caused the distress and wakefulness. Massage acts similarly when scientifically applied, and when unskilfully made use of may add to the discomfort; for example, if derivation from the head is set up by massage it will relieve cerebral hyperemia, but add to cerebral anemia, so this method must be resorted to with full knowledge of the physiologic results aimed at.

In a general way, we may classify hypnotic action as accomplished by derivation, such as by removing irritative quantitative causes; by elimination of quantitative or qualitative causes, as of some toxic agent; reconstructive action by resupplying parts in states of defective nutrition; sometimes by minimizing activity until rehabilitation can overtake waste with supply; by restoring normal function as with digitalis or alcoholics. The least desirable of all methods being such as merely stupefy and overload the circulation with effete or poisonous material through interfering with elimination, or by destructive changes induced in nerve tissues or the blood upon which the nerves depend for sustenance.

So eliminative functions should be kept in good repair, if possible, when almost any kind of a hypnotic is given, particularly such as are likely to add some toxic material to the system; but the ideal sleep procurer would be one that abstracted nothing from the nervous system that it contained normally, nor added thereto anything deleterious; and as sleep is a process of repair or feeding of the nerves and their ganglionic centers, still more effective would be whatever caused sleep by repair of such waste; and unless credible evidence to the contrary appears in the course of time, we are in possession of such a hypnotic in chloralamid.

"CAN TYPHOID FEVER BE ABORTED?"

A FEW ADDITIONAL CASES, THEIR PROGNOSIS AND TREATMENT.

Read before the Mahoning County Medical Society, Feb. 12, 1894.

BY JOHN ELIOT WOODBRIDGE, M.D.

YOUNGSTOWN, OHIO.

[Continued from page 187, Feb. 10, 1894.]

In my last paper, published in the current issue of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, I concluded the history of my cases with No. 41, John Holland, and with a promise to report the case of his brother, Ralph Holland, together with six or eight other cases under treatment. Some of these cases recovered without having developed pathognomonic symptoms of typhoid fever, and consequently can not be reported as such.

Case 41—is especially interesting. I was not aware until several weeks after his recovery, that his attending physician, a personal friend of mine, after having made a diagnosis of typhoid fever, had been discharged and myself sent

for, although I *did* think the family unusually inquisitive; and answering questions I gave a diagnosis of typhoid fever and a prognosis of ten or twelve days sickness—no danger. On the seventh day of treatment when the rose spots were abundant and other symptoms well marked I asked Dr. Thomas, one of the best diagnosticians in our Society, to examine him and make a diagnosis; he did so and said: "Doctor, that is typhoid fever, and I will sustain you in that diagnosis at any and all times;" and added: "My experience with cases of this character is that recovery is slow and tedious." I said: "Well, I shall ask you to come here in two or three days to see a case of *aborted* typhoid fever." I said further: "Doctor, would you dare to give this man solid food?" "If he were my case I certainly should not," he said. Turning to the man I warned him of the opinions held by the best thinkers of the profession, and then asked him if he would be willing to eat a piece of beefsteak. He said: "Yes, if I told him to." He ate the steak without ill effects and on the ninth day I asked Dr. Thomas to re-examine him when his temperature was 97. He was discharged cured on September 28. His brother, Case 47, residing with him, was taken sick September 29. Pulse 100; temperature 103. Tongue, severe headache and other symptoms characteristic; later, petechia abundant; dulness over spleen well marked. After treating him five days I wished to be away at the meeting of the Mississippi Valley Medical Association and the World's Fair, and asked Dr. McCurdy, a member of our Society, to take charge of him together with Cases 43 and 44 which he did continuing my treatment, so that in all these cases I had the advantage of his valued confirmation of my diagnosis. Temperature normal twelfth day.

Cases Nos. 43 and 44. Diagnosis, typhoid fever. Names, F. G. and Mrs. F. F. Date of admission, Sept. 27, 1893.

Case 45—was diagnosed by the attending physician, confirmed by counsel called from a neighboring town and after ten days I was sent for with the statement that little hope was entertained of his recovery. In five days his temperature was normal and recovery was rapid and complete. Oct. 31, 1893, Dr. J. J. Thomas who had seen the result of my treatment in two or three cases, telephoned me that he had a typical case of typhoid fever to which he would like to have my treatment applied. Examining the case, No. 49, I expressed the opinion that this was one of more than ten days' duration, that there was but a limited area involved, and that it was bordering closely on the stage of ulceration. He recovered in eighteen days.

Case 50—presented well-marked and characteristic symptoms. (Recovery followed by alopecia.)

Cases 40, 46 and 48—are excluded from the estimate, because they recovered before a positive diagnosis was possible, as is also Case 42, because there was unquestionably ulceration of Peyer's glands before I was called.

Case 51—In the evening of Jan. 22, 1894, I was called to see Angus McFee. Examining him I said: "This man has had typhoid fever more than two weeks." They said: "Yes, he had a chill two weeks ago last night." The next morning I took Dr. McCurdy with me. We failed to get his morning temperature, which the night before had been 105½. He was voiding both urine and feces involuntarily, teeth, gums and lips covered with sordes which his faithful nurse, his wife, was unable to keep cleared away. His bowels were intensely tympanitic; in short, all symptoms characteristic.

I hand you his chart to show the result of treatment during the first few days, which since has been far from satisfactory and the end is not yet. On returning from my first visit to McFee on January 22, I found a gentleman waiting to have me go to 221 Belmont Avenue to see Willis Hume supposed to have typhoid fever. He had been with his mother who was nursing her brother through a five weeks attack of the disease. His symptoms were well marked. Dr. Barnes examined him and confirmed my diagnosis. I hand you his chart, No. 52. Shortly afterward his brother, Guy Hume, was taken sick with symptoms of the disease. Pulse 112, temperature 104, but recovered before a positive diagnosis could be made.

On February 6 I was called to 940 Shely Street to see Thomas Murdock, living within a few rods of McFee, his helper in the mill, and his friend and nurse during his present sickness. His symptoms were characteristic and indicated the beginning of a very severe attack of typhoid fever. His chart, No. 55, shows the result of treatment to the present time. After visiting him two or three times I told him he had typhoid fever, would be able to sit up and eat solid food in a few days. That there was no danger of his being as sick as his friend, or of dying. Dr. Robert D. Gibson, our last President, visited this case and confirmed the diagnosis.

Case 43—Frank Vogelbarger was a rather severe case of typhoid fever. I had attended his brother through an attack of the same disease some time before, from which he made a most satisfactory recovery. However, I did not keep a special record of his case.

Case No. 47. Diagnosis, typhoid fever. Name, R. H. Date of admission, September 29.

With the exception of one patient who was dying when I was called, in consultation with the attending physician, and one other who had been sick thirty-five days, and recovered, and a few doubtful cases who recovered before a positive diagnosis was possible, these are *all* the cases of typhoid fever I have seen since my last paper was written. They round out more than twelve years of active work without a death in my private practice from this disease, while my brother practitioners are having no better average results than in former years, when *my* death rate was so high. Accept them for what they are worth, as additional evidence that my claim that typhoid fever can be aborted, and that the life of every uncomplicated case of typhoid fever can be saved is a valid one. That this claim will be hotly contested, no one familiar with the most recent literature on the subject can doubt.

What a contrast when compared with my personal experience during the first sixteen years of my practice, which amply justifies the editorial quoted in my last paper, when my death rate was enormous, and the average duration of illness of those who recov-

ered, as accurately as I can estimate it, was more than thirty-four days. As these estimates are made from memory aided by very insufficient data, the accidental omission of some of the milder cases may make both death rate and duration of disease too high. But giving myself the benefit of every doubt, and excluding the large percentage of those who died, the estimates show that those who recovered did so after more than a month of sickness that must have left their constitutions fearfully shattered. They

me, and during the following seven years to the beginning of 1882, when I had my last death from typhoid fever, my results were manifestly better, not alone in a greatly reduced death rate, but also in a great shortening of the average duration of sickness. In 1880, believing myself in possession of valuable knowledge on the treatment of typhoid fever, which ought to be given to my brother practitioners, I availed myself of the opportunity offered by a paper on the subject read in this Society by one of

Case No. 49. Diagnosis, typhoid fever. Name, W. S.

recovered, too, probably more in defiance than as a result of treatment; a sad commentary on sixteen years of careful and conscientious work according to the best light obtainable from any text-book within my reach at that, or at the present time, as far as internal medication is concerned.

Do not understand me to state that the result of treatment during all of those sixteen years was equally bad. In 1876 a new light began to dawn on

Case No. 50. Name, B. C. W. W.

its ablest members; after criticising the paper in most unmeasured terms, I gave my own theories, and was much chagrined to find myself standing entirely alone in the advocacy of a method of treatment which, though crude indeed, had yielded to me most excellent results as compared with my earlier experiences.

Years passed, and in 1891 another paper on the same subject was read in this Society, advising a

Case No. 52. Diagnosis, typhoid fever. Name, W. H. Date of admission, Jan. 22, 1894.

course of treatment only a little worse than the one I had so mercilessly criticised eleven years before. In criticising this last paper, after showing why its recommendations were not only unwise but absolutely dangerous, and driving its author to the refuge of the high authorities he had copied, and to the further statement that he had advised the remedies I had condemned as dangerous in *small* doses only; I said that I had long believed typhoid fever to be due to a germ having its earliest habitat in man in the ali-

mentary canal, and that when a germicide powerful enough to destroy the germ without detriment to the patient, could be brought in contact with it, that the problem of the abortive treatment of typhoid fever would have been solved, and that I believed the means of doing this were already at our disposal.

The questions now are, what are they, and how are they to be brought in contact with the germ they are intended to destroy, and what other object, if any, are we to seek to accomplish that we may most speedily restore our patients to their normal condition of health.

I must confess myself at a loss how to approach this part of my subject; admitting that the germ enters the system most frequently with the water and food taken into the stomach, finds lodgment there and multiplying, finds its way into the small intestines and further. I conceive that he will treat typhoid fever best who best measures the condition of his patient, or rather the extent of territory over which the germs have spread and the amount of mischief already done, and having done this, to select and apply his remedies in such manner as to most speedily stop their

Case No. 54. Diagnosis, typhoid fever. Name, D. N.

ravages and most effectually relieve the patient of the ptomaines, tox albumens, injuries to Peyer's glands or other ill effects of their temporary sojourn. This is a much too difficult task, I fear, for me to undertake to-night. Some time in the future I hope to give expression to my views on these points, but at present I think I can do no better than give the treatment of two or three typical cases, in connection with their bedside histories.

Case 51.—A. McF., (whose chart you have), as stated before, had been sick sixteen days when I was first called; his temperature was 105½; his bowels intensely tympanitic; he was voiding both urine and feces involuntarily. During the first two days he took about 60 minims eucalyptol, 15 minims guaiacol, 30 minims turpentine, and perpsaps 15 grains of the following mixture:

- No. 1.
- R Podophyllin, gr. i.
 - Hydrarg. chlor. mitis. ʒi.
 - Guaiacol carb. ʒ vi.
 - Thymol ʒ v.
 - Menthol ʒ i.
 - Sacch. alb. ʒ ii.
 - Eucalyptol, (as much as possible).

M. In very minute doses every half hour to one hour.

During the following three days, he took 2½ minims guaiacol and 5 minims eucalyptol every three or four hours all of the time, and part of the time double that quantity with an occasional 10 drop dose of turpentine added; and in addition small doses of quinin continuously every three hours; occasionally a 2½ grain tablet of Dover's powder. Nearly every day during his sickness, and sometimes twice a day, he had rubbed on his abdomen a mixture of eucalyptol and guaiacol, with the addition, sometimes, of turpentine. His kidneys failing to respond to the turpentine, there was given him a diuretic as follows:

- No. 2.
- R Potass acet. ʒi.
 - Spir. nitri. dulc. ʒss.
 - Aquæ dest. q. s. ad. ʒiv.

Sig. One teaspoonful every half hour in water or lemonade.

And when the bowels became constipated "glycerin suppositories" were used. Whisky, milk, eggnog and Fairchild Brothers and Foster's panopepton were given freely. This is the first and only case in which I have ordered thorough and systematic sponging, in my own practice, during the past twelve years; and I did so in this case only because he came under my care on the sixteenth day of his sickness.

Case 52.—W. H. took R No. 1 two days in about ¼ grain doses every thirty minutes.

For two days:

- No. 3.
- R Eucalyptol. ʒss.
 - Spir. rect. ʒi.
 - Guaiacol ʒii.
 - Aquæ dest. q. s. ad. ʒiv.

Sig. One-half teaspoonful every three or four hours.

For one day, No. 1; No. 3, two days; No. 1, one day; then No. 3 until the temperature had been subnormal two days.

Case No. 55. Diagnosis, typhoid fever. Name, T. M. Date of admission, Feb. 6, 1894. Diet: Ate beefsteak on eighth day, beefsteak and blanc mange on ninth day, and whatever food he desired thereafter.

Case 55—T. M. took No. 1 two days; eucalyptol and guaiacol, two days; No. 1, one day; eucalyptol and guaiacol in one mixture, and thymol in another, to the present time. (Feb. 12, 1894.)

This was practically the course pursued with the cases reported. I should have much preferred giving exact rules for a general course of treatment, applicable to every case, but do not feel competent to do so; nor do I know how much medicine has been given in any case because I never wrote a prescription for any of these preparations, but have always carried them with me and I poured out a sufficient quantity to last a day or two and when exhausted replenished it from my case. Since I see my dilemma, however, I shall leave a definite quantity and in a future paper

write more concisely; and yet I fear it will ever be a difficult thing to lay down fixed rules by which to treat such a disease as typhoid fever, in which the symptoms of the disease constitute a very imperfect criterion by which to measure either its duration or gravity, and almost none for treatment. While my cases may have been too few to establish the value of my theory of treatment, they have been too many and the results have been too good to admit of longer silence on my part.

Thus far in my private practice I have had no death from typhoid fever for twelve years. I have been able to abort two or three cases when first seen on the tenth day, and *all* who came under my care on or before the eighth day of sickness. It may not be possible to abort every case, beginning on the eighth day, nor is it necessary, for when the profession and the people understand that typhoid fever can invariably be cured when proper treatment is instituted at a sufficiently early period, the physician will no longer wait until his patient is covered with petechia, or has had one or more hemorrhages before making a diagnosis or beginning treatment.

In conclusion, I beg the gentlemen to understand that in criticising these papers by Youngstown physicians I wish to cast no slur upon my brother members of this Society. Their work was neither better nor worse than the teachings of the most learned members of the profession. I believe that the members of this Society are the peers of an equal number of the members of the profession in any spot on the globe. And when I invite criticism of my claims here, I feel that I am standing before a tribunal that would quickly find errors, if there were errors to be found.

OPERATION FOR THE RELIEF OF VALVE-FORMATION AND STRICTURE OF THE URETER IN HYDRO- OR PYONEPHROSIS.

BY CHRISTIAN FENGER, M.D.

PROFESSOR OF CLINICAL SURGERY, NORTHWESTERN UNIVERSITY MEDICAL SCHOOL AND CHICAGO POLICLINIC, CHICAGO.

In all cases of pyonephrosis we may expect to find some obstruction to the flow of urine either in the renal pelvis, the ureter, the bladder or the urethra. If the obstruction is external to the ureteral opening in the bladder, the pyonephrosis is double; if on one side, the obstruction must be in the ureter or the pelvis of the kidney.

Lumbar nephrotomy for pyonephrosis has a mortality of 23.3 per cent., and primary lumbar nephrectomy a mortality of 34 per cent. (Tuffier.)¹ Secondary nephrectomy must be made to close the fistula after some time has passed, but this should not be delayed until amyloid nephritis of the other kidney has set in. The mortality from this operation is low, 5.9 per cent. If we add the 5.9 per cent. mortality from secondary nephrectomy to the 23.3 per cent. mortality from primary nephrotomy, the total of 29.2 per cent. is still 7.8 per cent. less than the mortality from primary abdominal nephrectomy,

which is 37 per cent. and 4.8 per cent. less than the mortality from primary lumbar nephrectomy, which is 34 per cent. Consequently, in pyonephrosis, nephrotomy is the operation of choice. (Tuffier.)

The disadvantage of nephrotomy as compared with nephrectomy for pyonephrosis is that a fistula remains in 45 per cent. of the cases. This means that after a time a secondary nephrectomy must be made. Fistulas remained in 34 per cent. of the cases of calculous pyelitis and in 54 per cent. of the cases of non-calculous pyelitis. The smaller number of fistulas in calculous pyelitis is to be accounted for by the fact that in a certain number of these cases, the stone prevents the passage of urine, and with the removal of the stone, the obstruction is removed. Where there is no stone, simple nephrotomy will leave the impediment in all cases. If in both calculous and non-calculous pyonephrosis we can reestablish the permeability of the ureter, we may expect to materially diminish the percentage of permanent fistulas.

Tuffier, in the discussion of pyonephrosis, in his excellent monograph on surgery of the urinary organs remarks: "It would be interesting to know the condition of the ureter, the strictures, bands, valve-formations that transform an open pyelonephritis into a temporarily closed hydro- or pyonephrosis. As yet these investigations for the intermittent pyonephrosis have not been made."

VALVE FORMATION AND BENDING AT THE PELVIC ORIFICE OF THE URETER.

Valve formation and oblique insertion of the ureter was first noticed in a case reported by Glass² and cited by Rayer.³ A girl was born with right hydronephrosis and died at age of 23. At autopsy three gallons of liquid was found in the sac. On interior surface of sac the orifice of the ureter was seen as large as a goose quill. The ureter passed obliquely for twelve inches between the membranes of the sac, and was patent the entire distance to the bladder. On account of the non-obstruction of ureter, Rayer considers this the most remarkable case on record.

Rayer observed a case of double hydronephrosis in which the ureters were also patent, which he attributes to congenital malformation. The patient was a boy of 17, who had been sickly all his life, and had had pain for seven years in the region of the left kidney. A tumor was found and the diagnosis made of left hydronephrosis. He died from septic infection of the sacs. At autopsy, left ureter was found patent, the upper portion situated in wall of sac with an opening almost similar to a valve in a vein. Water passed easily from below upward, but not down from the sac into the ureter. There was a smaller hydronephrosis in the right kidney. The right ureter was dilated to the size of a lead pencil from the bladder up to the sac. At the upper end it was retracted and when water was injected from below, it entered the sac through an opening the size of the lachrymal punctum.

Virchow⁴ in discussing hydronephrosis remarks: "The cases are extraordinary in which hydronephrosis exists with the ureter patent. I have examined such cases several times, and have found in each case a valvular obstruction caused by folding of the wall, due to oblique origin of the ureter from the renal pelvis."

¹ A word of caution about gualacol and eucalyptol. Many of the specimens of both, obtained from highly reputable houses are wholly unfit for administration. In my earlier experience I had some very unpleasant results, especially from eucalyptol, much of which is inert and some absolutely poisonous. I have a dozen or more samples in my office now, all obtained from the best sources, and yet one-tenth of an ordinary dose of some of these would act as a most violent emetic. I believe gualacol carb. to be the best of its class.

Simon⁵ gives a full and comprehensive description of this condition. The ureter does not enter the pelvis of the kidney at its lowest point, with a funnel-shaped opening, but enters it at the side, at an acute angle, and often even runs for a variable distance in the wall of the pelvis. In two similar observed cases, the ureter ran, not in the wall proper, but between the wall and the peritoneal covering for seven to ten centimeters. In contra-distinction to the previous authors, who thought that valve formation was the cause of the hydronephrosis and therefore congenital, Simon believes that the hydronephrosis in its beginning causes the valve-formation and consequently that valve-formation is not a congenital affection. He has examined a specimen in which a stone was found in the ureter five centimeters from the pelvic orifice, in a case of hydronephrosis the size of a child's head, and with valve-formation in the upper end of the ureter. He believes that temporary obstruction from any cause may produce sufficient asymmetrical dilatation of the pelvis to give rise to oblique insertion and valve-formation, which when it once exists, even if the primary cause of obstruction disappear, may remain as a permanent obstruction of greater or less degree to the passage of urine. He considers valve-formation in hydronephrosis very common, as he found it in eleven out of eighteen reported cases.

The mechanical aspect of valve-formation in the causation of intermittent hydronephrosis was studied by Krakauer,⁶ who made experiments designed to explain the fact that spontaneous evacuation of urine is sometimes seen in hydronephrosis due to this cause. Acting upon the proposal of Simon, Krakauer produced an imitation of the hydronephrosis due to valve formation in the following manner: He caused to be made a rubber balloon having a capacity of 150 cubic centimeters with a tube which ran for several centimeters in the wall before opening at an acute angle into the side of the balloon. When the balloon was filled to distension he observed that the first fifty cubic centimeters were evacuated readily, the second fifty cubic centimeters less, and the remainder still less readily. From this experiment Krakauer concluded that a higher pressure in the balloon, equivalent to an over-filling of the distended pelvis, is capable of overcoming a greater hindrance or impediment in the tube of exit, the ureter, than is a lower pressure. Applying this fact to the obliquely inserted ureter in the dilated renal pelvis, he concludes that partial filling of the dilated pelvis will close the valve of entrance and permit no evacuation through the ureter; further accumulation of urine and over-distension of the dilated pelvis will overcome the obstacle and the urine will be evacuated through the ureter. This fact explains the intermittent hydronephrosis observed in Case 1.

Landau⁷ states that intermittent hydronephrosis, where there is no gross pathologic impediment to the passage of urine, is not so rare as might be judged from the infrequency of reports of this condition in the literature. He has seen four cases, all women aged from 30 to 60 years. In one case, infection pyonephrosis and perinephritis took place which necessitated nephrotomy.

The etiology of this condition was given by Landau as: *a*, bending; *b*, torsion; *c*, oblique insertion of the ureter. These conditions caused stagnation of

urine in the pelvis of the kidney, dilatation of the pelvis, and then compression of the upper part of the ureter by the distended pelvis. These pathologic conditions of the ureter are in many cases caused by floating kidney. Direct traction upon the ureter has also been reported as the cause of hydronephrosis in certain cases of prolapsus of the uterus.

The amount of secreting kidney substance left is very variable; more of it is to be found in the smaller tumors, but even in large tumors secreting kidney substance may be spread out over a large surface. In one of Simon's cases he could feel the calices from the tenth rib to the crest of the ilium.

The ureter is small on account of atrophy from non-use. Its upper portion, which passes up through or in the wall of the pelvis, is stenosed from pressure of the sac. Its opening into the pelvis is a narrow crescentic slit sometimes only a line in length and often difficult to find on the specimen. (Simon.)

Spontaneous cure with *restitutio ad integrum* is impossible, because more or less kidney substance must necessarily be destroyed by the dilatation; but a condition almost identical with recovery is seen when the obstacle to the passage of urine disappears spontaneously, as for instance when a stone passes away. This is only possible, however, when no secondary valve formation has taken place. (Simon.)

TREATMENT.

Nephrectomy.—In large hydronephroses, often mistaken for ovarian tumors, nephrectomy or rather extirpation, is exceedingly difficult, as hydronephrosis is a retro-peritoneal tumor, and as in the course of the extirpation the meso-colon must be divided. At the time of Simon's report the mortality was absolute; in two cases where total extirpation was made, and in four cases in which it was tried and given up as impossible, all the patients died.

Puncture and Aspiration.—are only palliative measures, and in only one out of eleven cases collected by Simon was there even temporary improvement.

Nephrotomy.—An abdominal opening into the sac of a hydronephrosis can not be done without first procuring adhesions to the wall, either by leaving the canula in or by Recamier's cauterization. The patients died either from the operation or later from infection through the fistulas, with the exception of two out of the eight, one of whom, (Spencer Wells' case) recovered accidentally by passing of stones. In the other case (Simon's) a fistula remained. Spencer Wells' case was as follows: "A woman of 50 had had intermittent attacks of pain in the region of the right kidney for seventeen years. Having made a diagnosis of intermittent pyonephrosis and finding a large tumor with indistinct outlines, on May 19, 1865, he evacuated by puncture through the abdomen with a fine trocar, two to three pints of pus. Eight days later he reopened the wound and dilated with a laminaria tent to evacuate the accumulated fluid. One month after the first puncture, on June 20, two uric acid calculi the size and shape of a broad bean passed, followed by relief. After a few weeks the tumor disappeared and the patient was well for the fifteen remaining years of her life."

Obliteration of Sac after Nephrotomy.—The difficulty, we might almost say impossibility of curing hydronephrosis without reestablishing the passage through the ureter, is well illustrated by one of Simon's cases. A man of 22 had a hydronephrosis

of sixteen years' standing, for which five abdominal aspirations had been made in seven years. A large abdominal incision was made after double puncture to get adhesions. Unsuccessful attempts were made to obliterate the sac by cauterization of the sac wall and its kidney substance. Partial extirpation of the secreting kidney substance was abandoned on account of hemorrhage. After this, the daily secretion diminished one-fourth, but 150 cubic centimeters were still secreted. He then attempted to open up the ureter from the pelvis, without success, in the following manner: He filled the sac with milk, but none passed down into the bladder. He therefore concluded to open the pelvic ostium of the ureter, or dilate it if valve formation was present. He enlarged the abdominal wound until the opening would admit the hand and then searched all over with artificial light and probes, but in vain. A year later the patient's condition was satisfactory as to general health, but 150 to 180 cubic centimeters of fluid containing 0.7 per cent. to 1.1 per cent. of urea was passed daily.

Simon therefore came to the conclusion that it is probably impossible to obliterate the sac of a hydronephrosis as long as secreting kidney substance remains.

Re-establishment of the Passage through the Ureter—would give the best results in the treatment of hydro- and pyonephrosis, even if no *restitutio ad integrum* of the kidney is possible. (Simon.) Spencer Wells' case has proven that a condition may result in which the patient may be restored to perfect health. If it should be possible to reopen the ureter, the same good results may be expected as in Spencer Wells' case.

There are two ways in which the ureter might be opened; from the bladder or from the pelvis of the kidney.

1. Catheterization of the Ureter from the Bladder.—This is considered by Simon as the more natural and easy way in women. He succeeded in finding the ureter in fifteen out of seventeen cases. He therefore proposes in this way to empty the contents of a hydro- or pyonephrosis, but he has never put the method in practice.

The catheterization proposed by Simon, was taken up by Pawlik⁹ who constructed his ureteral sound, later improved by Howard Kelly.¹⁰ The catheterization of the ureters in women has thus been made practicable, but for the purpose of overcoming stenosis, or the cure of pyo- or hydronephrosis, little or nothing has been accomplished.

Pawlik mentions a case from Billroth's clinic, of pyonephrosis in which he introduced through the ureter from the bladder, a long elastic catheter with a metal point, which passed through a stenosis of the ureter up into a cavity above. From previous nephrotomy, the patient had an abdominal fistula, a probe passed through which would touch the metal tip of the ureteral catheter. On attempting to withdraw the catheter, the tip was caught in the stenosis and broken off. Dr. v. Hacker removed it through the abdominal fistula.

Pawlik¹¹ cited by Alberran,¹² has two reports of cases of hydronephrosis in which his method was used. In one case (observation 6) cure was accomplished after thirty successive soundings of the ureter. In the other (observation 10) the ureter was impermeable and nephrotomy had to be resorted to.

As regards leaving the catheter permanently in the ureter, Pawlik mentions a case of uretero-vaginal fistula in which a catheter was left in for seven days. Force was necessary to remove it and it was found incrustated with salts.

2. Catheterization of the Ureter from the Pelvis of the Kidney.—Simon, after his unsuccessful trial in the case above cited, states that the opening in the pelvis must be large, in order to find the ureteral opening, and still, even if access is good, we will probably be able only in exceptional cases to sound the ureter and remove the obstruction, because in large tumors there is valve formation and so small a pelvic ostium that it can not be found in the large cavity, anatomic landmarks being absent, by inspection either with natural or artificial light. It would be only in exceptional cases where the pelvic ostium is dilated or not too small that it could be found and a probe inserted. If the pelvic ostium was found, a stenosis could be dilated with bougies or knives and the valve might be operated upon by cutting the inner wall away. Simon, however, never had occasion to bring these proposals into execution.

Landau recommends not nephrectomy but rather abdominal nephrotomy, eventually followed by probing of the ureter and perhaps by high fixation of the hydronephrotic sac, nephropexy, so as to facilitate the exit of urine from the pelvis into the ureter. Landau, however, has not yet operated in this manner.

The valve formation can be remedied by a plastic operation after previous opening of the dilated pelvis following lumbar nephrotomy. It is natural to select the lumbar region for entering the pelvis because the operation is extra-peritoneal, and consequently there is no danger of infecting the peritoneal cavity, and because the lumbar incision gives the readiest access to the upper portion of the ureter. If it is possible in this manner to re-establish the flow of urine, we can save for future function what active kidney tissue may be left, the danger of primary nephrectomy is avoided, and the patient may regain perfect health without urinary fistula. That this can be accomplished satisfactorily and promptly is illustrated by the following case:

Case 1.—Synopsis: Valvular stricture or stenosis of pelvic orifice of ureter in a somewhat floating kidney; intermittent hydronephrosis for eight years; more and more frequent attacks until finally one a week; nephrotomy in interval between attacks; no stone in pelvis; pelvic orifice of ureter could not be found through opening in kidney; incision of pelvis; valvular opening of ureter seen; plastic operation on valve; bougie left in ureter for two days; pelvic wound sutured; fixation of floating kidney; recovery without fistula.

Mrs. D. H. consulted me at my office Feb. 22, 1892. She gave the following history: Age 28; family history good; previous health good; married eight years; two children living, one dead. Four months after marriage had an attack of pain in the region of the left kidney, with the formation of a tumor at the site of pain, immovable and tender on pressure. At the end of two weeks, tumor and pain suddenly disappeared. Two or three days after the birth of her first child she had a similar attack which lasted about eight days. She had intermittent attacks, every month or two from that time until 1878. The attacks varied little in intensity and persisted usually for about one week. In September, 1888, after the birth of her third child she had a severe attack of pain in the region of the kidney with frequent shooting pains along the course of the ureter and accompanied by a swelling, tender on pressure, and by difficult but painless micturition. This attack lasted for two or three weeks. Since that time she has had similar attacks every two weeks, which last on the average two days, and

are always accompanied by difficult urination. The last attack, which occurred on Feb. 8, 1892, lasted for a week. Since that time she has had no pain.

The patient began to menstruate at 10 years of age and has been regular until a year ago. Flow normal, but considerable dysmenorrhea. For the past year menstruation has been irregular, every two to four weeks, but the flow has been normal.

Present condition: The patient is somewhat emaciated, has a nervous suffering expression, not pale, abdomen easy to palpate, heart and lungs normal. Temperature 99 degrees. Urine contains pus, but neither albumen nor sugar.

On March 11, during an attack of pain, a tumor could be felt in the region of the left kidney, but five days later no tumor could be found. During and immediately after the disappearance of the tumor the urine was milky from pus. May 24 she had another attack which lasted two days. During the days of pain, urine is scanty and dark-colored.

Diagnosis: Intermittent hydronephrosis; stenosis in pelvis of kidney or ureter, probably from stone. Advised nephrotomy, removal of stone from kidney or ureter without opening into ureter if possible. If necessary to open ureter, pass bougie from opening in kidney to bladder, and suture ureter over bougie.

Fig. 1.—CASE 1.—ILLUSTRATING OPERATION FOR VALVE FORMATION.

A.—Kidney and dilated pelvis 1, kidney; 2, opening on its convex surface after nephrotomy; 3, dilated pelvis, 4, with opening on its posterior surface from pelvotomy; 5, opening of the ureter into the pelvis, a small transverse crescent-shaped slit.

B.—Dilated pelvis and ureter, showing valve-formation. 1, pelvis; 2, mucous membrane; 3, muscular and external coat; 4, ureter; 5, valve; 6, line of incision dividing valve.

C.—Valve seen from the pelvis and divided to illustrate the plastic operation. 1, Inner wall of pelvis above the ureteral opening; 2, ureteral opening; 3, the divided valve; a and a' the corners of incision to be united by a suture.

Operation: May 31, at the Emergency Hospital in the presence of the doctors from the Policlinic, and Drs. Waters, Bernauer and Krost, the patient was anesthetized with ether, and placed on the right side with a pillow under the loin. No tumor could be felt. An incision four inches long was made from the angle of the twelfth rib and the extensor dorsi muscle, obliquely downward and forward to the iliac crest above the anterior superior spine. It was necessary to divide the quadratus lumborum for an inch and a half below the rib, in order to gain space for operating. The transversalis fascia was now divided. The retro-peritoneal adipose tissue was scanty. Two tumors could now be felt; one close under the margin of the ribs was recognized as the spleen. Behind and below this could be felt the convex posterior border of the left kidney. During inspiration the spleen was pushed down upon the kidney, but it could be

easily replaced. Dissection of the adipose capsule from the kidney was difficult, on account of a plastic perinephritis which had made the capsule tense and adherent to the kidney. The surface of the kidney was not smooth and glistening, but velvety from connective tissue strips. By pressure over the anterior portion of the lumbar region of the abdomen, the kidney was pushed into the wound and the adipose capsule dissected off by forceps and the finger, so as to permit palpation of the kidney between the thumb and index finger. The kidney was rather small, three and one-half inches long, one and one-half inches broad and one and one-half inches thick. Neither hard or soft spots could be felt. Palpation of the pelvis was accomplished by pushing the fingers of the left hand forward toward the hilum, holding the upper half of the kidney meanwhile between the thumb and index finger of the right hand. The pelvis contained no fluid and no stone could be felt. Following down from the pelvis no ureter could be felt, nor could any hard spot or stone be discovered.

A long exploring needle was introduced through the convex surface of the kidney, at a point between the middle and lower thirds, in the direction of the pelvis for a distance of two inches. An empty cavity was entered by the needle, in which no stone could be felt. The needle was next inserted into the upper half of the kidney but neither fluid or stone could be felt.

The pelvis was now opened through the kidney by means of the Paquelin cautery along the needle as a guide, in the middle third of the kidney. The hemorrhage was slight; no fluid escaped. The opening was dilated with forceps so as to permit palpation of the pelvis and calices with the left index finger. The calices were dilated, but still the kidney substance was half an inch thick. The pelvis was a large cavity extending to the lower border of the kidney with a round, smooth, soft surface. No stone could be felt, nor was the ureteral entrance perceptible to the finger. Through a small opening, or over a ridge, the palpating finger could be passed into the upper part of the pelvis. The calices here were dilated but no stone could be felt. Examination with a steel urethral sound gave similar negative results.

In order to find, if possible, a stone in the ureter a small bent metal probe was passed into the pelvis, but the ureteral entrance could not be discovered. The dilated pelvis was now isolated and opened for ocular inspection, to determine the pelvic entrance to the ureter. The lower third of the kidney was lifted forward and drawn into the wound by means of a blunt retractor passed through the wound in the kidney, the posterior surface of the pelvis isolated from the adipose tissue and an incision three-quarters of an inch to an inch in length, made obliquely downward from about one-quarter of an inch from the hilum of the kidney. The wall of the pelvis was two millimeters thick. Neither fluid or urine escaped. The borders of the wound were grasped and held open with forceps. The inner surface of the pelvis was now seen to be normal in color and appearance. At the lower posterior portion of its inner wall was seen a small semicircular opening two lines in length from above downward, and three lines in transverse diameter. The posterior border was convex; the anterior border straight. A metal probe introduced through this opening passed easily down seven or eight inches into the bladder without encountering resistance, either from stricture or stone.

An olive pointed bougie, No. 5 French, which was passed down was tightly grasped by the ureter. By lifting up the pelvis the ureter could now be palpated. The wall was thin and seemed liable to rupture unless great care was exercised. The bougie was removed and on again lifting the pelvis and inspecting the entrance into the ureter it was seen that the ureter came off not from the most dependent portion of the dilated pelvis, but from its posterior half or wall. Thus the anterior straight border of the ureteral entrance formed a valve or fold, resembling the valve in a vein, which would close against the posterior wall of the opening when the pelvis was filled with urine or fluid to a slight or medium degree. A greater degree of dilatation would push away the posterior wall of the pelvis and thus reopen the entrance to the ureter. This accounted for the evacuation of urine containing pus after a period of occlusion of two days duration.

To do away with this valve formation, the following operation was performed on the plan of the Heinecke-Mikulicz operation for stricture of the pylorus (Fig. 1): An incision two and a half lines in length was made through the mucous membrane into the muscular wall or fold of the pelvis. The terminal points of the incision through the valve were now approximated by a fine silk suture, thereby changing the

former vertical incision into a horizontal line. The entrance into the ureter was by this means made wider and more nearly circular.

A No. 11 French bougie was now passed through the opening in the pelvis down five inches into the ureter, and the upper end brought up through the pelvis and out of the wound in the kidney, to keep the opening into the ureter dilated during healing of the wound.

The incision in the pelvis was united by ten fine silk interrupted sutures passed through the pelvic wall but not including the mucosa. A piece of the cortical substance of the kidney was removed for microscopic examination.

The kidney was now replaced and fixed in normal position by two sutures passed through it which anchored it to the transversalis fascia. The pelvis was drained by a rubber drainage tube half an inch in diameter, inserted along the side of the bougie through the wound in the kidney, into the pelvis. The drainage of the external wound was accomplished by the employment of a gauze drain on anterior surface of the kidney, one on posterior surface of kidney, one down along the ureter and a rubber drainage tube on posterior surface of pelvis, over the wound in the pelvis. The lower part of the abdominal wound was united by silk sutures; the upper half left open for drainage and the usual dressings applied. The operation required two hours; at its close the patient was in good condition; pulse strong, 90; the operation was mechanically easy on account of the lax abdominal walls due to childbearing and the leanness of the patient.

The bougie was removed on the second day. The patient suffered considerable pain for four days; the pain along the course of the ureter persisted for two weeks. Four weeks after the operation the tube was removed and a smaller one introduced which was taken out a week later. The discharge was excessive at first but gradually decreased. Two weeks after operation she could lie on the left side without pain. The patient recovered without fistula and up to the present time has had no return of the hydronephrosis.

A somewhat different method of operating on this valve has been suggested by Küster,¹³ but has not yet been tried. He reports a case in which he divided the valve longitudinally as I did. He proposed to freshen each flap and unite it by sutures to the freshened inner wall of the sac. Küster was not able to carry out this plan because he found in addition to the valve, a stricture in the ureter two centimeters below the pelvis. This condition caused him to resect the upper three centimeters of the ureter and unite the upper end of the distal portion to the pelvis by a plastic operation to which I shall refer later.

It appears to me that my method of operating upon the valve is simpler than Küster's; his requires at least two sutures, mine only one; the method, moreover, proved efficient in my case just reported.

STRICTURES IN THE UPPER PORTION OF THE URETER.

It has been seen, in the description of valve formation, that stricture often forms in the portion of the ureter located in the wall of the dilated pelvis; but this stricture is treated by the operation for valve formation—as described above. Independent strictures below the pelvis require different treatment. If such strictures are single and accessible they can be operated upon with a view to reestablishing the continuity of the canal.

Outside of observations at the postmortem table, little attention has been called to the question of strictures of the ureter, because in the cases of hydro- and pyonephrosis operated upon, the kidney has been opened or extirpated, and no attention has been paid to the ureter. From the postmortem table we know that multiple strictures can be found as a result of chronic inflammation of the canal, as in the instance depicted by Hallé¹⁴ mentioned by Tuffier, in which not less than three strictures were found, the canal between the strictures being dilated. It is

doubtful if cases of this kind would be suitable for operation.

As a result of traumatism, limited strictures have been seen to be formed, as in the cases of Pye-Smith¹⁵ and Sollier.¹⁶ Pye-Smith reports the following case of stricture of the ureter and dilatation of the kidney, apparently of traumatic origin:

PYE-SMITH'S CASE.

Aug. 16, 1871. Guy's Hospital. Male, 24; farrier. Never had stricture. Frequently been kicked in abdomen. Two years before kicked on left side "under the short ribs" and passed blood with urine several days. In bed only three days. August 7, diarrhea, swelling of abdomen, vomiting, pain in abdomen. No difficulty in passing water. Examination: Large tumor occupying left half of abdomen, smooth, deep fluctuation. Urine contained trace of albumen. Diagnosis: Probable vascular fibro-cystic growth. August 22. Tapped, and six and one-half pints of a reddish fluid, containing pus and blood corpuscles flowed out. Tumor gradually filled and was again tapped. Patient improved and went home in October. He had return of the diarrhea and died October 14. Autopsy October 17: Renal tumor firmly adherent to surroundings. Right kidney swollen, early parenchymatous nephritis. Bladder normal, ureter dilated one and one-half inches, then contracted so as not to admit smallest probe. No impacted calculus; no sign of recent inflammation. Tumor; little renal tissue remained. Organ dilated into a series of communicating cysts containing yellow puriform fluid; scarcely any blood. No trace of calculus; no cheesy material. No abnormal tissue. In one of the cavities vegetable fibers, apple core and fragment of clove were found; therefore opening must have existed during life with communication with adherent bowel. Disease probably traumatic. Ureter probably injured. During two years following, canal was gradually contracting and forming stricture. Consequently, pelvis of kidney gradually expanded. Adhesion to colon determined diarrhea and suppuration from which patient died.

Sollier's case was one of traumatic stricture of the ureter in a man of 45 who, in 1870, sustained a traumatism by a kick from a horse in the left hypochondrium. The injury was followed by pain in the left side gradually increasing for nine years, when symptoms of nephritis appeared and the patient died from uremia. At the autopsy it was found that the left kidney had been transformed into a number of cavities the size of nuts. The calices, pelvis and upper portion of ureter were dilated. In the middle portion of the ureter was found a "cicatrical stenosis." Hypertrophy of the heart was found which had already been diagnosed during the patient's life.

Little is also known as to the frequency of strictures, but it may possibly be concluded from the frequency of permanent urinary fistulas following nephrotomy that they are not of infrequent occurrence. Tuffier states that fistulas followed nephrotomy in 45 per cent. of the cases collected, and we are forced to believe that the permanency of the fistula is caused by imperviousness of the ureter either from valve-formation or from stricture. How often this is caused by a stone lodged in the canal and how often by a stricture without stone we will not know until the ureter has been investigated by probing from above in a large number of nephrotomies. From the statistics collected by Tuffier, which show that nephrotomy for calculous pyelitis was followed by 34 per cent of fistulas in 114 collected cases, and that nephrotomy for non-calculous pyelitis was followed by 57 per cent. of fistulas, we can not draw any certain conclusions as to the frequency of stricture in non-calculous pyelitis as compared with the frequency of stones in the ureter; but it is likely that strictures are common.

As to the frequency with which strictures occur in different parts of the ureter, we have a statement from Tuffier to the effect that in twenty-nine instances of congenital hydronephrosis, a stricture was found in the upper end of the ureter in fifteen cases, and at

the lower end in fourteen. In Sollier's case of traumatic stricture, it was located in the middle portion of the ureter.

The question of gaining access to different portions of the ureter in order to overcome obstruction, has been solved as far as the removal of stones is concerned, by a number of operations already on record as follows: The vesical end of the ureter has been reached from the bladder by Emmet, Richmond and others; from the vagina, by Emmet and Cabot.

The pelvic portion of the ureter has been reached by extra-peritoneal lumbar incision, and the stones removed either by pushing them up into the pelvis, and pyelotomy in four cases (Tuffier), or by longitudinal incision of the ureter, in four cases (Tuffier), and in my case published in *Chicago Medical Recorder*.

From the middle portion of the ureter, stones have been removed in four cases (Tuffier,) by longitudinal ureterotomy by the prolonged lumbar incision. There is no difficulty in gaining access to the upper two-thirds or three-fourths of the ureter by the oblique lumbar incision. It is different with the lower third or fourth of the ureter, which is located deep down in the pelvis, and is even held by La Dentu to be inaccessible. But Cabot has justly pointed out that this portion of the ureter is also accessible without opening into the peritoneum by means of the sacral operation of Kraske, with removal of part of the sacrum, or temporary resection of the latter.

As far as strictures are concerned, there have as yet been made only two attempts at operating, namely, by Küster and myself, and a successful result in both cases was reached by a somewhat different method. Both were strictures in the upper part of the ureter close to the pelvis of the kidney.

Küster resorted to resection of the narrow portion of the ureter and united the distal portion to the pelvis of the kidney. His most remarkable and interesting case was as follows:

The patient was a boy 11 years of age. As a baby and until his fifth year he was sickly, but afterwards was healthy. In June, 1889, spontaneous enlargement of the abdomen was noticed accompanied by pain. This was diagnosed as left hydronephrosis. The urine was clear and sufficient in quantity, indicating open hydronephrosis. On June 23, Professor Braun made a lumbar nephrotomy which was followed by vesical anuria and the patient left the hospital with a fistula.

On May 25, 1891, the boy was seen by Küster. The fistula was permanent and little or no urine came from the bladder. The fistula in the lumbar region was dilated and digital exploration of the pelvis made. Catheterization of the ureter from the dilated pelvis could not be effected. The operation was followed by septic pyelitis.

July 14, 1891, it was decided to attempt to make the ureter patent, which was accomplished by Küster in the following manner: A lumbar extra-peritoneal incision was first made into the sac, but the ureter could not be found. The lower end of the sac, the dilated pelvis, was then incised, on the upper border of which was seen a layer of kidney substance the thickness of a thumb. The ureter could now be seen running several centimeters in or upon the posterior wall of the sac, and terminating in a slit in the pelvis. It was then intended to divide the pelvic wall of the ureter by pushing a probe-pointed knife down into the ureter from the pelvis to a point close to its exit from the sac to spread out the divided walls and unite them to the wall of the sac, thus making a funnel-shaped opening into the ureter. (See Fig. 2); but on attempting to introduce a fine probe into the ureter, a stricture was encountered two centimeters below the pelvis. The ureter was therefore divided from above downward, as far as the stricture, through which a fine probe could now be passed.

As cure seemed impossible without removing the stricture, the ureter was transversely divided below the stricture and at the entrance to the sac. The ureter was now united to

the pelvis by dividing the upper end of the ureter, unfolding the divided end, suturing it to the opening into the sac, and closing the remainder of the wound in the pelvis by catgut sutures.

The next day some bloody urine escaped into the bladder, but ordinarily the urine passed out through the lumbar fistula. From this time more and more urine passed into the bladder, until four months after the operation as much as 100 cubic centimeters passed in the twenty-four hours. The pelvis was now washed out for pyuria with one-fourth of 1 per cent. solution of nitrate of silver; this was followed by local and general improvement.

Nov. 6, 1891, the fistula was closed by curetting, dilating and closing the canal by step sutures. In the first twenty-four hours after the operation the patient passed 1,300 cubic centimeters of bloody urine from the bladder. He recovered, but with a lumbar hernia which had to be held in place with a bandage; the fistula remained closed. The boy is able to work and has excellent health. The urine contains a few pus corpuscles and a small quantity of albumen.

Fig. 2. CASE 2. ILLUSTRATING OPERATION FOR STRICTURE OF URETER.

A.—Sacculated kidney, dilated pelvis, ureter with stricture at its upper end. 1, kidney; 2, sacs corresponding to dilated callices; 3, nephrotomy; 4, dilated pelvis; 5, opening in posterior surface of pelvis-pyelotomy wound; 6, ureter below stricture; 7, stricture in upper end of ureter; 8, opening in ureter below stricture, extending up through the stricture into the pelvis; 9, sutures closing the upper half of the wound in the pelvis; a-a' and b-b', points of incision in ureter and pelvis to be united by sutures after folding the ureter upon itself at the place of stricture.

B.—Pelvis and ureter after union by sutures. 1, pelvis; 2, ureter; 3, fold of ureter at place of stricture; 4, sutures of wound in pelvis; 5, place of sutures between points a-a' and b-b'; 6, 6, additional sutures, as many as needed, to close borders of the fold formed by approximations of a to a' and b to b'.

Plastic operation on the stricture without resection of the ureter was practiced by me in the following case:

Case 2.—Synopsis: Traumatic stricture of ureter close to entrance into pelvis of the kidney; intermittent pyoneph-

rosis of four years' standing; increased frequency of attacks; nephrotomy; no stone found in sacculated kidney; ureteral entrance could neither be found through wound in kidney nor through incised pelvis; longitudinal ureterotomy revealed stricture at upper end of ureter; longitudinal division of stricture and plastic operation on ureter; recovery without fistula in six weeks.

W. B., a farmer 47 years of age came under my care Nov. 12, 1892. Father died as a result of accident. Mother dead; cause unknown; one brother died of phthisis. Patient's health good up to age of 13. The present trouble dates back thirty-four years, when as a boy of 13, in jumping from a horse to the ground, on account of miscalculation of distance he sustained a violent jerk, his feet not having touched the ground while his hands still retained hold of the hames. This injury was immediately followed by a sharp constant pain in the left side, which was mitigated by blistering, but he was obliged to remain in bed for a month. He suffered no inconvenience with the exception of slight soreness in the region of the left kidney, increased by hard work, until ten years later when, after over-exertion, he had an attack of sharp pain in the left side; at this time he was in bed about a week. One year later he had a third attack which followed free indulgence in liquor. This attack was attended by pain, soreness and obstinate constipation. For the next ten or fifteen years he had four or five attacks a year, lasting from two to three days and always after indulgence in liquor. During the last six years the attacks have apparently been caused by over-exertion, with the exception of one attack a year ago for which no cause could be assigned. The last attack occurred Oct. 22, 1892. It was no more violent than previous attacks but was of longer duration.

Examination: Nov. 12, 1892. Patient well nourished. In left hypochondrium could be found a tumor immovable, hard and not nodular, which extended two inches below the ribs and to within three inches of the umbilicus. Temperature 101 degrees; urine contained a little pus. Diagnosis: Nephrolithiasis in the pelvis or infundibulum, or pyonephrosis from stone or obstruction in the ureter.

November 26. For the past week there has been more pus in the urine, indicating that the contents of the pyonephrosis has been evacuated through the ureter. Examination in narcosis showed that the tumor had disappeared. Operation at the German Hospital. The patient was anesthetized with ether and placed on the right side with a pillow under the loin. An incision was made from the angle of the twelfth rib six inches downward and forward, to within one inch above and anterior to the crest of the ilium. The muscles were strong. After division of the transversalis fascia and removal of a layer of adipose tissue, the adipose capsule of the kidney was exposed, which was so adherent to the surface of the kidney that when it was removed the fibrous capsule was stripped off also. The exposed surface of the kidney was not shining but was red and velvety. It was nodulated, each nodule forming a flat prominence, about two centimeters in diameter. Each prominence was compressible and resembled a dilated calyx. The kidney was of normal size, about nine centimeters long, four centimeters broad and three centimeters thick. In one place a cyst the size of a pea with clear yellowish contents was seen. After excision of a piece of the kidney substance for microscopic examination, the dilated cavity of pelvis and calices was opened, and a jet of urine tinged with pus came out over the wound. The incision along the convex border of the kidney was enlarged by the Paquelin canterly.

Digital exploration revealed that the globular protuberances were dilated calices, which communicated with the pelvis, forming a common cavity. Some of the calices had openings large enough to admit the tip of the finger; others had openings which would admit a No. 10 urethral sound. No small abscesses could be seen on the surface of the kidney or in the incised substance. The protuberances now appeared to be collapsed, but a reasonable amount of kidney substance appeared to be present, especially in the lower part. The index finger was passed through the wound in the kidney down into the pelvis which was seven centimeters long and four centimeters deep. The wall was smooth and there was no stone or gravel. Neither by the palpating finger nor by the sound or probe could anything be discovered resembling an entrance to the ureter.

The kidney was therefore lifted up over the border of the twelfth rib, so that its anterior surface was directed upward and toward the median line, and its posterior surface backward and downward, thus exposing the posterior surface of the dilated ureteral half of the pelvis. A longitudinal incision, one inch long, was made in the pelvis and the

edges held apart with retractors. The pelvic mucosa looked red and inflamed, but no ureteral entrance could be seen or felt.

The external wound was now prolonged downward for an inch and a half, to within an inch of the anterior superior spine of the ilium, to secure more operating space. The ureter could now be seen as a string or band, not dilated. Its upper end for half an inch was imbedded in cicatricial tissue. A longitudinal incision one centimeter long was made in the ureter half or three-quarters of an inch below the pelvic opening. A small metal probe introduced into the ureter through this incision passed downward freely for six inches. In passing it upward, however, a stricture was found just below the point of entrance of the ureter into the pelvis. The ureter was adherent to the surrounding adipose tissue at this point. The adhesions were separated by the handle of the scalpel and the stricture opened by a longitudinal incision on the probe as a guide. The opened stricture was seen to be one centimeter long. The remainder of the ureter was examined by a French bougie, which would pass down four or five inches, but would then be caught by the ureter. There was no stricture, but a diffuse atrophic narrowing of the ureter. A fine probe or a small bougie could, however, be passed without difficulty into the bladder.

The patency of the ureter was reestablished by uniting the wall of the ureter below the stricture to the pelvic wall, leaving the stricture as a loop as shown in Fig. 3. This procedure was similar to the Heinecke-Mikulicz operation upon the pylorus.

The upper part of the wound in the pelvis was closed by sutures. No bougie was left in the ureter. The wound was drained by a large tube passed into the wound in the kidney three inches upward to the upper corner of the kidney. A smaller drain was passed down to the pelvis and ureter. Gauze strips were packed around the anterior and posterior surfaces of the kidney, and three inches down along the ureter. The divided muscles of the abdominal wall were then united, with the exception of the lower three inches, which was packed with gauze. The external wound was united by sutures and dressed in the usual way. The operation occupied two hours. The patient was weak at its close, pulse 130; much pain along course of ureter. The next day he passed naturally water containing no blood. The wound was dressed daily, and the dressings were found to be saturated with five ounces of urine. The amount was determined by the difference in weight of the dressings on application and after removal. The patient steadily improved. The pain decreased, and the amount of urine in the dressings became progressively less. November 29 to 31 blood was found in the urine, which showed that the ureter was patent from the third day after the operation. December 19, half the tube was removed and a day later the remainder was taken out.

Jan. 5, 1893, the wound was closed. The patient was well and strong, suffered no pain and could walk around all day. No tumor could be made out. Pressure in renal region was painless. The urine at this time was normal in quantity, forty-six ounces, and upon microscopic examination of the sediment a few pus cells could be seen. No trace of albumen could be found in the urine. The patient thinks he has gained flesh and is much better than before the operation.

November 14 while the tumor was present and the temperature high, the quantity of urine for the twenty-four hours was eighteen ounces. After the disappearance of the tumor on November 17 and 18, the temperature fell to normal, and the amount of urine increased to thirty-four ounces on November 19, and to thirty-two ounces on November 20. On the evening of the day of operation the patient passed eighteen ounces of urine; on November 27, twenty-six ounces; on November 28, thirty-two ounces, and from this time on the amount of urine passed averaged thirty ounces a day.

Reunion of a transversely divided ureter first studied experimentally on dogs by Tuffier¹⁷ and others, was not successful until the method of invaginating the upper into the lower portion was devised by Poggi¹⁸ and Van Hook. It was first practiced successfully in man by Kelly who used Van Hook's method. Poggi found that by invaginating the upper end into the lower, union would take place. He divided both ureters in dogs, dilated the lower end

with a forceps, invaginated the upper end into the lower and united with sutures. When the animals were killed fifteen days and three and one-half months later, respectively, he found union without stenosis at the point of operation.

Van Hook¹⁹ in a preliminary contribution has also succeeded in reuniting the completely divided ureter by a different method which might be termed lateral implantation of the upper into the lower end after the closure of the end of the latter. In a very elaborate paper upon the surgery of the ureter²⁰ he gives the reasons why his method of lateral implantation is preferable to the simple invagination of Poggi. He believes that the ureter can sustain resection involving a considerable amount of tissue, since ureters measuring ten inches while in situ will easily measure twelve to fourteen inches when removed, and he further remarks that traction on the divided ends, is probably admissible to a very considerable extent.

Fig. 3.—MY PLAN OF OPERATING FOR URETERAL STRICTURE ON EXTRA-PERITONEAL SURFACE OF URETER.

A.—Ureter showing stricture and line of incision.
B.—Opening through the stricture extending into the proximal and distal portion of the ureter. The extreme ends of the incision a and a' to be united.
C.—Ureter after suturing; a, the bend at the site of the stricture.

The first reunion of a completely divided ureter by uretero-ureteral anastomosis, or uretero-ureterostomy in the human subject has recently been reported by Kelly.²¹ Eight years ago his attention was called to the danger of cutting a ureter during operation for an abdominal tumor which had displaced it. He now reports:

Mulatto, 25 years of age, who had a large uterine myoma the uterus filled true and false pelvis and extended above umbilicus. Hysteromyomectomy was performed May 1, 1892. Ureter ligated and cut supposing it to be an engorged vein. Ureter was four times its normal size by reason of pressure from the tumor (hydro-ureter). On removal of upper ligature twenty cubic centimeters of clear urine escaped. Van Hook's plan tried of tying lower end of divided ureter, making slit in ureter below ligature and invaginating upper into lower end by means of silk traction sutures. Edges also sutured to intussuscepted portion by ten fine silk rectangular sutures passed through outer coat only. Gauze laid over anastomosed end, and brought out at lower angle of abdominal wound to insure drainage. No urinary odor about dressings. Passed water second day. Discharged in six weeks. After Kelly's successful operation Bloodgood made an experiment upon the dog. He performed anas-

tomosis of right ureter after section. Kidney and ureter were removed two and one-half months later. The kidney was found normal, ureter not dilated, caliber and mucous membrane restored without stricture.

CONCLUSIONS.

1. Exploration of the ureter as to its permeability should be done from the renal wound by a long flexible silver probe (a uterine probe) or an elastic bougie, either olive pointed or not. If the bougie passes into the bladder, the examination is at an end. The size of bougie that will pass through a healthy ureter is from 9 to 12 French scale.

2. If the pelvic orifice of the ureter can not be found from the renal wound, it should be sought for by opening the pelvis, pyelotomy, or by incising the ureter, ureterotomy.

3. A longitudinal incision, half an inch to an inch long, in the posterior wall of the pelvis can be made while the kidney is lifted upward against the twelfth rib. This procedure is easy if the pelvis is dilated, but may be impossible if the pelvis is of normal size.

4. A stricture in the ureter, if not too extensive, can be treated by a plastic operation on the plan of the Heinecke-Mikulicz operation for stenosis of the pylorus; namely, longitudinal division of the stricture and transverse union of the longitudinal wound. (Fig. 3). This method of operating for ureteral stricture seems to me preferable to resection of the strictured part of the ureter (Küster's operation) for the following reason: It is a more economical operation and preferable when the elongation of the ureter is not sufficient to permit the two cut ends of the ureter, after excision of the stricture, not only to come in contact but even to permit of closure and invagination without stretching.

5. Resection of the upper end of the ureter and implantation of the distal end into the pelvis has been performed in an important and interesting case by Küster, and the result was a brilliant success. His method was to split and unfold the end of the ureter, and to implant it into the opened pelvis, to which it was united with sutures.

6. In a similar case of stricture in the upper end of the ureter, especially if the ureter were not elongated or the kidney movable, I should prefer the plastic operation already described, as it is easier of technique, and as it proved successful in my case of traumatic stricture in the ureter below the pelvic orifice.

7. The ureter is accessible through an extra-peritoneal incision, a continuation of the oblique incision for lumbar nephrotomy, from the twelfth rib down along and one inch anterior to the ilium and along Poupart's ligament to about its middle. This incision gives access to the upper three-fourths of the ureter and down to within an inch and a half or two inches above the bladder.

8. The vesical and lower pelvic portions of the ureter may be reached, as Cabot of Boston, has pointed out, by means of the sacral operation, or Kraske's method modified by osteoplastic, temporary resection of the os sacrum. In woman, the vesical portion of the ureter is accessible through the vagina.

9. The vesical orifice of the ureter may be reached from within the bladder by supra-pubic cystotomy in man, or by dilatation of the urethra, or supra-pubic or vaginal cystotomy in woman.

In conclusion, I wish to cite literally the remarks made by Küster at the conclusion of his communication to the German Surgical Congress, because I fully

agree with Küster and think that his remarks apply well to my suggestions made above. Küster says:

"Gentlemen: When I bring this case before you, it is not to present to you a curious operation or a curiosity in the line of operating. The value of the observation appears to me to lie in the fact that it shows a method by which it may be possible to avoid the mutilating and dangerous operation of nephrectomy in cases of pyonephrosis where and when we do not know that the other kidney is perfectly healthy."

I would add—and a means to save or avoid some instances of permanent fistulas following nephrotomy for pyo- or hydronephrosis.

NOTE:—When I commenced to investigate the question of stenosis of the ureter and its possible operative treatment, I did not know that Küster had commenced work in the same direction. The first publication of Küster's case which reached me was his report before the Twenty-first German Surgical Congress, June 8 to 11, 1892, which appeared in the *Centralblatt für Gesamte Medicin*, for Aug. 13, 1892.

My first operation for stenosis was performed at a clinic and described in a clinical lecture given on May 31, 1892, at the Emergency Hospital, Chicago, for the Chicago Polyclinic.

THE IDEAL KNEE SPLINT.

BY JOHN RIDLON, M.D.

PROFESSOR OF ORTHOPEDIC SURGERY IN THE NORTHWESTERN UNIVERSITY MEDICAL SCHOOL; SENIOR ATTENDING ORTHOPEDIC SURGEON TO ST. LUKE'S FREE HOSPITAL; AND MEDICAL DIRECTOR TO THE HOME FOR DESTITUTE CRIPPLED CHILDREN, CHICAGO.

The ideal splint for treatment of disease at the knee-joint is one that gives 100 per cent. of immobilization and, at the same time, protects the joint from the traumatism incident to locomotion.

The early form of the Thomas knee splint, the one with the patten bottom, which is pretty generally used in this country, was markedly in advance of all the short splints, and of the splints making traction from adhesive plasters applied from the knee upward and downward; but the splint lacked somewhat in power to immobilize, and on that account confined the patient to bed unnecessarily long. Besides this,

a high patten was required for the opposite leg and the apparatus became a clumsy one.

The form of splint to which I wish to call attention is not new; it was used to the exclusion of the "patten" splint by Mr. Thomas for at least four years prior to his death, and has been exclusively used by Mr. Robert Jones and myself since that time. It

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

was called by Mr. Thomas the "Caliper" splint, and may be readily made without the help of the instrument maker from the "bed" splint.

The bed splint consists of a ring of iron wire to which is welded a long loop of the same wire, Fig. 1. The ring, in shape, is an irregular ovoid, flattened in front, and drawn out at the posterior and

inner portion so that when padded it shall fit the upper circumference of the thigh, Fig. 2, and as here observed, the inner wire of the loop B, is joined more anteriorly than the outer wire C. The ring slopes from without inward, and from backward in

anterior angle formed by the antero-posterior plane of the ring and the inner bar is about 145 degrees. The wire used depends upon the weight of the patient and is from three-sixteenths to three-eighths of an inch. In making the ring the ends should be joined by welding, and the side bars of the long loop are joined to the ring in the same manner. Few surgical instrument makers are good blacksmiths and therefore find it easier to braze than to weld, but a brazed joint breaks on bending, while a welded joint holds fast. The lower end of the long loop is dimpled somewhat to receive and retain the strap from the adhesive plasters. The ring is padded with boiler felting to the thickness of about half an inch in its outer portion and from an inch to an inch and a half in thickness at the inner posterior portion upon which the tuberosity of the ischium is to rest, and then covered with basil leather, tan sheepskin, put on wet, and sewed after the manner of the harness

Fig. 6.

Fig. 7.

Fig. 8.

Fig. 9.

such a way that the point A upon which rests the tuberosity of the ischium is the lowest part of the ring. Fig. 3 shows front view and Fig. 4 the rear view. The angle formed by the lateral plane ring and the inner bar is about 135 degrees, and the

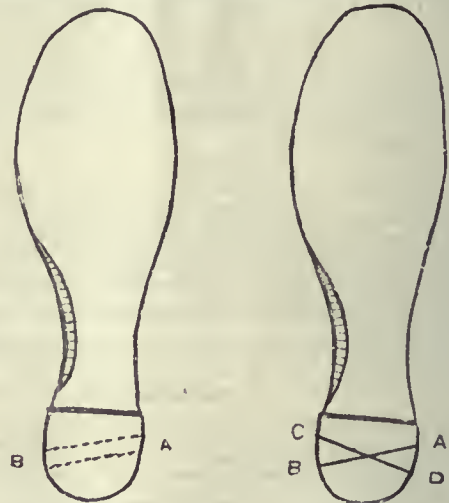

Fig. 10.

Fig. 11.

Fig. 12.

maker along the lower and outer border of the ring, i. e., where the seam will not chafe the patient. Two strips, from three to four inches wide, of the same leather, are sewed to one of the side bars, the other end being left free and of sufficient length to be drawn across to the opposite bar, and when sewed there, forms a support to the back of the limb when the splint is applied; one of these strips is to be back of the knee and the other back of the ankle.

The splint is applied by slipping the ring on over the leg and pushing it well up against the tuberosity of the ischium. If fixative traction is to be used, strips of long adhesive plaster in width about one-fourth of the circumference of the leg, and in length equal to the distance from the knee to the ankle, to the lower ends of which pieces of strong tape, webbing, or muslin bandage, have been sewed, are applied to the outer and inner surfaces of the leg; if these pieces of adhesive plaster are supplied with

narrow, oblique, lateral strips for winding around the leg, they will remain much longer attached to the skin. The plasters applied are held in place by an ordinary bandage. The surgeon now grasps the patient's foot, and pulls steadily downward, at the same time pushing the splint upward, and having straightened the limb as much as the patient will

one side bar and then the other; or a thick pad may be placed across the lower end of the thigh, well down upon the patella, and backward pressure made by a strong strip of muslin bandage, passed across

Fig. 17.

tolerate, ties the tape terminations of the adhesive plasters at the dimple, or upward bend, at the lower end of the splint. The lower leather cross strip is now placed back of the ankle, drawn snugly across and sewed fast. The other leather strip is placed back of the knee, or back of some part of the thigh if the knee is too greatly flexed to rest upon it, and it is drawn across to the opposite bar and sewed there. The knee is now pressed backward, straightening it as much as the patient will tolerate, and held there by a roller bandage carried back and forth across the front of the limb, and around first

from side to side and somewhat downward, and tied to each side bar by a half-hitch, and then carried across the pad and tied. After this, the traction tapes at the bottom are again tightened. The limb is left thus, if everything remains in place, for two or three days, when it can again be made straighter and the fastenings tighter. In this way, the limb is straightened. If the limb is to be straightened at once under an anesthetic, it is better to apply at once after the straightening, the caliper splint, which will now be described.

The caliper splint is made from the bed splint by

cutting off the lower end of the loop and bending an inch or more of each side bar inward at a right angle. Fig. 5. The bed splint is applied and pushed well upon the straightened limb, a point is marked on each side bar an inch below the sole of the foot, and an inch or an inch and a half below this; the side bars are cut off and the bend is made at the point marked. Figs. 6 and 7 show the tool used for cutting off these bars, and the process of bending them. A shoe is cut at the heel as shown at Fig. 8 or Fig. 9; a hole is bored through the heel, Fig. 10, line AB, or a slot made by a second hole, line CD, Fig. 11, and a tube inserted, Figs. 8 and 12, into the hole or tube the bent ends of the side bars are passed, the leather

Fig. 19.

strips drawn fast and sewed, and the limb tied or bandaged in place, as shown in Figs. 13, 14, 15, 16, 17. If the knee is swollen so that the inner bar presses against it, this bar is drawn outward with wrenches, or the tool, Figs. 18 and 19, employed. When a joint has been straightened under an anesthetic, it should be left in the splint, without change of shoe, stocking or bandages until all pain and tenderness have passed off. In a word, the joint has been more or less sprained by the maneuver, and must be treated with all the consideration which a sprain demands.

The deformity corrected, the patient should be kept off his feet until the muscular spasm which tends to deformity has subsided; then he may be allowed to walk about. If, for any reason, the patient has to be gotten up before this time, he should use crutches.

Is Fond of Press Clinics.—Superintendent Marks of the City Hospital, St. Louis, according to the veracious *Chronicle* of that city, has decided to admit reporters of the daily papers to the clinics of that institution.

STENOSIS OF THE LARYNX AND TRACHEA.

(Reported from the Transactions of the Chicago Medical Society.)

BY E. FLETCHER INGALS, A.M., M.D.

PROFESSOR OF LARYNGOLOGY AND DISEASES OF THE CHEST AT RUSH MEDICAL COLLEGE, ETC.

Dr. Ingals presented the history of a young woman, 23 years of age, who came under his care for stenosis of the larynx and trachea:

Five years previously she had been on the point of suffocation from the pressure of a large goitre, when tracheotomy had been done by Dr. Senn and artificial respiration established, which had saved her life. Dr. Senn had at that time removed a wedge-shaped piece of the thyroid and opened the trachea with the thermo-cautery. He had then introduced as a tracheotomy tube, a new device of his own, which possessed some advantages over the ordinary tubes.

Fig. 1.—Half size. Senn's tracheotomy tube.

A B—Rubber trachea tube. C D—Silver tube to be worn inside the rubber tube A B, as shown at c d.

This tube, represented in Fig. 1, consists of a curved silver tube about one-quarter of an inch in diameter and two and one-half inches in length, which was placed inside a rubber tube of the same caliber and about five inches in length, but which might have been either longer or shorter, according to the indications in the special case. The silver tube maintained the proper curve, and the whole was easily retained in the trachea. This tube, while in position, was cleansed by the patient by means of a feather, or after it had been worn for a few weeks it could be removed and cleansed, the patient having a similar tube to insert immediately after its removal to prevent contraction of the wound and trachea. The enlargement of the thyroid had practically all disappeared.

The patient had been referred to Dr. Ingals during the past summer by Prof. Senn, whom she had consulted at the Presbyterian Hospital, on account of inability to speak, or to breathe through the mouth. Dr. Ingals found complete closure of the lower portion of the larynx between the cords and the tracheal wound. Finding a cicatricial tissue so firm that it could not be torn, he passed a forceps down upon it from the mouth and cut down to the instrument from the external wound. The cicatricial tissue was very tough and about six millimeters in thickness. It was cut away upon the sides with the punch forceps shown in Fig. 2, which had

Fig. 2.—Ingals' punch forceps (half size).

been devised for this special purpose. The wound was then kept open by a rubber tube similar in size to that which had been used for the trachea. This tube was split down about three-quarters of an inch at one end, and the two sides were sewed together at the extremity, the edges of the cut being pared off so as to make an opening through which the tracheal tube could be passed. This laryngeal rubber tube

was passed upward, through the opening in the trachea, to the larynx, and the tracheal tube was passed through the place prepared for it in the end of the laryngeal tube.

Subsequently, after several experimental tubes had been made the laryngo-tracheal tubes, shown in Fig. 3 were constructed. Although somewhat larger in caliber than the rubber tube, the first of the silver tubes made had proven too small, and a tube, the caliber of which was about two millimeters greater than that of the rubber tube formerly worn had to be procured. Owing to the contraction of the trachea about two inches below the opening, whenever the tracheal tube was left out for fifteen or twenty minutes, it was necessary to make the silver tracheal tube long and formed, at its lower extremity, like the Durham tube. This silver tube the patient wore comfortably and with it was able to talk naturally. The author thought that the patient would be obliged to wear the tube the remainder of her life, because of the elastic stricture of the trachea about three inches below the glottis.

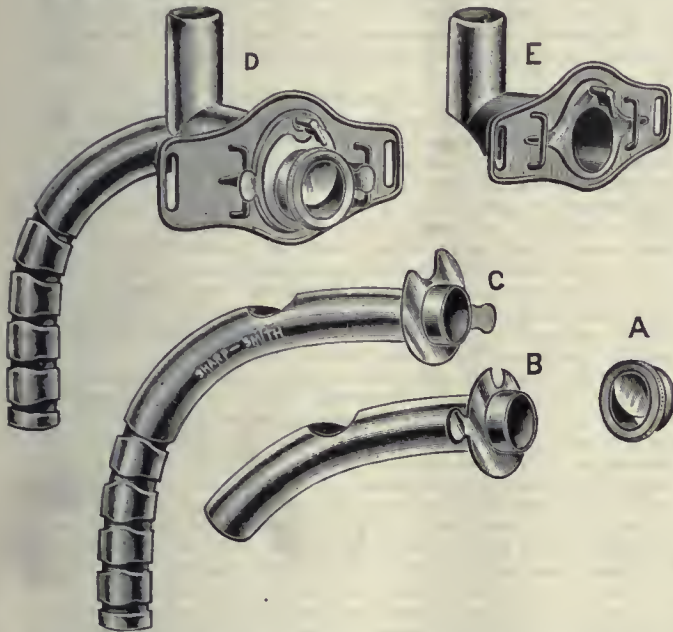

Fig. 3.—Ingals' laryngo-tracheal stenosis tubes (two-thirds size) A, cap with valve to prevent the escape of blast of air during phonation. B, middle tube. C, inner tube. D, instrument complete, all parts in position. E, outer tube.

In the discussion which followed, Dr. Wm. E. Casselberry referred to an interesting case which had been presented to the American Laryngological Association by Dr. Cohen, where the patient was able not only to speak, but to sing, although no air whatever could pass from the trachea to the mouth; and he inquired of the author of the paper especially regarding the voice in the case reported.

Dr. Ingals stated that the patient was unable to speak even in a whisper that could be understood; though by sucking air into her mouth before attempting to speak she could make some sounds with her lips, but the nurses and physicians at the hospital were unable to understand more than one word in ten; her friends, however, had learned to understand her by the movements of the lips.

Several months after the operation the patient was wearing the silver tracheal tube and speaking naturally.

A NEW RECTAL SPECULUM.

BY N. H. HENDERSON, M.D.
SURGEON LAKESIDE HOSPITAL, CHICAGO.

While one would think after examining the various rectal specula now on the market that there would be no room for another, experience has demonstrated

that there is. The new rectal speculum as shown in the cut below is sure to find a place in the hands of those who are giving attention to diseases of the rectum. By rotating handle, B, one-half, we completely close the opening, in which position the instrument should be when introduced. As will be observed, when the handle, B, is rotated directly over handle, A, we have a large opening, exposing almost one-half of the caliber of the rectum.

After introducing the speculum the handle, B, is to be rotated little or much, to expose little or much of the field as may be desired. In using the speculum in this way the plug is not necessary, but is only designed to be used in a rectum small enough to indicate a smaller sized speculum; in which case the inner speculum should be withdrawn and used with the plug. We now have two complete instruments capable of a great variety of adaptations.

It is not claimed for this instrument that it takes the place of all other rectal specula, but it will be found on trial, specially valuable in the management of diseases of the rectum. I claim for this speculum some advantages which others do not possess. Many patients present a redundancy of tissue just within the anus, so that when a bi-valve speculum is introduced the field of observation is obscured.

This speculum overcomes this, by supporting the entire circumference of the anus to a depth of three-fourths of an inch. It also holds back from the field of observation any fecal matter that may be in the rectum, which no other speculum does.

This instrument was made for me by Geo. Tiemann & Co., New York, and is also manufactured by Chas. Truax, Greene & Co., Chicago.

APPENDICITIS; WITH ORIGINAL REPORT AND ANALYSIS OF ONE HUNDRED AND FORTY-ONE HISTORIES AND LAPAR- OTOMIES FOR THAT DISEASE UNDER PERSONAL OB- SERVATION.

Read before the Pan-American Medical Congress.

BY J. B. MURPHY, M.D.
CHICAGO.

PROFESSOR OF SURGERY, AND CLINICAL SURGERY, COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO; PROFESSOR OF SURGERY, POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; ATTENDING SURGEON TO COOK COUNTY HOSPITAL; ATTENDING SURGEON TO ALEXIAN BROTHERS' HOSPITAL; CONSULTING SURGEON TO HOSPITAL FOR CRIPPLED CHILDREN, ETC.

(Continued from page 308).

Case 21.—Date of operation July 24, 1890. Operator, Dr. E. W. Lee. N. C., aged 34 years; female. Present sickness commenced July 16; complained of chills, fever, vomiting, and abdominal pain, latter more pronounced in ileo-cecal region. July 18, pulse 120, temperature 103 degrees. Slight tenderness in ileo-cecal region. July 21, pulse 124, temperature 102.5 degrees. Great pain over whole abdomen. Tenderness over ileo-cecal region marked and induration present. Operation: Appendicectomy. Appendix large, swollen, and tortuous; no perforation. Appendix contained enterolith in which was imbedded a small spicula of bone. There

were no adhesions around the appendix. Peritoneal cavity opened. No abscess. Pus in the appendix around the enterolith. Gauze drainage. Temperature fell to normal immediately after operation; recovery.

Case 22.—Date of operation Aug. 2, 1890. Operator, Dr. Lee. H. McQ., aged 10 years; female. Present illness of patient began July 27 with pain in ileo-cecal region and diarrhea. August 1, pulse 130, temperature 103 degrees. Tenderness in right iliac region; induration. Operation: Drainage of circumscribed abscess; general peritoneal cavity not opened. Appendix not removed. No foreign body found. Temperature fell to normal within twenty-four hours after operation; recovery.

Case 23.—Date of operation Aug. 22, 1890. Operator, Dr. Lee; present Dr. Bridge, Cook County Hospital. C. P. A., aged 21 years; male. Patient had a similar attack five years ago. Three days previous to operation, patient was seized with sudden pain in right iliac region, temperature 102.2 degrees; temperature August 20, 103.3 degrees; temperature August 21 100.8 degrees. Examination: Abdomen moderately distended, tympanitic. Dulness in right iliac region and marked tenderness over appendix. Tongue slightly coated. Operation: Incision over induration, escape of pus and two enteroliths. Drainage; recovery.

Case 24.—Date of operation Sept. 6, 1890. Operator, Dr. Lee. J. R., 16 years; male. Case occurred in the practice of Dr. McCarthy. Patient's present sickness began August 29 with acute pain in lower part of abdomen; diarrhea. Temperature 101.8 degrees, pulse 112, August 30; temperature 101.3, pulse 106 on August 31; on September 1, temperature 101.1 degrees, pulse 100; on September 2, temperature 101 degrees, pulse 98. Tenderness on pressure over lower part of abdomen which gradually became localized in right iliac region and induration developed. Operation: Incision and drainage of intra-peritoneal abscess. General peritoneal cavity opened. Appendix not removed. Temperature fell to normal inside of forty-eight hours; recovery.

Case 25.—Date of operation Sept. 18, 1890. Operator, Dr. Lee. F. W. H., aged 25 years; male. Case occurred in the practice of Dr. McCarthy. Present illness commenced suddenly September 14 with intense pain in right iliac region, persistent vomiting and diarrhea. General abdominal tenderness, more marked in the right iliac region. Tympanites. Patient lies with knees drawn up and bears a distressed look, temperature 102.2 degrees, pulse 116. September 15, temperature 102.6 degrees, pulse 122. Nausea, singultus. Tenderness and tympanites general. Slight induration in right iliac region. September 16, temperature 102.2 degrees, pulse 126, induration more marked and extensive, tenderness increased. Dr. Lee called in consultation. Diagnosis: Rupture of appendix with intra-peritoneal abscess. Operation: Typical incision; no induration to be felt after incision; dry septic peritonitis; appendix perforated; small abscess around base; drainage. *Exitus letalis* on third day. Postmortem: General dry septic peritonitis; perfect adhesions around gauze packing.

Case 26.—Date of operation Nov. 9, 1890. Operator, Dr. Lee. Cook County Hospital. Mrs. M. P., aged 32 years. Patient has had several attacks of same nature as present one in last three years. One week before admission to Hospital, present attack began with fever, chills, sweats and pain in right iliac region. Patient presents appearance of a grave typhoid, tongue and teeth heavily coated, lips covered with a herpetic eruption. At time of admission patient had a temperature of 104.6 degrees and had severe septic symptoms. In right iliac region, three and one-half inches from anterior superior spine of ilium is an induration. Operation: Incision over tumor into abscess; pus and feces escaped; packed with iodoform gauze. Death from pyemia, which was present at time of operation, three days later. Temperature reached 106 degrees several times. Frequent chills. No septic peritonitis.

Case 27.—Date of operation Nov. 15, 1890. Operator, Dr. Lee. O. P. P., aged 31 years; male. Patient had sudden attack; severe pain in right iliac region, chills, fever, temperature 103 degrees, vomiting, general abdominal tenderness, more marked in right iliac region where induration could be felt which was dull on percussion. Operation: Incision, drainage of an abscess without opening peritoneal cavity. Appendix not removed. Fecal fistula. Recovery. Patient subsequently had recurrent attacks and was again operated. (See history No. 30.)

Case 28.—Operation Feb. 14, 1891. Operator, Dr. E. W. Lee. R. S., male; aged 28 years. History: For past two years patient has been subject to frequent attacks, beginning with pain in right iliac region, generally accompanied with

nausea and vomiting. Attacks usually lasted from a week to ten days. During past six months patient had an attack about every three weeks. Examination: Induration in right iliac region. Operation: Appendicectomy. General peritoneal cavity opened. The vermiform appendix was found perforated near the base which communicated with an abscess cavity that had opened into the cecum. A probe could be passed through the opening into the cecum. Enterolith. Drainage; recovery.

Case 29.—Date of operation March 9, 1891. Operator, Dr. Murphy. Miss McC., aged 23 years. History: First attack of pain in 1889. Sudden pain in right loin followed by fever, tenderness and vomiting. The swelling gradually increased in loin and was seen by several physicians in the next year, all agreeing that it was a sarcoma of the kidney. It finally was opened in the back and a small quantity of pus escaped. Two fecal stones escaped from the opening after some months; this was followed by the discharge of berry seeds for several months, no other material escaping. At the end of about a month, I operated to close the fistula in the cecum. This was done by suture and was successful. The history of this case extends over a period of three years. Recovery.

Case 30.—Date of operation May 19, 1891. Operator, Dr. Lee. P. O. P., aged 31; male. Cook County Hospital. Patient had a primary operation for appendicitis in November, 1890. An intra-peritoneal abscess was drained but the appendix was not removed. In April, 1891, a laparotomy was performed for removal of the appendix, but on account of the extensive adhesions this was impossible. Patient was seen three days after onset of present attack and by an operation the appendix was amputated; two enteroliths were found in it; a rubber drain was inserted and the abdominal incision partially closed. Patient made a rapid recovery. There remained a small sinus leading down to the iliac fossa for several weeks.

Case 31.—Date of operation, June 4, 1891. Operator, Dr. Murphy. Cook County Hospital. J. H. C., male; aged 27 years. Patient was seen five weeks after onset of attack. His illness commenced with pain in right iliac region. Examination: Hard tumor in right iliac region, not movable, seemingly attached to ilium. Percussion dull over tumor, otherwise normal. Temperature 101.2 degrees. Operation: Incision into pus cavity. The appendix which was difficult to locate was drawn into abdominal incision, ligated near its base and amputated. Drainage; recovery in three weeks. The appendix was perforated near its base.

Case 32.—Date of operation June 9, 1891. Operator, Dr. Murphy. Alexian Brothers' Hospital. F. F., aged 18 years; male. Patient had a typical attack and entered the Hospital five days after the onset when he showed symptoms of a circumscribed suppurative peritonitis. The operation was at once performed and a large abscess drained. The appendix was not removed. Recovery.

Case 33.—Date of operation June 25, 1891. Operator, Dr. Murphy. D. M., male, aged 19 years. Alexian Brothers' Hospital. This case was operated on four days after the onset of a typical attack. A circumscribed abscess was opened; a fecal stone escaped. The appendix was perforated and was removed after simple ligature. Recovery.

Case 34.—Date of operation July 28, 1891. Operator, Dr. Murphy. J. A., age 56; male. Alexian Brothers' Hospital. History: Patient entered Hospital fourteen days after onset of a typical attack. A large induration in right iliac fossa to be felt. Operation: Incision into large pus cavity. Appendix not removed; drained. General peritoneal cavity not opened; circumscribed abscess. Recovery.

Case 35.—Date of operation Aug. 5, 1891. Operator, Dr. J. B. Murphy. Cook County Hospital. A. H., aged 30 years; male. Had an attack six months previous similar to the present. Typical attack July 27. Induration in right iliac region. Operation: Lateral incision. General peritoneal cavity opened. Peritoneum very much congested. Appendix situated along the lower border of ilium. Appendix perforated; one side surrounded by a mass of granulations where it was adherent to the cecum. The probe could be passed through a small opening into the cecum showing where the abscess had emptied. The appendix was ligated and removed. There had been a local gangrene, the defect now in process of cicatrization. Recovery. This is one of the cases that is classed by some authors as cecitis, but the opening in the cecum was made from without inward by an accumulation of pus around the gangrenous appendix.

Case 36.—Date of operation Aug. 10, 1891. Operator, Dr. Murphy. Cook County Hospital. F. D., aged 32 years. Patient was always healthy up to present illness. He was

taken ill with severe pain in the umbilical region; fever and vomiting. The pain increased rapidly and at time of operation was diffuse and uniformly severe. Examination; Pulse rapid and small; legs drawn up; percussion shows abdomen full of fluid nearly up to umbilicus; abdominal walls tense: tenderness diffuse. Operation: Median incision; escape of a large quantity of sero-purulent fluid with fecal odor. Drainage after irrigation of abdominal cavity. Appendix adherent. Patient died on following day. Postmortem: Appendix adherent to under surface of cecum except about one-half inch of tip which was free. At base of appendix was an ulcerated perforation. At side of perforation, enterolith, size of cherry stone. No evidence of a previous abscess cavity. General suppurative peritonitis which had developed before adhesions could take place. The peritoneum of the abdominal and intestinal walls was eroded of endothelium.

Case 37.—Date of operation Sept. 14, 1891. Operator, Dr. Murphy. G. A., male. History: Typical attack. Operation: A circumscribed intra-peritoneal abscess was opened and drained with iodoform gauze. A fecal stone escaped with the pus. Abscess extended deep into back. Recovery.

Case 38.—Operation Nov. 13, 1891. Operator, Dr. E. W. Lee. Miss B. aged 16 years. Sickness commenced with sudden pain in right iliac region; vomiting. Sudden rise of temperature (103 degrees) and pulse. Induration in right iliac region and tenderness more marked in this locality. Operation: Drainage of a large circumscribed abscess. Fecal calculus. Appendix not removed. Recovery.

Case 39.—Date of operation Dec. 14, 1891. Operator, Dr. J. B. Murphy. Miss F., aged 17 years. History: Typical attack. Operation: Performed on fifth day after onset. Intra-peritoneal pus cavity opened. Fecal stone removed. The appendix was gangrenous and perforated; amputated. Abscess cavity packed with iodoform gauze. Recovery.

Case 40.—Date of operation Dec. 19, 1891. Operator, Dr. Murphy. H. F., aged 24 years. History: For the past three years has had repeated attacks of pain in the right iliac region. With these attacks he occasionally had vomiting; always great tenderness in right side. Status Præsens: Patient is emaciated, has evening elevations of temperature and night sweats. For the last three days has suffered from great pain in right iliac region. Examination: Heart and lungs normal. An area of dullness in right side extending from Poupert's ligament to within two inches of the margin of the ribs and as far forward as the linea semilunaris. The induration extended behind from the crest of the ilium to the margin of the ribs. It was most sensitive and approximated the surface more closely an inch to the right and a little below the anterior superior spinous process. No induration could be felt from the rectum. Urine normal. Diagnosis: Recurrent appendicitis with extensive infiltration of the cellular tissue. Operation: Lateral incision an inch to the inner side of the spinous process. The cellular tissue was found infiltrated and indurated a quarter of an inch from the skin. This induration was perforated with the handle of the scalpel until an abscess was reached one and one-half inches below. A small quantity of thin odorless pus escaped. It was found on exploration with the finger that only a sinus had been opened. This sinus was followed upward and backward, and at the lower end of the right kidney was found a renal calculus the shape of a Maltese cross, the bars being one inch in length and three-eighths inches in diameter. It was broken with a heavy forceps and extracted. It had escaped completely from the kidney, and the opening closed, as no urine escaped at time of operation or subsequently. The closure of this opening accounts for the absence of pus in the urine at the time of examination. Patient made an uneventful recovery.

Case 41.—Date of operation Jan. 10, 1892. Operator, Dr. Hartmann. F., aged 9 years; male. Patient was seen one week after a typical attack; had quite a high temperature with a distinct induration over appendix. Operation: At time of operation temperature 105 degrees. An intra-peritoneal abscess was drained; the appendix was not removed. Recovery.

Case 42.—Date of operation Jan. 26, 1892. Operator, Dr. J. B. Murphy. Alexian Brothers' Hospital. J. J. G., aged 26 years; male. During past two years patient has had about a dozen attacks of appendicitis. Operation: (intermediate stage). Appendicectomy. Appendix was adherent to cecum and showed many cicatrices from previous perforations. Enterolith. Recovery.

Case 43.—Date of operation Feb. 20, 1892. Operator, Dr. E. W. Lee. Miss D., aged 25 years. Sudden attack of pain in

right iliac region. Vomiting. Diffuse abdominal tenderness. Temperature 105 degrees, pulse 130 at time of operation. Operation: third day after attack. Usual incision. Drainage of an intra-peritoneal abscess which had previously ruptured and caused a general dry septic peritonitis; no limiting adhesions. Enterolith removed. Symptoms of peritonitis continued and patient died in forty-eight hours. Autopsy not allowed.

Case 44.—Date of operation Feb. 26, 1892. Operator, Dr. Lee. Cook County Hospital. L. J., aged 19 years; female. Patient was admitted to the gynecologic ward of the Cook County Hospital, probably on account of an induration in the roof of the pelvis. The diagnosis of appendicitis was finally made. She was not operated upon until three weeks after beginning of her attack. The operation consisted of incision into abscess, irrigating and packing (with iodoform gauze); general peritoneal cavity not opened. Complete recovery in four weeks.

Case 45.—Date of operation March 11, 1893. Operator, Dr. E. W. Lee. F., 18 years; male. Patient felt perfectly well up to February 28. That day, while riding on a bicycle, the pedals of which were too low, he over-reached with his right foot, and felt a sudden pain in right lumbar region. Fever soon developed and vomiting occurred several times. Bowels constipated. He suffered from great pain above and behind the right anterior superior spinous process of ilium. Excessive tenderness over right side of abdomen, especially in the region of the right anterior superior spinous process. Abdomen very tympanitic; under anesthetic induration was felt which was not apparent before operation. Temperature 103 degrees. Drainage of circumscribed abscess, removal of enteroliths. Appendix not removed. Later fecal fistula developed, which closed spontaneously. Recovery.

Case 46.—Date of operation April 3, 1892. Operator, Dr. J. B. Murphy. Mrs. B., aged 52 years. Typical attack. Nausea, vomiting, local tenderness. No induration. Operation: Third day after the attack. Temperature 102 degrees. Appendicectomy. Base of appendix very much distended. No adhesions of appendix. A large typhoid ulcer in appendix. Drainage forty-eight hours; recovery.

Case 47.—Date of operation April 5, 1892. Operator, Dr. Murphy. A. K., age 26; male. Case occurred in practice of Dr. Davey. Patient was seen seventh day after attack. A large abscess was drained without opening general peritoneal cavity. The appendix was not removed. A foreign body was found loose in abscess cavity; recovery.

Case 48.—Date of operation April 5, 1892. Operator, Dr. Lee. Cook County Hospital. M. N., aged 52 years; female. Patient's trouble commenced with chills, fever, vomiting, general pain in abdomen which gradually became localized in right iliac fossa. The diagnosis of appendicitis was made and a circumscribed abscess drained. The appendix was not removed. No foreign body present. Patient had parotid abscess, otherwise an uneventful recovery.

Case 49.—Date of operation, April 21, 1892. Operator, Dr. Lee. Cook County Hospital. D. M., aged 28 years. History: Patient's present illness commenced with a sudden attack of severe pain, vomiting and great tenderness over the epigastrium. Had previous good health and no symptoms of pain and distress after taking food. The pain became very intense after a few hours and tympanites set in. The abdomen was uniformly sensitive. No induration could be felt on account of the distension. Temperature 101 degrees, pulse 96. Anxious expression. Diagnosis: General peritonitis from appendicitis. Operation: Lateral incision; general suppurative-peritonitis. The appendix was found inflamed in common with the other tissues; not removed. Cause of peritonitis not ascertained. Death twenty-four hours after. Autopsy: General suppurative peritonitis produced by small round perforating ulcer of stomach. It will be noted in this case there was absence of increased local tenderness in right iliac region and the pain was located in the epigastrium, also absence of history of ulcer of stomach.

Case 50.—Date of operation May 10, 1892. Operator, Dr. Murphy. Occurred in the practice of Dr. Oswald. C., age 23; male. History: Sickness commenced with sudden pain in right iliac region, vomiting and nausea. Examination: large induration over appendix. Operation: Five days after attack. Incision into abscess; escape of a large quantity of pus with enterolith. Appendix not removed. Abscess cavity packed with iodoform gauze. Recovery. Had one recurrence since; very light; not operated.

Case 51.—Date of operation May 11, 1892. Operator, Dr.

Murphy. T. H., age 46; male. Case occurred in the practice of Dr. T. J. Conley. History: Typical attack. Induration. Operation: Drainage of a large circumscribed abscess containing four ounces of pus. No foreign body. Appendix not removed. General peritoneal cavity not opened. Recovery. Three recurrences since operation. (Not operated.)

Case 52.—Date of operation May 14, 1892. Operator, Dr. Murphy. Alexian Brothers' Hospital. B., age 28; male. Typical attack. Operation several days after attack. An extra-peritoneal abscess was opened; the appendix removed, also enterolith and the abscess drained with iodoform gauze. Recovery.

Case 53.—Date of operation May 18, 1892. Operator, Dr. Murphy. Miss B., aged 24 years. Present attack commenced May 13, 1892, with general abdominal pain, nausea and vomiting. Induration. Operation: Five days after attack. Drainage of intra-peritoneal abscess containing about two ounces of pus. Recovery. Recurrence July 12, 1893. Operated. (See History No. 97.)

Case 54.—Date of operation June 20, 1892. Operator, Dr. Lee. E. B., aged 50 years; male. Seven days before operation patient was suddenly attacked with pain in the abdomen after having partaken of a heavy dinner. A few hours afterward he vomited, and fever set in (temperature 103 degrees.) Abdomen became rapidly distended and tender over the entire surface, more pronounced over the right iliac region. Patient seen on third day by Dr. Lee. Operation advised. Consultation the following morning resulted in postponement of operation. Symptoms continued the same except temperature, which fell to 101 and remained so. Further consultation on the seventh day, operation agreed to. Pulse 90, temperature 101 degrees at time of operation. Usual incision. General suppurative peritonitis present, result of rupture of a circumscribed abscess around appendix. No limiting adhesions. Bowel at seat of circumscribed abscess black and gangrenous. Appendix not removed. Second day after operation feces discharged freely through the wound. Pulse and temperature good. Third day. Escape of intestinal slough. Patient in good condition. Fourth day. Conditions improved. Fifth day. Profuse hemorrhage both from wound and rectum. Patient pulseless. Remained in bad condition and died on seventh day. Autopsy not permitted.

Case 55.—Date of operation June 25, 1892. Operator, Dr. Murphy. W. R., aged 17 years. Alexian Brothers' Hospital. History: Typical attack four weeks before operation. Continuation of fever and sweats with rapid emaciation and tenderness in right iliac region. Status Præsens: Induration extending half way to the umbilicus, tense and tender. Dull on percussion. Operation: Lateral incision. Opened a large circumscribed abscess. General peritoneal cavity not opened; appendix not removed; drainage with iodoform gauze; recovery. This case was re-operated on during a relapse. (See Case 108.)

Case 56.—Date of operation July 9, 1892. Operator, Dr. Murphy. Mr. S., aged 36 years. Case occurred in practice of Dr. Hoelscher. History: Typical attack. Examination reveals induration and dullness on percussion far beyond median line to the left. Operation twenty-eight days after attack. Lateral incision; about a quart of pus escaped; no fecal stone; appendix not removed; general septic peritonitis; recovery.

Case 57.—Date of operation July 16, 1892. Operator, Dr. Murphy. Cook County Hospital. H. W., 22 years; male. Typical attack. Operation four days after onset. Drainage of a large accumulation of pus (intra-peritoneal.) General suppurative peritonitis; appendicectomy. Local gangrene of appendix; no foreign body; recovery.

Case 58.—Date of operation July 28, 1892. Operator, Dr. Murphy. Miss R., aged 10 years. Case occurred in practice of Dr. Cotton. History: Typical attack, nausea, vomiting, operation eighth day after onset. Lateral incision; escape of about six ounces of pus from an intra-peritoneal abscess. No foreign body; appendix not removed; recovery.

Case 59.—Date of operation Aug. 27, 1892. Operator, Dr. Murphy. A. M., age 22; male. Alexian Brothers' Hospital. Typical history of appendicitis. Operation: Lateral incision. Circumscribed abscess opened. General peritoneal cavity not opened. Appendix not removed. Drainage; recovery. This case was operated upon twenty-four hours after admission to Hospital.

Case 60.—Date of operation Sept. 16, 1892. Operator, Dr. Murphy. J. McC., aged 11 years; male. Case occurred in practice of Dr. P. H. Conley. History: Typical attack. Operation fifth day after attack. Operation: Incision, gen-

eral peritoneal cavity opened. Pus found extending over bowels beyond median line. Escape of fecal stone with pus. Appendix not removed. Temperature at time of operation 99½ degrees; pulse 98. Facial expression good. Recovery in three weeks. Fecal fistula closed without operation in ten days.

Case 61.—Date of operation Oct. 11, 1892. Operator, Dr. Murphy. H. S., aged 34 years; male. Admitted to Hospital five days previous to operation. Patient gave a typical history of appendicitis; small induration, temperature 101 degrees. Operation: Lateral incision; drainage of circumscribed abscess without entering peritoneal cavity; recovery.

Case 62.—Date of operation, Oct. 15, 1892. Operator, Dr. Murphy. (Case occurred in the practice of Dr. Hoelscher.) Miss F. aged 16 years. History: Typical attack. Operation: Three days after attack. Drainage of circumscribed abscess. Appendicectomy. General peritoneal cavity was opened. Appendix was perforated, gangrenous and contained enterolith. Recovery.

Case 63.—Date of operation Oct. 15, 1892. Operator, Dr. Murphy. S., age 37; male. Case occurred in practice of Dr. McCarthy. History: Typical attack, nausea, vomiting. Operation: On sixth day. Large abscess containing about a pint of pus. General peritoneal cavity not opened. Appendix enlarged and gangrenous; ligated, amputated. A fecal stone removed. Abscess cavity packed with iodoform gauze. Recovery.

Case 64.—Date of operation Oct. 28, 1892. Operator, Dr. Murphy. Alexian Brothers' Hospital. F. R., aged 18 years. History: Attack typical. Operation: Several days after onset. Lateral incision. General suppurative peritonitis. The appendix and a fecal stone removed; a large quantity of pus escaped. Drainage with iodoform gauze. Recovery.

Case 65.—Date of operation Oct. 28, 1892. Operator, Dr. Murphy. Occurred in practice of Dr. Hoelscher. C. F. B., aged 18 years. Patient was seen eight days after onset of typical attack by Dr. Hoelscher. The temperature was 105 degrees, the pulse 130. Extreme tympanites and general tenderness present. Patient in a profoundly collapsed condition at time of operation. Operation: Drainage of abdominal cavity; a very large amount of pus escaped (about one quart). Death twelve hours after operation. General suppurative peritonitis at the time of operation. Patient also had pneumonia.

Case 66.—Date of operation Oct. 28, 1892. Operator, Dr. Murphy. Alexian Brothers' Hospital. H. G., age 26; male. Typical attack. Operation: Lateral incision. General suppurative peritonitis. Appendix perforated, gangrenous, non-adherent; appendix removed; drainage; recovery.

Case 67.—Date of operation Nov. 2, 1892. Operator, Dr. J. B. Murphy. Miss G., aged 14 years. History: Sudden attack on Oct. 30, 1892, two days before operation; nausea, vomiting, and sudden rise of temperature. Examination. Temperature 102 degrees, pulse 80, local tenderness, tympanites. Operation: Lateral incision over region of appendix into peritoneal cavity. Appendix adherent to side of cecum and covered with flakes of pus; mesentery also infiltrated with pus. Appendix ligated and amputated. Appendix found enlarged, adherent; no perforation, but ulceration of mucous membrane present. Recovery. Remarks: This case is very interesting, as it shows a purulent infection of the peritoneum and mesentery from an ulcer of the mucous membrane of the appendix without gangrene and without perforation. Peritoneal infection has been reported from ulcers in other portions of the intestinal tract without perforation, but this is the first case on record where such a condition is reported as occurring from the appendix without perforation or gangrene.

Case 68.—Date of operation Nov. 3, 1892. Operator, Dr. Murphy. W., aged 36 years; male. Case occurred in practice of Dr. O'Malley. History: Attack typical. Examination revealed a large area of superficial dullness. Operation eighth day. Incision and removal of appendix. General peritoneal cavity not opened. About a pint of pus escaped, also a fecal stone. Packing of abscess cavity with iodoform gauze. Recovery. Pathologic conditions: Appendix completely gangrenous and free in abscess cavity, nothing being left of it but its peritoneal covering.

Case 69.—Date of operation Nov. 11, 1892. Operator, Dr. Murphy. Miss F., aged 26 years. History: Ten days ago patient became very sensitive in right iliac region, and noticed there a hard swelling. There had been no perceptible swelling previous to that time. This increased rapidly in size, and when admitted to the Hospital extended up to the margin of ribs and could be felt distinctly behind. There

was no deformity in back, nor was there a history of trouble in the spine. Urine normal. Diagnosis: Appendicitis. Operation: Laparotomy. Lateral incision; abscess opened without entering the peritoneal cavity. Cellular tissue of abdominal wall very much infiltrated; this was due to a rupture of the abscess into retro-peritoneal cellular tissue by an exertion the day before onset of pain. Pus was odorless, which immediately caused doubt as to the etiology of the suppuration. Exploration of the abscess cavity revealed a sinus leading up to the third and fourth lumbar vertebrae which were tubercular. Rupture of the psoas abscess into the cellular tissue accounts for the sudden onset of symptoms, and the location of and limited disease of the vertebrae accounts for the absence of scoliosis or lordosis. Recovery.

Case 70.—Date of operation Nov. 14, 1892. Operator, Dr. Murphy. Case occurred in practice of Dr. T. J. Conley, Mrs. S., aged 24. History: Typical attack; induration, resonant on percussion. Operation: Fourth day after attack revealed intra-peritoneal abscess and perforation of appendix with enterolith. The appendix was amputated, the abscess cavity drained with iodoform gauze. Recovery.

Case 71.—Date of operation Nov. 26, 1892. Operator, Dr. Murphy. K., aged 14; male. Case occurred in practice of Dr. O'Shea. History: Typical attack. Operation seven days after onset. A large abscess was opened, which contained quite a quantity of blood. After pus escaped, a profuse hemorrhage took place which resembled that of aneurism, which was suppressed by packing with iodoform gauze. A fecal stone was removed; appendix not removed; recovery.

Case 72.—Date of operation Nov. 30, 1892. Operator, Dr. Murphy. Mrs. E., aged 22 years. Case occurred in practice of Dr. T. J. Conley. History: Typical attack. Operation on fourth day: Appendicectomy. A large circumscribed abscess was present. The appendix was gangrenous and had perforated. Fecal stone. Recovery.

Case 73.—Date of operation Dec. 7, 1892. Operator, Dr. Murphy. Miss S., aged 12 years. Case occurred in practice of Dr. Graves. History: Typical attack. Operation on the fourth day of sickness. Intra-peritoneal abscess, containing two ounces of very offensive pus was opened; the appendix was found to be partly gangrenous and perforated, and was removed. The cavity was packed with iodoform gauze. Recovery.

Case 74.—Date of operation Dec. 9, 1892. Operator Dr. Murphy. J. F., aged 25; female. Hospital. History: Patient had frequently complained of pain in right iliac region and occasionally had pains in back. Present attack began two weeks ago with classical symptoms of appendicitis. On examination a considerable induration was found in the right iliac region which appears to be near the surface. No induration could be felt from rectum. Superficial dullness on percussion. Operation: Lateral incision; circumscribed abscess; appendix not removed; general peritoneal cavity opened. Drainage; recovery.

Case 75.—Date of operation Dec. 16, 1892. Operator; Dr. Murphy. St. Joseph's Hospital. M., aged 28 years; male. One year previous to operation the patient had three attacks of local peritonitis. During the last attack Dr. F. S. Hartmann saw the case and advised operation. The last attack simulated intestinal obstruction very much, so that there was doubt as to the actual diagnosis. Operation: Appendicectomy. General peritoneal cavity opened. There was present a perforation of the appendix with a circumscribed abscess in region of umbilicus. The wall of the cecum enveloped the appendix. Drainage; patient made a good recovery.

Case 76.—Date of operation Dec. 16, 1892. Operator, Dr. Murphy. Case occurred in the practice of Dr. Wittwer. A., aged 26; male. Alexian Brothers' Hospital. Patient was seen several days after onset of attack and showed severe symptoms of general suppurative peritonitis. Operation: The usual incision was made, and a large quantity of pus escaped, which covered the bowels for an area of several inches. Slow recovery.

Case 77.—Date of operation Dec. 25, 1892. Operator, Dr. Murphy. H., aged 15 years; male. Case occurred in the practice of Dr. Mott. Two weeks previous to first operation, patient had a typical attack accompanied with pain, nausea, vomiting and tympanites. On examination a dullness on light percussion over entire abdomen below the umbilical line. Deep percussion resonant. Operation: Lateral incision, large quantity of pus all over the bowels; appendix not removed. Temperature dropped for three days and then rose again to 103 degrees. January 2, in consultation with Dr. Mott, it was found that left side of abdomen was not draining properly. Circumscribed adhesions had formed

around an accumulation of pus in that region. The abscess was drained; it was found that this abscess extended into the pelvis. Patient made a rapid recovery.

Case 78.—Date of operation Jan. 28, 1893. Operator, Dr. Murphy. K., aged 22 years; female. Sickness commenced with sudden pain and tenderness in right iliac fossa. At operation, which was performed four days after onset of attack, a large extra-peritoneal abscess was found, and was packed with iodoform gauze. The appendix was not removed. Two weeks after the operation a lobar pneumonia set in, which was followed by a hydrothorax; aspiration; recovery.

Case 79.—Date of operation Feb. 17, 1893. Operator, Dr. Murphy. R., aged 32 years; male. Case occurred in the practice of Dr. Turk. Ten days previous to operation sudden attack of pain and tenderness in right iliac region. Difficult urination; no induration. Operation: Lateral incision and removal of appendix; general peritoneal cavity opened. The appendix was adherent to its surroundings; a fecal stone was found and a perforation of the appendix had taken place. Local gangrene of appendix. Gauze drainage; recovery.

Case 80.—Date of operation Feb. 17, 1893. Operator, Dr. Murphy. Cook County Hospital. W. C., aged 16 years; male. Recurrent appendicitis; three attacks previously. Typical attack; no induration. No temperature at time of operation. Operation: Lateral incision, general peritoneal cavity opened. Appendix situated in the retro-cecal fossa, adherent, very much enlarged and edematous; ligated and amputated. No pus in peritoneal cavity. Drainage; recovery. Pathologic conditions: Mucous membrane ulcerated; very much swollen around the ulcer. Tension on serous covering great.

Case 81.—Date of operation March 9, 1893. Operator, Dr. Hartmann. B., aged 9; male. Patient's illness began one week previous to operation. Sudden attack of abdominal pain, nausea, vomiting, diarrhea, fever. Abdominal tenderness more pronounced locally; induration. Operation. Drainage of an intra-peritoneal abscess; recovery.

Case 82.—Date of operation March 18, 1893. Operator, Dr. Wittwer. W., aged 8; male. Case occurred in private practice of Dr. Hicks of Burlington, Wis. About two weeks before operation, patient commenced ailing, with an irregular temperature, sweats, occasional vomiting and later on, pain in lower part of abdomen, with a tendency to localization in right iliac region. Examination of urine revealed pus. Induration. Diagnosis: Large, circumscribed perityphlitic abscess with rupture into bladder. Operation: Median incision two inches above symphysis pubis; a large quantity of pus escaped which had involved the whole right iliac region. Two large rubber drains inserted. Complete recovery in four weeks. Appendix was not removed.

Case 83.—Date of operation, March 20, 1893. Operator, Dr. E. W. Lee. R., age 13 years; male. Case occurred in the practice of Dr. P. B. Hayes. Onset sudden, vomiting, pain in right iliac region, extreme tympanites, no induration. At the time of operation temperature 105 degrees F., pulse 124; had been so for three days. Typical typhoid condition. Operation: Appendicectomy; drainage; no peritonitis. Appendix unusually long and swollen; contained blood and pus; not perforated. Mucous membrane ecchymotic and ulcerated. Temperature fell promptly after operation to 102 degrees F. On the third day patient became deeply jaundiced; rapid recovery.

This is a particularly interesting case, the temperature keeping above 105, and the pulse 134 from the beginning of the attack up to the time of operation. Abdomen enormously tympanitic and tender. He presented all the so-called classical symptoms of general septic peritonitis. Note the pathologic conditions; no peritonitis, simple infection with retention in appendix. How could a diagnosis of the pathologic conditions be made by these symptoms?

Case 84.—Date of operation March 30, 1893. Operator, Dr. Murphy. M. L., aged 22 years; male. Cook County Hospital. History: Patient was transferred from medical division of Hospital after having been sick for five days. Five days previous to operation patient was taken with severe pain in right iliac region. Large doses of morphin were necessary to control the pain. Bowels moved as usual. Patient had noticed no swelling. On examination abdomen tympanitic, severe pain on slight pressure over the appendix; no tumor visible nor palpable; no difference in percussion resonance. The pain increased constantly from the beginning. March 29, 1893, pulse 120, temperature 103.4 degrees, respiration 42. March 30, A.M., pulse 132, temperature 102.2 degrees, respiration 36. Operation: Lateral incision; peri-

toneum opened; packed around seat of operation. Retrocecal abscess, one ounce of pus; appendix amputated; no foreign body or calculus. Sutures inserted, but not tied. Drained with iodoform gauze. In twenty-four hours pulse had subsided to 96, temperature 97.6 degrees, respiration 28. Subsequent convalescence uneventful.

Case 85.—Date of operation April 6, 1893. Operator, Dr. Murphy, M. S., age 30 years. Onset of typical attack April 2, 1893. A temperature of 103 degrees and a pulse of 92 were present at the time of operation. Increased local pain and general tympanites. Operation: Lateral incision; appendix invaginated in a fold of the cecum; a couple of drachms of very offensive pus around it; appendix was ligated near its base; amputated. Drainage; recovery. Appendix had no perforation. An ulceration was the cause of the infection. The mesentery was infiltrated with pus, and there were flakes of pus on the surface of the bowel in the region of infection. This is another illustration of local suppurative peritonitis from ulcer of the appendix without perforation. Patient had a temperature of 103 degrees every day after operation for three weeks, without any other symptom of sepsis or local trouble; as she expressed it, "one of her regular bilious attacks." It annoyed me very much, but no other explanation for temperature could be given. Recovery.

Case 86.—Date of operation April 6, 1893. Operator, Dr. Wittwer, B. L., age 10 years; school girl. History, as given by Dr. Wittwer: Patient was brought to my office two days before operation. Mother gives the following history: For the last two weeks child has been ailing; complained of pain all over body, principally in abdomen around the umbilicus. Child gradually lost flesh, her appetite failed, she had some diarrhea, occasional vomiting, so that finally a physician was called who treated her several days for rheumatism. When I saw her she had some temperature, cheeks flushed, walked into office like a case of hip joint disease. Right leg drawn up in recumbent position. Examination revealed a narrow induration about three inches long in the right iliac region. An operation was made two days later. Typical incision; appendix easily located and found adherent to surrounding tissues; some flakes of pus could be seen on outside of appendix, but no distinct accumulation of pus had formed. Appendix was ligated and removed, suture left in wound, and latter packed with iodoform gauze. Pathologic conditions: Fecal stone. No perforation of appendix. On opening appendix it was found that one-half of mucous membrane towards the cecum was thickened and infiltrated, but not gangrenous, while the distal portion of mucous membrane had become gangrenous and presented the appearance of a diphtheritic patch, ulcerated, with a dirty, thick, grayish, yellow base. There were present in appendix a few drops of pus; recovery.

(To be continued.)

ARMY MEDICAL SCHOOL; CLOSING EXERCISES OF THE FIRST SESSION.

[Reported for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.]

The first session of the Army Medical School was closed by appropriate exercises at 3 P.M. on Wednesday, February 28, in the Hall of the Library of the Surgeon-General's office. Most of the officers of the War Department were present, including General Schofield, commanding the Army, Major-General John Gibbon, Surgeon-General Sternberg, Quartermaster-General Batchelder, Inspector-General Breckenridge and others; Ex-Surgeons-General Hammond, Murray and Sutherland of the Army, and Medical Directors Gihon and Gorgas, with the medical officers of the Navy on duty in the Department and many prominent members of the profession in civil life, were also interested spectators of the closing scenes of the session. The officers of the graduating class presented a brilliant appearance in the blue and gold of their new uniforms. The members of the Faculty were also in uniform.

Colonel Alden, Assistant Surgeon-General, President of the Faculty, expressed in his opening remarks the gratification he felt at seeing so many present on

the occasion. He referred to the need of a special training for the Army medical officer, and enumerated the various duties which he is called upon to perform that are outside of the work of the physician and surgeon as that work is ordinarily understood. "Let us see now," said he, "how the course of instruction provided carries out the purpose indicated: Five courses of lectures are provided, with two courses of laboratory work and practical instruction in litter drill and first aid. The Department of Military Surgery, including, as it does, the care and transportation of sick and wounded and hospital administration, is naturally one of great importance. It takes up the study of modern military weapons, the wounds they produce, and the treatment they demand under the peculiar conditions imposed by the exigencies of the battle-field and the march; the arrangements necessary for the prompt relief of the wounded on the field of battle and their transportation to the hospitals. The Department of Military Hygiene treats of the important subjects of pure air and how to secure it; of water and its impurities and the dangers of disease therefrom; of sewage disposal and drainage; of healthy sites for and sanitary construction of barracks and hospitals; of food, exercise and clothing; of sanitary jurisprudence and quarantine, and of vital statistics and death-rates as indicative of the health of a community. In the Department of Military Medicine are considered the diseases caused by massing men together or those most apt to affect troops in barracks, on the march and in camp, in peace and in time of war; their causes, symptoms, treatment and mode of prevention. Since we all know that disease kills more than the sword, even in war, the importance of this branch is evident. The instruction in the Department of the Duties of Medical Officers is in some measure complementary. It is designed to give the young medical officer such knowledge of and familiarity with official forms and ways of doing Army business that he may apply his professional knowledge to the best advantage. Military administration is a highly organized and nicely adjusted machine, and special knowledge is necessary to its effective working. In this department the student officer is in the first place taught the necessity for and the requirements of military discipline and subordination as the foundation of his efficiency and success, and his relations to the commanding and other officers. He is taught, both theoretically and practically, how to examine recruits; how to examine into and report upon the sanitary condition of his post or camp; how to conduct sick calls; how to make out the certificates for discharge, especially in reference to the question of pension; how to care and account for public property; how to govern, provide for and instruct the men of the Hospital Corps detachment under his immediate command, with many other matters that need not be enumerated. The instruction given is distinctly practical and includes the making out of many papers."

The Laboratory courses from their practical character and the considerable time given to each, as we shall see, are of special prominence and importance. The course of Sanitary Chemistry, after preliminary work necessary to familiarize the students with principles and methods, took up the detection of poisons, such as arsenic in organic mixture, wall papers, etc., of antimony, mercury and lead; the analysis of the fluids of the body; the chemic examination of the

air and results of ventilation; the study of water and its impurities and their detection; the purity of articles of food, such as milk, butter, cheese, flour, baking powder, etc., and the study of important toxic animal and vegetable products. The instruction in the Department of Clinical and Sanitary Microscopy is entirely by laboratory demonstration and work. Here the student officer is made to become familiar with the use of the microscope in its important application to histologic and pathologic and diagnostic work and the technique necessary for the study of diseased tissues and of pathogenic organisms. A systematic study of the more important bacteria follows, such as the bacilli of anthrax, of typhoid fever, of tuberculosis, of diphtheria and of tetanus; the pyogenic cocci, the micrococcus of pneumonia and the spirillum of Asiatic cholera. In each case the forms and conditions of growth of these bacteria are carefully studied with a view not only to their recognition but to an understanding of the best methods of excluding them or arresting their production. Perhaps it is proper to say here to our non-medical friends that the day when bacteria were a scientific curiosity and their study a pastime or fad has passed. The investigation of these microscopic organisms and their effects lies at the very foundation of modern medicine and surgery, and of advanced medical and surgical practice. In this direction lies to-day our strongest hope and brightest prospects of preventing and arresting disease. Inflammation has been studied under the microscope as it actually occurs in various tissues when artificially produced; then the microscopic appearances as they occur in various diseases and various organs.

The Instructor in Hospital Corps drill has given the Student Officers important practical lessons in first aid to the sick and wounded in emergencies and on the battle-field, such as arrest of hemorrhage, application of splints, etc., and in the careful handling of patients in the litter and ambulance drill. The students are required not only to do these things themselves but practiced in giving directions to the men of the Hospital Corps in the performance of this work.

It will, I think, be conceded that the Student Officers have not been idle this winter. The daily exercises have been as follows: Work in the pathologic laboratory from 9 to 12; in the chemic laboratory from 1 to 3; lecture in one of the various courses from 3 to 4; on Saturday instruction in litter and ambulance drill and first aid in the field at Washington Barracks, at 9 o'clock and in riding at Fort Myer, Va., at 11 o'clock.

The School has been favored with several short courses of lectures by gentlemen not officially connected with it, which have been of great interest and value to the class: On Military Law by Major G. B. Davis, Judge Advocate, United States Army; on Comparative Anatomy, by Capt. J. C. Merrill, Medical Department, United States Army; on Medical Jurisprudence, by Dr. Robert Fletcher, F. R. C. S.; on Parasites of Man, by Dr. C. W. Stiles of the Agricultural Department; Professor W. W. Keen of Jefferson College, Philadelphia, has also delivered a most interesting and instructive lecture before the class on Recent Advances in the Surgery of the Head.

The thanks of the School are due these gentlemen for their kind help.

Five newly appointed Medical Officers have taken the entire course and four Assistant Surgeons of some years service have taken such part as their duties allowed. The Faculty have been much gratified by the interest and industry shown by the class. None have been absent from any exercise without cause, so far as reported to me. It should be noted that the newly appointed officers entered the School immediately after passing the severe ordeal of a long examination for which they had been preparing and were hardly in a condition to enter on four months more of hard work.

In conclusion I am directed to report the result of the examinations and to announce that the relative standing of the members of the class is as follows:

Assistant Surgeon D. C. Howard,
Assistant Surgeon A. S. Porter,
Assistant Surgeon W. H. Wilson,
Assistant Surgeon W. W. Quinton,
Assistant Surgeon T. S. Bratton.

Professor Osler of the Johns Hopkins University, was then introduced and delivered an admirable address to the class. After congratulating its members on their success he said he thought it fitting that the Surgeon-General should have invited a civilian to speak to them of their privileges. Knowing the difficulties and annoyances of civil practice he could the better appreciate and demonstrate to them the advantages of the life they had chosen for themselves. Prominent among these was the great advantage they had, not only over civilian members of the profession but also over their own predecessors in the Army, in being graduates of the Army Medical School, and thereby fully equipped to deal with whatever might come to them in the way of duties or responsibilities. He then spoke of the facilities possessed by Army medical officers for advancing many of the allied branches of medicine. Who, for instance, has a better opportunity to study the vegetation of the country than a young medical officer who sees every part of the United States during the course of his service? Army practice gives self-reliance. Stationed at a Western post without facilities for consulting any one older and more experienced than himself he has to call up the best of his own resources, and learns how needful it is to be prepared for all emergencies and to be independent of assistance. The varied character of the practice that comes under the eye of the Army surgeon tends to give him a place in the front rank of the profession. If of studious habits he can, when in the South, inquire into the etiology of malarial fevers and hematuria; or, while in the West, throw some light on the causation and treatment of mountain fever or study the effects of altitude on the capacity of the chest. Professor Osler then reminded them that many of their predecessors had achieved prominence by their contributions to medical literature or their original investigations, instancing Dr. Beaumont in earlier times, and Drs. Woodward and Smart more recently. In conclusion he cautioned the young officers not to hold themselves aloof from their confrères in civil life, but to join the medical associations, be present at their meetings and make friends in the profession.

Colonel Alden then introduced General Schofield, who conceived that little had been left for him to say, as the advantages possessed by the young Army medical officers had been so well shown in the admirable address just delivered. He congratulated

both the students and the Faculty on the work accomplished during the session. The need of a school of this kind had been felt for a long time, and the present Surgeon-General had done an excellent thing in inaugurating it. He desired to impress on the young officers the importance of their position in Army. The medical officer, he said, was more intimately associated with the line than the members of any of the other staff corps; but this they would soon learn, for they could not be an hour at any military post before they would be made to feel perfectly at home. He closed with a few remarks on discipline and obedience to orders, calling attention to the fact that a commanding officer in issuing his orders has at heart only the welfare of all under his command.

The young men were then introduced to the General and a kind of informal reception was held in the Hall, after which a visit of inspection was made to the lecture rooms and laboratories of the School.

In the evening a reception was given by Surgeon-General Sternberg at which the members of the class became acquainted with many officers of their own and other Corps of the Army.

LEGAL REQUIREMENTS FOR THE PRACTICE OF MEDICINE IN THE UNITED STATES.

[Compiled for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.]

So many changes have been made in the legislation regulating the practice of medicine in this country during the past three years, that the Illinois State Board of Health will include, in its forthcoming Report on Medical Education, the text of all laws on this subject in force at the beginning of the present year in the several States and Territories of the United States, and in the provinces of the Dominion of Canada. From this forthcoming Report, through the courtesy of the Secretary of the Board, Dr. J. W. Scott, some data have been gathered which will be of interest to the spring crop of new graduates, and to medical men generally.

Of the six New England States, Maine, Massachusetts, New Hampshire and Rhode Island have no legal requirements for the practice of medicine. Connecticut has adopted a medical practice act which went into effect Oct. 1, 1893, and in Vermont the law requires the registry of a diploma indorsed by a Board of Medical Censors or of a certificate of satisfactory examination by one of these Boards.

Exclusive of the four States first named, the other States and Territories may be roughly grouped into the following three classes:

In Alabama, Arkansas, Florida, Maryland, Minnesota, Mississippi, New Jersey, New York (act of May 9, 1893), North Carolina, North Dakota, Pennsylvania (after March 1, 1894), South Dakota, Texas, Utah, Virginia and Washington, the diploma confers no right to practice and has no legal value, except, in some cases, to give its possessor standing before an examining board. The right to practice in each of these sixteen States is determined by individual examination before boards of examiners created by law.

In California, Colorado, Connecticut (since October, 1893), Delaware, Illinois, Iowa, Kentucky, Louisiana, Missouri, Montana, Nebraska, New Mexico, Oklahoma, Oregon, Tennessee, Vermont and West Virginia, the diploma is subject to the supervision of some designated body vested by law with

authority to determine its validity as evidence of its possessor's qualifications for the practice of medicine. Failing the possession of such a recognized diploma, the right to practice may be acquired by passing a satisfactory examination.

In Arizona, Georgia, Idaho, Indiana, Kansas, Michigan, Nevada, Ohio, South Carolina (since the repeal of the Act of 1888), Wisconsin and Wyoming, the presentation of any kind of a diploma—provided only that it be from a "chartered" medical institution—is the sufficient warrant in law for county clerks, clerks of courts, registrars of deeds and similarly qualified judges of medical fitness to admit to practice.

Following is a résumé of the legal requirements for practice in each State and Territory of the United States, in force Jan. 1, 1894:

Alabama.—A certificate of successful examination by the State (or a county) Board of Medical Examiners. Diplomas confer no right to practice.

Arizona.—Registry, with a county recorder, of an unrevoked, uncanceled "diploma regularly issued by a medical college properly and lawfully organized under the laws of the State wherein said college shall be located."

Arkansas.—A certificate of successful examination by the State (or a county) Board of Medical Examiners. Diplomas confer no right to practice.

California.—A certificate issued on the diploma of a college in good standing or upon a successful examination by one of the State Boards of Medical Examiners—regular, homeopathic or eclectic.

Colorado.—Similar to California, except that there is but one State Board of Medical Examiners.

Connecticut.—A certificate of registration of the diploma of a college "recognized as reputable by one of the chartered medical societies of the State," regular, homeopathic, eclectic; or a certificate of satisfactory examination by a committee appointed for the purpose by the State Board of Health.

Delaware.—A certificate based upon the registration of a diploma from "a respectable medical college," or upon "a full and impartial examination by the State Board of Medical Examiners."

District of Columbia.—Nominally the indorsement of a diploma, or an examination, by a committee of the District Medical Society; practically no requirement.

Florida.—A certificate of satisfactory examination by the State (or a district) Board of Medical Examiners. Diplomas confer no right to practice.

Georgia.—The registration of a diploma from any "incorporated medical college, medical school or university." The clerks of the Superior Courts are the sole judges of the value of the diploma as evidence of fitness for medical practice.

Idaho.—The record of a diploma at a county seat.

Illinois.—A certificate issued by the State Board of Health upon the diploma of a legally chartered medical institution in good standing as determined by the Board, or upon a satisfactory examination by the Board.

Indiana.—The registration, in a county clerk's office, of a diploma "from some reputable medical college."

Indian Territory.—*a.* Cherokee Nation: An examination by the Board of Medical Examiners; *b.* Choctaw Nation: A certificate based upon a diploma or upon an examination by the Board of Medical Exam-

iners; *c.* Creek Nation: Payment of \$25 annually as a license fee.

Iowa.—Similar to Illinois.

Kansas.—The registry of a diploma from "some respectable school of medicine," or of a certificate of qualification from some State or county medical society.

Kentucky.—A certificate from the State Board of Health issued upon the "diploma of a reputable and legally chartered medical college."

Louisiana.—The record of a diploma from "any medical institution of credit and respectability" after indorsement by the State Board of Health.

Maine.—No legal requirement. In 1887 an act to regulate the practice of medicine was passed by the Legislature but was vetoed by the Governor.

Maryland.—A certificate issued upon a satisfactory examination by the State Board of Medical Examiners. Diplomas confer no right to practice.

Massachusetts.—No legal requirement.

Minnesota.—Similar to Maryland.

Mississippi.—Similar to Maryland—except that the examination is made and the certificate issued by the State Board of Health.

Missouri.—Similar to Illinois.

Montana.—Ten years of practice; a certificate upon the diploma of a college "in good standing," or upon an examination by the State Board of Medical Examiners.

Nebraska.—A certificate issued by the State Board of Health upon the diploma of "a legally chartered medical school or college in good standing," as defined in Section 8 of the Act of July, 1891.

Nevada.—The record of a diploma from "some regularly chartered medical school."

New Hampshire.—No legal requirement.

New Jersey.—A license issued upon a successful examination by the State Board of Medical Examiners. Diplomas confer no right to practice.

New Mexico.—A certificate upon the diploma of a legally chartered medical institution in good standing, or an examination by the Territorial Board of Medical Examiners.

New York.—A license issued upon a successful examination by one of the State Boards of Medical Examiners—regular, homeopathic, eclectic. Diplomas confer no right to practice.

North Carolina.—A license issued upon a successful examination by the State Board of Medical Examiners. Diplomas confer no right to practice.

North Dakota.—Similar to North Carolina.

Ohio.—The diploma of a respectable school of medicine, or a certificate of qualification from a State or county medical society.

Oklahoma.—A license issued by the Superintendent of Public Health upon a medical diploma or after examination.

Oregon.—A certificate on the diploma of a college "in good standing," or after examination by the State Board of Medical Examiners.

Pennsylvania.—A license issued after examination before one of the State Boards of Medical Examiners: Act of May 18, 1893; takes effect March 1, 1894. Diplomas will thereafter confer no right to practice.

Rhode Island.—No legal requirement.

South Carolina.—A certificate of verification of the diploma of a reputable medical college. An Act of Dec. 24, 1890, abolished the State Board of Medical Examiners created by the Act of 1888 and under

which the diploma conferred no right to practice.

South Dakota.—A license issued by the State Board of Health after examination. Diplomas confer no right to practice.

Tennessee.—A license on the diploma of a college "in good standing," or after examination by the State Board of Medical Examiners.

Texas.—A license issued after examination by a District Board of Medical Examiners. Diplomas confer no right to practice.

Utah.—A license issued by the Territorial Board of Medical Examiners after examination. Diplomas confer no right to practice.

Vermont.—The registry of a diploma indorsed by one of the Boards of Medical Censors, or a certificate of examination by one of the Boards.

Virginia.—A license issued after examination by the State Board of Medical Examiners. Diplomas confer no right to practice.

Washington.—Similar to Virginia.

West Virginia.—A license on the diploma of a reputable college, or after examination by the State Board of Health.

Wisconsin.—The indorsement of a medical diploma by the censors of either of the State or county medical societies.

Wyoming.—The record of a diploma with a registrar of deeds.

SOCIETY PROCEEDINGS.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 315).

DR. KELLOGG then read in abstract a communication from DR. GEORGES APOSTOLI of Paris, France.

I have received from Dr. Apostoli of Paris, a somewhat voluminous paper entitled, "Du Courant Alternatif Sinusoïdal en Gynécologie," by Mina Kaplan-Lapina, which gives a full account of thirty-four cases treated by the sinusoidal current by Apostoli, the treatment being begun before July, 1892. Since that time, Dr. Apostoli has applied the current in the treatment of sixty additional cases, the results of which have not yet been reported. Dr. Apostoli requested me, in a letter recently received from him, to present before this Society an abstract of this paper. The paper consists of 134 large pages of printed matter, so that anything like a complete abstract would be impossible, but I herewith present the following translation of the conclusions drawn by the writer of the paper from the observations recorded:

"In reading the thirty-four observations recorded, one recognizes very readily many weak points which it is sufficient simply to indicate. Some of these observations are incomplete, or without clinical value, by reason of the premature interruption of the treatment. In some cases the treatment was applied too infrequently, so that all benefit received was lost in the interval between the treatments. In other cases the treatment was not sufficiently vigorous, the application was too short, the number of alternations insufficient, or the voltage too low. I have presented the entire series of cases just as they were, since if some of them are without individual value, they form altogether a total which brings conviction, especially from the point of view of the innocuity of the method.

"In order that the new method should become popularized, it is first of all important that it should be studied with the most rigorous exactness.

"It is necessary that failures as well as successes should be known to all in order that each may be able to judge of the facts. At the beginning of the employment of new

methods choice is impossible, and the remedy must be applied imperatively, if one begins by treating uniformly all cases, even the most unlike. At Dr. Apostoli's clinic he has applied the remedy at first to all patients who have presented themselves, whether suffering from fibroma or lesions of the appendages, applying the new method uniformly; naturally the result has been variable, these variations have been closely observed, and have made it possible to make a selection of cases which was at first impossible.

"I can not do better, in closing, than to quote the following from the resumé of a communication presented by Dr. Apostoli at the International Congress of Gynecology at Brussels, September 15, 1892.

"The alternating sinusoidal current which M. D'Arsonval has introduced into electrotherapy is useful in gynecology, and the following are the general results of this new therapeutic agent:

"In five months, from March to August, 1892, thirty-four patients in my clinic, comprising twelve cases of fibroma and twenty-two cases of appendages, have been treated by the alternating current. In all these cases the application has been the same, one pole in the uterus and the other upon the belly. The duration of each seance was five minutes; the applications have been made two or three times a week.

"The rate of alternation has been varied according to the circumstances, or rather according to the sensibility of the patient, between a minimum of 4,000 to 6,000 and a maximum of 11,000 to 12,000 per minute.

"The apparatus which I have employed is the first model constructed by Gaiffe, which consists of Clark's magnetofaradic machine modified and transformed by D'Arsonval, going with great speed a maximum difference of potential of sixty-four volts, and with moderate speed a difference of thirty-two volts. This apparatus has been propelled by the pedals of a sewing machine. All my thirty-four patients have been carefully observed, and the following are the general conclusions which may be drawn from this initial period of treatment; conclusions which appear to be not yet entirely definite by reason of the imperfect character of the instrument employed, and the relative brevity of the experiments:

"1. The alternating sinusoidal current applied in the intra-uterine cavity, and in the conditions under which I operate, is always well borne and free from danger.

"2. Its application is followed by no painful or febrile reaction, and is, on the contrary, generally accompanied by manifest sedative effects.

"3. It appears to have no marked action upon hemorrhage as a symptom, but sometimes has a tendency to prolong this symptom.

"4. It exercises a very decided effect upon the symptom pain. This action was noticeable from the very first seance, and most often immediately at the end of the seance.

"5. It is a useful remedy in the treatment of leucorrhœa which under its action often diminishes or disappears.

"6. It has no appreciable effect upon hydrorrhœa or fibroma in certain cases.

"7. Its influence upon anatomic retrogression in cases of fibroma has not yet been clearly established.

"8. It increases the resolution of peri-uterine exudates."

The discussion was further continued by a paper on

FURTHER STUDY OF ELECTRO-ANESTHESIA AND FREQUENCY OF INDUCTION VIBRATION.

By WILLIAM F. HUTCHINSON, M.D., of Providence, R. I.

Read in the absence of the author by Dr. W. H. Herdman. Since I had the honor to lay before the Fellows of this Association, at the last annual meeting in New York, the results of experimentation in producing induced current vibrations of extreme rapidity and in counting them accurately, by means of comparison with musical tones, have been still encouraging. By means of one of Cook and Read's standard pitch pipes, which gives a double octave complete by turning a movable arm, more precision in count has been attained than was possible with any tuning fork, which could only give tones and half tones without musical interval. This greater accuracy of computation of wave lengths has led to confirmation of my previous idea, that it is necessary to have exactly a certain number of vibrations per second to produce the effect sought, viz: local anesthesia,—that a greater number increases pain; a lesser is without effect.

And it led to further studies which I am now to lay before you, whose upshot has convinced me that the reason, the cause of production of electric anesthesia, must be sought in that principle of mechanics termed "the superposition

of small motions." Since this may not be quite familiar to all, permit me to illustrate by imagining a slender wire such as a piano string, fixed at both ends, and stretched so that its tension greatly exceeds its weight.

Now let us see what happens when a small transverse disturbance in a single plane is imparted to this wire:

When one fixed end is reached by this wave, it is reflected along its path and back again until the filament is brought to rest by gravity, friction, etc. During these passages to and fro, it is found that a certain space upon the wire remains permanently at rest—is dead, so to speak, and that this space is about the middle of its length. Wave after wave passes through it as long as the original impetus or any new one lasts but, being of precisely equal lengths, neutralize each other at the dead point, where rest reigns.

It is in this way that I conceive electric anesthesia is created and maintained; only replacing the reflected wave on the wire by efferent impulses along the nerve whose tract of supply we seek to influence. And so it is seen that these two elements, the electric wave and that of the nerve, must be exactly alike, or no dead point—no anesthetized space, can occur. Now, to produce a reflex change in the nerve center a summation or addition of centripetal excitation is required, and when these reach a certain number, the center responds (Stirling).

Reflex actions require time. It takes a certain division thereof for a note of pain to reach the center and its sensory mandate to return, and if this be measured, taking into account how much is occupied by the passage of the nerve current along the nerves involved and the latent period of muscular contraction, and subtract this from the total time, the remainder will represent the time occupied by the changes in the center, or the reflex time. This has been found to vary from .0555 to .0471 of a second (Helmholtz). If these calculations of the physiologist are correct, it will follow that just as many vibrations must be imparted to a sensory nerve, inward bound, as are proceeding outwardly upon it, in order that a dead point, a zone of anesthesia, may be created.

To my satisfaction, this calculation corresponds closely to results reached by the singing rheotome. You will perhaps recall in my account of former experiments how, when the speed of the ribbon ran above a certain number of vibrations per second, pain was rather increased than lessened, and no anesthesia followed even prolonged applications. The speed then found useful was that of major C—or about 540 vibrations per second. Allowing for small variations of speed of nerve transmission in different persons, the rate of electric wave and that of nervous impulses is seen to be identical, thus proving, to my mind, that pain is simply a mechanical expression of disturbed energy, to be destroyed, at least temporarily, by such foreign vibratory action as will restore rest to a part of the path along which it moves.

And, since all morbid conditions of the body alter the rate of transmission of nerve impulses, it will be found necessary to ascertain accurately this rate before applying electrodes to painful spots, or an extraordinary increase of sensibility will follow. It is, however, a simple matter to do so by placing small electrodes along the course of any unaffected nerve trunk, like the median, and running up and down the scale with the ribbon, keeping within a tone of major C, until a tingle and subsequent numbness is felt in skin tracts supplied by said trunk. That sound means as many vibrations, may be read from a scale, and is the normal rate of nerve impulses in the case in question.

Sometimes I find this normal rate locally interfered with, as in a felon or carbuncle, when high inflammation has increased its speed; but as a rule for practice, the above is pretty safe to follow.

Perhaps some of the difficulties and failures I have experienced during the last year's work with the singing rheotome have been due to imperfect comprehension and unskillful application of the law.

I have found no cause to change my instrument, although Mr. Louis Downs, expert electrician, devised a plan whereby, by altering the extent of a magnetic field about a horse-shoe magnet, he obtained a note at least two octaves above any that I had been able to get, and it seems to me at present that it is sufficient to maintain the rate rather than seek for higher speed. Yet it is possible that the same tone an octave higher may do better work by producing anesthesia more rapidly, or extending its area, which still is restricted in my hands to a space scarcely longer than the electrode. I propose to use Mr. Downs' apparatus in a series of experiments later.

(To be continued.)

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 63 WABASH AVE., CHICAGO, ILLINOIS.

F. J. REBMAN, LONDON AGENT, 11 Adam Street, STRAND, LONDON.
W. H. LOWDERMILK & CO., WASHINGTON, AGENTS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, MARCH 10, 1894.

INTERNATIONAL SANITARY CONFERENCE.

Through the London *Standard* several days ago the intimation was made that the American delegates to the International Sanitary Conference, now in session in Paris were not in sympathy with the other delegates with regard to relaxing quarantine regulations to prevent the spread of cholera, and at the same time hinting that they were obstacles to the work of the Conference, and that it was a Conference of European Health Authorities, and that legitimately they had no business there.

At the Conference held at Venice about a year ago, to which the United States was not invited, there was a proposition to relax quarantine, and a number of the countries represented then were favorably inclined, France, though, still insisting on some kind of quarantine. Another Conference was held later at Dresden, when all agreed that were then present except Russia, Turkey, Greece and Spain. It was, however, found during the summer, that when threatened with cholera nearly all resorted to some kind of quarantine. England has for years been opposed to quarantine mainly from commercial reasons, and no doubt also to the fact of less liability to certain epidemics that affect the Continent, especially that portion bordering on the Mediterranean. It was also agreed at Dresden that whenever cholera made its appearance in any country, notification of the same should be given to the other members of the Conference. This agreement was not always carried out promptly, lest it might injure the business interests of the country or place.

The commercial aspects of an epidemic are more jealously guarded by the different countries of Europe, than by the different States in this country. The following cablegram explains itself, and is cor-

roborative of the intimation contained in the *Standard*:

PARIS, Feb. 27.—Several Paris newspapers remark with surprise that the United States delegates to the International Sanitary Conference oppose every proposal to relax quarantine restrictions, and support all measures tending toward more exacting regulations of immigration. The delegates from other powers are said to have become convinced that the American representatives wish to use the resolutions of the Conference as means of repressing emigration from Europe to America.

It is to be hoped that our delegates will insist that when cholera prevails in a country or place, that no immigrants be sent to the United States from the same. Cholera has always been introduced into the United States through the steerage, and the experience of the past shows how important this is to us. The conditions that obtain here are entirely different from what they are in Europe, especially when it is borne in mind what an important factor the steerage is, in the development and propagation of disease.

In the summer of 1892, Hamburg received immigrants from cholera infected districts of Russia, and fearing that the disease might break out in that city made arrangements to lodge them outside of the limits, and from there to send them direct to the steamer for shipment to the United States. It made no difference to Hamburgers how and where the disease was spread, but Fate decreed otherwise, and even after the cholera made its appearance in Hamburg, it was not announced until after eighteen days. Other instances, showing the cupidity of steamship companies and of cities occurred that summer.

In 1893 Naples for a time denied the presence of cholera in that city so that immigrants should be allowed to leave that city for this country, although the immigrants came from different places in Italy where cholera existed. In one instance they were inspected and supposed to be all right, when a few days after the departure of the steamer cholera broke out, and about the same time the Marine Hospital Inspector accidentally discovered that a number of cases had died of that disease in that city and fresh cases were occurring daily.

There is no more striking illustration of the disposition of steamship companies, than in the case of the steamer that left Genoa with 450 immigrants collected from places in Italy where cholera was prevailing, for Rio. Possibly there may not have been cholera in Genoa at the time, but not long after the departure of the steamer the disease was acknowledged to be there. Soon after sailing cholera broke out on the steamer, and before Rio was reached 150 cases and 70 deaths occurred. The steamer was not allowed to land, and on its return to Genoa, stopped at the Island of Teneriffe for provisions and water. As the result of being allowed to land, cholera was introduced into the Island, and before the epidemic was ended over one thousand died. In addition to the suffering of those on the steamer, the loss of life on the Island, and the horrors incident to such an epi-

demic may be justly attributed to the selfishness and cupidity of the steamship company.

Our delegates are right in trying to secure such safeguards, as will prevent the introduction of cholera into this country by immigrants. The more we impress the European authorities that this country will not permit them to do as they please in this matter, the more care will be exercised, if not from humane, from financial reasons. It is also claimed by some that there will be no danger from that source the coming summer. How do they know? This pandemic of cholera is not yet over in Genoa, and at this time recrudescence of the disease is occurring at a number of places, while at the same time it must be borne in mind that there are countries and places where cholera has not yet appeared during this visitation.

ARMY MEDICAL SCHOOL, NETLEY, ENGLAND.

From the *Lancet*, of February 10 we learn that on January 31 the sixty-seventh session of this School was brought to a close. This School was established a few years after the Crimean war to remedy deficiencies in the education of the medical graduates selected by competitive examination for service in the Army. The results of the recent examinations held in the School were read by Brigade-Surgeon J. LANE NOTTER in the presence of a distinguished company, including SIR ALFRED LYALL, SIR JOSEPH FAYRER, SIR THOMAS LONGMORE and others. The marks gained at the competitive examination for admission as the approved candidate are added to those resulting from the work done at Netley, and the commissions and rank of the graduates are determined by the combined numbers. Eleven candidates were approved for the Army Medical Service and twelve for the Indian Medical Service.

After congratulating the prize winners on having scored their first public success, SIR ALFRED LYALL in a felicitous speech reminded the young officers that the prizes of the world were before those who had not taken premiums, as well as before those who had lately proved themselves so successful. Success put good spirits into a man and sent him into the world with good hopes and with a well-merited degree of confidence in himself. He said he felt sure it was not necessary to warn the prize winners not to take away too much of this confidence. Though it was an excellent thing to have won prizes, prizes were not everything in life, and an examination did not test those very high qualities which come in with such effect later—qualities which formed the main-spring of professional success—judgment, activity and accuracy in thought and action. The whole history of professional career showed that those who had not won prizes were often later on in life very formidable rivals of those who had. He observed

that although the word, "luck," was an element in the success of many, yet the word formed by the prefix of a "p" would have far greater influence on the careers of those listening to him, and he reminded his hearers that no less than three officers of the service had of late been awarded the Victoria Cross for bravery in Burmah. In addressing the Indian officers he spoke of the immense field open to them, not only in the medical department of the army in India, but also in the civil departments in the goals and sanitary service. In speaking of the width of field he mentioned the names of distinguished officers of the Indian Medical Service who had been led away from medical work to become administrators and ambassadors. He advised all the officers of both Services, when in India, to cultivate the friendship of the natives, to get to know and understand them, for they were worth knowing; and to study their languages, their religions and their prejudices. In wishing the young officers prosperous careers he spoke to them of the preservation of their health, and reminded them that good health means steady nerves, and steady nerves power at critical times—power to cope with difficulties and to pass through times of stain in such a way that in future years such moments could be remembered with pleasure and satisfaction. He hoped that the young officers would ever do their duty in the spirit of men who remembered that they had in trust the reputation of England and the character and traditions of high and noble services.

SIR JOSEPH FAYRER spoke of the pleasure which he always felt in the opportunities accorded him of addressing a few words to the young officers before they left the Netley School. He said that he did not consider that they need much fear the Indian climate, for although epidemic diseases were common and severe in India, the influenza, pneumonia and bronchitis of this country were almost as much to be dreaded. He spoke of the enormous field of research open to the young officers of both Services; he reminded them that medical science was still in its infancy and that they should go to India and other parts of the world with unbiased minds ready to observe, record and discover. They left the Netley School splendidly equipped and in every way fit to go to India and other foreign stations and build up the science of the future. He also spoke to them of the preservation of their own health in tropical climates. He wished them good health and good fortune, and hoped that they might one and all some day revisit Netley.

Surgeon-Major-General BROKE-SMITH addressed a few words to the company, thanking SIR ALFRED LYALL for his kindness in coming to Netley to distribute the prizes and for the admirable address which he had delivered. The ceremony was brought

to a conclusion by a few words from Brigade-Surgeon-Lieutenant-Colonel NOTTER, in which he wished the young officers Godspeed. The company was afterwards entertained at luncheon at the Army Medical Staff mess.

PATHOLOGIC LESIONS IN INSANITY.

The pathologic anatomy of insanity in its simple, acute and so-called partial forms is yet largely a matter of conjecture. We have, it is true, the stigmata of degeneracy in the hereditary types and the congestion of mania and the ischemias attending many cases of melancholia, but these are not constant or even so frequent as for their occurrence to be considered the rule. In a very large proportion of the cases of acute insanity we are forced to fall back on the assumption of microscopic changes as yet beyond the scope of our powers of observation, or to assume as might, perhaps, be done in accordance with the later pathologic theories, a toxic action directly on the brain. The phenomena of simple insanity, mania, melancholia, and the so-called primary dementia, are not altogether inconsistent with the hypothesis of a toxine, but it will probably be a long time before the theory of such an origin will receive general acceptance. The difficulty of this hypothesis is a little greater with the systematized insanities, even those that are most purely psychoneurotic rather than degenerative in their nature. Still, even here, there are facts that may be held to support it, e.g., alcohol, which produces acute delirium and sometimes mania also gives rise to a characteristic paranoia. It is not unjustifiable to suppose, therefore, that a toxine which may in certain quantity overwhelm the nervous system and produce generalized derangement, may under other circumstances and in what we may call a continued dosage, bring about a condition of chronic partial alienation.

To those, however, who wish to hold to the theory of microscopic changes in the brain, the comparatively recent researches in the minute anatomy of the nervous system by RAMON Y CAPAL, KÖLLIKER, VAN GEHUCHTEN and others, may afford some suggestions. GOWERS, and more recently FERRIER, have emitted the supposition that derangements of the terminal end brushes of the spinal nerves may account for certain spinal diseases, Landry's paralysis for example, the pathology of which has thus far eluded our search; and TANZI, in a review of the recent progress of research in the anatomy of the nervous system, has suggested that the perfection or otherwise of contact, or rather contiguity, of these processes to the nerve cells will account for the facts of consciousness and mental capacity. According to his theory he accounts for certain actions, once conscious and labored, becoming unconscious and automatic, by the supposition that the contiguity of the

nerve fibrils to the cells has reached its maximum and thus affords the least possible interruption or hindrance to the nerve wave, and by the same method of reasoning he explains the various degrees of individual capacity for different kinds of work. It is not possible to give here his line of argument, but it is not difficult to see how it will apply to psychic derangements, and while the idea is purely hypothetical, it yet comes within the legitimate range of the scientific uses of the imagination. It suggests an interesting though rather difficult line of microscopic research which may or not be fruitful of results.

CHOLERA.

A recent cable from Athens says that it is learned from official dispatches that cholera has reappeared in Constantinople. A dozen deaths from this disease have recently occurred, chiefly in the barracks. It is believed that the authorities are hiding facts which would show the wide extent of the epidemic. A Berlin cable of February 27, says that a dispatch from Wundsbeck, three miles from Hamburg, says that two cases of supposed cholera have been found in the Poolstrasse in that town, and that the patients have been removed to the hospital. It is to be hoped that our delegates to the Conference at Paris will insist that when cholera does occur in a country, immigrants from that country shall not be sent to this country. The experience of the past has shown how important this question is to us. The conditions that obtain here are decidedly different from those in Europe; at the same time it must be borne in mind what an important factor the steerage is in the development and propagation of disease. During the past summer immigrants were hurried on board ship and not allowed to remain in ports, when the local authorities and the steamship companies knew that they came from infected localities, and how often.

YELLOW FEVER.

The presence of yellow fever at Rio Janeiro and the unusual conditions incident to the siege that obtain there, will not alone cause the quarantine authorities of the Gulf and South Atlantic ports, and the Marine Hospital Service to be on their guard, but also the Medical Department of the Navy. Already cases are reported on the *Newark*, and there is no telling when others will occur in the other vessels at that station. Yellow fever is said to be increasing, and the sanitary condition of Rio is very bad. The *Newark* has been sent further south where lower temperature prevails, others sent to sea, and every possible precaution is taken to prevent communication with the shore by the crews of those that remain. We shall watch with much interest the effort to purify, and prevent the spread of the infection on the *Newark*.

It is the first time for a number of years that the disease has appeared on a vessel belonging to our Navy, so early in the season.

The last number of the JOURNAL contained the recommendations given by a committee which had been appointed by the Conference of Gulf Quarantine Authorities, held in New Orleans, Feb. 2 and 3, 1894, with regard to the regulation of the fruit trade during the quarantine season. The recommendations differ slightly from the regulations of the Treasury Department, and the Conference asks that the regulations of the Treasury Department be so modified as to coincide with the views expressed by the Conference. The recommendations will no doubt receive due consideration, as Drs. Cochran, Patton and Hargis (the Committee) are old and experienced yellow fever experts, in fact none better living, and personally and officially interested in protecting their respective States from yellow fever.

RIGHT OF A STATE TO SUPPORT ITS INSANE IN PRIVATE ASYLUMS.

The Supreme Court of Missouri holds constitutional, in a decision rendered Dec. 23, 1893, in the case of State v. Seibert, State Auditor, section 8 of the Act of the Legislature of that State approved April 1, 1893, appropriating "for the support of the indigent insane in the insane asylum of the city of St. Louis, who belong to the State outside of the city of St. Louis, fifty thousand dollars, (\$50,000), which sum shall be paid upon the requisition of the treasurer, indorsed by the mayor of the city of St. Louis and approved by the Governor, in equal monthly installments." If the appropriation had been made for the support of the insane asylum of St. Louis, the court says there could be no doubt of its unconstitutionality, for the latter is indisputably a private institution, belonging to and controlled by the city, and the State constitution expressly forbids the Legislature making any grant of public money to any individual association, municipal or other corporation whatever. But while, regardless of constitutional restrictions and limitations, a Legislature has no power to raise money by taxation, or appropriate for purely private purposes, public money may be applied to the support of the insane. A private corporation or individual may be the recipient of the funds of taxation, provided that the use be a public one. And there being no constitutional inhibition against the State dispensing its public charity through the agency of a private institution, the court further says, it can see no reason why the insane of the State, not belonging to the city of St. Louis, who are found in the city, may not be cared for and supported in its insane asylum at the public expense, if it can be as well and economically done. The expediency of providing for their support is a matter that must be left to the discretion of the Legislature.

CONSENT AS A DEFENSE TO DANGEROUS OPERATIONS.

Consent to surgical operations in dangerous cases, where the effect is fatal, is only a good defense to a charge of manslaughter, where the operation is performed with due care and skill. It is no excuse for recklessness or even want of usual skill. So holds the Supreme Court of Washington in the case of State v. Gile, decided Jan. 9, 1894, where a conviction of manslaughter was effected. A number of expert witnesses testified in this case. Some of them were positive that deceased, an old man, died from the effect of a surgical operation performed upon his hip, it was alleged, without his consent, by a physician only employed to reduce a supposed dislocation of the head of the femur by simply pulling the bone into its proper place, while others seemed to think that death might have resulted from some other cause. The condition of deceased's hip at the time of the operation was shown to have been better than it had been for months previously. He was not shown to be suffering from any disease; but it appears that after the operation was performed he never rallied, but, on the contrary, steadily declined, until he died. With all the circumstances and evidence before them, the jury found adversely to the surgeon's contention that the cause of death was not shown beyond a reasonable doubt, and the Supreme Court states that it is unable to say that their conclusion was not supported by the evidence. It is also to be noted that the dying declaration of the patient, that he had been "butchered" by the doctors, it is held, simply meant killed in an unusual, cruel or wanton manner, was not a mere expression of opinion, and was admissible in evidence.

PRESIDENT GARFIELD'S CASE.

We shall begin, in an early issue, the publication of original notes of the case of PRESIDENT GARFIELD.

The late Dr. D. W. BLISS of Washington, would not permit them to go out of his possession during his life time. Recently the heirs of Dr. BLISS turned the record over to Dr. ROBERT REYBURN, who is now the sole survivor of the staff of physicians in attendance.

The notes were recorded at the time by Dr. REYBURN, and have a professional interest which time can not dim.

The melancholy fate of PRESIDENT-GARFIELD was made even sadder by the constant attacks on his physicians through the public press. These attacks were mainly due to misinformation, rather than to jealousy or malice.

Time has softened many of the asperities that were then manifest, and the profession are now quite prepared to give unprejudiced attention to this *cas célèbre*.

CAPTIOUS CRITICS.

We are naturally pleased to see the great interest taken in the articles from time to time published in the *JOURNAL*, but when the editors of other journals pervert friendly interest to carping criticism on what we do not publish, we have a clear right to invite their attention to a homely adage which reads, "*Mind your own business.*" It is with sincere regret that we apply the invitation to the editors of the *Philadelphia Medical News* and the *Pittsburg Medical Review*, but their bad manners in attacking Dr. WOODBRIDGE, a valued contributor, and a worthy member of the ASSOCIATION, for daring to divide his article in two parts; and attacking in savage strain the editor of this *JOURNAL* for presuming to publish the same (also in two parts), seems to show a desire to find fault, as ridiculous as it is senseless.

CORRESPONDENCE.

LETTER FROM EUROPE.

Major Girard, Surgeon U. S. Army, to Professor Senn.
No. I.

WÜRZBURG—JULIUS HOSPITAL—PROF. SCHÖNBORN—DR. HOFFA.
WÜRZBURG, Feb. 13, 1894.

Dear Dr. Senn:—On my arrival in Würzburg I proceeded to the Julius Hospital, where thirty-two years ago I had attended the clinics, and was greatly surprised and pleased that, instead of being directed to the old amphitheater in the main building, I was informed that a new operating room with attendant offices had been constructed in the second court and occupied since 1889. I repaired thither and presented myself to Professor Schönborn, the distinguished operator of this University. I met with the cordial reception usually bestowed upon Americans, especially when provided with an introduction from you. It being the hour for the clinical instruction we proceeded through a large anteroom paved with marble terrazzo to the amphitheater. This room has accommodations for about 200 students; the framework of the seats being of iron, the walls of cement, the floor of cement stone; the whole room can be and is treated twice a week with a powerful stream of water, thus effectually disposing of any accumulation of effete matter. In this respect, as well as in the lighting, it is superior to that of Göttingen. In this latter place a large glass front faces the amphitheater, which is also lighted by a skylight, while in Würzburg the three sides of the amphitheater above the seats and the ceiling are all of glass, providing an excellent illumination. Night operations are lighted by a gas chandelier, which can be raised and lowered. The operating-table is a marvel of ingenuity.

The clinic commenced with presentation of a spindle-celled sarcoma adjoining the knee, a pes valgus, an osteosarcoma of the femur and a fistula in ano. The consulting staff, as you call them, composed of three students of the advanced course, distinguished themselves by very brief answers in a low voice. The Professor excusing himself to me for this exhibition, I suggested timidity, but he bluntly called it ignorance. He operated on the fistula with the greatest care, curetting it after laying it open, carefully searched for possible side channels and then cut off with scissors all the superlying tissues, considering it all tubercular tissues. The usual iodoform gauze packing terminated the proceeding.

A patient was then brought in with a tubercular abscess over the manubrium sterni. After chloroforming an incision was made over the bulging abscess and a large quantity of pus escaped, which apparently had burrowed along the lower border of the clavicle. The whole clavicle was exposed by an incision and a large counter incision made in the axillary cavity, giving passage to an enormous quantity of pus, the origin of the abscess apparently proceeding from the under part of the sternum. This was removed by chisel, gauze, and rougeurs, exposing an extra-pleural cavity in the chest. The Professor indicated where he would incise the internal mammary artery, but found it impossible to seize the violently spurting vessel among the rigid tissues and after long continued ineffectual attempts he had to content himself with plugging the cavity with iodoform gauze and thus arresting the bleeding. I would have felt safer if the Paquelin cautery had been applied, but kept my own counsel.

I am promised for to-morrow by Professor Schönborn a high excision of carcinoma of the rectum, and by Dr. Hoffa, the orthopedist, an operation for congenital luxation of the hip joint.

I met Dr. Hoffa, who is quite well known in the Eastern States from a sojourn there, at his private clinic and was fortunate enough to witness the above operation, which is a specialty of his. He stated that he had made it seventy times with uniform success. I saw a number of convalescent cases with excellent results. A girl of 18, on whom he operated, had one side operated on with good motion. The peculiar lordosis of the unoperated case still existed, but disappeared at once after the second excision. His operation differs from that of Lorenz, by its being made with a posterior incision, which is more suitable for resection of the head of the femur. In very small children, he contents himself with excavation of the acetabulum, while in grown persons, owing to the difficulty of obtaining good adhesion, he saws off the head immediately above the trochanter. In the former operation Lorenz's method is claimed to be preferable, as causing less hemorrhage. This, however, seemed to be very slight even in Hoffa's method. A slightly curved incision about eight inches long parallel with the border of the ilium is carried down to the gluteus maximus which is divided in the direction of its fibers down to the gluteus minimus, which has to be divided transversely. The trochanter being reached its muscular attachments are peeled off beneath the periosteum and the bone sawed through, so that when it is brought into proper position the sawed surface is in exact apposition with the ilium above the acetabulum. The head is then removed and the capsule carefully excised. The periosteum of the part of the ilium, which is to receive the trochanter, is freshened. After careful flushing the limb, from the extreme flexed position maintained during the operation, is extended, the wound packed with iodoform gauze, and the limb placed in an extension apparatus. The operation appears to have obtained favor among the German surgeons, as I saw a convalescent from it at Koenig's clinic.

Dr. Hoffa has a very complete set of orthopedic apparatus, among which those liberating adhesions in joints by means of oscillating weights particularly attracted my attention.

The cases in Professor Schönborn's clinic were first, Rydygier's operation for carcinoma of the rectum. A short description of the operation as performed here may be of interest. A curved incision starts from about two inches of the anus along the left sacro-iliac articulation to the rim of the ilium, and is met by a transverse one along the upper border of the sacrum. The left sacro-iliac ligaments are divided. The sacral nerves of that side are sacrificed. The sacrum after blunt liberation from the soft parts is

tipped over and exposes the rectum. This part of the operation was complicated by severe hemorrhage, which required numerous ligatures. The rectum was ligated after the usual precautions and excised, after which the ovaries and some of the intestines came into plain view. Professor Schönborn is averse to suture of the peritoneum, as it greatly prolongs the operation and increases its dangers. The wound is simply packed with iodoform gauze. For the same reason he prefers bringing down the bowel to the external orifice and stitching it to an incision around the external sphincter, instead of making an intestinal suture. He also believes that in case the sutures do not hold, the disaster with external suturing is not as serious as when the feces escape into the pelvic cavity, between the ends of the bowel. He is not in favor of locking up the bowels, as eventually this brings a great strain to bear from the inevitable accumulation.

The next operation was for mastoid disease of only six weeks standing with otorrhea, which two weeks ago suddenly became arrested, resulting in rise of temperature, tenderness over the mastoid process, headache, etc. An incision parallel to the ear, over the process exposed the bone, which was at once attacked with chisel and gouge. Pus was only reached when the inner table was exposed, which already revealed a perforation and fibrinous deposit on the dura. Every vestige of diseased or infiltrated bone was removed by the gouge, the cavity packed with iodoform gauze and the external meatus filled with iodoform. Professor Schönborn insisted on early operation in all these cases and on its being made thoroughly. The most minute care was taken to preserve asepsis.

I may mention here, that I learned that the arrest of hemorrhage of the internal mammary in yesterday's operation by the iodoform tampon was successful. Professor Schönborn, on inquiry, informed me that he did not believe that the cautery would arrest hemorrhage from such a large vessel and that he had to resort to the tampon because it was impossible to seize and ligate the artery in the dense cicatricial tissues which surrounded it.

My next will be from Heidelberg.

Yours very truly, A. GIRARD.

The Therapeutic Use of the Sulphites.

PARIS, Feb. 19, 1894.

À M. le Rédacteur JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION à Chicago:

Très Honoré Confrère:—Je viens de lire dans votre numéro du 3 février une étude très intéressante, du Dr. Joseph Jones sur les *sulphites et hyposulphites*.

M' e' tant moi-même beaucoup occupé de la question.

Je vous prie de vouloir bien faire parvenir à votre collaborateur le Volume "traitement rationnel de la Phthisis Pulmonaire," qui contient un chapitre important sur la *Médication Sulfitée*.

Cette lecture lui permettra à une prochaine occasion de mentionner mon nom parmi les partisans de la méthode.

Veillez agréer avec mes remerciements anticipés l'assurance de mes sentiments très confraternels.

DR. DE PIETRA SANTA.

[TRANSLATION.]

"I read in your number of February 3 a very interesting study by Dr. Joseph Jones, on the sulphites and hyposulphites.

"I have myself been much occupied with this question. I beg you to bring before your collaborator the book 'Rational Treatment of Phthisis Pulmonalis,' which contains an important chapter on medication by sulphites.

"This reading will permit him on the next occasion to mention my name among the partisans of this method."

[The volume referred to by our distinguished confrère, who is editor of the *Journal d'Hygiène* of Paris, was published in 1875. Chapter VI of this book contains a strong argument in favor of medication by sulphites in cases of phthisis pulmonalis. He cites the monograph of Giovanni Polli (of Milan) 1860-1861, presented to the Royal Institute of

Sciences and Letters of Lombardy. "Sur les maladies par ferment morbifique, et sur leur traitement par les sulfites alcalins et terreux."

Dr. De Pietra Santa says:

"Sulphurous acid has the property of preventing and arresting all the fermentations of vegetable and animal matters. Its association with alkaline bases, as soda, lime and magnesia, far from modifying its manner of action, and destroying its antifermentative action, renders it on the contrary more regular, more energetic, more permanent, and permits the introduction in the organism, with known and ponderable doses, without altering the principles of organic life.

"The perfect innocuity of the sulphites, and their complete tolerance by the organism, in rendering possible the administration (prophylactic or curative) in all the affections produced by a pathologic ferment (virus, contagion, or miasm) as in intermittent or paludal fevers, acute and chronic exanthems, typhoid fevers, and diseases from purulent absorption."—EDITOR.]

Hay Fever.

CHICAGO, March 3, 1894.

To the Editor:—In reply to the question of Dr. F. C. Ewing in the JOURNAL of this date a list of the best hay fever resorts can be obtained by writing to one of the officers of the United States Hay Fever Association, for their last manual—for 1893.

Their addresses are: Hon. Frank B. Fay, Chelsea, Mass., President; Rev. John Peacock, D.D., Holmesburg, Pa., Secretary.

Yours truly, S. S. BISHOP.

No Smallpox in Minnesota.

RED WING, MINN., March 6, 1894.

To the Editor:—Please contradict the report of smallpox in St. Paul. There has been none there this year. The report of students exposed therefore is a mistake. There is none in Minnesota.

CHAS. N. HEWITT, Sec'y State Board of Health.

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Rio Grande Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville, Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland, thence east by way of the Northern Pacific R. R. to St. Paul; and Chicago, Milwaukee and St. Paul Ry., St. Paul to Chicago. A stop over at Yellowstone National Park for those who desire it has been arranged, and it is understood that at several places on the journey there will be short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentration on this train should be effected at Chicago and St. Louis.

SOCIETY NEWS:

The Ramsey County (Minn.) Medical Society met February 26. The following officers were elected: Dr. A. B. Ancker, President; Dr. Davis, Vice-President; Dr. H. Longstreet Taylor, Secretary; Dr. O. S. Pine, Treasurer and Dr. J. M. Finnell, Chairman of the Pathological Section.

The Colorado State Medical Society.—To the Members of the American Medical Association:—Members of the AMERICAN MEDICAL ASSOCIATION are cordially invited by the Colorado

State Medical Society to stop over in Denver on returning from the coast and attend the meeting of the Society convening on June 19 and continuing through June 20 and 21.

Members who expect to return via Denver are invited to correspond with the Secretary, that invitations to participate in the program, and proper entertainment may be arranged.

EDMUND J. A. ROGERS, President.

A. Stewart Lobingier, Secretary.

Onondaga Medical Society.—The regular quarterly meeting of the Onondaga (N. Y.) Medical Society was held in the Society's rooms February 28.

Papers were read as follows: Dr. H. L. Elsner, "On the Diagnostic Value of Stomach Inflation, Report of Cases and Presentation of Patients;" Dr. W. S. Cheesman, "Supra-pubic Cystotomy in Vesical Hemorrhage;" Dr. D. M. Totman, "A Case of Supra-pubic Cystotomy for Vesical Calculus;" Dr. John VanDyyn, "A Case of Cyst of the Kidney;" Dr. G. E. Clark, "Questions Concerning Nitro-glycerin."

Pennsylvania State Medical Society.—*Change of Place of Meeting.*—In view of the fact that the largest hotel in Gettysburg was burned recently, and will not be rebuilt in time for the meeting of this Society, it was deemed best after consultation with the Board of Trustees to change the place of meeting, and as the Philadelphia County Medical Society extended an invitation for the Society to meet in Philadelphia, it was deemed wise to accept the invitation.

The Forty-fourth Annual Session will be held in Philadelphia May 15, 16, 17 and 18, 1894.

H. G. McCORMICK, President.

Wm. B. Atkinson, Secretary.

The Hare Medical Society.—The Hare Medical Society of the Jefferson Medical College gave its annual dinner February 27 at the Penn Club, Eighth and Locust Streets. President C. S. Magnus acted as toastmaster. L. S. Bent responded to the toast, "The Trustees;" Professor H. A. Hare, to "Policy of the Faculty;" Professor E. E. Montgomery, to "The Jefferson Hospital;" Professor W. M. L. Coplin, to "A Tribute to Hygeia;" M. G. Moore, to "Class of '94;" E. A. Moye, Jr., to "Class of '95;" Professor G. E. DeSchweinitz, to "Hospital Appointments;" Dr. Thomas G. Ashton, to "Experiences of a Young Practitioner;" and Dr. J. Chalmers Da Costa, to "Men Who Have Made Jefferson Famous." The Entertainment Committee consisted of John W. F. Moore, B. J. Powell and W. W. Hoffman.

Florida Medical Association.—The twenty-first annual meeting of the Florida Medical Association will be held in Tampa, Florida, Tuesday, March 20, 1894. Officers: President, Frank H. Caldwell, M.D., Sanford; First Vice-President, A. J. Wakefield, M.D., Jacksonville; Second Vice-President, R. P. Izlar, M.D., Ocala; Secretary and Treasurer, J. D. Fernandez, M.D., Jacksonville; Librarian, J. H. Douglas, M.D., Jacksonville. Leslie W. Weedon, M.D., Tampa, Chairman Committee of Arrangements.

The meeting will be called to order Tuesday, March 20, by Dr. Leslie W. Weedon, Chairman Committee of Arrangements, who has charge of the opening exercises. The President's address will then be delivered.

The reading of papers and discussion of same will be commenced and continued, at the will of the Association, throughout the session.

BOOK NOTICES.

Proceedings of the Philadelphia County Medical Society. Vol. XIV, Session of 1893. LEWIS H. ADLER, JR., M.D., Editor. 8vo, cl., gilt top. Philadelphia. 1893.

This handsome volume of 484 pages contains the papers read before the Philadelphia County Medical Society, and the discussions thereon. These papers have been published elsewhere from time to time; several of them in this JOURNAL, but it is well to thus place them in enduring form for convenient reference and preservation.

Tenth Biennial Report of the State Board of Health of Maryland for the Two Years Ended Dec. 31, 1893. Annapolis: King Bros. 1894.

This report includes an account of the investigations and acts of the Board during the period mentioned.

Dr. C. W. Chancellor, for many years the efficient Secretary, was appointed U. S. Consul at Havre, France, and was succeeded by Dr. James A. Steuart, who was for several years Health Commissioner of Baltimore and therefore entirely familiar with the sanitary work of the Board.

The Year-Book of Treatment for 1894. A Critical Review for Practitioners of Medicine and Surgery, by twenty-four Contributors. Pp. 492. Philadelphia: Lea Brothers & Co. 1894.

This is a critical summary in convenient form of the literature of the year on the various branches of medical science, by well-known English authors. The power of condensation is very judiciously exercised by the editor, and the arrangement and selections in the present volume are in every way equal to the nine excellent year-books that have preceded it. It is very likely to be looked into for handy reference, when the ponderous and elaborate encyclopedic year-books are left upon the shelf.

A Practical Treatise on Medical Diagnosis, for Students and Physicians. By JOHN H. MUSSER, M.D., Assistant Professor of Clinical Medicine in the University of Pennsylvania, Philadelphia; President of the Pathological Society of Philadelphia, etc. Octavo, 873 pages, 162 engravings and two colored plates. Cloth, \$5.00; leather, \$6.00. Philadelphia: Lea Brothers & Co. 1894.

There are many works on the subject of medical diagnosis, and this of Dr. Musser's will take an honorable place among them.

An examination of the book shows that the author's omissions have been very few. It is divided into two parts, of which the first includes all topics relating to general diagnosis, and the second those of special diagnosis. There are six chapters in the first part; of which the first is devoted to the introduction; the second to the data obtained by inquiry; the third to the data obtained by observation; Chapter 4 to Bacteriological Diagnosis; the Examination of Exudations, Transudations, and Cystic Fluids; Chapter 6 to the Morbid Processes and their Symptomatology. In Part 2. the diagnosis of diseases of particular organs is set forth, and one chapter is devoted to the consideration of constitutional diseases. There are eleven chapters in this part.

The book is well printed, the paper is good, and the illustrations are excellent.

Transactions of the Royal Academy of Medicine in Ireland. Vol. XI. Edited by WILLIAM THOMSON, M.A., F.R.C.S., General Secretary. Surgeon to the Richmond Hospital, Dublin. Dublin: Fannin & Co. 1893.

This is a volume of 518 pages, well printed and well illustrated. It contains the List of Officers, List of Honorary Fellows, Rules of the Academy and the "Transactions" proper.

The work of the Academy is divided into six sections, viz: Section of Medicine; Section of Surgery; Section of Obstetrics; Section of Pathology; Section of State Medicine; and Section of Anatomy and Physiology. There are papers by various Fellows, all of which are interesting, and many of permanent value. The volume opens with an admirable paper by Dr. Joseph O'Carroll on "Saturnine Encephalopathy." Dr. Wallace Beatty reports "A Case of Myxedema Successfully Treated by Injections of Extract of Sheep's Thyroid." Dr. Charles Bell has an exhaustive illustrated paper on "Cancer of the Rectum." Dr. W. J. Smyly, the Master of the Rotunda Hospital, makes report of "112 Cases of Abdominal Section." Dr. T. More Madden furnishes a paper on "Removal of Gravid Uterus," and Dr. A. Birningham reports a case of absence of the ileo-cecal valve.

Tumors, Innocent and Malignant; Their Clinical Features and Appropriate Treatment. By J. BLAND SUTTON, Assistant Surgeon to the Middlesex Hospital, London. With 250 engravings and nine plates. 8vo, cl., pp. 511. Philadelphia: Lea Brothers & Co. 1893.

This book is handsomely printed and profusely illustrated. The illustrations are new for the most part. The text is peculiar in many respects; in the author's desire to be original he makes some curious statements, and throughout the book the histology plays but a secondary part. His classification also is *sui generis*, and it is obvious that a classification which leads the author to place the psammomata under the head of papillomata, is not in accordance with the generally accepted histologic facts. In the four pages devoted to the psammomata—if we except the opening statement that "these are tumors composed of globular bodies arranged in layers, usually calcified and imbedded in the connective tissue." . . . there is nothing to indicate their morphology, and their analogy if not identity with the sarcomata is not even hinted at.

Woodhead, whose authority is unimpeachable, says, 3d edition, p. 585:

"It (the psammoma) consists of a branching mass of spindle cells in which are numerous blood vessels, at the sides of which are a number of bud-like or club-shaped processes. The vessels themselves, seen in section, are surrounded by layers of spindle cells or flattened cells, which are prolonged on to the outer surface of the bud."

Cornil and Ranvier directly place the psammomata among the sarcomata by making them the sixth variety, under the name of *sarcoma angiolithique*. Rindfleisch places the psammoma in a new class which he termed endotheliomata. Quenu accepts Rindfleisch's classification as a subvariety of the vasculo-connective tissue type. We have made these comparisons for the purpose of showing how far our author is away from the standard teaching. Clinically the work is strong.

The chapters on the dermoid cysts are the most satisfactory of any in the book, but in general it may be said that so far as histology is concerned, it is lamentably deficient.

Medical Jurisprudence, Forensic Medicine and Toxicology. By R. A. WITTHAUS, A.M., M.D. Professor of Chemistry, Physics and Hygiene in the University of the City of New York, and TRACY C. BECKER, A.B., LL.B. Professor of Criminal Law and Medical Jurisprudence in the University of Buffalo, with many collaborators. Vol. I. pp. 845. New York: William Wood & Co. 1894.

This book when finished is intended to be a complete textbook on the subject. Volume I contains the "Introduction;" The "Legal Relations of Physicians and Surgeons," by T. C. Becker; "The Law of Evidence Concerning Confidential Communications," by Chas. A. Boston; "Synopsis of the Laws Governing the Practice of Medicine," by W. A. Poste and Chas. A. Boston; "The Legal Status of the Dead Body," by T. C. Becker; "The Powers and Duties of Coroners," by A. Becker; "Medico-Legal Autopsies," by H. P. Loomis; "Personal Identity," by I. C. Rosse; "Determination of the Time of Death," by H. P. Loomis; "Medico-Legal Consideration of Wounds," by G. Woolsey; "Medico-Legal Consideration of Gunshot Wounds," by Roswell Park; "Death by Heat and Cold," by E. V. Stoddard; "Medico-Legal Relations of Electricity," by W. N. Bullard; "Medico-Legal Consideration of Death by Mechanical Suffocation," by D. S. Lamb; "Death from Submersion or Drowning," by I. C. Rosse; "Death from Starvation," by E. V. Stoddard. The subjects connected with neurology, obstetrics, and the application of the microscope to forensic medicine are left to be included in the two remaining volumes.

The Introduction contains a historical account of the literature of the subject from the earliest times down to the present day, and the copious footnotes attest the painstaking labor which the editor-in-chief has given to the subject.

The article on the Legal Relations of Physicians and Surgeons by Mr. Becker, includes a discussion of their acquirement of the right to practice medicine and surgery; their legal duties and obligations; their right to compensation; their privileges and duties when summoned as witnesses and their liability for malpractice. These questions are treated with reference to the decisions of the courts and it would seem as if most questions of medico-legal character had now been so clearly commented upon by the courts, as to leave little actual doubt as to what the law is. In regard to the question of experts, Mr. Becker states:

"In some foreign countries, notably in Germany and in France, experts in medico-legal matters have an assured official position, and are generally not allowed to be selected at haphazard according to the will or length of purse of those who need their services. The consequence of this method of obtaining expert evidence is, that expert witnesses in those countries command a high measure of respect and honor. Unfortunately, however, in this country, where the opposite practice prevails, the weaknesses of human nature are such that the common people, newspaper, lawyers, and even the courts in some recorded opinions and decisions, have come to express a great want of confidence in the weight and value of expert testimony. This deplorable result of a bad system of procedure is universally recognized, yet our legislatures have as yet refrained from attempting to correct it."

The book will be found extremely valuable, not only as a reference book, but as an instructive and readable one.

A Text-Book of the Theory and Practice of Medicine by American Teachers. Edited by WILLIAM PEPPER, M.D., LL.D. In two Volumes. Vol. II. Pp. 1046. Philadelphia: W. B. Saunders. 1894.

The syndicate system of writing text-books has its commercial advantages, but individual writers however meritorious have no opportunity of placing their works before students, who are compelled to buy the syndicate books. From a publisher's standpoint it is only necessary to secure one professor to write an article from each of the principal medical colleges and the sale of the book is certain, and all possible rivalry reduced to a minimum.

In the book before us many of the objectionable features of syndicate book writing have been eliminated, as the author's name is attached to each article. We thus know what credit should be attached to each, and where to fix the responsibility.

One would be captious indeed could he find fault with those selected to write the articles in this volume, for their names are familiar to the entire profession, as those having a right to speak with authority, and they are not so numerous as in some other syndicate books. It is the system, and not the individuals that we criticise. Professor Henry M. Lyman contributes twelve chapters; Professor Pepper, thirteen; Professor James C. Wilson, four; Professor Fitz, three; Professors Osler and Delafield each two; and Professors Welch and Holland each one.

The volume opens with a chapter on the biology of bacteria, infection and immunity by Wm. H. Welch. His chapter is extremely interesting, gives the morphology and classification, the food, vital manifestations, distribution, agencies injurious to bacteria, modifications of characters, marks of differentiation, and general considerations concerning infection, general etiology, toxic products of bacteria, immunity, prophylactic and curative inoculations. In regard to serum-therapy Professor Welch says:

"It is evident that the difficulties to be overcome in the successful application of serum-therapy to large animals and to man are great. It is important not to generalize, but to work out for each disease separately a sound experimental basis for this mode of treatment, as has already been done with considerable success for tetanus. This statement is sufficiently evident when we consider the varying conditions which underlie immunity from different diseases, the varying degrees of immunity attainable, and our imperfect knowledge as to both of these points as regards many diseases."

The chapter on "Obesity" by Professor Lyman is one of the most original and practical of the many excellent papers in the volume.

The well considered chapter by Professor Osler "On Diseases of the Blood," is beyond praise, and we may conclude this notice by saying that the book, as a whole, is not only a highly creditable production, but reflects honor on American medicine.

The Journal of the American Medical Association

ORIGINAL ARTICLES.

MODERN HOMEOPATHY AND MEDICAL SCIENCE.

BY HENRY BIXBY HEMENWAY, A.M., M.D.
INSTRUCTOR IN LARYNGOLOGY, RUSH MEDICAL COLLEGE, CHICAGO.

Recent addresses by Mr. Ernest Hart of London, and Professors Roberts and Cohen of Philadelphia, together with the agitation relative to the revision of the Code of the AMERICAN MEDICAL ASSOCIATION, have caused considerable criticism in this country, pro and con, relative to homeopathy. It is not a question of taste or of fancy for the laity; nor is it simply an indication of bigotry, if a physician declines to consult with a homeopath. If homeopathy is right, a very large majority of physicians are mistaken. As a class they can have no possible object for opposing homeopathy except a firm belief that it is radically wrong. If homeopathy is wrong, thousands of our citizens are deluded and defrauded by this form of quackery. It is, therefore, a proper subject for careful consideration in secular as well as professional journals.

When the writer decided to study medicine, the homeopaths were at the height of their glory. Their practice had been constantly gaining in popularity. In number of practitioners, compared with the profession at large, they had not yet begun to decline. The writer was surrounded by a homeopathic community. His most intimate professional friend was a homeopathic physician. The writer had read such tracts as "Facts, Solid Facts," which had been widely distributed by homeopathic firms, and which made the claims of the sect appear plausible. He knew several personally, who, after graduating from such reputable regular schools as the Medical Department of the University of the City of New York, and after practicing medicine for a time, had studied homeopathy, and then pinned their faith to the dogma, *similia similibus curantur*. He did not then know any one who had taken up scientific medicine after having practiced homeopathy. Neither did he realize that very many of those attempting to practice scientific medicine achieve unsatisfactory results, because they practice *empirically*, blindly trying to follow those better qualified than themselves, and failing to grasp the principles involved.

In the place of cool argument, too often the defenders of rational medicine descended to ridicule in speaking of homeopathy. Although refined homeopathy¹ may well be called "the little end of nothing, whittled out sharp, and cut off," or "the shadow of the chicken in the pot," ridicule alone seldom convinces. Ribald jests arouse sympathy for the oppressed. On the other hand, a logical discussion, based upon admitted premises, proving rather than asserting the ridiculousness of the claims, is both convincing and proper.

Considering his surroundings, therefore, it is not strange that the writer decided to become a homeopathic physician. During his course in the literary college he did some reading, and even as an amateur practiced a little very satisfactorily with the pellets provided by his homeopathic friend. This friend, a man of education, and a successful practitioner, did not indorse the refined homeopathy of the high potentists. He did not confine himself to drugs, nor to homeopathic preparations. He one day said to the writer: "I hope that you will become a homeopathic physician, but do not decide yet. You know something of the homeopathic practice. Take at least one year in ——— College," (naming a prominent regular school); "keep your eyes open, and compare the two schools carefully. Do not decide until the end of the year. I have no fear of the result." About the same time another friend and thorough scientist, advised: "Don't fool away your time studying homeopathic nonsense." The very natural result of these two pieces of advice was to strengthen the faith in homeopathy.

Sir Walter Scott once said that he could always learn something, even from the most ignorant people; and the old English poet puts these words into the mouth of the shepherd as he talks with the Abbot of Canterbury:

"Did you never heare yet,
That a fool he may learne a wise man witt?"

The most learned and gifted may often profitably study the ideas of those less distinguished. The intolerant man is essentially a small man, whether he be found in law, theology, medicine, or in business. We would not agree with those who would ignore the homeopaths because of their inconsistencies or on account of their ridiculous pretensions. We would rather carefully examine both their doctrine and their practice, for truths which had hitherto been too much neglected. Truth is everywhere, and the successful physician must be ready to receive it wherever found. Though fully convinced that homeopathy is a delusion, and that there is no legitimate excuse for the existence of the sect, we believe that much good would result if the history of medicine, including that of the prominent sects, should be more thoroughly studied.

The object desired—the obliteration of the homeopathic sect—is not secured by ignoring its members, as some of the more narrow-minded doctors have done in the past. A very successful homeopath once said to the writer: "If I were to begin now the study of medicine, I should not go to a homeopathic school. It was the intolerance of the general profession that led me to study homeopathy." If, as regular practitioners claim, homeopathy is a delusion, rational medicine will lose nothing by association with homeo-

¹ The expression, "refined homeopathy," as used in this article is not intended as ironical, but as descriptive of the purest form of the doctrine, and represented by the high potentists.

3.12.41

paths, while the latter class may thereby be the better able to see the truth as it is.

The writer entered a regular college, located so close to a homeopathic institution, that the students frequently visited from one to the other. The contrast was very marked. In one the tissues of the body were studied most minutely. In the other, they were described in general terms. In one the students were asked as to the exact effect of atropin upon the different parts of the eye, or the action of strychnia upon the spinal cord and nerves; or what drugs were indicated in a case of rapid heart beat, without structural change in that organ. The homeopathic professor inquired what remedy was indicated if the patient dreamed of money, and what drug had given rise to the proving, "He sees a black gauze before the right eye."

The writer, during his first year in the medical school, became thoroughly disgusted with homeopathic superficiality, and ever since he has carefully sought for the causes of the former growth of the sect. He is thoroughly convinced that no one thing has done so much for them as the intolerant contempt of many members of the regular profession, making them pose before the lay public as martyrs from professional jealousy.

The writer has sought, therefore, to present to his readers simply a plain argument, showing that the homeopathic practice is not scientific, but empirical; that their practice is inconsistent with their doctrine; and that there is no longer any excuse for the preservation of the homeopathic sect. Only a few of the many quotations which might be given to illustrate each point have been presented, taken always from standard works or from recognized authorities. For the convenience of the student reference is made, in most cases, to the source from which the quotation is taken. To guard against a possible misrepresentation of homeopathic teaching, the article has been presented to educated homeopathic physicians for criticism and correction, though it would be too much to expect that they would agree with the writer in all of his deductions.

In order to make some comparison of modern homeopathic practice with general results, letters were sent to several hospitals, asking for the mortality in certain common diseases, during the last five years. For various reasons no figures were received, either from regular or sectarian institutions. From a prominent homeopathic hospital the following reply was received. Considering the doctrine of the potentist portion of the sect, the reply is noticeable. It said: "Our surgical service has been so much larger than the medical, that the statistics of the latter would give very little of value for comparison."

It is proper to state that, though the *sect* is not recognized by the regular profession, graduates from homeopathic colleges are recognized, just in proportion as they abandon homeopathy and call themselves simply physicians. As such they may join many of the regular societies.

Not from any feeling of personal animosity; not to add fuel to the fire of factional strife; nor in any way to attempt to restrict that freedom of action which should be exercised by every physician; but in the hope that in some degree they may help to hasten the time when there shall be *one* medical profession, whose members shall each feel free to use

his own individual judgment, unhampered by dogmatic barriers, and all shall meet on one common ground for the advancement of science, and the benefit of humanity, the following pages have been written.

Medicine is a science and an art. Originally the art element was the more prominent. Isolated facts were observed by the practitioner, who also collected information from others. These observations were used in the treatment of future cases. Reason entered but slightly into the practice. Success depended largely upon natural talent and memory.

Though neither the most successful, nor the most to be commended this method, called empirical, because based solely on practical experience, is still more or less common. If the empiricist is especially clear-headed, he may be able to select his remedy with considerable skill, but he has no definite idea of what he wants to do or how his medicine works. He has in mind only the ultimate object. A person may go to New York from Philadelphia by way of Buffalo, but he may save both time and trouble by going more directly. In a like manner, a physician may cure his patient much more quickly and satisfactorily with one remedy than with another. The empiricist, having in mind only the ultimate object, without understanding the intermediate steps, is liable to take a very roundabout way. Empiricism, therefore, is nearly a pure art.

The *science* of medicine began when the accumulation of observations made classification a practical necessity. The difference between the scientific and empirical practice of medicine may be illustrated by other natural sciences. In botany, for example, the empiricist, in trying to find the name of a new plant, must look through the descriptions of all species, until he finds one applicable. Such a botany as he would construct would be a ponderous volume, since to give a full description under every name would necessitate great repetition.

The scientific botanist would, at a glance, by generalization limit his investigation to a small family, and by the aid of further classification he would find the name of his specimen before the empiricist had fairly begun his search. The scientific botany by classification avoids unnecessary verbiage. With the same amount of information, therefore, it may be easily seen that the empiricist labors at a great disadvantage, compared with the scientist.

In every science, errors of observation have resulted in false classification, or in wrong deductions. Medicine is no exception, as the relics found in its nomenclature show. Arteries were called by that name signifying air-carriers, because in dissection they were found filled with air.

In the latter part of the eighteenth century a German physician, while laboriously translating an English work on *materia medica*, noticed an apparent similarity between the symptoms produced by Peruvian bark and those of malarial fever, for which the bark was considered a specific. He made a few experiments upon himself and friends, and in 1790 published to the world his dogma, *similia similibus curantur*; similars are cured by similars. Hahnemann was not the first to notice that patients are sometimes benefited by drugs having effects closely resembling the disease treated. Hippocrates, over four hundred years before the Christian era, prescribed for mania "a draught made from the root of a man-

drake, in a smaller dose than sufficient to produce mania." We find in literature many other suggestions pointing to similar observations. Paracelsus, over two hundred and fifty years before Hahnemann, wrote, "*similia similibus curantur*," and in his *Fragmenta Medicina* he further wrote, "*similia, similibus cura, non contrarium*." Hahnemann was the first, however, to attempt to formulate a system upon this as an universal law. He called his system, "homeopathy," from Greek words signifying a similar condition, and coined the name, "allopathy"—opposing condition—as descriptive of the common practice.

That Hahnemann greatly benefited humanity and medical science, no careful student may deny. He stimulated the study of the action of drugs, and showed that large doses are productive of more harm than good in many cases. His greatest service to the profession was the substitution of simple drugs in the place of the heterogeneous mixtures formerly used, thus rendering the remedies at the same time more certain in action and less unpleasant to take.

At the time that Hahnemann first published his dogma, the world was in a good condition to receive it. Medical practice was far from satisfactory. Purging, bleeding, blistering, and other weakening practices were carried to a great excess. "Shot-gun prescriptions," i.e., mixtures made of a large variety of drugs in the hope that something might "hit the case," were common. It is not at all improbable that the doctors then did far more harm than good.

A few years before, in Edinburgh, that independent and intelligent physician, Dr. John Brown, had called forcible attention to some of these facts. At home, owing to the general reverence for Cullen, Brown's work did not receive the attention which it deserved. On the continent, however, his book, written in pure Latin had aroused great and friendly interest. It caused men to think, and to look about for something better. His ideas of treatment were so thoroughly at variance with previous customs, that a majority could not at once adopt them. Hahnemann came forward and occupied a sort of middle ground. He abandoned the strong depleting treatment, but he theoretically recognized the necessity for something more than the stimulants suggested by Brown. He really demonstrated to the profession that no treatment at all is better for the patient than the unreasonable practice then in vogue, though it took half a century for the general profession to acknowledge this fact.

If the dogma, *similia similibus curantur* is granted, simple medication, that is, the use of one remedy at a time, is almost a necessary corollary. The distinguished doctor was also led to prescribe his drugs in minute doses. The small amount of medicine given afforded a greater opportunity for the *vis medicatrix nature*, and in many instances perhaps the remedies assisted in the cure. It may be well believed that the early homeopathic practitioners were usually successful, compared with their neighbors, not because of deeds of commission, but of deeds of omission.

Emboldened by his successes, Hahnemann made the most ridiculous declarations. He taught that a medicine increased in potency in proportion to the amount of its dilution, and that the potency was also increased by shaking and by triturating. In his "Lesser Writings" he says: "If we wish, for example, to attenuate a drop of the juice of sundew to the

thirtieth degree, but shake each of the bottles with twenty or more succussions from a powerful arm, in the hand of which the bottle is held—in that case this medicine which I have discovered, the specific remedy for the frightful epidemic—whooping-cough of children—will have become so powerful in the fifteenth attenuation (spiritualized), that a drop of it given in a teaspoonful of water would endanger the life of such a child; whereas, if each dilution bottle were shaken but twice, (with two strokes of the arm) and prepared in this manner up to the thirtieth attenuation, a sugar globule, the size of a poppy-seed, moistened with the last attenuation, cures this terrible disease (whooping-cough) with this single dose, without endangering the health of the child in the slightest degree." Hahnemann devoted much time to making provings, as they are called, of various drugs. He would take a dose of the substance to be proved, and then carefully note down all that transpired, even to the kind of thoughts or dreams that happened to flit through his mind. Since he failed to distinguish between accidental concurrences, and the results of the drugs, a large proportion of his provings are absolutely worthless. This is illustrated by the experience of Professor C. Wesselhoft of Boston. He made some provings of *carbo vegetabilis* upon members of the class in the Boston University Medical School. Unknown to the class he began by administering blank powders of sugar of milk. He received from his subjects a large number of reports of symptoms produced by these blank powders. It must be admitted that Hahnemann and his followers have been very diligent in their enthusiasm, some even proving such things as lice and insects, the water in which a virgin had taken a bath, as well as bottled sunshine.

Until the last decade the homeopathic sect gradually increased in numbers, especially in the United States. According to the Homeopathic Directory, there are now in Europe 1,022 homeopathic physicians practicing medicine. In Great Britain and Ireland in 1875, there were 269 homeopathic doctors, and in 1889 there were 256, a decrease of nineteen, though both the population and the number of physicians in the land increased. Professor H. C. Wood remarks: "It is very interesting to note that the largest proportion of homeopathic practitioners, according to the population, on the continent of Europe, is to be found in Spain—the one country where the general level of education is the lowest."²

In this country, too, the number of homeopaths is not increasing as fast as formerly. In fact, though there is an absolute increase in the number of members of that sect in the United States, yet compared with the total number of doctors of medicine, and also compared with the population, there is a relative decrease in the number of those calling themselves homeopathic practitioners. The Illinois State Board of Health has probably done more than any other one organization to raise the standard of medical education in this country. To aid in this work, it has kept close track of the number of matriculates in, and the number of graduates from, every medical college in the United States and Canada, since the session of the schools in 1877-78. By the aid of its reports on medical education, published in 1885 and 1891, the following table has been constructed, giving the proportion of homeopathic graduates, in the

² Hare's System of Practice, Vol. I, p. 18, Note.

United States and Canada, from 1877 to 1890, inclusive. Though there happens to be no homeopathic school in Canada, and though the two countries are under different governments, their interests are so much the same, and residents of one so frequently go to the other for their professional education, that it seems proper to treat them as one country. To satisfy the desire of some to see the figures for the United States alone, these are also given.

RELATIVE PROPORTION OF HOMEOPATHIC GRADUATES TO TOTAL NUMBER OF MEDICAL GRADUATES IN THE UNITED STATES AND CANADA, FROM 1877 TO 1890, INCLUSIVE.

Session year.	Number. Total.	Homeopaths.		In U. S. only.	
		Number.	Per cent.	Total Number.	Per cent. Homeopaths.
1877-78	2,901	349	12.03	2,837	12.30
1878-79	2,882	316	10.99	2,775	11.30
1879-80	3,475	331	9.52	3,379	9.79
Total 3 years	9,258	996	10.75	8,991	11.77
Average annual	3,086	332		2,997	
1880-81	3,985	412	10.30	3,882	10.61
1881-82	4,571	395	8.64	4,466	8.84
1882-83	4,235	445	10.56	4,051	10.98
1883-84	4,091	412	10.07	3,938	10.46
1884-85	3,824	398	8.84	3,657	9.24
Total 5 years	20,686	2,002	9.68	19,994	10.01
Average annual	4,137.2	400.4		3,998.8	
1885-86	4,043	374	9.25	3,812	9.81
1886-87	3,835	352	9.18	3,620	9.72
1887-88	4,142	386	9.32	3,815	10.11
1888-89	4,543	375	8.25	4,268	8.79
1889-90	4,853	391	8.06	4,492	8.70
Total 5 years	21,416	1,878	8.77	20,002	9.38
Average annual	4,283.2	375.6		4,000.4	

These statistics, taken as they are from a most reliable source, show that the homeopaths are not holding the ground gained in the profession of this country.³ Taking the census of the United States in 1880 and 1890, and that of Canada in 1881 and 1891, as a basis of computation, we find that for every average annual graduate in 1880, there was a population of 17,709.3; and in 1890 a population of 15,809.4. This shows that there is an increase in the total number of graduates, compared with the population. In 1880, for every average annual graduate in homeopathy, there was a population of 164,430.5. In 1890 the proportion of annual homeopathic graduates had decreased to one in 180,284.8 population. In the United States alone the figures are as follows: In 1880, one graduate in medicine in 16,772.1 population; in 1890, one graduate to 15,719.8 population; homeopathic graduates, in 1880, one to 151,403.9 population, and in 1890, one to 167,426.9 population.

The above figures are here given, because the homeopathic sect have repeatedly claimed that the facts are quite different, and their positive assertions, though unsupported by evidence, have sometimes seemed to have considerable influence in proselyting.

Out of 118 nominal homeopathic practitioners in Austria, only forty-four practice that system exclusively. In the United States prominent members of the homeopathic societies have recently affirmed that there are practically no homeopathic physicians in this country. Though a majority of them regard as visionary most of the teachings of Hahnemann, there are still a large number of physicians claiming to

treat disease according to the dogma, *similia similibus curantur*.

The great number of believers in the teachings of Mohammed does not prove the truth of those teachings, but it does furnish a reason for examining the evidence of his claims. Thus the proportion of homeopathic physicians does not prove their right to exist as an independent sect, but it challenges investigation.

It must be remembered that there is a vast difference between rational medicine and homeopathy. The one is a science; the other a system. As the pine, beginning in the little germ, gradually increases in size until it becomes the tall and stately tree, so the science of medicine is not the product of any one man or age. Hahnemann, alone, presented to the world homeopathy, as an artist produces a statue. Others may have polished off some of the minor imperfections, but the system is essentially the same that it was when it was first originated. The sculptor, failing to grasp the artist's idea, sometimes in trying to perfect the statue removes too much, and materially modifies the ideal of the master. In art, to comprehend the master's thought, we study his models and pencil sketches, as well as the finished work. In order to fully understand modern homeopathy, we may best begin by studying the system as first proposed by its author, although fully recognizing that the homeopathy of to-day is not the same that it was sixty years ago, in many of the less important details.

The *Organon*⁴ is considered Hahnemann's greatest work. It is practically the only book, written by him, which is now read by the general practitioner. In this treatise, he devotes much space to decrying medicine as he supposed it to be generally practiced. He said: "They fancied they could find the cause of disease, but they did not find it, because it is unrecognizable, and not to be found;"⁵ and yet the causes of many of the zymotic diseases have since been seen and handled. He ridiculed the study of pathologic anatomy—the examination of dead bodies, saying: "That is, they will not cease for the sake of those foolish and groundless hypotheses, to be immaterial modifications of our sensorial condition."⁶ This statement agrees closely with the teaching of so-called Christian science of to-day. On the other hand, very much of our present knowledge of the diseases of the brain, for example, are the direct result of the examination of dead persons; and the information thus gained, which could only have been gained in this manner, has enabled the surgeon to unerringly open an apparently healthy skull, and remove a small tumor, or empty an abscess, thus saving the life of the patient, or relieving him of terrible tortures. For acute dyspepsia, with cold extremities, dull head, and eructations of tainted food, Hahnemann advised that the patient *smell once* of a granule of sugar, not larger than a grain of mustard seed, moistened with the *highly diluted* juice of *pulsatilla*.⁷ He did not even sanction the administration of vermifuge remedies for intestinal worms. He declared that so long as the patient was healthy, the worms would cause no trouble;⁸ and distinctly advised that only the

⁵ *Organon*, p. 18.

⁶ *Organon*, p. 20.

⁷ *Organon*, p. 43, Note 6.

⁸ *Organon*, p. 52, Note 14.

³ During the period, 1877 to 1890, inclusive, there graduated in America, 51,360 physicians. Of these, 4,876 were homeopaths; 2,886 were eclectics; 272 were physio-medicals; 55 belonged to other irregular sects; and 43,271 graduates from "regular" colleges.

general symptoms be treated. It is well known, however, that the most serious trouble, even death, has been produced by these intestinal parasites.

Although Hahnemann ridiculed pathologic study, and the searching for a cause, he most positively stated, as though by divine revelation, that all chronic diseases originate from syphilis, sycosis, or the itch. "Psora (the itch) is the only real fundamental cause and source of all the other forms of disease figuring as peculiar and definite diseases in books of pathology, under the names of nervous debility, hysteria, hypochondriasis, mania, melancholy, idiocy, madness, epilepsy, and convulsions of all kinds, softening of bones, cancer, gout, hemorrhoids, dropsy, asthma, deafness, sick headache, cataract and glaucoma, renal calculus, paralysis," etc.⁹ He, therefore, frequently urges the importance of antipsoric treatment. It is now well known that the itch is the product of an insect, and that it has nothing to do with the diseases mentioned.

Since Hahnemann's pathology is dogmatic, and not at all scientific, any treatment founded on his pathology must, therefore, be empirical, not rational. His general statement, *similia similibus curantur*, is also pure empiricism. In fact, this is admitted by Dr. C. Wesselhoeft in the introduction to his edition of the Organon, where he says: "We accept it as an empirical fact, not as a theory, or hypothesis, as our opponents quite erroneously term it. The explanations of its workings are as numerous and varied, as they are unsatisfactory, from Hahnemann to the latest expounder."¹⁰ In support of this "empirical fact," we find the oft repeated statement: "In all ages those sufferers who were really cured rapidly, permanently and visibly through medicine, were cured alone by a remedy possessing the power of producing by itself a similar morbid condition."¹¹ Hughes says: "All treatment by single medicines used for their direct effects upon the disease is truly of this kind, though it knows or acknowledges it not."¹² These statements, though often repeated, are both contrary to reason and contrary to fact. In refutation of their affirmations, we need only to point to the experience and observation of scientific physicians generally. They are not so false as to cling to what experience has taught them to be error, especially since it is not in the least to their advantage to continue in their false position. That the profession generally is not averse to accepting new ideas, and that it is ever ready to investigate every claim, is apparent to every thoughtful person. Witness the studies of Pasteur and Koch, of Vaughan and Sternberg, and the zeal with which Lister's surgical dressings were adopted. If Hughes said truly, what possible reason could be given to explain the attitude of the general profession towards homeopathy? Are men alive to facts generally, and yet unable to see a fact which should be constantly before them, if the homeopathic statements are true? Or in what possible way can it be for the advantage of physicians generally to conceal this fact, if it be a fact? Can ergot produce diabetes? In many cases the use of ergot alone cures the patient. Digitalin is curative in some forms of heart disease, in which the homeopathic law does not at all explain

its usefulness. Such illustrations might be given by the page, but *one* is sufficient to prove the statement of Hughes false.

Hahnemann's method of preparing fresh plants is as follows: Express the juice and to it add an equal quantity of alcohol. This mixture is called the "mother tincture." Taking two drops of this tincture, add 98 drops of alcohol and shake twice, to make the first dilution. Put one drop of the first dilution into 99 drops of alcohol, and shake twice, to make the second dilution. Repeat this latter process, taking one drop of each dilution to form the next higher, until the thirtieth is reached.¹³ By a similar process, triturations are made by the addition of sugar of milk in the place of alcohol, rubbing instead of shaking the mixture. Triturations are especially used in preparing materials which are insoluble in water or alcohol. Mercury, or quicksilver is of this nature. After making one or two triturations, sometimes the process is continued in dilutions. In such cases the solution contains none of the originally insoluble drug, unless a chemie change has taken place in the trituration. The writer has several times examined low dilutions of mercurius vivus, prepared by one of the most reliable homeopathic drug firms in the country, without finding the *slightest trace* of mercury. If the dilution should have been made from an old trituration, it is possible that with some substances a soluble oxid might have been formed by the decomposition of the sugar of milk. Even this action is impossible in preparations of metallic mercury.

A row of thirty phials containing these dilutions, or triturations, gives no idea of the credulity necessary for the use of the thirtieth dilution. Prepared according to Hahnemann's directions, two drops of the juice of a plant would be sufficient to make in the *sixteenth* dilution a quantity *larger than this earth*. In spite of this fact, *the most pronounced symptoms* have been asserted as the result of the use of the *thirtieth* dilution. Salt (sodium chlorid) is a common article of diet. Almost everything we eat contains salt. Remembering this, and the small amount of salt in the higher dilutions, consider the testimony of one of the recent writers, whose work is used as a text-book in the homeopathic schools. He says: "And let me say here, that salt will cure more cases of intermittent fever, both acute and chronic, than any other known remedy. *With the thirtieth dilution I have cured several hundred cases, with this drug alone.*"¹⁴ (Italics ours.)

To the thoughtful person, such propositions appear so thoroughly absurd, as not to deserve even a passing notice. Burt practically says in the above quoted statement, that salt, taken in the food has very little or no effect; but when an infinitesimal quantity is given as medicine, it has a powerful medicinal effect. So, too, *carbo vegetabilis*—charcoal—which one constantly takes in food, without any apparent effect; yet one grain of which, according to Hahnemann's plan, if finely powdered, and cast into the head-waters of the Mississippi River, is more than enough to render powerfully medicinal the water of the Atlantic Ocean.

While the vast majority of those calling themselves homeopaths agree with Hughes, when he says: "To make the Hahnemann of 1830 to 1843 our guide, is,

⁹ Organon, Sec. 80, p. 110.

¹⁴ Burt's Physiological Materia Medica, p. 632.

I think, to commit ourselves to his senility,"¹⁵ yet we must not forget that there still exists a set in this sect, who not only indorse Hahnemann in the use of high potencies, but they go beyond him, using not only centesimals, but also millesimals. One of these high potentists recently told the writer that though in its crude state lycopodium is inert, yet in the *thousandth dilution* it is a powerful drug.

In this country the high potentists have organized themselves into societies. They have under their control hospitals, and recently in Chicago they have established a new college, the students of which are not only to use the high dilutions, but to depend upon the internal administration of drugs, to the exclusion of all local or mechanical treatment.

It may be proper to ask: Is alcohol relatively so weak in its physiologic effect, that a drop of aconite in a hog'shead of alcohol will still give, when administered, the effect of the aconite alone? Has charcoal, (or carbo veg., as they call it) which is an impure form of carbon, such a powerful medicinal effect upon the human system, as is asserted; and yet has sugar of milk, which contains carbon, so little influence that it can safely be entirely disregarded in prescribing triturations?

Treatment with these high dilutions may, perhaps, well be called materialistic faith cure. It differs from ordinary faith cure in using an external object as an aid to faith. It is well known among physicians that faith is a great aid in the treatment of disease. Almost every practitioner has seen cases in which faith has reduced inflammation, or the lack of it has materially increased the trouble. Acute diseases are generally, by nature, self-limited, and if the strength of the patient holds out the patient recovers, even if no medicine be given. The fact that many cases do recover without medicinal treatment is no indication that all cases would get well either more quickly or more perfectly without treatment.

Suppose one of these ultra, or refined, homeopaths should be called to a case of poisoning from the swallowing of strychnia, arsenic or belladonna berries! If he knew the cause of the sickness, he would probably first give an emetic, and then an antidote. Such treatment is not homeopathic. In the case of acute dyspepsia above cited from Hahnemann, there is a poison produced in the stomach. Why is an emetic allowable in one case, and not in the other?

Sometimes the bowel becomes so twisted as to cause intense pain, and often death within twenty-four hours. In such cases, opium or other narcotics may relieve the pain, but as a rule, medicines alone are powerless to cure. It not seldom happens that the fatal result comes before the character of the case is fully recognized. Such cases as these most need the doctor's energetic care, but the refined homeopathy can offer no relief. Under its useless watching much valuable time would be lost, and the death of the patient be thereby practically insured. Though these high potentists are probably far less dangerous than the polypharmaceutical leeches of a century ago, yet it is well for humanity that there are as few of them as there are.

Before discussing further the homeopathy of to-day, it may be well, by way of contrast, to state the general rules governing the scientific practice of medicine.

When called to a patient it is the first duty of the

physician to determine wherein, and to what extent, his physical condition deviates from the normal standard.

2. He should, if possible, determine the cause of the disease and check its operation. A recent writer has well said: "He is the best practitioner who has the keenest scent for unfavorable surroundings and hurtful habits,—who is most thorough in his supervision of work and rest, of open air exercise, clothing, diet and sleep, of sloth and strain, and manner of living."¹⁶

3. He should use such means as are best calculated to restore the health of the patient. This includes the sustaining of strength, and the neutralizing of dangerous symptoms. In the selection of remedies he should be untrammelled by any dogma or prejudice. He should be free to use mineral as well as vegetable remedies, in large as well as small doses as he deems them indicated. Baths, electricity and massage are equally at his disposal with drugs. Not so the homeopath. Hahnemann condemned external treatment. Homeopathy, "the only law of cure," entirely disregards all other means of treatment besides internal medication according to the dogma of *similia*. A man who advertises himself as a homeopath is in duty bound to strictly adhere to homeopathic laws. He obtains his patrons as a homeopath, and whenever he deviates from pure homeopathic practice, unless he plainly calls the attention of his patrons to the fact, he is really sailing under false colors, and obtaining money under false pretenses.

The common defense made by members of the sect, for violating the so-called law is: "The allopaths use our remedies." Though Hahnemann to contradict distinguish his followers called the regular practitioners, "allopaths," this title has never been accepted by any body of men for themselves. So far as it means anything, it gives a false impression. It is generally regarded as an insult by those to whom it is applied. The scientific physician of to-day relatively seldom uses what could be called properly an "allopathic remedy." He avoids all sectarian designations; he limits himself to no particular method. There is no school of astronomy, chemistry, engineering, or other science, and the scientific physician denies the real existence of a school of medicine.

The fact that a scientific physician uses homeopathic preparations, would be no excuse for a homeopathic practitioner's violation of the *similia* rule, even if the scientific physician had taken an oath not to practice homeopathy. Though both use the same remedy in the same kind of a case sometimes, the homeopath uses it empirically, while the scientist has a reason for his practice. For example: A person of nervous temperament may, as the result of some atmospheric change or other slight irritation be thrown into a high fever, with full bounding pulse, congested conjunctivæ, flushed face, headache and coated tongue. Both physicians may use aconite; but whereas the homeopath uses it without any reason, blindly following the imaginary rule of *similia*, selecting the aconite because it accidentally produces similar symptoms in a healthy person, the scientist selects aconite because of its sedative effect upon the nervous system, especially upon the sensory nerves, and because of its quieting influence upon the circulation of the blood. Large doses of ipecac produce vomiting; small doses are frequently given

¹⁵ Opus cit. p. 91.

¹⁶ Dickenson, in Hare's System of Practice, Vol. III, p. 730.

to allay vomiting. If the vomiting is the result of over-sensitive nerves, the ipecac will be of little benefit. When, however, there is a catarrhal condition of the stomach and bowels, small doses of ipecac, by stimulating the secretion from the mucous membrane, making it less viscid, and by increasing the secretion of bile, promote digestion, and thus relieve the nausea of indigestion.

Modern homeopathy has for its chief characteristics:

1. A belief in the dogma, *similia similibus curantur*.
2. Use of single remedies.
3. Use of the smallest quantity of drugs sufficient to produce the desired result.
4. To a greater or less extent, dependence upon internal medication to the exclusion of all local or non-medicinal constitutional treatment.

Except the first, none of these characteristics are peculiar to homeopathy. In the third and fourth, there is more difference between those claiming to be homeopaths, than there is between the ordinary homeopath and his scientific neighbor. Many use electricity freely, and most of them use local medication, baths and massage to a greater or less extent, although all are foreign to pure homeopathy. So, too, some claim that high potencies should be used, while their more rational brethren scoff at the idea, and prescribe as large doses as their "regular" neighbors.¹⁷

The use of single drugs necessitates greater care in their selection. This stimulates the practitioner to study more closely the indications for particular drugs. Among homeopathic doctors this study is purely empirical. The scientific man studies rather the exact action of the drug, not the gross symptoms. In proportion as drugs are mixed, there is a tendency toward carelessness in their selection. Often more is given than is needed, and from this cause or because of poor selection, other remedies must be added, to counteract the undesired results. The patient, therefore, has to contend with drug poisoning, as well as disease. With simple medication and minimum doses, clearly there is the greatest chance for the *vis medicatrix nature*. Medicines may help, but they can not alone cure the patient. It is the healing power of nature upon which we must ultimately depend. Although simple medication is, therefore, greatly to be desired, and it is in harmony with the most scientific treatment, yet it sometimes occurs that mixtures increase the efficiency of the remedies, or render them more convenient to take. It must be noted that while theoretically teaching simple medication, a majority of homeopathic physicians practice polypharmacy, by alternating remedies.

Against mixed drugs, it has been claimed that the mixture changes the character of the medicines, so as to make the results uncertain. For example: If nearly equal parts of gum camphor and carbolic acid crystals are ground together, in the place of the solids we have a fluid. Although a 10 per cent. solution of carbolic acid generally has a decidedly escharotic effect, this mixture containing 50 per cent. of the acid has but slight escharotic effect. Such results are relatively rare. They must always be borne in mind by the prescriber, but the example

given shows the advantage sometimes found in mixtures, for the carbolized camphor is a more active germicide than either drug would be alone, when used in safe quantities.

Diseases differ greatly in their nature and causes, and the kind of treatment must also vary. They may originate from general, or from local causes. Very many nervous disorders originate from local irritation. Reason dictates that in such cases the treatment should be local. In them, general treatment can be but palliative. Hahnemann, however, recommended that only constitutional treatment be used. In a case of partial paralysis of one leg, the writer recommended circumcision, on the hypothesis that the irritation from phimosis produced the change in the spinal cord. At the same time, homeopathic practitioners of good reputation scoffed at the idea, and insisted upon constitutional treatment. Their advice was followed without benefit. Then circumcision was performed without constitutional treatment and the patient recovered and remained well. Convulsions or epilepsy from a similar cause may be held in check by drugs, so long as the drugs are taken. A slight operation would produce a permanent cure, but unfortunately the doctor's receipts would be diminished. Such examples are so very common as to clearly demonstrate to any impartial person the utter fallacy of Hahnemann's objection to local or non-medical treatment.

Acceptance of the dogma, *similia similibus curantur*, is the *real* characteristic of the homeopathic sect. This phrase, similars are cured by similars, is a positive statement. It either tells the truth or a falsehood. There are three possible legitimate excuses for a dogmatic statement. The fact may be axiomatic, one which is self-evident to all. *Similia similibus curantur* is not axiomatic. Truths are sometimes revealed by God to man. Possibly Hahnemann was inspired, but if so, we should hardly have expected to find so much nonsense in his books as it is generally admitted that they contain. Lastly, a statement may be made which is capable of proof. Can the statement, *similia similibus curantur* be proven?

It has been claimed that as an empirical fact, it has been shown that homeopathic physicians are more successful than others in the treatment of disease. In proof of this assertion, statistics are produced. These statistics are so thoroughly admixed with error, however, that they are of little or no value.

1. There is a vast difference between treatment by a nominally homeopathic doctor, and homeopathic treatment. It has not been shown that the cases claimed have really been treated homeopathically. Burt¹⁸ recommends common salt for intermittent fever. Salt does not produce symptoms like those of intermittent fever. It does not produce the regular periodic chill, recurring at a certain time every day, or every second or third day. By mental suggestion in a susceptible person almost any symptom may be produced; but if the person experimented upon does not know what symptoms are desired, the recurring chill and fever will not appear.

2. It is well known that a century ago, often more harm than good resulted from the administration of drugs. Some years since, out of eighty cases of cholera upon a certain ship, forty-three were treated with drugs, with a mortality of seventeen, or 40 per

¹⁷ It must be remembered that in many cases, being made from fresh, or green tincture, the homeopathic tincture is much stronger than the official tincture of the same drug. Also, since fine division favors absorption, triturations are sometimes more efficient than the crude drug.

¹⁸ Loco cit.

cent., while from thirty-seven receiving no medicine only one died. So compared with the old practice, it may well be believed that homeopathy as practiced would be very successful, not because of positive value, but because it did no harm. The medicines used had little or no effect.

3. In the statistics given, hygienic conditions have been ignored.

4. Exact diagnosis has not been assured. As a matter of fact, physicians who depend only on general symptoms, ignoring the aid of the microscope, and other instruments of precision, are quite likely to make errors of diagnosis. In one instance, three scientific physicians had an epidemic of about 160 cases of r otheln, a mild disease which resembles scarlet fever, though distinct from it, and one which is seldom or never fatal. They saw no cases of scarlatina. At the same time, two other doctors in the same locality reported about 140 cases of scarlatina, none of whom proved fatal. Clearly, statistics based upon that series of 140 cases of scarlatina would be of doubtful value.

5. In statistics given, homeopathic practice of to-day is contrasted with the common results of fifty years ago.

How can medicine cure when used according to this dogma? Jousset, in *L'Art Medical*, affirms that:

"1. Every medicine produces on the healthy body two successive actions, primary and secondary. These two actions are always opposite one to another.

"2. The stronger the dose of the medicine, the less marked is the primary action. If the dose is excessive, the secondary action only is developed.

"3. The weaker the dose, the more manifest the primary action."¹⁹

Another way of putting almost the same idea, is that every drug has a certain effect upon the system. There is in life a tendency to react against external agents and thus retain health. We have, therefore, the action of the drug, and the reaction of the system, which are opposite the one to the other. With small doses the reaction is the more apparent, and with large doses the action is the more noticeable. Since homeopathic writers differ greatly in the use of the terms, primary and secondary, we shall speak only of the action and reaction.

If it is granted that we get opposite results from the administration of large and small doses, it must be admitted that a drug which in a large dose produces the most similar symptoms to the disease treated, would in small doses be the most exact neutralizer of the disease. The curative action in this case would be antipathic, as Dr. Dyse Brown of England has affirmed, not homeopathic. Dr. E. M. Hale, however, in his "New Remedies," says: "If the primary symptoms of a disease are present, and we are combating them with a remedy whose primary symptoms correspond, we make the dose the smallest compatible with reason," etc. He, therefore, would indorse strict homeopathic treatment. The wide and radical difference found among homeopaths in the interpretation of the dogma of *similia* can but weaken the confidence of the student in its value.

If it is true that every drug produces opposite results in large and small doses, it must follow that there is an intermediate point, at which its effect would be nothing. No such neutral point has ever been demonstrated. Granting that these opposite

results arise from the action of the drug, and the reaction of the system, the relative results may be illustrated graphically. (The same is true using the idea of primary and secondary action.) The real action increases with the size of the dose. It may be represented by the triangle ABC, in Figs. 1, 2 and 3. If the real reaction is always the same in quantity, it may be represented by the parallelogram ADGC in Fig. 1. If the real reaction increases with the size of the dose, the quadrilateral ADGC, in Fig. 2, illustrates that; or if the real reaction decreases with the increase of dose, that is shown by the triangle ADC, in Fig. 3. In all the figures, the distance from A on the line AC shows the size of the dose. It will be noticed that at F there is no apparent action or reaction, for the one neutralizes the other. In all the figures, the triangle AED represents the apparent reaction; and BEG, (or BEC in Fig. 3,) shows the apparent action; and the shaded portion, AEGC in Figs. 1 and 2, and AEC in Fig. 3, shows the portion

of the action which is neutralized by the reaction, and hence is non-apparent. From these illustrations it is evident, that if from the neutral point the dose be increased, the apparent action will also be increased; and from the same point the more the size of the dose is decreased, the greater will be the apparent reaction. In other words, if the dose is decreased to an infinitesimal, the apparent reaction will be the greatest. If this be so, Hahnemann and the high potentists are correct. An infinitesimal is practically equal to zero. According to this reasoning, therefore, if no medicine be given, the apparent reaction will be the greatest. This is absurd.

One thing is similar to another, just in proportion as it resembles the other. The most exact similar is, of course, identical. It is well known that at least a large proportion of diseases are the result of some form of poisoning. Strict homeopathy would demand that in such diseases the same poison be used in the treatment of the case, as that from which the patient might be suffering. This is so manifestly absurd that very few would think of indorsing it, though an

attempt has been made to establish such a system of treatment. That the homeopaths do not generally indorse this method, may be seen from incidental remarks in their books. Hughes²⁰ mentions a case in which the doctor was about to prescribe *apis mel*, the poison of the honey bee, but changed his mind because he found that the patient had been stung by a hornet. He, therefore, gave a vegetable remedy.

In the foregoing, it has been taken for granted that opposite results are obtained from the administration of large and small doses. Is it true that we do obtain such results? Our geometrical demonstrations show that we can not. Jousset and others claim that we both can and do obtain such opposite results; but after a careful study of the subject, the writer must say that though there are numerous instances of such apparent opposite results, he does not know of a single instance of such real opposite action of large and small doses. To illustrate:

A small dose of alcohol apparently strengthens the muscles, and stimulates the brain. A large dose paralyzes and stupefies. A closer study shows, however, that after taking a small dose of whisky, the person lifts more, or uses his mind with less fatigue, not because of additional strength, but because the sensory nerves are so benumbed that he does not realize when he approaches the limit of his strength. A larger dose carries the benumbing effect over to the motor system and the intellect.

Again: Convulsions are produced by strychnia, but a larger dose causes paralysis. It is, however, clearly proven that the convulsions are produced by stimulating the spinal cord, making it more sensitive to external impressions. The paralysis is produced by the direct effect of the drug upon the motor nerve, and sometimes when convulsions have occurred, by exhaustion of the motor nerve. The action is always the same on each part of the body, whether the dose be large or small, but the apparent results may vary with the degree of involvement of different organs of the body.

Another class of drugs presenting apparently opposite results sometimes, is illustrated by digitalis. In the smaller doses it generally strengthens the action of the heart, but in larger quantities it may paralyze that organ. It is found, however, that digitalis contains among its active principles three whose action is always to strengthen the heart, either directly or indirectly. It also contains another principle called digitoxin, which weakens the heart muscle directly, and in large quantities it paralyzes that muscle. In the smaller doses the poisonous effect of the digitoxin is practically insoluble in alcohol. Consequently, we seldom or never get the heart paralysis from the tincture of digitalis; but when sufficient of the powdered drug, or especially, of the infusion is given, the direct weakening effect of the digitoxin more than counterbalances the good results of the tonic principles. In other words, the contrary actions are not found here in a simple drug, but in a mixture of dissimilar agents.

It is one of the principles of homeopathy to use only simple drugs, and yet they freely use such drugs as nux vomica, veratrum and digitalis, which are not simple, but each of which contain two or more dissimilar active principles. In the use of these, therefore, they are not consistent.

It is somewhat remarkable, considering the fact that the sect has centered its attention upon the action of drugs, that their text-books are silent upon the exact action of such drugs as digitalis, nux vomica, ergot and belladonna upon the nervous system and the circulatory organs, except as they may quote from some standard work like that of H. C. Wood or Bartholow. They usually ignore the existence of active principles, and discuss only the crude drug. They are largely filled with general statements and subjective symptoms. Hahnemann's *Materia Medica Pura* gives 638 symptoms for arnica, and later writers have nearly if not quite doubled that number. The symptoms given include even the character of thought, and other purely accidental observations. Illustrative of this fact are the following quotations, taken from Burt's *Materia Medica*, a standard homeopathic text-book. They are not rare examples, but they may be easily duplicated from almost any homeopathic work on the subject. As provings of common table salt, he gives: "Extreme despondency; melancholy; depressed and weeping; consolation aggravates; prefers to be alone; dreams of robbers, so vivid that house must be searched." Under *pulsatilla* we find: "Timid and fearful, mild, gentle, yielding; weeps easily; she weeps at every nursing; does not want to go to bed." Under *rhus*: "Satiety of life; with fear of death; wants to go from bed to bed." It may be positively stated that not one of the above symptoms was the result of taking the drug mentioned, but all were merely accidental concurrences.

Such provings as those just given are regarded by most homeopathic practitioners as mere curiosities of homeopathic history. They strongly object to having such records taken as indicative of their common sense or professional knowledge. On the other hand, the high potentists still accept these provings.

A careful study of the homeopathic works on *materia medica* shows that in place of telling the action of a drug they devote the space to a discussion of the indications for its use: "Or symptoms *ex usu in morbis* have been introduced, and the names of diseases supposed to have been cured by the drug are incorporated with the pure symptoms."²¹ Homeopathy, therefore, is pure empiricism. Its followers take the dogma, *similia similibus curantur*, as "an empirical fact," and they follow their leaders in the empirical use of drugs, making little attempt to explain their action. They make themselves as nearly like machines as possible, mechanically comparing the symptoms with their lists of provings.

Wesselhoeft says of homeopathy: "It means in regard to disease, we should make clinical use of only such facts, characteristics or symptoms, as we can with our aided or unaided senses grasp or accept as facts, without doubt or cavil."²² What sense, aided or unaided, can without doubt grasp the dogma, *similia similibus curantur*?

The nearest approach to homeopathy, in the medical science of to day, is found in inoculation, as with the vaccine virus. This is not to cure disease, but to prevent it, or more correctly to make it less severe. In the place of poisons, disease germs having life are implanted in the system. It is known with regard

²⁰ Opus cit., under head of *Apis mel*.

²¹ Carroll Dunham, in *Homeopathy, the Science of Therapeutics*, p. 42.
²² Boyleston Address, p. 10.

to tetanus (lockjaw), diphtheria, and some other diseases, that when these organisms are introduced into the system, a chemic substance is produced which kills the germs, and neutralizes their poisonous products. This substance is called an antitoxin. The existence of sufficient of the antitoxin of any disease in the system, makes it impossible for the bacilli of that disease to develop in the system. A less quantity of antitoxin hinders their development, and renders the disease more mild. The antitoxin not only prevents the disease, but if it is introduced into a person sick with the disease it shortens its course and renders the disease less virulent. The antitoxin is the preventive and curative agent, and its effect is never like that of the poison of the disease. Even here, then, the so-called law, *similia similibus curantur*, is not operative.

It is a remarkable fact that though this sect has been in existence a hundred years, it has made no contributions to science. It has, perhaps, added a few drugs to the Pharmacopœia, but its disciples have never published a single discovery in anatomy, histology or pathology.²³ During the same time, almost everything that is now known relative to the nervous system, for example, has been discovered. Even in the last score of years the most important discoveries have been made in the relation of bacteria to disease, and in what may be called pathologic chemistry.

Members of the homeopathic sect frequently seek to excite opposition against the scientific physician by calling him "old school." They imply and often affirm that the regular practice of to-day is practically the same that it was 2,500 years ago. The fact is that during the last century, homeopathy has made no essential progress, but scientific medicine has shown such continual change and rapid development, that it has almost nothing in common with the science of 1800. Homeopathy has, perhaps, lopped off some of its eccentricities, but it has added practically nothing to our knowledge of disease and the curative properties of drugs, and it has made little attempt to keep up with the recent discoveries. If we grant the existence of schools of medicine, the term "old school" must, therefore, be applied to the homeopathic sect, rather than to rational medicine.

It has been said, that if rational medicine is changing so rapidly, it can not properly be called a science. During this century, much has been learned in chemistry, and with advancing knowledge, theories have been reconstructed. A perfect science we nowhere have. Although we do reconstruct our chemic theories, chemistry is a science. So is astronomy, though it is too much to believe that we know all in astronomy that it is possible to learn. Medicine is a science, and it is fast approaching a perfect state, though it will not attain that point for many years.

It has now been clearly demonstrated that the symptoms of Asiatic cholera are the result of poisoning with the ptomaine produced by a certain bacillus. Rational treatment, therefore, demands either the destruction or the neutralization of the bacillus and its product. Homeopathy, however, continues to treat purely according to general symptoms. An attempt has been made to show that the former

homeopathic treatment is scientific, because in some instances the remedy used proved to be germicidal for that particular disease in which it was prescribed.²⁴ It must be remembered that such evidence only proves that the particular remedy studied owes its efficiency, perhaps, to its germicidal property, and falls far short of demonstrating the scientific value of homeopathy.

To the strict homeopathist, looking only at the totality of symptoms, there is little necessity for a differential diagnosis between paralysis resulting from cerebral congestion, a tumor, spinal disease, or apoplexy. For the scientific practitioner this distinction is of the greatest importance, and often the life of the patient depends upon its correct determination.

While bacteriology, chemistry and histology are taught in homeopathic colleges, they have no part in the ordinary homeopathic practice and are, therefore, too much neglected. The homeopathist has little use for the microscope, but for the scientific physician it is a necessity.

If it is true, as we have tried to show, that there is no such thing in reality as opposite results with large and small doses; and if it is true that there is no genuine homeopathic practice, how has the sect thrived in the past as it has?

"Nothing succeeds like success," is an old saw. The fact that homeopathy has thrived in the past, in spite of opposition, is for many a reason for trusting it without investigation. Though influential to increase clientage, it is no proof of its value. The oily-tongued quack, absolutely without moral principle, and with the merest smattering of medical lore, can always get testimonials from all sorts of people. The very blackest of them secure the strongest recommendations from honored clergymen.²⁵

The homeopaths have constantly traded upon the name of their sect, printing it upon their cards, bill-heads and door-plates. They have sought to make people believe that nauseating mixtures, polypharmacy, and drug poisoning were essential parts of the regular practice, though, in fact, such treatment is as thoroughly condemned by the scientific doctor of to-day as by the homeopaths. Though the practice of the modern homeopath differs but little in reality from that of his scientific neighbor, the homeopaths erect an artful barrier, exclude themselves from the society of the general profession, and then pose as martyrs. Homeopathic practitioners, who honestly admit that they do not regard *similia similibus curantur* as "the only law of cure," who practically use the law only in the absence of more scientific treatment in the less common diseases, still persistently refuse to join regular societies, when the only thing demanded of them is, not that they shall change their practice, nor their honest convictions, but that they shall drop the designation "homeopathic."

Some years ago, when the homeopaths were trying to get a homeopathic department in the University of Michigan, it was stated that about one-half the practitioners of the State were homeopaths. At that time there was no way to prove the falseness of the statement. In 1883 a law was passed requiring all physicians in the State to register. Out of 3,400

²⁴ See article by A. F. More, in the New England Medical Gazette, February, 1892, p. 66.

²⁵ One of the greatest obstacles to the elevation of the standard of the medical profession to-day, is found in the attitude of the clergy. Knowing nothing practically of medicine, they are constantly indorsing orally, and in public print, quacks and patent medicines.

²³ The above statement relative to homeopathic work in science, has been frequently made, and so far as the writer has been able to find, never denied.

who complied, 510, or 15 per cent. were homeopaths, of whom only 382 claimed to have graduated from any medical school. A recent writer made the assertion that in the State of Illinois, "three-fourths of the most intelligent class of citizens" are homeopathic patrons.²⁶ Though this statement is without the slightest foundation, the fact that it was printed publicly, in a reliable newspaper, or one generally so considered, is sufficient reason for many to take it as "gospel truth," and to act accordingly.

The average homeopath regards refined homeopathy as a form of fanaticism. The pharmacist who sells bottled sunshine, and other chimerical remedies, he considers as either mentally or morally insane. He uses antidotes for poisons, and freely resorts to surgical and other mechanical means of treatment. He frankly admits that according to the more recent discoveries in science, many if not most diseases are the result of poisoning, and that analogy demands that these cases be treated—not homeopathically—but by antidotes. Many further claim that with advancing knowledge, the true scope for the use of homeopathy is decreasing. They are reserving it for only the doubtful cases. They no longer take it as the "only law of cure." In other words, there is little to distinguish the practice of the liberal homeopath from that of the ordinary practitioner.

On the hand, the high potentists claim that they themselves are the only true homeopaths. Though they are but a handful in the sect, and though they, too, have discarded Hahnemann's pathology, and his teaching relative to potentialization by succussions, the impartial student must admit that their claim is apparently well founded.

It is sometimes claimed by homeopaths, that mechanical treatment, electricity, antidotes, et cetera, which they use, do not cure, but only prepare the patient to be cured. If it were added that nature cures the disease, the statement would be correct; but that is not their meaning. They claim that the cases are cured after such a preparation by homeopathic drugs. Their claim is exactly on a par with that of the cancer quack, who removes the cancer *without pain* (after having made the patient endure untold agonies, while caustics slowly burn out the disease). The cancer quack simply lifts out the slough remaining after his inhuman treatment is over.

It is proper here, to refer to another charge, which is frequently made by homeopaths against the regular profession. They say that medicines are frequently adopted from the homeopathic school, without giving it any credit for bringing the same to notice. That is mentioned as an injustice. The fact is that the profession gives individuals credit for any investigations of merit, but it recognizes no school, and hence never gives any *school* credit for anything. Further, the standard works on *materia medica* seldom mention the names of those bringing a drug into prominence. There is, therefore, no injustice done the homeopaths, singly or collectively, in the matter, and any attempt to stir up sympathy on this score is out of place. With reference to this charge, an article headed "Who does the Stealing?" in Vol. I of this JOURNAL, page 434 (1883), receives additional interest from the tragic death of the writer, the late Dr. P. H. Cronin, of Chicago.

It has been claimed that homeopathy is scientific

because it alone recognizes a single law of cure. Carroll Dunham objects to regular medicine as unscientific because "hence, a new science must be formed for every new type."²⁷ It is surprising that such a man should confuse *law* and *science*. There are many laws in physics besides that of gravitation. The existence of magnetism does not prove that gravitation does not exist, although they may oppose each other. There is no science within the writer's knowledge, which recognizes a *single* law. Is it not too much to expect, therefore, that the supposed law of similars is universal? If it is not universal in its application, it can only be recognized in the science of medicine when its limitations are recognized.

In conclusion: Since there is nothing of value which is peculiar to homeopathy; since the dogma upon which homeopathy is founded is contrary to reason and contrary to fact; and since a large portion of the sect no longer bind themselves closely by the dogma in practice, but hang on to the designation apparently for advertising purposes, the existence of the *sect* is not conducive of advancement in the science of medicine, and its further life as a sect should be in every way discouraged in all intelligent communities.

THE MEDICAL EXPERT WITNESS.

Read before the McLean County Medical Society, Bloomington, Ill.,
Feb. 5, 1894.

BY JOHN A. STERLING.

ATTORNEY AT LAW, BLOOMINGTON, ILL.

The field of medical jurisprudence, by the necessities and conditions of the times has been enlarged, until it now assumes a phase of high importance to the profession, both of medicine and law. Its principles were applied in a primitive form centuries ago, but not until recent years has it developed into a science. It has made its present growth largely within the present century, and is now fully recognized by the general practitioner of both professions, as an indispensable part of his professional learning. This increased importance of the new science is due to two causes:

1. The science of medicine has been improved. Its rules and principles have been reduced to greater certainty; and the accuracy with which they have come to be administered, has firmly established the profession in the confidence of the people.

This was absolutely necessary to render medical knowledge available for the purposes of the law. In general theory the law of evidence deals only with facts, and not until the science of medicine had by experiment, observation and learning, been reduced to practical truth, was the medical expert an important factor in the administration of pure justice. But when he had arrived at that point in learning and skill where his opinion could be received by the court and jury with the force of a fact sworn to, then it became admissible as testimony, not so much as an exception, but rather because in effect, if not in fact, it came within the general rule.

2. The increased importance of medical jurisprudence is due to the changed necessities of the legal profession. The growth of population; the application of law principles to new fields of enterprise; the use of new inventions and motor power, increasing the number of "dangerous avocations;" the gen-

²⁷ Homeopathy, the Science of Therapeutics, p. 19.

eral growth of life insurance, and the frequency of insanity inquisitions, all tend to increase the number of cases where the medical expert is useful and necessary; and the general recognition, by the legal profession of the value of this kind of testimony, as a means of arriving at the truth, impel lawyers to resort to it whenever applicable to the case in hand. In this connection, Justice Foster of New Hampshire, in *Dole vs. Johnson* said: "In the multiplication of interests connected with the application of the laws of science, which are daily growing more and more numerous and refined, it is hardly possible to dispense with the aid of experts in determining the rights of parties."

To define the term, medical jurisprudence, it is perhaps sufficient to say: "Medical jurisprudence is that science which applies the principles of medicine and surgery to the purposes of the law. Presumably the purpose of all law is justice; and when the established facts pertaining to the medical profession will contribute to that end, justice, then it is not only legitimate but highly proper for the court, the medium through which justice is administered to litigants, to resort to them to ascertain the truth. It is the general rule that witnesses are permitted to testify only to facts; and it is sometimes said that the admission of medical expert testimony, is an exception to that general rule. In a sense this is true, and it is on this account that there has grown up a system of legal rules governing the subject matters of expert testimony, the qualifications of the competent medical expert, the manner of his examination, the manner of weighing his testimony, the means of discrediting him, his compensation and his responsibility, and these rules have become so well established by long usage and general approval that they are now the principles of medical jurisprudence and constitute it a science. It is of the expert witness and his relation to these several rules that I wish to treat.

The first question to be determined when the medical expert takes the witness stand, is whether he is qualified to testify on the subject matter of the examination. The necessity of resorting to this character of evidence arises from the fact that the subject matter of inquiry is such that unskilled and inexperienced persons are not capable of forming a correct judgment on it, without assistance of this kind. If the expert, by study, training, experience and observation has become specially skilled in a particular science or profession, then he can speak with sufficient authority to entitle him to testify. It is not required that he should have gained eminence or distinction by his learnedness, or that he should understand the minutæ or technique of the science. It is sufficient if he has made a special study or practice of the science or profession. The knowledge must be peculiar to himself and his profession, and not common to mankind generally. It is this general rule that admits the testimony of the physician or surgeon on all subject matter pertaining to the field of medicine and surgery. He need not have had any actual practical experience in the particular disease or injury to which he is called to speak, and even his scientific observation need not extend to that particular branch of the medical science. For example, the expert may never have treated a fracture, and yet be competent to testify as to the best methods of reducing it. He may in his practice

never have seen a case of strychnia poison, yet he is entitled to speak on the witness stand of the symptoms of that poison, and its effect on the human system and of its antidotes. His information and learning concerning the particular case in hand, may be based entirely on the books and still he is competent to testify. It is considered that his study and reflection on the subject, and his observation and treatment of its analogies enable him to speak with authority. It is not sufficient, however, that a person not a physician or surgeon should read the medical books, and then testify to the information gathered therefrom, neither is it competent to read to the jury from medical books, even though they be the same from which the medical expert gathers his learning on the subject in hand. To admit the contents of such books in evidence, would be to accept the statements of the author unsworn to; and to permit the person unskilled in medicine and surgery to testify to what he had learned solely from such books would be in effect to admit as evidence the statements of a third person, and hearsay evidence is always incompetent. But perhaps a more important reason why such statement is not admissible, is due to the fact that the jury, being men unskilled in the science, is not capable of drawing correct conclusions from the matter read to them from the books, or related to them by the witness. It is just here that the usefulness and reliability of the medical expert is important.

1. He is capable of knowing what authors are standard authority.

2. He understands the technicalities of the medical author's language and properly interprets them to the jury.

3. Being skilled in the study of the principles of the science he can draw correct conclusions from what he has read.

So while it is competent that the jury may know what standard authors may say on the subject in hand, it must come through the proper channel—the man who has given the matter study and reflection—and in a sense has mentally digested it for the jury, who otherwise could not have assimilated and appropriated it to the purposes of the questions involved in the litigation. If it were possible to have a jury of twelve medical men in all cases where medical evidence is required, then the medical expert would be unnecessary. But he stands in two relations to the court:

1. As an interpreter, he translates the terms and language of the science to the jury.

2. As a thirteenth juror he draws conclusions from medical facts in evidence, and gives them to the other twelve.

The rule as to the necessary qualifications of the expert, generally, is so ably laid down by the authority above cited and it is so applicable to the medical expert particularly, that I quote the following:

"The object of all testimony in courts is to place before the jury a knowledge of facts pertaining to the case under consideration, and it is a serious departure from this purpose even to admit, instead of actual knowledge, mere opinion, however correct it may probably be, and therefore, opinion if admitted at all, should be as nearly approximated as possible to the actual knowledge of facts for which it is substituted; and it should always be required of an expert that he should at least be sufficiently acquainted

with the subject matter of his testimony to *know* what its laws are, and not merely to conjecture or to have an idea about it. That is, he should be really a man of science. The science (especially in the absence of skill) which an expert should be required to possess and employ on a given subject, implies that special and peculiar knowledge acquired only by a course of observation and study, and the expenditure of time, labor and preparation, in a particular employment and calling of life. . . .

"We admit the wisdom of the rule which, permitting a man of genuine science to give as his opinion the results of study and research into books of knowledge and authority, yet will not allow such books to be read in court to the jury. The rule is founded partly in the delay which would thus be occasioned to the business of courts, and partly in the idea that it is safer, on the whole, to trust to the judgment of learned men, acquired by study, observation and skill, than to the imperfect deductions of jurors hastily derived from readings not familiar to them, unassisted by study, examination and comparison of kindred subjects. . . .

"But so long as the opinions of the most distinguished and most learned authors in the world, expressed through the direct and pure media of their celebrated works, are thus excluded from the jury, surely it can be neither wise nor prudent to admit opinions unsustained by the slightest experience or even observation, the deductions of readings at best scanty and superficial, because not pertaining to the special study and business of the reader. . . .

"Of course it must be admitted that the testimony of knowledge and opinion, obtained from mere reading, without study, reflection or observation, is no more than a relation by the witness of that which the policy of the law excludes, namely, the books themselves which the witness has read.

"The limit of safety in this direction is reached, it would seem, when we admit the opinions of medical men with regard to a disease (or injury) which in actual practice they may not have treated, but concerning which the science and skill of long experience in the affinities and analogies of the subject have prepared them to speak with confidence, from a knowledge of the rules and laws governing the special subject of inquiry. . . .

"And so the practice in this State permits the skilled practitioner, who has made himself familiar with the science of medicine and surgery by a long course of study and practical experience with kindred subjects, to testify as an expert; and common sense demands that such a man shall have respect given to his opinion, though he may have had no practical experience in a particular case."

It would thus seem that to render the medical expert qualified to testify, he must really be a man of science, a practitioner, or one fitted by study and reflection to be a practitioner of medicine and surgery. The question as to whether or not the qualifications of the witness bring him within that rule, is a preliminary question for his honor on the bench, and with which the jury have nothing to do. If his honor finds on preliminary examination that the qualifications of the witness are such as to bring him within the rule, then his testimony is admissible, and his views are entitled to go to the jury. The weight to be given his testimony, is a matter purely within the province of the jury, and to enable them to act

intelligently in weighing his testimony it is proper that they should know any and all facts pertaining to the knowledge of the witness, of the subject matter of which he testifies, the time spent in the study of the science, his years of experience, the extent of his observation, and whether or not the witness bases his opinion on the study of the books, or on his practical experience and observation, or both. And the law makes it the duty of the jury to take these matters into consideration, when they come to say whether they will give his statement much or little weight.

Assuredly it is not in all cases an easy matter for the court to determine the question as to whether the qualifications of the witness admit his opinions to the jury as an expert. Certainly the quack and the mountebank are not to be ranked as competent to give an opinion on which the life or property of a litigant may depend. They may be practitioners of medicine, yet poor reliance on which to hang important rights. But who is the quack? The man who first derogated from the practice of bleeding the patient, once so universal with the profession, may have been called a quack. He who first insisted on other remedies, than calomel, for certain diseases, perhaps violated the rules laid down and followed by the profession. At one time the man who dared to administer cold water and ice to the fever-stricken patient, might have been refused admission as a member to your honorable society. Such men may, in their day, be called quacks, and yet they are pre-eminently qualified to render an opinion, because they are truly men of science. He who by his diligence in study and research makes new discoveries in any science, is first of all entitled to speak, and yet it is not always an easy matter for the court, who is not a scientist in that line, to distinguish him from the mountebank and impostor.

"Nor does the court consider, in passing upon the qualifications of the expert, whether he belongs to this or that school of medicine. It is not presumed that he can say which is right and which is wrong, in their theory and practice of the profession; nor from what particular college he happens to hold a diploma. These are facts which the jury are entitled to know, and it is within their province to say on their oaths how much weight they will give to the opinion of the Regular, the Homeopath and the Eclectic.

Before leaving this phase of my subject it may be of interest and profit to refer to what the Supreme Court of our own State says on the qualifications of the medical expert, in *Siebert et. al., vs. The People*: "A licensed, practicing physician who is shown to be a graduate of a regular medical college, and to have practiced his profession for many years, is competent to give his opinion upon an hypothetical question setting forth the symptoms of a person immediately prior to his death, whether the death was from the effects of arsenical poison, although he may not be shown to have had any case of such poisoning. A medical witness, in giving his opinion as an expert, is not confined to opinions derived from his observation and experience, but may give an opinion based upon information derived from medical books."

While the courts of this and of European countries have very generally recognized the wisdom of resorting to expert opinion, to determine rights involving medical scientific questions, yet the manner of select-

ing the expert witness differs widely in the different countries; and there has been no little discussion as to what is the best method. In France it is made the duty of the court to appoint the expert, and it then devolves upon him to investigate the medical questions involved in the case, and report his conclusions to the court. In Germany, the state, after an examination as to competency, appoints medical men as experts to testify in cases where such testimony is required; and if desired by the litigants the opinions of these may be referred to a higher tribunal of medical experts, also appointed by the state.

In Prussia, the law provides for the appointment of a physician and surgeon in each county to act as medical experts. In case an appeal is desired, the matter is submitted to the medical college of the province in which the county is situated; and a still higher appellate authority is provided, by the appointment of a national commission of medical experts, which is a court of last resort.

In this country as in England, the manner of selecting medical experts is entirely different, and as we believe far superior to that of the countries named. Here each litigant may call from the profession whoever he chooses, to testify in his behalf, or in support of his theory of the case. It has been urged against this method that it offered too great inducement to fraud; that the expert would appear rather as an advocate, working for a fee than as a non-partisan witness; but this objection has but slight weight when placed in the balance with the objectionable features of other systems. The same may be charged against all other plans with equal force, for it simply means that there is danger of the litigant bribing the witness. The other plans mentioned involve the danger to which all appointive offices are more or less subject, namely, partisan prejudice and political corruption, and to the still greater danger of absolute incompetency and ignorance. There is no substantial objection to the American plan. The profession is made up very generally of men whose high moral and social standing is a guaranty against dishonorable means. There is perhaps no class of men, taken as a body, who have a deeper professional pride than that of physicians and surgeons. It is with them as with Cassio—it is reputation—and there is but little to fear of the medical expert risking his reputation by an unlawful collusion with the litigant who calls him. Moreover, if he should attempt to prostitute the science to false and fraudulent ends, he can hardly hope to escape disaster when it comes to cross-examination, for a false or ignorant *expert* witness is more vulnerable than any other. This is true because under the American plan he can be met by the most talented men in the science, and can be confronted by the very works on which he chooses to base his opinions. If the cross-examiner is equal to the occasion—and if he does his duty to his client he is thoroughly familiar with the medical side of his case—he will detect the falsehood or error of the testimony and disclose it to the jury. The very strength of the system is its tendency to encourage the selection of the best talent the profession can boast.

The manner of the examination of medical experts has occupied the minds of medico-legal text writers perhaps as much as any other one phase of the subject, and it is a matter on which there has not always been uniformity of opinions in the decisions of the

courts. If the witness was the attending physician, he is asked to state his conclusions from the facts as he observed them, but if he has had no personal connection with the case, the facts, or what is claimed by the litigant calling him, to be the facts, are stated to him hypothetically and he must state his conclusions, drawn from the hypothetical statement of facts. Certainly if the facts are conceded or agreed upon by the litigants, or if they are proven and undisputed, then they need not be assumed. But if there is contention as to what the facts are, then counsel is bound to state the facts hypothetically according to his theory of the case, and call for the professional opinion of the witness thereon; and opposing counsel on cross-examination may propound to the same witness the hypothetical question based on *his* theory of the facts. If the facts are agreed on, or conceded, then the question must contain all the facts agreed on or conceded, and no more, for if the conclusion of the expert is based on more or less than the actual facts it is the duty of the jury to take that into consideration, and they could not logically give weight to an opinion based on a state of facts different from that involved in the case. When the facts are in dispute then counsel may assume any state of facts, pertinent to the case, of which there is any evidence before the jury, and the first thing for the jury to determine, when they come to consider the expert testimony, in making up their verdict, is whether or not the facts assumed in the hypothesis are the facts proven in the case, and if they believe from the evidence that they are, then they should give the conclusion of the expert, based on the hypothesis, due consideration, and such weight as they deem it entitled to. On the other hand, if they find from the evidence that the facts assumed by counsel in the hypothetical question are not the facts proven in the case, then, although the opinion of the expert is correct from the standpoint of counsel, yet it is of no value to the jury in arriving at the truth, because it is not applicable to the case proven, and they have no right to consider it. It is doubtless true that much profound medical learning and many able professional opinions have been wasted on the "desert air" simply for the reason that unskilled or unfair counsel do not embody the true state of facts in their hypothesis. If the hypothesis of the lawyer falls, the conclusion of the doctor falls with it. It is a pure, simple syllogism; if one premise fails the conclusion fails. As to the duty and rights of counsel in this matter I quote the following from Rice on Evidence:

"Counsel in framing hypothetical questions to be put to expert witnesses, are not confined to facts admitted or absolutely proved; but facts may be assumed, where there is any evidence on either side to establish them, which are pertinent to the theories which they are attempting to uphold. In the direct examination of their own witnesses, it would tend to confusion if facts were assumed in hypothetical questions which did not bear upon the matters under inquiry, or which were not fairly within the scope of any of the evidence. Upon the cross-examination of an expert, counsel may not be so narrowly confined but may, in putting hypothetical questions, assume any facts pertinent to the inquiry, whether testified to by witnesses or not, with the view of testing the skill and accuracy of the expert; but such cross-examination must, to some extent, be under

control of the trial court. The proposition here contended for, finds ample vindication in a recent decision of the New York Court of Appeals."

It is the prevailing rule that the expert witness is entitled to demand and receive adequate compensation for his opinions on the stand; and he can not be required to speak until it is assured. This applies only where he is called to give a professional opinion on a scientific question. He may be required to testify to matters of fact without other reward than the non-expert is entitled to, even though he becomes possessed of the facts while acting in his professional capacity. Thus, if a physician be called to attend a dying patient and the cause of the death should afterwards become a question involved in a suit at law, the physician may be required to testify to all facts he learned while attending the patient, and to all material matters observed by him. And this he does with the same rights as an ordinary witness, although his statement of the symptoms may be much more valuable than that of a non-professional man. But when the examination goes beyond the range of fact and calls for an opinion on a question on which none but a man of science is competent to give an opinion, then the expert may decline to answer until he is fitly rewarded for the information which the litigant seeks. This is so because this information is property. It is the physician's capital. To acquire it, cost him the expenditure of labor and money, and he can not by any rule of law or morals be compelled to divulge it in court for the benefit of the litigant who calls him, without pay, no more so than if called professionally to the bedside of the same party to administer to him. If the law were different it might create a great hardship on some members of the profession. It would be dangerous to acquire great distinction or eminence. The man, most learned in this or that specialty of the science would be sought after on all occasions where questions in his line were involved. He thus might be called upon to devote his whole learning and energies to the benefit of parties in court to the demoralization of his own personal and private affairs and to his great loss. Law requiring this would seem to be hardly consistent with reason and justice, yet some courts have so held. We believe the Supreme Court of this State has not passed on the question. In general, that for which the expert is entitled to extra pay is his answer to the hypothetical question; yet there may be many other questions incidental to the leading issues that call for expert opinion, and to which the rule equally applies. The pay must necessarily be demanded from the party calling the witness. The testimony is presumably for his benefit, and he must pay; and this is true, even though the testimony should prove disastrous to his cause. The expert can not require pay from both sides of a case so long as his testimony is confined to the subject matter on which he was examined primarily. Thus if he offers an opinion on the plaintiff's theory of the case, he can not require pay from the defendant on cross-examination on the same subject. The defendant is entitled to have the jury know the qualifications of the witness, his means of knowledge and the authorities on which the opinion is based, and his reasons for his conclusions. He is bound to submit himself to all the legal tests, and he may be required to answer questions purely for the purpose of deter-

mining his credibility and reliability. But if the cross-examination goes beyond this and outside of the subject matter of the direct examination, and calls for a scientific opinion on other matters, the witness may refuse to answer on the ground that he has not been paid for the information sought.

Can a physician be compelled to divulge in court professional secrets, if a reasonable and satisfactory fee is first tendered? This is a question on which there seems to have been some diversity of legal opinion in the past, and a number of the States have settled the question by statutes governing the matter. We are not aware that the Supreme Court of Illinois has passed on the question, but in those States generally where it is not controlled by statute, the courts have held that the physician can not refuse to answer on the ground that his answer will divulge professional secrets, or that it is privileged communication; and that is the common law. As to the amount of the compensation, the law only requires that it shall be reasonable and its reasonableness should be measured largely by the qualifications and professional reputation of the witness, and the importance and difficulty of the questions on which he is called to testify.

It would be impossible for me in this paper to speak at length of the duties of the medical expert. His duties are so broad and varied, even a review of them can not be covered in so short a time. The chiefest part of them arises and must be performed before he is called to the witness stand. This is specially true of the physician who happened to be connected professionally with the case. It is not infrequently, that the very source of justice or injustice may be traced to the attending physician. For example, a physician is called to attend a person injured in an accident. The patient dies from the effects of the injury, and the question of the cause of the death arises in court in a suit for damages. If the physician has had an eye to the medico-legal phase of the case it often happens that through him the exact truth may be discovered, and if not through him it may not be discovered at all. It may be that a thorough and minute examination of all the details of the person and his injuries will disclose the source of the injury, and locate the negligence that caused it. He may be able to tell whether the force came from behind or in front, or whether the patient himself, by his negligence, contributed to the injury; and numerous other facts may be developed from the observations made by the physician. Again, he may be called to attend a patient to whom poison or abortifacients have been criminally administered, and while he is endeavoring to save the life of his patient he should gather and retain every fact that will tend to the discovery of the criminal. Every symptom that indicates the nature of the poison, should be carefully noted and the statements made by the patient not forgotten. And in case of death, no more valuable service can be rendered the cause of justice than that of taking in legal form the dying declarations of the victim. These statements, to render them admissible must have been made *in extremis*, under a sense of impending death, and at a time when the patient has lost all hope of recovery. It is better, though not imperative, that they be reduced to writing, read over to, and signed by the patient. Courts have expressly recognized the fact that these statements are more valuable if made to a medical attendant. Courts have admitted this kind

of unsworn testimony on the theory that the solemnity of the hour and the belief that death is imminent, and at hand, dissolves every motive to falsehood and impels the person to speak the truth. From these considerations courts give to such statements the sanctity of an oath. In a case of this kind a postmortem examination of the deceased is often absolutely necessary to discover the true cause of death, and should never be omitted, even though it adds but little to the physician's knowledge of the case. Every postmortem symptom should be noted and every part and organ of the body likely to disclose the kind of poison, should be preserved for chemic analysis. If the attending physician would bear in mind that the slightest minutiae and detail are often of the utmost importance when it comes to the medico-legal side of the case, his sense of justice would prompt him to faithfully preserve them for use in court. If he should wilfully neglect or discard them from his mind to avoid the inconvenience or embarrassment of being called as a witness, he is simply guilty of professional cowardice.

It is only fair to the expert who has had no professional connection with the case, to state to him fully before he is called as a witness, all the facts in the case pertaining to the medical side of it. He may thus be placed to some extent on the same footing as the attending physician. It enables him to consider the facts in connection with his knowledge of medicine or surgery and reviews, if he desires, the authors he read in his novitiate. He can consequently give a more certain and mature and hence a more valuable judgment to the court and jury.

The duties of the medical man in cases where legal questions arise, are so numerous and important that no member of the profession can afford to be indifferent to them. To act as a witness in court may be odious to him but it is not optional; and however secure he may feel himself to be from the demands of the court he is almost certain, sooner or later, to be connected with a case where he is a material witness and will be required to testify. If he has had a due regard for his medico-legal duties as a physician he may be prepared to establish an important right, or redress a grievous wrong. If he has failed to note any material facts, it will likely prove the vulnerable point of attack on cross-examination. His dereliction will be made the most of by artful opposing counsel. The responsibility of the medical expert is commensurate with his duties; as the one is important so the other is grave. While he is by no means legally liable for an honest mistake of judgment, yet there is a moral responsibility from which there is no escape. There is perhaps no instance where the private citizen is placed in a more onerous position than the doctor, when called to the witness stand in certain cases. It is frequently the case that great property rights turn on the truth or error of his judgment; and he confronts a still more serious condition when the liberty or life of a citizen hangs on his testimony. Through his mistake a death by fiendish murder may be ascribed to innocent causes, or, what would be almost as bad, by an error on his part the guilty man would go unhung. It is true the medical expert has been the subject of much harsh criticism and abuse, and even courts in the past have spoken adversely to that character of testimony. Numerous decisions not a quarter of a century old may be found where high legal authority has de-

nounced it as unreliable and unworthy of consideration. But later decisions indicate that courts have radically reformed their opinions in this direction and have come to regard medical expert testimony of the highest importance in determining rights involving medical and surgical problems. I venture the opinion that if to-day a case involving intricate medico-legal questions, were submitted to the Supreme Court of the State of Illinois for consideration, in which no medical expert testimony had been offered to assist it in arriving at the truth, it would censure counsel for what it considered a gross neglect of duty. In short, it has come to be regarded as absolutely indispensable to the functions of the court in many cases; and the physician who is ready, when called, to give an honest and mature judgment on questions in his line is a powerful and important factor in the administration of justice.

CONGENITAL AND HEREDITARY GOITRE.

BY CHAS. W. ROOK, M.D.

QUINCY, ILL.

Case 1.—Frederick, second child of Mr. and Mrs. F. B., was delivered by me, Aug. 22, 1893. Position of child in utero, L. O. A. Because of maternal exhaustion, the labor was terminated instrumentally. For a few hours, the child was cyanosed and respiration stridulous. The right lobe of the thyroid gland was of the size of a hen's egg, while the left was one-third less in size. Although the goitrous tumors have gradually decreased in size, the child involuntarily keeps its head extended that respiration may be more easily performed.

The mother, aged 23, and her sister aged 26 years, have been goitrous since the ages of 12 and 17 years respectively.

The notes of Cases 2, 3 and 4, the latter being a case of hereditary goitre, were kindly furnished me by my friend, Dr. E. B. Montgomery, of Quincy, Ill.

Case 2.—Mrs. W. H. M., aged 29 years, was attended by me, May 24, 1893, in her seventh labor as she had been in the previous six accouchements; she has been goitrous since her marriage thirteen years ago. The other children were all sound, healthy and free from blemish. The seventh child had, at birth, a very large goitrous tumor, extending well over the entire neck and up into the submaxillary regions and by pressure rendering the breathing stridulous as in laryngismus stridulus.

The infant remained cyanosed and the respiration noisy and croupous until its death, which occurred eight hours after birth.

Case 3.—Infant daughter of Mr. and Mrs. R.W.F., born Oct. 24, 1893. Each lobe of the thyroid gland was markedly enlarged. Respiration stridulous for twelve hours, after which it became easier. The following very unique family history was obtained: An elder brother of Case 3, nearly 5 years old, has been goitrous since birth. The mother of these children, aged 22, and her sister aged 19 years, each have well marked goitres; and the father, aged 28, and his sister aged 24 years, have goitres which they have carried since their earliest recollection; while the father's mother is also goitrous.

Case 4.—Miss E. B., aged 23; goitrous tumor involving the right lobe of the thyroid. Miss B. has always had a fat neck, but whether her goitre was congenital or not is unknown. The mother of Miss B. is about 50 years of age and also has a very large goitre, the growth being much larger on the right side. A daughter of the mother's sister is also goitrous.

For references to the literature of this subject, I am indebted to Surgeon J. S. Billings, U. S. A., and the *Index Medicus*.

Dr. Geo. S. Chalmers, now of Galesburg, Ill., mentions, in the *New York Medical Record*, Oct. 6, 1883, Vol. xxiv, p. 390, "A Case of Congenital and Hereditary Goitre."

He writes: "A few days ago I was called to a lady

in labor, and in due course she was delivered of a large boy. There was nothing remarkable in the progress of delivery, except that when labor had progressed well into the last stage, things almost stood still with the head firmly wedged in the lower strait. Imagine my surprise to see a well developed goitre on the child's neck. The swelling came up under the ears and with quite an enlargement over the windpipe. The goitre felt moderately firm as if from simple enlargement. The child was cyanotic at first, and had to be encouraged by cold water douches and manipulation before it commenced breathing; and then it was fully an hour before its color became natural. We soon discovered that if the head was kept fully extended, breathing progressed naturally, but if the head became flexed, breathing became irregular and the face cyanotic. It is now doing well, six days after delivery, and is a vigorous feeder.

"The mother is exophthalmic, with quite an enlarged neck and noticeably prominent eyeballs. I have never seen a case of congenital goitre recorded. What can be done for a case like this?"

From a recent correspondence with Dr. Chalmers concerning the above mentioned case the following notes are extracted:

"In regard to the case you speak of, I would say that the subject has been under my almost daily observation since his birth until somewhat over a year ago. He was a puny lad and I hardly expected to see him pull through the period of adolescence but, thanks to kindly care and the best of home surroundings, he has developed into quite a boy. His goitre never increased; in fact, is not as noticeable now as it was at birth. He is now tall for his age but slender, with rather a pale face. He is not bright; is somewhat dull of hearing and inclines to stutter in his speech. He is of an extremely nervous temperament, easily startled and, in that respect, quite childish. He has kept his place in school without falling noticeably behind and, if nothing happens, is likely to go through the high school course.

"The mother, also of a very nervous temperament but in better health than before the birth of the boy, is quite noticeably exophthalmic."

Captain J. C. Worthington, M.D., Asst. Surg., U. S. A., reports in the *New York Medical Record*, 1883, Vol. ii, p. 708, "A Case of Congenital Goitre Cured by a Single Application of Mercuric Binioidid." He writes:

"I first saw the patient, S. D. B., a well developed male infant, July 26, 1883, six hours after birth. The mother, a native of Prince Edward Island, and for a year past resident on her husband's ranch on the Uncompahgre River, Colorado, had had a slight goitre for over two years, the swelling having first been noticed during her previous pregnancy. The family was much alarmed at the appearance of the child's throat. On examination, I found a marked goitrous swelling, soft, but not fluctuating, on the right side of the trachea. The tumor was as large as a hen's egg. I advised that nothing should be done until the child was three months old, when I would attempt to cure it by an external application, which I thought would not be advisable before that time. I did not see the child until November 12, when it was brought to me by the mother for the treatment that I had promised. I found him a well nourished baby, healthy in every respect except the deforming tumor on the right side of his throat,

which had increased with his growth, and filled the whole space between the chin and sternum on that side. His mother stated that the tumor now interfered with his breathing when he lay on his back. The flattening of the crown of the head, mentioned by Aitken, was now well marked. I confess it was with some misgivings that I prescribed for the child the treatment mentioned in Aitken's 'Practice of Medicine' as having been attended with such wonderful success in India. I ordered the following:

R. Mercuric binioidid gr. x.

Lard ʒi.

M. S. Apply as directed.

"I directed as follows: At 10 A.M. on a bright, sunny day, rub well into the skin over the whole of the tumor a lump of the ointment the size of a filbert. Then hold the child, with the tumor exposed to the sun, at a closed window, as the weather was cool, for half an hour, then for an hour in front of a fire. At 2 P.M. of the same day repeat the application, and expose to the sun and fire as before. On November 28, the child's mother brought him to me—cured. She stated that the treatment had been carried out as directed on the 17th, except that the exposure to the sun in the afternoon had been for less than thirty minutes, on account of its being so painful to the little patient; that he had had much pain and cried a great deal the following night; that the skin had become very red and had peeled off wherever the ointment had touched it; that she thought the next day the swelling seemed smaller and on the 20th, three days after the application, the tumor was almost gone, and had grown smaller ever since until it entirely disappeared. When seen November 28, eleven days after the application, there was no evidence of cutaneous irritation, and the thyroid gland was just perceptible to the touch as in a normally formed infant. The cure was complete. No salivation or other indication of constitutional effects of the mercury occurred."

A. T. Sloan, M.D., Edinburgh, writes in the *British Medical Journal* for 1886, Vol. ii, p. 859, "Is Goitre Hereditary?"

"Whatever may be the primary source of goitre, there is every reason for supposing that, once established, it is often continued in families by inheritance, or at least, in this manner a strong predisposition to the disease is acquired. The question whether the malady is hereditary or not has given rise to much discussion; and not a few writers, including St. Leger, dispute the fact. (See *Cretinisme*, p. 108.) His arguments, however, are by no means convincing, and confirm the typically endemic nature of the disorder, without in the least degree proving that a disease which is endemic can not at the same time be hereditary. That heredity plays an important part in the production of goitre, a study of my cases clearly shows; thus of twelve cases collected by me at Wishaw, Lanarkshire, eight show distinct heredity. In six, the mother and grandmother both suffered from goitre; while, of the remaining two, one had a cousin affected with the disease, while the other's mother died of the exophthalmic variety. It is interesting to note this case; the mother for years subject to exophthalmic goitre, and the daughter, a strong, healthy girl, now with the ordinary variety.

"Of eighteen cases collected at Penrith, Cumberland, ten are distinctly hereditary; in eight the mother being affected, in two the father suffering

from goitre. In one case grandfather, mother and aunt were afflicted with the disease; in another, it revealed itself in grandmother, mother and aunt; while a third was congenital, the mother also being goitrous. No less than five cases instance the occurrence of the affection in members of the same family, those affected being sisters. Some of these had lived for a long time in different parts of the country. Dr. Croford mentions the case of a woman with goitre, whose grandmother, father, paternal aunt and cousins also had it, although they did not live in the same place and no other person in their neighborhood was affected with the disease. (*Cyclop. of Prac. Med.*, p. 335.)

"The disease is not only hereditary, but may even be sometimes congenital. In one of my own cases the goitre has existed from birth, and recently I had notes sent me of two cases of congenital bronchocele where the mother also was affected. Dr. Keiller (*Edinburgh Medical Journal*, 1855), records an instance where he delivered a Mrs. K., aged 24, of her first baby, which with the exception of a very large goitrous tumor, was a remarkably fine male infant. Mrs. K. was brought up in Cumberland, her mother being a native of Keswick. None of her immediate relations had goitre.

"Dr. James Reid, (*Edinburgh Medical Journal*, 1836, p. 49) has seen three infants who had the thyroid tumor fully developed; and Fodère thinks he observed a distinct goitre in three cases of newly born children. M. Godelle, physician to the hospital at Soissons, had a preparation of the body of an infant, which lived a few hours only, and which came into the world with a goitre, the mother being afflicted with the same disease. Mr. Bromley affirms that in India both children and animals are born with it; and cases of congenital goitre have been recorded in Derbyshire.

"I think the facts just mentioned go to prove that goitre is really a hereditary disease."

Dr. A. W. McAlester, Columbia, Mo., reports, in the Transactions Missouri State Medical Association, 1882, a case of "Congenital Multilobular Cystic Degeneration of the Thyroid Gland," from which report I take the following extracts:

"By the courtesy of Dr. Trimble, I was called in consultation June 4, 1881, to see the child of Mrs. B. When first seen by me, the child, a girl, was ten days old. I found a tumor, with irregular outlines, extending from the angle of the right lower jaw to the median line of the neck, seven inches, thence towards the opposite side, two inches; from center of right clavicle to middle of lower jaw, five and a half inches; lobulated, translucent and, as I thought, fluctuant, with somewhat of a solid base near the median line and lower part of the tumor. The child grew and did well for three months, after which time it became emaciated, the tumor still growing, thus showing that the child was not capable of standing this division of nutrition, to-wit to nourish the growth and the body at the same time. The emaciation continued, and the tumor increased until the day of the death of the child, Oct. 21, 1881. Pneumonia was the immediate cause of death. At the postmortem held the following day, the tumor was found attached to the hyoid bone, thyroid cartilage and three adjoining rings of trachea, thus making an attachment of two inches. Its dimensions were, long diameter, eleven inches; transverse, six and a half inches;

weight two pounds, and was partly cystic and partly solid. The fluid evacuated from the cysts was transparent, odorless and composed largely of albumen."

Lennox Browne, F.R.C.S., Ed., reports in the *Lancet* (London), Aug. 9, 1890, a case of "Congenital Enlargement of the Thyroid; Removal, Recovery," from which report I make the following extracts: "M. T., female, aged 10 years, was admitted to the Central London Throat and Ear Hospital on Nov. 21, 1889. The patient was born with a 'lump' in her neck the size of a marble, which has been growing ever since. When admitted, there was in the region of the thyroid gland a large irregular tumor about the size of a fetal head at 7 months. Dec. 22, 1889, Mr. Lennox Browne removed the tumor under chloroform, the resulting wound healing by Feb. 24, 1890. The growth was a fibro-cystic goitre originating from the isthmus of the thyroid gland."

George H. Ormsby, M.K.Q.C.P.I., reports in the *Lancet* (Lond.) Feb. 25, 1888, the following case of "Congenital Goitre:"

"On February 10 I attended Mrs. T. in confinement. She had a rather tedious time owing to the pains being feeble, but in every other respect the labor was natural, and she was delivered of a son. The cord was round the neck once. Immediately the child was born, I noticed the large size of the neck in front, and at first thought it was due to constriction by the cord. However, on examination it proved to be a true case of enlargement of the thyroid on both sides, the right side being much larger than the left. When I told the patient what was the matter with the baby's neck, she said she was not surprised, as her own neck had troubled her a good deal since last September, at times causing her some pain and a good deal of uneasiness. About the same time it began to enlarge, and she was in the habit of frequently feeling it; but though it bothered her, she did not think it worth while getting advice about it.

"Goitre is very common in this district, and I have two cases of Graves' disease under my notice at present. I have only had one case of goitre in the male, and have never till now heard of or seen an instance of congenital goitre. Taking the mother's statement into consideration, I am inclined to think that 'maternal impression' has had some influence in producing the complaint. I have seen the child again to-day (February 17), and although the left side seems a little smaller, the right is still the same size. The deformity does not in any way interfere with the child's breathing, or with his taking food. Perhaps some of your readers will kindly say if they have met with a similar case, and what treatment, if any, they adopted. I feel inclined to leave it alone for the present, and see what nature will do."

Dr. Frank J. Lutz, St. Louis, Mo., presents in the Transactions Missouri State Medical Association, 1882, a report upon "Congenital Cysts of the Thyroid Gland." From the Doctor's report the following cases are obtained:

"Berand and Dangan, (*Bulletin de la Société de Chirurgie*, 1861, p. 108) reports the case of a five and a half months fetus, which was born alive, with a vascular, soft, follicular struma extending from one parotid gland to its opposite fellow."

Virchow, (*Die Krankhaften Geschwulste*, Vol. iii, p. 51) "observed a case, also, in a five and a half months fetus, in which the struma was covered with veins and weighed 16 grams."

Boucher, (Kystes Congenit. du Con. Thèse de Paris, 1868, p. 108) "saw blood effused into a congenital cyst of the thyroid in a seven months fetus."

Bednar, (Die Krankheiten Neugeborenen und Sauglinge, Vol. iii, p. 80) narrates a case "in which there existed congenitally a cyst as large as a walnut in the right lobe of the thyroid."

Hecker (Monatschrift fuer Geburtskunde, 1868, Vol. xxxi, 2 and 3, p. 119) reports the "case of a child which at birth weighed seven pounds, and which died immediately afterwards of asphyxia. It had a goitre weighing 41.6 grams; the normal weight of the thyroid gland being between two and seven grams."

Hubbaner, (Wertembergsche Zeitschrift fuer Chirurgie und Geburtskunde, 1858, p. 1, and Honel Soc. Anat., Oct. 3, 1873) mentions the "case of a boy from whose left lobe of the thyroid gland there grew a soft fluctuating tumor much larger than the child's head, constituting an impediment to delivery."

V. Ammon, (Die Auebornen Chirurg. Krankheiten des Menschen, p. 57) details a "case reported to him by Adelman, who observed it in Dieffenbach's clinic. The child was fourteen days old when seen by Adelman. The goitre was so large that several physicians diagnosed a fetus in fetu. When the child cried, the goitre became of a dark red color, and the veins of the neck became immensely swollen. The child lived ten months, and at the postmortem examination serous cysts and cartilaginous formations were found."

Demme, (Gerhard Handbuch der Kinderkrankheiten, Bd. 111, 2d Haelfte, p. 390) mentions a case in which he "observed a neoplasm of the thyroid which weighed 102 grams. The child died thirty-six hours after birth." The same author (p. 391) illustrates the case of a "twin boy with a congenital cystic struma. The twin sister of this boy was also born with a congenital enlargement of the entire thyroid, hyperemic in its nature. Both the father and mother of these children have bronchoceles; the former's being follicular, the latter's cystic." Demme also gives the following statistics: "Of 462 cases of struma observed in the Children's Hospital, Berne, Switzerland, 53 were congenital. Of the 53 congenital cases, 27 were simply hyperplastic in their nature, 14 were follicular and 9 were cystic."

VACCINATION.

BY JOHN H. RAUCH, M.D.

Owing to the increase of smallpox in the United States during the last two months, the State Boards of Health of Ohio, Iowa and Wisconsin have ordered vaccination of all the school children, and in some

cases of the entire population, as they were authorized to do by the laws creating them in order to protect the public health. At least 90 per cent. of the population of this country are favorable to vaccination. Still, in certain localities in Iowa, Wisconsin, Springfield, Ohio, and Williamsport, Pa., opposition has sprung up against the enforcement of vaccination. This opposition arises from prejudice, ignorance and resentment against a supposed interference with personal liberty and the dispensations of Divine Providence. The writer, during a professional experience of over forty years, and an official sanitary experience of over thirty years, has vaccinated or personally superintended the vaccination of more than two hundred thousand individuals, and has never known any one to die because he had been vaccinated, but has known thousands to die because they had not been vaccinated and re-vaccinated. While there are no doubt cases where vaccination has been the direct or indirect cause of death, still, they are so rare that compared with the protection given, the objection can not be regarded as valid, and from a general standpoint the refusal to submit to this measure of protection can not be tolerated. Individual rights must be respected, certainly, but it is the right of no man so to use his liberty of action as to endanger the rights and lives of others.

In Illinois, during the epidemic of 1881-1883, the recovery of the vaccinated was 94 per cent. and the mortality 6 per cent.; while of the unvaccinated 51 per cent. recovered and 49 per cent. died. Smallpox proved to be as destructive of life as in any epidemic of the pre-vaccination period wherever its contagion was introduced among the non-vaccinated, the mortality rising in this class to nearly 50 per cent. On the other hand, just in proportion as vaccination and re-vaccination had been efficiently performed, that mortality was diminished—falling from a death rate of over forty-four in a hundred attacked who had not been satisfactorily vaccinated, to absolutely no deaths among the few who, having been efficiently vaccinated, were still attacked with the disease, but were again successfully vaccinated after exposure. The duration of the disease, its severity, and its results were found to bear a direct relation to the vaccinal history of the patient; where this was *nil*, there was the longest duration (except where terminated by death), the greatest severity, and the most disastrous sequelæ; where the vaccinal history was good, the disease was mild, often of only a few days' duration and never followed by disfigurement or loss of sight or hearing, or by other disability. It was also found that, after the contagion had obtained a foothold in a community where vaccination had been neglected, no enforcement of sanitary measures, nor isolation of cases, then availed to restrict the epidemic influence or tendency until vaccination and re-vaccination had been made general. It was not until vaccination and re-vaccination became general in this State that the epidemic was stayed.

A recent report of the Philadelphia Municipal Hospital shows that of seventy-eight unvaccinated infants under one year of age admitted while suffering from smallpox, fifty-seven or almost three-fourths, died; while of vaccinated infants of the same age none died. In Leicester, England, during the epidemic of 1893, there were 126 persons who had never been vaccinated, and who caught smallpox, 83 were under 10 years of age, and in 9 of these the dis-

ease was fatal, whereas there was no instance of smallpox occurring in a vaccinated child under 10 years of age; and of the 155 cases of the disease occurring in persons who had been vaccinated, but not re-vaccinated recently enough to save them from varioloid, there were no deaths. The effect of compulsion in the matter of vaccination is forcibly demonstrated by a comparison of three European nations which make it optional—Austria-Hungary, Russia and France—where the number of deaths from smallpox in two recent years ranged between 157 and 583 per million; and as many nations which make it compulsory, Denmark, Sweden and Norway having no deaths at all during either of the years, and the proportion in the German Empire being only 0.8 and 1.8 per million in the two years.

of water and milk which he had originated. His method is a new one to me, and I think to the rest of the profession; it consists in the use of hermetically sealed bottles.

I have used a simple contrivance which has served me much better than any other sterilizer. I use pint beer bottles with "lightning stoppers." (Fig. A.) They can be obtained of any liquor dealer or grocer.

The bottles are placed in a vessel (Fig. C), a six quart tin bucket is a suitable size for family use, as about six pints of milk or water can be sterilized at a time. The lid of the bucket has six one and one-half inch openings through which the necks of the bottles pass. (Fig. C.)

A loose false bottom rests on the true bottom. (Fig. D.) This is raised one inch from the true

It is undoubtedly the duty of all health officers to secure the vaccination and re-vaccination of every person in the community so far as it is possible.

Medical men and nurses when called upon to attend cases of smallpox, no matter what may have been their previous personal experience, either as regards vaccination or smallpox, should at once be vaccinated as a matter of precaution, both for their own safety and that of the public.

STERILIZING WATER AND MILK IN HERMETICALLY SEALED BOTTLES.

BY W. E. GAMBLE, B.S., M.D.
CHICAGO.

Professor C. A. Cary of Auburn, Ala., while visiting me last summer, called my attention to a sterilizer

bottom, by two strips standing on their edges rising at right angles to each other and soldered to under surfaces of false bottom. This apparatus should not cost more than one dollar.

In using this appliance space must be left to allow room for the expansion of steam, and yet I have been careless as to the amount of space to leave for that purpose without untoward results; however, the space between the bend in the bottle, x, (Fig. B.) and the cork should remain unfilled.

To raise milk to 150 degrees F., not higher than 167 degrees, Professor Cary has by experiment found the following conditions necessary:

Bottles are filled to x, Fig. B, closed and placed in sterilizing vessel; cold water is poured into sterilizing vessel until it rises one-fourth of an inch above false bottom, the sterilizer is then placed over the

fire and heated until water in vessel boils eight to fifteen minutes. As a rule eleven minutes is sufficient. But should water in vessel be heated very rapidly let it boil fifteen minutes. If water comes to a boil slowly, say thirty minutes, allow it to remain eight or ten minutes. The vessel should be taken from stove and covered with dry cloths and allowed to stand for about a half hour.

A temperature of 140 degrees F., which is sufficient to destroy growing and adult germs can be obtained without the scrupulous care mentioned above. A higher degree of heat than 167 degrees is not desirable in sterilizing milk, on account of the chemic disorganization which takes place.

A temperature of 200 to 212 degrees F. is desirable in sterilizing water. This high temperature is easily obtained by filling the sterilizing vessel with cold water as high as the level of the water in the bottles, i. e., x, Fig. B. Cover the perforated lid with cloths; then allow water in vessel to boil from thirty to sixty minutes; after bottles are partially cooled, they can be transferred to ice chest.

Water or milk sterilized in this manner does not taste "flat." They lose none of the absorbed oxygen or nitrogen which makes them palatable. The question is often asked at our table: "What mineral water do you use? It is so palatable."

It is the simplest way to sterilize water and remains air tight until used. The cheapness of the apparatus is another factor in its favor. Professor Cary says that milk can be raised to higher temperature in this way without chemic change than by the open method.

264 S. Halsted Street.

APPENDICITIS; WITH ORIGINAL REPORT AND ANALYSIS OF ONE HUNDRED AND FORTY-ONE HISTORIES AND LAPAR- OTOMIES FOR THAT DISEASE UNDER PERSONAL OB- SERVATION.

Read before the Pan-American Medical Congress.

BY J. B. MURPHY, M.D.

CHICAGO.

PROFESSOR OF SURGERY, AND CLINICAL SURGERY, COLLEGE OF PHYSICIANS
AND SURGEONS, CHICAGO; PROFESSOR OF SURGERY, POST-GRADUATE
MEDICAL SCHOOL AND HOSPITAL; ATTENDING SURGEON TO COOK
COUNTY HOSPITAL; ATTENDING SURGEON TO ALEXIAN
BROTHERS' HOSPITAL; CONSULTING SURGEON TO
HOSPITAL FOR CRIPPLED CHILDREN, ETC.

(Continued from page 352).

Case 87.—Date of operation, April 9, 1893. Operator, Dr. Murphy. Miss W., aged 12 years. Case occurred in practice of Dr. T. J. Conley. Typical attack. Examination: Induration with resonance on percussion, tenderness general. Temperature at time of operation 99 degrees, pulse 96. Operation: Lateral incision into general peritoneal cavity, escape of about one quart of pus. No foreign body to be felt. Appendix was not removed; general suppurative peritonitis. The coils of intestines were covered with a thick layer of fibrin, which, I believe, accounts for the absence of absorption and toxic symptoms; recovery.

Case 88.—Date of operation April 21, 1893. Operator, Dr. Murphy. Mrs. L., aged 24 years. Case occurred in practice of Dr. Heartler. Present illness commenced with sudden general abdominal pain and vomiting; fever. Examination revealed tenderness over appendix; induration. Operation on fourth day after attack. Lateral incision into peritoneal cavity; circumscribed intra-peritoneal abscess. Appendix removed; drainage; recovery. An extensive gangrene of the appendix was present, but no perforation.

Case 89.—Date of operation May 6, 1893. Operator, Dr. Murphy. R. C., aged 13 years; male. Case occurred in practice of Dr. McKee. Patient was sick one month before

seen by operator. Onset typical. Examination: Large induration extending over lower half of abdomen; tympanites; tenderness. Patient very much emaciated and cachectic. Temperature normal. Operation: Abdomen opened at most prominent point of induration, which was to the left of the median line; appendix not removed; drainage; recovery. A general suppurative peritonitis was present. The intestines were covered with a layer of fibrin.

Case 90.—Date of operation May 13, 1893. Operator, Dr. Murphy. Alexian Brothers' Hospital. H. S., iron worker, aged 26 years. Patient had first attack about two and one-half years ago, which came on suddenly while riding in a street car; the sudden pain commenced in the right iliac fossa and soon spread over the entire abdomen. Patient has always had more or less tenderness over the appendix since this time, and has had quite a number, twenty-four, similar attacks in intervals of five or six weeks. The attacks consisted of pain in right iliac region, vomiting, nausea, slight chills and fever. Bowels have always been kept regular by use of cathartics. During the attacks there has been a desire to micturate which persisted until attack subsided. This attack has been more severe than any other. Herpes zoster in right iliac region. Operation: Appendicectomy and drainage. Time, four and one-half minutes. Temperature after the operation remained below 100 degrees. Recovery.

Case 91.—Date of operation June 3, 1893. Operator, Dr. Murphy. Mr. K., aged 22 years. Was operated upon five months previous. Recurrent attack; patient sick five days. Operation: Lateral incision; intra-peritoneal abscess. Appendicectomy; enteroliths; drainage; recovery. Appendix was perforated and showed local gangrene.

Case 92.—Date of operation June 4, 1893. Operator, Dr. Murphy. C. H., male, aged 28 years. Patient was taken sick May 31, 1893, with moderate pain in abdomen which gradually became worse and localized in lower half. Nausea, vomiting. On the second day pain became localized in the right iliac region and gradually increased. In the evening of the third day he experienced a sudden severe pain accompanied by a sensation as if something had ruptured within the abdominal cavity. Examination: Tenderness, induration and dullness in right inguinal region. Operation: Appendicectomy. Intra-peritoneal abscess incised; fecal stone escaped with pus. Fecal fistula followed operation which lasted for ten days. Temperature ranged up to 101.5 degrees after operation. Recovery. Subsequent examination showed protrusion of abdominal wall; a small hernia.

Case 93.—Date of operation June 5, 1893. Operator, Dr. Murphy. Alexian Brothers' Hospital. P. H., aged 30 years, male. About six years previous to operation, patient was attacked with severe pain in the abdomen, followed by nausea and vomiting. The pain was very intense for five hours, then the fever set in. He has had a dozen similar attacks since; felt drowsy and sleepy the day before each attack. Had chills and fever each time. Examination: Induration, increased local tenderness; tympanites. Operation sixth day after onset. Lateral incision; general peritoneal cavity opened; appendix adherent, removed; fecal stone. Drainage; recovery. For twelve days after operation temperature remained below 100 degrees. On the 16th rose to 103 degrees, but fell to normal shortly.

Case 94.—Date of operation June 16, 1893. Operator, Dr. Murphy. F., aged 18 years; male, Woodstock, Ill. Case occurred in the practice of Dr. L. C. Waters. Sickness began five days ago with a typical attack. Examination: Induration, local tenderness, temperature 99.5 degrees at the time of operation. Operation: Lateral incision, intra-peritoneal abscess; appendix adherent, removed. Drainage; recovery. Pathologic conditions: Fecal stone, local gangrene of appendix, perforation.

Case 95.—Date of operation June 16, 1893. Operator, Dr. Murphy. Th. M. G., aged 13 years, male. Case occurred in the practice of Dr. P. H. Conley. Illness began June 9 with sudden pain and tenderness in the abdomen; this was soon followed by vomiting and fever. This condition lasted until time of operation. General tympanites, circumscribed induration in right iliac region, local tenderness; temperature before operation 102 degrees F., pulse 110. Operation: Lateral incision, large intra-peritoneal abscess; appendicectomy; no foreign body; appendix ulcerated, not perforated. Recovery.

Case 96.—Date of operation July 8, 1893. Operator, Dr. Murphy. W. F., aged 16 years, male. Case occurred in the practice of Dr. W. H. Bouton. Commenced with sudden attack of pain in right iliac region, extending all over

abdomen. Fever, slight induration, which was more pronounced under anesthesia, and under the influence of the latter, appendix could be outlined. In attempting appendicectomy the ligature, which was tied around the base of the appendix cut through; no further attempt at ligation was made; intra-peritoneal abscess at seat of operation drained. Appendix slightly adherent, adhesions easily separated, owing to a complete gangrenous condition of appendix, which also accounted for the ease with which silk tore through in attempting ligation. Appendix not perforated. Fecal fistula on third day, which closed in thirteen days. Temperature subsided immediately after operation; recovery.

Case 97.—Date of operation July 12, 1893. Operator, Dr. Murphy. Female, 26 years of age. Patient had a typical attack on the 9th of July, 1893, three days before operation; had pain, tenderness, vomiting, temperature and slight induration. Operation: Incision and removal of appendix; about an ounce of pus escaped, which was of a very offensive nature. Drainage; recovery. The appendix showed a perforation on its side near the base. No foreign body. Cicatrix showing seat of previous perforation. This case was operated upon May 1, 1892. Simple drainage of abscess.

Case 98.—Date of operation July 13, 1893. Operator, Dr. Murphy. Case occurred in practice of Dr. Hoelscher. Mrs. N., aged 24 years. Present illness began five days before operation, with severe vomiting and slight pain in right iliac region. The vomiting persisted up to the time of the operation regardless of treatment. *No induration, no local tenderness, no temperature*, pulse 120, anxious expression. Operation: Lateral incision; general peritoneal cavity opened; no peritonitis. Cecum drawn over towards uterus, and firmly held there by the appendix, which was adherent to the uterus and produced intestinal obstruction. Appendix removed; twenty-four hours drainage; rapid recovery. Appendix very much elongated; contained no pus; ecchymotic at the end where it was adherent to the uterus.

This case is very instructive as the symptoms corresponded exactly with the pathologic conditions, and did not suggest acute appendicitis, but intestinal obstruction, and is the only case in which there was an absence of pus or cicatrices showing the previous existence of pathologic conditions.

Case 99.—Date of operation July 18, 1893. Operator, Dr. Murphy. I. D., aged 56 years, male. Alexian Brothers' Hospital. Four weeks ago patient experienced a sudden attack of severe pain in right half of abdomen. Progress of disease characterized by a dull, heavy, aching pain in right groin and hip. Patient jaundiced since commencement of attack. Stools normal; difficulty in micturition; great tenderness on palpation over right iliac region; induration. Patient is unable to completely extend right thigh. Operation: Drainage of a large circumscribed abscess containing about three pints of pus. Appendix situated behind cecum; not removed. Recovery.

Case 100.—Date of operation July 23, 1893. Operator, Dr. Murphy. Mrs. C., aged 25 years. Patient was attacked on July 19 with severe pain all over abdomen; the pain was more severe over right side. It was accompanied with nausea and vomiting, which continued up to time of operation. Temperature July 19, 103 degrees; pulse 96; 20th, the same; 23d, 10 P.M., temperature 102 degrees, pulse 90. Abdomen enormously distended, dull over lower half. Operation: Lateral incision: a quart of fluid of sero-purulent nature escaped from the general peritoneal cavity, which covered the bowels to a great extent. Drainage; recovery.

Case 101.—Date of operation July 24, 1893. Operator, Dr. Murphy. T. S., aged 25 years; male. Alexian Brothers' Hospital. Twelve recurrent attacks during the past two and one-half years, lasting from three to ten days. Appendicectomy in immediate stage; drainage; recovery. Appendix extensively adherent; mucous membrane ecchymotic. A marked stricture in middle of appendix, resulting from cicatricial contraction of former ulcerations.

Case 102.—Date of operation July 25, 1893. Operator, Dr. Murphy. J. H., aged 14 years; male. Case occurred in practice of Dr. Quine. Patient had a typical attack of appendicitis two weeks previous to the operation accompanied by fever, local tenderness, induration. The temperature subsided on the tenth day to normal, and remained so for three days when it gradually began to increase and by the thirteenth day reached 102 degrees. The area of induration increased rapidly and was somewhat tender. On the fourteenth day there was a large induration in right iliac region. Pulse and temperature both good. Operation: Lateral incision directly into an abscess. General

peritoneal cavity not opened. There was no gush of pus when the abscess was opened as is usually the case, showing an absence of tension in the abscess. There was considerable fresh blood in the abscess cavity. Two fecal stones. No effort made to locate or remove the appendix. Drained. After recovering from the anesthetic the patient complained of intense abdominal pain and vomited persistently. Tympanites rapidly set in; patient collapsed, and died fourteen hours after the operation. The course of this case after the operation indicated that the abscess ruptured between the coils of the intestine and the pus emptied into the peritoneal cavity before the incision was made, explaining the reason why pus did not escape when abscess was opened, as well as the hemorrhage into the abscess. This opening was not detected at the time of operation, nor could it be seen that the pus escaped into the peritoneal cavity, as that was not opened beyond the line of adhesion. This also accounts for the collapse of the patient, for the symptoms were those of a fatal sapremia.

Case 103.—Date of operation July 26, 1893. Operator, Dr. Murphy. Case occurred in practice of Dr. Rohr. F. O., aged 43 years; male. A week before operation patient was suddenly attacked with pain in right iliac region, followed by vomiting, nausea and tympanites. Pain and tenderness all over abdomen, especially in lower half. Temperature 99½ degrees at time of operation; pulse 100.

Operation: Lateral incision. General peritoneal cavity opened. A general dry septic peritonitis present. Appendix situated behind cecum, very difficult to locate; the adhesions around the same were loosened and the appendix removed. The appendix was large, gangrenous and showed perforation through which a fecal stone projected. Iodoform gauze drainage.

I desire to call your attention especially to the fact that this patient was not collapsed at the time of operation, that his temperature was 99½ degrees, and his pulse 90, notwithstanding that he had a general septic peritonitis involving all of the abdominal viscera, and had it for some time previous to operation. Death twenty-four hours after operation.

Case 104.—Date of operation July 27, 1893. Operator, Dr. Murphy. M. O. C., aged 22 years; male. Patient suddenly attacked with pain in region of right kidney. Extreme tenderness over appendix extending high up above crest of ilium and up to margin of ribs behind, but not in front. No tympanites until the morning of operation. At 4 A.M., on day of operation patient felt the abscess rupture; he described a sudden bursting in his abdomen, followed by great pain and depression. Operation four days after attack. Incision; appendix difficult to locate; an abscess cavity was found and the appendix formed a part of its wall; it was gangrenous, had ruptured and located behind cecum. Two fecal stones were removed. There was present a dry septic peritonitis, the result of a rupture of the abscess the morning of the operation. The intestines were denuded of their endothelium and flakes of pus and some sero-purulent fluid rested between the coils. The operation was refused forty-eight hours preceding the rupture of the abscess, and the delay sacrificed the patient's life. Death thirty-six hours after operation from sapremia.

Case 105.—Date of operation July 28, 1893. Operator, Dr. Murphy. T., aged 18 years; male. Case occurred in practice of Dr. Berry. Patient complained of abdominal pain and vomiting on the night of the 24th. Called the doctor on the evening of the 25th, temperature at this time was 103 degrees; pulse 120. July 26, A.M., temperature 102 degrees, tympanites increased, pain diminished. July 27, P.M., temperature 101 degrees, pulse 100, very little pain. July 28, temperature 101 degrees, pulse 100. Operation: Lateral incision, circumscribed abscess, general peritoneal cavity not opened. Fecal stone escaped with pus. Appendix not removed. Drainage; recovery.

Case 106.—Date of operation July 28, 1893. Cook County Hospital. Operators, Drs. Murphy and La Count, House Surgeon. J. M., aged 32 years; male. Patient's trouble began twelve days before entrance to hospital, with severe pains in abdomen, accompanied by vomiting. Later on a dull aching pain developed in the right iliac fossa which was persistent; vomiting continued a little every day until day of operation. Could keep nothing on stomach. Bowels moved daily. No chills; no fever. Later on an induration became visible in right iliac region. Operation: Usual incision: general peritoneal cavity not opened; escape of eight to ten ounces of purulent, fecal smelling pus. Digital

examination of pus cavity detected sacculated condition which was broken down and made into single cavity. Packed with gauze. Upper part of wound sutured with silk. Patient made rapid recovery.

Case 107.—Date of operation July 31, 1893. Operator, Dr. Murphy. A. J., aged 22 years; female. Case occurred in practice of Dr. P. H. Conley. Patient had a previous attack about a year before operation, but not as severe as present one. Sudden attack July 24, 1893; pain in right iliac region, nausea, vomiting, tympanites, induration, dulness on percussion. Operation: Lateral incision; extensive suppurative peritonitis extending into Douglas pouch and up behind the cecum and colon to the kidney; drainage; recovery.

Case 108.—Date of operation Aug. 5, 1893. Operator, Dr. Murphy. R. W., aged 18 years; male. Alexian Brothers' Hospital. Patient had had previous attack June 25, 1892, for which he was operated; simple drainage (see Case 55). Had a second attack in August, 1892, which only lasted a few days. The present attack (third) began with sudden pain in the abdomen caused by straining himself while working at his lathe. The pain and vomiting were so severe that he was compelled to go to bed. At first, pain was located in right iliac region, but in a few hours it extended over the entire abdomen. Examination: The temperature reached 102 degrees, fifteen hours after onset, and he presented himself for operation sixteen hours later. Temperature 99.7 degrees; pulse 80. Tympanitic, general abdominal tenderness; dulness on superficial percussion over lower half of abdomen. Operation: Lateral incision; general peritoneal cavity opened; found full of a thin purulent fluid. The wall of an old circumscribed abscess was seen in which was detected a small opening. On opening this wall extensively half of the appendix was found to protrude into it. The appendix was very much enlarged, thickened, and at its tip an enterolith protruded. This condition had existed for a long time, as could be seen from the pathologic condition of the opening. Although the peritoneum of the intestine and omentum was congested, it still retained its gloss, and was not eroded of its endothelium. Appendix ligated, amputated. Recovery.

REMARKS.—The cause of the peritonitis in this case was the rupture of a circumscribed abscess that had existed since the previous August, or the time of the second attack. The wall of the abscess was very firm. It will be noted that while a general suppurative peritonitis was present at the time of the operation, and had existed for thirty-one hours, the patient was not collapsed; his temperature was only 99.7 degrees, and his pulse 80.

Case 109.—Date of operation Aug. 8, 1893. Operator, Dr. Murphy. J. J. D., aged 23 years; male. Present attack began July 28 with sudden pain in the region of the umbilicus, which rapidly localized itself in the right iliac region. Marked induration over appendix. Temperature 102 degrees day before the operation. Has vomited several times since the onset of attack. Temperature on morning of operation 100 degrees. Operation: Lateral incision, general peritoneal cavity opened; circumscribed abscess found which contained half a pint of pus. Appendix amputated. Drainage; recovery. Pathologic conditions: Appendix enlarged, local gangrene with perforation. No foreign body.

SOCIETY PROCEEDINGS.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 356.)

FURTHER STUDY OF ELECTRO-ANESTHESIA AND FREQUENCY OF INDUCTION VIBRATION.

The following illustrations will show what class of cases I have found benefited by the anesthetic current, where other forms of electricity failed:

Miss F., age 25, a strong, handsome woman, had been for several years a victim to supra-orbital neuralgia of an aggravated type. During the crises she was in the habit of taking large quantities of drugs to quell pain, principally such derivatives as antipyrin, acetanilid, etc., until stomach action was greatly impaired and heart rhythm completely

broken up. Fortunately, she had avoided opium, having sense enough to know that remedy to be worse than disease.

Examination of heart gave 110 beats, with a confused mixture of sounds from which nothing normal could be extracted, considerable dyspnea, aversion to food and general hyperesthesia of nerves. She came to my rooms in a violent attack, pain being too severe to admit careful testing of nerve impulse rate, and faradism employed with the rheotome sounding C major. In fifteen minutes the painful spot was anesthetic, all suffering gone and patient happy.

Tests were then made to ascertain normal speed of nerve force, with a result of .0500, corresponding to a tone very slightly above major C, closely enough for practical work.

Miss F. is now in her third week of daily twenty minute sittings, and the neuralgia has only recurred once, in a much modified form. I propose to continue the treatment a month longer and then suspend for a month, when, if there is no trouble, I shall dismiss the case.

Miss S., age 48, nurse. Pure nervous temperament, slender, sallow. For years Miss S. has been under more or less medical treatment for uterine displacement and catarrh. In 1882, I operated upon her electrolytically for rectal stricture, during the course of which she had formed opium habit, which required four months to cure. Pain during defecation and afterwards was so severe that any habit was as nothing compared to relief at the time.

From that time until two months ago I lost sight of her, when she returned with a beginning of the old sensations of uneasy rectum, difficult, spindling stools and general nervousness, together with intense pain in right flank, extending down the front of leg on that side. Rectal examination showed no stricture, but a mass of hemorrhoidal veins nearly occluding the canal, some protruding through the sphincter, contraction of which probably caused the pain. The muscle was stretched and veins obliterated by fine electric needles, but the neuralgia persisted, recurring at irregular intervals and aggravated by patient's nervous hyperesthesia.

She was placed upon Mariani's Thè Cocoa, a preparation which I have found almost magical in relief of nervous debility, and soon grew better of her restless uneasiness. Still the sharp pain kept up.

Some two weeks ago, on a stormy day when leisure was plenty, I spent several hours measuring her nerve rate, using both medians, both sciatics and the long thoracic trunks. There was remarkable unanimity of speed, a dead point being reached by C a little sharp in each nerve, which is about normal.

She was therefore placed under faradic treatment with rheotome singing sharp C, one electrode, a broad sponge, at the sacrum, the other at the motor point of adductor muscles just inside the knee. A sharp thrill followed circuit closure which went to the toes, and after ten minutes a certain sense of numbness in the thigh, but not much relief to pain. I suspected that neuritis had begun, but sent her away to wait three days. Upon her return she reported improvement, and the same applications were continued until the present, with steady gain, but slow. In this case it was impossible to produce anesthesia extending far enough to be of value; yet the curious sense of numbness in the foot which follows circuit closure each sitting, indicates clearly that it is not the fault of the remedy that she is not cured; it is but the ignorance of the operator.

I do not know why pain should subside under the electrode alone, while every experiment I have made shows that an entire nerve trunk, when intercalated, is traversed and physiologically affected by the electric energy employed.

Some of you may recall that during the discussion which followed the reading of my paper before you last year, Dr. Herdman remarked that purely mechanical explanation was sufficient to account for the action of the singing rheotome, and Dr. Num said that there is undoubtedly a percussion taking place through the cells of the body when a muscle contracts under the influence of induced electricity.

These later studies seem to indicate that the keen perception of these gentlemen was right, and that mechanical vibration may enter into diagnosis and treatment of nervous disease more than before. Yet, bearing in mind my own therapeutic failures when percussion without electricity was employed, I believe that the latter is a part of effect, not the former.

And I desire to thank these gentlemen who have taken the trouble to provide themselves with a singing rheotome, in order to confirm my experiments, or to fail, as I have often done myself. Let us hope the former.

The following communication on

ALTERNATING CURRENTS IN ELECTRO-THERAPY

by DR. GEORGES GAUTIER and J. LARAT of Paris, France, was then read in abstract by Dr. LAPHORN SMITH.

Preamble.—In reviewing the works, treatises and monographs relating to medical electricity that have appeared during the last fifteen years, we find that so far from remaining stationary, electro-therapy has extended its domain, multiplied and defined its applications, but using only forms of electricity already known: Franklinism, faradization, galvanism.

During the last twenty months, however, an altogether new way has been opened to electro-therapeutists. It is a method not yet used in medicine; alternating currents with high and low potential, with medium and extra rapid frequency.

It is well first to define these terms before proceeding to show what physiologic or clinical results have been already obtained by the use of these currents or what future one has to expect from the use of them.

The common faradic current, furnished by a Ruhmkorff's coil, connected with a vibrator is in the strict sense of the word an alternating current, since, if we consider one of the rheophores, this is alternately positive and negative; but it has defects or rather qualities which distinguish it essentially from the current which we mean when we use the word *alternating*. Let us consider the nature and action of the current which is produced during an oscillation of the vibrator. At the moment that the hammer by its electricity or weight comes in contact with the block, the circuit is closed and we have the inducing current which develops by induction a secondary current (induced) in the opposite direction (it is understood that we leave out the question of extra currents which do not belong here); but this momentary current has sufficed to render the soft iron a magnet, the hammer is attracted by the electro-magnet and oscillates in the space, to come in contact with the soft iron. At the moment when it leaves the contact, we get the induced current in the same direction. During this oscillation there is no induced current, and as the duration of this oscillation is very long in proportion to the time of contact the time lost is considerable.

The faradic current then possesses the property of being very rapid and consequently of attaining its maximum very rapidly. It is a current essentially intermittent and a simple graphic representation explains the nature and form of the electro-faradic wave.

The current which we propose to study under the name of alternating, produced by alternating dynamos, (Siemens, Patin-Ferranti, etc.,) attains its maximum very gradually and no time is lost. It can be represented graphically by a curved line, somewhat undulated on account of phenomena of self-induction which the scope of this article does not permit us to analyze.

On the one hand, then, the *time* during which the current acts is more considerable on account of no time being lost; on the other hand, its *potential* can be born, higher; the irritation of the sensitive nervous system being, as demonstrated by Prof D'Arsonval, a factor in the variation of the fall of potential ($e=Ict$). In a word the alternating form permits the use of a greater quantity of electricity: ($Q=It$).

The "current sinusoidal" differs from the preceding only in that the undulation is perfectly regular without any notch. From this short description it is evident that the use of the alternating current is a thing altogether new from the point of view of electro-therapy. Also the physiologic properties of these currents are themselves new and full of interest.

Physiologic effects of the alternating current at low frequency.—The alternating current of low frequency, i.e., presenting a maximum of 20,000 per minute, has been first studied by Prof. D'Arsonval, who in his laboratory of the College of France has measured on the human subject and on animals, on the one hand the variations in the absorption of oxygen, in the production of carbonic acid; and on the other hand the modifications in the production of heat, by his calorimetric method. *Without any muscular contraction*, without any pain, it is shown that it is possible to increase instantaneously by more than a quarter the activity of the gaseous respiratory changes.

It seemed probable that this powerful action on the gaseous changes would be accompanied by a correlative increase in the excrementitious products and we have in fact shown by several hundred analyses of urine that the amount of urea is always increased in a variable proportion and that it can reach double the amount eliminated before the experiment.

Besides, certain substances eliminated by the urine seem to be transformed. Thus, to cite an example, the urine no longer has the characteristic odor after the ingestion of asparagus. We are continuing our researches on this subject.

When not proceeding experimentally, there seems to be no difficulty in producing muscular contractions; on the contrary, general faradization by means of a bath modifies itself the nutritive changes, augmenting the production of heat.

The other physiologic effects are on the one hand partially those of the faradic current, on the other partly those of the continued current. Like the latter, the alternating current produces a chemic action, weaker, it is true, but very distinct; like the faradic it determines vaso-motor changes and muscular contractions.

THERAPEUTIC EFFECTS.

1. *General.*—In order to obtain the maximum effect by applying the current to the whole surface of the body we have adopted water as a conductor. The patient is plunged into a bath of lukewarm water containing starch, the starch rendering the water opaque for purpose of decency. The bathtub may be of marble or porcelain, or of iron carefully enameled, or of wood. A series of nickel-plates (nickel to avoid oxidation) can be arranged around the inside of the tub, hung by conducting cables, isolated by rubber and provided with hooks. A system of movable plates permits the localization of the maximal action of the current and is preferable to fixed plates, difficult to cleanse. The carbon plates which we used at first are too heavy and break the threads that support them very easily.

We speak here only of the therapeutic results which we consider absolutely determined. We are studying others, as the application of electric douches to hysterical subjects, but our experiments are of too recent a date to make them worthy of mention here. Since the principal effect of the alternating current is increased action in the nutritional changes, it is rational to think that a retardation in this process, would be amenable to this treatment; and in fact arthritic subjects generally do well on it. Rheumatism in its subacute and chronic form, especially the rheumatic neurites are rapidly improved by the alternative baths.

It is, therefore, diseases of this order, characterized by a retardation in the nutritive process that have been the first to be the object of our researches. We have already made known in a certain number of previous publications the favorable results of our method of treatment. We have called attention to the good effects obtained in obesity, in chronic gouty subjects and in dyspeptics. Our attention has also been called to chronic skin diseases and especially to eczema. Eighteen cases of eczema of long standing have been rapidly improved and all had resisted numerous treatments. In a case of vitiligo we have been able to obtain a marked diminution in the dyschromatic lesion after fifty baths.

The treatment of sciatica has given results to which no other medication can pretend: fifteen cases, fourteen successful. In infantile paralysis, in pseudo-hypertrophic paralysis the improvement has been more rapid than by other electrical treatment.

Thanks to the enlargement of our electro-therapeutic laboratory, we have been able to extend the field of our researches during the past year. We have been able to treat about a hundred patients, children and adults, with anemia, lymphatism, scrofula, adenitis and rickets. We shall publish later interesting observations on the results which we have obtained. Dr. Segretti of Rome, who considers rickets as a functional derangement of the trophic nervous system which always manifests itself by the lack of calcareous salts in the osseous system, as chlorosis always manifests itself by the lack of iron in the blood, has been recommending for some time past the use of hydro-electric baths in this disease and has obtained the best results from this medication.

2. *Local Effects.*—One of the first aims of our researches was to take all the advantage possible of the use of the alternating current in gynecology. In our article read in 1891 at the Academy of Science of Paris, we called attention to the great advantages to be derived from the use of this form of electricity in the diseases of women, promising to give later the indications. Pure results obtained can be formulated as follows:

1. The alternating current is always contra-indicated when the hemorrhagic symptom is marked. It is useful in amenorrhea and dysmenorrhea.

2. In inflammations of the uterus, in fibromata, the continuous action is preferable to the alternating.

3. In inflammations of the ovaries, tubes and pelvic tissue, the alternating current has rendered such services that the other medications must give place to it.

4. When properly applied it is the treatment par excellence for pain.

These statements need explanation which will be given in extenso later.

We have already mentioned the applications of the alternating current in a large number of affections such as: Muscular atrophy, dilatation of the stomach, neuritis, etc. We add summarily that we now recommend it in constipation, hemorrhoids, engorgements of the prostate and certain forms of cystitis. In torticollis and lumbago, one sitting is usually sufficient to bring about a permanent relief.

Finally, the alternating current increases indisputably the domain of electro-therapy; as a local agent it enjoys therapeutic properties worthy the attention of electricians; its application is painless and dosage easy. Lastly in its action on those nutritive derangements which constitute the diatheses, the source of numerous chronic diseases, the alternating current is one of the greatest acquisitions of therapeutics.

Production and Transformation of the Alternating Current.—The electric energy which we use is produced by the machines of Ferranti. It is known that Ferranti has modified the Siemens' machine, which is the type of the machines with alternating currents, whose coil does not contain iron, by giving to this latter a special form presenting many advantages. This coil is constructed by winding a long copper band in a wavy curve, a sort of circular zigzag. Several of these can be superimposed, separated from each other by vegetable fiber. The two extremities of the metal end in two metallic collars on which rest friction plates (rubbing surfaces). The current engendered by the Ferranti machine comes into our cellar where it is transformed, the strength being reduced from 2,400 volts to about 110 volts. Thus transformed it is easy, by the aid of apparatus for reduction of potential of different types, to utilize it either locally or in baths, beginning with a minimum and increasing gradually to a dose that is beneficial and can be borne.

The apparatus for reducing potential consists of liquid resistances or of solenoids in the interiors of which move cores of soft iron which have the property of reducing considerably the alternating current.

The graduation of the current is obtained by means of a coil of very fine thread which can be passed more or less over another coil which is directly connected with the potential reducer.

Alternating Current with High Frequency.—We only recall to memory the well-known experiments of Tesla and E. Thomson, not dwelling on them. After the demonstration of Tesla at Paris and the conferences of Prof. d'Arsonval, having obtained sufficient knowledge of these currents, we tried for a year and a half to render them utilizable in medicine.

The method used for demonstration and in laboratories is lacking in one essential quality for current usage; it is not practical. As well known, we use piles or accumulators as the source of the current, as a transformer we use Ruhmkorff's coil. Now, on the one hand, the source is exhausted too rapidly, hence the necessity of constant and troublesome changes; on the other hand, the vibrator of the coil soon gets out of order. These defects in apparatus have permitted us to pursue our experiments only intermittently.

The solution for us who had at our disposal the alternating current of the city, was to use this. Unfortunately all the transformers which we applied to this current either did not give sufficient voltage or became heated after a few minutes trial. It is only after all these trials that we, with the aid of the firm Ducretel, have succeeded in finding a coil which works perfectly. This coil gives a transformation of 1-100. Its inductor is composed of three layers of copper thread of 22-10=531 turns; its length=48 cm.; weight of thread = 2,900 kilos, (6 lbs), its resistance = 0, 57 ohm. Its induced coil is composed of fifty layers of copper thread of 21-100 = 53,000 turns. Weight of copper thread = 5,200 kilos; its resistance = 8,600 ohms.

The current which we have under 100 volts traverses at first a series of coils of resistance, arrives at the transforming coil, whence, like d'Arsonval, we let it pass through a battery of Leyden bottles to end either in a final transformer plunged into oil or in a solenoid in the center of which the patient is placed.

Our experiment is too recently completed to have made its application to patients possible as yet.

From an experimental point of view, we have been able

to reproduce all the experiments of M. d'Arsonval; to light a lamp held in the hand, the current passing through the human body without being perceived, provided that the conductor fixed to the wires attached to the lamp is of sufficient surface; to prove the local anesthesia which is produced by this imperceptible current and the accompanying vaso-motor dilatation, etc. When the person is touched at one of the poles, the other being in connection with the ground, a short spark and local heat is observed.

In the solenoid when the vibrations are extra rapid and with a spark from the condensers of three millimeters at least and very bright, a sort of general vibration is felt. Under these conditions a lamp held simply between the hands is lighted. We propose next to try the treatment on hysterical subjects, with the coöperation of M. Gilles.

(To be continued.)

NECROLOGY.

G. V. Ewing, M.D. of Ogden, Colo.

Butler E. Turrill, M.D. February 24.

G. Wyman, M.D. of Topeka, Kan., March 3.

W. C. A. Banes, M.D., New Albany, Ind., March 6.

H. S. Stimson, M.D., of Athens, Ohio, February 25.

R. H. Johnson, M.D. of Atlanta, Ga., February 19.

H. W. Simmons, M.D. of Conneaut, Ohio, February 19.

C. Loftus Martin, M.D. of Janesville, Wis., February 24.

H. K. Porter, M.D. of Duluth, Minn., March 2, aged 30 years.

Dr. Stevens of Windsor, Ohio, February 9, aged 90 years.

C. L. Martin, M.D. of Janesville, Wis., February 23.

James Shook, M.D. of Chillicothe, Ohio, February 18.

W. B. Lapham, M.D. at Togus, Maine, February 21, aged 66 years.

G. W. Norton, M.D. of Earlville, Ill., died March 2, aged 80 years.

Henry B. Mathiot, M.D. of Smithfield, Pa., died Feb. 24, 1894, after a brief illness in the 79th year of his age.

De Casper Vitzhum, M.D., formerly of Moline, Ill., died February 24, aged 71.

J. C. James, M.D. of Bradford, Pa., February 25, aged 42. He was a graduate of Bellevue Medical College, New York.

J. C. Snively, M.D., ex-President of the Lancaster County Medical Society, and ex-member of the Legislature, at Manheim, Pa., February 26, aged 75.

E. E. Hutchins, M.D. of Clyde, Ohio, was killed by the explosion of a new self-lighting kerosene lamp, February 28. He was a graduate of Jefferson Medical College, and was 48 years of age.

N. G. Thompson, M.D. died suddenly of heart disease at Coatesville, Pa., March 1. He was one of the best known physicians in Chester County, and was a graduate of the Philadelphia Medical College, class of 1852, and for forty years successfully practiced his profession at Brandywine Manor. Tiring of country life two years ago he removed to Coatesville, where he erected a handsome residence.

Charles H. Bressler, M.D. died at York, Pa., February 21, aged about 72 years. He was stricken with apoplexy about ten days before and had been slowly sinking ever since. Dr. Bressler was always prominent in Republican politics, having been a candidate several times for Congress in this district, and also was several times a candidate for Congressman-at-large. He was appointed by Governor Curtin Sheriff, to fill the vacancy caused by the death of Sheriff

Wolfe. He was a member at times of the City Council. He was a consistent member of the Methodist Church, and also of the Masonic fraternity.

Bernard Segnitz, M.D. of New York died February 23. Dr. Segnitz was 84 years old and was one of the best known German physicians in this country. Among his writings are "The Physician and His Work," "Mortality Versus Progress" and "Fashion and Medicine." He recently invented an inhaler for use in diseases of the respiratory organs, and was engaged in perfecting it when the stroke occurred that caused his death. He had been House Physician to Baron Mayer, Carl von Rothschild and Prince Isenberg Birstein. His fame in Germany grew rapidly, until he took a stand against the Government and became a political refugee. Dr. Segnitz was a strong advocate of the prohibition of marriage to consumptives.

Joel Seaverns, M.D. of Roxbury, Mass., died March 1. Joel Seaverns was born at Jamaica Plains, N. Y., May 25, 1828. At the age of 18, he graduated from the Roxbury Latin school. Leaving college in 1850, he spent one year in teaching, when he entered the Harvard Medical School, from which he graduated in 1854. Commencing private practice then at Jamaica Plains, he continued there until May 25, 1862, when he entered the Army as Acting Assistant Surgeon, holding this position until Dec. 4, 1863, when he was appointed Assistant Surgeon of U. S. Volunteers, and promoted March 30, 1864, to the rank of Surgeon. In 1865 he was made Brevet Lieutenant-Colonel for faithful and meritorious service. His first two commissions were signed by Abraham Lincoln and his last by Andrew Johnson. During his army life he was Surgeon-in-Charge of hospital ship, the *New World* and of steamer *De Molay*. Before and after that time he was Post Surgeon at Fort Warren in Boston harbor.

Michael Jean Baptiste Messemmer, M.D. died at Mentone, France, February 21. He was born in New York City of German and French parents, forty-five years ago. As a boy he attended a Roman Catholic parochial school, and before he was of age he graduated from St. Francis Xavier's College. Later he studied law for two years, but he decided not to be a lawyer, and began the study of medicine. In 1885, he was graduated from the College of Physicians and Surgeons. Before he had gained much of a practice at his office in Second Avenue, he began to take an active part in politics, and in 1881 he was appointed a deputy coroner by Coroner Merkle. He was elected coroner before the expiration of Merkle's term of office to succeed him, and he was reelected in 1887 and in 1890. He was large and stout, with ruddy face, blue eyes and large flowing sidewhiskers. His congenial habits made him popular with his Tammany supporters. He was a bachelor and belonged to many clubs. He also held memberships in several medical societies, and in the Liederkrantz and Arion Societies, and was physician to the outdoor poor department of Mt. Sinai Hospital. His last term of office as coroner did not expire until Dec. 31, 1893, but he performed no duties connected with his office for many months previous to that time.

Paul Diday, M.D.—In M. Diday, who died a short time ago at the age of 83, Lyons loses one of its leading surgeons and the medical profession in France one of its most distinguished members. Born at Bourg in 1812, he studied medicine in Paris, where he was a favorite pupil of Dupuytren, and afterward of Ricord. Soon after taking his degree he became surgeon to the Antiquaille Hospital at Lyons, a post which he continued to fill for many years. It was largely owing to his influence that this institution was transformed from a mere special hospital into a school of scien-

tific syphilography, where much work of the greatest value was done by Diday himself and his pupils.

Early in his career Diday was appointed General Secretary of the Lyons Société de Médecine. Into the duties of this office, which he held for thirty-four years, he threw himself with the greatest enthusiasm. He was one of the founders and the first editor of the *Lyon Médical*, and for twenty-five years he was a constant contributor to its pages. He also wrote largely, though anonymously, in the *Gazette Médicale de Paris*. His literary activity was extraordinary, and continued to the end, a paper from his pen on the expediency of subjecting a primipara, presumed to be syphilitic, to mercurial treatment having appeared in the *Lyon Médical* on December 24.

Of his books the best known are the *Traité de la Syphilis des Nouveau-nés et des Enfants à la Mamelle* (1854), *Histoire de la Syphilis* (1863), *Thérapeutique des Maladies Venériennes* (1876) and *Pratique des Maladies Venériennes* (1886). At his best Diday was a brilliant writer, incisive, epigrammatic and exquisitely lucid.

Diday had suffered for some time from an affection of the bladder, for which he was successfully operated on (a fact which he commemorated in verse only a few weeks ago). His death appears to have been due to a tumor of the chest wall which was discovered quite recently; it proved fatal by extension into the pleural cavity. He was buried on January 11 in the presence of an immense concourse of his professional brethren and friends, including all the academic and official notabilities of Lyons.—*British Medical Journal*.

The Numbers of the Profession.—The Medical Directory for 1894, now published, gives the following as the numbers of the medical profession for the year 1894: In London, 5,590; in the provinces, including Wales, 14,897; in Scotland, 3,107; in Ireland, 2,485; registered practitioners resident abroad, 3,209; Naval, Military and Indian Medical Services (excluding those which appear also in other lists), 2,426; "too late" list—additional names, 58. The total number of practitioners in the "Directory" for 1894 is 31,772, as against 30,759 in the previous year. This shows an increase in the twelve months of 1,013. The obituary list, which seems to be wonderfully complete, gives the deaths as 639. The above figures give one medical practitioner in London for every 750 of the population; in the provinces, one in 1,650; in Scotland, one in 1,300; in Ireland, one in 1,900; and in the United Kingdom generally, one in 1,450.—*The Lancet*.

The Statistics of the Medical Profession in Austria.—According to the official statistics published recently there were in Austria, 6,057 physicians holding the diploma of M.D. in the year 1891, and 6,565 in 1892. In the former year there were also 1,588 surgeons of the old surgical schools, but in 1892 this number had been reduced by death to 1,582. The total number of medical practitioners in Austria in 1892 was 8,097 against 7,645 in 1891. The figures for 1893 have not yet been published.

The Medical Profession in Italy.—According to the *Annuario Statistico Italiano* for 1892, just issued under the authority of the General Direction of Statistics at Rome, the total number of medical practitioners in Italy in that year was 19,120, being a proportion of 6.2 per 10,000 of population. The ratio varied in different parts of the Kingdom from 11.1 per 10,000 in sixty-nine chief towns of provinces to 5.3 in the rural communes. The following figures show the numbers of practitioners and the proportion to population per 10,000 in several of the principal cities: Rome, 510 (11.6); Naples, 1,506 (28.3); Milan, 374 (8.8); Turin, 292 (8.8); Palermo, 225 (8.2); Genoa, 255 (12.0); Florence, 258 (13.1); Bologna, 144 (10.2); Venice, 127 (8.5); and Catania, 114 (9.5). Between 1878 and 1892 the absolute number of doctors increased by rather more than 1,000 (19,120 as against 18,044), but the relative number decreased from 6.5 to 6.2 per 10,000 of population.—*British Medical Journal*.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly. All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, MARCH 17, 1894.

MEDICAL EDUCATION IN THE UNITED STATES.

Report of the Illinois State Board of Health on Medical Education and the Regulation of the Practice of Medicine in the United States and Canada. Revised to Jan. 1, 1894.

In an address delivered before the Section on Pedagogy of the Pan-American Medical Congress,¹ by J. COLLINS WARREN, M.D., President of the Section, the speaker took occasion to pay the following tribute to the Illinois State Board of Health: "The reports on medical education by the Illinois Board, I do not hesitate to say, have exerted a more powerful influence on the movement in education than any other publication which our medical literature has produced."

The latest volume of this series, recently completed for the Board by its former Secretary, Dr. F. W. REILLY, presents a collection of facts and figures which seem to fully justify Dr. WARREN's recognition of the value of these publications. The reports were projected in 1880 by Dr. JOHN H. RAUCH, member, President and Secretary of the Board from its organization in 1877 until 1891, and the eight volumes prepared by him are a monument to his ability, sagacity and untiring zeal in the cause of higher medical education. A brief summary of what has been accomplished by the Board, directly through its own action and mediately through the influence of these publications, can not fail to be of interest:

The Illinois Medical Practice Act of 1877 empowers the State Board of Health to determine the "good standing" of any medical college whose diploma may be presented to the Board as the basis for the license or certificate authorizing the practice of medicine and surgery in the State. The necessity of some standard by which to determine this point was soon apparent, and the Board early in its existence addressed itself to an investigation of the methods and character of instruction in vogue among the medical schools of the period—the requirements and condi-

tions upon which they conferred the degree of Doctor of Medicine upon their students.

Of the 57 institutions in the United States whose diplomas had been presented to the Board prior to October, 1880, and which thus became the legitimate subjects of this investigation, there were 43 regular schools, 10 homeopathic, 3 eclectic and 1 physio-medical. It was found that qualifications for matriculation were exacted by only 15 of the total 57 schools—14 regular and 1 homeopathic; in the remaining 42 schools no evidence of preliminary education was required before students were permitted to enter the lecture room. By 30 of the 43 regular schools, 8 of the 10 homeopathic and the 3 eclectic schools the degree of M.D. was conferred after two years of study and attendance upon two annual courses of lectures of an average duration of 22.6 weeks—included in the two years of study. Only 13 regular and 2 homeopathic schools required three annual courses of lectures and three full years of study before graduation. More than half the regular schools had lecture courses averaging less than 20 weeks duration.

After a careful study of the facts disclosed by this investigation the Board framed a schedule of requirements for medical colleges which desired to be recognized as in "good standing." This schedule prescribed certain matriculation qualifications; the branches of medical science to be included in the curriculum of instruction; the duration and number of lecture terms; the percentage of attendance upon lectures, recitations and quizzes; the amount of dissection to be performed and of attendance upon clinical and hospital instruction; the period of study; the character of the corps of instructors and of the teaching equipment. This schedule was promulgated in 1880, and the Board announced that, after the sessions of 1882-83, it would recognize no college as in "good standing" that did not conform to these requirements.

The following table shows to what extent this schedule was complied with during the next three years:

Requirements of Colleges in 1880 and 1883	Regular.	Homeopathic.	Eclectic.	Percent-ages of Totals.
Colleges listed by the Illinois Board in 1880	43	10	3
Colleges listed by the Illinois Board in 1883	91	13	5
Colleges exacting matriculation qualifications in 1880	14	1	0	26.8
Colleges exacting matriculation qualifications in 1883	61	11	7	66.4
Colleges requiring attendance on three courses of lectures in 1880	13	2	0	26.8
Colleges requiring attendance on three courses of lectures in 1883*	16	2	0	15.1
Colleges requiring three full years of study in 1880	13	2	0	26.8
Colleges requiring three full years of study in 1883	68	2	1	59.6
	Weeks.			Gen. Aver.
Average duration of lecture terms in 1880	22.8	22.7	22.0	22.5
" " " " " in 1883	24.4	23.7	20.9	23.0

¹ Journal Amer. Med. Ass'n, Sept. 9, 1893.

* In the following year, 1884, these figures changed to 79 out of 87

Following are the figures for 1893:

Total number of existing medical colleges in the United States January, 1894. 136
 Number exacting matriculation qualifications 131
 Or 96.3 per cent. of the whole number.

All of the 19 homeopathic colleges, the 8 eclectic and 104 out of 109 regular colleges now require some sort of preliminary education before admitting students to the lecture classes. The five exceptions are the Medical College of Georgia, the Atlanta (Ga.) Medical College, the Southern Medical College of Atlanta, the North Carolina Medical College (newly organized) and the University of Virginia Medical Department.

The proportion of schools requiring attendance upon three or more courses of lectures before graduation has also risen from 26.8 per cent. in 1880 to 96.3 per cent. in 1893. There are now 11 regular schools and 1 homeopathic that require attendance upon four annual courses of lectures; and 45 regular, 17 homeopathic and 6 eclectic schools require four or more full years of study before graduation. No school required four courses of lectures or more than three years of study in 1880 or in 1883.

The only schools which still graduate upon two courses of lectures are the Atlanta Medical College, the Baltimore Medical College, the University of Virginia, the Medical College of Virginia and the Georgia College of Eclectic Medicine and Surgery. The Georgia schools still adhere to the system of repetitional lectures; in all other cases, with the exception of one newly-organized homeopathic school, the lectures are graded.

In 1880 the average duration of the lecture term was a fraction over 22 weeks; of the 56 colleges examined, 38 had terms of less than 24 weeks and 18 had terms of 24 weeks or more. During the current sessions, 1893-94, the average duration of the lecture term is 28.19 weeks; only 10 schools have terms of six months or more.

In 1884, immediately following the enforcement of the Illinois Board's schedule of minimum requirements, there was an extinction of 4 regular and 3 eclectic, and the number of regular schools did not again reach that of 1883 until 1888. The eclectic schools have steadily diminished in number from 15 in 1883 to 8 in 1893, while the homeopathic schools have increased from 10 in 1882 to 19 in 1893.

Missouri and Ohio are the most prolific States in the Union as to medical-diploma issuing institutions. Each has 16 existing medical colleges—Missouri, 12 regular, 2 homeopathic, 1 eclectic and 1 miscellaneous; Ohio, 11 regular, 3 homeopathic, 1 eclectic and 1 miscellaneous. Since 1840 Missouri has had 38 schools—25 regular, 9 homeopathic, 2 eclectic and 2 miscellaneous; since 1819 Ohio has had 42—20 regular, 6 homeopathic, 7 eclectic, 9 miscellaneous.

regular schools, 13 homeopathic and 7 eclectic, which required attendance upon three courses of lectures before graduation, and the percentage of schools requiring attendance upon three courses of lectures rose from 26.8 in 1880 to 88.3 in 1884.

The fluctuations in the numbers of regular, homeopathic and eclectic medical colleges since 1882 are shown in the following:

Years.	Schools.			Totals.
	Regular.	Homeopathic.	Eclectic.	
1882	78	10	10	98
1883	91	13	15	119
1884	87	13	12	112
1885	89	13	11	113
1886	90	13	10	113
1888*	91	14	10	115
1889	101	14	9	124
1890	111	13	9	133
1893†	109	19	8	136

Net losses	2

THE MICROBIC DISEASES OF THE NERVOUS SYSTEM.

The microbic or, to speak more exactly, the infectious diseases of the nervous system at present recognized are very few in number and this recognition is, except in the case of hydrophobia, entirely a matter of recent date. Even now, if we except tetanus, rabies, diphtheritic paralysis, cerebro-spinal meningitis, certain forms of neuritis, one or two tropical disorders and the tubercular affections, a spinal infectious etiology is not generally admitted. Perhaps we ought to add tabes and paresis to this list in view of their probable specific origin, and there are one or two affections such as LANDRY'S paralysis that stand as yet in an undetermined position in this respect. Apart from these forms any infectious nature of diseases of the nervous system is seldom admitted.

It is a question, however, whether we may not, in the near future, have to enlarge our ideas to some extent, and put poliomyelitis, syringomyelia, and possibly gliomas in general into this category. It is just probable that even some of the disseminated scleroses and paralysis agitans may be found to have special germs that cause their appearance and may have to be classed with the microbic diseases. Suppurative inflammations wherever they occur, whether within the cranium or elsewhere within the nervous system, are in all probability attended with the usual organisms of suppuration, and it seems probable from certain observations that have been reported, that other microorganisms than those usually found may sometimes be their exciting causes. The nervous system, protected and resistant as it is, presents constantly points of weakness which the roving microbes in the system may attack.

It is a rather significant fact as regards the future that tetanus, the one purely nervous disorder that is a typical bacillary disease, has only been recognized as such within the past few years. It is not altogether improbable that discoveries as striking as that of NICOLAËR'S bacillus will yet be made in the pathology of diseases of the nervous system; the

* No report published in 1887. † No reports published in 1891-92.

possibilities are not exhausted, indeed, we are probably only at the threshold of the investigation.

Setting aside the necessity of specific microbes, and admitting only a toxine action we find that the latter plays a most important part in these disorders. The number of nervous structural diseases that follow acute infectious fevers is in evidence, to say nothing of the known effects of such agents as alcohol, lead, mercury, and other mineral and organic poisons. The nerve centers are influenced from every part of an organism, which has been truly called a laboratory of poisons, and every failure in their elimination through disturbances of function reacts at once upon the brain and cord. The recent discoveries in regard to the thyroid gland are in evidence here, to say nothing of the long known effects of disorders of the organs of excretion. The part played by toxins in the etiology of these diseases is one of the most important if not actually the predominant element of their causation.

IMMIGRATION STATISTICS.

The United States Commissioner of Immigration at New York in a recent report states that there were 352,885 immigrants received into the United States during the year ended Dec. 31, 1893.

The comparative figures of the six leading nationalities are as follows; Italy, 69,074; Germany, 55,981; Russia, 37,100; Ireland, 30,236; Sweden, 28,965; Austria, 28,872. The number of illiterate, those who could neither read nor write, was 52,919, and of these Italy furnished by far the largest number with Russia a close second, while only 530 out of the nearly 29,000 Swedish immigrants did not have the rudiments of an education.

Thus we have more than fifty thousand illiterates added to our population who are practically certain, sooner or later, to become inmates of our charitable institutions, and nearly the whole number will be added to the already large class of persons seeking employment. In ordinary times this mass of humanity could be taken care of with comparative ease but at this time, when there is much suffering and too little work, it is not doubtful that a temporary suspension of immigration would be in the common interest of intending immigrants, not less than in the interest of those already among us.

REGARDING THE PRACTICE OF MEDICINE IN KENTUCKY.

The Kentucky State Board of Health has succeeded in removing nearly all the opposition to the new law regulating the practice of medicine in that State. The courts have sustained the validity of the Act, and the Legislature which has just adjourned was in thorough sympathy with the manner in which it was enforced. One of the results is that

now they do not have an advertising or traveling doctor in the State. The COPELAND advertisers that infest so many of the States, made a strong fight, and were the last to surrender and leave the State. Kentucky is to be congratulated.

AN EXPLANATION.

The *Pittsburg Medical Review* in an ill-natured commentary on Dr. COHEN'S letter lately published in this JOURNAL, refers to our foot-note that the letter was "published by order of the Trustees." That foot-note simply meant that as the article was an attack on the Board it was only printed by their own order.

CORRESPONDENCE.

"The Code."

To the Editor:—Doubtless there are many good men in favor of revision, but I believe each of these good men will admit that they have been benefited by adhering to the Code, and I believe that most of these good men will say that no man was ever injured in reputation by adhering to the Code. Now if it is true that the Code will benefit all of its adherents and at the same time injure none of them, it ought not to be changed in any way. Ever so small a change in a *perfect* instrument may make it useless. When a patient is doing well on any special treatment, the prudent doctor will hesitate before making a change. The same principle applies in all things. *Sometimes* a change makes the patient improve faster, but this is the exception, not the rule.

The strongest reason outside the above, why the Code should not be changed is, that the enemies of the ASSOCIATION and regular medicine are clamoring for a change. Editors of medical journals who interleave their pages with such nostrums as "Cactina Pillets," "Vinola Cream," "Malto Yerbine," "Sing," "Chionia," "Sanmetto," "Terraline," "Uric Solvent," and the host of nondescript compounds, have no use for a code. They claim that the "Golden Rule" is a sufficient code. So it is, but if a man will knowingly violate the present Code every day of his life, is there any hope of that man's adhering to the Golden Rule? The Golden Rule without penalties for its violation or rewards for its fulfillment would be a dead letter.

The irregulars have made war upon regular medicine for the past century. They have told the people that regular medicine was a "humbug" and none but the "reformed" men were doctors. The men who never use "calamy" (calomel) or other minerals; the men who claim that venesection is a crime and who give little doses of pleasant medicines were the ones to employ. Not satisfied with telling what they knew was false, they now have the "cheek" to ask regulars to change their rules of action (their Code), that they (the little pill men) may unite with us. What for? If we are humbugs and commit crime by our methods of practice why do they want to join our ranks? Why do they not keep themselves "unspotted from the world?" They call us all manner of mean names and then ask us to meet them in consultation, and because we refuse they are furious and want us to change this part of our Code. Shall we do it? I say, no. We have prospered wonderfully under the present Code, we are decidedly "on top" in every branch of medicine. Why should we step down and out and let our enemies dictate what is best for us? If they are so "tony"

and can do so much better by their patrons than we can, why do they not take the advice of the Kentucky doctor, who advised them to roost where they belonged? Surely we do not need them nor their suggestions. There has been a hue and cry for *union, union, union*. Union of what? Regular and irregular medicine? "No sir-rec." These are incompatible. They might make a *mixture* but no solution. The mixture would kill the ASSOCIATION so dead that the buzzards would not eat. The next meeting of the ASSOCIATION will be in a place where it will be costly for many to attend, and there will be a strong effort made to revise the Code. It is to be hoped that every member of the Society who can will be present and do all he can to prevent any legislation that has for its object the union of regular medicine with quacks. Write up your objections and send them to the JOURNAL. Show the rascals up in their proper colors, and instead of making a change in the Code whereby these high-toned gentlemen can be admitted, make it more difficult for them to enter. Let it be universally understood that no vendor of nostrums need apply. I am sorry I can not paint them in more natural colors.

Very respectfully submitted,

W. P. HOWLE, M.D.

Tscherning's New Theory of Accommodation.

PARIS, Feb. 22, 1894.

Dear Doctor:—I have been told by Dr. Javal and others that Tscherning's theory of accommodation has not yet been published in the English language, inasmuch as it has just appeared for the first time in the *Archives de Physiologie*, published in Paris. I therefore thought that it might be of interest to the medical profession in America. I shall not undertake to give a complete exposition of this theory, but only a brief resumé of its most important features. I will say, however, that the conclusions to which Dr. Tscherning has arrived have been the outgrowth of a vast deal of very careful study in the laboratory of Javal in the Sorbonne, and from my limited personal acquaintance with him I would judge that his inquiries have been conducted in the proper spirit of scientific investigation. His numerous experiments on the lower animals and his accurate observations on the human eye by the aid of the aberroscope and ophthalmophakometer (specially devised by him) have furnished him with the data upon which he has founded his new theory of accommodation in opposition to the well-known theory of Helmholtz which has existed so long. According to the latter the increased refractive power of the eye during accommodation depends upon a relaxation of the suspensory ligament which allows the lens to assume a more spherical form, and that this relaxation of the suspensory ligament is brought about by the contraction of the ciliary muscle. Now Tscherning's view is quite different from this. He holds that *one* action of the ciliary muscle is to render *more tense* the suspensory ligament, thus giving to the lens by an active and not by a passive process a form which is responsible for the augmentation of its refractive power. Tscherning's theory seems to explain not only the mechanism of refraction in the human eye but also is applicable to the various modifications of refraction observed in the lower animals. For example, in the case of fishes the crystalline lens is perfectly spherical in a state of repose and hence could not become more spherical during accommodation, which would be required by the theory of Helmholtz if his theory is universal.

The following is a resumé of Tscherning's conclusions:

1. During accommodation the summit of the anterior surface of the lens remains almost stationary.
2. The anterior surface of the lens during repose resembles

the surface of a sphere, but during accommodation it approaches that of an hyperboloid of revolution.

3. During accommodation the peripheral parts of the anterior surface of the lens are flattened, and the central parts become more convex.

4. During accommodation the refractive power of the anterior surface increases throughout, but especially towards the middle.

5. The spherical aberration diminishes during accommodation on account of the flattening of the peripheral portions.

6. The central part of the lens increases in thickness on account of the flattened peripheral portions.

7. The rate of curvature of the posterior surface of lens increases a little at the center.

8. The lens recedes a little, at least in certain cases.

9. The pupil contracts. The contraction commences a little after the change in the lens. During this contraction even the most peripheral parts of the iris take on a centripetal movement which does not occur after a simple incidence of light.

10. The plane of the iris changes. The central parts and the peripheral parts remain in the same plane, but the intermediate parts undergo a slight depression.

11. The ciliary processes advance slightly towards the axis of the eye.

12. The choroid is drawn forward.

13. The tension in the anterior chamber is diminished.

Without attempting to decide as to the value of these observations, I simply present them as being, in my opinion, worthy of consideration. Very sincerely,

JNO. McREYNOLDS, B.S., M.D.

To Dr. R. H. CHILTON,
Dallas, Texas.

Dallas, Texas.

Not Persons but Principles; Not Words but Actions.

PHILADELPHIA, Feb. 20, 1894.

To the Editor:—Your correspondent, "Constancy," objects to the language in which I criticised the action of the JOURNAL in disobeying the order of the ASSOCIATION and the provision of the Code prohibitory of nostrum advertising. I am unaware of anything "unprofessional" in my remarks,—but, be that as it may, if my letter is worth noticing at all, the question is not as to the literary merit of my style, but as to the justness of my contention; not as to my words but as to the Trustees' acts. While I am perfectly willing to be criticised, I do not desire to obtrude, or have others obtrude, my personality into what should be a discussion of principles. Let us avoid side issues of all kinds and stick to the main point.

The facts are undisputed, that: 1, the Code and, by resolution at Detroit, the ASSOCIATION, have prohibited the advertising of nostrums (i.e., secret preparations) in the JOURNAL of the ASSOCIATION; and 2, the JOURNAL, notwithstanding this repeated prohibition, does publish such advertisements. I would therefore respectfully ask "Constancy" for a direct answer to the following question: "Is the JOURNAL justified in publishing advertisements of nostrums?"

Yours truly,

S. SOLIS-COHEN, M.D.

The Advertising War.

CHICAGO, March 6, 1894.

To the Editor:—I write simply to endorse in their entirety the contents of Dr. Solomon Solis-Cohen's letter published in the issue of Jan. 20, 1894, of the JOURNAL, with reference to *nostrum* advertising. Unlike "Constancy," I see *nothing* undignified about Dr. Cohen's letter. It is precisely the

attitude of "Constancy," that is, one of timidity as to the statement of the bare truth, that is threatening the overthrow of medical ethics. There is no doubt that a lukewarm consideration of the subject makes the enemies of medical ethics still bolder.

My individual opinion on the matter at issue has already been expressed elsewhere, and now I only desire to be placed on record as indorsing every sentence of Dr. Cohen's letter.

Very truly yours, DAVID CERNA, M.D.

LETTER FROM EUROPE.

Major Girard, Surgeon U. S. Army, to Professor Senn.

No. III.

HEIDELBERG—PROFESSOR CZERNY—STRASSBURG—PROFESSOR LUECKE—PROFESSOR VON RECKLINGHAUSEN—BALE—PROFESSOR SOCIN.

HEIDELBERG, Feb. 14, 1894.

Dear Dr. Senn:—The purpose of my visit to Heidelberg was to see Professor Czerny and observe the management of his clinic. If I am a little disappointed I must ascribe the major cause to the miserable weather and lack of expected news from home, both of which will to a certain degree affect even a stoic. Perhaps, to the taste of the distinguished Professor, I was not a big enough personality, and when on inquiry, if I was a Surgeon-General, I replied in the negative I thought I perceived a shade of difference in manner, all of which may be a result of my mental depression and goes to show that, even with the most honest intentions, reports of clinics depend to a certain degree on the mental condition of the writer.

Professor Czerny is one of the foremost of German surgeons, and is spoken of as the successor of the lamented Billroth. He is said by his assistants to have deprecated any intention of leaving Heidelberg, a view ardently indorsed by those who well know that with him one of Heidelberg's brightest stars will leave; but it stands to reason that he can not refuse one of the greatest chairs in Germany (including Austria among the German-speaking universities). The present operating room of the clinic is very antiquated and will be replaced in May by one in course of construction, of which anon.

While the cases presented in the clinic were not of the brilliant kind, they still conveyed valuable lessons. A woman with a synovitis of the knee joint of a metastatic nature, in consequence of an attack of quinsy, had been aspirated some weeks ago and allowed at once to return to her home. Result: Severe inflammation. The lesson conveyed was that an aspiration should not be considered a slight operation and absolute immediate rest in bed must be insisted on.

A case of non-venereal multiple papillomata of penis and scrotum was operated on by one of the assistants with scissors and the Paquelin knife, while the Professor proceeded to operate on the case of the day. A boy of about 18 had been suffering with tubercular perforation of the squamous portion of the temporal bone and of the mastoid process, both of which were in communication with the external meatus. Gradually cerebral symptoms set in, leading to the suspicion of pyemic infection and thrombosis of the sigmoid sinus. With chisel and gouge the canal of the sinus was laid open, without revealing the expected thrombus. The operator then dissected down to the internal jugular and found no evidence of thrombus there. He was certain of the presence of a pyemic focus somewhere, but deemed ligation of the jugular or further investigation unjustifiable and the prognosis more grave on account of his inability to locate the trouble.

The wards of the surgical clinic are built on the two story

pavilion system, eight in number, each abutting on a central corridor, and accommodating about forty public patients and some private ones. The new operating amphitheater is at the end of this corridor and has on its lower floor rooms for the surgical polyclinic, and on the second one, beside the large operating room, the office of the Professor and several rooms for special examinations such as ophthalmoscopy, cystoscopy, etc. The operating room faces north and, as far as illumination is concerned, combines the advantages of Würzburg and Göttingen.

STRASSBURG.

I visited Prof. Luecke at his clinic.¹ The buildings pertaining to the clinical departments of the University have all been built, with the exception of the internal clinic, since the Franco-Prussian war, and are beautiful structures and in every way equal to those heretofore described in other places. Asepsis is carried out so scrupulously in Luecke's clinic that visiting physicians, who in the area are more or less in contact with the operating paraphernalia, are invested with operating aprons and sleeves, a good precaution no doubt. Ether has been introduced in this clinic for several months. Fearlessness of the results has, in my opinion, led to the practice of too profound an anesthesia, approaching asphyxia, and sooner or later fatal cases will be reported which will unjustly be attributed to ether—it should be abuse of ether.

The first case, enucleation of a large lipoma of the occipital region (large orange), calls for no special remark. Prof. Luecke operates rapidly and nervously and his assistants have no easy task.

The next case was a suicidal attempt of an actor—three pistol wounds inflicted with a small pistol on right temple and forehead. Two bullets were found flattened against the temporal bone, without injury to the osseous tissues (!) The third entered the right supra-orbital arch, under which it passed to the right frontal sinus, which it entered. The opening was enlarged with the chisel, but the bullet was not found. The usual packing with iodoform gauze terminated the operation. A Nélaton probe, which would have found special application in this case for location of the bullet among the osseous tissues, had unfortunately been mislaid and was not available.

The third case was a tubercular abscess over the ninth rib of the right side. After incision and evacuation a small focus was discovered, which was cut out with the spoon. I remarked, that Prof. Senn did not believe the spoon sufficient to prevent recurrence, upon which (possibly it might have been done without it), subperiosteal resection of the rib through sound tissues with the bone forceps was immediately performed. Prof. Luecke agreed entirely with your views on the subject.

To-day I witnessed an operation for removal of a goitre, which by compression of the trachea threatened the life of the patient. The tumor being almost solid was not suitable for Socin's enucleation, and it was removed *in toto*. The only point of importance was that the anterior superior thyroid artery was enormously distended, and being incised caused an extraordinary hemorrhage, which left the patient pulseless without alarming the operator, who as sole measure of restoration ordered hypodermic injection by hydrostatic pressure of the 3 per cent. solution of sodii chlorid with perfectly satisfactory results, since the patient was restored to consciousness by the time the various ligatures had been applied.

I learned various points of Prof. Luecke's methods in conversation, when he very kindly made the rounds of his clinic

[¹ The press dispatches announce the death of Prof. Luecke February 20. The clinic here reported by Major Girard must have been one of his last.—EDITOR.]

with me. The same obtains here as at other similar institutions in Germany, i. e., the director of the clinic, meaning the professor of surgery, selects the cases for admission. The patients generally pay two marks (50 cents) a day and in exceptional cases only are admitted gratis.

Prof. Luecke rarely resorts to extra capsular resection of the head of the femur for cavities. He cuts the upper rim of the acetabulum from an interior incision and either removes the head inside the capsule with the chisel or only the diseased parts with the sharp spoon. I saw several cases which made an excellent recovery with free motion of the joint.

He exhibited to me his modification of Glück's method in pseudarthrosis and arthrodesis. Glück drives a hollow ivory nail with lateral perforations into the medullary canal of each of the bones to be united and connects them with a screw peg. Luecke, finding that this peg produced an impassable bridge for bone formation, does not attempt bringing the two hollow pegs forcibly together, relying for this on the elasticity of the muscles and only prevents lateral displacement by the introduction of a central peg, like the pencil in a pencil holder. I saw a foot which had been operated on in this manner a few days ago for paralytic varus, the joint surfaces having first been denuded. It appeared already fairly solid.

A little boy with gastrostomy with valvular opening was cheerfully perambulating the ward. Three children had been successfully operated on in this manner during the year and in all three cases lye was the irritant which brought about the stenosis of the esophagus. Dilatation from below was not attempted.

I met in Strassburg in the Pathological Institute Professor von Recklinghausen, who was first assistant to Virchow, when I made my studies there in 1859 and 1860. His pathological establishment is on a large basis, the collection very rich and, no doubt, would offer a splendid school for Americans, who desire engaging in that particular study.

My next stop was in Bale, where my principal purpose was to visit the clinic of Professor A. Socin, who had been my teacher thirty years ago. He is rated among the prominent surgeons of Europe. I found him as fresh as ever, a painstaking, thorough clinical teacher and a fearless, but careful operator. His clinic was in proportion to the number of students in the University very well attended, better than any of those I had visited heretofore. His plan is to operate as little as possible during the hours of clinic, but to present the cases and submit them to an exhaustive clinical analysis, during which the "consulting staff" have no easy time, but are induced into methods of careful reasoning and defense of views.

Among the cases I witnessed in the clinic I will mention a hydrocele combined with irreducible inguinal hernia. The canal was opened by an incision extended down to the scrotum, the hernia liberated and reduced into the peritoneal cavity, without attempt at radical cure. The hydrocele was treated according to Volkmann's method, incision, ablation of part of the walls of the sac, suture of sac with external integument, application of a solution of carbolic acid, and then again suture of the scrotal wound. I relate the disposition of the hernia as a matter of observation.

The next case was a recurrent carcinoma of orbit, necessitating the removal of the margin with chisel and gouge. The wound was packed with iodoform gauze after sterilization of whatever skin covering was left. No attempt at primary transplantation.

A "cold" abscess at the lower angle of the scapula was the next case, patient being a young man of about 20, existence of the swelling having been noticed about four years and no tubercular localization having been found on

palpation in scapula or ribs; simple evacuation by means of trocar was deemed the safest treatment. In this connection Prof. Socin related a remarkable case of his practice, which has not yet been published.

A young man presented himself with a swelling in the groin, with impulse on cough, having all the other appearances of a hernia. He had had some disease of the spine some years before, leading to scoliosis. Prof. Socin diagnosed a cold abscess, incised in the groin and evacuated several pints of pus with pieces of the dorsal vertebræ.

The next case, a return of carcinoma in upper maxilla was treated by incision. Injury to the internal maxillary leading to great hemorrhage, which was arrested with a Langenbeck serre-fines, left in the wound, led to abandonment of further procedure.

A metastatic sarcoma of the size of a child's head in the groin was another case presented. It was the result of osteo-sarcoma of the great toe, which was amputated about two years ago. The Professor drew attention to his method of making a semi-plantar, semi-internal flap, thus bringing the cicatrix where it would be free from any pressure.

The inguinal sarcoma was operated on, not with the hope of cure or prolonging life, but to alleviate the annoyance to the patient resulting from probable extensive ulceration and the danger from hemorrhage.

An operation for radical cure of hernia presented some novel features. Prof. Socin makes a *horizontal* incision about two and one-half inches long about the level of the inguinal ring. He claims that being in a line with the natural folds, it heals more readily and gives sufficient room. The sac is passed through an incision in the transverse fascia, to which it is stitched with catgut. Four catgut sutures fasten it then in the inguinal canal. No attempt is made to approximate the pillars of the ring, which accounts for returns of the hernia, he is said to have. Owing to considerable handling of the tissues holding the spermatic cord, he introduced a glass drainage tube in the lower part of the canal. The natural opening is accurately closed with continued suture. He uses for that purpose a very fine aluminium wire, as flexible as silk, the proper alloy of which he determined after numerous experiments. He has not published yet his results.

I saw among other cases operated on, a nephrectomy for tubercular kidney, in which a considerable part of the peritoneum had been removed, an excision of the tongue for carcinoma with preliminary tracheotomy, and numerous other major operations, showing, that while Prof. Socin deprecates the excessive use of the knife, owing to the impunity conferred by Lister's discovery, he is well in the advance in the boldness of his operations. In his clinic he predicted that in the next generation a reaction would set in and that many surgical diseases, which at this time led to operations, will be cured by internal medication, and that internal medicine, which has been thrown into the shade by surgery during this age of new operations, will recover its place.

Sincerely yours,

A. GIRARD.

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Rio-Grande Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville, Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland, thence east by way of the Northern Pacific R. R. to St. Paul. C. M. & St. P. R. St. Paul to Chicago. A stop over at Yellowstone National Park for those who desire it has been arranged, and it has been understood that at several places on the journey there will be

short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentrating on this train should be effected at Chicago and St. Louis. For all information relating to this train, fares, etc., address G. M. Connell, 212 Clark st., Chicago, or any agent of Santa Fe line in other cities. Rates promised are the lowest excursion rates at time of departure.

Hotel Rates.—The following hotels, centrally situated and convenient to the place of meeting, have quoted special rates for members and their families, which will apply during the entire stay of the guests, who should, upon registering, signify that they are in attendance upon the meeting of the ASSOCIATION.

The rates quoted are for single persons, the variation depending upon the size, situation and appurtenances of the rooms, as single, en suite, with private bath, etc. Special arrangements will be made for families, or parties, on timely notice.

Some of the hotels entertain upon the American plan only, some upon the European plan only, and some upon either plan to suit guests.

Palace Hotel (headquarters) American plan (rooms and board) \$3.50 to \$5.50 per day; European plan (rooms only) \$1.50 to \$3.50.

Baldwin Hotel, American plan \$3.50 to \$5 per day; European plan \$1 to \$3 per day.

California Hotel, American plan \$3.50 and up per day; European plan \$1.50 and up per day.

Lick House, American plan \$2.50 and up per day; European plan \$1 and up per day.

Russ House, American plan \$2 to \$3.50 per day; European plan .50 to \$2.00 per day.

Occidental Hotel, American plan only, \$2.50 and up per day.

Hotel Pleasanton, American plan only, \$2.50 to \$5 per day.

Grand Hotel (connected with the Palace by a glass enclosed bridge across New Montgomery Street), European plan only, \$1 to \$2 per day.

In addition, there are many other hotels, boarding houses, lodging houses and restaurants contiguous to the place of meeting where one can be made happy and comfortable at less cost.

Post Office Section K is located in the Palace Hotel, on the office floor, adjacent to the registration room, where members can receive all mail matter by having it so addressed.

R. H. PLUMMER, Chairman.

San Francisco, March 4, 1894.

Section on State Medicine, AMERICAN MEDICAL ASSOCIATION
It is proposed that diphtheria shall be the prominent subject of discussion at the coming session of this Section, to be held June 5, in San Francisco. Original work is desired, and all members of the ASSOCIATION interested in preventive medicine are invited to participate in the discussion. Papers on any subject relating to public health or preventive medicine will be welcome. Kindly notify, as soon as convenient, by sending title and outline of paper to

CHAS. H. SHEPARD, Secretary.

81 Columbia Heights, Brooklyn, N. Y.

Section on Surgery and Anatomy, AMERICAN MEDICAL ASSOCIATION, San Francisco meeting, June 5-8, 1894. It is proposed to devote a portion of the time of this Section to the systematic consideration of a few selected subjects, upon which papers, each not occupying more than ten minutes will be read. It is hoped that speakers discussing these papers will confine their remarks to brief addresses of five minutes' length. The topics and papers to be so presented are as follows:

I.—MALIGNANT GROWTHS.

The Pathology of Malignant Growths; E. Laplace, Philadelphia, Pa.

A Critique of the Sporozoan Theory of Malignant Neoplasms from a Micro-technical Standpoint; A. P. Ohlmacher, Chicago, Ill.

Clinical Recognition of Malignancy in Tumors; C. A. Wheaton, St. Paul, Minn.; Henry W. Coe, Portland, Oregon.

The Necessity of Early Surgical Interference in Malignant Tumors; R. A. McLean, San Francisco, Cal.

The Value of Caustics in Malignant Growths; John Parmenter, Buffalo, N. Y.

The Radical Cure of Malignant Tumors by Operation; J. H. Wythe, Oakland, Cal.

The Value of Inoculations with Septic or Toxic Agents in the Treatment of Malignant Neoplasms; John A. Wythe, New York, N. Y.

2.—TUBERCULAR DISEASE OF JOINTS.

Early Symptoms and Diagnosis of Tubercular Joint Disease; Emmet Rixford, San Francisco, Cal.; A. B. Judson, New York, N. Y.

Conservative Treatment of Tubercular Joints; R. H. Sayre, New York, N. Y.; Harry M. Sherman, San Francisco, Cal.; James E. Thompson, Galveston, Texas.

Operative Treatment of Tubercular Joints; Robert W. Lovett, Boston, Mass.

Treatment of Tubercular Joints by Injections of Iodoform; N. Senn, Chicago.

Treatment of Tubercular Joints by Injections of Corrosive Sublimate; R. H. Plummer, San Francisco, Cal.

3.—HERNIA.

The Causation and Prevention of Hernia; James T. Jelks, Hot Springs, Arkansas; C. M. Richter, San Francisco, Cal.

The Management of Reducible Hernia; Emory Lanphear, Kansas City, Mo.; C. M. Fenn, San Diego, Cal.

The Treatment of Irreducible Hernia; James B. Eagleson, Seattle, Washington.

The Treatment of Strangulated Hernia; Joseph Ransohoff, Cincinnati, Ohio.

The Radical Cure of Hernia; W. E. S. Davis, Birmingham, Ala.; H. O. Marcy, Boston, Mass.

4.—HEMORRHOIDS, FISTULE, AND FISSURE.

The Pathology and Symptomatology of Hemorrhoids, Anal Fistule, and Anal Fissure; J. M. Matthews, Louisville, Ky.; David Powell, Marysville, Cal.

Treatment of Hemorrhoids; H. M. Bishop, Los Angeles, Cal.; Charles B. Kelsey, New York, N. Y.

Treatment of Anal Fistule; J. McF. Gaston, Atlanta, Ga.; G. B. Somers, San Francisco, Cal.

Treatment of Anal Fissure; Thomas W. Huntington, Sacramento, Cal.; Lewis H. Adler, Jr., Philadelphia, Pa.

5.—FRACTURES.

Treatment of Fractures of the Lower End of the Humerus; Oscar H. Allis, Philadelphia, Pa.

Treatment of Fractures of the Lower End of the Radius; P. T. Conner, Cincinnati, Ohio; C. L. Bower, Philadelphia, Pa.

Treatment of Fractures of the Neck of the Femur; Bedford Brown, Alexandria, Virginia.

Treatment of Gunshot Fractures; George A. Goodfellow, Tucson, Arizona.

Treatment of Fractures of the Shaft of the Femur; Llewellyn Eliot, Washington, D. C.

Treatment of Open or Compound Fractures; H. H. Mudd, St. Louis, Mo.

6.—OBSTRUCTION TO URINATION IN THE MALE.

Effects of Obstruction in Urination Upon the Bladder and Kidneys; J. William White, Philadelphia, Pa.

Diagnosis and Treatment of Enlargement of the Prostate Gland; Hunter McGuire, Richmond, Va.; Wm. T. Belfield, Chicago, Ill.

Symptoms and Treatment of Stone in the Bladder; Wm. T. Briggs, Nashville, Tenn.

Symptoms and Treatment of Tumors of the Bladder; John B. Deaver, Philadelphia, Pa.; C. F. Buckley, San Francisco, Cal.

Treatment of Stricture of the Urethra; J. Rosenstein, San Francisco, Cal.

Members who have patients or specimens to exhibit bearing on these topics or who wish to make remarks in the discussion of them are cordially invited to be present during the meetings of the Section. The titles of other papers to be presented to the Section will be published when the program of the meeting of the ASSOCIATION is issued by the Committee of Arrangements.

JOHN B. ROBERTS, Chairman,

1627 Walnut Street, Philadelphia, Pa.

LLOYD W. McRAE, Sec'y, Atlanta, Ga.

The Coming Meetings.—"We doctors ought to feel happy; we can pay our money and take our choice—the State Medical at San José in April, or the National at San Francisco in June. We can also combine business with pleasure by at-

tending the greatest attraction ever seen on the Pacific Coast, and, in many respects, save the World's Columbian Exposition, the greatest exhibition ever in America. This latter will be an extra inducement to the Eastern visitors to come to the Pacific Coast. So very rare is it for the National Association to go so far from the popular center; it behooves us to show our appreciation of the compliment by attending in large numbers and by causing a respectable increase in membership.

Los Angeles, considering her importance as a noted health resort and number of physicians, ought to have a larger representation in the National Association. Of all places in the world, this city can least afford to be local, and that, too, upon medical matters. With us there will be a twofold good—the benefit derived from the attendance upon the meetings of the Society, and the indirect advantage accruing to the city. Many of the visitors will undoubtedly pay their respects to Los Angeles. All Southern California representatives will be eagerly questioned. The old story told on the Californian visiting his Eastern friends is probably true. So frequent had been his praises of the magnificent weather of this favored State, that by preconcerted arrangement every one of his callers asked, "How did you leave the climate?" Though this was a joke, yet the inquiry as to climate is the first question asked in good faith by the rest of the country—save the dwellers in Florida, or some other place of low latitude.

In pleading for the National we by no means wish to belittle the claims of the State Association. Southern California is a very important part of the State climatically, and it is very essential for its proper recognition that a goodly number of its physicians be present in San José in April.

On the day before the convening of the State society there will be held Monday, the 16th inst., the second annual State Sanitary Convention. The time is so arranged so as not to interfere with the sessions of the State Society, and at the same time allow one trip to do for both. There is room for a great deal of work in this direction. As this will be under the auspices of the State Board of Health, its utterances will have a semi-official bearing and corresponding weight with the laity. Preventive and State medicine will be the themes chiefly discussed. A topic, which is otherwise mentioned in this number, will be discussed under the following resolution:

Resolved, That hereafter consumption (and other diseases due to the bacillus tuberculosis) should be included in the list of diseases dangerous to the public health; requiring notice by householders and physicians to the local health officer as soon as such disease is recognized.

The utter disregard of many patients and landlords for the health of others can only be overcome by proper measures initiated by the physicians themselves.—*Southern California Practitioner*.

SOCIETY NEWS.

The Second Sanitary Convention of the State of California.—The second annual Sanitary Convention will be held at San José on April 16, the day preceding the meeting of the State Medical Society. The convention will be held under the auspices of the State Board of Health, which will pay all the bills. Invitation is extended to all medical men and sanitarians to be present and to present papers in the interest of preventive measures.—*Pacific Medical Journal*.

The Morgan County (Illinois) Medical Society held its regular monthly meeting in the Society's rooms, Jacksonville, March 8; President Frank P. Norbury in the chair. C. E. Ruth, Professor of Anatomy and Clinical Surgery, Keokuk (Iowa) Medical College; by special invitation demonstrated, upon a dog, the use of the "Murphy button" in intestinal surgery. The meeting was well attended. A vote of thanks was tendered Prof. Ruth for his highly interesting and scientific address and demonstration.

The Medical Society of the State of California.—The twenty-fourth annual session of the Medical Society of the State of California will convene at San José, April 17, 18 and 19,

1894. Chairmen of committees are requested to send the titles of their papers by the middle of March, to the Secretary of the Committee of Arrangements, Dr. John Wagner, Sixteenth and Valencia Streets, San Francisco. A large and interesting meeting is promised, and it is hoped that all members will endeavor to be present to give our friends in San José a chance to show what they can do when they try.—*Pacific Medical Journal*.

The Association of Military Surgeons.—The fourth annual meeting of the Association of Military Surgeons of the United States will be held in Washington, D. C., May 1, 2 and 3, 1894.

This National organization is composed of medical officers of the U. S. Army, U. S. Navy, National Guard of the United States and the Hospital Marine Service—in whose service are many of the most celebrated and distinguished surgeons of our country. A brilliant and able literary program will be presented. The afternoon of one day will be set apart for an object lesson from the "Manual of Drill," by the Hospital Corps. The evenings will be given up to social entertainments. There will be about five hundred delegates in attendance.

GEORGE HENDERSON,
Chairman Committee of Arrangements.

Twenty-first National Conference of Charities and Correction, Nashville, Tenn., May 23-28, 1894. Provisional Program. The Twenty-first National Conference of Charities and Correction will be held at Nashville, Tenn., beginning May 23 and closing Monday, May 28.

The Executive Committee has adopted the following provisional program, which is subject to amendment. A revised edition will be published later:

Wednesday—May 23, 8 p.m., Opening Exercises and Reception.

Thursday—May 24, 9:30 a.m., Reports from States. 10 a.m., State Boards of Charities. Papers and Discussions. 2 p.m., Section Meetings. 8 p.m., Charity Organization in Cities. Ten minute reports from cities upon this winter's emergency work.

Friday—May 25, 9:30 a.m., Reports from States. 10 a.m., The Insane. Papers and Discussion. 2:30 p.m., Section Meetings. 8 p.m., Juvenile Reformatories. Papers and Discussions.

Saturday—May 26, 9:30 a.m., Reports from States. 10 a.m., The Feeble Minded. Papers and Discussions. 2:30 p.m., Section Meetings. 8 p.m., Sociology in Institutions of Learning. Papers and Discussions.

Sunday—May 27, 11 a.m., Conference Sermon. 8 p.m., Child Saving Work. Ten minute addresses.

Monday—May 28, 9:30 a.m., Reports from States. 10 a.m., Prisons and Reformatories. Papers and Discussions. 2:30 p.m., Section Meetings. 8 p.m., Training Schools for Nurses. Brief Addresses. Closing exercises of the Conference.

The membership of the Conference includes members of State boards of charities, delegates from charity organization societies, officers of public and private charitable and correctional institutions, official delegates appointed by the Governors of States, and all other persons directly or indirectly connected with charitable work. All persons included under this general description are invited to attend the Conference, and the boards in charge of charitable or correctional institutions, public or private, are invited to send delegates.

The Conference is non-sectarian and non-political, whose aims are purely scientific and philanthropic.

The local arrangements for this meeting are in charge of a local committee composed of some of the best citizens of Nashville, who will make the necessary arrangements for reduced railroad and hotel rates, of which due announcement will hereafter be made.

A large attendance is expected, and the papers and discussions will be of a high order of scientific value and practical utility.

Persons receiving this circular will confer a favor by sending the Secretary the names of persons in their cities or States who are officially or personally interested in charitable or correctional work, for the purpose of having circulars sent them. Please give the official relation to institu-

tions or societies, and in large cities the street and number of residence, if possible.

L. C. STORRS, Lansing, Mich., President.
A. O. WRIGHT, Madison, Wis., Secretary.
JOHN M. GLENN, Baltimore, Md., Treas.

MISCELLANY.

Dr. J. W. C. Neal of Gettysburg, Pa., at a meeting of the State Board of Charities held at Harrisburg on March 1, was chosen a member of the Lunacy Commission.

Died of Ruptured Heart.—Sewall Parker, a young man of 23, died suddenly March 4, at Toledo, Ohio, while sparring with a friend. The postmortem examination made two days after showed that Parker's death was caused by a broken heart, that organ being literally rent in two.

Registration of Tuberculosis.—The State Board of Health and Bureau of Vital Statistics of Washington, at its recent annual meeting, passed an order requiring physicians practicing within the State to report all cases of pulmonary tuberculosis.

No attempt will be made at isolation, but a printed circular containing full directions for the sanitary care of such patients will be sent out by the Board for the guidance of the persons having them in charge.

Yellow Fever Spreading at Rio.—A cable from London bearing date March 7, says Captain John Piper, who succeeded Captain Lang as senior officer of the British fleet at Rio Janeiro, cabled to the Government to-day that yellow fever is spreading in the city. He recommends that all vessels be withdrawn from the entire harbor and that the port be closed. Advices from Rio Janeiro of March 9, state that all the foreign vessels of war have left the harbor, with the exception of Admiral Benham.

Dr. J. H. Ford of Wabash, Ind., has been appointed chief surgeon of the "Big Four" Railroad system. It is the intention to establish a hospital system like that on the Wabash and Missouri Pacific Roads. Dr. Ford will have jurisdiction over the "Big Four" and the Peoria & Eastern. It is the intention to erect a large hospital at Indianapolis to accommodate the divisions centering there, and to establish a hospital in every other division if the employes are favorable.

He Likes Our Reviews.—It was with pleasure that we read the greater portion of our review of Dr. Matthieu's book on diseases of the stomach, and the major portion of our notice of Professor Koch's book on operative surgery, in the March number of the *Southern Practitioner*. It would have added to our pleasure if the articles had been properly credited to the *JOURNAL* instead of being used as original matter of the *Practitioner*. The notices in question appeared in our issue of February 17.

Faxton Hospital, Utica, N. Y.—The following staff appointments have been made by Dr. James H. Glass, Surgeon-in-Charge of Faxton Hospital:

Surgical Service—A. R. Simmons, Judson G. Kilbourn, F. F. Ellinwood.

Medical Service—H. C. Palmer, Charles B. Tefft, F. H. Brewer, James M. Ross, Walter B. Palmer, LeRoy Jones, L. F. Pattingill, M. J. Davis, William Powell, W. H. Brownell, C. R. Ward, H. E. Shumway.

Eye, Ear and Throat Service—A. R. Simmons; Charles W. Crumb, Assistant.

Obstetrical Service—F. H. Brewer, W. H. Brownell.

Gynecological Service—James H. Glass, Judson G. Kilbourn.

Pathologist—Theodore Deecke.

Consulting Staff—G. Alder Blumer, Utica; Stephen A.

Ingham, Little Falls; Claude Wilson, Waterville; J. F. Huntley, Oneida; L. Swartwout, Prospect; George Graves, Herkimer; D. A. Barnum, Cassville; D. H. Roberts, Trenton; J. W. Douglas, Boonville; G. I. Pollard, Oriskany Falls; H. G. Dubois, Camden; M. W. Hurst, Holland Patent; G. A. Armstrong, West Winfield; I. M. Comstock, New York Mills; O. Langworthy, Hamilton; J. E. Casey, Mohawk; I. S. Edsall, Middleville; C. R. Hart, New Hartford; C. M. Sefler, Gloversville; George Fisher, Clayville; Alfred Goss, Adams; C. C. Veeder, St. Johnsville.

Home for Feeble Minded Children.—The Board of Directors of the Pennsylvania Training School for Feeble Minded Children, at Elwyn, Pa., at their meeting on March 2, elected a medical board of consultants for the first time in the history of the institution. These gentlemen have consented to give their professional services gratuitously and to aid in the cure and the mental and physical improvement of the children. They are: Surgeons, Dr. John B. Deaver, Dr. W. W. Keen; physicians, Dr. John Madison Taylor, Dr. D. T. Laine; neurologists, Dr. S. Weir Mitchell, Dr. H. C. Wood, Dr. C. K. Mills, Dr. James Hendric Lloyd; orthopedic surgeon, Dr. G. T. Morton; otologist, Dr. C. S. Turnbull; ophthalmologist, Dr. S. D. Risley; laryngologist, Dr. S. Solis-Cohen; gynecologist, Dr. Anna E. Broomall; pathologists, Dr. H. W. Cattell, Dr. Joseph Leidy; dental surgeon, Dr. Thomas C. Stellwagen.

The chief physician, Dr. Martin W. Barr, and the assistant physicians, Drs. Frank White and Louise H. Llewellyn, are also members of the medical board. There are at present 909 children in the school, of whom 100 are supported by the city of Philadelphia, 550 by the State of Pennsylvania, and the remainder by the District of Columbia, by relatives, or by the "Free Fund" of the institution.

Appointed General Superintendent of the Canadian Quarantine Service.—Dr. Frederick Montizambert, has recently been appointed by the Dominion Government, General Superintendent of the Canadian Quarantine Service. Dr. Montizambert has for many years had charge of the Quarantine Station at Grosse Isle, in the St. Lawrence River about thirty miles below Quebec. This station during the cholera and ship fever times, commencing in 1832 and extending about, to 1855, was the best equipped in the world. Steam having supplanted the sailing vessel, the plant was for many years crippled, on account of the steamships not being able to land at the wharf. About ten years ago Dr. Montizambert began to urge the building of a pier to deep water, so that vessels could come alongside, and other improvements and additions to the plant as experience demonstrated were necessary. He finally succeeded, so that by the beginning of the quarantine season of 1893 the changes desired were completed, and with the sub-station at Point Levi near Quebec it is once more the most complete quarantine station in the world. During the past season all the baggage of immigrants was inspected and disinfected whether cholera, or cholera suspects were on board or not, and in this way afforded greater protection to the United States (as nearly all the immigrants went to the United States) than any of our own quarantines. It not alone protected us from cholera, but other infectious diseases. He now will have supervision of the stations at Halifax, Grosse Isle, and those on the Pacific coast. Would that we could have such supervision of the quarantines of the United States. Dr. Montizambert is one of the best quarantine officers on this continent; a good executive, and an accomplished sanitarian, and always acts in harmony with the sanitary authorities of the United States. In 1890 he was elected the sixteenth President of the American Public Health Association, the first time in the history of that organization that a non-resident of the United States was selected for that honorable position.

Water Supply of Bridgeport, Conn.—Dr. Garlick of the Bridgeport Board of Health, made a statement before the Water

Investigating Committee, February 28, the substance of which was that the water taken from the upper and lower dams for the purpose of examination was found impure and highly prejudicial to the health of the community. According to the Bridgeport *Farmer*, he asserted that the typhoid fever outbreak last summer was caused by impure water. There were in all several cases, two of which were fatal.

He gave the details of the examination of the water which he said was performed by Dr. Foote, the bacteriologist of Yale. The result of the test demonstrated the presence of germs which, while corresponding with and possessing all the known features of the typhoid fever germ, might not have been the real thing.

Speaking of his visit to the dams last summer for the purpose of securing the samples of water for analysis, the Doctor said:

"We found evidences of filth and uncleanness on all sides. Especially filthy were the quarters occupied by the Italian workmen. It was clear that the sanitary condition of the surroundings was not what it should have been. The privy vaults were in a deplorable condition, and had a heavy rain storm or freshet occurred the refuse of these depositions would in all probability have been forced back into the reservoirs, with the result of tainting the water which flowed to the consumer."

The Doctor believed that the impure water and surroundings were responsible for the illness of the typhoid fever victims among the workmen.

President Sherwood, of the Hydraulic Company, inquired if Dr. Garlick was positive that the disease the men died of was typhoid fever, and the latter replied affirmatively.

Mr. Sherwood asserted that Dr. Bill, who attended some of the men, said that the symptoms were not those which indicated typhoid, but fever of another type. Dr. Garlick said examination of the water drawn from the faucet in his office showed it to be exceptionally pure, and from this he judged that it was on account of its being filtered. At that time the Board of Health recommended the use of private filters in all homes and also wherever possible the boiling of the water used for drinking purposes.

When asked if he had any idea of what would improve the quality of the public water supply he said that as an individual he did not care to take the responsibility of offering a suggestion but intimated that the Health Board might submit a proposition for remedial measures.

Engineer Hotchkiss, of fire steamer No. 3, and Engineer Tracey, of No. 4, said that as a general thing the fire supply was adequate, but on several occasions they had been compelled to remain idle owing to the apparent absence of sufficient force in the water pipes. In their opinion this was due to some irregularity of the water mains and not the hydrants.

Health Officer FitzGibbon substantiated the statements of Dr. Garlick. Of 102 cases of typhoid fever reported since 1889, 38 proved fatal. Some of the fatal ones were in his opinion due to impure water.

James Lyons, engineer at Hincks & Johnson's carriage factory, said he often found that there was not enough water in the boilers to get up steam. President Sherwood said that the capital stock of the Hydraulic Company was between \$700,000 and \$800,000. He refused to say how much the Company expended in constructing its system, intimating that the question was an improper one. City Attorney Davenport explained to the committee the legal relations between the Company and the city, and an adjournment was made subject to the call of the chair.

Philadelphia Notes.

THE POLYCLINIC TRUSTEES have just signed the contract for improvements which will cost near fifty thousand dollars this sum having been appropriated for the institution by the State Legislature at the last session. Among the additional accommodations are a three story laboratory building, a mortuary or autopsy room, a clinical amphitheater, and wards aggregating about fifty beds. The alterations will be made during the summer and completed by September.

THE GERMAN HOSPITAL—has also just adopted plans for enlarging its administration building by bringing it out to Corinthian Avenue. The addition will be modern in style 80 feet front and 25 feet in depth, and three stories in height, and will afford additional wards and private rooms.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from March 3, 1894, to March 9, 1894.

Major JOHN VAN R. HOFF, Surgeon U. S. A., is hereby assigned to the charge of the office and duties of the Medical Director, Hdqrs. Dept. of the East, during the temporary absence of Col. JOSEPH R. SMITH, Asst. Surgeon General, Medical Director of the Department. First Lieut. CHARLES WILCOX, Asst. Surgeon U. S. A., is relieved from temporary duty at Boise Bks., Idaho, and ordered to return to his proper station, Presidio of San Francisco, Cal. Par. 7, S. O. 54, A. G. O., Hdqrs. of the Army, March 5, 1894.

Capt. R. B. BALL, Asst. Surgeon U. S. A. (Ft. Monroe, Va.), is hereby granted leave of absence for one month.

Capt. R. W. JOHNSON, Asst. Surgeon U. S. A., will proceed to Ft. Monroe, Va., for temporary duty during the absence on leave of Capt. R. B. BALL, Asst. Surgeon. Upon the return of the latter from leave, Capt. JOHNSON will return to his station, Washington Bks., D. C.

Major TIMOTHY E. WILCOX, Surgeon U. S. A., is granted leave of absence for one month.

Major JOHN D. HALL, Surgeon U. S. A., leave of absence granted is extended one month.

Capt. HENRY I. RAYMOND, Asst. Surgeon, is granted leave of absence for four months, to take effect on or about Aug. 10, 1894.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending March 10, 1894.

P. A. Surgeon F. W. OLCOTT, from Naval Hospital, New York, and to the "Richmond."

P. A. Surgeon S. S. WHITE, from the "Richmond," and to the Naval Academy.

P. A. Surgeon L. W. CURTIS, from the Naval Academy, Annapolis, and wait orders.

P. A. Surgeon G. T. LUMSDEN, from the "Kearsarge," and wait orders. Medical Inspector W. H. JONES, ordered before the Retiring Board.

Asst. Surgeon C. E. RIGGS, from Naval Hospital, Mare Island, Cal., and to Naval Laboratory and Department of Instruction, New York.

Surgeon D. N. BÉTOLETTE and Asst. Surgeon J. M. MOORE, ordered to the "Atlanta."

Asst. Surgeon J. E. PAGE, ordered to examination preliminary to promotion.

APPENDICITIS OBLITERANS.

Read before the Chicago Academy of Medicine, March 16, 1894.

BY N. SENN, M.D., P.H.D., LL.D.
CHICAGO.

PROFESSOR PRACTICE OF SURGERY AND CLINICAL SURGERY RUSH MEDICAL COLLEGE; PROFESSOR OF SURGERY CHICAGO POLICLINIC; ATTENDING SURGEON PRESBYTERIAN HOSPITAL; SURGEON-IN-CHIEF ST. JOSEPH'S HOSPITAL.

The successful surgical treatment of peritonitis caused by infective lesions of the appendix vermiformis constitutes the most brilliant chapter of modern aggressive surgery. The surgeons have taught physicians by scientific research, as well as by lessons learned from clinical experience, that peritonitis, in the majority of cases, is a secondary affection, and that its successful treatment depends largely upon the detection and removal of the primary cause. The present large amount of knowledge concerning appendicitis and its complications is largely the result of the work of American surgeons. The European surgeons are slow in accepting the teachings and practice, as developed and promulgated in this country, but in the near future they will have to submit to the most convincing proof—the results of clinical experience. During the last five years so much literature on the surgical treatment of inflammatory affections of the appendix has accumulated that this subject has become somewhat threadbare and confusing. For a number of years it was customary for a certain class of abdominal surgeons to report the result of their annual work on ovariectomy; then it became the fashion to give the statistics of tubal surgery, but at the present time the appendix vermiformis is the favorite topic of discussion, and to it is assigned a liberal space of the medical press and the programs of medical societies, both large and small.

It appears to me that it would be more profitable in the future for this department of abdominal surgery to write less concerning individual experience, and elaborate more thoroughly upon a pathologic basis the conditions which demand surgical interference. The surgeon must bring more convincing proof than the simple recovery from the operation, viz.: The reasons for the necessity of operative intervention, in order to convince the mass of the profession of the correctness of the ground taken by a number of surgeons, that the appendix should invariably be removed when it is the seat of an infective lesion. There are exceptions to nearly all rules, and the surgery of the appendix vermiformis has not advanced sufficiently to enable us to lay down cast iron rules when and when not to operate. Pelvic surgery has been degraded by the modern *furor operativus*, and the same fate threatens the surgery of the appendix. The conscientious surgeon must bring his work in consonance with the pathologic conditions

which he is expected to correct or remove. If it were my intention to report the result of my own work in the surgery of the appendix, I should certainly feel inclined to offer an apology in view of what has been presented by the medical journals, especially those of our country during the last five years, but as I propose to limit myself to the description of a special pathologic form of appendicitis, I am confident that I have opened up a field that will afford ample space for future investigations of a similar character and which will, in the course of time, furnish a foundation for accurate diagnosis and an improved technique.

I have, for a long time, been convinced that appendicitis is an infective disease, caused by pathogenic microbes which reside in the normal intestinal canal and exercise their specific pathologic properties in the appendix whenever the essential *locus minoris resistentiæ* is produced by other conditions. The anatomic location of the appendix is such that retention of its secretions is liable to occur, particularly in cases in which the lumen at the proximal end has become narrowed by congenital stenosis or antecedent affections of the cecal wall. From a bacteriologic aspect the appendix may be regarded as an open test tube, and the retained secretions a culture medium. I have but little doubt that future research will demonstrate that the most frequent microbic cause of appendicitis is the bacillus coli communis. Pus microbes undoubtedly enter largely into the etiology of mixed infections here as elsewhere. Intensity of the inflammation is determined more by the quantity than by the pathogenic quality of the microbes. The same cause which in one case produces a mild form of inflammation may in others determine speedy death from gangrene or perforation and acute sepsis.

I have performed at least 150 operations for lesions of the appendix, but instead of giving a detailed account of these it is my intention, in writing this paper, to call the attention of the profession to a pathologically and anatomically well-defined form of appendicitis that has heretofore not been separately described. For a number of years I have noticed in the examination of specimens removed from cases of recurring appendicitis, varying degrees of contraction of the lumen of the appendix, differing in extent from slight stenosis to complete obliteration. In recent cases I have invariably found the wall of the appendix more or less thickened at the seat of constriction. Similar observations have been made by other surgeons, but I have not seen anywhere special mention of this particular form of appendicitis. The *Medical Record*, July 15, 1893, alludes to a specimen described by Dr. Biggs, which had been removed from a man dying of chronic alcoholism. The appendix consisted of a small pouch about 3.1 ctm. in length, and beyond this a fibrous

cord 2 mm. in diameter, which, apparently as a result of an old inflammation, had been united by adhesions to the neighboring tissues. The effect of this appendicitis had been to cause a complete obliteration of more than one-half of the lumen of the appendix. Sections of the fibrous cord showed, under the microscope, unstriped muscular tissue, fibrous tissue and many small round cells. Fenger ("Remarks on Appendicitis," *American Journal of Obstetrics*, No. 2, 1893), has described a similar specimen. Nearly one-half of the appendix on the distal side was found obliterated. (Fig. 1. "Obliteration of Appendix on Distal Side." Fenger's case.) T. G. Morton ("Two Recent Cases of Excision of the Vermiform Appendix for Chronic Relapsing Appendicitis in the Interval," *Medical and Surgical Reporter*, Dec. 23, 1893) has recently removed an appendix for recurring inflammation in which obliteration had taken place on both sides. "It measured rather more than three inches in length; it was greatly distended near its middle, and the proximal and distal ends were thickened and swollen; a section showed total obstruction of the organ except its middle or distended portion, which was filled with about two drachms of very offensive pus." Lange, of New York, has also described several similar cases.

Fig. 1.

My attention has recently been called forcibly to this form of appendicitis, as within the short space of two months four cases have come under my observation. I have designated this form of appendicitis as appendicitis obliterans, because the most conspicuous pathologic condition presented by the specimens is an obliteration of the lumen by cicatricial contraction. The pathologic processes resemble very closely a similar condition in the terminal arteries designated here as arteritis obliterans. The patients presented before the operations a complexus of clinical symptoms which, when grouped together, will enable the surgeon to at least suspect, if not positively predict, this condition. I will briefly report the four cases of appendicitis obliterans which have recently come under my observation, and later utilize them as a text upon which to base some general remarks on the pathology of this form of appendicitis.

Case 1.—H. M. Stewart, aged 26; business, book-keeper; residence, Lyons, Kansas. Admitted into St. Joseph's Hospital, Sept. 30, 1893.

The patient states that his health had been fairly good until three years ago, when he suffered from an attack of "cramps in the stomach," and pain and tenderness in the ileo-cecal region. This attack lasted about eight hours. Similar attacks followed at intervals of two or three months, becoming more frequent until during last year they occurred every four to six weeks. The acute symptoms would, as a rule, subside in from six to fourteen hours, to be followed by a dull aching pain in the right iliac fossa accompanied by tenderness on pressure which would continue for ten days to two weeks when he would be able to resume his occupation, but more or less soreness and ten-

derness remained. The last attack which was unusually severe occurred in June. Operation was performed Oct. 2, 1893. The appendix was found behind the cecum directed inward and upward. It was adherent to the cecum and a loop of the ileum, mesenterium shortened and much thicker than normal. The organ when removed measured about three inches in length and presented a peculiar club-shaped appearance, the constricted portion being on the proximal side while the free end was bulbous. (I am indebted to Dr. Mellish for the illustrations in this paper). The wall of the free bulbous portion was much thickened. About one-third of the lumen on the proximal side was completely obliterated. The excluded part contained a viscid fluid, of a brownish color. The temperature ranged between 99 and 100 degrees F., for four days when it reached 101½ degrees F., on the fifth day, after which it became normal. The patient left the Hospital at the end of the fourth week.

Case 2.—J. Barzof, aged 25; German-American; dentist; residence, Manitowoc, Wis. He entered St. Joseph's Hospital at the request of his attending physician, Dr. Pritchard, Nov. 4, 1893. Operation on the following day. General health fair. In the summer of 1888 he was taken with the first attack in the form of severe vomiting, diarrhea and intense pain in the abdomen, radiating upward and downward to the right of the median line. The first seizure lasted about four days. Similar attacks occurred about four times every year. In the spring of the present year it appeared that the attacks were provoked by change in diet. Pain often more severe when stomach was empty. Dietetic treatment had no effect in preventing recurrence of the difficulty. No constipation. Last and most severe

Fig. 2.

Appendix laid open from tip to near proximal end; Mrs. W.; Nov. 13, 1893. 1. Bulbous extremity. 2. Everted exceedingly vascular mucous membrane. 3. Obliterated portion. 4. Central part showing location of obliterated lumen.

attack about September 20. This was preceded by a somewhat hard swelling extending from umbilicus to the right inguinal region which was followed by a severe chill, vomiting, diarrhea and the characteristic sharp lancinating pain more severe in the ileo-cecal region. Highest temperature 102 degrees F. The pain and tenderness in the ileo-cecal region never disappeared completely after this and were relieved only by rest in the recumbent position. On opening the abdominal cavity the appendix was seen at once. It measured at least five inches in length and was firmly attached to the caput coli and extended behind the colon. The distal bulbous end was small. A similar bulbous expansion was found near its attachment to the cecum. Between these bulbous expansions the organ was not larger than a small lead pencil, anemic and very dense. Owing to the length of the mesenterium it had to be tied in four sections. The glands in the vicinity were found much enlarged, some of them had attained the size of an almond but none of them presented any evidences of caseation. Examination of the specimen after its removal showed that nearly the entire lumen had been obliterated, only a small portion on the distal and proximal side remaining patent. The open spaces contained a catarrhal viscid secretion of a brownish color. The temperature in this case never reached 100 degrees F., and the patient left the Hospital at the expiration of four weeks.

Case 3.—Mrs. E. A. West, aged 28, American, housewife; residence, Decatur, Ill. Entered St. Joseph's Hospital at the suggestion of the family physician, for the purpose of having the appendix removed for a recurrent inflammatory affection in the right iliac region of long standing. Her mother died of pulmonary tuberculosis when patient was only six months old, and the latter has always been

in delicate health. Married two years; no children. Six years ago was taken suddenly ill with symptoms indicating peritonitis. The pain was diffuse and of a grinding character. The acute symptoms subsided in five or six hours, but she was confined to the bed for four days. The tenderness in the right iliac region remained for a number of days. Later, in the same year, had a similar attack and during each of the succeeding four years the same experience was repeated from two to four times. Beginning with September, 1892, she had an attack each month until February, 1893, six in all. The attack in February was so severe that a physician was called for the first time. As in all previous attacks, pain passed off in a few hours but patient was confined to bed for four or five days, and tenderness persisted for as many more days. She was never aware of the exact location of tenderness until she was examined by her physician. The last and most severe attack occurred in July of the present year, which lasted twelve days. She was attended by Dr. Bumstead, who recognized the difficulty and advised a radical operation. During the last attack the temperature reached 103 degrees F. Vomiting and nausea were not conspicuous symptoms during any of the attacks. In the beginning of the acute exacerbations the pain was generally diffuse; later, localized in the ileocecal region. Hot applications always afforded prompt relief, and she believes that they were the means of cutting short

He attributed the difficulty to a strain produced by lifting. The second attack in April, the following year, commenced with a sudden, sharp, intense pain confined to the right side in the region of the appendix. The acute symptoms continued for one month, during which time he was confined most of the time to bed, but at any time, if assisted to his feet he could walk with the aid of a cane. During the second month he improved sufficiently to resume his work. A sense of soreness and tenderness in the ileocecal region remained. Vomiting occurred on the evening of the second day. Tympanites absent. Diagnosis of appendicitis was made on the fourth day by the attending physician. Third attack February, 1893, resembled the second in every respect. There remained not so much tenderness on pressure, as a soreness or pain from a slight jar, as would happen when riding in a buggy when the wheel struck a stone. Could not stand perfectly erect, but would incline the body slightly forward and to the right with feet about twelve inches apart. Examination before operation revealed tenderness in the region of the appendix on deep pressure. Operation Dec. 8, 1893. The appendix was readily found as it was directed forward and to the right, occupying a groove in the caput coli. During its separation from the cecum I expected every moment to make a rent in the bowel as the peritoneal coat of the latter appeared to be absent and the muscular coat very much attenuated. The dissection was

Obliterated appendix showing small pervious spaces at each end, the intervening part converted into a solid cord.

1. Proximal end completely obliterated. 2. Narrow stricture dividing completely the remaining lumen into two unequal portions; great thickening of wall near distal end.

several of the attacks. When examined after her admission into the Hospital the appendix could be felt as a firm cord, and tenderness was limited to this structure. Operation November 14. In this case the appendix was directed downward and inward toward the pelvis; adhesions old and firm. Mesenteriolum very short and adherent to appendix. It was tied in several sections. About one-fourth of the lumen on the proximal side was obliterated and the corresponding portion of the appendix transformed into a firm fibrous cord. (Fig. 4.) Beyond this obliterated part the lumen was much dilated, and subdivided into two unequal portions by a thin partition composed of cicatricial tissue. Wall of appendix much thickened and dense. Both compartments contained inspissated pus which resembled liquefied caseous material. Lymphatic glands in the vicinity of the appendix much enlarged and exceedingly vascular. Patient recovered without an untoward symptom. A small stitch abscess at the end of a week gave rise to a slight elevation of temperature, and slightly retarded the healing of the wound.

Case 4.—J. H. Croskey, aged 33, American; farmer by occupation; residence Farmer City, Ill. Entered St. Joseph's Hospital Dec. 5, 1893. Family history good. Patient was never sick until November, 1891, when after a hard day's work, he experienced a dull pain in right side and lower part of abdomen. He was able to sit up but could do no work for three days, when all symptoms passed away. There was no nausea or vomiting; a little tympanites and consti-

made slowly and carefully and mainly with the aid of blunt instruments. The mesenteriolum was incorporated so firmly in the adhesions that ligation was rendered superfluous. A number of bleeding points were ligated. The appendix when removed measured three inches in length, and on slitting it open it was found that about one-third of its lumen on the distal side was completely obliterated. (Fig. 5.) The distal end tapered into a sharp point. Wall of remaining portion only slightly thickened. Mucous membrane intensely congested. At a point about half an inch distant from obliterated part, both the wall of the appendix and its lumen showed changes which indicated the first stages of the formation of a circular stricture. Mucous membrane much thickened.

In this case the second attack of appendicitis produced an intense localized plastic peritonitis which gave rise to the extensive and firm adhesions of the appendix to the cecum, rendering the operation one of great difficulty. During the dissection I feared that a perforation at the tip of the appendix had taken place, followed by rupture of a small abscess into the cecum, and on this account anticipated injuring the wall of the bowel. Examination of the specimen, however, proved conclusively that this had

not occurred and that the adhesions were caused by a plastic peritonitis without perforation.

Since writing this paper the following interesting case of appendicitis obliterans has come under my observation in the clinic of Rush Medical College:

Case 5.—Jas. McChane, occupation, farmer, aged 35 years, married; mother died of phthisis. Personal history: Never a very robust man. Had "ague" eight years ago lasting three months. Regular in habits; no venereal history.

In August, 1893, the patient, while threshing wheat, was attacked with a severe paroxysm of pain in the right lumbar region. He had to stop work but did not go to bed. He has not been able to do a day's work since, although he has not been confined to his bed. The pain is always present, a dull aching pain, and the least exertion aggravates the difficulty and tenderness. The pains are always referred to the same point, a few inches to the right and below the umbilicus.

The bowels have been constipated and the patient resorts to the use of enema to relieve them. The appetite is very poor and he has been steadily losing flesh. When admitted the patient's temperature is normal in the morning with a slight evening rise.

On physical examination, a point of tenderness found corresponding to McBurney's point, with some induration and fixation of head of cecum.

From the clinical history and existing symptoms I was able to make the diagnosis of appendicitis obliterans before the operation. The operation was performed in the clinic. Photograph of specimen herewith shown. The distal end was patulous and is slit open, showing interior view with the obliterated portion at the proximal end.

Appendix, about one-third natural size.

GENERAL REMARKS.

The cases just reported present many clinical features in common. The age of the patients varied from 25 to 38. Four were males and one female. In all of them the acute exacerbations were characterized by symptoms of peritonitis of varying inten-

a—Appendix laid open from proximal end as far towards distal end as it is pervious, and a little farther. *b*—Transverse section of same, showing bulging of the mucous membrane.

1. Narrow circular strip of appendix much thickened, lumen much contracted; early stages of circular stricture. 2. Distal obliterated end tapering into a sharp point.

sity. Swelling does not appear to have been a constant feature, either during or after the acute attack. In most instances the pain was at first diffuse or referred to epigastric region; later, localized in the ileo-cecal region. In most of the cases, tenderness in the region of the appendix remained a long time

after the subsidence of the acute symptoms, or remained as a permanent condition. In all of the cases I was able to produce pain on making deep pressure directly over the appendix. The point of tenderness therefore varied according to the location of the appendix. The febrile disturbance during the acute attack appears to have been moderate and of short duration. Nausea and vomiting were not constant symptoms. Tympanites depended on the extent of the peritoneal involvement. The most constant and characteristic feature was recurrence of the acute exacerbations which set in from once a year to every few weeks. As a rule, the attacks became gradually more frequent. In two out of the four cases, some of the most important symptoms remained in a masked form during the intermissions. This was noted particularly in the cases in which the appendix was obliterated on the proximal side. I should suspect, very strongly, appendicitis obliterans in cases of recurrent appendicitis in which no complete intermission takes place during the interval between the acute attacks, and no appreciable swelling can be found in the region of the appendix. From what has been said it will be seen that the most conspicuous symptoms of this form of appendicitis are: 1, short duration and moderate intensity of the acute exacerbations; 2, slight or no swelling in the region of the appendix; 3, recurrence of acute attacks varying in frequency from a year to several weeks; 4, persistence of some soreness and tenderness in the part affected during the intermissions.

Appendix of rabbit, lymphatics injected. *ff*—Outer follicles with lymphsinus, *ss*. *f'f'*—Inner follicles. *ll*—Lymph vessels which leave the lymph follicles. *m*—Mucous membrane with dilated glands; *e*—their epithelial cells; *rr*—their recesses. *r'*—Recess; point of entrance does not correspond with level of section (Orth).

Etiology.—I have already made the statement, in the introductory remarks, that this as well as other forms of appendicitis is caused by pathogenic microbes, and therefore regard all acute inflammatory affections of the appendix as infective lesions. A glance at the anatomy of the appendix, as well as an examination of the most constant pathologic conditions, will corroborate the correctness of this assertion. The appendix is richly supplied with lymphatic vessels, and it is through these that infection most frequently takes place. Orth (*Cursus der Normalen Histologie*, etc., Berlin, 1878,) has fully described the lymphatic structures in the appendix of the rabbit, and Morris has recently alluded to the lymphatic channels of this structure as a route of infection in man.

It is not difficult to understand that an ordinary

catarrhal inflammation would render the mucous membrane permeable to the passage of pathogenic microbes, rendering it possible for them to pass from the lumen of the appendix into the lymphatics, the essential cause of the inflammation thus coming in direct contact with every anatomic constituent of the wall of the appendix, its serous investment and even the free peritoneal cavity without any ulceration or perforation. The distribution of the microbic cause through the lymphatic route has been demonstrated by many postmortem examinations and appendices removed by operative treatment. Minute miliary abscesses have often been found in the wall of the appendix and underneath the peritoneal coat, and usually in locations formerly occupied by lymphatic channels. There can be no question that the exciting cause can often be traced to a trauma, indiscretion in diet and exposure to cold. In none of the cases of appendicitis obliterans did I find a foreign body or an enterolith. In Fenger's case in which the obliteration was on the distal side, two grape seeds, one fecal concretion the

examinations. He found partial or complete obliteration in 25 per cent. of these cases. He believes that this change is due to involuntory changes in the majority of cases. One reason for entertaining this idea is that this condition of the appendix is met with more frequently in persons advanced in years. The influence of age is shown in the following table:

1	decennium	4	per cent.
2	"	17	"
4	"	27	"
5	"	36	"
6	"	53	"
7	"	58	"

In favor of the inflammatory origin of appendicitis obliterans it can be said that appendicitis is a comparatively rare affection in children, and that the longer the person lives the greater the liability to suffer from an attack. I have no doubt that obliteration of the appendix occasionally occurs as a congenital condition. Atresia of the lumen of this organ is probably more liable to occur during intra-

Appendix (Stewart). + section through cicatrix, one-half circumference. size of a split pea, and the husk of an oat were found in the appendix. In the event of incarceration of a foreign substance or fecal concretion on the distal side of the obliteration, I should expect more pronounced symptoms during the intervals between the acute attacks, and apprehend great danger of perforation with all its immediate disastrous consequences. In only one case did the inflammation result in supuration on the distal side of the obstruction, and in this case the pus had become inspissated. In all the other cases the excluded part of the lumen of the appendix contained from one to a few drops of viscid fluid stained a brownish color. It is evident that a plastic peritonitis in the vicinity of the appendix can be produced by pyogenic microbes without visible pus within the appendix or its wall.

Ribbert (*Virchow's Archiv*, 1893,) wished to ascertain the frequency with which the appendix vermiformis undergoes obliteration, and for this purpose noted the condition of this organ in 400 postmortem

uterine life than the same condition in other parts of the gastro-intestinal canal.

Pathology and Morbid Anatomy.—Ranvers (*Zur Pathologie and Therapie der Perityphlitis Deutsche Med. Wochenschrift*, 1891, No. 5,) found the appendix completely obliterated in thirteen postmortem examinations. All of the specimens showed evidences of circumscribed plastic peritonitis. He believed that in some of these cases perforation had taken place, and that the disease ultimately cured itself. In one specimen he found a small fecal concretion, surrounded by a capsule of cicatricial tissue. The most striking morbid changes in obliterating appendicitis are found in the different tissues of the organ, and these are directly concerned in the gradual and progressive obliteration of its lumen. A stricture of the appendix, like that of any other hollow organ, may be brought about by: 1, destruction of the mucous membrane by ulceration; 2, infiltration, thickening and contraction of the muscular coat; 3, prolonged cic-

tricial contraction of exudates upon its serous covering; 4, or, in consequence of a combination of two or more of these causes. In a former communication on relapsing appendicitis, ("A Plea in Favor of Early Laparotomy for Catarrhal and Ulcerative Appendicitis, with the Report of Two Cases," JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Nov. 2, 1889.) I described an appendix in which the mucous membrane was extensively ulcerated. ". . . . On inspection of the mucous membrane lining it, an oblong ulcer was discovered near the middle and opposite mesenteric attachment. The ulcer measured about half an inch in length, and a quarter of an inch in width. Its greater diameter corresponding to the long axis of the appendix. The margins of the ulcer were regular in outline and not undermined. It presented no evidences of repair. Its greatest depth corresponded to its center. The whole mucous membrane was exceedingly vascular and much thickened, the submucous infiltration being uniform over its entire area. A transverse section of the appendix through the center of the ulcer, examined under

circumference of the appendix near the occluded part. Most of the spaces shown in the scar tissue were evidently formerly occupied by submucous glands. A few of them represent lumina of blood vessels.

The mucous membrane is almost completely destroyed, only a few remnants at *d* remaining. The place formerly occupied by the mucous membrane is now the seat of active cell production from the submucous connective tissue. The numerous vacant spaces in the fibrous tissue are empty glandular and lymph spaces, in which the parenchyma of gland tissue was destroyed, either by the infective inflammation or later by pressure from cicatricial contraction. The inflammation started in this case either in the mucous or submucous tissue, and extended towards the periphery of the organ, as indicated by the pathologic changes. The peritoneum, with the exception of the adhesions, had undergone but slight textural changes, while the tissues underneath were not much affected.

Fig. 7 represents the same section under higher

Same section as represented in drawing No. 6, showing remains of mucous membrane mingled with granulation tissue— $\times 75$ diameters

the microscope, showed that the entire thickness of the mucous membrane and part of the muscular coat were destroyed by the ulcerative process, and that the remaining thickness of the wall, as far as the peritoneum, was infiltrated with embryonal cells and leucocytes which were closely grouped together in the connective tissue reticulum. The submucous tissue and part of the muscular coat were similarly infiltrated throughout." The healing of such an ulcer would naturally produce stenosis and eventually complete obliteration of the lumen of the appendix. Such an event would presuppose subsidence of the infective inflammation, the lining of the floor of the ulcer with active granulations and the transformation of embryonal into cicatricial tissue endowed with the characteristic intrinsic tendency to progressive contraction. Such a mode of obliteration is shown by illustrations, Figs. 6, 7 and 8. The sections were taken from near and under the obliterated part of the appendix removed from Mr. Stewart.

Fig. 6 represents a section through a portion of the

power. It shows the remnants of glandular tissue and the almost complete destruction of the epithelial cells lining the interior of the appendix, and an abundance of scar tissue taking largely the place of muscular tissue. (Fig. 8). This section was taken from near the distal extremity of the excised appendix where the mucous membrane was least affected, and demonstrates that the primary lesion commenced some distance from the terminal end of the lumen, and that the process of obliterating cicatrization extended from here in both directions. It also illustrates that the fibrous thickening of the wall takes place largely by proliferation of the submucous connective tissue. It appears from these illustrations that while the primary microbic cause in such cases acts with sufficient intensity to destroy the mucous membrane, producing more or less suppuration, the destruction of tissue is limited to the epithelial lining and perhaps the submucous glandular and lymphoid tissue; when it comes in contact with the connective tissue its pyogenic function is limited and an abundance of

granulation tissue is formed, which not only limits infection but likewise brings about obliteration of the lumen which in many instances assumes a progressive character. The adjacent mucous membrane not only suffers from continual exposure to the primary infective cause, but also from impairment of nutrition from gradually increasing cicatricial contraction. It is probable that in this way obliteration of the entire lumen would be finally accomplished, and that this termination is most likely to occur if the obliterating process begins in the distal part of the appendix.

I am, however, inclined to believe that in the majority of cases the obliterating appendicitis has a deeper and more serious origin in the direction of the lymphatic glands and channels. In such in-

illustration of this type of obliterating appendicitis. The clinical symptoms in this case pointed to severe circumscribed plastic peritonitis, and the pathologic conditions revealed at the time of operation extensive and very firm adhesions. The appendix removed was occluded for about an inch at the distal extremity. The non-occluded portion showed the presence of catarrhal inflammation with the characteristic bulging of the mucous membrane after the appendix was laid open.

Fig. 9 represents a section through one-third to one-half of the entire circumference of the obliterated portion of the appendix. The section includes only a small part of the peritoneum which was very much thickened and the subserous vessels dilated.

As compared with the other illustrations the sec-

stances the mucous membrane at some point furnishes the necessary infection-atrium through which the microbes enter the lymphatic channels resulting finally in an interstitial inflammation, with more or less involvement of the peritoneal coat. The acute exacerbations in this variety of appendicitis obliterans are more intense, because the primary seat of infection is nearer the peritoneal coat, and the route of infection towards it more direct. The interstitial inflammation may result in the formation of small inter-mural abscesses which are more likely to reach the mucous than the serous surface. The mucous lining of the lumen of the appendix becomes implicated by the inflammation extending from glandular structures and connective tissue underneath it, and later from cicatricial contraction. Case 4 furnishes a good

tion through the obliterated part shows fewer empty glandular spaces and more blood vessels. The glandular structure was destroyed by the inflammation at an early date and not starved out, as was the case in the former instance. The former lumen of the appendix is here indicated by a mass of embryonal tissue in various stages of transformation into connective tissue. Reduction in the size of the obliterated part of the appendix was brought about in part, at least, by constriction of the peritoneal adhesions.

Fig. 10 represents the appearance of the tissues in a section near the obliterated part. At *a*, the superficial glands remain while in close proximity to it at *b*, the epithelial lining and glands are destroyed and their places are occupied by granulation tissue. The submucous tissue is again the seat

of active tissue changes, especially under the mucous membrane at *a*. The continuance of inflammation at the proximal end of the obliterating process, is indicated further by the presence of an extravasation of blood at *f*, and the masses of embryonal cells near the muscular coat at *g*. The thickening of the wall of the appendix is most marked during the acute exacerbations and in the excluded part. In the obliterated part the diameter of the organ is gradually diminished until it is transformed into a firm solid cord while its length, owing to adhesions, is often elongated instead of undergoing shortening (Case 2).

Among the cases which I have reported there is no instance of obliteration from cicatricial contractions of peritoneal adhesions alone, nor have I been able to find such a case in literature; but that such an occurrence is possible we know from analogy. In Case 4, we have reason to assume that the extensive and firm peritoneal adhesions aided the obliterating

purative type, are produced. I found more or less enlargement of the lymphatic glands in all cases in which the product of the inflammation was thus imprisoned. In Cases 2 and 5 a number of lymphatic glands the size of almonds were found. The operative removal of such glands is superfluous as the removal of the depot of infection will be promptly followed by resolution. The great thickening of the wall of the appendix in the part excluded must be attributed, in part at least, to the vain attempts of the organ to evacuate its contents.

Operative Technique.—The operation performed in these cases for the removal of the appendix, as in other forms of relapsing appendicitis, was in all essential points the same as described in my paper referred to above. The abdominal incision was made from a point half way between the anterior superior spinous process of the ilium and the umbilicus in a vertical direction down to near Poupart's ligament.

Appendix (J. H. Croskey). process. In reference to the contents of the excluded portion of the appendix we find that in two cases it consisted of a small quantity of viscid fluid devoid of odor and stained a brownish color, while in one case the cavity contained inspissated pus. In Morton's case it contained two drachms of fetid viscid material. In distal obliteration the proximal patent lumen usually contains the characteristic catarrhal secretion. One of the interesting pathologic conditions attending proximal obliteration which attracted my attention is the implication of the lymphatic glands in proximity to the vermiform appendix. In such cases the escape of septic material into the intestinal canal is prevented by the occlusion, and indefinite accumulation is prevented only by the passage of the products of the septic inflammation through the lymphatic channels. In this way lymphangitis and lymphadenitis, usually of a non-sup-

The cecum was used as a guide to the appendix. The free abdominal cavity was protected by sterilized gauze during the isolation and removal of the appendix. The mucous membrane of the stump was cauterized with pure liquid carbolic acid, the surplus acid carefully removed with a gauze sponge, the stump dusted with iodoform and buried by three or more Lembert sutures of fine silk, which included the serous and muscular coats of the cecum on each side. The line of suturing was made in accordance with the conformation of the cecum, in a direction which would cause the least tension, and without causing any unnecessary encroachment upon its lumen. I look upon this method as the ideal one in disposing of the stump, as it most efficiently guards against the two most serious after complications in such cases—infection and formation of a fecal fistula. I appreciate more and more the difficulties which so

often confront the surgeon in performing this operation. Although I have had but one death in about thirty-five operations, for recurring appendicitis, I am always prepared to meet unexpected complications and inform the patient of the possible risks which he assumes in subjecting himself to the operation. As in none of the cases of obliterating appendicitis pus was found outside of the appendix, flushing and drainage were dispensed with. The external incision was invariably closed by four rows of sutures, the first of catgut including the peritoneum only, the second of the same material embracing the fascia of the external oblique, the third of silkworm gut including all of the tissues, and, finally, the fourth of very fine catgut in the form of a continued suture, to bring the skin in accurate contact. As I have observed a number of cases of ventral hernia following operations upon the appendix in my own, as well as in

destruction of all glandular tissue and obliteration of the entire lumen.

4. The incipient pathologic changes occur either in the mucous membrane of the appendix, in the form of superficial ulceration, or as an interstitial process following lymphatic infection.

5. The most constant symptoms which attend this form of appendicitis are relapsing acute exacerbations, of short duration, moderate or no appreciable swelling at the seat of disease, and persistence of soreness and tenderness in the region of the appendix during the intermissions.

6. The process of obliteration may begin at the distal or proximal end, or at any place between, or it may commence simultaneously, or in succession at different points.

7. Obliteration on the proximal side gives rise to retention of septic material which finds an outlet through the lymphatics giving rise to non-suppurative lymphangitis and lymphadenitis.

8. Circumscribed plastic peritonitis is an almost constant concomitant of appendicitis obliterans, and hastens the process of obliteration.

9. Complete obliteration of the lumen of the appendix results in a spontaneous and permanent cure.

10. In view of the prolonged suffering incident to a spontaneous cure by progressive obliteration, and the possible dangers attending it a radical operation is indicated, and should be resorted to as soon as a positive diagnosis can be made.

Appendix (J. H. Croskey). Proximal end; + section through about one-sixth of its circumference— $\times 25$ diameters.

the practice of other surgeons, I am exceedingly anxious to prevent this occurrence by bringing the most important tissues in accurate contact by separate rows of the buried suture. I never permit patients to leave the bed in less than four weeks, and I advise them to wear a well-fitting bandage for six months as an additional safeguard against this exceedingly undesirable remote complication.

CONCLUSIONS.

1. Appendicitis obliterans is a comparatively frequent form of relapsing inflammation of the appendix vermiformis.

2. It is characterized by progressive obliteration of the lumen of the appendix, by the gradual disappearance of the epithelial lining and glandular tissue, and the production of granulation tissue from the submucous connective tissue which by transformation into connective tissue and cicatricial contractions starves out remnants of glandular tissue, and finally results in obliteration.

3. The obliterating process manifests a progressive tendency, and may finally result in complete

CLINICAL HISTORY OF THE CASE OF PRESIDENT JAMES ABRAM GARFIELD.

BY ROBERT REYBURN, A.M., M.D.

PROFESSOR OF PHYSIOLOGY AND CLINICAL SURGERY MEDICAL DEPARTMENT HOWARD UNIVERSITY, WASHINGTON, D. C., AND ONE OF THE ATTENDING SURGEONS IN THE CASE OF PRESIDENT GARFIELD.

I

ASSASSINATION OF PRESIDENT GARFIELD.

On the morning of July 2, 1881, President Garfield accompanied by Secretary Blaine drove up to the B Street entrance of the Baltimore and Potomac depot, Washington, D. C., intending with a party composed of members of his family, Cabinet and personal friends, to take a pleasure trip through the New England States. At 9:30 A.M. President Garfield and Secretary Blaine were walking across the ladies' reception room on their way to take the train, when a pistol shot was heard, which was immediately followed by a second report. There was a rush of those who were present to the reception room, where the President was found lying on the floor with blood streaming from two wounds, one a slight flesh wound of the right arm, and one of the right side of the body. The President turned at the first shot, and fell on his knees at receiving the second shot. The first ball from the assassin's revolver struck the upper portion of the right arm inflicting a slight flesh wound. The second bullet entered the right side of the back, four inches to the right of the spinal column, and on a level with the twelfth, or lowest of the dorsal vertebrae, and passing at first forwards, fractured the eleventh and twelfth ribs, then being deflected to the left, passed through the body of the first lumbar vertebra in an oblique direction to the left, and emerging thence,

passed behind and below the pancreas, where it was found at the postmortem examination. The second ball in its course penetrated some of the branches of the mesenteric arteries and grazed the splenic artery.

The President was laid upon the floor until a mattress could be procured, and he was at once removed to a room in the second story of the depot; when he turned deathly pale, and soon after he was carried up stairs he vomited. The assassin attempted to run out of the Sixth Street door of the depot, but for some reason turned back and was arrested by Officers Scott and Kearney. The President's eldest son was with him at the time he was shot as well as Secretaries Blaine, Hunt and Lincoln, and Postmaster General James.

Dr. Smith Townshend, the district Health Officer was the first physician who came to the assistance of the President. He arrived about four minutes after the shooting, and states that he found him lying upon the floor of the depot, surrounded by an immense throng of people. He was in a fainting condition, and apparently dying. Dr. Townshend administered a stimulant, and by his orders he was removed upstairs. Immediately after this Drs. Purvis and Bliss arrived at the depot.

Secretary Blaine came out of the reception room following a man, and calling, "Rockwell! Rockwell! Where is Rockwell?" The man was seized by Officer Kearney, and Mr. Parks, the depot policeman, and proved to be Charles J. Guiteau.

Secretary Blaine was not going with the party, but came down to bid the President good-by. He said: "The President and I were walking arm in arm toward the train. I heard two shots, and saw a man run. I started after him, but seeing he was caught just as he got out of the room, I came to the President, and found him lying upon the floor. The floor was covered with the President's blood." The weapon used by the assassin was a five chambered revolver of the English bulldog pattern, with an ivory handle, and was about seven inches long. This is a weapon of strong propulsive power, and experiments made with a similar weapon during Guiteau's trial showed that it had power enough to penetrate a two inch plank at a distance of one hundred feet. When arrested Guiteau said: "I did it, and want to be arrested. I am a stalwart and Arthur is President now. I have a letter here I want you to give to General Sherman; it will explain everything. Take me to the police station."

Officers were sent to the police headquarters, by order of those around the President, to get the name of the assassin. He very willingly wrote his name and address on a sheet of paper, as follows:

"CHARLES GUITEAU,

ATTORNEY-AT-LAW,

CHICAGO, ILL."

The following letter was taken from the prisoner's pocket at police headquarters, showing conclusively the intention to kill the President:

July 2, 1882.

To the White House:

The President's tragic death was a sad necessity, but it will unite the Republican party and save the Republic. Life is a flimsy dream, and it matters little when one goes. A human life is of small value. During the war thousands of brave boys went down without a tear. I presume the President was a Christian, and that he will be happier in Paradise than here. It will be no worse for Mrs. Garfield, dear soul, to part with her husband this way than by nat-

ural death. He is liable to go at any time, anyway. I had no ill-will towards the President. His death was a political necessity. I am a lawyer, a theologian and a politician. I am a stalwart of the stalwarts. I was with General Grant and the rest of our men in New York during the canvass. I have some papers for the press which I shall leave with Byron Andrews and his co-journalists at 1420 New York Avenue, where all the reporters can see them. I am going to the jail.

CHARLES GUITEAU.

On the morning of July 2, 1881, at about 9:45 A.M. whilst in my office, I was suddenly summoned by a messenger from Dr. D. W. Bliss, who informed me that President Garfield had been shot by an assassin, at the Baltimore and Potomac depot, and requesting my immediate assistance. At first I refused to go, being incredulous, but after a few moments' consideration, I deemed it advisable to go and see for myself if there was any truth in the story, and drove rapidly in the direction of the depot. I was soon certain that something terrible had just happened. From all directions I could see people hastening towards the depot as to a common center. Hastening up stairs on my arrival I saw President Garfield lying on a mattress, which had been hastily procured for him, and which had been placed on the floor of a room in the second story of the depot. He was lying in the northeast corner of the room when I first saw him. I asked him, "Mr. President, are you badly hurt?" He answered: "I am afraid I am." The President was deathly pale, almost pulseless and apparently dying from internal hemorrhage. Dr. Bliss was present, surrounded by a number of physicians, and was evidently recognized by all who were there as in full charge of the case. The following account of the condition of the President, when first seen by Dr. Bliss is a verbatim copy of his statement made to me at the time, and immediately recorded by me in the note book of the case: "I recognized a very feeble pulse of about forty beats per minute, and a marked pallor of the face; skin cold and covered with a clammy perspiration. There was sighing respiration which was slow, being about twelve to fourteen per minute. The lines of expression of the face were changed, and evidences of his having recently vomited were apparent. I then learned from Dr. Smith Townshend who had preceded me, that he had administered one ounce of brandy and one drachm of aromatic spirits of ammonia to the President. I then proceeded to examine the wound, and carefully introducing my little finger detected fractured portion of the eleventh rib and determined that the ball had passed forwards and slightly downwards into the abdominal cavity. I found a clean cut wound four inches to the right of spinous process of twelfth dorsal vertebra, between the eleventh and twelfth ribs. After withdrawing my finger, I introduced a Nélaton probe with great caution to the extent of three inches, where its progress was arrested by the soft tissues. Deeming it hazardous to make any forcible exploration I desisted, and then informed the medical gentlemen who were present that I deemed it unwise to make any further examination. I then asked the physicians who were present to retire to one of the corners of the room for consultation (there being no other available place) respecting the propriety of removing the President to the White House, and whether or no more stimulants should be given. It was then thought best on account of his weak condition to give him another half ounce of brandy."

The physicians present at this consultation were Drs. D. W. Bliss, Smith Townshend, N. S. Lincoln, Basil Norris, P. S. Wales, John B. Hamilton, C. M. Ford, D. C. Patterson, C. B. Purvis and Robert Reyburn. The President repeatedly and urgently requested that he should be removed to the White House. After the examination of the wound the President inquired as to the gravity of his injury; Dr. Bliss replied to him that it was quite impossible to give a definite opinion at this stage, disguising his own fears as to the gravity of the case. The President complained very much of a sense of weight and heaviness in his lower extremities. After a few minutes he said he had a sensation of tingling in his feet, and very soon these sensations changed to severe and distressing pains in the lower extremities. Half an hour after the injury the President's pulse was fifty to the minute, and though feeble was more full. After the consultation it was deemed expedient to remove the President to the White House and the ambulance was ordered for that purpose. I think I can see now the sea of human faces that completely filled the space in and around the depot, as we carried him down the stairs, and through the depot, with the mingled expressions of pity and consternation that sat upon each of them. The President was tenderly and carefully taken up by eight men and carried on the mattress to the ambulance, and was slowly driven to the White House. Dr. Bliss and Dr. Townshend accompanying the President in the ambulance.

At the time of his removal, 10:30 A.M., he complained of pains in his feet and legs, pulse 60 to 65. At 11 A.M. pulse 74 with more character; patient slightly restless, was offered water which he took with half an ounce of brandy. After arriving at the White House he received a hypodermatic injection of one-quarter of a grain of sulphate of morphia, and one ninety-sixth of a grain of sulphate of atropia. At 12 A.M. pulse 94, soft and compressible; he complains of spasmodic pains in the extremities, which he describes as shooting up the legs towards the body. These pains became very severe. There is a considerable hemorrhage which has taken place from the wound since his arrival at the White House, and there is probably also internal hemorrhage taking place. At 12:30 P.M. pulse 88, no material change except interruption of pulse; 12:45 P.M. patient vomited and on recovering himself said: "Well, Doctor, I suppose that was the result of your hypodermic." At 1 P.M. pulse 100 and very feeble, sighing respiration but complains less of pain in the extremities, has pains in the right hip. At 1:30 P.M. patient is restless, has had nausea and has vomited twice; complains of constant pain in the feet, surface cool, temperature 96.8, respiration 30 to the minute. The pulse and respiration are increasing in frequency, whilst the temperature is falling; an ominous sign.

At 1:40 P.M. pulse 124 and feeble. Pain in the extremities continues about the same; patient gives evidence of extreme prostration; 2:15 P.M. pulse 124 and a trifle better in character; respiration 32 per minute; complains much of pain in the lower extremities. After consultation one-quarter of a grain of sulphate of morphia was given hypodermatically; 2:45 P.M. pulse 116 and a trifle more full; respiration 38 per minute; has less pain and feels more like sleeping; is thirsty and asks if it will injure him to take water freely. At 3:40 P.M. pulse 130, pains in the feet more severe. After consultation it was decided

to give another quarter of a grain of morphia hypodermatically. At 4:15 P.M. pulse 128; respiration 30 per minute. Seems easier since receiving the hypodermatic injection; but has just vomited freely a watery fluid. Percussion reveals a marked and well-defined dullness in the right hypochondriac region, (below lower margin of the liver).

The President has just made inquiry of Dr. Bliss concerning his real condition, which was explained to him and he took the announcement of his dangerous condition quietly and calmly. At 4:40 P.M. complains of pains in both feet and ankles, but is otherwise comfortable; 5:30 P.M. pulse 140 and respirations 28 per minute. The President has just vomited; is free from pain, but has a sensation of numbness in his hands and arms and wants them rubbed. The respiration is abdominal in character, and is more full on the right side than on the left; 6:30 P.M. pulse 150 and respirations 28 per minute; occasional sighing respiration. The President is cheerful and inclined to talk to his family and friends.

COMMENTARY ON THE STATE OF THE PRESIDENT.

In spite of the cheerful condition of the spirits of our patient as mentioned above, our prognosis of his case at this time was of the most discouraging character. He was evidently bleeding internally, and unless reaction would soon take place, it was evidently impossible that he could long survive. Mrs. Garfield was absent at Elberon, N. J. She had been telegraphed for, and was coming as fast as the express train could bring her to Washington, and yet we had grave and well-founded fears that he would die before her arrival.

Our patient lay on the wounded side to facilitate drainage from the wound. He had a sighing respiration, a feeble and scarcely perceptible pulse; the lines of the face hippocratic in character; frequent movements of the lower limbs, with regurgitations from the stomach. Our anxieties increased with each hour. No indications of reaction could be discovered even by the most sanguine. We measured the time with beating hearts, hoping that the illustrious sufferer might again see the face he loved so well. The President several times made inquiry as to the cause of Mrs. Garfield's delay, and, appreciating the gravity of his injury, was extremely anxious lest she should be too late for an intelligent interview. Upon her arrival, at 6:40 P.M., he requested that their interview should be entirely private. Thus the prostrate and apparently dying husband met his wife. She remained by his side not more than five minutes. The words of love, hope and cheer given him are known only to themselves and to God. It is a fact, however, that within an hour the President's symptoms began to indicate reaction.

The President rarely spoke of his condition, seldom expressed a want, and only once, in my hearing, referred to the circumstance of his shooting. He asked the Secretary of State, in the afternoon, the name of the assassin. On being told, he said: "Why should he have wished to shoot me?" It was explained that he had probably been disappointed in seeking some office.

Commentary continued from 8:30 P.M. July 2, to morning of July 4. The favorable reaction that took place in the condition of the President at 8:30 P.M. July 2, gave a relief to the feelings of the attending surgeons that may be imagined, but scarcely be ade-

quately described. The hemorrhage from the splenic artery, and which was probably also due to injuries received from the bullet by the mesenteric arteries was spontaneously arrested, just as our patient was on the brink of death. This favorable condition of our patient continued during the night, and on the morning of July 3 his temperature was 98.6 (normal); pulse 126; respirations 18 per minute. Drs. Bliss and Reyburn remained on duty all the night of July 2 and 3. Colonel Rockwell, General Swaim, several members of the Cabinet, Miss Edson and Steward Crump were also at hand to render any needed aid. The President enjoyed, upon the whole, considerable refreshing sleep, broken about every half hour by regurgitation of the contents of the stomach. The morning of July 3 found him comparatively cheerful and hopeful, and with a full appreciation of his surroundings. At this time he inquired of me what his chances of recovery were, saying, in his bright and cheerful way, that he desired a frank and full statement—that he was prepared to die, and feared not to learn the worst. He added that personally he was willing to lay down the heavy burden thrust upon him. I replied:

“Mr. President, your injury is formidable. In my judgment, you have a chance for recovery.”

He placed his hand upon my arm, and, turning his face more fully toward me, said, with a cheerful smile:

“Well, Doctor, we’ll take that chance.”

It was perfectly apparent that there were more physicians in attendance upon the President than were needed, and Dr. Bliss determined to ascertain the President’s wishes in the matter. On the morning of July 3 after the morning consultation and dressing of the wound, Dr. Bliss went to the President and said: “Mr. President, there are a number of the physicians of the city who have kindly volunteered their services and have been associated with me in conducting your case successfully through the day and night since your injury, and have contributed largely to the prospects of your recovery. Now that Mrs. Garfield has arrived and you are so comfortable, we wish to retire from the case and ask you to select your permanent surgeon and his counsel.” The President replied:

“I wish you to retain charge of my case, and select such counsel as you may think best. Your judgment is better than mine on that subject.” Dr. Bliss then said that if it was agreeable to the President and Mrs. Garfield, he would select Surgeon-General Barnes, U. S. A., Surgeon Woodward, U. S. A., and Dr. Robert Reyburn as his counsel, giving his reasons in each case for making the selection. The President replied:

“Doctor, your selection is eminently satisfactory.”

Dr. Bliss then requested permission to thank the medical gentlemen in the name of the President and Mrs. Garfield, which was accordingly done. As many statements have been maliciously made to the effect that Dr. Bliss in assuming the charge of the President did so without due authorization, I herewith submit the following documentary evidence which will settle the point beyond question. Before me lies an official copy of the affidavit made by the Honorable Robert T. Lincoln, Secretary of War, and dated, War Department, Washington, D. C., May 23, 1882, and from which the following is an extract: “When the President was shot my carriage was at

the door of the railway station, and within a few seconds I hurried it off to bring you (Dr. Bliss).” Farther on in the same affidavit the Secretary again says: “You (Dr. Bliss) at once took charge of the President, acting with the other surgeons who came quickly to his help.”

II.

The duties of the attending surgeons were at this time systematically divided among them as follows: Dr. Bliss as chief surgeon in charge of the case remained on continuous duty every night at the White House, from the time the President was shot until he was taken to Elberon, N. J., and he continued his vigils there until the death of the President. During a long and varied professional career, I have known many instances of the self-sacrificing devotion of physicians to their patients, but I have never known such complete self-abnegation as was manifested by Dr. Bliss in his care of the President. He seemed to neither think nor speak of anything, except what concerned the welfare of his illustrious patient. All the medicine and all the articles of diet were either administered by him or under his immediate direction. Surgeon-General Barnes came twice a day in consultation with the other surgeons. To Dr. J. J. Woodward was intrusted the duty of preparing and writing the daily bulletins of the case, and along with Dr. Robert Reyburn assisted in taking the temperature, pulse and respiration, which was done at least three times a day. This naturally became after a while rather wearisome to the President. On my coming into the room one day he smiled, and said: “Here comes old tempera-ture again.” To Dr. Reyburn was assigned the duty of taking notes of the case, which were written each day by him in a book procured for the purpose. Drs. Woodward and Reyburn slept each night alternately in the White House, and were always on hand to furnish such assistance as might be required. The nursing of the President was done by Colonel Rockwell, General Swaim, Dr. Boynton, Dr. (Miss) Edson, Steward Crump, and the faithful body servant of President Garfield. These all rendered faithful and meritorious services, and their devotion to the President deserves the highest praise. Mr. J. Stanley Brown, Private Secretary to the President was on almost continuous duty during the President’s illness, and gave all the aid in his power. The labor of nursing the President, I may here remark, was much more severe than it would seem to be. In the first place, during a large part of the President’s illness it was impossible for him to turn in bed, or even to bend his spine. In order, therefore, to promote his comfort and prevent bedsores, it was necessary to turn him, or to change his position in the bed very many times during the twenty-four hours—this would sometimes reach fifty, sixty or even one hundred times a day. Strong linen sheets were kept under him for the purpose of moving him. When he required a change of position, three persons, either doctors or nurses (as they happened to be in the room at the time) came on each side of the bed, and taking hold of the sheets gently rolled him over to the side he wished to go. For the same reason every passage of his bowels and urine required the same attendance bestowed upon a young infant. The President was a man of large and massive frame (he was over six feet in height and weighed two hundred pounds the day before he was shot), so

it will be readily understood that the physical labor devolving upon his nurses and medical attendants was quite severe. Until the President was removed to Elberon, N. J., the medical bulletins of his case were prepared in conjunction with the other attending surgeons exclusively by Dr. Woodward and myself. Mentioning this fact recalls the many harsh criticisms which were made concerning the roseate statements which the bulletins gave of the President's condition. These bulletins were often the subject of animated and sometimes heated discussion between Dr. Bliss and the other attending surgeons, the surgeons usually taking one side of the question and Dr. Bliss the other. The ground taken by Dr. Bliss was that in the President's case it was vitally necessary to keep from him every unfavorable symptom, for by so doing we gave him his only desperate chance of recovery. It must be remembered that during almost all of his illness he was able to have the newspapers read to him, and he always asked for them every morning. If the slightest unfavorable symptom was mentioned in one of the bulletins, it was instantly telegraphed all over the country, and appeared in every newspaper the next morning. In fact, during the early part of the case he very often read the newspapers himself. We were placed in a very embarrassing position; on the one hand we did not wish to dishearten our patient by circulating discouraging reports of his condition, and on the other hand we wished to do our duty to ourselves and to the people of the whole country, who watched with such intense eagerness every word of intelligence that came from us.

During the early part of the day of July 3 the President's temperature remained about normal; towards evening a slight rise in temperature took place, reaching 100 at 10:30 P.M. He slept a good deal during the night of July 2-3, and in the morning took with relish equal parts of milk and lime water. He complained often during the day of severe pains of a lancinating character in the scrotum, both feet and ankles; he complained also of sensations of pricking and numbness in the same members. These symptoms were no doubt due to the concussion of the spinal cord produced during the passing of the bullet through the body of the fourth lumbar vertebra. So marked were these symptoms for the first few days after he was wounded, that it was feared that the spinal cord itself might have been injured. Of course the after history of the case (from the gradual disappearance of these symptoms) showed that such could not have been the case. Applications of cloths wrung out of hot water not relieving him entirely, he was given a hypodermatic injection of one-quarter of a grain of sulphate of morphia. He seemed cheerful and full of hope and amused himself by telling us a laughable incident of his early life. Slight tympanites was detected during the day, but no pain on pressure, nor any marked rigidity of the abdominal walls. This was the only symptom that pointed to the existence of peritonitis during the whole history of the case. During the night of July 3-4 the patient dozed at intervals. When awake he complained so much of the pains in his feet that he was given another quarter of a grain of sulphate of morphia hypodermatically; 7:30 A.M. he has vomited at intervals of twenty minutes during the past two hours. Gave one-half ounce of milk and lime water every hour, with powders of

four grains of subnitrate of bismuth, two grains of oxalate of cerium in each one; to be given when required. Surgeons Dr. D. Hayes Agnew of Philadelphia, and Dr. Frank Hamilton of New York, having been summoned in consultation, arrived this morning. Dr. Agnew arrived at 4:30 A.M., and saw the President, but postponed the examination of the wound until the arrival of Dr. Hamilton at six o'clock. They were formally presented to the President and we held our consultation at 7:30 A.M. On dressing the wound there was found to be a very slight discharge from it, and scarcely any swelling or inflammation around the track of the wound. A careful review of the case was given to the consulting surgeons by Dr. Bliss, with the request that they should, with the data before them, examine the case thoroughly, as though it was their own, and freely express their views concerning the character and gravity of the injuries, and the course of treatment up to that time. He also gave them a detailed account of the explorations made in the wound, and the unsettled opinions as then held as to the course of the missile, and the organs involved in the injury. Carefully weighing all the evidence, the more prominent symptoms upon which the diagnosis was made were presented in the following order: The relative position of the assassin to the President at the time of the shooting, the direction of the bullet through the tissues as far as it could be determined, the amelioration of pain and hyperesthesia in the feet and ankles and scrotum, the repeated unsuccessful efforts to pass a probe or flexible instrument more than half an inch in any direction beyond the fractured rib, except in a direction downward, a little forward and anterior to the twelfth rib, where it could be passed about two inches. Neither the significance of the profound shock was underestimated, nor the lengthened period of collapse which followed, and which seemed to point to extensive lesions of important viscera. However, the fact that the kidneys, intestine and peritoneum had not been seriously injured, was shown by the passage of normal urine, the spontaneous movements from the bowels of natural feces, the discharge of flatus, and the absence of other symptoms of peritonitis. It was found to be impossible to determine positively the course taken by the bullet, but the indications pointed to a downward course into the pelvic cavity. The absence of any symptoms that could be attributed to a lesion of the liver, also showed that it had escaped serious injury.

They individually examined the wound with great care. These examinations consisted in the introduction in different directions, of probes and flexible bougies, in order if possible to determine the course of the bullet. With the evidences developed by this personal examination, together with the complete history given them of the shooting of the President, the consulting surgeons proceeded to discuss the possible course of the bullet and the organs involved. The propriety of making extensive incisions and dissections, so as to explore the fractured ribs and remove as much as might be necessary to reveal the true course of the bullet, was fully considered. It was finally determined, however, that the favorable condition of the President thus far, did not warrant such interference, and further such an operation would seriously complicate the case and diminish the prospects of recovery.

The consulting surgeons issued the following bulletin to-day after the consultation :

JULY 4, 1881.

We held a consultation with the physicians in charge of the President's case at 7:30 A.M. to-day, and approve in every particular of the management and care of the case, and of the course of treatment which has been pursued.

FRANK H. HAMILTON of New York.
D. HAYES AGNEW of Philadelphia.

At the time of the consultation his temperature was 99.4; pulse 104; respiration 19. He suffers considerably from pains in the feet, and cloths saturated in camphorated tincture of opium were applied to them; some vomiting of a clear fluid tinged with bile. Stopped giving nourishment at 10:30 A.M., and gave two teaspoonfuls of lime water with cracked ice. At 1 P.M. it was deemed necessary to give him another hypodermatic injection of one-eighth of a grain of sulphate of morphia. He then received the following prescription: Carbolic acid solution fifteen drops and lime water four ounces; mix and give a tablespoonful every hour.

At 3:30 P.M. The President has slept at intervals, and on waking expressed himself as feeling more rested. Still continues to vomit at intervals of about thirty minutes, without straining or nausea, and only about an ounce of fluid is ejected each time; 4:30 P.M., patient is more restless, and is more indifferent to surroundings; received another eighth of a grain of morphia hypodermatically; 7:45 P.M., (bulletin.): The President is not so comfortable. He does not suffer so much pain in the feet. The tympanites is again more noticeable; temperature is 101.9; pulse 126; respirations 24.

Telegrams of inquiry and condolence were showered in a perfect avalanche on the White House during the early part of the President's illness. They came from Vice-President Arthur, ex-President Grant, from the officials of the various States of the Union, and indeed from almost every prominent public man in the United States. This interest was not sectional in character. South as well as North, East as well as West, vied with each other in showing their sympathy with our stricken Chief Magistrate. Probably never in the history of the world was there such an outpouring of friendly feeling as was manifested in the case of President Garfield. The Queen of England was among the first to express her sorrow and best wishes for his recovery. This was followed by messages from all the crowned heads of Europe, as well as from many of the officials and public men of the different countries of Europe.

As to the letters received, their name was legion. During the whole time, indeed, of our attendance upon the President the mail received at the White House assumed alarming proportions. We received every morning literally bushels of letters, and many of them were of the most ordinary character. Every crank and vendor of patent medicines in the country seemed to think himself called upon to offer to cure the President. One man gravely suggested that the President's body should be inverted for some hours in order that the bullet might gravitate downwards, and thus aid in its removal. Another sent a drawing of a machine composed of a rubber tube and an air-pump. The rubber tube was to be introduced into the wound until it came in contact with the bullet, then the air-pump was to be attached to it, and by suction the bullet removed. I wish now I had retained some of the most absurd of these mis-

sives, but at the time of receiving them we were too busy to appreciate either their absurdity or comicality.

July 5, 8:30 A.M. The President has passed a comfortable night, and his condition this morning is decidedly more favorable. There has been no vomiting since last evening at 8 P.M., and he has been able to retain the liquid nourishment administered. There is less tympanites and no abdominal tenderness except in the region of the wound. Temperature 100; pulse 114; respirations 24.

The following dispatch was sent by the surgeons in charge to the consulting surgeons:

JULY 5, 9:30 A.M.

After you left the urgent symptoms continued. There was much restlessness, constant vomiting, and by 8 o'clock P.M. the President's condition seemed even more serious than when you saw him. Since then his symptoms have gradually become more favorable. There has been no vomiting or regurgitation of fluid from the stomach since 8 o'clock last evening. The President has slept a good deal during the night, and this morning expresses himself as feeling comparatively comfortable. The spasmodic pains in the lower extremities have entirely disappeared, leaving behind, however, much muscular soreness and tenderness to the touch. There is less tympanites and no abdominal tenderness whatever except in the hepatic region. Since 8 P.M. (July 4) he has taken an ounce and a half of chicken broth every two hours and has retained it all. The wound was dressed antiseptically this morning. Altogether but one-half a grain of morphia has been given hypodermatically during the past twenty-four hours, and it has been found quite sufficient. His pulse, however, still keeps up. At 8:30 A.M. it was 114; temperature 100.5; respirations 24. Seventy-two hours have now elapsed since the wound was received. We can not but feel encouraged this morning, though of course we do not overlook any of the perils that still beset the path towards recovery. The course of treatment agreed upon will be steadily carried out.

D. W. BLISS,
J. J. WOODWARD,
J. K. BARNES,
ROBT. REYBURN.

July 5, 12:30 P.M. The favorable condition of the President continues, and at noon he had a natural sleep. Temperature 101; pulse 110; respirations 24. July 5, 8:30 P.M. Favorable condition unchanged. Temperature 100.9; pulse 106; respirations 24.

As above mentioned, the wound of the President was dressed antiseptically, and this continued to be the case during the entire time of the treatment. The most scrupulous cleanliness of the instruments, and surgical appliances was observed, and also of the antiseptic solutions used for the daily washing out of the wound, and every effort was made to render them as aseptic as possible. The solution used was a freshly made one of carbolic acid in water, varying in strength, sometimes a 1 per cent. and sometimes a 2 or 3 per cent. solution being made. With this a solution of permanganate of potash of the strength of one to three grains to the fluid ounce of water was alternated: The carbolic spray was also invariably used during the dressing of the wound. It must be remembered that the technique of antiseptic, or more properly speaking, aseptic surgery was not so thoroughly appreciated or carried out by operating surgeons in 1881 as it is in 1892.

July 6, 8:30 A.M. The President slept well, and said this morning that he passed the most comfortable night he had had since he had been shot. He feels some desire for solid food, but was only given chicken broth, with white of egg, one ounce every

two hours. Temperature 98.9; pulse 98; respiration 23. July 6, 12:30 P.M. Temperature 98.7; pulse 100; respiration 23.

July 6, 8:30 P.M. His condition continues favorable, and he takes more nourishment than yesterday. Temperature 100.6; pulse 104; respiration 23. July 6, 11 P.M. The President continues to take chicken broth with white of an egg one ounce every two hours.

At 9:30 P.M. received one-quarter of a grain of sulphate of morphia, hypodermatically, and is now sleeping quietly, though he occasionally awakes and asks for ice water. A decidedly yellowish hue of the skin has made its appearance during the past two days, but is scarcely pronounced enough to call it icteroid. He complains of great muscular weakness and of the tenderness of the skin of the feet and ankles.

July 7, 9 A.M. The President slept last night until 8:30 this morning, when he awoke feeling refreshed and free from pain. He retains his nourishment. The wound was dressed antiseptically; very little discharge from the wound. Temperature 98.2; pulse 108; respiration 23.

(To be continued.)

EXERCISE—ITS PHYSIOLOGIC FUNCTIONS.

Read before the Topeka Academy of Medicine.

BY W. L. SCHENCK, A.M., M.D.

PROFESSOR PREVENTIVE AND STATE MEDICINE, KANSAS MEDICAL COLLEGE, TOPEKA, KAN.

South says: "God made no faculty but also provided it with a proper object on which to exercise itself." As God does no unnecessary thing, exercise is essential to the health and development of each organ of the body, each faculty of the soul. Progress demands constant renewal and readjustment. Change is the changeless law of nature. The old must give place to the new. The present is but the everchanging eternal link that binds the future to the past, and in all organic life, with properly regulated activities, each new link will be stronger than the last. Evolution is the law of God. Crabbe defines exercise as "repeated or continued exertion, coupled with purpose." Physiologically, it is that wisely regulated activity through which, by one of those beautiful compensations, so often observed in nature, both the force expended and the atoms destroyed are renewed in more potential form. It is the application of stored up force for the generation of greater force. Whether life was created merely for the reproduction of species, or for that evolution that changes and vivifies matter until at last a super-added spirit finds through it all its possibilities until it reaches that final change beyond which science can not go, the continuous change incident to exercise is essential to both physical and spiritual development. Exercise, voluntary and involuntary, is necessary to constructive and destructive metamorphosis, the vital forces that keep the body new and strong. The functional activity of an organism destroys and removes its atoms while it provides material for their renewal. When exercise is moderate and the material rich in nutritive elements there is increased development, and when the size or number of the cells is greatly increased there is hypertrophy or hyperplasia. On the other hand, atrophy and degeneration follows want of exercise and nutrition.

The body is a marvelous piece of mechanism, whose several parts are so fitly joined that we can

not comprehend any one without comprehending all. Impressions made on any one part are in touch with all. In discussing exercise, we must remember that it is but one of many instrumentalities through which the body, mind and soul reach their possibilities, and that we can not confine the effects of its developmental force to the single organ or system we subject to its methods. But more largely than any other force it is the means to the end. It supplies to the cells the material they convert into protoplasm, while it returns them to original elements. It furnishes the force that vitalizes and energizes, while it consumes it. Properly applied it develops and preserves both the form and functions of the several parts of the body and their harmonious relations, and so secures the ends for which they were created. Improperly used, it brings disease to individual organs and interferes with the harmonious action of the organism. Thus by the proper exercise of the organ of vision its functions become clear and strong, the perceptions become more acute, life is more joyous and the vitality of the whole organism is increased. Improperly used, the organ is injured, various diseases are developed, and their effects are not confined to the injured organ. Through proper exercise, the vocal organs are so educated that they convey in varied tones all the emotions of the soul, while through improper use they cease to be its servants, and may produce far reaching disease. The trained muscles, under the control of the will are equal to every contingency. The skilled surgeon plunges his knife where the deviation of a line might prove fatal, with perfect confidence in his ability to control every movement of the hand; the gymnast performs his wonderful feats with full faith that his muscles will obey his will, while the athlete develops a muscular power that scarce knows its bounds. By properly regulated exercise the brain cells, through which are the activities of the spirit, enable it to reach ever upward toward the Infinite; to comprehend the minutest molecule; to weigh in the balance the remotest world; to understand and to utilize the varied laws by which the Omniscient governs the universe, and through its acquisitions in art, rhetoric and science prove its kinship with the Eternal. Without properly regulated exercise, all the forces of the body, all the faculties of the soul retrograde. With improper exercise, they fall beneath the palsied hand of disease. Exercise increases in force and frequency the pulsations of the heart and the rapidity and volume of the respiration. More oxygen is absorbed, more carbon dioxide eliminated, and by exercise that calls into action the whole organism, vitality is increased and life prolonged. But it has its limitations, and the important question is how much is necessary to secure the best results. That will depend largely upon the purpose of life.

Those who live on the fruits of their muscles should take such exercise as will secure their healthful development, and such perfect obedience to the will as will make them the efficient servants of the spiritual man. As the cells of the cortex of the brain are comparatively independent of the functions of the mere animal life, being evolved for spiritual purposes, and simply receiving nourishment and purification through the activities of other portions of the organism, their exercise is rarely a source of disease, the diseases so often attributed to brain work being due to irregularities and improprieties. Other

things being equal, brain work is healthful and brain workers long lived. The frequent "heart failures," and "Bright's disease," and other pathologic conditions common to brain workers, especially in the political arena, can be accounted for on sounder physiologic and pathologic principles. Brain work only requires such physical exercise and development as will keep the organism in health, that it may supply the cells of the cortex with the elements of life and development and remove waste, and exercise for this purpose should be regular and bring into action all parts of the body, but never excessive, as the healthful action of the intellectual brain is never benefited, but always injured, by excessive muscular effort and development, force and nourishment that should sustain intellectual action being expended to create and sustain massive muscles, useless to spiritual activity, but once developed demanding excessive and continued attention, and ever liable to various diseases.

That the proper amount of exercise may be taken during the developmental period of life, and applied where needed, that its function may be understood and regular habits and self-control established, there should be a department of physical culture in all our schools, both for the benefit of the individual members of the school, who too often graduate into early graves, and for the good of the State, that intellectual and moral culture may mean, as well, physical vigor and long and useful lives. And the duties of such a department might have a wide reach, as all intellectual and moral development is through the instrumentality of the body. A one-sided education that develops the cells through which particular faculties act, leaving those of other faculties undeveloped, makes one-sided men; the cranks who curse the State and disgrace humanity, often obscuring the line that separates sanity from insanity. We have all known such cases as that of Prof. A. of — University, a most distinguished mathematician, but innocent of common sense, and we have known too well the Guiteaus and Prendergasts. While men may with advantage devote themselves to special departments, distinction involves a wide range of knowledge. The specialist in medicine who believes his patient all eye, or ear, or throat, or even alimentary canal, illustrates the saying of Wilhelm Meister: "He who knows it half speaks often and is always wrong;" and proves the prescience of the poet who wrote:

"A little learning is a dangerous thing,
Drink deep or taste not the Pyerian spring."

Every cell and every organ of the body was created for use. By way of illustration, let us confine our thought to the effects of exercise upon the muscular system. We know that the contraction and relaxation of muscular fibers changes and sustains the volume of the circulation in their capillaries, and that the cells exhausted by increased activity eagerly appropriate its elements, and that when supply and appropriation are stimulated beyond the normal, there is hypertrophy.

We have an apt and beautiful illustration of the effect of regular and moderate exercise in the pulsations of the heart. Day and night, year after year, the blood is drawn into and driven out of its muscles in such well measured quantity that without fatigue, and without increase or diminution in development the muscles of the beating heart contract and relax

sixty or seventy times each minute throughout life. If, like the voluntary muscles, this important organ had been left under the control of a capricious will, the grave hypertrophies and atrophies, the valvular lesions and irregular innervation that from violence, irregularity and disease occasionally endanger or destroy life would have been the common lot of mankind. The preservation of the form and function of this organ, never resting but for an instant, emphasizes more than argument or illustration, the importance of the regular and measured exercise of the whole organism.

Muscles do not develop alone. Their activity involves activity in every other part of the organism. We readily note their impress upon the nervous system, whence comes all that energizes. The central cells are stimulated by reflexes, nervous force is generated and distributed to the acting organs, and nervous power developed. But we must remember that the exercise of organs of vital function has only an indirect influence on those of spiritual function. Though we may not comprehend *how* the muscles are strengthened and controlled by the action of the will, or what nervous force is, we know the results. Under systematic training Sandow is able to sustain a weight a thousand times greater than even his massive muscles would support if dissected from his body, and the skilled workman performs the most delicate and rapid movements with accuracy and ease; muscle and nerve being developed, *pari passu*. But when the acting muscles draw too heavily upon the vital forces there may be sudden failure of innervation, or other parts of the organism may be dwarfed through inanition.

Muscular effort, in any part, demands increased activity of heart and lungs, absorbents and excrements, and there is increased force given to all; but the athlete never gains intellectual or moral vigor from pounding his sand bags, and the blacksmith may hammer his anvil "from early morn till dewy eve," without becoming a "learned blacksmith," unless, like Elihu Burritt, he gives other training to the cells of his brain. The football champion may, by his persistent training, develop a fine physique, and so may the champion of "the ring," but neither will thereby develop the cells through which the spirit acts, except as the emotions and passions of the actors and visitors, intent upon victory at any cost, may find harmful development. Yet we might infer from the expressions of the press, and of some of the professors in our universities that the development of muscle was the *sine qua non* of a college course, and that the college whose "team" could "paint red" all its opponents in a "knock down and drag out" game of football was, *par excellence*, the educational institution of the age. While we can understand how professors of moral science and mathematics, and of Latin and Greek, through lack of a knowledge of physiology and hygiene may believe that great muscular development is essential to a strong life, and close mental application, we can not understand how those who appreciate the dignity and grandeur of the intellectual and moral forces can consent to practice in the gymnasium, or fight sand bags by the month that they may kick a leather ball farther than their opponents, or beat into insensibility a fellow mortal, or how instructors in mental and moral science can believe that a student with his mind intent on football, or anything foreign to mental training, with

frequent interruptions of his college course given to exciting exhibitions of his muscle, is in line with the best educational methods and results. The development of the organism is in line with its exercise. The college should be a gymnasium of mental training for beneficent purposes, for developing the organs through which knowledge and wisdom are attained, and not a gymnasium for forcing the development of mere animal life.

The college professor knows, or should know, that the forces through which the spiritual life is developed are rested by a change of studies; that the cells through which the mathematics are developed are not developed by the activities of the imagination; that those of the imagination are not developed by the study of moral science, and that the whole attention given to one branch of learning makes one-sided men; though by alternation of studies one faculty rests while another works, the habit of mental application continuously improves. Much more should these professors know that if the exercise of the cells of one portion of the intellectual brain can not develop the cells of other portions, that the exercise of those of merely animal function can not develop those of intellectual and moral function; that their only relation to the cerebrum is the preparation and supply to its cells of necessary nutriment, and that while for this a well balanced and healthful activity of the whole organism is required, an overgrown animalism demands so much of vital force that that portion of the body created for spiritual activity is dwarfed and atrophied.

As an illustration of modern methods of education, take the two leading orthodox universities, Princeton and Yale. After numerous breaks in the college course, and months of training, they met on the 30th ult—Thanksgiving day—on the Manhattan field, and Princeton reached home the victors of a bloody fight, when we are told by a laudatory press, "the bells of Princeton rang for four hours, and everybody in this staid old Presbyterian college, from President to janitor, rushed to a mass meeting, when the President said: 'It was a glorious day for Princeton,' and Dr. Green, 'Yale was nowhere; Princeton was everywhere,' and Dean Murray, 'wait till next week that we may have the opportunity of assisting in a glorious celebration;' and after promenading the city until the small hours of the morning with foghorns and tin pans and drums they waited, and had a *glorious celebration.*"

Let us look at the other side of the great college spectacle. The New York *Tribune*, an advocate of the game, says: "About the entrance of the hotel were perhaps five hundred people waiting to see what the defeated Yale looked like. And they saw. But they never saw a more woe-begone, used up, pale-faced, bruised and bloodied lot of respectable, healthy sane young men before. One of the players crawled down off the coach and passed into the hotel through the alley made by the police through the crowd. Two of the players had to be helped, half carried. The men had just come from the battlefield; their faces were muddy and marked with bloody streaks; their sweaters were stained and reddened. In their dilapidated condition they did not look the strong, powerful young giants who had driven away, so full of confidence, earlier in the day."

Harper gives its picture of the victors at the same hour. It says: "People who live far away from New

York, and who can not understand from the faint echoes they receive how great is the enthusiasm, may get some idea from an incident in the Princeton dressing room. The team was being rubbed down for the last time after three months of self-denial and anxiety, and the hardest kind of work that young men are called upon to do, while outside thousands of Princeton followers are jumping up and down and hugging each other, and shrieking themselves hoarse, when one of the Princeton coaches came into the room out of this mob, and holding up his arm for silence, said: 'Boys, I want you to sing the Doxology.' And standing as they were, naked and covered with mud and blood and perspiration, the eleven men who had won the championship sang the Doxology from beginning to end, solemnly and seriously. . . . while the defeated team was lying on the benches of their dressing room, sobbing like hysterical school girls."

One more thought on this great moral exhibition, which we also quote from its champion, *Harper*. In speaking of "Billy" Edwards, an ex-prize fighter, fit adjunct to the moral drama, it says: "He keeps guard over the glassware of the Hoffman House bar, and goes to sleep on the eve of Thanksgiving day with as much as fifty thousand dollars in his possession,"—money bet on the game. And that we may know who deposits with him, it says: "The collegians begin to arrive on Wednesday and one sees nothing but young men enveloped in huge great coats and ulsters. They make Broadway, between the Fifth Avenue Hotel, where the Yale team lodges, and the Hoffman House, where odds are given and taken on the game, almost impassable."

The disregard for limb and life, the brutality and betting on the football field, and in the ring are much the same, differing mainly in the culture and character of the actors. For the one, they are recruited from the college where young men of promise are sent from Christian homes to develop the nobler faculties of mind and soul, drawing from the college and from the same class of society their henchmen and hooters, and here loss by death or demoralization brings sadness to many hearts and loss to the State.

In the other, they are the habitues of the grogshop and the gambling den, who can scarce reach a lower level, and when "knocked out" are little missed.

If the football teams from our colleges are such models of propriety and scholarship as represented, how great has been the wrong to them, their friends and society. We know it is claimed that football develops determination, will force, quickness of perception, the self-restraint incident to months of training and courage. The same is claimed, and with equal reason, for the ring. Purpose is the foundation on which moral qualities are built. Character may be bad as well as good. The determination may be to do wrong as well as right.

"There is a divinity that shapes our ends,
Rough hew them how we may."

"Men do not gather figs from thistles nor grapes from thorns." The means must not only be equal to the ends, but in line with the ends. The Jacksons and Sullivans are the fruits of the ring. Those of the modern football team are not yet ripe, but how much prescience is required to tell the results of a game where a half score of players jump upon an opponent, and where the contestants fight with hands

and feet, breaking noses, ribs and limbs, dislocating joints, slugging on the sly, and in not a few instances taking life. And is this great intellectual and moral drama necessary to the development of courage and the nobler qualities of manhood? When this country has called to arms have not Americans from every department of life freely responded, and were the sluggers in personal encounter the men who stood firm where shrieking shells and hissing bullets fell thick and fast? Is not a prize fight where the combatants boldly declare their purpose, both a moral and scientific exhibition, compared with a modern football battle?

This may seem a diversion from the thought of our subject, but all the activities of the body, mind and soul are through the development of the physical organism, and if it is important that he who makes physical life his study should know the laws by which muscles are developed, how much more important that he should understand the laws that govern the development of those faculties that distinguish man from the brute, and the relation of each to the other?

Ethics may picture to the ethical the athlete transfigured into an intellectual and moral giant, but science beholds him transformed into a prize animal. The one looks at an ideal spiritual growth; the other at the absolute of physical life. One sees what he ought to be; the other what he is. Ethics has an ideal that science will not permit it to realize, for it knows that "they who sow to the spirit shall of the spirit reap," and "they who sow to the flesh of the flesh." Exercise is the stimulus to the metamorphosis of physical life whereby the old atoms are removed and renewed, and its action is largely confined to the organs exercised.

Man differs from the brute only as he has superadded to his animal a spiritual life that can control his will and direct his developmental forces. It requires generations of careful training and breeding to build up the massive muscles of the Percheron and Norman horse, or to produce the speed and endurance of the "thoroughbred," while man, through a well-directed will force makes equal development in a few years. Thus Sandow, the Prussian athlete, who belongs to a family never noted for either strength or athletic tastes, and when 18 years of age possessing no marked muscular characteristics, by localizing muscle building, and associating with muscular training voluntary control, in a few years reached his present wonderful development. He is now 26 years old, and though only 5 feet 8½ inches in height, he measures around the chest 46 inches; about the waist 29 inches; under the axilla and over the deltoid 17 inches; under the axilla and over the shoulder 21 inches; over the biceps 19¼ inches; around the forearm 19 inches; thigh 27 inches; calf 17½ inches; and has an expansive mobility of the chest of 14 inches. He lifts from the floor, with apparent ease, with one hand, at arm's length, straight above his head, a hollow dumb-bell, with a man in each globe, weighing 305 pounds, and as easily lets it down again; or he performs with apparent ease the still greater feat of placing his feet and hands on the floor and on a platform resting on his knees and chest supports three horses; weighing 2,800 pounds, while his lungs move quietly and his well developed heart sits lightly on its throne. But while Sandow has acquired volitional control over his muscles, even with his phlegmatic

temperament, he fails to control his appetites and passions, but eats and drinks and smokes regardless of consequences, and is far from being an intellectual or moral giant.

From Samson, shorn of his strength by the seductions of Delilah, down to drunken John Sullivan, neither athletes or gymnasts have been distinguished for spiritual refinement or power, while in thousands, from the poet king of Israel; the blind bards of Greece and England; the Little Corporal, who conquered the nations of Europe, to Longfellow, and Gladstone, the great English premier, who has passed the age of fourscore years, giant intellects have developed through comparatively frail bodies, and without muscle, have gained as distinguished conquests in the world of mind as have athletes and gymnasts, without mind, in the world of muscle. And science teaches that the great animal development, consequent upon gymnastic and athletic training and contests, tends to sudden, or at best, premature death, and science is supported by vital statistics. If sudden death does not follow a heart taxed beyond its power of innervation, the overgrown muscles must be exercised in proportion to their development, while the digestive organs must be overtaxed to feed them, the circulatory system to carry their nutrients, the respiratory to oxidize their blood and the excretory to eliminate their waste. To stop the excessive exercise of these over developed muscles is not less dangerous than to continue it. There will come a time when physical life reaches the down-hill grade, when it must cease, and the involution of over developed organs invite all manner of diseases, both from within and without. Man was not made to be developed into an ox or a behemoth. He may energize for a time overgrown organs but, as when a ten-horse power engine is forced to do the work of a fifty-horse power, there is constant danger of explosion, and at best it is soon destroyed by excessive wear and tear, or its fires are smothered by accumulations from the consumed fuel; its premature destruction is a foregone conclusion.

To briefly summarize the relations of exercise to physical and spiritual life and health:

1. Exercise is essential to vital metamorphosis.
2. The cell growth of muscles and groups of muscles is rapidly increased by properly regulated volitional exercise, with a corresponding increase of nerve force and organic activity, provided there is a proper supply of muscle-building and force-producing food.
3. When an excessive development of an organ is produced, it involves its excessive and continued use, its cessation being full of danger.
4. Overgrown, hypertrophied organs are unnecessary and injurious, while their normal development and innervation is essential to life and all its activities.
5. The cells of the gray matter of the brain are not developed by the stimulus that energizes mere animal life, being an evolution for the activities of a superadded spiritual life.
6. Their relation to the merely animal organism is only one of supply and depuration and of their power of energizing through the action of the will.
7. While a harmoniously developed and healthful physical organization is essential to spiritual activity, spiritual life is handicapped by an overgrown animalism.

8. The development of the various organs of the body is in line with their activities.

9. By proper exercise the organs of animal life, receiving proper nourishment and development, healthfully perform all their functions, while the perceptions, correlated through the cells of the brain cortex, develop force in line with their correlation, and man reaches his ideal.

SUBVOLUTION—A NEW PTERYGIUM OPERATION.

BY BOERNE BETTMAN, M.D.

CHICAGO.

PROFESSOR OF OPHTHALMOLOGY AND OTOTOLOGY IN THE COLLEGE OF PHYSICIANS AND SURGEONS; PROFESSOR OF OPHTHALMOLOGY IN THE CHICAGO POST-GRADUATE MEDICAL SCHOOL; OCUList AND AURIST TO THE MICHAEL REESE AND GERMAN HOSPITALS; ATTENDING SURGEON TO THE ILLINOIS CHARITABLE EYE AND EAR INFIRMARY.

Many theories have been advanced to explain the origin and mode of growth of pterygium. Arlt ascribes it to an erosion of the cornea at the scleral margin, which in healing pulls the conjunctiva into the cicatrix. Poncet found micrococci in some of his pathologic preparations, and regarded them in the light of etiologic factors. Theobald concluded that the long-continued action of the recti muscles, usually the interni, was the responsible cause. Mannhardt regarded episcleritis as the promoting element.

None of the explanations, however, are entirely satisfactory. A thorough and critical examination of this subject has recently been made by Fuchs of Vienna, who after long-continued clinical and microscopic investigation concluded that a pterygium results from a pinguecula; that the hyaline degeneration which occurs in this pathologic product is continued on the adjoining corneal tissue over which the conjunctiva is pulled.

As many methods of operation have been introduced for the successful eradication of pterygium, as there have been theories advanced for the elucidation of its growth and pathology. These may be all grouped under the following heads:

Transplantation of the pterygium; excision; strangulation, and evulsion.

The simplest, and according to Arlt, the most efficient operation is that of excision as first practiced by Coccius. It consists in separating the pterygium from the underlying cornea, and excising it with a triangular piece of conjunctiva. The conjunctival wound is closed by a suture placed a few millimeters from the cornea-scleral margin.

In the following diagram, Fig. 1, *a*, represents the pterygium; *b*, the triangular piece of conjunctiva to be removed; and *c, c*, the sutures which are to unite the cut.

Fig. 1.

Wright of Columbus, and Prince of Springfield, report favorable results following evulsion. The

former tears the pterygium with a forceps. The latter loosens it from the cornea with a strabismus hook, and then proceeds as in the operation of excision.

Fig. 2.

Demarres (Fig. 2,) practiced transplantation as early as 1855. After dissecting loose the flap on the cornea and on the sclerotic, he makes a conjunctival incision downward, commencing from the lower border of the base. Into the lower edge of the triangular gaping wound, the apex of the pterygium is sewed.

Knapp's modification consists in dividing the pterygium when large from apex to base, into two flaps. The ends are cut off and each flap is transplanted into its corresponding upper and lower conjunctival wound. The exposed surface of the sclerotic is covered by first dissecting up and then drawing together the conjunctiva.

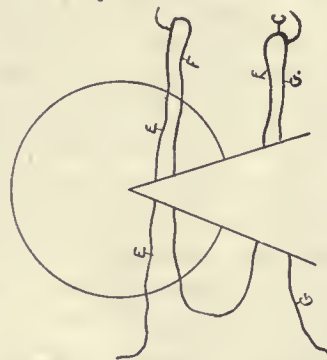

Fig. 3.

Strangulation is advocated by Szokalski and Galozowski. The first (Fig. 3,) passes a thread, armed with two needles, under the corneal and sclerotic portions of the pterygium. The thread is cut close to the needles leaving three threads. The ends of each are tied, a knotting of the middle one puckers the pterygium and all three of them cut off its circulation.

Fig. 4.—Thread in position; both ends are knotted, thus strangulating the pterygium.

Galozowski (Fig. 4,) separates the pterygium from the cornea, passes both needles at either end of the thread through the apex from above downward, leaving a loop on the upper surface. The needles are again entered at either border of the base through its under surface. It will be observed that the flap

is turned downward upon itself, its upper surface being brought in contact with the sclerotic. The two ends of the suture are tied together, thus strangulating the pterygium at the base.

Fig. 5.—I I, Sutures under pterygium.

Fig. 6.—J, Denuded surface of cornea; K, pterygium turned under its base, dotted lines its edges; L L, suture knotted.

Hotz recently read a paper before the AMERICAN MEDICAL ASSOCIATION, recommending transplantation of a Thiersch's graft taken from the arm to replace the defect produced by retraction of the dissected pterygium.

Most of these procedures are frequently followed by a renewal of the growth. There are two fundamental principles involved in all these operations. One is destruction of tissue; the other is its preservation and growth in a new direction. None of the authors, however, take into consideration the salient feature involved in all plastic operations of the conjunctiva, namely, the prevention of contact between two raw surfaces. In excision, strangulation, and transplantation, the cut edges of the conjunctiva must necessarily be apposed to the denuded surface of the cornea. To me, this accounts for the relapses which so frequently occur.

Fuchs has shown that with the growth of the pterygium there is associated a fibrillar degeneration of the cornea, which involves Bowman's membrane and even the superficial layers of the cornea proper. In dissecting off the wing-shaped formation, a raw uneven surface is exposed. If now the cut surface of the conjunctiva comes in contact with this, or the proliferation at the cornea-scleral margin, it will unite with it and is liable to be again drawn over the cornea.

During the last six years I have followed my own method which satisfactorily overcomes the objection just stated. Its underlying principle is to prevent re-adhesion by placing a mucous surface in contact with a raw one. To do this, I turn the triangular flap underneath, which action can be best described by the term, subvolution, (turning under). In order to carry out this rule I have made the operation in the following manner:

The pterygium is gathered up by the two branches of a fine forceps serrated at the ends. A knife is passed underneath it close to the cornea, and the triangular membrane is dissected off toward the apex. A suture with a needle at each end is passed through the apex. Both needles are inserted from above downward, thus leaving a loop of thread on its outer

surface. The needles are now passed through the base from below outward. The points of puncture being the ends of parallel lines drawn from the punctures in the apex, and just far enough back, so that when the flap is turned upon itself underneath the base, the roll will correspond with the cornea-scleral margin.

The two ends of the suture are now firmly tied. We have induced a condition similar to gumming the flap of an envelope to its body. The under surface of the pterygium is brought in contact almost throughout its entire extent and adheres. A re-adhesion to the cornea is prevented by the roll of mucous membrane at the cornea-scleral margin.

This operation to a casual observer is similar to Galozowski's, of whose method I only recently learned while looking through ophthalmic literature. But the principle involved is entirely different. He aims at destruction of tissue. I, at its preservation and the prevention of the renewal of the growth, by apposing a smooth surface to a raw one.

The only seeming drawback to this procedure is the temporary unsightly thickening produced by the folding. This, however, disappears in a few days, and after a week or two flattens and settles down to the *niveau* of the adjacent parts of the eyeball. It adheres to the sclerotic. The raw surface of the cornea is covered with scar tissue and regenerated epithelium.

No matter how much the base of the pterygium contracts after dissection from the cornea, sufficient allowance can always be made by stitching the apex more or less forward.

The apex may be cut off, or not, depending entirely upon the degree of thickness. It is hardly necessary to state that the eye is bandaged and cleaned daily with a boric solution, and that the thread is removed after two or three days.

My operation is especially in large pterygia. Even in smaller ones, where the growth contracts considerably after having been separated from the cornea, it is followed often by good results. In these cases, adhesions will form, which will draw the turned flaps over the sclerotic up to the cornea-scleral margin.

My friend, Dr. Beard, informed me only two days ago that he had seen Dr. Landolt of Paris, turn the pterygium under as I do, and then sew the dissected conjunctiva from above and below over the denuded sclerotic. This latter act, however, I regard as an objectionable feature, since it defeats the very object of my operation by placing the cut edge of the conjunctiva in contact with the raw corneal surface.

34 Washington Street.

THE BOARD OF HEALTH OF PHILADELPHIA has adopted the report of its sanitary committee in regard to the compulsory registration of cases of pulmonary phthisis among the contagious diseases, and has decided in accordance with the recommendation of the College of Physicians, not to make such registration compulsory. At the same time, the infectious character of the sputa of consumptives being considered as fully established, physicians are requested to report localities needing disinfection, especially where a death has occurred, and they are urged to use proper precautions with regard to preventing the spread of the disease by destroying sputa and fomites. Circulars of information have been prepared for distribution to householders with instructions as to the sanitary measures thought advisable.

APPENDICITIS; WITH ORIGINAL REPORT
AND ANALYSIS OF ONE HUNDRED AND
FORTY-ONE HISTORIES AND LAPAR-
OTOMIES FOR THAT DISEASE
UNDER PERSONAL OB-
SERVATION.

BY J. B. MURPHY, M.D.

CHICAGO.

Read before the Pan-American Medical Congress.

PROFESSOR OF SURGERY, AND CLINICAL SURGERY, COLLEGE OF PHYSICIANS
AND SURGEONS, CHICAGO; PROFESSOR OF SURGERY, POST-GRADUATE
MEDICAL SCHOOL AND HOSPITAL; ATTENDING SURGEON TO COOK
COUNTY HOSPITAL; ATTENDING SURGEON TO ALEXIAN
BROTHERS' HOSPITAL; CONSULTING SURGEON TO
HOSPITAL FOR CRIPPLED CHILDREN, ETC.

(Concluded from page 389).

Case 110.—Date of operation Aug. 17, 1893. Operator, Dr. Murphy. Case occurred in practice of Dr. Pigall. R. S. B., aged 33 years; male. Post-Graduate Hospital. Patient was kicked on July 31 in the right side by a man. The same night, at 2 A.M., he was attacked with sudden pain in right iliac region, followed by fever, tenderness and tympanites. These symptoms continued up to the time of operation. Examination: Large tumor in right iliac region, extending almost to umbilicus; no fluctuation could be detected; no edema or redness of the wall; dull on percussion, both superficial and deep. A differential diagnosis was made between rupture of kidney, rupture of cecum and appendicitis in favor of the latter. Operation: Lateral incision; abscess wall adherent to anterior wall of abdomen; general peritoneal cavity not opened. Abscess circumscribed; drained; appendix not removed; recovery.

Case 111.—Date of operation Aug. 22, 1893. Operator, Dr. F. S. Hartmann. A. K., aged 18 years; female. Primary attack. Sickness began August 17 with colicky pains in region of stomach, followed by nausea and vomiting. Later, pains extended to lower part of abdomen. The following day fever appeared and the pain increased. Two days later patient felt practically well, and went about as usual. During the afternoon of this day a second severe attack developed with pain, nausea and vomiting, etc. The following day she felt perfectly well again, but a third similar attack occurred later in the day. She was first seen on this day. Temperature 104 degrees, pulse 114. Large induration in right iliac region. Operation on fifth day. Drainage of intra-peritoneal abscess containing about three ounces of pus; three fecal stones removed; appendix not located; gauze drain; fecal fistula; recovery.

Case 112.—Date of operation Aug. 25, 1893. Operator, Dr. Murphy. F. H. C., Buffalo, aged 28 years; male. Case occurred in the practice of Dr. J. C. Cook of Hyde Park. Appendicitis began on morning of 24th at 7 A.M., with sudden attack of pain in right iliac region, followed by nausea and vomiting. Tenderness all over abdomen; very sensitive on deep pressure in right iliac region. Abdomen tympanitic; induration.

9 A.M.	August 25,	Pulse, 96,	temperature, 98.3 degrees.
8 P.M.	"	"	" 100 " 102 "
11 P.M.	"	"	" 120 " 103 "

Operation 11:30 P.M. Lateral incision; peritoneal cavity opened. No adhesions to anterior wall. Appendix situated in front of cecum, surrounded by omentum. Appendix gangrenous; showed no perforation. Two drachms of pus outside of the appendix, which was amputated. Enterolith in appendix. Drainage; recovery. Remarks: Instructive in showing purulent infection of peritoneum (two drachms of pus) without perforation.

Case 113.—Date of operation Aug. 28, 1893. Operator, Dr. Murphy. Alexian Brothers' Hospital. P. McG. P., aged 27 years; male. Patient was taken with typical attack three days before operation. In spite of the very severe pain he worked the whole of the first day. The pain at first was general, but gradually became localized in right iliac region. There was marked muscular resistance, but no perceptible induration over appendix. Temperature at time of operation 100.3 degrees. Operation: Lateral incision, appendix situated two and one-half inches below the umbilicus and near the median line. Small circumscribed abscess; no adhesions to anterior wall; adhesions to omentum. Appendix perforated; fecal concretion; appendix excised; simple ligature of base; drained; recovery. Temperature at no time after operation exceeded 100.4 degrees.

Case 114.—Date of operation Aug. 28, 1893. Operator, Dr.

Murphy. Mrs. C., aged 52 years. Occurred in practice of Dr. T. J. Conley. Attack began six days before operation with typical symptoms. A general suppurative peritonitis existed before operation. The operation showed that a circumscribed abscess existed and had ruptured. Operation: Temperature at time of operation 104 degrees, pulse 120. An incision was made and the abdominal cavity drained. Appendix removed; gall-bladder elongated and adherent to abscess wall. Patient died three days after operation, of sapremia. No autopsy.

Case 115.—Date of operation Aug. 31, 1893. Operator, Dr. Murphy. Male, R. H., aged 16 years. Case occurred in practice of Dr. J. C. Cook. Patient was suddenly taken sick at Waukegan (August 29) with nausea and vomiting; severe pain in right iliac region; had been eating grapes the day before. Temperature August 31, 101 degrees. Operation thirty-nine hours after onset of symptoms. Lateral incision. Appendix completely surrounded by omentum at least one and one-half inches thick, except at tip, where only the thin gangrenous peritoneal wall of appendix separated the pus in the appendix from the peritoneal cavity. This whole mass was ligated and amputated; a drain of iodoform gauze inserted. Patient made a rapid recovery. Silkworm gut was used to ligate the appendix; this had to be removed as it did not slough off or was not absorbed.

Case 116.—Date of operation Sept. 19, 1893. Chas. B., aged 11 years; male. Post-Graduate Hospital. Operation by Dr. Hartmann. Patient was taken sick on the morning of Sept. 16, 1893, with dizziness and headache. Went to bed at noon, slept, and on awaking at 3 P.M. dizziness and headache had increased and he had developed a fever and backache. Diarrhea and griping present. The following day (September 17) 6 P.M., pulse was 150, temperature 105 degrees; typhoid condition; abdomen somewhat tympanitic; general tenderness. September 18, A.M., pulse 135, temperature 105 degrees; general condition same; abdominal tenderness more marked in right iliac region; no induration, but slight nodules could be felt in this region, which at time of operation proved to be swollen mesenteric glands. Operation: Appendicectomy; small iodoform gauze drain; sutured; appendix was non-adherent; external appearance normal except the end, which was somewhat swollen, was of rather unusual length, and upon being opened was found to contain a grape seed, and was ulcerated. Recovery. Ventral hernia; latter resulted from wound opening during a severe attack of typhoid fever which immediately followed the operation.

Case 117.—Date of operation Sept. 24, 1893. Operator, Dr. Murphy. K. S., aged 50 years; male. Case occurred in practice of Dr. Venn. Patient has had a number of previous attacks. Present attack began about seven days ago with severe local pain at umbilicus, nausea, vomiting, fever, tympanites. *Status præsens*: Large induration in right iliac region, dull on superficial percussion, resonant on deep percussion. No edema of wall. Temperature 101 degrees, pulse 90, at time of operation. Operation: Lateral incision; abscess opened without opening the unaffected portion of peritoneum; abscess circumscribed; appendix not removed. Drainage; recovery.

Case 118.—Date of operation September 24, 1893. Operator, Dr. Murphy. H. C., aged 22 years; male. Case occurred in practice of Dr. O'Malley. Date of attack September 13, beginning with pain in umbilical region, followed a few hours afterwards by vomiting. On September 15 temperature 103 degrees. On September 16 temperature normal, and remained so up to day of operation. Sept. 24, 1893, 8 A.M., pulse 104, temperature 99 degrees. The induration extended to the median line as high as umbilicus and within three inches of ninth costal cartilage. Resonant on deep percussion and flat on light percussion over that area. Operation: Lateral incision; abscess circumscribed, i.e., the abscess was opened directly through the abdomen without disturbing the uninfected portion of the peritoneum. Appendix not removed; drainage; recovery.

Case 119.—Date of operation Sept. 27, 1893. Operator, Dr. Murphy. Alexian Brothers' Hospital. W. McK., aged 15 years; male. Six months previous, patient had been operated upon for general suppurative peritonitis following appendicitis. The abdomen had been drained; appendix not located. The wound healed nicely, but has opened and discharged pus three times since the operation. The present operation was performed for the purpose of removing the sinus and determining the cause of the same. Operation: Incision two inches to the inner side of the opening. Peritoneal cavity opened. Cecum found adherent in the iliac fossa and to the lateral parietal peritoneum. Appendix imbedded in adhesions adherent to wall of cecum and parietal

wall; the end was considerably distended. The cavity of the appendix was shut off from the cavity of the cecum by a large cicatrix. There were three openings in the appendix. The cicatricial occlusion of the base of the appendix accounts for the recurrence of the attacks. Appendix removed. The opening in the side of the appendix was connected with the opening in the abdominal wall. Drainage; recovery.

Case 120.—Date of operation Sept. 28, 1893. Operator, Dr. Murphy. F. B., aged 35 years; male. Case occurred in practice of Drs. McKee and Pigall. During the night of Sept. 21, patient was attacked with severe abdominal pain. This was shortly followed by nausea and vomiting. The following morning patient's temperature was 102 degrees. Vomiting and pain continued during the following seven days. The patient became very tympanitic and rapidly lost strength. Examination Sept. 28. Patient's facial expression bad; skin cold; gulping every few minutes; abdomen extremely distended. Dull on light percussion over lower half. Temperature 101 degrees; pulse 135. Operation: Lateral incision; abdomen full of sero-purulent fluid. Endothelium of intestines eroded. The appendix was easily located and removed; adherent, gangrenous and perforated. Drained. Death thirty-three hours after operation.

Case 121.—Date of operation Oct. 2, 1893. Operator, Dr. F. S. Hartmann. E. S. W., aged 32 years; male. Evening of Sept. 30 patient experienced abdominal pain which was relieved by an anodyne. The following morning pain returned, but patient went around as usual. In the evening pain became very severe, and during the night was so intense that hypodermic injections were given. October 2, A.M., pulse 95, and strong; at noon pain became somewhat localized in the right iliac region. At 4:30, had a very severe chill. Examination 6:30 P.M.: Tympanites, general abdominal tenderness, more marked in lower portion of abdomen and right iliac region; induration in the latter location. Operation: Appendicectomy; drainage of septic peritonitis; appendix gangrenous, perforated, containing enterolith; adhesions of bowel to parietal peritoneum, limited septic process above and to the inner side of incision; toward the pelvis no adhesions were to be felt. Patient died on October 4.

Postmortem revealed presence of general septic peritonitis; folds of intestine were agglutinated and presented many pockets of suppuration.

Case 122.—Date of operation Oct. 12, 1893. Operator, Dr. Murphy. Alexian Brothers' Hospital. Ed. B., aged 21 years; male. Onset Oct. 7, 1893, with intense abdominal pain, more severe in right iliac region. Treated "expectantly" for one week. Was up and about after the first few days. Vomiting continued at intervals from beginning of the attack. Patient collapsed two days prior to admission to Hospital, and when admitted in very bad condition; respirations irregular, almost entirely thoracic, pulse feeble and rapid, temperature 102 degrees; general pain and tympanites all over abdomen. Induration not palpable, most sensitive in right iliac region. Diagnosis: Appendicitis, perforation, general suppurative peritonitis. Operation: Lateral incision; about a pint of pus escaped. Appendix perforated; firmly adherent; not removed. No limiting adhesions; pus distributed throughout entire peritoneal cavity. Strands of gauze placed in all directions. No irrigation. Hypodermic injections of strychn. sulph. gr. one-sixteenth every hour. Patient rallied completely in forty-eight hours. Temperature dropped to 99 and remained so; he improved rapidly until October 22, when he was attacked with a double pneumonia, and died Oct. 24, 1893. All of his abdominal symptoms had subsided before the attack of pneumonia began; the drainage, however, had not been removed. I have placed this case in the list of recoveries, as I believe the cause of death was independent of his peritonitis. This is one of the very few cases that rallied from the collapse of general suppurative peritonitis.

Case 123.—Date of operation Oct. 14, 1893. Mary S., aged 11 years. Operation by Dr. Hartmann. On October 8, immediately after dinner, patient vomited very freely; the rest of the day felt as well as usual. During the night she again vomited. Felt quite well on waking the following morning, October 9. During the afternoon developed pain in the region of the navel, which was relieved by hot applications. October 11, on awaking, felt quite sick; intense pain in abdomen almost constant; remained in bed that day; during night developed a fever, which continued until the time of operation. Operation: Appendicectomy; small iodoform gauze drain; suture; appendix swollen and mucous membrane gangrenous; recovery.

Case 124.—Date of operation Oct. 23, 1893. Operator, Dr. Hartmann. Post-Graduate Hospital. Mrs. M. O'B., aged 27 years. Since May, 1892, had ten attacks; always suffered with intense colicky pains in epigastrium, accompanied by vomiting of bile. The attacks occurred mostly during the night, came and disappeared suddenly. October 21, 6 P.M., patient experienced continuous pain in epigastrium, accompanied by persistent vomiting lasting until 4 o'clock the following day, when, after having ceased for a couple of hours, returned again. First complained of pain in the right iliac region during afternoon of 22d; chills in afternoon of same day. Examination: No tympanites, slight induration, tenderness confined to the right iliac region. Operation: Drainage of local septic peritonitis; appendicectomy; appendix gangrenous, perforated, adherent; recovery.

Case 125.—Date of operation, Oct. 23, 1893. Alexian Brothers' Hospital. N. E., aged 24 years; male. Operator, Dr. Murphy. History: Patient admitted to medical ward of Hospital October 11, with a history of having been sick for ten weeks. Bloody stools for five days previous to operation. Severe pain and tenderness over abdomen general; diarrhea during entire ten weeks. Passage once every hour since entrance to Hospital; some pain during micturition; temperature 101 degrees, pulse 104, respiration 25. October 13, twenty-five stools in twenty-four hours; October 16, lumbar myositis, most painful in right side. October 20, great tenderness with tumefaction and tympanites. October 23, Dr. Murphy saw patient, and decided to make an exploratory laparotomy. Usual incision; about half a pint of very offensive fecal smelling pus, as well as fragments of necrotic tissue (three inches long) escaped. The cavity, had the appearance of a large diphtheritic abscess. Iodoform gauze used as drainage. Condition gradually became worse, and patient died at 2 P.M.

Postmortem: Total destruction of mucous membrane of colon, in parts resembling microscopically the appearance of honeycombed tissue. Mucous membrane loosened from submucous tissue, and gangrenous, having lost all resemblance of a mucous membrane. The incision was directly into the cecum. Appendix not affected in any way.

Case 126.—Date of operation Nov. 1, 1893. Operator, Dr. Murphy. Mrs. J. C., aged 44 years. Case occurred in the practice of Dr. Wm. E. Quine. Patient suffered from five attacks in the eight months preceding the operation; the last one, three weeks before the operation, was more severe than the former attacks. Began with severe pain in right iliac region and gradually extended all over abdomen. It was shortly followed by nausea and vomiting. Temperature reached 103 degrees. There was increased sensitiveness as well as induration in right iliac region; general tympanites shortly followed. After five days the symptoms began to subside and disappeared entirely. The operation was performed after all the inflammatory symptoms had subsided. Operation: Lateral incision; appendix found firmly adherent to side of cecum; distal end distended and somewhat edematous. Proximal end close to cecum very much contracted. Ligature applied at seat of contraction; packed with iodoform gauze; time of operation, six minutes; gauze removed in forty-eight hours, and sutures tied. Convalescence uneventful. Examination of appendix showed complete occlusion at the neck. Cicatrices at the side showing where it had ruptured into the cecum. Repeated accumulation in the appendix without an outlet was evidently the cause of the recurrences.

Case 127.—Date of operation Nov. 2, 1893. Operator, Dr. Murphy. Alexian Brothers' Hospital. A. B. L., male, age 26 years. Case occurred in practice of Dr. Hoelscher. Patient felt slightly indisposed Tuesday, October 30. November 1, severe pain in abdomen, exaggerated in right iliac region. Patient seen on that evening by Dr. Hoelscher, and transferred to Alexian Brothers' Hospital at once. Temperature 101 degrees.

November 2, 9 A.M. Patient had considerable pain during the night; is very sensitive over the appendix; no induration; temperature 100 degrees. Operation: Lateral incision; appendix reached without difficulty, very much distended, gangrenous on one side, had not ruptured, no infection of the peritoneum. Appendix drawn out of the wound, packed about with iodoform gauze, ligated, amputated, top-sewed, sutures inserted, iodoform gauze drain. Removed drain in twenty-four hours; sutures tied; time of operation, ten minutes. Patient made a rapid recovery. Highest temperature after operation 100.4 degrees.

Case 128.—Date of operation Nov. 4, 1893. Operator, Dr. Murphy. T. D., aged 44 years; male. Attack began evening

of October 26 with intense pain in the abdomen which continued for several hours; it was accompanied by nausea and vomiting. October 27, pain less severe, tympanitic, sensitive all over abdomen, most marked in right iliac region; very slight induration; pulse 90, temperature 103 degrees. Patient had a severe purulent bronchitis accompanying the attack. The symptoms continued until November 3, when he had a chill, followed by a temperature of 104 degrees. Following morning, laparotomy. Lateral incision; circumscribed abscess, retro-cecal. Packed around with iodoform gauze before opening. Appendix not removed. Following morning pulmonary symptoms more severe; bowels moved, temperature subsided to 101 degrees. Pulmonary symptoms continued to increase, and patient died on the fifth day. Postmortem not allowed.

Case 129.—Date of operation Nov. 5, 1893. Operator, Dr. Murphy. Miss N., aged 17 years. Case occurred in practice of Dr. Rose. October 22, 6 A.M., patient's illness commenced with a gnawing pain in the stomach; dressed herself with difficulty on account of soreness; not localized as far as she noticed. October 23 and 24 pain was accompanied with nausea and vomiting. Enema of hot water was given which relieved the symptoms. Induration felt. Patient did not manifest any serious symptoms for the following two weeks. Very slight elevation of temperature with slight digestive disturbances. Induration remained. Gives history of diarrhea with slight hemorrhage. November 5. Case seen by Dr. Murphy. Operation: Lateral incision; general peritoneal cavity not opened; appendix not removed; circumscribed abscess, a large quantity of pus; drainage; recovery.

Case 130.—Date of operation Nov. 10, 1893. Operator, Dr. Murphy. W. M., aged 12 years; male. Case occurred in practice of Dr. Hayes. On November 3 patient was suddenly attacked with pain in the right side. On November 4 nausea, vomiting, increase of pain which patient described as cramps. As the symptoms had not subsided, on the next day the attending physician was called in. Examination on November 5 temperature 105.5 degrees; pulse 120. Tympanites; abdominal tenderness general, but most marked in the right iliac region. An opiate was administered, which relieved pain. November 6, discontinuation of opiates resulted in return of pain. An operation was now advised, but was not consented to. The symptoms continued up to November 10, when an operation was agreed upon. Temperature at time of operation 99 degrees, pulse 90. Operation: Lateral incision; general peritoneal cavity opened; a general suppurative peritonitis present; the bowels were covered with flakes of pus; appendix not removed; drainage; recovery.

Case 131.—Date of operation Nov. 23, 1893. Operator, Dr. Wittwer. L. P., aged 16 years; male. Case occurred in practice of Dr. Bergeron. Family history good. Ten days before operation patient complained of pains around umbilicus, later localized in right iliac region; no vomiting; tympanites appeared after a few days; pain was more severe two days before operation; limbs constantly flexed. Last three days frequent urination; complete loss of appetite. *Status præsens*: Pinched features; limbs flexed; a very tympanitic abdomen, very sensitive to pressure; induration in right iliac region not well defined on account of tympanites; not much pain at time of operation unless abdomen was touched. Operation: Usual incision in right iliac region; upon entering the peritoneal cavity, the intestines were found agglutinated to the anterior abdominal wall. Upon severing the recent adhesions a large quantity of thin, purulent, very offensive pus escaped. Intestines found covered with large flakes of lymph. Finger was used in separating all the adhesions that could be reached, and finally a large abscess was opened which was in contact with the bladder. Glass drain was introduced into abscess cavity near bladder; four days later a smaller one took its place; gauze drain also used; appendix not removed. No enterolith found. Ten or twelve days after operation boy commenced to vomit and complained of pain in left iliac region. His bowels had not moved for four or five days, and all evidences of a second abscess to the left of the urinary bladder were present. With the intention of making a secondary operation, patient was again visited, but it was found that by pressure from the outside and insertion of another glass drain the second abscess could be drained without another incision. Boy had no further trouble. Jan. 24, 1894, boy is up and around and is feeling perfectly well.

Case 132.—Date of operation Nov. 25, 1893. Operator, Dr. Murphy. Charles B., aged 40 years; male. Case occurred in practice of Dr. Rohr. Patient gives a history which leads

to suspicion that he had previous attacks of appendicitis. Present attack began forty-eight hours before operation, with sudden pain in abdomen, nausea, vomiting and moderate rise of temperature (about 101 degrees). On second day extreme tympanites developed, the pain had increased, no induration to be felt. Operation: Appendicectomy; the general peritoneal cavity was opened, and a general suppurative peritonitis found to be present without adhesions. Pus covered the bowels to a great extent. The appendix was located, brought into the abdominal incision, ligated and amputated. The abdominal cavity drained with iodoform gauze. The temperature at no time was over 101 degrees, the pulse was very rapid, 140 at the time of operation. The appendix was gangrenous, not perforated, contained no foreign body. Patient had persistent vomiting for three days after operation, which then subsided and he made an uneventful recovery.

This is another illustration of extensive purulent infection of the peritoneal cavity forty-eight hours after the onset of symptoms, in which there was no perforation, but a gangrene of the wall. The bowel was eroded somewhat of its endothelium, but not sufficient to admit of the fatal sapremia.

Case 133.—Date of operation Nov. 28, 1893. Operator, Dr. Murphy. Alexian Brothers' Hospital. Thos. S., aged 32; Case occurred in the practice of Dr. Rohr. History: Patient states that he had two similar attacks. Present illness began November 26 with colicky pains after a dose of oleum ricini to move bowels. November 27, 10 P.M., pains had continued, accompanied by nausea and vomiting, and did not cease until November 28, 3 A.M. Pain localized in right iliac fossa. Examination: Tenderness and induration in right iliac fossa on pressure; temperature 104 before operation. Operation: November 28, 2 P.M. Usual incision; no circumscribed abscess; appendix almost entirely covered with omental adhesions. Had not perforated. However, pus oozed out through punctures made by forceps used for holding it up for ligation. Appendicectomy; appendix found to contain about half a drachm of pus; its tissue was gangrenous. Appendix three inches long and thickness of little finger. Flakes of pus visible on opening peritoneal cavity. Time for entire operation, seven minutes. Temperature fell to normal after operation, and patient made an uneventful recovery.

Case 134.—Operation Dec. 19, 1893. Operator, Dr. Murphy. M. W., aged 28 years; female. Case occurred in practice of Dr. Berry. December 16 complained of being tired and feverish. December 17, slight soreness in right iliac region; December 18, tenderness over entire abdomen. Temperature 100 degrees, pulse 80. December 19, temperature 101 degrees, pulse 85, before operation. Operation: Lateral incision, intra-peritoneal, retro-cecal abscess around appendix; flakes of pus on bowels outside of abscess. Peritoneum protected with iodoform gauze. Abscess opened. Appendix adherent to posterior parietal wall, easily elevated and amputated. Drainage with iodoform gauze; recovery. Pathologic conditions: Circumscribed abscess; appendix perforated; flakes of pus on bowel outside of abscess.

Case 135.—Date of operation Dec. 20, 1893. Operator, Dr. Murphy. E., aged 26 years; female. History: December 7 typical attack. Pain at first general, later local; no tympanites; temperature 100 to 103 degrees in first forty-eight hours. First constipated, then had an attack of diarrhea. Marked induration over appendix. Operation: Lateral incision; protection of peritoneal cavity with iodoform gauze, and drainage of an intra-peritoneal abscess; glass drainage and iodoform gauze used. Glass drain removed in two days. Temperature remained at 101.5 degrees for ten days after operation; then ran up to 103 degrees, and remained so for forty-eight hours. Temperature again normal on twentieth day; recovery. Pathologic conditions: Intra-peritoneal abscess extending down into the pelvis; about six ounces of a very thick creamy pus containing the appendix escaped; latter was entirely gangrenous and perforated at its base.

Case 136.—Date of operation Dec. 22, 1893. Operator, Dr. Murphy. O. S., aged 20 years, male. Case occurred in the practice of Dr. Hoelscher. On November 22 patient was attacked with sudden, severe, colicky pains in abdomen causing indisposition for a couple of days, after which he was able to be about again. These attacks occurred occasionally for the following twenty-six days. At no time was he well, though able to be about. On December 18 the pain became extremely severe, was located in right iliac region, and was shortly followed by nausea and vomiting. It increased in intensity; the temperature rose to 101. This condition continued up to the time of operation, four days

later. Examination: Abdomen tympanitic, uniformly distended, no induration; excessively tender in right iliac region. Operation: Lateral incision; general peritoneal cavity opened; an abscess of considerable size was seen situated around the head of the colon and in the retro-cecal fossa. General peritoneal cavity protected with iodoform gauze packing; abscess opened; about eight ounces of pus escaped, and in it the gangrenous appendix. Glass drain; recovery. Pathologic conditions: Appendix completely gangrenous and separated from its attachment at the base; all of its coats were macerated except the peritoneal, which could be filled with water and resembled the rubber of a toy balloon. Two fecal stones.

Case 137.—Date of operation Dec. 29, 1893. Operator, Dr. Murphy. Mrs. G., aged 24 years. When performing laparotomy for tubal disease, the appendix was found very much elongated, congested, swollen and adherent to side of uterus and proximal end of right tube, causing traction upon cecum, and undoubtedly accounted for some of the symptoms from which she was complaining; recovery.

Case 138.—Date of operation Dec. 31, 1893. Operator, Dr. Murphy. Case occurred in practice of Dr. Weatherly. J. L., aged 21 years; male. Patient was seized with a chill December 29; severe pain when walking. This pain lasted through the night, and was accompanied by vomiting and fever. Dr. Weatherly saw the case December 30 at 8 P.M. Patient was sent to hospital December 31, P.M., temperature 101 degrees, pulse 83. Operation: Appendix found partially adherent to liver, two inches necrotic, but not perforated; not covered by omentum. No foreign body; when appendix was elevated, pus oozed through the pores in its wall, showing that perforation was about to take place. The mucous membrane had entirely disappeared and was commingled with the fluid debris. No pus outside of appendix; twenty-four hours' drainage; recovery.

Case 139.—Date of operation Jan. 4, 1894. Operator, Dr. Murphy. D. H. M., aged 25 years; male. Case occurred in practice of Dr. Geo. Barnett, Ishpeming, Mich. Recurrent appendicitis. First attack May 30, 1891, sick for six days; second attack Sept. 23, 1892, sick for ten days; third attack Dec. 24, 1893; began with sudden severe pain in the abdomen, followed by vomiting, great tenderness; temperature 103 degrees; after two days, temperature dropped to 99.5 degrees, and remained so until December 31, when it suddenly rose to 104.2 degrees, with pulse 120. Marked tumor was present in right iliac region at that time. Operation was urged by the Doctor and consented to. Examination: No tympanites, no general abdominal tenderness, a distinct tumor in right iliac region, which appeared to come close to the skin; temperature 100 degrees. Operation: Lateral incision into an abscess, which had already penetrated the walls of the abdomen and invaded the subcutaneous cellular tissue. This opening was enlarged by the finger, and the abscess cavity within the abdomen examined. No fecal stone. Appendix could not be located. Drainage; recovery.

Case 140.—Date of operation Jan. 6, 1894. Operator, Dr. Murphy. L. B. C., Detroit, Mich., 35 years of age; male. Case occurred in the practice of Dr. Riese. Patient was attacked with severe pain in the right side of abdomen, followed by nausea and severe vomiting. Temperature on morning of operation 101 degrees; no induration; no tympanites. A very sensitive point could be felt in right iliac region; the appendix could be outlined. Operation: Lateral incision; Appendicectomy; gauze drainage; sutures inserted but not tied. The appendix was not adherent; appeared normal on its peritoneal surface, although very hard to the touch. Mucous membrane inflamed, swollen, gangrenous in spots, contained a number of seeds. Gauze drain removed in twenty-four hours; sutures tied; recovery.

Case 141.—Date of operation Jan. 15, 1894. Operator, Dr. Murphy. Alexian Brothers' Hospital. C. G., aged 30 years; male. Present illness began fifteen days before operation with pain in abdomen, accompanied by fever and sweats. The pain gradually centralized in the right iliac region; was able to be up and about and came to office day of operation. Examination: No tympanites; induration and tenderness in the ileo-cecal region, extending down to pubes. Nothing to be felt from the rectum. Operation: Lateral incision; general peritoneal cavity opened; tip of appendix firmly adherent over iliac vessels; liberated with difficulty; body free; removed. Sutures inserted, but not tied; iodoform gauze drain; the distal half inch of a very much elongated appendix (four inches) was swollen to three times the size of the remaining portion. Minute gangrenous

spots on mucous surface. No perforation; gauze drain removed in twenty-four hours, and sutures tied. Recovery.

Case 142.—Date of operation Jan. 30, 1894. Operator, Dr. Wittwer. L., aged 30 years; male. Occurred in the practice of Dr. Bergeron. Three days previous to operation patient was suddenly attacked with pain in right iliac region; this was followed within an hour by vomiting; temperature 102 degrees. The following day the abdomen was tympanitic and very tender on right side. On morning of the third day, patient had a severe chill. Temperature at time of operation 100.5 degrees. Operation: Lateral incision over induration which was more marked under the anesthetic. General peritoneal cavity opened. Flakes of pus over cecum and omentum. Appendix adherent, necrotic; small circumscribed abscess at base, containing thin sero-purulent fluid. Adhesions liberated; appendix ligated; iodoform gauze drain; recovery. Pathologic conditions: Appendix perforated in one spot, also showing two other gangrenous places ready to perforate.

Case 143.—Date of operation Feb. 6, 1894. Operator, Dr. Murphy. J. M., aged 19 years; female. Case occurred in practice of Dr. Berry. Primary attack. Present illness commenced three and one-half days prior to operation, with intense pain in right iliac region, which rapidly spread over entire abdomen. Nausea and vomiting followed within an hour. All these symptoms and tympanites were present on second day. Vesical tenesmus severe. Examination: Time of operation, temperature 102 degrees, pulse 120. Very anxious expression; mental exhilaration, great thirst, gulping, extreme tympanites; a complete absence of peristalsis; not a sound could be heard in any portion of the abdomen, for fully ten minutes. No dulness either on light or deep percussion. Operation: Lateral incision; general peritoneal cavity opened; at once a small quantity of sero-purulent fluid escaped, which was very offensive. There were no limiting adhesions. Every separation of the coils of intestines was followed by an additional discharge. Douglas' pouch full of pus. Appendix adherent to fundus of bladder, liberated and removed without rupturing. Iodoform gauze and glass drainage. Intestines denuded of their endothelium, resembling a blistered surface. Symptoms of sapremia continued and patient died twenty-two hours after operation. General suppurative peritonitis. Pathologic conditions: Appendix enlarged to size of thumb; gangrenous, full of pus; enterolith size of grape seed; no perforation, still, general suppurative peritonitis.

Case 144.—Date of operation Feb. 9, 1894. W., aged 19 years; male. Operator, Dr. Murphy. Case occurred in the practice of Dr. J. M. Anld, who made a diagnosis and advised operation three hours after onset of attack for which he deserves the congratulations of the profession and the patient. Patient had a similar attack (first one) a year ago, and a second three and one-half months before the present one. He was operated upon at the time of the second attack; a circumscribed abscess was drained; the appendix was not removed. The present attack began day before operation with sudden pain, followed by nausea and vomiting. The patient was brought to the Cook County Hospital on the first day of sickness, and early the next morning he was operated upon, eighteen hours after onset. Temperature at the time of operation 99 degrees, pulse 100. Slight tympanites; no induration to be felt. Operation: Lateral incision an inch towards the median line from the old scar. General peritoneal cavity opened. Sero-purulent fluid around the head of the colon. Peritoneum congested, but not abraded. The appendix was situated across the iliac vessels, adherent behind, half of it hung over brim of pelvis. Appendix and cecum were elevated out of the wound. About three drachms of sero-purulent fluid was sponged out. There were no limiting adhesions around the pus. The seat of penetration of infection could be easily recognized on the peritoneal surface of the appendix. Appendix ligated, amputated; gauze drain; recovery. Pathologic conditions: The proximal two-thirds of the mucous membrane of appendix greatly swollen. A small ulcer existed where the infection penetrated the wall, but there was no perforation. What could have been the result in this case under expectant treatment?

Case 145.—Date of operation Feb. 12, 1894. Operators, Drs. Murphy and Verity. Mrs. E. P., aged 42 years. Patient had first attack in July, 1893. Had a second attack Jan. 14, 1894, which commenced with severe pain just below the margin of the last rib. This was accompanied by nausea, but no vomiting. For the first few days there was fever; temperature not taken. This subsided, but the pain and tenderness continued until the time of operation. Patient

had never been jaundiced. Examination: With anesthetic; an induration extending from the margin of the ninth costal cartilage downward three inches could be felt distinctly. It was stationary during the respiratory act. It could not be separated from the abdominal wall, nor could it be displaced to the left. It could not be separated from the kidney, nor could the kidney be outlined. Operation: Temperature at the time of operation normal. Incision over induration. Peritoneal cavity opened. Colon was found adherent to lateral wall of the abdomen, just below the margin of the ribs. The adhesions were separated and the remains of an abscess detected; no pus; the cecum was adherent to and folded upon the posterior surface of the ascending colon. The appendix was found perforated at its tip communicating with the abscess cavity. It could be seen where the abscess had emptied into the posterior wall of the colon at its hepatic flexure. Appendix ligated, amputated. Recovery.

Remarks: This is the first time I have found the cecum folded on to the posterior surface of the colon. The abscess was situated just below the edge of the liver.

SOCIETY PROCEEDINGS.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 391).

DISCUSSION.

DR. MORTON thought all must feel gratified at having papers presented to the ASSOCIATION from such eminent foreign writers.

THE PRESIDENT exhibited an apparatus which the Kidder Manufacturing Company had constructed for him. It was a commutator attached to a motor so that an alternating current could be sent through the primary of his induction coil. The secondary current was used in the usual manner. If the alternations be made too frequently, sufficient time is not allowed for complete magnetization and de-magnetization of the core and the effect is nil. When revolving 2,400 times per minute, the apparatus give 800 alternations per second. At this speed with five Leclanché cells in the primary, the current was almost imperceptible to the hand with the bipolar electrode, but produced a very appreciable effect in the vagina. The reed vibrator on his faradic apparatus was said to give 300 to 350 vibrations per second, but on comparing it with the interruptions obtained from other forms of apparatus, it seemed to him that the frequency was not so great.

The speaker said he thought the alternating current through its action upon the vaso-motor supply relieved pelvic congestion and pain consequent upon it. He had been able repeatedly to cure active endometritis by bipolar faradization. This might seem a remarkable statement, but in many instances endometritis is secondary to pelvic congestion, and by relieving this congestion the endometritis is cured. In many instances where the canal is not patulous, occasional applications with the negative pole were given to facilitate drainage, but these same applications had not proven, in themselves, competent to bring about a cure. It is in this way that he claimed to cure certain diseased conditions of the appendages. Having first assured himself of free drainage from the uterus he was satisfied that in many instances the tubes could be emptied into the uterus. He believed with Bland Sutton that in the great majority of cases the tube is only obstructed by tumefaction of the mucous membrane, and if this be removed, a result quite possible by a proper application of electricity, drainage can be secured through the uterine cavity. It is thus, in direct obedience to one of the important laws of surgery—the maintenance of drainage—that he cured these cases, using electricity to accomplish this end.

DR. KELLOGG said he had been much interested in the apparatus just described, and in the remarks. He had been doing work in this line. About a year and a half ago he began experimenting with the arclight current of 12,000 alternations per minute. As would be seen from the graphic curve which he exhibited, it was in reality a sinusoidal current. He first uses a rheostat, reducing the current by a transformer to fifty volts, and then passing it through an induction coil. The curve shown was from a secondary current from the alternating arc light current. It produces a

very strong humming sound, and this sound is present with an instrument made without a rheotome. This point is very interesting. Tests made with the esthesiometer showed that in some cases the effect of this current was to reduce sensation one-half. The apparatus described by Dr. Goelet really gave an interrupted current.

(The discussion was here interrupted to allow of Drs. Morton and Kellogg demonstrating to the members individually the character of the sinusoidal currents produced by their machines).

DR. MARTIN asked why the muscular contractions were so much more distinct in one arm than in the other.

DR. MASSEY thought it questionable whether the amperage of the current from Dr. Morton's machine would be sufficient for practical purposes, and he asked whether it could be made as good as Dr. Kellogg's.

MR. SMILES replied that it was a simple matter of supply of current to the field.

The power of the machine was as great as could be used upon any patient, and quite sufficient for all purposes.

DR. A. LAPHORN SMITH said it had been claimed that the sinusoidal current increases nutrition, but without wishing to dampen the enthusiasm of some of our investigators, he would remind all that the same increase in nutrition—increased interchange of oxygen and excretion of urea—is accomplished by walking upstairs. The speaker asked why the interruptions of the fine wire coil produced anesthesia. The point raised that it is not the length of the fine wire, but the number of turns of wire which gives the peculiar effect is valuable, and is certainly not generally known. He had found by personal experiment that a piece of ferrotype metal would give very fine buzzing vibrations, the tone produced being like that made by a mosquito.

After a careful reading of Apostoli's monograph, he found that every effect claimed for the sinusoidal current is obtained by fine wire faradism. After the enthusiasm over the sinusoidal current has subsided, we shall probably come back to the fact that fine rapid vibrations are like the rapid strokes of a hammer, which may be used to drive in a nail with very little force, if the blows be very frequently repeated.

It is the alternate relaxation and contraction of the muscles which increases their nutrition. A muscle is weakened by prolonged contraction, but every time it relaxes and contracts, owing to the valves in the veins, the blood is hurried on towards the heart. Physiology teaches that one of the principal aids in circulation is muscular contraction, and therefore the current which causes spasm of a muscle is defeating our purpose. From this it follows that the current must be decidedly interrupted.

DR. KELLOGG then showed his method of obtaining a graphic record of the sinusoidal current.

DR. HERDMAN criticised the demonstration by saying that the patient should be interpolated.

DR. KELLOGG replied that this would not make the slight difference in the curve.

DR. HERDMAN said he had had very little personal experience in dealing with these high frequency currents. He had been using for the past three years the Thomson-Houston dynamo current, giving alternations of about 10,000 per minute. This is the current used for incandescent lighting, only reduced to fifty-two volts in his office. It is an agreeable and bearable current, but has a peculiar effect on the vaso-motor system. Dr. Goelet had referred to the effect on the vascular tissue. In one of his patients this result was exceedingly remarkable. The patient was suffering from a peculiar nervous prostration, associated with purpura and frequent suffusions about the face, ears and eyes. To tone up his vaso-motor constrictors, every form of electricity at hand was tried, but nothing exerted such a satisfactory effect as this dynamo current; it seemed to tone him up and relieve his mental depression more rapidly than anything else. Its nutritional effect is no doubt due to an immediate action on the vaso-motor system, and perhaps directly upon the muscular structures. He could not account for the increased consumption of oxygen and excretion of urea except in some such way; certainly it is not in the action upon the striped muscular tissue.

Within the range of harmonics, a certain range of vibration can be determined accurately by musical tones. Some of the statements in Dr. Hutchinson's paper he considered rather speculative, but we must admit that the vibrations producing musical tones do have some special physiologic effects, but the range is limited, for we obtain remarkable effects in interruptions beyond those corresponding to musical tones.

DR. ENGELMAN thought the faradic current had been handled in a pitiable way, and new systems brought forward. He had seen the work of these foreign investigators, and had examined their patients, yet he had seen no results which he could not obtain from the faradic current; in fact, they claim very little.

The faradic apparatus has been spoken of as it was formerly. For instance, Dr. Kellogg objected to it, and very justly, because the vibrator gives an irregular current. We know that every variation of the vibrator changes the current, and it is for these reasons that he had introduced the instrument with the separate current to actuate the vibrator, and a separate coil current. For a rapid rate of vibration, a strong current is required to actuate the vibrator, and hence a mild current can not be used on the patient. If they are separated, one can obtain any rate of interruption and yet not affect the coil current. Determining the rate of vibration by the musical note is good in theory, but it is bad in practice on account of the differences in ears, and the time consumed in testing by this method. Faradism, as it will probably be used in the future, will do away with these objections and faradic apparatus thus regulated will enable one to do a vast deal more than at present. Our committee on coils has told us nothing about coils; we have simply heard objections to these instruments. We must have coils of definite construction for definite purposes.

The speaker said he had had no experience with the sinusoidal current, but from what he had seen of it from those who introduced it, he had not been tempted to experiment with it.

DR. MORTON, in closing the discussion, said it had brought out many new lines of thought which amply justified the expenditure of so much time upon it. In regard to the theory of interfering vibrations referred to in Dr. Hutchinson's paper, if he understood the author correctly, we are given 540 vibrations per second, and are asked to assume that this rate and that of nerve impulses—11 to 19 per second—interfere. This he could not comprehend. He must now, as last year, deprecate the fact that electro-anesthesia was not demonstrated to the Association, for many, including himself, do not believe that electricity can produce a true anesthesia, although admitting moderate analgesic effects.

He thought Dr. Engelman's position was well taken, for the criticisms concerning induction coil currents were based on the assumption that those currents were excited by the ordinary vibrator, which we all admit is very unreliable and unsatisfactory.

The following paper on

PRESENT POSITION OF THE ELECTRICAL TREATMENT IN ECTOPIC GESTATION.

by DR. A. BROTHERS of New York City, was then read by title:

This treatment was first employed by Baccetti in Italy in 1853, and later in England in 1866, by Braxton Hicks. In this country the first case treated by this method occurred in the practice of Allen of Philadelphia, in 1869, and since then it has remained an almost purely American plan of treatment. In a paper which I wrote five years ago, (*American Journal of Obstetrics*, May, 1888) I collected statistics of forty-three cases in which this treatment was resorted to with only one death. In a later paper on the "Subsequent Behavior of Cases Treated by Electricity," (*American Journal of Obstetrics*, 1890, Vol. xxiii, p. 113) I find that twenty-five patients whom I had been able to trace were doing well after a lapse of one to eight years, and that not one of this number had been compelled to undergo secondary operations. Many of these patients, it is only fair to add, carried traces of the old trouble but they gave rise to no inconvenience.

Within the last few years the epidemic of laparotomy fever which originated in Europe has invaded our shores and spread over our continent to such an extent as to temporarily displace the electrical treatment from its deserved position. As a result, the literature of the past few years shows a smaller number of published cases than we should have expected, judging from the past history of this treatment. There still exists, however, a certain proportion of very able physicians who continue to adhere to their convictions and employ the electrical method under judicious restrictions wherever it is properly indicated.

To bring the subject partially down to the present, I have looked over the literature at my command and have been able to prepare the accompanying table, which represents

nearly all the cases which have been published up to the time of writing:

This table represents eighty-five cases of extra-uterine pregnancy in which electricity was employed to destroy the fetus. The list is not complete, for a certain number of cases must have been overlooked, and other cases have not as yet been published.

In two cases (60 and 61) the treatment apparently failed in the hands of very able men—Coe and Wenning—but subsequent laparotomy showed the diagnosis to have been at fault, the pregnancy being normal in both cases. Coe saved his patient after she aborted, but Wenning, who had resorted also to aspiration, was unfortunate in losing his case. In the case of Lewis (81) electricity was discarded and laparotomy done. This patient recovered. In one of Blackwood's cases (62) the extra-uterine mass had shrunk two years later one-half in size and he advised the use of galvanism to assist in its absorption but the patient fell into the hands of a specialist who performed laparotomy from which she died. In none of these cases did the electrical treatment do any harm.

Collapse during the employment of this agent has occurred in the cases of Mundé (23), Janvrin (34), and Coe (54), but only one of these—that of Janvrin—proved fatal. In two of Blackwood's cases (63 and 64) symptoms of internal hemorrhage (such as shock, faintness, debility, etc.), supervened but both patients nevertheless made good recoveries under the electrical treatment.

Aspiration was associated with electricity in the three cases of Hicks (2), Lusk (30), and Wenning (61). Hicks and Wenning lost their patients—the latter supplementing the aspiration by a laparotomy—but Lusk saved his case after the fetus was discharged through a vaginal rent.

In five cases—those of McBurney (6), Garrigues (29), Grandin and Cole (83), Blackwood (67), and Carriker (84)—the fetus was displaced from the tube into the uterine cavity. These cases were all of the interstitial variety.

The case of Landis (5 and 11) is unique in that the accident of extra-uterine pregnancy occurred twice in the same patient and was twice successfully treated by electricity.

In Westcott's case (17) the extra-uterine pregnancy was associated with normal pregnancy which was not disturbed by the electrical treatment and the patient of Bierwirth (52) was simultaneously suffering from typhoid fever.

After the death of the fetus by electricity it was discharged through vaginal or rectal rents in four cases—those of Lusk (30), Chadwick (39), and Blackwood (65 and 66)—with ultimate recovery of all the cases.

Only one death—that of Janvrin (34)—can be attributed to the use of electricity in seventy-eight cases where this agent has been used without puncture; and in this case there were symptoms of hemorrhage previous to the resort to electricity.

The nature of the current employed has not been the same in the reported cases. Faradism was employed in twenty-seven cases, galvanism in twenty-five cases, either current (not stated) in nine cases, both currents successively in sixteen cases, electro-puncture in seven cases, statical electricity in one case. Of the seven cases treated by electro-puncture there were five recoveries and two deaths. This proves the method to be exceedingly dangerous—the bad results being due rather to the accompanying puncture than to the electricity. Similar bad results have followed the use of simple puncture with aspiration or with the injection of drugs, even where no electricity was used. In my first paper I referred to fourteen cases of failure or death after the use of simple tapping or the injection of drugs.

Although the electrical treatment is chiefly American, my table shows the interesting facts that it has been employed five times in Russia, five times in England, and once in Italy, Canada, Germany, France and Australia.

The treatment of extra-uterine pregnancy by electricity has in late years been so violently assailed that it may be well just here to quote the most recent opinions of some of the most eminent practitioners and writers who continue to approve of the method. Playfair, in his last edition, (*A Treatise on the Science and Practice of Midwifery*, London, 1889) says: "This practice is perfectly safe, and there can be no rational objection to its being tried." Lusk, in the last edition of his work on "The Science and Art of Midwifery," (New York, 1892) says: "All men are not experts in pelvic surgery. The danger which threatens the life of the patient is often imminent and assistance from afar is not always easy to obtain. Under these conditions the indication for treatment is plainly the adoption of measures to destroy the life of the fetus, and thus, by arresting the growth of the ovum, to diminish the chances of rupture and

hemorrhage." In a personal interview with Prof. Lusk he stated that he was as much interested in the electrical treatment as ever, but of late had only met cases in which previous rupture allowed of none but operative interference. He was perfectly convinced of the efficacy of electrical treatment in suitable cases and was perfectly sure that in the cases in which he had successfully resorted to it there was no possibility of a mistake in diagnosis.

Prof. T. G. Thomas, early in the summer, also told me that he continued to be a firm believer in the efficacy of electricity in the treatment of ectopic gestation. In the last edition of his work on "Diseases of Women," (Philadelphia, 1891), revised by P. F. Mundé, he says: "At one extreme, stand able and conservative practitioners who appear to favor the position, that as a very general rule, we should stand calmly by with folded arms and accept without effort or resistance the terrible chances of death which attend these cases. At the other, we see enthusiastic ones with strong surgical proclivities, who would apparently resort to laparotomy in every case in which diagnosis is possible. On a middle ground, one lying between these extremes, the truly conservative surgeon will find his appropriate position."

Although Pozzi in his "Treatise on Gynecology" (American Edition, New York, 1892) condemns the use of electricity, the able translator of this work (Wells) says: "If we have a case of extra-uterine pregnancy in the early months it is safe to destroy the fetus by electricity and keep the patient in bed until absorption has noticeably commenced."

Parvin in his work on "The Science and Art of Obstetrics" (Philadelphia, 1890) says: "Throwing aside all doubtful cases, there remains a strong argument from actual experience in favor of the treatment of ectopic gestation, prior to the rupture of the fetal cyst, by electricity."

The works on electricity in its relation to gynecology—such as those of Goelet ("The Electro-Therapeutics of Gynecology," Detroit, 1892) and Grandin and Gunning ("Practical Treatise on Electricity in Gynecology," New York, 1891)—are likewise strongly in favor of the employment of electricity in the treatment of early cases of ectopic gestation. To save entering into further detail, I will simply add that authorities like Byford, Mann, Skene and Wilson have also within the past few years expressed themselves in favor of this plan of treatment.

The Boston Medical Society at its meeting held on Nov. 12, 1892, received the report of the chairman of a committee appointed to investigate the present condition of medical opinion with regard to the subject of extra-uterine pregnancy (E. Reynolds, *Boston Medical and Surgical Journal*, January, 1893, Vol. cxxviii, p. 107). The report reads as follows: "Immediate celiotomy, so soon as the diagnosis is established, is then, in the judgment of your committee, the only treatment which should be considered before rupture of the tube." If this committee can spare the time to study the facts gathered in this paper, I think it may in its charity modify its former conclusion and allow the electrical method a small place in the treatment of some cases of extra-uterine pregnancy. The fact is that most of those loudest in denouncing and ridiculing the electrical treatment have never tried it. The present paper attempts to deal with facts and not opinions—and facts will ever remain indisputable.

The eminent English laparotomist, Lawson Tait, has recently put forth the claim that feticide in these cases is unjustifiable and criminal. We can only answer to this highly moral objection that the majority of physicians, like the majority of the laity, will always continue in the future, as they have in the past, to consider the interests of the mother as paramount to those of the fetus.

There can be no question that a case of extra-uterine pregnancy in the early months ought to be terminated as early as discovered. If this can be done with safety to the mother we are justified in sacrificing the interests of the fetus. If this can be done without a mutilation of the mother we ought to prefer such a method to an operative procedure. And if such a method has been proved to be fairly free from risk, we certainly ought to resort to it. And herein lies the chief fact to be gleaned from this article, viz.: *Beyond one death in seventy-eight cases, no injury has ever been done the mother after the use of electricity.*

Moreover, where the electrical method has been abandoned for subsequent laparotomy—as in the cases of Coe (60) and Lewis (81)—the patients have done well and no harm has come from the previous treatment. Hence, although in the eyes of some it has appeared "ridiculous" and "cowardly" and the product of "ignorant obstinacy,"

the treatment continues to assert itself as a simple, innocent and harmless procedure which has its own proper sphere of usefulness.

What is this sphere? A case of extra-uterine pregnancy of less than ten or twelve weeks' standing—even if the diagnosis is somewhat doubtful—in which the symptoms of rupture are absent or very slight, is the proper one in which to employ this treatment. The method of Rockwell, in which the galvanic current is gradually increased to forty or fifty m. a. and then as gradually diminished, is probably the most rational. The same plan could be followed with the faradic current. Electro-puncture and aspiration should be unqualifiedly discontinued. If it is possible to treat these cases having all the preparations ready for a laparotomy it will remove the last vestige of doubt. For the only fatal case which died of internal hemorrhage after the use of electricity required forty minutes from the beginning of the hemorrhage until the fatal issue. This was certainly a sufficient length of time—if preparations had been made—to open the abdomen and arrest the hemorrhage.

(To be continued.)

The Royal Society of New South Wales.—ORIGINAL RESEARCHES. The Royal Society of New South Wales offers its Medal and £25 for the best communication (provided it be of sufficient merit) containing the results of original research or observation upon each of the following subjects:

Series XIII. To be sent in not later than May 1, 1894.

No. 43. On the Timbers of New South Wales, with special reference to their fitness for use in construction, manufactures, and other similar purposes.

44. On the Raised Sea-beaches and Kitchen Middens on the Coast of New South Wales.

45. On the Aboriginal Rock Carvings and Paintings in New South Wales.

Series XIV. To be sent in not later than May 1, 1895.

No. 46. On the Silver Ore Deposits of New South Wales.

47. On the Physiologic Action of the Poison of any Australian Snake, Spider, or Tick.

48. On the Chemistry of the Australian Gums and Resins.

Series XV. To be sent in not later than May 1, 1896.

No. 49. On the origin of Multiple Hydatids in man.

50. On the Occurrence of Precious Stones in New South Wales with a description of the Deposits in which they are found.

51. On the effect of the Australian Climate on the Physical Development of the Australian-born Population.

The competition is in no way confined to Members of the Society, nor to residents in Australia, but is open to all without any restriction whatever, excepting that a prize will not be awarded to a member of the Council for the time being; neither will an award be made for a mere compilation, however meritorious in its way. The communication, to be successful, must be either wholly or in part the result of original observation or research on the part of the contributor.

The Society is fully sensible that the money value of the prize will not repay an investigator for the expenditure of his time and labor, but it is hoped that the honor will be regarded as a sufficient inducement and reward.

The successful papers will be published in the Society's Annual Volume. Fifty reprint copies will be furnished to the author free of expense.

Competitors are requested to write upon foolscap paper—on one side only. A motto must be used instead of the writer's name, and each paper must be accompanied by a sealed envelope bearing the motto outside, and containing the writer's name and address inside.

All communications to be addressed to the Honorary Secretaries.

T. W. E. DAVID, }
J. H. MAIDEN, } Hon. Secs.

The Society's House, Sydney, Dec. 13, 1893.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, MARCH 24, 1894.

PROGRESS IN MEDICAL EDUCATION.

Judged by some recent jeremiads on the subject, progress in medical education in the United States must be something like the result obtained by that ingenious Irishman who reversed the connections of his gas meter and so brought the company in his debt at the end of the month. Like the Frenchman's crab the progress, apparently, walks backward.

As shown in a previous number of the JOURNAL the facts and figures set forth in the Report on Medical Education by the Illinois State Board of Health effectually disproves the assertions made as the occasion for these lamentations. Some of the statements are specifically dealt with in the Report. For example: In an address before the Harvard Alumni Association the speaker, after asserting that the chief difficulty in the way of a high standard of medical education in this country arises from the great number of medical schools—which is undoubtedly true—rather illogically and quite inaccurately said:

"Some years ago there were nearly three hundred [medical schools]. Now there are not far from one hundred and fifty and they are dying at about the rate of three a year.

One of the tables in the Report shows that the greatest number of regular medical schools in this country was 111 in 1890, and that for the past twelve years there has been an average annual increase of 2.2 regular medical schools, instead of deaths, "at about the rate of three a year."

In another recent contribution to the study of medical education in the United States, based on the Report of the U. S. Commissioner of Education, 1889-90, the following conclusions are drawn:

"1. The average course of study in the United States is still less than three years, i.e., eighteen months.

"2. The antiquated method of repetition [of lectures] still prevails in the majority of medical schools.

"3. The number of students of medicine is absolutely increasing, but (in relation to population) relatively diminishing. The homeopathic and eclectic schools are hardly holding their own.

"4. The education of the average medical student is superior to that

of ten years ago; but the ratio of matriculates having degrees in science or arts is actually diminishing even in the richest, best located and only endowed medical schools."

If these conclusions were based on existing facts the outlook for medical education in this country would, certainly, be most discouraging. The facts and figures given in this most painstaking and exhaustive Report do not, however, warrant the conclusions—rather do they sustain a diametrically opposite set. Thus, instead of the general assertion that "the average course of study in the United States is still eighteen months," the Report shows that of the existing 136 medical schools in the United States in 1893, 115 (nearly 85 per cent.) require three or more years of study and of this number 70 (over 50 per cent.) require four or more full years of study.

Instead of repetitional lectures "in the majority of medical schools," only five out of the 136 existing schools follow this antiquated method, to-wit: Three regular schools and one eclectic in Georgia and one newly-organized homeopathic school in Illinois.

Whatever may have been the fact as to the number of students of medicine at some remote period, it has not been true for the last half dozen years or more that the number is "(in relation to population) relatively diminishing." At the sessions of 1885 the total attendance was 10,891—9,245 regular, 1,032 homeopathic, 614 eclectic. During the sessions of 1893, the attendance was 18,910—16,759 regular, 1,410 homeopathic, 741 eclectic. These figures show gains in eight years of 73.6 per cent. in the total attendance—81.2 per cent. for the regular students, 30.6 per cent. for the homeopathic, 20.6 per cent. for the eclectics—an average annual increase of 9.2 per cent. during the period. The average annual increase of population during the same period was less than 2.5 per cent. So that instead of there being a diminution of students of medicine in relation to population, there is a relative increase nearly four times greater than that of population. As a matter of practical interest to the profession it may be noted that there is an average increment of nearly 6,000 new home-made physicians every year, and that while the population increased 24.8 per cent. during the decade 1881-1890, the number of newly-graduated physicians increased over 50 per cent. during the same period; last year, 1893, the increase was a trifle over 8 per cent. As is quaintly observed in the Report: "There would still seem to be doctors enough to go 'round."

In the final conclusion, above cited, it is conceded that "the education of the average medical student is superior to that of ten years ago," even though he does not possess the outward and visible sign thereof in the form of a diploma of science or arts. But the value of this concession is lessened by the wail over the declining "ratio of matriculates having degrees

in science or arts even in the richest, best located and only endowed medical schools." The Dean of the Harvard Medical School, DR. BOWDITCH, may best answer this. Commenting, in a recent report, upon this diminution in the proportion of college-bred men who have entered the Harvard since 1884, he says:

"Among the influences that have contributed to this result it is fair to assume that the increasing demands of our medical colleges upon the time of the undergraduates and a growing conviction of the importance of beginning professional studies at an earlier age than that at which most students obtain the degree of A. B., have played an important part. This view derives confirmation from the fact that there is a large and apparently increasing number of students in every entering class who have received a certain amount of collegiate education, but who have left their colleges without taking a degree."

It may be justly said that, on the whole, medical education in the United States was never before in such a satisfactory condition; never before were classes so large nor so well prepared, nor instruction so thorough, nor teaching equipments and "plants" so complete. There is, it is true, still great room for improvement; but the progress of the past decade is the sufficient promise that such improvement will be effected in the near future. For the present we may, to adapt the language of PROFESSOR PEPPER in his address as President of the first Pan-American Medical Congress,¹ point with justifiable pride to the admirable and sweeping reforms which have already been instituted.

PROPOSED REDUCTION OF THE MEDICAL CORPS OF THE ARMY.

A standing committee of a legislative body is the guardian and defender of special interests against harmful or hasty action by the general body. Rarely does legislation adverse to those interests originate with such a committee; yet at the present time we have an illustration of its occurrence in the proposed cutting down of the Medical Department of the Army by the Military Committee of the House of Representatives in the Army appropriation bill as reported to the House: "and no appointments shall be made to the office of assistant surgeon until the number of assistant surgeons shall be reduced below ninety, and thereafter the number of officers in that grade in the Medical Department shall be fixed at ninety." The present number is 125.

Of course the object of this is economy. The assumption is made that there are more army doctors than are needful; yet the Army with its attaches requiring medical attendance is as large now as when Congress in its wisdom fixed the present limits of the Medical Corps. The argument for reduction is that of late years the troops have been aggregated at larger posts so that now with only 120 posts we have as strong a medical force as when there were 200 different stations, each requiring medical attendance. But

this argument overlooks the fact that in those days over a hundred civilian physicians were employed under contract,—Acting Assistant Surgeons they were called—at the smaller posts. As these were discontinued the contracts with civilian physicians were annulled, and at the present time no such outside assistance is employed. Money saved by reducing the Corps below its present limits would have to be spent for contract services. Would there be economy in that? If the object were merely to provide medical attendance to sick soldiers it is probable that it could be effected *in toto* by contract with private physicians more economically than by an organized medical staff. But the care of the sick is only a part of the duty of an army medical officer. He must discipline, train and educate the constantly changing *personnel* of the Hospital Corps to have an efficient medical service in the event of war; and his own training for such an event is of the first importance. It may be said that there is little likelihood of any need for this training; but if this is accepted as an argument it operates as much against our whole military force as against its Medical Department.

If the appropriation bill were to pass in its present form, no new appointments could be made until the Corps became reduced to its new limits. Instead of gradually filling up its ranks with bright young men, graduates of the Army Medical School, the progress of which during the past year has been the object of so much interest to the profession, there would be no appointments, no school, no education in the methods of war until all those qualified to teach by their experience in actual war have passed away. This would be a grievous squandering of dearly bought knowledge. In our issue of March 10 last we had great pleasure in reporting the exercises at the closing of the *first* session of the Army Medical School, and in the same issue we presented a view of the corresponding exercises at the *sixty-seventh* session of the British School at Netley, England. Our army medical friends are struggling to place their Corps on such a footing of efficiency as is held by the Medical Departments of European armies; and it does seem discouraging that just as the prospects were brightening under the able administration of SURGEON-GENERAL STERNBERG, and the cordial approval of the Secretary of War, there should appear a possible bar to all future progress. We are proud of our Army Medical Department as a body of able physicians, surgeons and sanitary officers, and have full confidence in the efficiency of its organization to care for the wounded that are so often uncared for in the first battles of an unexpected war. We feel confident that we give expression to the sense of the medical profession in urging Congress not only to sustain the Army Medical Department in its present status

¹ Journal Amer. Med. Ass'n, Sept. 9, 1893.

but to support the efforts of the SURGEON-GENERAL in raising the standard of medical education, inasmuch as these efforts conduce to the well being and efficiency of the Army, and have a reflected value through the medical profession on the whole of the American people.

WEAK HEART—CARDIAC INADEQUACY VERSUS CARDIAC ASTHENIA.

DR. J. M. DA COSTA, who has already contributed to the literature of cardiac disorder, two classical monographs on "Irritable Heart," and "On Strain and Over-action of the Heart," has further enriched the subject by a lecture upon "Weak Heart," given during the present month. The latter was delivered before the students of the Medical Department of the University of Pennsylvania, by solicitation of the Provost, DR. PEPPER, who, with others of the Faculty, were present in honor of the occasion.

The subject selected by the distinguished clinical teacher was the discussion of the symptom, "weak heart," especially considered from the standpoint of causation, diagnosis, prognosis, and treatment. The lecture reviewed the several forms of weak heart, the cases being grouped into three main divisions:

1. Those accompanied by organic change in the walls of the heart, the impairment of the heart's action being the consequence of such lesion; illustrations of this are to be found among elderly gouty subjects with rigid arteries and flabby tissues, who become breathless under slight effort, such as the exertion of going up a flight of stairs; such cases are to be ascribed to fatty degeneration of the cardiac muscle fibers. There is also the class of organic affections with weak heart accompanied by dropsy of which dilatation is the prominent type.

2. Those due to some toxic substance in the blood, either a toxin of unknown character as in influenza, typhoid fever or diphtheria, or some poison of recognized character, such as tobacco, alcohol and the gout poison.

3. Those in which the feeble action of the heart is to be ascribed to essential weakness of the cardiac muscle, and with this there may occur more or less myocarditis; and, finally, those which must be called "cardiac asthenia," which are of nervous origin. The last named group should receive special consideration since they do not obtain the recognition which they deserve, and they are not described in our usual works of reference. Two cases were cited of the latter character, in which depressing emotions suddenly and profoundly affected the heart's action; the patients collapsed suddenly, with failure of pulse, great weakness of the heart's action, vertigo or syncope upon lifting the head from a horizontal position, the extremities cold, the skin pale or bluish, and death apparently imminent from cardiac asthenia.

The differential diagnosis of these different groups of weak heart presents no special difficulties. In the fatty heart of gouty subjects the age, the presence of the usual signs of gout, the state of breathlessness brought on by slight exertion, sufficiently indicate the cause.

In the toxic group, the diagnosis is obtained from the clinical history rather than from the physical signs. The heart symptoms of dyspepsia probably are partly due to ptomaines in the blood from imperfect digestion of food in the stomach, and are partly reflex. They do not properly belong among cases of weak heart now under consideration being more of the type of irritable heart.

The main interest lies in the distinctions between the weak heart of essential muscular defect and the weak heart of nervous origin. With regard to the cause of the latter, the lecturer was inclined to locate the nerve lesion in the cardiac ganglia and connecting fibers rather than in the pneumogastric or in the medulla oblongata. In the diagnosis between the last named classes of weak heart, he had not found the sphygmograph of as great assistance as he had hoped; but he noted that in the nervous form, although the line of ascent was of considerable amplitude, yet it was more slanting than usual and might even show some irregularity or wave motion, and the line of descent also wavering, indicating low tension in the arteries. In the cases of muscle weakness, the line of ascent was more vertical, but did not attain the height that was observed in the first group; its descent was also wavering and irregular.

Dyspnea was a marked symptom of the muscle-weak hearts, and was not seen in the asthenic cases, in which vertigo and syncope were more common. The physical signs also were capable of affording some points of diagnosis. In the asthenic cases, the first sound of the heart was short and distinct and was followed by a valvular second sound, while in the other group the first sound was longer but lacking in volume, and was at times associated with a murmur, while the second sound was also indistinct. The pulse, in the former, may vary in force at different periods, but it does not as often intermit or become irregular as it does in the latter.

The prognosis varies in the different groups. In the fatty heart, or impaired heart associated with dropsy, the disease may be palliated, but in the end it is fatal. The toxic group, being dependent upon different causes which usually are removable generally recover; although deaths do occur, as happens not uncommonly in diphtheria. No one can explain why this fatal heart failure in diphtheria should occur; but there can be no question that asthenia is the immediate cause of death and not the heart clot which is only incidental to the weak action of the heart. An important question with regard to the

cases of essential muscular weakness and, as well of cardiac asthenia, is whether or not they may lead to organic disease. This may occasionally occur with the former. The weak heart sometimes becomes dilated, degeneration takes place in the muscular fibers, and valvular insufficiency also develops; a condition which the lecturer summed up in the very expressive term of "heart-wreck." In the asthenic cases, organic heart disease does not occur, but breast-pang, more or less severe, is one of its symptoms. Fatal results from "heart-failure" will happen occasionally, in spite of the disinclination of insurance companies and health boards to accept this diagnosis in a death certificate. These cases occur, it might be said, in both sexes, but more frequently in the male sex than among women. One complication of the asthenic cases to be especially noted is that after a few months, they may be attacked by diabetes mellitus, of purely nervous origin, and unfortunately fatal in character.

The treatment of these two forms of weak heart is in the main much the same. The best form of heart tonic, either from asthenia or weak muscle, by far, is strychnin, given in moderate cases one-fortieth grain. Arsenic is also of great service, especially in the cardiac asthenic cases, in combination with the preceding, and continued for weeks or months. Alcohol is often necessary, in decided doses, to overcome the tendency to fatal syncope and collapse. Along the same line is digitalis and also strophanthus, though with a large gap between. Adonidin and cactus grandiflora have not produced decidedly beneficial results. Rest in bed is a requisite of treatment in the nervous cases, since syncope and threatened collapse attend efforts to assume an upright posture. In cases of muscular weak heart, exercise is valuable. When the patient has begun to mend, a change of residence from the city to a sanitarium or watering place is generally advisable. With careful management, in the course of time to be measured by months or years, the patient may ultimately be restored to a perfectly normal condition and be as well as any one.

ORDEAL OF THE BIER.

Superstitions live long and die hard. A most singular reference to one is furnished in the case of *State v. Wisdom*, which was decided by the Supreme Court of Missouri, Jan. 31, 1894. This was an appeal from a conviction of murder. In the course of the examination of one of the witnesses, he was asked to tell what happened down at the morgue by the dead body, when another witness and the prisoner were there, prior to the inquest. This was objected to as immaterial, and the objection was overruled. The witness answered that they were told to put their hands on the murdered man; and that he and the other witness referred to did so, but the prisoner would not do it. An officer corroborated this state-

ment. The prisoner objected to the latter's statement but assigned no reason. The action of the trial court in this regard was assigned as error. Who it was that told them to put their hands on the dead body did not appear.

The request to touch the body, the court says, was evidently prompted by the old superstition of the ordeal of the bier in Europe in the Middle Ages, which taught that the body of a murdered man would bleed freshly when touched by his murderer, and hence it was resorted to as a means of ascertaining the guilt or innocence of a person suspected of a murder.

This superstition has not been confined to one nation or people. It obtained among the Germans prior to the twelfth century, and is recorded in the "Nibelungenlied," a great epic poem of that century, in the incident in which the murdered Siegfried is laid on his bier, and Hagen is called on to prove his innocence by going to the corpse, but at his approach the dead chief's wounds bled afresh. That it dominated the English mind is attested by the passage of Matthew Paris that when Henry II. died at Chinon, in 1189, his son and successor came to view his body, and, as he drew near, immediately the blood flowed from the nostrils of the dead king, as if his spirit was so indignant at the approach of the one who caused his death that his blood thus protested to God. And SHAKESPEARE voices the same superstition in Richard III., (Act 1. Scene 2) thus:

"O, gentlemen, see, see! Dear Henry's wounds
Open their congealed mouths and bleed afresh."

And so does DR. WARREN, in "Diary of a Late Physician," (volume III, p. 327). That it was a prevalent belief in Africa and Australia, in another form, see *Encyclopædia Britannica*, pp. 818, 819. This superstition has come to this country with the emigration from other lands and, although a creature of the imagination, it does to a considerable degree affect the opinions of a large class of our people.

It is true, it was not shown that the prisoner believed that touching this body would cause any evidence of guilt to appear, or that he entertained any fear of possible consequences; but it was simply a test proposed by some bystander, and it was offered as showing the manner in which the three suspects conducted themselves when it was proposed. While the prisoner had a perfect right to decline, either because of his instinctive repugnance to the unpleasant task, or because no one had a right to subject him to the test, and his refusal might not prejudice him, in the minds of a rational jury, on the other hand, a consciousness of guilt might have influenced him to refuse to undergo the proposed test, however unreasonable it was, and the court holds that it was one of the circumstances of the case that the jury could weigh. The jury could consider that, while it was a

superstitious test, still the prisoner might have been more or less affected by it, as many intelligent people are by equally baseless notions, as shown by their conduct and movements. If often happens that a case must be established by a number of facts, any one of which, by itself, would be of little weight, but all of which, taken together, would prove the issue.

THE VALUE OF A WOMAN'S HEALTH.

The Supreme Court of Minnesota holds, in the case of *Galloway v. Chicago, Milwaukee & St. Paul Railway Company*, decided Jan. 30, 1894, that where the evidence tends to show that prior to sustaining a personal injury a woman was healthy and active, but by such injury is rendered a helpless invalid an award of \$10,000 damages is not so large as to warrant a reviewing court in saying that they are excessive. The immediate injury in this case, for which that amount of damages was awarded, was a wound on the knee, seemingly, in and of itself, a comparatively small one. But it was claimed, and the evidence tended to prove, that this caused a nervous shock, which resulted in the development of heart disease, and in traumatic neurosis. It will further be seen to have been one of the class of cases where about the only available evidence tending to prove the connection of cause and effect, aside from chronological coincidence, is that of medical experts.

CORRESPONDENCE.

LETTER FROM EUROPE.

Major Girard, Surgeon U. S. Army, to Professor Senn.

No. IV.

BERNE—PROFESSOR KOCHER—DR. QUERVAIN.

BERNE, SWITZERLAND.

Dear Doctor Senn:—I have made here several visits to the "Inselspital," and from what I have seen so far, I expect to witness as high a perfection in surgery as may be seen anywhere. I have heretofore in my letters avoided invidious comparisons and personalities, and will here also remain true to my plan. The buildings of the Hospital are not ten years old yet, consist of a number of detached structures—the pavilion style—and are heated by a central steam plant and ventilated partly by aspiration, partly by propulsion. I may revert to the description later on.

The clinic (surgical) is under the charge of Prof. Th. Kocher, whom I have heard you mention as the foremost surgeon of Europe. The surgical material is divided among three pavilions, two of them under Drs. Girard and Niehaus, noted surgeons, are not available for clinical instruction by the nature of the bequests of the founders. The material controlled by Prof. Kocher, however, appears rich, since during the last year 600 major operations were performed in the clinic. Some two years ago Prof. Kocher, who is an extreme believer in aseptic surgery, had a glass room constructed for his operations, which contains nothing but a copper operating table. The dressings are held in cylinders, which are sterilized from an adjoining room and open with air tight doors into the operating room. The amphitheater,

where the clinical lectures are given, is not used for operations, to which usually only six students are admitted. This arrangement, beside facilitating asepticism, is claimed to be more profitable for the students as they can closely watch the operations to which they are admitted. Kocher operates with only one assistant, beside the Sister of Charity, who presides with extreme skill and foresight over instruments and ligatures. Another assistant gives the anesthetic. In connection with this, I may mention an ingenious contrivance, suitable particularly for struma operations, which are frequent here. It is a bow attached to the head of the table, from which a rubber veil passes to the chin of the patient, protecting the operator from the anesthetic and the wound from possible pollutions by the patient.

Kocher is very particular in his hemostasis and seizes even minute blood vessels with his forceps, of which often twenty or thirty surround the place operated on. The superficial vessels after completion of the operation are treated by torsion except in struma, the deeper and larger vessels ligated. In this manner his operations are nearly bloodless. He proceeds with great deliberation, but divides each layer of tissues with one stroke of the knife with great accuracy.

The first operation I saw him perform was for catarrhal appendicitis in a young woman. His manner of effecting removal of the appendix may be of interest. He first circumcises the peritoneum, strips it back and divides the appendix with the Paquelin knife between two ligatures and finally ligates the peritoneum over the stump. The mesentery of the appendix is meanwhile held with long-bladed forceps and then ligated and divided. The ends of the incision are then hooked up on sharp hooks, peritoneum, fascia and muscles are included in one continuous suture, and over this the skin.

The next operation was a cholecystectomy for gall stone. The gall bladder was found to contain a stone about three inches long, filling its whole lumen. It was attached by adhesions throughout, which were lifted up piece after piece with his director—one of the most useful instruments in surgery—and ligated prior to division. The gall bladder was excised *in toto*, in a manner similar to the appendix, blood vessels treated as usual, and same suture. The operation was practically bloodless and excited my greatest admiration.

The third operation was his modification of Alexander's operation for retroversion and prolapsus. The right round ligament was readily found, drawn out about five inches (which were cut off), and sewed with four silk stitches into the fascia of the m. obliq. externus and the canal closed with two or three more sutures. Blood vessels and skin sutures same as usual. On the left side it was found that the patient had sustained at some time before at another hospital an operation for radical cure of hernia and the ligament had been cut away, as it could not be found. Vaginal examination showed that the uterus was drawn upward and to the right.

The anesthesia in all these cases commenced with chloroform and after insensibility was produced, it was continued and kept up with ether. This method seems very satisfactory and no annoyance was caused by the anesthesia.

Prof. Kocher appears to be overwhelmed with private operations and consequently leaves considerable operating work to be done by his first assistant, Dr. F. de Quervain, who is favorably known to the profession by his monograph on "Cachexia Thyreopriva." He is an expert operator and is considered one of Kocher's ablest disciples. Yesterday he made three radical operations for hernia, which unfortunately I missed. This morning he opened a mastoid abscess with a thermo-cautery knife and subsequently operated on a compound double fracture of tibia and fibula.

After carefully disinfecting the surface and applying the Esmarch tourniquet, he exposed the fractured tibia, made resection of the fractured ends and by sawing out a step from each end brought them in apposition. The comminuted parts of the fibula were removed with the forceps. Wiring of the ends of the tibia made shortly after the accident,—caving in of a bank of earth—which had led to the fracture had failed, the wires cutting through the bone. The limb was placed in a plaster-of-paris dressing with the necessary fenestræ, strengthened with strips of veneering, a procedure novel to me.

A resection of the knee joint, which had been made by him and was healing by first intention was then placed in a plaster splint. I remarked that he deviated from the practice of the German surgeons—and I believe also yours—in making the resection so as to have the limb perfectly straight. I was informed that the results of partly flexed position had not been found satisfactory as the flexion gradually became more pronounced and the limb useless.

This afternoon Prof. Kocher made his modification of Alberti's operation of gastrostomy. He makes a vertical incision about four inches long in the usual place, to about two inches above and to the left of the umbilicus. With his usual care he proceeded with the hemostasis and division of the several layers and drew out part of the stomach. With artery needle he ligated the vessels on both sides where the sutures were to be inserted. He then closed the abdominal opening to about two inches in the manner described heretofore, and after having drawn the stomach out about four inches, stitched it to fascia and peritoneum with continued suture. He then prepared a channel for the part of the stomach drawn out, by separating bluntly the skin from the ribs and made an incision at about the sternal end of the sixth rib, into which he *forcibly* drew the pouch and with four interrupted sutures sewed it to the margin of the incision. This method is said to make a perfect valve, requiring no pad and not liable to eventual change, as in Alberti's operation.

The next operation was excision of a carcinomatous mamma. After carefully outlining the shape of the gland and marking the margins with a nick of the knife, he made a circular incision and dissected gland and fascia from the pectoralis muscle. The incision was carried into the axillary cavity and every vestige of lymphatic glands, (which appeared perfectly sound) dissected in the most painstaking manner from the axillary blood vessels. The skin was then united with continued suture and a small remaining defect covered with Thiersch graft.

BERNE, February 27.

To-day's surgical clinic was about as exquisite to my taste as one of Thomas' concerts would be to a music lover. First two women were presented to the class, both with typhlitic abscess. The "consulting staff" were well quizzed by Prof. Kocher and acquitted themselves very creditably. The attendance in the clinic was the best I have seen so far anywhere, except at Rush. The first woman exhibited had a fluctuating tumor in the right hypogastric region. No local disturbance discoverable in the anamnesis, except some diarrhœa. The tumor had gradually grown during four weeks and discoloration of the skin was pronounced. A careful analysis, positive and exclusive, of all possibilities was made and probable perforative appendicitis, possible perforation of cecum or colon diagnosed. With the aspirator syringe a small quantity of ill smelling pus was removed, which confirmed the diagnosis. The crucial test was established by microscopic examination, which revealed a great cavity of microorganisms, among them staphylococcus, streptococcus, diplococcus, bacillus coli and even the comma bacillus.

The other one was still more remarkable, for the tumor was on the *left* side of the umbilicus.

Both cases received hypodermic solution of cocain and the abscesses were incised with the thermo-cautery (to prevent infection) with escape of enormous quantities of fecal pus. The plan of treatment is irrigation several times daily with one per cent. salicylic acid and an antiseptic dressing until granulation is well advanced, then radical operation. In this manner, infection of the wound is prevented.

These operations were made in the amphitheater, since no danger of infection existed for these infected abscesses and they would have lamentably affected the aseptic condition of the operating room, to which Prof. Kocher and the chosen few adjourned, for the second, the operative part of the program, four capital operations.

1. *Excision of a Struma.* Horizontal incision, careful hemostasis, double ligature of the capsular tissues and division between the ligatures. The operation was almost bloodless and performed in an incredibly short time. I have heretofore omitted stating, that Prof. Kocher uses for buried sutures almost exclusively silk; this is due to occasional infections from the use of catgut, owing to careless preparation of the makers.

2. *Ovariectomy of a single tumor without adhesions.* After division of the tissues in the linea alba, evacuation of the tumor with Spencer Wells trocar (probably two gallons of fluid), upon which the tumor was turned out and the pedicle ligated with silk in two parts and returned to the abdominal cavity. Peritoneum and fascia were then united with a continuous suture and then the skin likewise. No drainage.

3. *Radical Operation of Inguinal Hernia.* Oblique incision. The sac was forcibly drawn out of the ring, (about five inches) then passed through an incision about one and one-half inches above in the transverse fascia, to which it was stitched before and behind with wire sutures. Then it was laid down in the inguinal canal and connected with three more wire sutures and the remaining end cut off. A superficial continued suture completed the operation.

4. *Excision of Carcinomatous Mamma* in a male, age 50. The nipple being in an ulcerated condition was as a preliminary step thoroughly cauterized with the Paquelin. The remainder of the operation was similar to the one heretofore described.

I am about at the end of my description of the Berne clinic, as the "semester" is nearly over. A struma of the size of a large orange was excised from a boy of 14. The reason leading to the operation was that from a tracheotomy performed in childhood, the cricoid cartilage had not recovered the normal strength and even this small goitre caused dyspnea by compression of the trachea. On excision of the tumor the breathing became free, but the slightest pressure on the cartilage led to suffocative attacks.

The next case of struma operated on was a cystic tumor, apparently without adhesions and only cocain hypodermically was used as an anesthetic. Since, however, additional cysts had formed, penetrating deeply into the intermuscular spaces, the operation was considerably prolonged and a severe tax on the fortitude of the patient.

The next operation was an "Alexander" for prolapsus with cysto- and rectocele. It was performed quickly and with apparent ease, at once correcting the faulty position of the uterus.

A tubercular osteitis of the tarsus led to amputation. First the cuboid bone being diseased was re-articulated, then the head of the astragalus, then a cuneiform bone, and finally pus exuding from the ankle joint; conservative treatment had to be abandoned, and the choice lay between a Pirogoff and amputation. The skin was too much infil-

trated for the former, however, and the latter, for which the consent of the patient had been obtained previous to etherization, was performed with a lateral flap.

This morning, on my arrival at the clinic I met Prof. Kocher leaving. He informed me that he had to go to Lucerne to make a severe operation and that Dr. de Quervain would make the operations this morning. (I learned later that the operation spoken of by the Professor was a removal of the Gasserian ganglion—for neuralgia of the trifacial—by resection and turning back of the zygoma.) Dr. de Quervain made four operations, a double radical operation for hernia, two single ones and exsection of the skull for tubercular disease. In the double hernia the bowel had not passed much beyond the external ring, causing some trouble in finding the sac. Dr. Quervain remarked on the fearlessness of the people in submitting to operations, even for slight defects. The second case was a very large hernia of many years' standing, with a greatly thickened sac. It was operated on in the usual manner expeditiously. The third case was a return of hernia after operation two years before. It was found that the silk sutures, which had closed the canal had cut through the ligament of Poupart. All but one suture were intact.

The exsection of the skull was made with a semi-circular incision. After scraping back of the periosteum three perforations about two inches apart and two erosions presented themselves. With gouge and hammer one of the perforations was enlarged and a piece of bone about two by four inches removed with the rougeur, showing the dura mater covered with unhealthy fibrinous deposit. This was scraped off with the spoon, the brain covered with iodoform gauze, and the flap, after excision of the diseased parts, sutured over the opening. No bone grafts were used.

I have given the surgical clinic of Berne a rather large share of my letters for two reasons: One, because I prolonged my stay here, and the other because everything in the operating line was so exact and fascinating that I was greatly attracted.

I may yet send a letter from Zurich, but will probably suspend my epistolary activity until I reach Rome, when I propose sending you an account of the work of the Surgical Section, with which I intend connecting myself.

My letters must certainly have the stamp of impromptu writing, as most of them are written at night, by the light of a tallow candle, after fatiguing traveling and sight seeing, and I hope that shortcomings will be dealt with leniently. Sincerely yours,

A. C. GIRARD.

Prevention of Yellow Fever.

AUGUSTA, GA., Feb. 16, 1894.

DR. J. McFADDEN GASTON, Atlanta, Ga.:

Dear Doctor:—I have just read your "Open Letter upon the Prevention of Yellow Fever by Inoculation" in the January number of the *Southern Medical Record*, reprinted from the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, of January 6.

If by this writing I can "hold up Moses' hand" I shall feel repaid, however unnecessary that aid may appear to one, who, in the strength of his resources, proclaims his ability and purpose to present "before the medical profession at an early day, facts in his possession confirmatory of all that has been alleged in favor of the results of inoculation against yellow fever, as practiced by Domingos Friere in Brazil."

The subject is one of overwhelming importance as well as public interest. That your presentation of the data at hand will be acceptable, I need not assure you; the profession will await it with expectant interest, increased if not prompted, by the hope that whatever prejudice to the cause

of the prophylaxis of yellow fever by this means, has resulted from the action of the Commission, may be speedily removed, and at least the hopeful attention of the scientific world be again accorded to the investigator.

I can plead an early interest in this subject, as the author of a petition signed by the Georgia Medical Society of Savannah, the Board of Health and the Academy of Medicine of this city, to the Congress of the United States in 1884, to offer a reward, "open to the world, for the discovery of the true cause or germ of yellow fever, or any certain means of effecting its prevention, destruction, or harmless modification." This was done with a view to "stimulate inquiry in this direction," which seemed in the then state of knowledge the only one of promise as to the control of this epidemic disease. Dr. Friere's appearance upon the stage of action about that time was to me, as it doubtless was to others, especially interesting and timely.

Dr. Friere will be fortunate if he encounters opposition in only official form. The path of independent research and discovery in such matters is a thorny one indeed, and he who pursues it needs alike the patience of Job and the "courage of his convictions." Witness Jenner the great exemplar, of whom it is said: "During six years no member of the profession ever received more anathemas or scurrilous abuse. He was attacked by the leading physicians and surgeons of Great Britain, and persecution and ridicule so followed him, that placards with caricatures of Jenner were posted throughout the streets of London and the principal towns of Great Britain; Jenner kept steadily at work and repeated his experiments, until he became fully convinced that by vaccination perfect protection could be obtained against smallpox."

Science has never yet discharged the debt of obligation it justly owes to tradition and *empirical popular* observation by the discovery of vaccination through that medium. "In 1771, a Holstein schoolmaster vaccinated three pupils, and in 1774, an English farmer vaccinated his wife because of his belief in the power of bovine virus as seen in his dairy maids." It was twenty-five years later (1796) that Jenner made his first vaccination on man. This obligation can never be discharged, as the occasion that created it led to the first experimental demonstration of the now more fully established theory of the "attenuation of viruses," the vista through which hope sees in the distant future the revelation of a power over contagious epidemic diseases unauthorized by all other human means.

You foreshadow objections to Dr. Sternberg's "mode of conducting the investigation" that led to his unfavorable report. Now without meaning to criticise this distinguished officer, it can be said that commissions of inquiry into matters of this kind, especially when prefaced by a certain degree of incredulity on the part of the individuals composing them as to the observer whose work is to be examined, or incredibility as to the subject under investigation, can not, or ought not to, be taken as final. As evidence of this, I need only refer to that admirable "Report on the Cholera in Europe and India," made in 1890 by Dr. E. O. Shakspeare, A.M., M.D., Ph.D. of Philadelphia, who was appointed by the U. S. Government, Special Commissioner for that purpose. That report, commendable alike for its impartiality, ability and fidelity to the trust imposed by the Government which he represented, is a model of its kind.

Among other matters of investigation incident to this mission was that of the anti-choleraic inoculations practiced by Dr. Ferran of Spain. Whether of value or not, they had attracted the attention of Europe and the scientific world. Commissions were sent by different countries to look into the merits of this so-called discovery. Among them, one from France, headed by Brouardel. Appointed by the

Minister of Commerce, his Commission also bore a letter to Dr. Ferran from the immortal Pasteur, before whom both science and commerce in their approaches may be fitly represented in a kneeling, if not worshiping, attitude, with upturned palms ready to receive the gifts of God transmitted through this medium.

Reading the report of this Commission, one is lamentably impressed with the shortcomings of human nature. Because Dr. Ferran saw proper to withhold "his mode of attenuation of the cholera virus," although offering every facility for the examination of the "vaccinal liquid" in his laboratory, the Commission made a report disparaging to his preparation and outfit for the work; intimated a want of "honesty of the man," and while admitting that the "inoculations upon man may appear harmless," yet represented him as the subject of an imprudent "infatuation" which committed him to its premature trial on man; in extenuation of their position pleading the example of Jenner who "hesitated nine years before daring to inoculate James Phipps, May 14, 1796." If this Commission had simply reported their inability to pursue the objects of their inquiry on account of the refusal of Dr. Ferran to disclose or subject to examination his mode of preparation of the virus, its duty would have been discharged; but in reflecting upon Dr. Ferran in the above manner, it sacrificed its own prestige and influence to bitter prejudice or disappointment.

The U. S. Commissioner says: "After having read so much in the current literature of the day about the ignorance of Dr. Ferran of the modern methods of research among bacteria, and of his inability to make decent microscopic preparations, and of his absolute ignorance of the method of staining, I confess that it was with some surprise that I witnessed the facility with which he performed all these operations—a facility which indicated the habitual practice of no mean skill in the performance of these somewhat delicate operations; and my astonishment when for the first time I examined with the Hartnaek microscope one of the cover-glass preparations which I had seen him make. Honesty and regard for fair dealing require me to say that if there are more beautifully stained microscopic preparations of bacteria, especially of the comma-bacillus of Koch, and of the Finkler and Prior bacillus, in Europe, I have never seen them." "I found him to be a quiet, reserved, courteous, intelligent and generally well-informed physician. The impression which I formed of his theoretical knowledge of bacteria and of the modern methods of research in the field of natural history, have compared very favorably with those of most of the leading bacteriologists with whom I have come in contact." (Page 714.)

Moreover, as you propose to furnish data confirmatory of the discredited results of Dr. Friere's yellow fever inoculations, it may interest you if I quote in this connection Dr. Shakspeare's statement of the results of the anti-choleraic inoculations in Spain.

After citing statistics he adds: "It appears, therefore, that among the population of villages wherein anti-choleraic inoculations had been more or less extensively performed, the liability of the inoculated to attacks of cholera was 6.06 times less than that of the non-inoculated; whilst the liability of the inoculated to death by cholera was 9.87 times less than that of the non-inoculated. (Page 715.)

Between Drs. Ferran and Friere there exists a close analogy in their respective spheres of observation. Hitherto unknown members of the profession, and alike bold in the practical application of the results of their researches, they first fell heir to incredulity, if not prejudice in the minds of the profession, and invited a burden of proof positive as to the value of their observations which, to say the least, it is extremely difficult to furnish under present circumstances.

Their tasks embraced not merely the finding of a missing link in the development of the bacillus anthracis, or the isolation of the germ of cholera or tuberculosis, like Koch, but much more, the immediate practical application and use of a virus for the prevention and modification of the two remaining unmitigated scourges of mankind—yellow fever and cholera. The discovery of the bacillus-tuberculosis and the comma-bacillus has done little or nothing for the treatment of the diseases of which they are the respective causes; while inoculations against cholera and yellow fever become from their very nature and objects the full equivalent of the highest therapeutic results. A stronger proof, more difficult to furnish than the demonstration of a microorganism, is necessary with the latter, and even if brought to naught in the end, may not be without useful lessons to future investigators. It will doubtless prove an acceptable duty to you to show the full value and usefulness of Dr. Friere's labors and researches.

Yours truly, W. H. DOUGHTY.

The Advertising Question.

PITTSBURG, March 10, 1894.

To the Editor:—I observe, sir, that but one side of the advertising case has been presented by the Hebrew children of Philadelphia and Pittsburg. I always bear in mind, sir, the old advice to beware of the Greeks bearing gifts, "*Timeo Danaos et dona ferentis*." The spasms of virtue which are bringing Solomon of Philadelphia, and Isaac of Pittsburg, to the fore, may be in the nature of friendliness to some of the rival works. This is perhaps creditable, but it ought to be considered with their remarks. It is somewhat singular that you do not see these people attacking "Europhen," "Trional," "Losophan," "Piperazin," "Antipyryn," "Anti-febrin," or "Sulfonal." The difference between these and American secretly prepared pharmacy products is that one is from abroad and probably of Hebrew manufacture, while the others are indigenous. I must say, Mr. Editor, that I occasionally use "Phenacetin," and also "Listerine," and I intend to continue their use until the Pharmacopœia supplies me with something better to use in their place. I have never prescribed any of the others of the category, but when convinced of their utility I may do so. There is a great deal of humbug and tomfoolery in the row that has been raised. These American pharmacists are not publishing to the people a quack remedy. They offer their products to the medical profession alone, and ask to be tried by professional standards. There is a very wide difference between the "patent" medicine man who issues an almanac to everybody, and reputable pharmacists who put "Europhen" and "Listerine" on the market. Not only that, but the ingredients are not secret; they are known. The process of manufacture, like that of handicraft, is individual. Everybody not a veritable chump knows that the Code of Ethics, written years ago, when individual pharmaceutical processes were unknown, had reference only to patent medicines—the variety that supplies the family almanac and recommends the same secret compound for a variety of diseases as a specific. This patent medicine specific was the object aimed at by the paragraph in the Code, as the modern "Sennine" and compounds of its class were unknown when the Code was framed.

The resolution claimed as governing was introduced without notice and passed without comment or debate; not a half-dozen members paid any attention to it.

Even the shriekers profess to desire that our JOURNAL shall be a creditable one in its reading pages, and that it shall show in its news columns and general make-up no inferiority. It costs money to make a JOURNAL like ours.

How can it be maintained on an equal footing with other journals if one-third of its income be suddenly cut off? Why should our JOURNAL be handicapped with any such restrictions as Dr. Cohen proposes? The *British Medical Journal*, the highest type of the most ethical medical body in the world, contains the advertisement of "Cactina Pillels," and others of its class. There is not one of the American medical weeklies that does not carry the advertisements in question. Our members demand of the Trustees a JOURNAL equal to any. It simply can not be made equal if the line on American pharmaceutical products is drawn where the shriekers want it. These views, Mr. Editor, may not conform to the views of rabid fanatical sentiment, but they are those of common sense. There is no sense in placing the American pharmaceutical compounds of the class named by the Hebraics, among the quack nostrums. It is so manifestly unfair, that the fact only needs to be stated, to be appreciated. However, we may well ask, who will draw the line, and where will he draw it? Will it be drawn only against home products, or will those of foreign countries fall equally under the ban, whether from the New Jerusalem or the Old?

MEDICUS.

[This discussion, in the opinion of the editor, is profitless. Let the matter be brought to an issue on the floor of the ASSOCIATION, and there end.—EDITOR.]

Why "Moonshine Pills" Flourish?

TECUMSEH, MICH., March 17, 1894.

To the Editor:—In your last week's issue of the JOURNAL, ten or more pages are given in exposing the vagaries of homeopathy, in which the author of the paper explains how near he got in the slum.

It is my impression that if the medical schools of our country will raise the standard of medical education equal to that of European countries, we will be cursed with less quacks, homeopaths, and other sects.

They will not flourish any more than they do in Austria and Germany.

Very truly yours,

J. F. JENKINS, M.D.

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Rio Grande Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville, Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland, thence east by way of the Northern Pacific R. R. to St. Paul. C. M. & St. P. R. St. Paul to Chicago. A stop over at Yellowstone National Park for those who desire it has been arranged, and it has been understood that at several places on the journey there will be short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentrating on this train should be effected at Chicago and St. Louis. For all information relating to this train, fares, etc., address G. M. Connell, 212 Clark st., Chicago, or any agent of Santa Fe line in other cities. Rates promised are the lowest excursion rates at time of departure.

This is the only route on which arrangements have been perfected by the Trustees.

Points of Interest.—While San Francisco is a comparatively new city it is not lacking in places of interest to the visitor. About a half mile to the northward of the city limits, nestling in a little valley and surrounded by evergreen trees is the Presidio, the U. S. Army station. A short distance beyond is old Fort Point upon the waters'

very edge—the waters of the bay dashing upon its cement abutments are broken into spray and lost upon its walls.

McDowell Avenue leads from near the Fort around the top of the cliffs overlooking the Golden Gate, and the broad expanse of the Pacific Ocean.

Vessels of all nations and descriptions can be seen in the offing or quietly gliding through the waters of the Gate.

The Cliff House—a famous resort—is situated upon a promontory directly overlooking the ocean. In the distance on a clear day the Farallone Islands—twenty-five miles away—are seen rising abruptly from the water, while less than one hundred yards from where one stands, the "Seal Rocks" jut up from the waves and the loud barking of the seals and sea lions upon them tell why they are so named.

Sutro Heights are just above the Cliff House. Here nature and art have so blended their works that the visitor is truly astonished and delighted with what he sees. The Committee of Arrangements are planning an entertainment at this place for the wives and daughters of visiting members to the ASSOCIATION. All San Francisco is justly proud of Golden Gate Park. What was once dreary sand dunes, has been transformed into a very garden. Flowers bloom throughout the year, and the grasses are always green.

Broad avenues wind in and out past the conservatory, the deer paddock, around the base of Strawberry Hill and on to the ocean beach.

The California Mid-winter Fair is being held in the Park at the base of Strawberry Hill and occupies a space many acres in extent.

This Fair has an individuality peculiarly its own, and offers much of interest to every visitor.

San Francisco, March 14, 1894.

Section of Neurology and Medical Jurisprudence.—PARTIAL PRELIMINARY PROGRAM.—The following papers have been promised for presentation in this Section:

1. Chairman's Address—"Medical Expert Testimony and the Common Law." James G. Kiernan, Chicago, Ill.

2. "Medico-Legal Aspects of the Cronin Case." Judge R. M. Wing, (Counsel for the Defense) Chicago, Ill.

3. "Medico-Legal Superstitions Concerning Criminal Inebriates," T. D. Crothers, Hartford, Conn.

4. "A Case which Illustrates the Medico-Legal Relations of Bacteriology," A. Walter Suiter, Herkimer, N. Y.

5. "Degeneracy from an Oral and Dental Standpoint in Regicides and in Aristocracy," Eugene S. Talbot, Chicago, Ill.

6. Paper—Title to be announced later, H. N. Moyer, Chicago, Ill.

7. "Recent Discoveries in the Minute Anatomy of the Nervous System and their Bearings on Practical Neurology," Chas. K. Mills, Philadelphia, Pa.

8. "Auto-infection in the Production of Diseases of the Nervous System and some Suggestions as to Treatment," D. R. Brower, Chicago, Ill.

9. "Is Locomotor Ataxia a Nervous Disease?" L. Harrison Mettler, Chicago, Ill.

10. "Some Observations and Remarks on Insanity of Adolescence," Frank P. Norbury, Jacksonville, Ill.

11. "Sexual Animus; Its Relation to Health and Disease," Charles Everett Warren, Boston, Mass.

12. "Laryngismus Stridulous," Rosa Engelmann, Chicago, Ill.

More papers will be announced later.

FRANK P. NORBURY, Secretary,
Jacksonville, Ill.

Section on Materia Medica and Pharmacy.—Members of the ASSOCIATION and delegates are invited to prepare papers on appropriate topics to be discussed before this Section. It is especially requested that the titles of papers should be sent to the Chairman or Secretary at as early a date as possible in order that the program may be arranged. A number of pharmaceutical papers have already been promised, and the titles of others should be sent in at once either to the Chairman Dr. Frank Woodbury, Philadelphia, or to Dr. George F. Hanson, 761 Valencia Street, San Francisco, who has kindly consented to serve as Secretary *pro tem* in place of Dr. Stewart who will be unable to attend the meeting.

SOCIETY NEWS.

The Ohio State Medical Society will hold its forty-ninth annual session at Zanesville, May 16, 17 and 18. President, N. P. Dandridge, Cincinnati; Vice-Presidents, F. C. Larimore, Mt. Vernon; Wm. Caldwell, Fremont; W. T. Corlett, Cleveland; L. L. McCurdy, Dennison; Secretary, Thomas Hubbard, Toledo; Assistant Secretary, Chas. Graefe, Sandusky; Treasurer, James A. Duncan, Toledo.

Medical Association of Georgia.—The forty-fifth annual session of the Medical Association of Georgia will meet in Atlanta, Ga., on April 18, 19, 20. The officers are: President, W. H. Elliott, M.D. of Savannah, Ga.; Vice-Presidents, G. T. Miller, M.D. of Americus, H. McHatton, M.D. of Macon; Treasurer, E. C. Goodrich, M.D. of Augusta; Secretary, Dan H. Howell, M.D. of Atlanta, Ga.

DAN H. HOWELL, M.D., Sec'y.

The Association of Military Surgeons of the United States.—The fourth annual meeting of the Association of Military Surgeons of the United States, will be held in this city May 1, 2 and 3, 1894. A brilliant and able literary program will be presented. The evenings will be given up to social entertainments. Transportation will be satisfactorily reduced on all railroads to and from this meeting, and all the hotels in the city will give greatly reduced rates. The Ebbitt House will be the social headquarters. A large attendance is anticipated, and a cordial invitation is extended to all to be present.

GEORGE HENDERSON,

Chairman Committee of Arrangements.

Washington, D. C., March 1, 1894.

Cincinnati, Ohio, Academy of Medicine.—The annual election for officers for the Academy of Medicine was held March 5. Dr. Southgate, a graduate of the Woman's Medical College, was elected Corresponding Secretary.

The other officers elected were: E. G. Zinke, President; Joseph Eichberg, First Vice-President; David De Beck, Recording Secretary; Dr. George E. Jones, Treasurer; Miss Glaezer, Librarian; Dr. John A. Murphy, W. P. Dandridge and James T. Whittaker, Trustees.

The Academy is in a prosperous condition. The report of the officers, the valedictory and inaugural addresses were given on the 12th, and the banquet was held on the 15th at the Gibson House.

The St. Louis Medical Society held a meeting March 3. Dr. Outten presided.

Dr. Alleyne was reelected Treasurer in place of Dr. Hunt, resigned. Drs. P. C. Witherspoon, Philip Hoffmann, J. L. S. Jennings, Louis Crusius, Lloyd Simpson, Howard Carter and Alex P. Jordan were elected members of the Society.

The report of the committee appointed to examine the accounts of Dr. Hunt, the retiring Treasurer, was read and adopted. It shows the Society to be in good financial condition, there being a balance on hand of \$597.25.

Denver Medical Alumni.—The regular monthly banquet of the Denver Medical Alumni Association was held March 3. After the regular program the usual monthly banquet was held. Dr. J. N. Vroom acted as toastmaster. Toasts were responded to as follows:

"Our Oldest Graduate," Dr. P. V. Carlin; "Bacteria and Beards," Dr. I. B. Perkins; "Physicians without Beards," Dr. C. H. Manly; "Hospital Work," Dr. G. H. Stover; "City Suicides," Dr. Carl Johnson; "Bald-headed Doctors," Dr. M. A. Walker; "Denver Alumni Association," Dr. J. T. Davison; "Populist Party," Dr. Coleman; "Antisepsis," Dr. E. A. Sheets; "Our West Side Practitioners," Dr. David Thompson; "The Church and Medicine," Dr. E. H. Allison.

Shelby County (Ind.) Medical Society will hold its annual

meeting at Blessing's Opera House, April 9, 1894. Preliminary program: Diphtheria, Dr. E. S. Elder, Indianapolis. Discussion: Dr. I. N. Love, St. Louis.

Exhibition of Pus Tubes, recently removed, Dr. W. H. Wathens, Louisville, Ky. Discussion: Dr. T. A. Reamy, Cincinnati.

The Diagnosis and Treatment of Floating Kidney, Dr. R. Harvey Reed, Columbus, Ohio. Discussion: W. N. Wishard, Indianapolis.

Nasal Reflexes, Dr. J. A. Thompson, Cincinnati. Discussion: Dr. H. W. Loeb, St. Louis; Dr. L. C. Cline, Indianapolis.

The County Medical Society, Dr. J. C. Culbertson, Cincinnati. Discussion.

The Treatment of Gun-shot Wounds of Chest, Dr. A. G. Bernays, St. Louis. Discussion: Dr. P. S. Conner, Cincinnati.

Is the Usual Treatment of Postpartum Hemorrhage Correct? Dr. W. G. McFadden, Shelbyville, Ind.

Papers have also been promised by Dr. R. B. Hall, Cincinnati, Dr. Max Thorne, Cincinnati; Dr. Jos. Ransohoff, Cincinnati; Dr. E. F. Wells, Chicago; Dr. J. O. Stillson, Indianapolis, the titles of which have not yet been received.

A banquet will be tendered the visitors at Blessing's Opera House in the evening.

The following have accepted invitations to respond to toasts: Dr. I. N. Love, St. Louis; Dr. J. McLean Moulder, Kokomo, Ind.; Dr. C. A. L. Reed, Cincinnati; Dr. T. A. Reamy, Cincinnati; Dr. E. S. Elder, Indianapolis; Dr. J. M. Mathews, Louisville, Ky.; Dr. R. Harvey Reed, Columbus, Ohio; Dr. L. S. McMurtry, Louisville, Ky.; Hon. W. S. Ray, Shelbyville; Hon. L. J. Hackney, Shelbyville; Dr. D. S. Reynolds, Louisville, Ky.; Dr. E. F. Walker, Evansville, Ind.

American Surgical Association.—Session of 1894. Special subjects for discussion are as follows:

"The Surgical Treatment of Empyema," by John Ashurst, Jr., M.D.

The discussion of the paper will be opened by Drs. N. P. Dandridge, C. B. Nancrede, T. F. Prewitt, and D. F. Willard. "Methods of Teaching Surgery," by J. S. Billings, M.D.

The discussion of the paper will be opened by Drs. J. C. Warren, N. Senn, W. W. Keen, E. M. Moore, W. T. Briggs, and Hunter McGuire. It is desired that the discussion of this paper should be participated in by the Fellows generally.

"The Surgery of the Kidney," by L. M. Tiffany, M.D.

The discussion of the paper will be opened by Drs. M. H. Richardson, H. H. Mudd, C. H. Mastin, and Ford Thompson.

"Methods of Controlling Hemorrhage in Amputation at the Shoulder," as illustrated by three cases of amputation at the shoulder-joint and of the entire upper extremity, by W. W. Keen, M.D.

The discussion of the paper will be opened by Drs. Roswell Park, C. B. Porter, and J. William White.

Paper by Hunter McGuire, M.D.; Paper by Joseph Ransohoff, M.D.

Fellows who desire to present volunteer papers are requested to send the titles of the papers to the address of the Business Committee, 1429 Walnut Street, Philadelphia, not later than April 18, 1894.

The Sessions of the Association will be held in the Lecture Room of the Medical Department of the Columbia College, 1325 H Street, N. W., Washington, D. C., on May 29, 30, 31, and June 1, from 10 A.M. to 1 P.M.

The sessions of the Congress will be held in Metzgerott's Hall, corner of Twelfth and F. Streets, N. W., in the afternoon from 2 to 5 o'clock.

The office of registration of the Congress will be at the Arlington Hotel. Registration of individual members of the constituent associations of the Congress is necessary to make them members of the Congress.

Dinner to the guests of the Congress at the Arlington Hotel, Wednesday, May 30, 7 P.M.

Reception by the President of the Congress, Thursday evening, May 31.

J. R. WEIST, M.D., Secretary.

Illinois State Medical Society.—The forty-fourth annual meeting of the Illinois State Medical Society will be held at Decatur May 15, 16 and 17, 1894. The meeting will be called to order Tuesday morning, at 10 o'clock.

OFFICERS.

President, Otho B. Will, Peoria; First Vice-President

Daniel R. Brower, Chicago; Second Vice-President, Abby Fox Rooney, Quincy; Permanent Secretary, John B. Hamilton, Chicago; Assistant Secretary, E. J. Brown, Decatur; Treasurer, George N. Kreider, Springfield.

JUDICIAL COUNCIL.

Charles C. Hunt, Dixon; Richard Dewey, Chicago; Isaac N. Danforth, Chicago; John P. Matthews, Carlinville; Francis P. Haller, Vandalia; Edgar P. Cook, Mendota; E. Ingals, Chicago; C. B. Johnson, Champaign; W. J. Chenoweth, Decatur.

SECTIONS.

Practice of Medicine, Medical Specialties, Materia Medica, Therapeutics.—Chairman, T. J. Pitner, Jacksonville; Secretary, H. McKenna, Paris; Address, Prof. Victor C. Vaughan, University of Michigan.

Surgery, Surgical Specialties and Obstetrics.—Chairman, D. W. Graham, Chicago; Secretary, Ellen H. Heise, Canton; Address, Edmund Andrews, Chicago.

Etiology, State Medicine and Medical Jurisprudence.—Chairman, Geo. W. Webster, Chicago; Secretary, G. A. Zeller, Peoria; Address, W. E. Quine, M.D.

COMMITTEES.

Executive Committee (ex-officio).—Otho B. Will, Peoria; T. J. Pitner, Jacksonville; John B. Hamilton, Chicago; D. W. Graham, Chicago; C. Chenoweth, Decatur; Geo. W. Webster, Chicago.

Committee of Arrangements.—C. Chenoweth, H. C. Jones, Wm. Barnes, E. J. Brown, Wm. M. Catto.

Committee on Publication (ex-officio).—John B. Hamilton, Chicago; Otho B. Will, Peoria; Geo. N. Kreider, Springfield.

Committee on Medical Legislation.—A. B. Strong, Chicago; Walter Watson, Mt. Vernon; B. M. Griffith, Springfield; The President (ex-officio).

Committee on Necrology and Biography.—John H. Hollister, Chicago; Robert Boal, Peoria; John H. Rauch, Chicago.

Committee on Medical Societies.—William O. Ensign, Rutland; James L. Reat, Tuscola; Chas. W. Hall, Kewanee.

Committee on Registration (ex-officio).—Geo. N. Kreider, E. J. Brown.

SPECIAL NOTICES.

1. The usual reduction in railroad fare is promised by the Committee of Arrangements, on the certificate plan. The certificate *must be secured when ticket is bought at local railroad office.*

Failure to obtain the certificate will prevent the delegate from securing the reduction on the return trip.

2. Membership is acquired according to the following:

ART. III.—MEMBERSHIP.

SECTION I.—All regular resident members of County and District Medical Societies organized in harmony with the spirit and objects of this Society are eligible to membership.

SEC. 2.—They may become members at any time by furnishing the Treasurer or Permanent Secretary a certificate of membership and good standing in such local society, the certificate to be signed by the President and Secretary thereof, and accompanied by one year's dues, \$3.00.

Those who desire to attend the meeting who are not already members should bring the prescribed certificate.

3. Members desiring to read papers should notify the officers of the appropriate Sections at once.

4. A detailed program will be issued and mailed to members before the meeting.

5. Delegates to the AMERICAN MEDICAL ASSOCIATION, which meets in San Francisco June 5, will be appointed at this meeting.

The question of change in the Code of Ethics and Constitution of the AMERICAN MEDICAL ASSOCIATION is also to be submitted for instruction of delegates.

A general invitation is extended to all members of the regular profession in the State to attend the meeting and join the Society.

JOHN B. HAMILTON, *Permanent Secretary.*

PUBLIC HEALTH.

The Philadelphia Board of Health Declares Consumption Infectious and Prepares a Circular Showing How to Combat It.

The Sanitary Committee at the meeting of the Board of Health on March 6, made a report to the Board, which recommends the postponement, for the present, of the compulsory registration of cases of tuberculosis, but expresses the opinion that the disease is infectious, and recommends,

among other things, that the premises occupied by a tuberculous patient be thoroughly disinfected after death.

The report upon which the committee bases the recommendation is very strong, the recommendation very good, and the action taken conservative and judicious, at the same time showing a careful study of the subject. The report says, in part:

"There are certain incontestable facts which should have great weight in forming a decision. There is also a latitude for doubt as to the practicability and advisability of adopting, at the present time, some of the radical measures proposed for inauguration under official direction.

"Consumption is an infective disease caused by the bacillus tuberculosis. All cases take origin, directly or indirectly, from other cases. A most common mode of infection is by inhaling dry and pulverized tuberculous expectoration. It is a distinctly preventable disease. If all this be true, and it is based upon the most reliable scientific data, it becomes imperative that all known precautions should be employed to prevent the spread of the disease, and, particularly, because it is one of the most widespread of maladies.

"It would seem wise at this stage of the agitation of the subject to act most discreetly and cautiously, in view of the danger of antagonism of public sentiment (not yet sufficiently educated and aroused to the necessity of official interference), and its intolerance of publicity and official espionage, which would strike terror into the hearts of these unfortunate sufferers.

"There is a middle course that may be pursued at this time with safety and propriety, without its workings becoming offensive, at the same time that they are beneficent, and this course is proposed for adoption. Encourage registration as a preliminary to a future requirement; circulate information with regard to the means of prophylaxis, directly or indirectly; require disinfection when the attending physician so advises, and always after the removal or death of the patient."

Resolutions were submitted and adopted, to the effect that enforced registration should be postponed for the present; that circulars containing rules for the prevention of the spread of the disease be prepared, published and distributed; that physicians be earnestly requested to cooperate with the Board in the distribution of these circulars, and, further, notify it promptly, whenever disinfection is necessary; that a medical inspector visit houses where deaths have occurred and satisfy himself that they have been thoroughly disinfected, and that all cases that may be reported, be recorded in a book to be kept for that purpose.

THE CIRCULAR ON THE MATTER.

The circular on the subject of tuberculosis, which has been prepared and will be distributed, is as follows:

All cases of tuberculous disease of the lungs (consumption) take origin directly or indirectly from other cases. This is now an established fact. Infection, however, is easily provided against if certain simple precautions are taken.

The chief modes of infection are:

First and foremost—By inhaling dry and pulverized expectoration.

This is apt to occur when an ordinary pocket handkerchief is used by a tuberculous person for expectoration. When such a handkerchief is opened the dried expectoration is likely to be pulverized and diffused through the air. Thus it may be inhaled by others as well as by the patient himself, who is likely to suffer from drawing disease germs into portions of lung previously unaffected.

Another and the most common source of pulverized expectoration, is the habit of spitting carelessly and indiscriminately, as on the floor or ground. The expectoration becomes dried and mixed with dust, and then is easily carried into the air, and is breathed into the lungs or swallowed. The habit, therefore, is not merely offensive, but dangerous.

2. By using spoons, cups and other articles of the kind which have not been properly washed after having been used by tuberculous persons.

3. By kissing.

This source of infection is especially to be guarded against in the case of children.

Self-infection may occur, in addition to the ways mentioned, by swallowing the expectoration. The habit is likely to lead, sooner or later, to the infection of the intestines with tuberculous disease.

There are other modes of infection, as, for example, by

consuming the flesh and milk of animals having the disease. But this source is less common, and, as prolonged high temperature destroys the germ, if we cook our food (including milk) thoroughly, there will be no risk of becoming infected in this way.

PRECAUTIONS TO BE TAKEN.

Knowing the channels of infection, we can easily take effective precautions.

1. The sputum must be destroyed and must not be allowed to become dry. A spitting cup or flask containing just enough disinfectant solution to cover the bottom of the vessel should always be used for the expectoration. Out of doors a pocket-spitting flask should be employed.

In the house it would be well to use a pasteboard or paper cup, which should set in a china or metallic holder. This cup with its contents should be burned at least once a day; but if the expectoration is considerable, much oftener.

Pieces of linen or calico about ten inches square may also be carried. These should be used in cases of absolute necessity only, and should be burnt as soon as possible afterward. No piece should be used more than once.

2. Bedrooms that have been occupied by tuberculous patients should be thoroughly disinfected before they are occupied by other persons, and a declaration or assurance on the point should always be demanded.

If the previous occupant of the room never allowed furniture, hangings or carpets of the room to be contaminated with sputum there would be little need of this precaution. But as people ordinarily of cleanly personal habits sometimes show a surprising amount of ignorance or carelessness in this respect, the following points should be insisted on:

a. Carpets, curtains and bed coverings should have been exposed to superheated steam under high pressure.

b. The floor and walls of the room should have been properly disinfected. Rubbing with new bread, followed by the application of corrosive sublimate solution (a tablet of seven and three-tenths grains added to a pint of water) is probably the most effective practical method.

There is no danger of infection from the mere breath of a tuberculous patient. The risk is from the dried expectoration. Danger of social intercourse arises from the neglect of the precaution described.

Fresh air is of the highest importance for tuberculous persons. Hot and stuffy rooms have an evil influence over the disease. Except in special circumstances the bedroom window should be kept open by night as well as by day.

MISCELLANY.

Should be Elected.—Dr. Charles L. Thomas of Crawfordsville, Ind., is a candidate for mayor of that town.

Dr. H. C. Wilson of Goodsell Observatory, Minneapolis, Minn., has discovered a new asteroid.

Madison Board of Health.—Dr. Philip Fox has been appointed Health Officer of Madison, Wis., *vice* Dr. W. W. Gill, resigned.

The Doctor Won.—Dr. Cleaver of Council Bluffs, Iowa, was elected mayor of that city March 5.

Louisville Medical College.—There were 191 graduates at the Commencement of Louisville Medical College held March 6.

A Thirteen Class.—There were thirteen graduates at the Annual Commencement of the Northwestern Medical College at St. Joseph, Mo., March 2.

The Health Authorities of San Francisco have decided that the present morgue in that city should be condemned and will recommend that it be located in the basement of the new City Hall.

Kansas Board of Health.—Dr. B. E. Jones of Buffalo, Wilson County, has been appointed a member of the Kansas State Board of Health, to succeed Dr. H. D. Hill of Augusta, whose term expires April 1.

Investigation of American Viticulture.—Dr. Vicente Vera, who was one of the Spanish Commissioners to the World's Fair,

is said to have been instructed to examine carefully into the wine-growing industries of the United States.

Cremated at Davenport.—The remains of Dr. Casper Vitzhum of Rock Island, were cremated at the Davenport (Iowa) Crematorium according to his wish expressed just before his death.

Coroner's Office Condemned.—Dr. Keeney, the Health Officer of San Francisco, March 3 reported the city morgue and the coroner's offices therein as unfit for human occupancy. The Board of Health concurred in the report of the Health Officer and declared the building a nuisance.

The Woes of the Montagnes.—The "Montague Treatment Company" was sued at Cedar Rapids, Iowa, and on March 7 a verdict was given against them for damages amounting to \$1,000 for malpractice.

E Pluribus Quinque.—The State Board of Health of Connecticut recently appointed a committee to examine applicants for license to practice, under the new law. Of eight applicants five were found qualified.

Dean of the Dental Department.—Dr. Clarence V. Rosser has been elected Dean of the Dental Department of the Southern Medical College at Atlanta, Ga. Dr. Floyd McRae was elected President of the Faculty and Dr. L. D. Carpenter Secretary and Treasurer.

Smallpox.—In view of the possibility of the spread of smallpox, several towns have decided to erect pest houses. Negaunee and Menominee, Wis., and Dubuque, Iowa. At the latter place there is a brisk struggle going on as to the location of the institution. No property owner wants it very near him, consequently the erection of the building is yet "in the air" rather than on *terra firma*.

Army Medical Examinations.—The Board of Examiners for candidates for position in the Medical Department of the Army met at the War Department in Washington, D. C., on Monday 12th inst., to make arrangements for the examination of over fifty candidates whose applications had received the approval of the Secretary of War. As certain of the young men live at long distances from the place of meeting of the Board it was planned, in accordance with the views of the Surgeon-General, to have the examination in their physique and general education conducted at the military post nearest to their respective homes, so that no one manifestly disqualified in either of these respects should be put to the expense of a profitless journey to Washington. The Board divided the candidates into five lots, one of which should be examined weekly, beginning on Monday, March 26. But in view of the proviso in the Army appropriation bill, since then reported to the House of Representatives by its Military Committee, reducing the number of Assistant Surgeons from 125 to 90, it is understood that these arrangements will fall and the order convening the Board be revoked. This will be a disappointment to the candidates. If the Corps be permitted to retain its present membership the Board will meet and examine candidates in September to have its work finished before the commencement of the Army Medical School on November 1; but if the proposed reduction be made, few of those now candidates will realize their hopes of entering the service, for by the time another Board will be required most of them will be inadmissible on account of being over age.

Hospital Notes.

Dr. William P. Northrup has been recently appointed Adjunct Professor of Diseases of Children at Bellevue Hospital Medical College, New York.

Hospital in San Francisco.—The Ancient Order of Foresters have decided to build a hospital in San Francisco, solely for the use of the members of their order.

Dallas, Texas, Hospital.—The Health Officer of Dallas, Texas, has reported that the new city hospital will be ready for occupancy within sixty days.

St. Mary's Hospital, Minneapolis, Minn., was incorporated March 1. The provincial superioress in the diocese of St. Paul and her assistants are members of the corporation, and are to choose ten other members from the Sisters of Charity.

Attempt to Burn a Hospital.—At Topeka, Kan., March 2, an incendiary attempt was made to burn the Capital City Hospital, but the flames were extinguished without material damage. This is the third attempt to burn this Hospital within a short time.

Sleep on the Floor.—An inspection of the Flatbush (L. I.) Hospital by an investigation committee February 21, showed that "the overcrowded condition of the Hospital is reprehensible, and that on the day of inspection 195 patients were found sleeping on the floor. There were no rooms for isolation, and the wards contained more insane patients than they could conveniently accommodate."

Winnipeg General Hospital.—At a meeting of the Board of Directors of the Winnipeg General Hospital, held at the Hospital, February 26, there were present: Wm. Hespeler, President; Judge Bain, Honorary Secretary and Treasurer; Geo. J. Maulson, Thos. Bennett, Dr. Lynch, J. S. Aikins, S. Nairn and Isaac Campbell, Q. C. The accounts for the month of January, amounting to \$3,783.53, were submitted and approved for payment. The statements for the month of January were submitted and approved.

Memorial to John Hunter at St. George's.—Mr. Alfred Gilbert, R. A., has undertaken to prepare the memorial to be erected in St. George's Hospital, to perpetuate the memory of the connection of John Hunter with the institution. The subscribers to the fund who, at a numerously attended meeting were presided over by the Earl of Cork and Orrery, K. P., unanimously approved the action of the Executive Committee of the fund, may be congratulated on having enlisted the sympathy and coöperation of a sculptor so eminently fitted for the task. Mr. Gilbert proposes to execute a large bust, probably in bronze, with hands, placed on a suitable pedestal. Hitherto scant justice has been done to John Hunter in sculpture, and the rendering of an artist so original in his treatment as Mr. Gilbert can not fail to be of the highest interest. It is proposed that the bust shall be placed, tentatively, at least, in the central hall of the Hospital. We are informed that a sum of about £20 is still required, and with so admirable a prospect of a worthy monument to the great pathologist and surgeon, there ought to be no difficulty in raising the amount.—*British Medical Journal.*

San Francisco Notes.

At the regular monthly meeting of the San Francisco Medical Society Tuesday, March 14, it was voted to appropriate \$1,500 to assist the State Medical Society in entertaining the AMERICAN MEDICAL ASSOCIATION in June.

The Committee of Arrangements for the meeting of the AMERICAN MEDICAL ASSOCIATION have sent copies of the following letter to all regular physicians in the State who are not at present connected with some society recognized by the State Medical Society:

SAN FRANCISCO, CAL., Jan. 10, 1894.

Dear Doctor:—The AMERICAN MEDICAL ASSOCIATION will meet in San Francisco June 5, 6, 7 and 8, 1894. The ASSOCIATION consists of delegates and members. Each State and local society in affiliation with the AMERICAN MEDICAL ASSOCIATION is entitled to send one delegate for every ten members or fraction thereof. Any member of such societies, in good standing, is eligible to membership in the ASSOCIATION, without attending a meeting, on presentation of a certificate of membership in the affiliated society signed by its president and secretary, accompanied by \$5.00 annual dues. This entitles him to receive the JOURNAL of the ASSOCIATION.

It will advance the interest of the profession on the Pacific Coast, and will be a fitting evidence of our appreciation of the NATIONAL ASSOCIA-

TION, if we have a large representation at the meeting, and a larger accession to the membership. United effort will accomplish this, and will assure success. We therefore urge every physician who is not a member of a State or local society to become enrolled as such. If, on account of distance or other sufficient reason, it be impracticable to join an existing society, it is desirable that he unite with neighboring physicians to form a local or district society that will obtain recognition from the State society where one exists.

It will facilitate the work of this Committee if you will favor us with the name of your local or district society, its membership and the name of its president and secretary, together with the names of eligible non-members in your vicinity.

A blank application for membership in the AMERICAN MEDICAL ASSOCIATION is enclosed, which may be filled out and forwarded to R. J. Dunglison, M.D., Treasurer, lock box 1274, Philadelphia, or to this office with an additional ten cents to pay money order, when we will gladly attend to it. Membership is a prerequisite to entitle one to the privilege of reading a paper in the meeting.

Our Midwinter Fair (January to July) is assuming such proportions as will present additional inducements to visit San Francisco, and our hotel and railroad managers are supplementing these by assurances of marked reductions to members of the AMERICAN MEDICAL ASSOCIATION.

We hope the profession on the Pacific Coast will turn out *en masse* and give the ASSOCIATION a royal welcome.

R. H. PLUMMER, Chairman.

THE OFFICIAL REGISTER OF PHYSICIANS AND SURGEONS of California just issued (January, 1894), shows that 260 licenses have been issued to regular graduates, 43 to "homeopaths," and 36 to "eclectics" in 1893, while the deaths in the three classes number respectively 52, 7 and 8.

Dr. E. C. COOPER attempted to start a subscription beneficiary scheme in conjunction with his "Waldeck" Hospital, a private institution in San Francisco. His plan was to secure subscribers who would pay an initiation fee of \$5 and \$1 each month, and thus secure for themselves all the medical attendance they required without further pay. The French and German benevolent societies in this city have similar schemes, but some of the regular practitioners insisted that in organizing a private enterprise on those lines Cooper had stepped entirely outside the bounds of those much-mooted ethics of the profession.

Cooper, however, announced that he had secured as consultants Dr. Henry Gibbons, Dr. W. F. McNutt, Dr. W. S. Thorn, Dr. D. W. Montgomery, Dr. Winslow Anderson, Dr. Pichel and Dr. J. D. Arnold.

Dr. Jules Simon, Chairman of the Committee on Ethics, reported that Dr. Cooper's "consultants" had supposed that they were merely connected with the Waldeck Hospital, and not with the beneficiary scheme. The report further said that when Dr. Cooper found that his scheme was objectionable he had abandoned it at once.

Philadelphia Notes.

THE PENNSYLVANIA COLLEGE OF DENTAL SURGERY held its thirty-eighth annual commencement at noon on the 8th inst., graduating sixty-two students. Professor Henry Liffmann delivered the valedictory address, and President I. Minis Hays conferred the degrees.

THE PHILADELPHIA DENTAL COLLEGE also held its thirty-first annual commencement, on the same day, at noon, at the Chestnut Street Opera House. Prof. L. B. Howell delivered the Faculty address and Dr. Samuel H. Miller, D.D.S. gave the valedictory to a class of seventy, of whom two were women. General James A. Beaver, President of the College, conferred the degrees on this occasion.

THE PENNSYLVANIA STATE VETERINARY ASSOCIATION has just closed a successful annual meeting in this city, the sessions being held in the hall of the College of Physicians and Surgeons. Dr. W. Horace Hoskins, President of the Association occupied the chair. This meeting was largely attended and a number of interesting papers were discussed. The next meeting will be held at Harrisburg in September.

THE D. HAYES AGNEW MEMORIAL WARD of the Hospital of the University of Pennsylvania will probably be built during the coming summer. It is estimated to cost over a hundred thousand dollars, of which the greater part has been collected, although the opportunity of contributing to this memorial is still open to those desirous of joining in this good work. It is in the form which Dr. Agnew himself would have chosen, as it is known that he was averse to the

posthumous fame to be gained by marble busts, or memorial shafts, which he regarded as monuments to vanity.

THE TRUSTEES OF THE UNIVERSITY OF PENNSYLVANIA have recently received a large sum of money from Messrs. Alfred C. William W., and Chas. C. Harrison for the purpose of erecting a new chemical laboratory, which will be called the "John Harrison Laboratory of Chemistry." The donors are the grand-children of Mr. John Harrison now deceased, who was a pioneer in industrial chemistry in this country, and one of the Trustees of the University. Mr. Harrison, who was on intimate terms with Priestley, was influential in securing his election to the Chair of Chemistry in the University as the successor to Dr. Rush.

APPENDICITIS.—As a contribution to the discussion on appendicitis now going on in the journals, it may be mentioned that Dr. T. G. Morton successfully operated upon an adult patient who had had eight attacks. The operation was done in the interval when no local signs of inflammation were present. In another case that of a boy 12 years of age living out of the city, Dr. Morton operated successfully although he had with him only the instruments contained in a small pocket case; there being no time to send home for his instruments and antiseptic outfit. Dr. Morton has observed in a number of cases of acute appendicitis, that temporary glycosuria occurs, the cause of which has not been very clearly made out.

PROF. J. M. DA COSTA delivered his second and final lecture, before the medical students of the University of Pennsylvania, on the 6th inst. His subject was "Lithemia," which he declared to be a modified form of gout, but quite distinct in its manifestations from the latter disease. It is the form which gout particularly assumes in this country. It may be acquired by over-eating and deficient exercise, or it may be inherited from gouty ancestors. Vertigo is a prominent symptom; depression of spirits is another. In the treatment, he advised the use of very little meat and avoidance of sugar and alcohol, (except that elderly subjects might take with their meals, whisky and water, or a sound claret). Carbonate of lithia is a useful remedy which may be combined with nux vomica. Laxatives, especially salines are advisable.

THE COUNTY MEDICAL SOCIETY devoted its meeting of February 28, to the consideration of papers on "American Grip," the "Ancient Lore of Influenza," and "Influenzal Neuritis." Dr. Carl Seiler maintained his view that American grip was distinct from the Russian influenza. He proposed the name of "epidemic myxœdema" for the new disease, which is distinguished from influenza by the absence of catarrhal symptoms and of continued fever. The most prominent lesion of American grip is submucous infiltration of the mucous membranes, especially occurring in the throat often threatening suffocation, and patches of false membrane may be seen on the tonsils. The nervous symptoms are very marked, including neuralgic and myalgic pains in the head and extremities. He had found so much benefit from the use of benzoate of sodium in these cases as to regard it as a specific. Quinin he pronounced useless, even positively injurious by increasing the cerebral symptoms.

Erratum.—In the editorial article on "Medical Education in the United States," printed in the JOURNAL of March 17, occurs the following paragraph:

"In 1880 the average duration of the lecture term was a fraction over 22 weeks; of the 56 colleges examined, 38 had terms of less than 24 weeks and 18 had terms of 24 weeks or more. During the current sessions, 1893-94, the average duration of the lecture term is 28.19 weeks; only 10 schools have terms of six months or more."

The last sentence should read, as originally written:

During the current sessions, 1893-94, the average duration of the lecture term is 28.19 weeks; only 10 schools have

terms of less than 24 weeks, while 126 schools have terms of six months or more.

Gentlemen preserving their JOURNALS, are requested to refer to this correction on the article itself.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from March 10, 1894, to March 16, 1894.

Capt. WALTER W. R. FISHER, Asst. Surgeon U. S. A., is granted leave of absence for six months, to take effect on or about May 1, 1894, with permission to go beyond the sea.

Major JOHN H. BARTHOLF, Surgeon U. S. A., retirement from active service, March 13, 1894, by operation of law, under the provisions of the Act of Congress approved June 30, 1882, is announced. By direction of the President.

First Lieut. PAUL F. STRAUB, Asst. Surgeon U. S. A., is relieved from duty at Ft. Riley, Kan., and ordered to report in person to the commanding officer, San Carlos, Ariz., for duty at that post, relieving First Lieut. HARLAN E. McVAY, Asst. Surgeon U. S. A. Lieut. McVAY, on being relieved by Lieut. STRAUB, will report in person to the commanding officer, Whipple Bks., A. T., for duty at that post.

A board of officers to consist of: Lieut.-Col. CHARLES R. GREENLEAF, Deputy Surgeon-General U. S. A.; Lieut.-Col. ALBERT HARTSUFF, Deputy Surgeon-General U. S. A.; Major BENJAMIN F. POPE, Surgeon, is appointed to meet at the call of the President thereof, at San Francisco, Cal., for the examination of Capt. WILLIAM R. HALL, Asst. Surgeon, with a view of determining his fitness for promotion, as contemplated by the Acts of Congress approved Oct. 1, 1890, and July 27, 1892. Capt. HALL will report in person to the President of the board for examination at such time as he may designate.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending March 17, 1894.

Surgeon L. W. SPATLING, ordered to the U. S. S. "Alert."

Surgeon E. J. DEAR, ordered to the U. S. S. "Raleigh."

Asst. Surgeon E. M. SHIPP, ordered to the U. S. S. "Raleigh."

P. A. Surgeon W. C. BRASTED, ordered to hold himself in readiness for U. S. S. "Columbia."

Surgeon G. E. H. HARMON, from the U. S. S. "Yorktown," and three months' leave.

P. A. Surgeon G. P. LUMSDEN, ordered to the U. S. S. "Yorktown."

ORIGINAL ARTICLES.

THE PSYCHO-PHYSICAL RELATIONS OF MAN, CONSIDERED FROM THE STANDPOINT OF A PRACTITIONER OF MEDICINE.

Read before the Binghamton Academy of Medicine Oct. 19, 1893.

BY JOHN M. FARRINGTON, M.D.

BINGHAMTON, N.Y.

A recent number of the *Literary Digest* states that, "on both sides of the ocean, and in every language that has a periodical literature, psychic phenomena, the occult, the mysterious, are being discussed with an interest, a freedom and a voluminousness heretofore unknown. There is undoubted evidence that this interest is growing and spreading, and that with its widening circle have been developed new sources of information derived from personal experience heretofore untold. A spirit of earnest and impartial investigation seems to be taking the place of the credulity which unquestioningly accepts and the skepticism which arbitrarily condemns without trial. Evidence is being gathered, personal experience generalized, and phenomena which have been called 'supernatural' are being examined with scientific care and accuracy."

The *Medico-Legal Journal* says:

"The marvelous growth of interest in psychological subjects from year to year promise a wide outlook for the future in the ready adaptability of facts, as fast as obtained, to the most absorbing questions of life. A complete revolution in educational methods is pending; the medical and legal aspects of criminals and of the insane are assuming new and strange complications, and great light seems ready to break upon many moral and religious problems. Not a month passes without report of better means of observation and experiment, and the colleges and universities are constantly adding to laboratory apparatus, and to the breadth and extent of their elective courses in experimental psychology. All indications point toward developments in the near future which will be of signal value in their bearing upon science and man."

Expressions of this character and the interest attaching to this subject has led me to re-write a paper prepared by me thirty-six years ago and in which I have found no reason to make any material change. I trust that its statements will not be without practical interest to you.

The veterinarian, in the study and practice of his science finds much of profound interest in his subject. The study of the structure and the functions of the animal framework is full of attraction; so likewise is the application of medicaments in the treatment of its derangements and surgical appliances, and operations when demanded, to restore, so far as possible, the integrity of its configuration and the normal action of its functions.

What distinguishes the practice of our profession in treating the diseases and repairing the injuries of the *genus homo* from that of the veterinarian? From one point of view, his is the most comprehensive science, for while our attention is directed solely to one family of animals, the veterinarian, in this country at least, attends to two species, belonging not only to different families, but to two distinct orders of animals. True, the being who constitutes the subject of our study and practice stands preëminent in the list or classification of animals, as made by zoölogists; and hence we find that he is more complete in structure, with an increase in the number and diversity of his functions, consequently requiring a greater amount of study to understand his anatomy and physiology than is requisite for that of lower animals. When we state that man stands at the head of all created beings we do not mean to affirm that he combines in himself every physical attribute in the perfection that is found in all animals below him. For sight he can not compete with the eagle, for scent with the hound, for swiftness with the deer, for strength or size with the elephant or the horse; yet in man is found the sum of all these qualities in a greater perfection than in any of the lower animals, and though many animals may excel him in the enjoyment of one of these senses, yet in the harmonious development of all the physical powers man stands unrivaled.

Yet I conceive that were we to consider man merely as an animal, our vocation would be but little more important or ennobling than that of the veterinarian. But there is an interest attached to the study of the human body that transcends all that can be presented by any or every other member of the animal creation, important and interesting though they be. What is this element characteristic of man which distinguishes him in so marked a manner from all other animals and gives to the study of *human* anatomy and physiology supreme importance; investigations in regard to the lower order of animals being most interesting and important when they can aid us in understanding man? We know that it is naught else but the mind. This superadded element constitutes the true worth of man and attaches to him immeasurable importance. Hence for centuries has he been the subject of protracted study and investigation, and thanks to the indefatigable labors and researches of our honored ancestors in the medical profession, there has come down to us for our inheritance and appropriation a rich fund of useful knowledge upon everything pertaining to man. May we so live as to show ourselves worthy of such an important trust and be able to say at the close of our earthly career, that we have not allowed the talents committed to us to rust but have like faithful stewards added interest thereto.

Our libraries groan with the weight of accumulated

volumes of classic medical literature; we have the sum total of the lifelong labors of hundreds of able and earnest investigators of the structure and the functions of the human body, and of the application of therapeutics and surgery to the treatment of its ailments and deformities; but does inquiry stop here? Have all the questions in reference to the matters of medical science been settled? By no means, and is it not exceedingly gratifying to know that never before were there such an array of intelligent and active minds at work in investigation and experimentation as at present? Every year, yea, every month teems with discoveries or improvements more or less important as bearing upon disputed points in our science. The field for discovery is yet broad, much, very much is still unknown, and much of time and labor must continue to be expended in these investigations ere our science may be termed a perfect one. For there are many phenomena in the animal economy that yet remain unsolved and such there probably will ever be to challenge the investigation of the student and the philosopher.

It is the *worth* of man, that has led to such laborious study and protracted investigation, both in ancient and modern times, to obtain a knowledge of his constitution and thus be prepared to apply means and employ measures to preserve or restore health to his body and prolong a life so dear to its possessor, and so important to the world. Herein, then, does the medical profession rise above the veterinary. The one has to care for rational beings, the other for animals destitute of reason. The life of the latter bears no comparison to that of the former, and hence the responsibility of treating the diseases of the cow or horse will differ very materially from that imposed upon him who assumes to practice upon man. This fact, then, is the one that elevates our profession, viz: That there is a union of the mind with the body, and he who ignores the mind of man in treating his diseases may well be classed with the veterinarian.

It is not our purpose to enter into a metaphysical discussion of mind and matter, but briefly to notice some of the relations existing between them and the bearing which these known relations have upon the practice of medicine.

Body is animated matter, while mind is incorporated spirit; both are of necessity intimately connected in the phenomenon of life, yet of the nature of this connection we know nothing. But, as an able investigator has said: "As the naturalist knows and applies electro-magnetism in its relations, without comprehending its essence, as the astronomer calculates the movements of the planets without knowing their nature, so can we duly appreciate spirit and matter in their relations to each other as body and mind without being able to explain their nature or their relations."

We have presented to us two distinct theories or doctrines upon this subject, each having their supporters though they are clearly antagonistic. The one denominated the materialist would have us believe that all the operations of the mind are but manifestations of changes that are being produced in the substance of the brain; thus reducing man to a mere machine the movements of which depend upon its *material* construction. With this view of the

subject we see that man's mental development is to be attained only by those things which tend to develop his physical system. He has no power of self-government or direction but must act in obedience to the material changes which his body is undergoing.

The other doctrine called the spiritualist, teaches that although the mind has a connection with the body it does not depend upon corporeal conditions for its *operations*; though its *manifestations* may be interfered with by the defects of the body, still its existence and its operations are always independent of any changes in the physical system. And, also, that it gives to man complete power of self-government and culture, and, contrary to the previous doctrine holds him responsible for all his acts. This doctrine carried still farther would teach us that all mental diseases are not perversions of the mind, which remains perfectly sound, but merely derangements of the bodily instrument. We recognize important truths presented by both of these theories and yet we can not but observe that both are opposed to facts of which we are daily cognizant in our own experience and observation. To notice first the materialist's doctrine, we know that there is an intimate relation existing between the mind and body, that physical changes do affect the psychical conditions; yet we can not go so far as to say, as the alienist, that the mind's manifestations are nothing but the evidence of molecular changes taking place in the brain; our own consciousness appears to disprove it. Neither can we fully adopt the spiritualist view, for while we steadfastly believe in the distinct existence of the mind and its power over the conduct of man we must deny the assertion that its manifestations are not influenced by physical changes, for we are made aware from our own individual experience as well as from the testimony of others, that the mental operations are influenced by differing states of the physical system. We every day witness phenomena to prove this assertion, e. g., a little alcohol or opium in the blood proceeding to the brain quickens the intellectual faculties and exalts the passions, then suspends the controlling power of the will and finally extinguishes for a time all mental activity; that the deficient elimination of the constituents of the bile from the circulatory fluids tends to weaken the intellectual powers, and to induce depression of spirits even exciting the desire of self-destruction; also the perverted reasoning of the delirious from fever and the melancholic pictures drawn by the hypochondriac. Nor can we doubt, if we examine the subject attentively, that the development of the mind and its subsequent improvement, depends somewhat upon the healthful activity of the corporeal organism. Finally, therefore, we are led to embrace a portion of each doctrine, while at the same time we must reject other parts of both. We believe that the mind possesses an independent existence, but that its operations are modified by corporeal conditions. That as it possesses an influence over the physical system and modifies its functions so in turn does the condition of the body affect the psychical states. In fact how many affections of the intellect, of the temper, or of the passions are clearly traceable to a perverted condition of some part of the bodily system. Our very familiarity with this class of phenomena has been an obstacle to our deeper scrutiny into its nature. Much has been written upon this subject

¹ Alienist definition of mind: "The mind is simply the functional activity of the physical elements of the brain—a product of brain energy—that has no tangible independent existence."

without elucidating any new truths, and consequently our knowledge upon the points in question remains very limited. We have an abundance of theories offered to explain the nature of the mind, and the relation that it sustains to the body, but these are satisfactory only to the few supporters which each particular doctrine has. The subject is of grave importance and involves the most solemn issues of human life and yet we probably will ever remain ignorant of the great facts connected with the spiritual essence of the mind and the true nature of its connection with the material essence of the body. In the language of the bard we must be content to say:

"Hence 'tis we wait the wondrous cause to find,
How body acts upon impassive mind;
How fumes of wine the thinking part can fire,
Past hopes revive, and present joys inspire.
Why our complexions oft our souls declare,
And how the passions in the features are;
How touch and harmony arise between
Corporeal figure and a form unseen.
How quick their faculties the limbs fulfill,
And act at every summons of the will;
With mighty truths mysterious to descry
Which in the womb of distant causes lie."

"There is one view of the connection of mind and matter," says Professor Dugald Stewart, "which is perfectly agreeable to the just rules of philosophy. The object of this is to ascertain the laws which regulate their union without attempting to explain in what manner they are united." This relation has probably been most satisfactorily explained by those who compare the mind's action upon the body with that of vital force. For example, in reference to emotional excitement it is a well observed fact that any violent disturbance of the feelings quickly subsides when these unrestrainedly expend themselves (so to speak) in their natural expression. There is an instinctive restlessness, or tendency to general bodily movements in some individuals when they are suffering under emotional excitement, the indulgence of which appears to be a sort of safety valve for the excess of nerve force, while the attempt at its repression is attended with an increase in the excitement. Most persons are conscious of the difficulty of sitting still when they are laboring under violent agitation, and of the relief that is afforded by active exercise, and this is particularly the case, when the movements are such as naturally express the passion that is excited.

As we are ignorant of the precise mode of union of the immaterial mind and the material body we can not properly speak of the former as occupying any space or organ of the latter. Nevertheless we have abundant evidence to induce us to believe that the cerebral hemispheres are the organs of the mind. Not that the mind resides within the encephalon, nor that the brain is essential to its action but that the cerebrum is in some mysterious manner the organ in and through which the mind manifests itself to other minds. As Professor Mayo has said: "The brain in the higher animals and in man is the essential organ, in which through a mysterious union, sensation and volition, instinct and reason temporarily reside; if its function be extinguished death is the result, whether we regard man whose death is the separation of the body and of an immortal spirit, or animals whose death is the suppression of a narrower consciousness."

Yet while attaching so much importance to the

hemispheres of the brain, physiology teaches us that the other parts of the nervous system are the real organs of common sensation, and that still higher manifestation, the perception of the senses; though it is to the brain that all these sensations and impressions are conveyed; as the great center of animal life it becomes cognizant of and directs every voluntary manifestation of vital force. When we examine the location and the phenomena of the five senses, viz: Touch, taste, smell, sight and hearing, we are led to the conclusion that these form collectively the receptive medium of the organism by means of which the mind becomes acquainted with the external world, and that the nerves affording the sensations and impressions of external objects are but media of communication from the external world to the mind. The hand does not feel, the tongue does not taste, nor the eye see, but the mind through the medium of these organs and the brain feels, tastes and sees. There are therefore two systems of perceptive faculties in man; one called body, the other mind. The former is dependent upon external excitements, the whole of which we collectively call nature. The latter is dependent upon internal excitements the whole of which we collectively call spirit.

Were we to consider fully the psycho-physical relations of man we would need first to study them as belonging to man in general; next it would be essential to examine them as they differ in distinct classes of men and in individuals. Age, sex, climate, temperament, education, occupation, condition, habit and idiosyncrasies all and each exert an important influence upon the individual and modify his or her psycho-physical relations. The limits of our paper will not permit so comprehensive a treatment of the subject, and we shall needs consult brevity in presenting illustrations of these interesting relations.

We will first notice how changes in the physical system affect the psychical, and secondly, how mental states influence the physical organism. The blood sustains an important relation to the mental condition but it doubtless acts indirectly through its influence upon the nervous centers. Experiments upon animals prove that the blood influences their nature, although the psychical functions of animals do not admit of a well founded comparison with those of man. The wilder animals into which the blood of tamer ones had been transfused showed themselves to be of milder nature and the older animals into which the blood of younger ones had been introduced to be more lively and active. Thus experiments upon man have been made, and developed much of interest. One man who had lost his memory, was drowsy and indolent, after transfusion, became much more lively; another who lay in a state of lethargy accompanied with convulsions, after the injection of some calf's blood became quite conscious; another was cured of insanity by transfusion and a fourth of paralysis and mental debility. The state of the blood vessels influences the psychical condition. A replete and active condition of them stimulates to activity the nervous filaments encompassing them, and thereby heightens the psychical affections. Yet a plethoric condition of the vascular system causes drowsiness, mental lassitude and indolence. Vacuity and a relaxed condition produces an opposite effect similar to the tone of mind which exists subsequent to venesection or profuse hemorrhages;

vertigo and syncope or at least mental inertion. If the loss of blood be very great, the syncope is very profound and the return to consciousness is manifested by delirium, convulsions and death.

A peculiar delirium is one of the most common effects of excessive vascular depletion. A corrupt state of the blood, whether it arises from a sporadic, miasmatic, contagious, or any other cause has the effect of depressing the spirits. This is a fact so well known, that all of our works on the practice of medicine mention this change in the psychical condition, when classifying the symptoms of certain diseases; thus a knowledge of this effect is in many cases an important aid in forming a diagnosis of the malady present and also which stage of the disease has been reached. The exciting or depressing effects of alimentary and medicinal substances as produced through the blood upon the mental state has been recognized by every one of us. M. Otto, in a long series of careful experimentation, demonstrated to his satisfaction that each drug beside its general and special action upon the organs of the body, exerts at the same time an effect upon the mental faculties. Stimulants increase to a greater or lesser degree the quantity of blood which flows to the brain in a given time; as a consequence the whole brain is excited, provided the stimulation does not exceed a certain limit; but the local excitement differs according to the stimulant employed. Thus ammonia, musk, castor and ether increase the power of imagination and perception; the empyreumatic oils cause peevishness, melancholy and visions. Phosphorus acts upon the generative functions; so, likewise, does iodine and at the same time induces sadness, cathartics excites, while camphor diminishes the sexual propensity. Arsenic causes melancholy, gold hope, mercury increases mental sensitiveness and carbonic acid gas, placidity. Among the narcotics opium stimulates the sexual desires, the intellectual powers and the imagination. Belladonna dulls the mental faculties; hyoscyamus causes moroseness, jealousy and violence, cicuta weakens the understanding; digitalis diminishes and saffron increases the sexual desires; cannabis causes calmness, and amanitia muscaria courage. Tobacco operates in the same manner as opium. A dose of nitre is said to convert a state of cheerfulness into low spirits. Professor Otto also affirms that if the psychologic action of medicines were better known medical men might be able to vary their exhibition according to the character and mental peculiarities of their patients. The treatment of the various kinds of monomaniacal derangements also might be improved; and it is not improbable, that even a favorable change might be wrought on certain vicious and perverse dispositions which unfortunately resist all attempts at reformation whether in the way of admonition or even of correction.

The respiration being intimately connected with the circulation can not fail to exert through the latter an influence upon the psychical condition. The unimpeded function of the lungs in the respiration of pure air has a tendency to induce a cheerful and happy frame of mind, while their impeded action induces a feeling of mental depression. The inspiration of certain gases acts as a stimulus to the intellectual faculties whilst other gases produce depressing effects when inhaled. A remarkable difference has been noticed in the psychical condition of those

who live in different climates. The courageous and cheerful people of the mountainous region contrast strongly with the effeminate and morose inhabitants of lowlands and the crowded portions of great cities. This influence even affects dreaming, the images that float before the eye being frightful and unpleasant when the respiration is impeded, while they are pleasing and beautiful when it is free.

The skin is rightly considered as having psychical relations because of its intimate connection with the respiration and circulation. Its function of elimination, if impeded has a depressing effect upon the feelings, while if performing well its office a sprightly and cheerful condition of the mind is induced.

The function of digestion has an especial influence upon the mind. This is clearly evidenced in the change which takes place in the psychical feelings when a person languid from fasting has partaken of a full and wholesome meal. It is a common saying that if you wish to obtain a favor of, or strike a good bargain with a man, interview him *after* his dinner, when a full meal has put him in a more genial and generous frame of mind than you would have found him had you approached him only one hour sooner. Though moderation in eating has the effect of favorably inciting the mental faculties, the consequence of excessive indulgence is to paralyze them. Some persons attach so much importance to the pleasures of the table, which so much absorbs their time and attention that they are rendered unfit for intellectual exertion—they live to eat until they truly become

"Fixed like a tree to some peculiar spot,
To draw nutrition, propagate and rot."

Vegetarians claim, and perhaps with some show of proof, that animal food has a tendency to stimulate the passions, and animalize the nature, while a vegetable diet has a more refining influence upon the intellect and morals.

An obstruction of the normal excretions is antagonistic to a benevolent and cheerful disposition. "Could we penetrate into the secret foundations of human events, we should frequently find the misfortunes of one man caused by a morbid condition of the intestines of another, whom the former endeavored to inspire with sympathy in his fate at a moment when the frame of mind of the latter was affected by impeded secretion. An hour later and his fortune would have been made." The peevish, morose and often melancholic mood of the dyspeptic is too frequently observed to require other proof of the importance of a healthy action of the digestive organs to a pleasing and cheerful state of the mind.

The sexual function is perhaps the most potent of the physical influences upon the mental condition. The physical metamorphosis which takes place with puberty itself is too great to escape the notice of the most careless observer. It is then, as the German author Feuchtersleben has said, that, "the mind of the young man is powerfully impelled in the direction of the will, that of the maiden in the direction of feeling; images of undefined delight float before their minds; the enchantress, Fancy, reigns in all her loveliness; soothing and rapturous emotions alternate in a constant tumult of ecstasy; and love as a passion, with flattering but despotic hand—fortunate those who are able calmly to guide it—seizes the scepter. When happily controlled, whether designedly through education, and self-reflection, or undesignedly by a harmonious proportion of the de-

sires in the natural disposition, love becomes the source of the most beautiful psychical developments and he who never loved, is, or will become egotistical, mean, narrow-minded, covetous, timid, and but too often an unnatural sensualist. If ill directed the terrible passion becomes a source of most deplorable sufferings."

The gratification of the sexual desire has a decidedly psychical effect. If rationally indulged it exerts a wholesome influence upon the mental powers, while if inordinately gratified produces exhaustion of nervous power, mental depression and if carried to the extreme a total loss of every mental quality. Frightfully large is the list of victims of excessive sexual indulgence. Physical health and strength have been prostrated by it, intellectual powers have been totally destroyed, the moral element of the nature has been entirely subverted and a pitiful wreck of being has been left to drag out a most miserable existence in melancholy or it may be in insanity or idiocy.

Menstruation is in many women productive of mental changes. Pregnancy is marked by its peculiar longings. The climacteric changes in some females give occasion to an altered and often to a melancholic frame of mind.

We will now proceed to notice the influence exerted by the mind over the physical system. It is a phenomenon which we all experience personally, observe continually in others, reflect upon but little and act upon far less than we might. Few have formed any adequate estimate of the source of bodily ills which have their origin in the mind. Physicians continually concentrating their attention upon the physical are prone to neglect the mental causes of disease; and probably not infrequently subject a patient to heroic medication, the true origin of whose malady was a deep-rooted sorrow which a moral balm alone could reach. In considering the influence of the mind upon the body, we would still further define the mind as the superintending, the guiding power over corporeal manifestations; it directs all the movements of the body, over which it has complete control; it is to the body what the engineer is to the steam engine, the body being but a mere machine suited to develop the operations of the mind and preserved and kept in order by the organic functions.

We assert that the mind derives none of its faculties from the body; it only employs the senses and their relation to the brain to form ideas, and it inherently possesses the power of so doing. The mind is dependent upon the body and external things for its knowledge in regard to them, but after that knowledge has been once acquired it is retained and may be recalled at pleasure. In the language of the great Abercrombie we would say: "The mind remembers, conceives, combines and reasons; it loves and fears and hopes in the total absence of any impressions from without that can influence in the smallest degree these emotions; and we have the fullest conviction that it would continue to exercise the same functions in undiminished activity, though all material things were at once annihilated." This opinion does not conflict with what we have previously said of the mind being influenced by external objects or corporeal conditions. Our own individual experience is constantly giving us proof of the correctness of both of these opinions, viz.: Of the dependence of the mind upon the body for its powers of manifesta-

tion and its independence of material things in the exercise of the qualities above mentioned, yet it is bound to earth for a purpose known only to the Great Creator.

But, to resume more directly our subject—the influence of the mind on the body—we would first observe that *feeling* exercises a marked influence over the animal economy, and when of a disproportionate character may become a great excitant or depressant. Many instances are recorded where death has been produced by sudden joy, others again by sudden grief. Sophocles, at an advanced age, and in the full possession of his intellectual power, composed a tragedy, which was crowned with such success that he died through joy. Chilon of Lacedemonia, died from joy, whilst embracing his son, who had borne away the prize at the Olympic games. Juventius Thalma, to whom a triumph was decreed for subjugating Corsica, fell down at the foot of the altar, at which he was offering up his thanksgiving. Fouquet, upon receiving the intelligence of Louis XIV having restored him to liberty, fell down dead. The Roman matrons after the battle of Cannæ, on seeing their sons whom they supposed had been killed, dropped dead upon the spot. These I have quoted from ancient records but every day, almost, brings us reports of like instances happening all about us. Fewer cases of sudden death from grief have been recorded, a longer time having elapsed after the cause of the emotional excitement before death ensued. Continued grief is the cause of many organic diseases. Many persons have become insane in consequence of being suddenly reduced to poverty, while on the other hand from a sudden accession of wealth, many have shared a like fate and become inmates of a lunatic asylum. Excessive feelings of displeasure when protracted produce a deficiency of innervation and quite a list of pathologic conditions have been attributed to this cause, e.g., muscular debility, dyspnea, typhus, amenorrhea, chlorosis, dropsy, scurvy, tuberculosis, scirrhus, medulla sarcoma, etc. Some might reasonably question the assertion that mental feelings are capable of producing such pathologic conditions, for it is a matter difficult to prove, and yet there are doubtless many, very many cases of disease induced by mental conditions when we are not aware of the true cause. Some silent grief is gnawing at the vitals, and inducing disease varied in kind and degree, and in many cases causing death where no one, save the sufferer, knows the cause of his malady.

We are too apt to overlook the mental condition of our patients and the mental causes of their diseases. Here is a field for exploration wide and interesting, the psychologic causes of disease. "If a patient dies," says M. Reveille-Parise, "we open his body, rummage among his viscera, and scrutinize most narrowly all the organs and tissues in the hope of discovering lesions of some one sort or another; there is not a small vessel, membrane, cavity or follicle which is not attentively examined; the color, the weight, the thickness, the volume, the alteration, nothing escapes the eye of the studious anatomist. He handles, touches, smells and looks at everything; then he draws his conclusions one way or the other. One thing only escapes his attention; this is, that he is looking at merely organic effects, forgetting all the while, that he must mount higher to discover their causes. These organic alterations are observed perhaps, in the body of a person who has suffered deeply

from mental disease and anxiety; these have been the energetic cause of his decay; but they can not be studied in the laboratory or the amphitheater. . . Many physicians of extensive experience are destitute of the ability of searching out and understanding the moral causes of disease; they can not read the book of the heart, and yet it is in this book that are inscribed, day by day and hour by hour all the griefs and all the miseries and all the vanities and all the fears and all the joys and all the hopes of man, and in which will be found the most active and incessant principle of that frightful series of organic changes which constitute pathology."

(To be continued.)

THE THERAPEUTIC VALUE OF WEAK LENSES.

Remarks made in opening the discussion at the meeting of the Chicago Ophthalmological Society, March 13, 1894.

BY F. C. HOTZ, M.D.

CHICAGO, ILL.

The editorial on "Superfluous Spectacles" which a few weeks ago appeared in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, very justly and ably criticised the tendency, manifested in the practice of many oculists of the present day, to prescribe spectacles in every case of asthenopia. While formerly "weak eyes" have too often been regarded as the result of gastric disorders or systemic weakness, oculists of the modern school are evidently going to the other extreme in assuming anomalies of the refraction or the ocular muscles to be the only sources of discomfort in the use of the eyes. While formerly patients with "weak eyes" have often received unnecessary medicines, they now often receive superfluous spectacles.

I fully agree with the writer of that editorial, that it is time to call a halt to this one-sided practice. In my clinic it has always been my aim, at every suitable opportunity, to impress upon the minds of my hearers the fact that the complaints of "weak eyes" may be due to a great many other conditions (local and general) independent of the refraction.

But while I am in perfect accord with the intent and purpose of the editorial, I can not sustain the position the writer takes in regard to the lowest degree of ametropia which can be considered as the cause of eye strain; I can not agree with him in drawing the line of usefulness against the glasses of very low power; and I wish to present to you the clinical facts in support of my opinion on this very important and interesting question.

The statements in that editorial to which I wish to take exception are the following:

1. That the cases in which half a dioptre of astigmatism leads to discomfort or headaches are exceptional and occur, as a rule, only when the general health is below par.

2. That the 0.25 cylinders or spherical glasses less than + 0.75 D. are merely of mythical value.

A careful study of my own observations has led to different results; it has led me to regard the 0.50 hypermetropic astigmatism as one of the most frequent, if not the most frequent source of eye discomfort and headaches caused by refractive errors. But inasmuch as the editorial admits that this degree of astigmatism is occasionally a disturbing factor, and that its correction may benefit the patient; inasmuch as it there-

fore concedes the propriety of prescribing the $\frac{1}{2}$ D. cylinders under certain circumstances, I shall not discuss this point any farther, but confine my remarks to the second statement, which absolutely denies the efficacy of the 0.25 cylinder and of spherical lenses less than + 0.75 D. If such weak lenses have really no therapeutic value they should justly be denounced as "superfluous glasses;" if they have any value it behooves those who have tested their efficacy to accept the challenge to furnish convincing proofs for the same.

The mere fact that in a large number of cases of eye discomfort these low degrees of refractive errors are found, proves nothing, since we know these slight departures from emmetropia are so very common in the human eye. To assume that the patients would have returned for further treatment if the glasses prescribed had not given relief, is not an argument worthy of notice. And even the mere statement that the patient was relieved is in itself not sufficient evidence for the curative power of these glasses. If such glasses are prescribed to a patient suffering from slight blepharitis, or chronic conjunctivitis, or conjunctival irritation due to lachrymal obstruction or nasal catarrh, and his asthenopic complaints disappear under the treatment of these affections, we should not feel inclined to attribute the relief of the eye discomfort to the use of the glasses prescribed, but should rather consider them superfluous under such circumstances. Or if a patient has been working almost constantly by artificial light, and changes his habit after he received the glasses, we certainly could not regard the relief in such cases as convincing proof for the efficacy of the glasses.

But if all local or distant conditions which we know to produce ocular distress independent of refractive errors, are absent, or have been removed without restoring comfort to the eye; if the eyes are used under precisely the same conditions after the glasses have been prescribed as they were used before; or if an irritability of the eyes has resisted all treatment but is speedily relieved by glasses; then, and then only, we are warranted in attributing the relief of the eyes to the correction of the existing slight refractive errors. These conditions have been strictly adhered to in every one of the cases I now wish to present as clinical evidence of the therapeutic value of weak lenses. And from the fact that among the many cases of asthenopia and headaches I have seen in the last two years, there are only fifty cases in which I have prescribed such weak glasses, this fact alone may assure you that I have not prescribed glasses whenever a small refractive error was found, but that I have carefully considered all the conditions of the case before I decided that the use of the glasses was indicated.

In order to confine myself strictly to the question at issue (the value of sphericals less than 0.75 D. and 0.25 cylinders) I have selected cases only in which 0.25c, 0.50 D., or combinations of 0.25 or 0.50 with 0.25c were prescribed.

In all patients under 40 years, the refraction was taken under the influence of cocain and homatropin, but the eyes were tested again after the effect of the mydriatic had disappeared, before the glasses were prescribed.

To every patient who had not afterward reported, a letter was sent, requesting him to inform me whether he had used the glasses and whether they

relieved his complaints. By these means I have secured the desired information in thirty cases.

I have divided the whole series of fifty cases into four groups according to the different kinds of discomfort of which the patients chiefly complained.

But I do not propose to give a full report of all the thirty cases; I think a selection of a few cases from each group will answer our purpose as well and will be less tiresome.

I.—INDISTINCT VISION. TWO CASES.

Usually people with a slight degree of astigmatism do not experience any trouble in distant vision; but in the case of a lady, 33, whose left eye was amblyopic, the slight disturbance of vision in the right eye was decidedly annoying; V = 20-30 which was improved to 20-20 by +.25c 110.

The other case of this group is a very instructive instance to show how sensitive some eyes are to the accurate correction of a slight refractive error.

Case 2.—A gentleman, 46, has been using —.75 D for distant vision since twenty-five years; but though he can see with the glasses pretty well, they do not give him that clear and easy sight to be perfectly satisfactory. He can read 20-20 with —.75, but the letters are not clean cut; with —.50 V decidedly more indistinct. The round apertures of my astigmatometer appear horizontally oblong with —.75; and vertically oblong with —.50; but perfectly round with —.50 C 25c 180; and with these glasses the test types and distant objects are perfectly clear. He has used the new glasses now a whole year with the greatest comfort and perfect satisfaction.

2. *Great irritability of the eyes; constant scowling and winking; sensitiveness to light; in reading the eyes become red, smart and burn and weep.* 12 cases; reports received from nine; all satisfactory.

Case 25.—Boy 12, constant frowning; eyes red and lids swelling after reading a short time. Refraction + 50 = + 25c 180; ordered + 25c for constant use. Was relieved, and because his eyes had been doing so perfectly well he left off his glasses several months ago; but after a few days was compelled to wear them again because the old symptoms had returned.

Case 33.—Girl, 15; dull pain in eyes; constant winking; very sensitive to light; mild conjunctivitis. Refraction + 50. Treatment removed the conjunctivitis in six weeks; but had no effect upon the other complaints; thus + 25 was prescribed for constant use for trial. The glasses brought relief at once; and after one year she reports "they still continue to do me good service."

One of the most convincing cases, I think, is the following:

Case 40.—Bookkeeper, 20; since more than a year has not been free from eye discomfort. After a few hours' work they burn and smart, and often a dull pain compels him to stop work in the afternoon. Very sensitive to light, can not read at all at night. Marked conjunctival irritation and slight fullness of the retroarsal folds of upper lids. Refraction —1 = — 25c 180. Conjunctiva was treated; and while patient was not working his eyes rapidly improved; but when he went back to his books the old discomfort returned. After four months' fruitless treatment, + 25c 90 was given for near work, and the topical applications were discontinued. This was six months ago; and he has been working over his books every day without the slightest discomfort.

3. *Asthenopic symptoms: Distant vision is very good, but reading causes pain in the eyes, or headache, a strained feeling over the eyes; a feeling of weariness and fatigue; sight becomes indistinct and unsteady.* 31 Cases. Reports received from sixteen; all favorable.

Case 14.—Boy, 14, never can read longer than a half hour; eyes get red, full of tears and painful. Refraction + 25c 180. These cylinders were ordered for school work; and he reported after two months that the glasses had relieved him at once and continued to be satisfactory.

Case 41.—Miss N., 22, severe headache after reading or sewing; after twenty minutes' work sight becomes very unsteady; has to close her eyes to rest them a few minutes to continue her work. Refraction + 50 = 25c 90. Ordered + 25c for work. Asthenopia was entirely relieved.

Case 49.—Mrs. G., 30; since two years frequent headaches and a strained feeling after reading. Last year she was advised to use + 75 for near work, but received little benefit from these glasses. Refraction + 25 = + 25c 90; has used these lenses for reading, and writes now (after eight

months): "I do not have the headaches I used to have before, and the print is never blurred as it used to be, which is very satisfactory, for it annoyed me exceedingly."

4. *Headache and other nervous symptoms which the patients do not connect with the use of the eyes.* 5 Cases. Reports received from 4; one negative, three favorable.

Case 4.—Mrs. D., 29; since many years headaches for which her physician could find no relief; when recently she complained of pain in the eyes, he referred her to me for examination. Refraction, R. E. + 50 = + 25c 180; L. E. + 50 = + 25c 90. The 25c were prescribed for constant use, but her husband wrote me, "the headaches were traced to other causes and the glasses therefore discontinued."

Case 15.—Mrs. B., 35. Since twenty-five years has been doctoring for dyspepsia, frequent attacks of vomiting, and a very distressing tight feeling round her head. Sight very good; her eyes have never troubled her in reading or other near work. Two years ago one oculist prescribed glasses (+.75) which seem to have been of some benefit to her, inasmuch as the vomiting became less frequent. Refraction + 75 = + 25c 90. Ordered + 50 = + 25c 90 for constant use. After one week she called to tell me her head was entirely relieved of that tight band and her appetite much better; and two months later she reported she had had no attack of vomiting since she wore the glasses, and had improved very much in health.

Case 43.—Mr. B., 44; since seven or eight years almost every day frontal headache which usually begins at noon and lasts till he goes to bed; has tried all kinds of treatment advised by different physicians. Refraction + 25c 180; the cylinders were given for constant use (and in addition + 50 for reading) and he returned after six and a half months to tell me he has had no headache since.

Case 47.—Miss M., 31; since childhood subject to headache starting over the eyes. In the last year the headaches were so frequent that she became quite nervous; can see very well and does a great deal of needle work without ever feeling the slightest discomfort in her eyes. Refraction + 50. I should not have thought of prescribing these glasses, had not the lady remarked that her head felt so much relieved after she wore them five to ten minutes at her second visit when the eyes had recovered from the effect of the homatropin. So I decided to let her wear the + 50 for trial; and she has called repeatedly to report of the continued great relief she has experienced.

Résumé: Of the fifty cases treated with weak lenses, thirty patients have reported good results, one patient has reported a negative result, and nineteen patients have not been heard from. If we take the most unfavorable view possible, and count every one of the nineteen cases not heard from as a failure, we may still be well gratified by the results of the treatment; for it has been successful in thirty out of fifty cases, or in 60 per cent. In the sight of these clinical proofs, it must be conceded that these weak cylinders are not superfluous glasses; that their therapeutic value is not mythical, but real; and that the oculist will render his patients a great service by prescribing these weak glasses whenever in his judgment he has good reason to believe that the existing low degree of ametropia is the source of the patient's distress.

We must not forget that the eye is the most successful in correcting by accommodative efforts the optical disturbances produced by slight degrees of hypermetropia or astigmatism, while in the higher degrees of these refractive errors it does not succeed, and therefore abandons the efforts. The moderate degrees, therefore are the prevailing errors of refraction found in patients complaining of the symptoms of eyestrain.

The degree of ametropia does not constitute the principal condition in the production of distressing symptoms; and experience does not sustain the statement that hypermetropia or astigmatism less than 0.75 D. seldom cause discomfort or headaches. The state of health, the condition of the nervous system, the occupation are very important factors,

and frequently account for the fact that in many persons a slight hypermetropia or astigmatism causes great distress, while other persons never experience the slightest discomfort from the same ametropia in kind and degree.

Many eyes can endure a great amount of strain with impunity, while other eyes are so constituted that their powers of endurance are quickly exhausted. One person may need glasses for the correction of a small amount of ametropia, while in another person the correction of a much higher degree is unnecessary, and glasses would be superfluous. We can not draw the line at a certain amount of ametropia; but should correct it, no matter how slight in degree, whenever it leads to disturbances for which eyestrain constitutes the most frequent cause.

Venetian Building.

REMARKS ON VAGINAL HYSTERECTOMY.

BY L. H. DUNNING, M.D.
INDIANAPOLIS, IND.

Vaginal hysterectomy is an operation so frequently done with such a high degree of success by so many different surgeons that I would not attempt to remark upon it, had I not had an unusual experience in two recent cases.

Having had my attention called to Pratt's modification of the operation, I procured copies of the *Medical Century* containing several articles by the author of the method, and others who had observed his work. The essential characteristics of his operation, so far as they differ from other methods, are as follows:

The uterine cavity is tightly packed with antiseptic candle-wicking to distend the uterus and make distinct its outlines. The Simons' position is employed and the uterus brought into view in the usual manner and stout threads passed through the anterior and posterior lips of the cervix. The initial cut around the cervix is made nearer the os than usual. The separation of the vaginal and cellular tissue and bladder is carried very close to the uterus and as high as the margin of the lower border of the broad ligament. This separation is effected by a spud or by the author's sickle knife. It is carried farther up before and behind, until the peritoneal reflection is reached, always keeping close to the uterus. The peritoneum is incised in front and posteriorly and severed close to the uterus laterally in either direction, as far as the broad ligaments. The index finger is passed beneath the broad ligament upon one side, so as to put it upon the stretch and to serve as a guide in severing the broad ligament from its attachment to the uterus. This is effected by cutting it very close to the uterus with the sickle knife, when the one upon the other side is treated in a like manner. This procedure, the author states, is effected with the loss to the patient of very little blood. It is said that the success of the operation all depends upon keeping close to the uterus, and that the uterine artery or some of its branches will sometimes be severed and much hemorrhage result if the tissues are separated even one thirty-second of an inch away from the uterus. The author in one article says he has performed forty-nine vaginal hysterectomies by this method, with the death of but one patient. It is further asserted that the recovery of the patients is greatly facilitated because there are no ligatures

left behind to cause suppuration, or crushed tissues to necrose and slough away; lastly, that no nerve tissue is crushed or compressed.

Being favorably impressed by the advantages of this method, if safe, I decided to employ it in the first suitable case that presented to me for operation.

January 31 Mrs. A., aged 63 years, came to my private hospital for operation for cancer of the body of the uterus. She had passed the menopause ten years previously. She began having hemorrhages three months ago. These were not profuse and were irregular. There were fetid watery discharges. Friable particles had been previously removed by curettement and the pathologist pronounced them carcinomatous in character. I prepared to employ the method proposed by Pratt, and carried the method forward to the point of severing the broad ligaments from the uterus. (Here my courage failed me, probably on account of having lost a patient four years ago of hemorrhage in a similar case from a defective forceps.) The clamps were applied to the broad ligaments. The clamp upon the left side was applied so close to the uterus that when the uterus was cut away no tissue was left projecting beyond the inner blades of the forceps, so that while applying the forceps to the opposite ligament the forceps upon the left side pulled off and fell out of the hand of the assistant, falling upon the floor. Inasmuch as no hemorrhage followed this pulling off of the forceps, no attempt to secure the liberated broad ligament was made. The tampon was placed and the patient put to bed. She made an uneventful recovery, there being no post-operative hemorrhage. The forceps upon the right side was removed in sixteen hours, instead of allowing it to remain twenty-four hours, as had been my former custom. There was during this operation the loss of not more than one-half ounce of blood and not an artery tied and only one forceps left. Upon examining the uterus after its removal we found but two small arteries upon each side entering the uterus; one midway between the external and internal os and one about one-half inch above the internal os.

In commenting upon this case at a meeting of the Marion County Medical Society, I stated that I could see no reason why this uterus could not have been safely removed without the use of a ligature or forceps, and that I thought I should try the procedure in the very next case I operated upon.

February 9 the opportunity presented itself. Mrs. B., aged 36, came into my ward at the City Hospital for the removal of the uterus for an aggravated case of procidentia with dislocated bladder. There was also complete prolapsus of the vagina, and the bladder when filled with urine formed a tumor anterior to the uterus and all hung without the vulva between the limbs. Certainly here was a fine opportunity to do a new operation in distinct view. The packing of the uterus was omitted. The cervix was seized with a volsellum forceps to steady it and control its movements. The dissection of the lower segment of the uterus was carried forward with blunt pointed scissors. The uterus was hugged closely in the dissection. By the time we had reached the lower margin of the broad ligaments, five small arteries had been severed and were spurting vigorously. They were caught with catch forceps. We had by this time concluded it would not be safe in this case, at least, to sever the broad ligaments without clamps or ligatures, nevertheless, I concluded to sever one broad ligament before tying or clamping. So at the proper stage of procedure I began cutting from below upon one side, but I had not proceeded far when a quite large artery was cut across and bled freely. From this time forward we returned to the old method of ligatures. On examining the uterus removed, a very different condition of the circulation was found than was present in the former case. There were five or six small arteries entering the uterus upon each side, and each one was nearly or quite as large as those in the former

case. The increased vascularity of the latter case probably could be accounted for on the ground that the woman had not reached the menopause and the uterine and peri-uterine tissues, in consequence of their prolapsus, had been for a long time in a condition of congestion. In the former case, normal atrophy of the sexual system had taken place. Not an artery spurted in the whole operation, while in the latter case not only did the numerous arteries bleed, but free oozing took place from the incised vaginal tissue.

These experiences lead to the old and oft repeated conclusion that a procedure which would be safe in one case if followed in some other would result disastrously. The wise and skilful surgeon must himself determine the course to be pursued in each case.

In the February number of the *Indiana Medical Journal* appears a translation from an article by Landau of Berlin, (translated by Dr. Bell) which credits Sauter of Constance, Germany, with having done the first hysterectomy in 1822. In the technique of the operation, without the use of speculum or retractors, the broad ligament attachments are severed from the uterus with the knife, and no clamps or ligature employed upon these structures.

Thus, at that early day, was performed and described in a monograph a vaginal hysterectomy, which in its essential features is identical with the one so recently brought forward by Pratt.

Dr. Bell informs me that Sauter's first case was successful, in that the patient lived four months, at the end of which time she died of edema of the lungs.

The tendency is strongly toward simplifying vaginal hysterectomy, but every operator is, I think, impelled to employ sufficient painstaking care to protect the patient against the greatest danger of the operation, viz: hemorrhage.

A CASE OF CYST OF THE CEREBELLUM.

BY WM. F. WEGGE, M.D.

SUPERINTENDENT NORTHERN HOSPITAL FOR THE INSANE,
WINNEBAGO, WIS.

For the history of this case previous to the patient's admission to this hospital, I am indebted to Dr. W. H. Gunther.

J. B., admitted Oct. 18, 1893, aged 40 years. Occupation, sewer-builder; education, fair; a native of Canada; was first taken ill in the spring of 1893.

The first symptoms were observed by his fellow-workmen who noticed that at times the patient would stop in the midst of his work and appear unconscious of his surroundings for periods of varying duration. At such times his left eye would wink frequently. His work was always well done and nothing irrational was noticed. He frequently complained of headache, and claimed to have had a similar attack ten years previously.

Dr. Gunther was first called on Sept. 8, 1893, when he found the patient in bed, rather stupid; complaining of severe general headache, vertigo and numbness of all extremities. His temperature was 97 degrees F.; the pulse was small, weak, intermittent, and beating at the rate of 108 per minute. He was very much constipated. There were present singultus and belching of gases, but no vomiting.

The left eye was closed spasmodically at intervals; the pupil was very much contracted and responded rather slowly to the action of light. The right pupil was dilated; light reflex almost absent.

The tongue was protruded slowly, and was slightly drawn toward the left. Speech was tremulous, and sentences were frequently left unfinished. Hearing was defective.

He assumed the erect posture only with difficulty and some assistance. He showed a marked tendency to falling toward the right. At times a general tremor of the body

lasting several seconds was observed. Motor and sensory disturbances were noted.

There was a gradual improvement lasting about one week, after which he again grew worse; urine and feces were passed involuntarily and his mind became more affected.

Status præsens: The patient is a man of rather below medium height, with poorly developed muscles and subcutaneous fat tissue. His complexion is sallow; the face is dull, expressionless and rigid; his neck is apparently held rigidly in position and is thrown slightly backward. (There are no evidences of syphilis.) He lies on his back with the body inclined toward the left. He is aroused with considerable difficulty; answers simple questions correctly but apparently fails to comprehend more complicated ones. Respiration is normal; pulse 100.

On examination there is no evidence of paralysis of the muscles supplied by the facial nerve; the tongue is protruded straight; hearing is somewhat impaired but swallowing is not materially interfered with.

There is weakness of all the extremities but no paralysis. Patellar reflexes are exaggerated, but there is no ankle clonus. The pupils are dilated, pupillary reflexes are absent and there exists total blindness. There is no indication of paralysis of the extra-ocular muscles. Ophthalmoscopic examination discloses a double optic neuritis.

The patient is unable to stand or walk alone and shows a marked tendency to falling backward and toward the left. Bowels and bladder are emptied involuntarily and, it appears, unconsciously.

It is difficult to estimate the amount of urine passed, but it is not excessive as near as can be estimated. It is of a light straw color; of acid reaction; has a specific gravity of 1025, and contains no albumen but sugar is quite abundant.

The subsequent events were marked by little of special interest. His mind became more clouded and for some time previous to his death was almost a total blank. At no time were there epileptiform convulsions or vomiting. Death occurred somewhat suddenly on Jan. 19, 1894.

An autopsy was made thirty-six hours after death, the brain being the only organ examined.

The dura was rather thick in several places and adherent to the pia at these points. The blood vessels were distended with blood; the convolutions were flattened; the ventricles enormously distended and filled with a clear fluid.

The basilar artery lay in a deep groove on the surface of the pons. The right olivary body and the right olfactory bulb were absent.

The left lobe of the cerebellum was much larger than the right; the former bulging anteriorly. On incision about one and one-half to two ounces of a clear colorless fluid escaped. A tumor of about the size of a filbert was found imbedded in the cyst wall.

On looking over the literature on the subject, I find one case of cyst of the cerebellum reported by Munnell in 1889,¹ who trephined for and evacuated it successfully.

Dr. Wm. C. Krause² has also reported a case in which an antemortem diagnosis was made.

Dr. W. W. Keen³ says that, "with the latter (referring to tumors of the cerebellum) the knee-jerks are habitually diminished;" and in a footnote suggests that this may be a useful detail in distinguishing between tumors of the pons and those of the cerebellum.

In my case the knee-jerk was distinctly exaggerated and it was slightly exaggerated in the case of Dr. Krause. I merely wish to call attention to this, because it tends to show that it is not well to pay too much attention to the fact that the knee-jerk is excessive in making a diagnosis in tumors of this region.

¹ Reference Hand-book, Vol. 1x, p. 126.

² Journal of the Amer. Med. Assn., Vol. XXI, p. 481.

³ Reference Hand-book, Vol. 1x, p. 133.

Why the tendency to fall toward the right was marked during the early stages of the disease, and was later changed to a tendency to fall toward the left, I will not attempt to explain.

It may be of interest to note that in my case the glycosuria was permanent, while in that of Dr. Krause it was temporary.

THREE CASES OF EXTRA-UTERINE PREGNANCY.

ONE BEING COINCIDENT WITH NORMAL UTERINE PREGNANCY, AND ONE BEING A CASE OF ABDOMINAL PREGNANCY—OPERATION AND RECOVERY IN ALL.

Read before the Union Medical Association of Northeastern, Ohio, at Akron, Ohio, Aug. 8, 1893.

BY J. A. DICKSON, M.D.

YOUNGSTOWN, OHIO.

Case 1.—On Sept. 18, 1891, I was called by telegram to see Miss S., with the injunction to come by daylight in the morning, prepared to operate. I found my patient to be a young girl 18 years old and unmarried, with the history of suppressed menstruation for two periods. Two weeks before the time for the third period she was seized with abdominal pain and uterine colic, with a profuse discharge of clotted and shreddy blood, which was supposed to be a return of the long delayed menstrual flow. This peculiar flow continued for two weeks, but its long continuation was not a source of anxiety to patient or friends, on account of the long delayed menstruation. On the 18th, one week after the cessation of the flow, she rode fourteen miles, over a rough road in a huge Pennsylvania wagon. She was seized that night with terrific abdominal and uterine pain, with a resumption of the bloody discharge. On the morning of the 19th I found her exsanguined and apparently in collapse.

Upon examination I found a large mass on the left side, and the pelvis full of an undefinable substance. Womb pushed to the right. I elicited no information from either patient or friends except that of delayed menstruation, and a black clotted discharge lasting for two weeks, with its resumption now, after severe exercise, with pain, exsanguination and collapse. Suspect extra-uterine pregnancy and advise operation, with no idea that it will be accepted. To my surprise patient and friends readily accept. Operated at 11 A.M.; incision six inches in length in middle line. Upon reaching the peritoneum I find it black, and it readily ruptures upon being taken up in the bite of catch forceps, with a gush of dark clotted blood. I enlarge the incision to eight inches, and discharge a large quantity of blood clots and detritus. The fetus is washed out with the blood clots, apparently from eight to ten weeks old. Find the left tube to contain the ruptured fetal sac. Remove it entirely, tying close down upon the womb. Right ovary and tube perfectly healthy. Leave them, *in situ*, unmolested. Wash out abdomen with a Price irrigator, using common boiled water, as the operation was done in the country and such was the desperate condition of the patient that I could not send for distilled water. Closed incision with eight stitches. Dress with iodoform, and bichlorid gauze and put patient to bed with hot water bottles. So sure was I that the patient would die within the hour that I was glad, leaving her in good care, to get out of the house and take the train for home. Received a telegram the next morning that patient had reacted nicely, and was doing well. Saw her on the evening of that day. Temperature 101.4-5, pulse 98. The subsequent history of the case is that of uninterrupted recovery, without a bad symptom. The lady is now in Iowa, teaching school, having learned, it is hoped, a good lesson herself in the school of experience.

Case 2.—Mrs. F. aged 28 years. Married twelve years. Four children; two dead, two living; and two miscarriages. I was called to see her Oct. 17, 1891, when I found her miscarrying at about the fourth month. Fetus and membranes expelled *en masse* with no subsequent hemorrhage. After fourth week the menstrual period not appearing, she came to me for advice. Advised her to drift, and gave tonics. After eighth week saw her again. Upon examination find os soft and velvety, uterus enlarged, and mucous membrane of vagina dark, and purple in color. Probable pregnancy

and advise her to wait and go through with normal pregnancy.

December 26 called to see her again, just ten weeks from former miscarriage. Flooding, fetus and membranes cast off *en masse* as before. Jan. 10, 1892, called to see her again. Flooding; discharge, clotted and shreddy; chills, severe abdominal pain, and bearing down sensations. She thinks that she "has piles" that "the trouble is in the bowel." Upon examination I find uterus above the pubes, but do not recognize it as such at the time, but think it the cervix of a retroverted womb. On account of normal pregnancy do not dream that it was complicated by extra-uterine. I find a large mass back of uterus in cul-de-sac, which I mistake for gravid retroverted womb, containing the remaining twin of a plural pregnancy. Try to replace uterus by gentle taxis, but find it to be impossible.

January 15, called early in the morning. Wasting, chilling, lips bloodless, pulse thready and weak, severe abdominal pain, tympany, collapse. Examined her under ether. Find everything as described before. Pass sound gently and find that it passes into small mass just above pubes which proves to be the womb. Mass back of uterus feels as large as small fetal head, soft and boggy like a cyst. Either a cyst or extra-uterine pregnancy. Probably extra-uterine on account of history and symptoms. Advise operation, which was as promptly refused. The history from this time until January 23, is that of recurrent bleeding, external and internal, peritonitis, tympany, excruciating abdominal pain and collapse. Jan. 23 seeks operation. Operated with assistance of Drs. A. C. Wilson, and M. S. Clark. Small median incision. Upon reaching peritoneum find it black with coloring matter of extruded blood. Find uterus, *in situ*, in normal position. Find mass back of uterus to be a mass of friable partly organized blood clot, in which is imbedded the ruptured left tube. Abdomen full of blood. Enlarge incision to pubes and through the umbilicus, as I find that I must introduce my hand in order to tease out the tube which is as thick as the wrist. Break through the nest of adhesions which seal over the mass, and scoop out with my hand a wash basin full of blood clots. Release tube from many firm adhesions and tie it off, close down upon the womb. Examine the other ovary and tube, and finding that they also are diseased remove them. Wash out the abdominal cavity with hot distilled water, with a Price irrigator, until the water comes away sweet and clear. Close up incision with seventeen stitches, introducing a drainage tube well down in Douglas cul-de-sac. Dress with iodoform and gauze and apply bandage, with rubber dam over the bandage for drainage tube. Time of operation fifty-five minutes. Dress tube every hour until serum comes away discolored. Remove tube on the second day. The history of this case is one of speedy recovery. Under small doses of antkamnia she has a minimum of pain, and secretions are left normal, which can not be said of morphia. Not a stitch abscess or a drop of pus about the incision. Remove stitches on the seventh day. Patient now perfectly well. Upon examination of the specimen find fetal membranes within the tube; the fetus having escaped into the abdominal cavity, is lost among the blood clots and detritus. For fear some of my confrères may be disposed to criticise my long incision, I may say that through my initial short incision I was absolutely unable to reach the tube, such were the extent of the adhesions, and I would not have been able to deliver the tube, such was its size, through the short incision had I been able to reach it. Adhesions were simply frightful. I do not believe that the short incision is the *sine qua non* in abdominal surgery when there are such complications as were found in this case. Although the history of long incisions is not as good as that of short ones, I believe that with proper care, attention and cleanliness, a long incision is as safe as a short one.

My excuse for reporting this case at length is that with but one exception it is unique, and it may be of interest to the profession at large. The only other parallel case which I am able with references at my command to find, is one reported in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, March 29, 1890, by the Vienna correspondent of the *Medical News*, of which the following is a brief résumé: "A few days ago Dr. Rosthorn, assistant at Professor Chrobak's gynecological clinic, operated upon a case of apparent ovarian cyst. Eight weeks before, the woman was delivered of an eight months child; labor normal.

The operation was made in the ordinary way and supposed cyst removed. At one portion a peculiar cord-like process was attached. Rosthorn examined the other ovary; it was normal, but while examining, a small hand slipped out from between the intestines. This was seized and a child was removed from the abdomen and to its umbilicus was attached a cord exactly similar to that found on cyst. They then looked for fetal membranes, and found them very deep and everywhere adherent to the intestines and peritoneum. The woman rallied and seven days after the operation was doing well. The careful examination of removed cyst showed that the tumor was merely the placenta, coiled up where it had been fastened to the left Fallopian tube." The following résumé of this case, quoted from same article, *JOURNAL AMERICAN MEDICAL ASSOCIATION*, March 29, 1890, might also be a verbatim résumé of my case: "There was an extra-uterine pregnancy and an intra-uterine pregnancy went on normally at the same time." It can not be established, though it is probable, that the

two children were really twins, and one developed within, the other outside of the uterus. The article quoted further says: "Thus it stands without a parallel in the history of obstetrics, etc." The history of this case makes mine all the more interesting to me, and I hope also to the profession.

Case 3.—On Wednesday, Aug. 12, 1892, I was called out of town to see a patient suffering from "inflammation of the bowels," as the message expressed it. I found my patient to be a young widow woman, 31 years old. Husband dead for thirteen months. History shows that at the time of death of her husband she had thought herself pregnant for about three months. At that time due, it was thought, to the sudden and accidental death of her husband, she had an attack of what was thought to be inflammation of the bowels but was evidently peritonitis. She was ill, and confined to her bed for several weeks, and the attack was very nearly fatal in its consequences.

After her recovery from this sickness she slowly regained her general health, with the exception that she complained of a dragging sensation in her left side, and thought that when she turned from one side to the other in bed she could

feel something move in her abdomen. Bowels were constipated and there seemed to be more or less of an obstruction when they moved. Menses did not reappear until the third month after the death of her husband, when they came on with a scanty, not deeply colored flow at first, and gradually resumed their normal characteristics. From this fact she comes to the conclusion that she was mistaken regarding her pregnancy, and that up to the time of her husband's death it was simply delayed menstruation, and that its non-appearance after his death, was due to the shock resulting from his death, and the long severe attack of "inflammation of the bowels."

Her health continued to be fairly good until Aug. 11, 1892 when, while she was standing on a step ladder only two steps from the floor, her foot slips and she falls to the floor, striking her left side upon the ladder during her descent. From this time on she has the most severe abdominal pain, with symptoms of peritonitis, swelling, tympany, and most exquisite tenderness, so great indeed that she can not allow the bed clothing to touch her. Limbs drawn up, and can not allow herself to be moved and scarcely to be touched. In this condition I find her, on August 12 on my first visit. Pulse 140, very weak and thready. Temperature 104.4. Abdomen very much distended—so much so in fact that the surface is glazed and shining. Face pinched and anxious; nose, ears and finger tips cold, and all the other symptoms of collapse.

Upon making a bimanual examination I am unable absolutely to map out anything; such is the distension of the abdomen, the pain and anxiety of the patient, that she is unable to make the abdominal wall flaccid, and I am afraid in the present condition of patient to give her ether, as she seems to be dying. Although I recognize the gravity of the case, and the fact that it is certainly an operative one, yet on account of the seemingly near approach of dissolution, I decline to operate and come away, deeming it best if she must die not to interfere. Perhaps also I am influenced to this decision, by the fact that I am not prepared to operate, as the message says: "inflammation of the bowels," and I supposed the case to be one for medicinal rather than surgical treatment.

I fully expect in the morning to hear of her death, but during the night receive a message that she has rallied wonderfully, under treatment, and that she and her friends wish me to come immediately, prepared to operate, and that they will assume all responsibility. Go to her early in the morning. Pulse 100. Temperature 101. She seems much brighter and more hopeful. Decide at once to operate. With a probable operation in view, had the room cleaned and prepared the night before, rather hurriedly but still as carefully as possible, and operate at once.

Upon making the abdominal incision in the median line, so great is the distension or from the fact that there has been an old hernia, I immediately strike subperitoneal fat and peritoneum and enter the cavity. There is a rush of dark grumous but not offensive liquid, in which is floating a quantity of peculiar flocculent material. With the gush of water comes a fetal hand and arm. I grasp this and with gentle traction deliver a fetus, to which is attached the cord. Upon making gentle traction upon the cord it separates, but with small catch forceps I grasp the distal end. With this as a guide I follow out to the site of the placenta to which is attached the fetal sac, and am able without the slightest difficulty to peel it off with my fingers. This is accomplished easily, probably on account of fatty degeneration at placental site.

Examine the left ovary and tube, find many adhesions at the site of old rupture and remove them. Right ovary and tube seem to be healthy and leave them.

The peritoneum and bowels appear to be in pretty good condition, although there are several places on the bowel where there are deposits of lymph, and one or two where surfaces are attached by adhesive inflammation. These I detach by gentle sponging with a fine sponge, being careful not to injure the bowel in the least, fearing that if I allow them to remain I will get knuckling of the bowel or at least loops into which other portions of the bowel may find their way. After removing all possible debris, and inspecting bowels carefully, I replace everything and wash out with hot water. Irrigate until the water comes away perfectly pure and clear; then close up with silkworm gut sutures.

Time of operation, from the time of incision until sutures were in place and incision closed, thirty-five minutes. Dress with a mixture of iodoform and boracic acid, gauze and cotton, apply bandage and put patient to bed. Patient rallied well and was soon out of danger. Remove stitches on seventh day, with a clean wound, without a drop

of pus. Pulse never went above 110, and temperature 102 after operation, and both were normal after tenth day. Bowels moved on the second day, spontaneously, and regularly afterwards every day. Gave no morphia whatever, to which fact I attribute the splendid condition of the bowels. Patient did nicely, during her whole convalescence, and sat up on the seventh-day for the first time. She is now well and a very grateful woman. I did not explain to her her condition, until several weeks after the operation, when I explained it to her as I have given it below in my conclusions, and it seemed to satisfy her perfectly.

From a résumé of this case, I conclude:

1. That this was an honest woman, and the child her husband's.
2. She was pregnant, with fetus in left tube, at the time of her husband's death, and the shock of his accidental death produced a rupture of the tube which brought about severe peritonitis, the so-called attack of "inflammation of the bowels."
3. Rent in tube did not cause death by hemorrhage; she recovered from peritonitis; fetus, through the placenta, formed its attachment in new position, flourished here for a time, and finally died, becoming encapsulated.
4. Fall from stepladder ruptured fetal sac, and fetus escapes into the abdominal cavity, becoming a foreign body, and gets up a peritonitis which called for the operation.

THE FUTURE OF MEDICINE.

Opening Address delivered before the College of Physicians and Surgeons, Boston, Mass.

BY EPHRAIM CUTTER, M.D., LL.D.

NEW YORK.

PROFESSOR OF CLINICAL MORPHOLOGY AND APPLIED MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, BOSTON, MASS.

I felicitate you, students of medicine, on the plane of the profession being higher than that of forty years ago, when I was in your place. The profession then, was not registered; now there are listed over 100,000 persons practicing medicine in the United States; some state the number to be 162,500. Then, medical students were attending some schools in bodies of 500 or so at a time. Now, their catalogues show between 800 and 900 in attendance in a single institution, and about 17,000 in the United States in 100 or more medical schools. This is a large number to be increased by the veterinarian, the dental and pharmaceutical students, but it is to be observed that the labors of medical men are so severe that but 17 per cent. will hardly cover the annual death rate.

Then, the medical organizations were few. The Massachusetts Medical Society with some 1,200 members was the largest. Now, we have national, international, Pan-American, district, city, State and specialist societies in all the schools of medicine. The Tenth International Medical Congress, Berlin, 1890, was said to be the largest gathering of scientific persons ever held. It numbered about 7,000. There were some 700 papers on its published program, indicating an intense activity of medical thought perhaps before unequalled.

Then, the medical journals were comparatively few. Now, the astounding number of about 250, are said to be published in the United States. Beside, medical books are published in large numbers. I have been told that from one publishing house in the West, where religion and medicine are conjoined, systemic medical treatises have been sent off by the car load! No other profession approaches, I think, this number of ephemeral and permanent vehicles

of information on technical knowledge. In the light of these facts, complaints as to medical illiteracy, although not without foundation, are not fully sustained, and I doubt if there is any such exhibition of professional self-denial and seeking for others good, as shown in medical journals which are really maintained by gratuitous contributions.

Within forty years, such men as Pasteur, (a medical Moody) Claud Bernard, and Brown-Sequard in France; Virchow and Koch in Germany; Lister, Richardson and Mackenzie in England; Sayre, Sims, Salisbury, Beard, Elsberg, Holmes, D. H. Storer and Marcy in America, and many other masters in medicine well worth naming, have shed a flood of light in which you to-day can rejoice. Another remarkable evidence of advance is the division of the curriculum into three and four year courses. The writer when a medical student, made such a division for himself, adding special courses in chemistry, surgery, physical exploration and microscopy. The Post Graduate schools were foreshadowed by these special courses. But we must not think there were only ignoramuses forty years ago. As President Dwight truly said: "Our fathers, if they did not know everything, knew something." They made mistakes; we do. "It is human to err." Daniel Webster said: "I would not give a cent for a man who never made a mistake." Another of our high dignitaries has said: "One who never made a mistake never made anything." The fathers were pressing onward and upward in a path of investigation which has made the advances of our profession possible. Please permit a concrete illustration of the position of the medical profession forty years ago:

A student of medicine had been through college, taught school a year, and was consulting with his father about entering a medical school, since he was in doubt as to his course. Among other things he said: "Father, I do not want to study medicine to practice it as you have, but I would like to study medicine to learn about the causes of disease." The father, a beloved physician of brain, tactful, and of good judgment, keen in diagnosis and prompt and bold to act, with a large practice, for some minutes reflected and replied: "I would like you to study medicine and the causes of diseases all you wish. I will help you all I can, but there are three things I want you to study: 1, what is the cause of consumption? 2, what is the cause of diseases of women? 3, what is the cause of diseases of the nervous system? We doctors do not know anything about it!" No more was said, but the son was almost overwhelmed by eight words, which self-dethroned his revered father from the high position he had occupied as his son's idol, (as knowing everything); but the father's words forcibly depict the state of knowledge then; thank God, not now; as all three questions have been answered to the son's satisfaction as well as to other medical minds. Through the vista of four decades, this father appears, most honorable for his frankness, decision, judgment and forecast in giving to the son a grand life task. *I was that son.*

PRESENT STATUS OF MEDICINE.

Those of you who attend the course of lectures given by the well-qualified professors and lecturers of this College, will have more than work enough for four years, to understand this part of my subject. This good Faculty will give a far better presentation

than I can here or elsewhere. Hence I beg your indulgence to listen briefly to what seems to me to be the

FUTURE OF MEDICINE,

as influenced by American ideas, which my distinguished associates may think belongs to the chair of clinical morphology and applied medicine. I say American advisedly, for while we give credit to all discoveries, we can not slight our own and be just. What I say is said on my own responsibility, and comes from the depths of my heart, prompted by filial love and an earnest purpose to do well the life task set as above.

1. The medical science of the future will include a new physical sign of the pre-tubercular state. That is, it will detect consumption any time within a year before the lungs are broken down, and in ample season to anticipate the usual signs furnished by auscultation and percussion, and to make proper treatment and cure not a dream but a tangible possibility. It consists in peculiar phases of the blood taken in connection with the other evidence which I have termed, "the morphology of consumptive blood," for several years, and which medical men have used for more than a quarter of a century; and this physical sign is most valuable because any disease is most hopefully treated before it is fully developed.

As foreshadowing what will be attained in this direction, I beg leave to refer to an essay written in 1877, illustrated with micro-photographs, original as to subjects and highest power objectives, that have been examined by leading microscopists in Paris, London, Berlin and America, and pronounced to be skilful as delineations and valuable as sources of scientific investigation. The regard of the writer for this sign, is seen from his motto for 1879, and his expressed belief that should the experience of two physicians for the past twenty-five years be realized by the regular profession of the United States, at least 13,000 lives annually would be saved.

The regard of such men as Dr. J. Marion-Sims may be inferred from his saying that this means of diagnosis was one of the greatest discoveries of the nineteenth century. The lapse of fourteen years, only confirms this opinion.

2. Another idea potential, is that chronic diarrhea is consumption of the bowels. This has so little actual energy that a late colossal medical dictionary disposed of it in the following six words: "Consumption of the bowels. Phthisis intestinalis." And yet it is a common disease best understood from the morphology of the feces, and traced to results of alcoholic fermentation.

If it is the physician's business intelligently to treat disease, then here is a fine field for future development. The prime cause is in improper feeding and the cure is based on proper feeding. I speak from experience, as I almost died from it in youth, but was cured by proper food.

It is my opinion that the cause of consumption is the acetic acid fermentation. For more than forty years, botanists have known of the bacillus of Koch, as pointed out, but have disagreed as to its relation to alcoholic and vinegar yeast. The morphology of common yeast shows this bacillus, so that the cause comes in with our food. This has been proved by pathologic synthesis of consumption in animals, and by cures by diet, forty cases of which, cured, most

of them of ten years standing, were reported at the Tenth International Congress by the writer.

3. Bad feeding is one great cause of the diseases of women. Society ethics as to eating, exalt the carbohydrates, and demand the impoverishment of flour as to mineral elements in order to have bread white. Sweets are at a premium because of ethical esthetic taste. Women grown on society diet can not have full development. Hence in my opinion, the decline in the birth rate, and so much gynec disease. To use a womanly illustration, as well expect a dress-maker, who is furnished all materials for a dress, to make a garment with a dress pattern, a pair of scissors and a needle, as to expect to make up a good human body on carbon, hydrogen and oxygen when, it is said, forty elements are required by nature. While it is right to use all the peripheral means of treating gynec diseases, the central or centrifugal one of a proper diet should not be neglected. There are many opinions as to what a proper diet for gynec disease is, but my experience leads me to the conclusion that in cases uncomplicated with grave chronic disease, a diet of two-thirds animal and one-third vegetable is the best.

In this connection, may I say that in 1877 I published cures of uterine fibroids by diet in confirmation of what others have done. After the lapse of sixteen years, I re-affirm this position, and report that cases which had evidence enough to be called uterine cancer, have recovered by diet. If I said this was not so it would be daily denied by my wife, who was a case in 1877, and was cured.

4. Diseases of the nervous system, as apoplexy, paralysis, paresis, softening of the brain, sclerosis, locomotor ataxia "heart failure," a term too commonly used. These masquerade as nerve diseases, but are really mainly due to fatty and fibroid degenerations. It is impossible to separate the nerves from the organs and tissues involved in disease. A tooth with a killed nerve is dead practically. The pulsations of the heart come from nerve force. I never knew nerves caused apoplexy. Take the case, as reported, of the richest man in New England, found dead on the steamer, *Pilgrim*. This probably depended on the fatty degeneration of the muscular coats of the basilar arteries. There was a rupture and extravasation of blood into the brain tissue, which pressed on the nerve centers of respiration and cardiation so that the man was struck down dead as with a blow, hence the name, *apo*, from, and *plessein*, to strike down. Now what made the fatty degeneration of the muscular fibers in question? Answer, the impeded and sluggish circulation (English idea). The carbohydrates and fat food in excess, and their prolonged fermentation in the alimentary canal. (American idea). The treatment of apoplexy should be that of fatty degeneration, to-wit, the withdrawal of carbohydrates and fats, and the substitution of food which digests easiest, furnishes the most life and will replace every normal tissue in the body, as proved by trial. Nature, like the good dressmaker, furnished with all materials will take up and replace this fatty degeneration wherever found.

As a cause of sudden death, heart failure is often reported. It shows a poverty of diagnosis, but the morphology of the heart would show often fatty degeneration.

Angina pectoris is termed a sclerosis of the coronary arteries. But the gravelly atheroma made up of choles-

terin and other bodies goes along with fatty degeneration. I know of a bad case of angina pectoris cured by diet. Asthma may be termed a neurosis, a bronchismus or spasm of the bronchi, from the irritation of gravel in the air passages, as the morphology of the sputum shows, and sometimes from the additional presence of a beautiful alga parasite, called the spirulina asthma, an American discovery of more than twenty-five years ago. Asthma has been termed a "gravel of the lungs" on this evidence. Now diet is the foundation way to remove the gravel and spirulina, and thereby the asthma. I thus cured a case of asthma of twenty-six years standing. Hay fever is "gravel of the lungs" also, the exciting cause being the pollen of plants, ipecac, castor oil, bean, pumice, etc.

To properly treat disease you must remove the predisposing and exciting causes, and nature cures. When you fire a gun you remove the charge (predisposing cause) as also the cap, (exciting cause). If the gun is not loaded it will not go off.

I do not know but that rheumatism may be called a disease of the nerves. The intense suffering of rheumatism would be *nil*, without nerves. When people do not suffer they do not usually call themselves sick. Now rheumatism is gravel of the blood, as shown by an American years ago. The morphology of the blood shows this in the latent and actual stages. Food is usually the cause of gravels found in the human body. An American idea, adopted in Paris, is to wash out the gravels by distilled water; to this should be added food that will not produce gravel. A hint of what kind is seen in the action of a physician 40 years old, who was president of a vegetarian society in Germany, and found his temporal arteries atheromatous. He said: "Rigid arteries at my age, mean death." So he resigned and went on to animal food.

Gout is a variety of rheumatism which has a gravel of urate of soda. Any of the crystalline bodies found normally in the urine and feces may, when in the blood whence they come, cause rheumatism. The blood morphology also shows increase of fibrin filaments, red corpuscles, ropy, adhesive and coagulating in winrows. No one is really cured of rheumatism unless the morphology of the blood is normal. The enlargement of the heart found in rheumatism is mostly due to the resistance of the blood circulation. The heart has ganglionic nerve centers enough to be autonomic. The Bible statement, "the heart is deceitful above all things," sustains the heart's autonomy. The heart has something like cerebation in the brain, which I call *cardiation*. The heart knows when it should beat harder and does so, growing big by the excessive work. If it did not grow big, its work would not be done and death would follow. One way to treat cardiac hypertrophy, is to make the blood normal and nature will bring it down to normal size, other things being equal. I have seen this happen so often, that I am convinced of its truth. I feel sure that the future of medicine will embrace it, for no one wants a diseased heart when a normal one can be had.

THE RELATION OF FIBROID DEGENERATION TO NERVE DISEASES.

Whenever by improper feeding the nutrition is disturbed so that fibrous tissues replace that of normal spinal cord, sclerosis or hardening results,

so that the fibrous sheaths of the spinal or cranial nerves are thickened and pinch the axis nerve cylinder. These are decidedly enough to cause nerve diseases which are recognized and are common. So far as I know, these lesions are incurable save by American plans of diet. I have seen cures. Some of the cases are mistaken for rheumatism but the morphology of the blood corrects this mistake, when taken along with the other evidence. The principle of the treatment is that nature cures fibroid lesions if the causes are stopped and food is used which is easiest digested, best assimilated and most nutritious, combined with other rational aids to treatment. How I have longed that our nerve specialists would take to this idea!

EAR AND EYE AFFECTIONS AS NERVE DISEASES.

It is an American idea that these are food complaints mainly. Certainly, when the ear communicates air vibrations up to 42,000 per second, and when the eye communicates vibrations of ether three thousand billions per second, it is because of the exquisitely marvelous development of the terminal nerves of the ear and eye! No nerves, aural or ocular, mean blindness and deafness. This subject is of great importance. It is stated that from 20 to 30 per cent. of the children in primary schools have defective hearing. Steps have been taken to relieve this class of unfortunates. The writer was called on to suggest some means of relief for this class and read a paper on the subject before a teachers' convention lately.

The pedagogic ground was taken that if the children with defective hearing could have a two-thirds animal and one-third vegetable diet, other things being equal, they would improve. The technical ground was that most of the defective hearing came from a fibroid thickening of the Eustachian tubes, and that the way to treat these cases was the same as when fibroid tumors had been removed by the diet.

Again, the cause of deaf mutism is largely from scarlet fever. But I say that had these cases been fed rightly, they probably would not have had scarlet fever so severely as to cause the lesions of deaf mutism. On this diet, a case of severe scarlet fever in my own family was fed, where there were abscesses in both ears and neck swelled even to the chin; the recovery was perfect, there being no deafness though it was feared. I am happy to say that Prof. Currier, Principal of the New York Asylum for deaf mutes, agrees with me as to the relation of food to deafness. If this is not a field for a splendid future of medicine now uncultivated, where is there one?

FOOD AND EYES.

When a distinguished oculist says that most eye diseases depend on difficult digestion; when cataract, arcus senilis, glaucoma and retinal apoplexy are forms of fatty degeneration; when the want of proper mineral matter in the food produces weak corneas and thus affects the sight, we need search no farther for a trophologic cause of defective vision, or imperfect ocular nerve action. Probably the common use of flour and sugar has a great deal to do with diseased eyes. As foods they are deficient in elements for ocular tissues. In the future of medicine this subject will be better understood and less grievous. The diet will contain the proper proportion of organic and mineral elements, the best to make normal ocular tissues.

BALDNESS.

Since twenty kine were wintered with water, hay, grain and salt, and came out with fine sleek skins, and another twenty kine were kept all winter in the same barn and on the same diet, minus salt, and came out with the loss of a large part of their hair, it would seem that food had something to do, with baldness in these cases. Salt and air are food. Anything taken from without the body to sustain life and become a normal part of that body is a food.

The winter spent by the medical student above, in a chemical laboratory, taught that salt was an element in every tissue of the human body. The future of medicine will not overlook baldness, and rational treatment must look to food as a strong point, but not the only one.

The prevalence of defective teeth is so great, that we have a distinct department of medicine therefor. I am happy to state that the dentists generally admit the relation of feeding to the teeth and, so far as they can, insist on proper feeding. One of the most significant instances was given by Dr. Harri-man of Boston, when in a three months' time a firm fibrous texture was restored to chalky and friable teeth by an outdoor life, and a diet of animal food. If such dense stony structures are so soon affected by diet, what must be said of the soft tissues?

The general profession should be proud of the advance made in its dental division. To it we owe surgical anesthesia. The admission of dentists to the AMERICAN MEDICAL ASSOCIATION is a great step for a more harmonious and effective medical future, and I fervently hope the time will come when food in motherhood shall be such that children will not be born with such defective teeth as now.

EVIDENCE.

I beg to show some evidence that the three queries put forty years ago have been answered, which would be satisfactory to the propounder were he alive to see it.

1. A report was made to the Berlin Tenth International Medical Congress, of 100 cases of consumption, 40 per cent. cures.

A young woman in consumption was consigned by her physician to a funeral. She took the plans hinted at here. Diagnosis confirmed and treatment guided by the morphology of consumptive blood. Christmas evening, 1889, she was married, and now has a family. Her case shows a romance in medicine, which I hope will be more common. My son, Dr. J. A. Cutter, married a like case. In the light of the 100 cases it can not be said that love cured these two cases without doubt.

2. In 1888 a feeble, married, childless, menopausal woman, came under my care for cancer of the left breast, which was of a hard, dry, flattened character, involving the pectoral boundary of the axilla. Over the right breast and in the middle of the right popliteal space, each, was a cauliflower cancer, with a stalk of one inch nearly. The nerves were shattered. Great pain was complained of in the right hypochondrium, where the abdominal wall was thickened and hard like a board. There was complete anteversion, vaginal and uterine hyperesthesia, which was removed by iodoform vectores and capsules. The cauliflower excrescences were removed by galvano-caustic and have not returned. The patient was put on the diet approved for cancer. In June, 1889, contrary to my

expectations, I introduced one of my stem pessaries, just as I left for the British Medical Association meeting at Leeds. Dr. J. A. Cutter attended her in my absence. She wore her pessary till I returned, five months. It did not kill her, as one medical gentleman said it would, but was worn with relief, a space of four years! Sept. 11, 1893, a correspondent writes of her: "With other friends who have been here, I am surprised to find her so well and cheerful, assisting Addie, (her girl) in light duties, riding and enjoying herself generally. She still wears her instrument and has no trouble with it. Her husband had an ill turn for a week and she cared for him most of the time. *Diet was the great underlying principle of her treatment.* I would not be ashamed anywhere to present this answer to Query 2. A case of chronic rheumatism with ankylosed right knee joint, anteversion and hyperesthesia of the uterus, was entirely cured by diet treatment and my stem pessary. The uterus remained in situ at last accounts, after the pessary was removed.

DISEASES OF THE NERVOUS SYSTEM.

A few years ago, a boy 11 years old, was paralyzed below his waist so that he could not walk, and was deemed incurable. He ate largely of oatmeal, which of itself is a paralyzing food. His oatmeal was stopped. His diet followed the principles here advocated. In a few months the paralysis was gone and he is expected here to-day for you to judge of the reality of his cure.

Another case was a man of 28 who was unable to walk without help on level ground, or to get up stairs without climbing by the banisters. When he recovered so far as to walk alone, his head fell to the right, and had to be supported by his left hand. His right arm hung below the right knee. His nude body showed a genuine torso. The pains in the head and neck and right side were excruciating. The morphology of his blood showed absence of rheumatism. It was deemed a case of locomotor ataxia, from sclerosis of the spine. To confirm this an autopsy is needed, but if doctors must kill their patients in order to make a diagnosis, the future of medicine will be darker than it was forty years ago from the difficulties of medical jurisprudence. Unlike the veterinarians who kill for diagnosis, we must treat cases of sclerosis, and if we do not have verifying autopsies, but cures, it is rather a matter of rejoicing from a clinical standpoint. In about two years and a half treatment, in which no opiates nor anodynes were used, this case walks upright and is working on a farm. It might be said that a physician at the seashore who saw this patient carried there on a litter at the outset, and afterwards locomoting naturally, said to him: "I can not believe you are the same person;" but he could not gainsay the evidence, nor can I.

CONCLUSION.

Such is the partial prediction I have the honor to make, as mainly to be realized in clinical morphology and applied medicine. This is the field which lies before the students of medicine to-day. The progress that has been made is great, but as compared with that which our profession is bound to make in the near future it is slight. Before us lies the great ocean of medical truth, and the long line of our predecessors and our gifted and advancing contemporaries have but gathered a few pebbles upon its shore.

In sincerity, with humility and with courage should the medical student of to-day enter upon his advanced and ever advancing opportunities for usefulness and distinction.

CLINICAL HISTORY OF THE CASE OF PRESIDENT JAMES ABRAM GARFIELD.

BY ROBERT REYBURN, A.M., M.D.

PROFESSOR OF PHYSIOLOGY AND CLINICAL SURGERY MEDICAL DEPARTMENT HOWARD UNIVERSITY, WASHINGTON, D. C., AND ONE OF THE ATTENDING SURGEONS IN THE CASE OF PRESIDENT GARFIELD.

(Continued from page 417).

July 7, 2:30 P.M. The President vomited twice this morning, and complains of acidity of the stomach. Powders containing each fifteen grains of bicarbonate of soda were given him, and the surface of his body thoroughly and frequently sponged off. Temperature 101.4; pulse 108; respirations 24.

July 7, 8 to 11:30 P.M. He asked for the hypodermatic injection at 8 P.M., and slept until 11 P.M. He then awoke suffering very much from pain in his ankles. Some solution of bromid of potassium was sent for, but he fell asleep before it could be administered. Temp. 100.2; pulse 106; respirations 23.

July 8, 8:15 A.M. The President slept well during the night, and awoke at 6:30 A.M., in good spirits. Wound dressed antiseptically at 8:15 A.M. A slight slough separating from edges of wound with laudable pus. Very little inflammation around edges of wound. At 8 A.M. he took five grains of bisulphate of quinia. Temperature 99.2; pulse 96; respirations 23.

July 8, 1 P.M. Temperature 101.4; pulse 106; respirations 24.

Bulletin to consulting surgeons, Drs. Agnew and Hamilton:

July 8, 1 P.M.

The President's condition has not changed materially since our last telegram to you yesterday. During yesterday afternoon he was again troubled with acid eructations, and the administration of nutrients was again suspended for a few hours. One quarter of a grain of sulphate of morphia was given hypodermatically at 8:30 P.M., and was followed by tranquil sleep; towards midnight, however, he became restless, and complained a good deal of muscular soreness in his feet and ankle joints, so that we were on the point of administering an additional anodyne, when he fell asleep and on awaking was so free from pain that it was not administered. After 1 A.M. he passed the night tranquilly, sleeping composedly much of the time. He at intervals since that time has taken one ounce of albuminized chicken broth, alternating with an ounce of milk to which a teaspoonful of very excellent rum has been added; all this has been retained as well as five grains of bisulphate of quinia taken this morning at 8 A.M. The yellowish hue of the skin mentioned in our last telegram has sensibly diminished. When the antiseptic dressing was renewed this morning, the wound was found to be discharging a small quantity of healthy looking pus. The reaction accompanying the establishment of suppuration is, as might be expected, marked by a slight rise of temperature and pulse as compared with the same corresponding hours of yesterday; this however, we do not regard as unfavorable under the circumstances, and we should not be surprised if it continued during this afternoon and evening, or even for a day or two. July 8, 8 P.M. Temperature 101.3; pulse 103; respirations 24.

(Signed)

D. W. BLISS,
J. J. WOODWARD,
J. K. BARNES,
ROBT. REYBURN.

July 8, 10 P.M. During the afternoon and evening, the milk in one ounce doses was given with one teaspoonful of rum, alternating with albuminized chicken

broth, and at 7:30 P.M. his wound was again dressed. He expressed himself as feeling very tired, and a quarter of a grain of sulphate of morphia was given hypodermatically; after this he slept for nearly three hours. The same nourishment was continued during the night, and no nausea or other inconvenience was experienced.

July 9, 3 A.M. Came in and found him complaining of pains in the ankles; found them cold and wrapped them up in warm blankets, giving relief. July 9, 8 A.M. Wound was dressed antiseptically, and a small slough separated from the edges of the wound, with about two drachms of pus. Two ecchymoses showed themselves in the right hypochondrium. He was given at 9 A.M. ten grains of bisulphate of quinia, and the milk in doses of one and a half ounces with a teaspoonful of rum was steadily given during the day. Temperature 99.4; pulse 100; respirations 24. July 9, 1 P.M. Temperature 101.2; pulse 104; respirations 22. July 9, 7:15 P.M. Temperature 101.9; pulse 108; respirations 24. July 9, 8:15 P.M. Received a quarter of a grain of morphia hypodermatically, and went to sleep in a few minutes.

July 10:8 A.M. The President passed the most comfortable night he has experienced since he was wounded, sleeping tranquilly and with few breaks. July 10, 8 A.M. Temperature 100; pulse 106; respirations 23. July 10, 1 P.M. Temperature 100.5; pulse 102; respirations 22. July 10, 7 P.M. Temperature 100.9; pulse 108; respirations 24.

The wound was dressed at 8 A.M. and he expressed himself as feeling easy with a desire for further sleep; after the wound was dressed he fell asleep for nearly an hour and his pulse fell to 100. The milk and rum were continued during the day. His condition was favorable until 5 P.M. when he complained of great weariness and required many changes of position. The wound was dressed at 6:30 P.M. and one-quarter of a grain of morphia was given hypodermatically.

Dispatch to the consulting surgeons, Drs. Agnew and Hamilton:

July 10, 1881.

Such slight changes as have taken place in the President's condition since our telegram of yesterday are of a favorable character. About 7 P.M. his bowels were freely moved; shortly afterwards he received a hypodermatic injection of a quarter of a grain of morphia. He slept more naturally during the night than he has done since he was shot, and this morning is taking his nourishment well and appears on the whole better than hitherto. During the last twenty-four hours he has taken altogether fourteen ounces of milk and one ounce of rum. This morning at 10:30 he again received ten grains of bisulphate of quinia. Both yesterday and the day before, the wound was dressed antiseptically twice in the twenty-four hours. This morning it is discharging less pus than yesterday, but its appearance is healthy.

(Signed)

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBT. REYBURN.

July 11, 8 A.M. Temperature 99.2; pulse 98; respirations 23. July 11, 1 P.M. Temperature 99.8; pulse 106; respirations 24. July 11, 8 P.M. Temperature 102.8; pulse 108; respirations 24.

The President slept well during the early part of the night. From 2 to 5 A.M. was wakeful, but after that time slept well until 8 A.M. Has taken more nourishment and with relish this morning. The heat of the weather at this time was simply dreadful, and the President suffered greatly from it. An effort

was made to cool the air of the room by hanging long strips of muslin over light wooden frames, and keeping them wetted with ice water; this proving ineffective was abandoned. Mr. R. S. Jennings of Baltimore, had in operation to-day an apparatus for cooling the air in the President's room which was very successful. Air was drawn in by an exhaust fan through a subterranean chamber, filled with partitions half an inch apart, covered with Turkish toweling. The toweling was kept saturated from above by the dripping of water holding in solution ice and salt. The apparatus furnished from eighteen to twenty-two thousand cubic feet of air per hour at a temperature of 54 to 56 degrees Fahrenheit. At 11 o'clock this morning the outside temperature was 90 degrees Fahrenheit; at the outlet of the flue from the apparatus below, the temperature was 54 degrees, while at the head of the President's bed twenty feet from the outlet the temperature was 75 degrees. The President complained somewhat of a feeling of oppression in the chest; opening the window, however relieved him. The President was somewhat restless this afternoon, and after 2 P.M. began to be more feverish.

Dispatch to the consulting surgeons, Drs. Agnew and Hamilton:

July 11, 1 P.M., 1881.

During the past twenty-four hours the favorable progress of the President has continued. He has taken and retained twenty-two ounces of milk and one ounce of rum. This morning at 9 A.M. he had a slice of bread softened with milk. At 11:15 A.M. he took fifteen grains of bisulphate of quinia. There has been no irritability of the stomach at any time. Last evening at 7:15 P.M. he received a quarter of a grain of morphia hypodermatically and slept well during the night. The wound was dressed antiseptically yesterday evening and this morning, and continues to discharge a small quantity of healthy pus.

(Signed)

D. W. BLISS,
J. J. WOODWARD,
J. K. BARNES,
ROBT. REYBURN.

July 11, 7 P.M. Received his hypodermatic injection of a quarter of a grain of morphia, and went to sleep almost immediately and slept at intervals during the night. His temperature began to fall early in the night, and profuse sweating took place.

July 12 at 4 A.M. his pulse was 94 and his respirations 21 per minute while he was asleep. July 12, 8 A.M. Temperature 99.6; pulse 96; respirations 22. July 12, 1 P.M. Temperature 100; pulse 108; respirations 23. July 12, 7 P.M. Temperature 102.4; pulse 104; respirations 24.

July 12, 8 A.M. The President is feeling comfortable this morning. The rise in temperature noted in last evening's bulletin recurred, but came on an hour later. Wound was dressed antiseptically, very little secretion from wound. A two-inch decalcified drainage tube was tied into the wound. July 12, 1 P.M. The President is passing a comfortable day, and is much less restless than yesterday. Has more strength and power of movement in his limbs.

The following dispatch was sent to the consulting surgeons, Drs. Agnew and Hamilton, to-day:

July 12, 1881.

During the afternoon yesterday the President's temperature rose to the highest point it has yet attained. It began to fall, however, immediately after he received his evening dose of morphia—one grain of the sulphate hypodermatically, and this morning it corresponds with previous days. About 6 P.M. he had a copious and consistent movement from the bowels. His wound was dressed antiseptically yesterday evening and this morning. He continues to retain all the nourishment prescribed him, and has had twenty-four ounces

of milk and one ounce of rum during the past twenty-four hours besides a small quantity of milk toast this morning. At 8:30 P.M. he received ten grains of bisulphate of quinia. His general condition this morning appears to us to be rather better than yesterday morning.

(Signed)

D. W. BLISS,
J. J. WOODWARD,
J. K. BARNES,
ROBT. REYBURN.

July 12, 7 P.M. The President's wound was dressed antiseptically, the drainage tube was removed, thoroughly cleansed, dipped in carbolized oil (1 to 12) and reinserted. The secretion from the wound was much more abundant than in the morning, and was rather serous in character. At 12 P.M. the President received his usual hypodermatic injection of a quarter of a grain of sulphate of morphia, and slept quietly during the greater part of the night, occasionally awaking. At 5 A.M. (July 13) he took four ounces of milk and one teaspoonful of rum.

July 13, 9 A.M. Temperature 98.5; pulse 90; respirations 20. July 13, 1 P.M. Temperature 100.6; pulse 94; respirations 22. July 13, 7 P.M. Temperature 101.6; pulse 100; respirations 24.

July 13, 8:30 A.M. The President is doing well this morning. His gradual progress towards recovery is manifest and thus far without serious complications. He took ten grains of bisulphate of quinia at 8 A.M. He took four ounces of milk and one teaspoonful of rum every two hours during the day, also a slice of milk toast and a little breast of woodcock. The President had less fever this afternoon than either yesterday or the day before. Wound was dressed at 6:15 P.M. Pus flowing freely from it. At 6:30 P.M. had the usual hypodermatic injection of a quarter of a grain of sulphate of morphia.

Dispatch to the consulting surgeons, Drs. Agnew and Hamilton:

July 13, 1 P.M.

The febrile rise yesterday afternoon was less marked and occurred at a later hour than on the previous day, and to-day for the first time the President's temperature fell to the normal point. The general progress of his symptoms appear more favorable than hitherto. During the last twenty-four hours he has taken thirty-two ounces of milk and one ounce of rum. This morning he had also a slice of milk toast, and chewed the breast of a woodcock, but did not care to swallow the meat. He had last night one-quarter of a grain of sulphate of morphia hypodermatically. In no twenty-four hours during the past week has he received more than a single dose of this quantity, and he slept well during the night. This morning he received ten grains of bisulphate of quinia. (Signed)

D. W. BLISS,
J. J. WOODWARD,
J. K. BARNES,
ROBT. REYBURN.

July 14, 7:30 A.M. The President slept quietly during the greater part of the night, but was awake from 1 to 3 A.M. Wound dressed at 7:45 A.M., free suppuration from the wound, and a new drainage tube was inserted. He had ten grains of bisulphate of quinia at 8:15 A.M. Takes his milk and rum every two hours. He ate a slice of milk toast this morning. After his wound was dressed, about 8:30 A.M., he had a profuse sweat and complained of coldness of the extremities. Bottles of hot water were applied and he was wrapped in hot blankets until reaction took place, which occurred in about one hour and a half.

July 14, 8:30 A.M. Temperature 99.8; pulse 90; respirations 22. July 14, 1 P.M. Temperature 98.5; pulse 94; respirations 22. July 14, pulse 94; temperature 98.5; respirations 22. July 14. The President during the greater part of the day was free from fever, but was sweating quite profusely.

Bulletin to the consulting surgeons, Drs. Agnew and Hamilton:

July 14, 1 P. M.

The President has continued to progress favorably during the last twenty-four hours. The febrile rise yesterday afternoon was again less than on the preceding day. He has taken since our last telegram twenty-nine ounces of milk, and an ounce of rum, as heretofore, beside a small slice of milk toast this morning, and at noon a small sandwich of scraped raw beef, with two teaspoonfuls of Valentine beef juice, and an ounce of Tokay wine of 1868. The medication has consisted of a single hypodermatic injection of one-quarter of a grain of morphia, given last night, and ten grains of bisulphate of quinia at 8 A.M. to-day. We administered yesterday at 6 P.M. an enema of soap and water which was promptly followed by a copious movement of normal consistence and color.

(Signed)

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBT. REYBURN.

The febrile rise this afternoon was less pronounced, and did not cause so much discomfort as yesterday. At 8:15 P.M. three-sixteenths of a grain of sulphate of morphia was given him. He went to sleep very soon and slept profoundly the greater part of the night.

July 15, 8:30 A.M. Temperature 98.5; pulse 90; respirations 18. July 15, 1 P.M. Temperature 98.5; pulse 94; respirations 18. July 15, 7 P.M. Temperature 100.4; pulse 98; respirations 20. This morning the President partook of some juice of rare roast beef on toast, and Valentine meat juice with a glass of Tokay wine. His wound was dressed at 8 A.M. and was suppurating freely; the drainage tube was reinserted.

July 15, 9:30 A.M. three grains of bisulphate of quinia was given, and this dose was repeated at 4 P.M. and at 8 P.M. At 12 M. he received fifteen drops of aromatic sulphuric acid and also at 5 P.M. During the day the President took more solid food. He complains of pains in his feet, but does not sweat as much as yesterday.

The following report was sent to the consulting surgeons, Drs. Agnew and Hamilton:

July 15.

The President continues to do well. The afternoon fever is daily less marked. A smaller quantity of milk has been given, and solid food substituted and relished. He has had less rum, and at intervals of several hours has taken some Tokay wine, in all about two ounces and a half of the latter. Last night his hypodermatic injection consisted of three-sixteenths of a grain of morphia which proved sufficient to secure rest. This morning we have altered the dose of quinia to be taken three times a day.

(Signed)

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBT. REYBURN.

July 15, 7 P.M. The President has continued to do well during the day. The afternoon fever has been slighter than on any other day since the 3rd of July. At 8:15 P.M. he had a hypodermatic injection of one-eighth of a grain of sulphate of morphia. He slept well during the night and awoke in the morning much refreshed.

July 16, 8:30 A.M. The President has passed another good night, and seems to steadily progress towards convalescence. July 16, 8:30 A.M. Temperature 98.4; pulse 94; respirations 18. No bulletin issued at 1 P.M. July 16, 7 P.M. Temperature 100.2; pulse 98; respirations 19.

Bulletin to the consulting surgeons, Dr. Agnew and Hamilton:

JULY 16, 7 P.M.

The President progresses steadily towards convalescence. During the last twenty-four hours he has had but one-eighth

of a grain of sulphate of morphia, in a single hypodermic injection at bedtime. He slept well and this morning expresses himself as feeling quite easy. The quinia is continued in three grain doses three times a day. He is taking a still larger proportion of solid food, and with more relish than hitherto. Some old port wine has been substituted for the Tokay, its flavor being preferred by the patient. The febrile rise yesterday was less than on any day since you saw him. Hereafter our daily dispatch to you will be sent after the evening consultation.

(Signed)

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBT. REYBURN.

July 16, 7 P.M. The President has passed a better day than any since he was hurt. At 6:30 P.M. he received one-eighth of a grain of sulphate of morphia hypodermatically, and slept excellently during the night. July 17, 8:30 A.M. Temperature 98.4; pulse 96; respirations 18. July 17, 1 P.M. Temperature 98.5; pulse 90; respirations 18. July 17, 7 P.M. Temperature 100.2; pulse 98; respirations 20. July 17, 8:30 A.M. The President continues to improve; he passed an excellent night, and has a good appetite this morning. He took oatmeal and milk, lamb chops and bacon for breakfast.

Dispatch to the consulting surgeons, Drs. Agnew and Hamilton:

JULY 17, 7 P.M.

Since our dispatch of yesterday the President has done as our hopes then indicated. He has had a single hypodermatic injection of one-eighth of a grain of sulphate of morphia at bedtime, and slept well. Quinia in three grain doses has been continued, as well as the plan of nourishment hitherto reported. His bowels have been kept free by enemata. The wound is dressed with antiseptic precautions twice daily; there is now a free discharge of healthy pus. The afternoon fever both yesterday and to-day has been comparatively slight.

(Signed)

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBT. REYBURN.

July 17, 7 P.M. Our expectations of favorable progress have been fully realized by the manner in which the President has passed the day. He has taken more solid food and with greater relish than hitherto. His afternoon fever which is as slight as that of yesterday came on later. He received his hypodermatic injection of one-eighth of a grain of sulphate of morphia at 8:15 P.M. and went almost immediately to sleep. He slept well until between 4 and 5 A.M. of July 18.

July 18, 7 A.M. The President had a profuse perspiration this morning after 5 A.M., and felt quite tired after his wound was dressed. He ate some steak, and a poached egg, with potatoes and toast this morning. He had a nap from 10 to 11 A.M., and awoke quite refreshed.

July 18, 8:30 A.M. Temperature 98.4; pulse 88; respirations 18. July 18, 1 P.M. Temperature 98.5; pulse 98; respirations 18. July 18, 7 P.M. Temperature 100.7; pulse 102; respirations 21. July 18, 5 P.M. The President has suffered from nausea to-day, and nourishment was suspended. The wound was dressed at 6 P.M. and pus came freely from it. July 18, 7 P.M. The President had more fever this afternoon.

Bulletin to the consulting surgeons, Drs. Agnew and Hamilton:

JULY 18, 7 P.M.

Shortly after our dispatch of yesterday the President received a hypodermatic injection of one-eighth of a grain of sulphate of morphia. He slept well during the night, and this morning had a temperature of 98.4; pulse 88; respira-

tions 18. His day, however, was not quite so comfortable as yesterday. A slight gastric disturbance was noted towards noon, in consequence of which the quantity of nourishment administered was temporarily diminished. This was followed by rather more fever than yesterday, but the difference was not great, and is thought to be merely a temporary fluctuation.

(Signed)

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBT. REYBURN.

July 18, 7 P.M. He received one-eighth of a grain of sulphate of morphia hypodermatically, and went to sleep soon afterwards.

July 19, 8 A.M. The President is sleeping soundly and quietly. He is sweating, though not profusely. This morning he took beef juice and milk with rum and one slice of milk toast. As he did not seem to relish solid food it was deemed best to give him chiefly liquids and in diminished quantities. During the morning he seemed quite bright and cheerful, and had very little fever.

July 19, 8:30 A.M. Temperature 98.5; pulse 90; respirations 18. July 19, 1 P.M. Temperature 98.5; pulse 92; respirations 18. July 19, 7 P.M. Temperature 99.8; pulse 96; respirations 19.

Bulletin to the consulting surgeons, Drs. Agnew and Hamilton:

JULY 19, 7 P.M.

Last evening the President received a hypodermatic injection of one-eighth of a grain of sulphate of morphia, and slept well during the night. He continues to take sulphate of quinia in three grain doses thrice daily, and has enemata when required. As anticipated the increased fever of yesterday proved only temporary, and he has had a better day to-day than on any day since he was injured. The wound looks well, and is discharging healthy pus freely.

(Signed)

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBT. REYBURN.

July 19, 8 P.M. He received his hypodermatic injection of one-eighth of a grain of sulphate of morphia, and slept well during the night. July 20, 8 A.M. The President's wound was dressed, and it showed evidences of granulations.

July 20, 8:30 A.M. Temperature 98.4; pulse 86; respirations 18. July 20, 1 P.M. Temperature 98.4; pulse 88; respirations 18. July 20, 7 P.M. Temperature 99.6; pulse 98; respirations 19.

July 20, 8:30 A.M. The President took some milk toast and codfish for breakfast this morning. During the day took some milk and rum alternately with Valentine beef juice every two hours. He has also had three three grain doses of bisulphate of quinia, and three doses of fifteen drops each of aromatic sulphuric acid. He passed a comfortable day and was quite cheerful, and had scarcely any evidence of fever until about 4 P.M. July 20, 6 P.M. The President's wound was dressed and quite a free discharge of pus came from it.

Bulletin to the consulting surgeons, Drs. Agnew and Hamilton:

JULY 20, 7 P.M.

During the past twenty-four hours the President's progress has been uniform and satisfactory. He had a good night, and has expressed himself throughout the day as feeling quite comfortable. The indications reported in our last telegram have continued without change.

(Signed)

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBT. REYBURN.

At 8 P.M. he received his hypodermatic injection of one-eighth of a grain of sulphate of morphia, went

to sleep at 9 P.M. and slept well during the night. At 8 P.M. he also received three grains of bisulphate of quinia and fifteen drops of aromatic sulphuric acid.

July 21. At 8:20 and 2:40 A.M. he took some milk and rum and afterwards Valentine beef juice. The President had a good night, and expressed himself as feeling excellently this morning. He took stewed chicken and toast for breakfast. July 21, 8:20 A.M. Temperature 98.4; pulse 88; respirations 18.

July 21, 1 P.M. Temperature 98.4; pulse 92; respirations 19. July 21, 7 P.M. Temperature 99.9; pulse 96; respirations 19. July 21. At 10 A.M. he took three grains of bisulphate of quinia and fifteen drops of aromatic sulphuric acid. During the afternoon he seemed quite tired, though he took a fair amount of liquid food. At 6 P.M. his wound was dressed and a small portion of the shirt was discharged from it when it was dressed this morning.

Bulletin to the consulting surgeons, Drs. Agnew and Hamilton:

JULY 21, 7 P.M.

Since our telegram of yesterday the President has continued to do well. He passed a comfortable night. This morning a morsel of clothing, about one-quarter of an inch square, came away spontaneously with the pus from the deeper parts of the wound. It proved on examination to consist of cotton fibers with a few woolen fibers adhering. Medication continued without change.

(Signed)

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBT. REYBURN.

July 21, 8 P.M. One-eighth of a grain of sulphate of morphia was given hypodermatically. The President slept well, and took nourishment twice during the night.

July 22, 8 A.M. The President's wound was dressed and a large quantity of pus flowed from the wound, with a small scale of bone and some fragments of clothing and a small slough. July 22, 8:30 A.M. Temperature 98.4; pulse 88; respirations 17. July 22, 1 P.M. Temperature 98.4; pulse 98; respirations 18. July 22, 7 P.M. Temperature 100.2; pulse 98; respirations 19.

July 22, 8:30 A.M. The President rested well, and took for breakfast milk toast with a little dried beef. During the day he took buttermilk alternately with milk and beef juice.

July 22. During the early part of the day the President seemed as well as usual; but became quite restless and tired towards evening. At 5:30 P.M. he had an enema, and at 6 P.M. the wound was dressed as usual. A free discharge of pus came from the wound, but not so abundantly as in the morning. During the day he took three doses of three grains each of bisulphate of quinia with two doses of elixir of gentian and tincture of chlorid of iron, each consisting of two drachms. He received one-eighth of a grain of morphia hypodermatically at 7:15 P.M. and soon went to sleep.

Bulletin to the consulting surgeons, Drs. Agnew and Hamilton:

JULY 22, 7 P.M.

The President rested well last night, and has been easy during the day. At the morning dressing the wound, which is looking very well, discharged several ounces of healthy pus. A little solid fragment that floated out with the discharge proved to be a thin scale of bone about one-eighth of an inch in length, with a morsel of sloughing fibrous tissue and a number of adhering fibers of cotton and wool. He continues to take and digest a reasonable quantity of nourishment. The evening hypodermatic injection of sul-

phate of morphia (one-eighth of a grain) and the quinia (three grains thrice daily) have also been continued.

(Signed)

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBT. REYBURN.

July 22, 8:30 P.M. He complained of feeling chilly; this was followed by a febrile rise of temperature which lasted until 10 P.M. (Temperature 101.) During the night he was restless and did not sleep well.

July 23, 7 A.M. The President fell asleep towards morning, and the dressing of the wound was delayed until he awoke. July 23, 7 A.M. Temperature 98.4; pulse 92; respirations 19. July 23, 10 A.M. Temperature 101; pulse 110; respirations 24. July 23, 12 M. Temperature 104; pulse 125; respirations 26. July 23, 7 P.M. Temperature 101.7; pulse 118; respirations 25.

July 23, 10 A.M. The President was more restless last night, but this morning at 7 A.M., while preparations were being made to dress his wound his temperature was found to be normal. At 7:30 A.M. he had a slight rigor, in consequence of which the dressing of his wound was postponed. Reaction followed promptly, and the dressing has just now been completed. July 23, 12 M. He is feverish and quite restless, and has vomited three times this morning a fluid tinged with bile. At the noon consultation to-day on account of the unfavorable change that has taken place in the symptoms presented by the President, it was deemed best to telegraph for the consulting surgeons. This was done accordingly, and Drs. Agnew and Hamilton arrived at 8:15 P.M.

July 23, 2 P.M. He has just fallen asleep. He slept until 3:45 P.M. 4:40 P.M. Again asleep and slept until 5:45 P.M. 6 P.M. He took three ounces of milk and one teaspoonful of rum. At about 12:45 P.M. the President began to perspire and his temperature began to fall gradually, until at 7 P.M. it had fallen to 101.7. There has been a free discharge of pus from the wound during the day.

At 11:30 P.M. President Garfield had another rigor (the fifth he has had since 7:30 P.M. of July 22) and afterwards sweat profusely during the night.

(To be continued.)

A JURY OF TWELVE MEDICAL MEN.

BY EPHRAIM CUTTER, M.D.

NEW YORK.

In the March 17, 1894, number of this JOURNAL, John A. Sterling, Esq., ably treats "The Medical Expert Witness." On page 378, column 2, line 46, he writes: "If it were possible to have a jury of twelve medical men in all cases where medical evidence is required, then the medical expert would be unnecessary." I think not, but that he would be needed more than under our present American system of medical jurisprudence, which for more than a generation has been an *opprobrium medicorum*. This opprobrium can not be changed because the bar does not want it. Well do I remember the efforts made some thirty years ago to change this system, which were led by my late honored and honorable teacher, Prof. R. E. Rogers of the University of Pennsylvania. Probably there never was a more eloquent lecturer in a medical college. He made the dry subject of chemistry so juicy and oratorically palatable that his lectures were always crowded, and teachers of elocution

brought their pupils to study his deliveries as models of excellence. I well remember his Demosthenic plea before the AMERICAN MEDICAL ASSOCIATION. Yet his work was fruitless, not because it did not have all the elements of truth, active and professional disgrace (to quell); but because of the apathy of the profession itself. Prof. Rogers' words have had a potential power with me, and when I read the above quotation, it seemed to me that through it the dead eloquence of the talented and courteous Rogers might live to do good, and hence I write.

Why not have, in medical cases, a jury of medical men? There is no law against it, is there? Then it would need no extra legislation to have such a jury. Such a course would elevate America to the sensible plane of French and German medical jurisprudence.

As Prof. Rogers said, it is a disgrace to the medical profession to go into court and have different members swear to opposite facts in the same person. For example, to have six to eight medical men swear that a man had post-paralytic dementia, to be followed by homicidal mania, and then to have a set of the best alienists in America to swear that this was not so!

This question might well be discussed at San Francisco next June. *Why is it not possible, in cases requiring medical evidence, to have a jury of twelve medical men?*

FRAUDULENT MEDICAL INSTITUTIONS.

[Compiled for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.]

Of the twenty-one more or less active diploma "mills" still in existence in the United States, as described in the Report on Medical Education, by the Illinois State Board of Health, the following are among the most noteworthy:

"Chicago Correspondence University," Chicago, Ill. Incorporated in 1885; re-incorporated in 1887. "National University of Illinois," Chicago, Ill. Incorporated July 25, 1889. These two institutions, incorporated by the same person have had no existence as teaching bodies for purposes of medical instruction, but are operated solely for the sale of their so-called "diplomas." A "diploma" of this "National University," signed "F. W. HARKINS, Præses," and issued to THOMAS J. REDMOND, "*datum pridie Januariæ, Anno Domini, MDCCCLXXXIV*," was offered for record by the said REDMOND in Logan County, Idaho, May 14, 1891. The discrepancy between the date of incorporation, 1889, and the date of the "diploma," 1884, has not been explained.

In September, 1892, the secretary of the "University," one RUDOLPH A. VAN ANGELBECK, "Lit. D. F. N. U.," wrote from Pella, Iowa, offering the degree of M.D. to a graduate of the Chicago Ophthalmic College. The following is an extract from VAN ANGELBECK's second letter: "In case you are afraid your diplomas do not entitle you to the M.D. degree, apply at once for a Fellowship, remitting \$30 for same. Our Fellowships entitle holders to any degree." VAN ANGELBECK was arrested and indicted in March, 1893, for misusing the United States mails in carrying on his sale of the degrees of the "National University."

In November, 1892, the HON. JOHN W. FOSTER, Secretary of State, forwarded the complaint of the Department of Justice of the city of Amsterdam, Netherlands, showing that "this 'National University of Illinois' at Chicago has been selling medical

diplomas to foreigners who have not taken its courses." One "PROF. BLACKBURN, M.A., D.Sc., LL.D.," was the agent for sale in London, England,—"price two guineas."

During 1893 it transpired that these "diplomas" were being peddled under representations leading to the belief that they were from the new University of Chicago. DR. GOODSPEED, Secretary of the Chicago University, has no doubt that the University is being injured by HARKINS and his "diploma mills" and "would like to see the matter thoroughly exposed everywhere, particularly in England and Canada."

"*Malok's Brood.*"—During the past three years one JOHANN MALOK of Chicago, has profited by the wide-open incorporation laws of Illinois to the extent of securing charters for a brood of fraudulent diploma-selling institutions ostensibly formed,—according to the language of their articles of incorporation—"To instruct students in medicine and surgery and to give diplomas to graduates;" "to educate pupils in medical science, to graduate them and to issue degrees of M.D., and honorary degrees of M.D., and to issue diplomas as graduates of obstetrics for accoucheurs and midwives;" "to educate people in all branches pertaining to medical science and obstetrics, dentistry, hydrotherapeutics, magnetism, hypnotism and in everything that is for the benefit of the human body; and to graduate in the same and to issue diplomas and all kinds of degrees and honorary degrees for the same in present or absent." This last quotation is the "enlarged object of the German Medical College," chartered by the State of Illinois, Dec. 28, 1891, certificate of "enlargement" filed by the Secretary of State, July 14, 1892.

The first formed of the Malok brood was the "German College of Medicine and Obstetrics," charter granted Feb. 19, 1891. Then the "German Homeopathic Medical College," charter granted Dec. 8, 1891. Then the "German Medical College," charter granted Dec. 28, 1891; and the "German-American Homeopathic Medical College," the "German College of Gynecology, Pædology and Obstetrics," the "German Academy of Physiatrie Physicians," etc. These institutions have been repeatedly and publicly denounced as fraudulent by the Illinois State Board of Health and their so-called "diplomas" refused recognition. Nevertheless they are legally incorporated under the laws of the State of Illinois.

Evidence of the sale of the Malok "diplomas" in Germany and elsewhere is being accumulated with the view of securing a repeal of these charters.

"*Indiana College of Medicine and Midwifery.*" Indianapolis, Ind. Chartered in 1878 by one CHARLES P. HEIL, who, at the time the Illinois Medical Practice Act went into effect, was at the head of the "Northwestern College of Midwifery," in Chicago. His "college" was refused recognition and he, himself, was denied a certificate by the State Board of Health. Being thus compelled to leave Illinois he removed to Indianapolis, where he started his "Indiana College of Medicine and Midwifery," attention to which was first called by PROF. AUSTIN FLINT of the Bellevue, in a letter to the Secretary of the Illinois Board, April 9, 1890.

DR. FLINT inclosed a diploma of HEIL's institution, issued March 12, 1890, and conferring the "degree of Doctor of Medicine and Midwifery" upon one ALEXANDER KUNTSCH, by whom the diploma was presented to DR. FLINT for registration under the laws

of the State of New York. Certificates of the institution were presented to the Illinois Board by midwife graduates, but were refused recognition and HEIL's subsequent career may be found under the title, "Ohio College of Obstetrics, Medicine and Midwifery"—*q. v. infra.*

HEIL also announced his Indianapolis institution as the "Department of Obstetrics, Indiana Eclectic Medical College," a college not recognized by the Illinois State Board of Health.

"*Ohio College of Obstetrics, Medicine and Midwifery.*" Cincinnati, Ohio. This institution was originally located at Indianapolis, Ind., see "Indiana College of Medicine and Midwifery," *supra.* In 1889 HEIL, the projector, obtained a charter under the laws of the State of Ohio and began operations in the city of Cincinnati. In 1891 he was reported in the *Medical and Surgical Register* of the United States as living in Covington, Ky., Dean of the Faculty of the Ohio College of Obstetrics, Medicine and Midwifery, Cincinnati, Ohio." The so-called "College" never had a local habitation or existence—a name only, under which to issue diplomas.

After leaving Illinois, HEIL was "graduated" upon one term of lectures by the Eclectic Medical College of Indiana, an institution not recognized by the Illinois State Board of Health. He appears in the current *Medical and Surgical Register* of the United States in capital letters as:

"HEIL, CHARLES P., A.M., Ph.D. (Ecl), Ind. Ecl. Med. Coll., Indianapolis, Ind., 1883; Late Prof. of Obstetrics in Ind. Ecl. Med. Coll.; Surg-Steward in the U. S. Navy and Hospital Steward U. S. Army Late War; Mem. of National and Ind. State Ecl. Med. Assn's; Examining Surg., The Brotherhood of Railroad Trainmen; Late Dean of the Ind. Coll. of Med. and Midwifery, Indianapolis, 1696 3d av. New York, N. Y."

"*Vermont Medical College—the Second Medical College of the American Health Society.*" Rutland, Vt. This institution has no existence in Rutland, Vt., except on Commencement day, when one GEORGE DUTTON of Boston, Mass., who comprises the "Dean and Faculty" of the concern, takes his "graduating class" from Boston to Rutland and there holds "graduating exercises" and issues his diplomas.

DUTTON first attempted to organize what he styled the "First Medical College of the American Health Society" in Boston; but the Massachusetts Act of 1883, forbidding corporations created under the general incorporation laws from conferring degrees in medicine, secured through the exposure by the Illinois State Board of Health of certain bogus "diploma mills" in Boston, frustrated this attempt. He then incorporated this "Second Medical College" at Rutland in 1883, under a Vermont act authorizing the creation of corporations to establish and maintain literary and scientific institutions.

Although his "diplomas" are issued in Vermont, they do not entitle their possessors to practice in that State, the Supreme Court having decided, in the case of one of DUTTON's "graduates" against the State Board of Censors, that such institutions are not empowered to confer degrees or issue diplomas. DUTTON gives "instruction" in Boston, and has issued some forty-five or fifty Vermont "diplomas" on which persons are practicing medicine in States which recognize "diplomas or licenses from legally chartered medical institutions."

SOCIETY PROCEEDINGS.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 430).

The following paper by HENRY W. McCLURE, M.D., of Cromer, England, was read by title:

AN UNCONSIDERED AND IMPORTANT FACTOR IN THE EXPLANATION OF THE ACTION OF ELECTRICITY IN UTERINE DISEASE.

I might have given my paper another title possibly more appropriate, and that title would have been "A Plea for more Consideration for the Dielectric Tissues of the Human Body," yet in order to put the matter in a more concrete form, I have chosen to take the uterus to illustrate my thesis. My contention is shortly as follows: That the tissues of the human body are no exception to the general law that all opaque bodies are necessarily conductors and all transparent bodies insulators or dielectrics, more or less perfect; and that such a dielectric tissue as the serous coat of the uterus possesses the vital property of retraction, and such retraction may be quite independent of muscular contraction. This retraction is evidenced by a diminution of the superficies of the membrane; in other words, the serous coat shrinks, and that a portion of the current of electricity gets entangled in such a membrane in passing, but the force or energy is not lost. The kinetic electrode is merely made static, the shearing stress of the current has altered the condition of the molecules, inducing a strain in the dielectric, and I believe that this strain of molecular tension is analogous to, and identical with vital retraction or shrinkage.

Such a contention thus briefly stated I venture, not without extreme diffidence to bring before this important scientific Association, in the hope that it may lead to some discussion.

With your permission I will now bring what evidence I am able, in support of my thesis.

Professor Stephenson of Aberdeen, has devoted a great deal of time and labor to this subject of uterine retraction. Quoting the late Mathews Duncan he says: "It is certain that contraction does not necessarily imply retraction; that retraction is not dependent on contraction is difficult to prove, and that the only true safeguard against postpartum hemorrhage is this retraction of the uterine tissues." Professor Stephenson goes on to say that there is a way out of the difficulty; that is to exclude for the time being all muscular fiber out of the problem. The serous coat of the uterus manifests this phenomenon of retraction in a marked degree; that it possesses the property of shrinking in a perfect manner, and to produce the shrinking there must be definite tension of the membrane. It is the sole cause of the permanent shortening of the fiber, for after contraction alone (retraction being absent) we must always admit relaxation and the capability of the fibers to resume their original length; it is not an expulsive force.

From the revelations of frozen sections of the parturient uterus, it is evident that under retraction alone the uterine walls gather themselves around and are molded to the uterine contents, be they child, placenta or clot. To this molecular tension or retraction is due the permanent diminution in the superficies of the uterine walls.

Whatever electricity is, we must be convinced that it obeys the laws and acts as an incompressible fluid would act; that in passing through a conductor it meets with a certain amount of resistance or friction-like obstruction, but there is no tendency to reverse discharge or spring back. In an insulator, the electricity becomes entangled and this reverse discharge or spring back force is observed; in other words, the kinetic electricity has assumed the static form, electrical potential is stored up—a strain of the molecules has been produced; it is as if a bow were bent, the dielectric is able to give back again the same energy that was given to it by a reverse discharge—just as the arrow is propelled from the bow.

This condition of strain has been conclusively proved by examining by means of polarized light the glass in a charged Leyden jar.

Now, by the laws of electrical radiation, we find that the transparent tissues of the human body must necessarily be insulators or dielectrics, and that they are subject to the laws governing inorganic dielectrics; that is to this condi-

tion of strain, and that this condition theoretically in an animal membrane traversed by a current of electricity would cause tension in the lines of electrical propagation and pressure at right angles to this; in other words, it corresponds to shrinkage or the vital property of retraction, as demonstrated by Professor Stephenson in the serous coat of the uterus. No one doubts the power of the current, at least, at make and break, of exciting muscular contraction, a vital phenomenon. I do not see why we should deny it the power of exciting retraction, a function so closely allied yet seemingly independent. I use the word, seemingly, advisedly, as it may be that the non-conducting elements of muscular tissue may play a part of some importance in contraction.

We know that the skin offers an enormous resistance to the passage of the current, and if it were not for the many passages through it, the application of electricity to the human body would be almost impossible. According to Erb, muscle is the best conducting element in the body, and he would attribute the conducting power of the tissues to depend upon the blood and interstitial fluids. But he calls attention to the fact that nerve and muscle offer a much greater resistance to currents traversing them transversely than longitudinally; five to 1 in nerve, 9 to 1 in muscle. Imbibition of saline liquids does not, therefore, determine resistance altogether. I consider this has an important bearing on the subject under discussion, and to my mind the only solution to the problem is that the transparent elements of nerve and muscle are in the way of the current; so much electricity apparently disappears it is used up in producing strain of the medium. In the longitudinal direction there is nothing in the way; the electricity flows in the fluids between and outside the fibers. We find that a constant galvanic current during its flow does not excite muscular contraction.

We might here shortly review our knowledge of the action of electricity on a uterine fibroid. That inter-polar electrolysis can have very little influence I think must be admitted, save in that it is the means of conveying the electricity. But the products of electrolysis, the acids and oxygen at the positive electrode, the hydrogen and bases at the negative electrode have an evident and important action. This is the galvano-chemic cauterization on which Apostoli places so much reliance. By his large clay electrode he nullifies this action upon the skin; the active pole or electrode being intra-uterine which may be the positive, acid, hemostatic, or the negative—where caustic alkalies are liberated. "The tangible effect at the points of entrance and exit of the current which according to the dose and duration will be chemic cauterization, more or less severe, variable in conformity with the pole and different in its character at the two poles."

Apostoli speaks also of the inter-polar action of the current as setting up a process of disintegration proportionately wide and lasting, of the morbid products through which it is made to pass. So we have a chemic caustic action at the poles; of this there is no doubt, and according to Apostoli the result of this intra-uterine cauterization is production of contractile cicatrices which he believes to be the efficient cause in arresting hemorrhage.

Now what occurs between the poles? This is the important question.

We have the cataphoric action of the current by means of which fluids can be moved from one electrode to the other in the direction of the current. Quinin and iodid of potassium have been introduced into the body in this way, and their presence detected in the urine.

Erb confesses that we know practically nothing of the electrolytic and cataphoric action of electricity on the body, and with regard to the so-called catalytic influences of which we have to speak so often, he says we must confess they are purely hypothetical and that this expression is merely a collective name including several effects, of the individual nature of which we are still ignorant. Who can affirm that there are not other influences exerted by the current upon the human body, such as alterations in the molecular nutrition; in the production of heat; in the elementary affinity; in the osmotic phenomena on which the chief therapeutic phenomena depend. Among these, I would ask not an unimportant place for this theory of dielectric strain, which is manifested to a greater or less extent by all the transparent tissues of the body. We must all admit that when an electric current encounters a dielectric some of this electrical energy seems to disappear, but it is not lost we know; that whenever energy disappears in one form it reappears without loss in another. That is, the electrical energy that has seemingly disappeared has reappeared as molecular strain.

If, as Professor Stephenson has shown, the peritoneal coat of the uterus possesses this power of shrinking and so reducing the volume of the uterus, it is quite easy to conceive it so acting on a tumor situated in the uterine wall, under the stimulating action of a galvanic current and, be it remembered, a galvanic current of high intensity.

That a uterine tumor can be influenced by an electric current through the abdominal wall and made to shrink has been shown by a former President of this Association—Dr. Massey. I have had personal experience of the influence of the constant current in arresting hemorrhage in uterine fibroids where the electrodes were exterior to the uterus. Such experiences surely would lead one to look for another factor beyond the galvano-cautery, and I would ask at least your consideration of the problem of *dielectric strain*. To my mind, also, it plays a part of great importance in the action of static electricity on the human body; as I fail to see, if the body is a conductor, how the slightest influence could be exercised on tissues lying beneath the skin, but if we admit this dielectric tension and *lines of slip*; then all becomes plain and corresponds with our experience, as it has been most ably shown by Dr. Morton and the former President of this Society, that static electricity has a penetrating power equal if not superior to current electricity.

A. LAPHORN SMITH, M.D., M.R.C.S., Eng. Fellow of the American Gynecological Society; Gynecologist to the Montreal Dispensary; Surgeon to the Women's Hospital, read a paper on

THE TREATMENT OF DYSMENORRHEA BY THE GALVANIC CURRENT.

In a paper read by Dr. Apostoli at the International Congress at Berlin, in 1890, occurred these words: "Open all the classical text-books and you will see that uterine atresia is a common cause of dysmenorrhea. I, myself, shared this opinion until facts, themselves, proved to me the contrary. Seeing in fact, one by one, patients whom I had treated since 1882 and who consequently followed intra-uterine treatment, which has necessitated the free introduction of the sound, I was struck with the great number of semi-atresias which I found. Seeing that the same sound could no longer enter, I was still more surprised with the reply which these patients always made, who had been nearly all suffering from dysmenorrhea before my treatment, and who had since then found themselves free from these symptoms, and remaining so notwithstanding the narrowing of the canal. These facts have led me to believe, contrary to the general opinion, that dysmenorrhea is most often an ovarian symptom. The intra-uterine galvano-cauterization which I employed has, therefore, in its favor the distinct advantage in the greater or less atresia which it eventually provokes without interfering in any way with the evolution of the periods—atresia which remains a posthumous witness to the cure of certain cases of endometritis, and which I consider as a vigilant sentinel which prevents a return of hemorrhage. But you will say, Then what about pregnancy? Yes, at the beginning of my practice I believed theoretically that pregnancy would be impossible, but theory has had to give way before facts, and to-day I can furnish thirty cases among my patients who have undergone intra-uterine galvano-cauterization, even positive ones, and who without any difficulty became pregnant and went to full term."

Now my own experience has fully borne out on this point as it has on every other particular, the wise sayings of my distinguished friend. In nearly every case of fibroid treated by Apostoli's method in which the hemorrhage was diminished, the dysmenorrhea was cured at the same time. In one of the cases which I reported a year ago in the *American Journal of Obstetrics* sent to me by Dr. Jeanotte of Montreal, there was a large fibroid with very little hemorrhage, but with such severe dysmenorrhea that the patient had for eight years before coming under my care been obliged to go to bed for more than a week out of every month, and to have at least two hypodermics of morphia a day during the whole of her menstrual periods. This patient was completely cured and has remained cured now for more than four years.

At first I thought, as Apostoli did, that dysmenorrhea was due to stenosis of the internal os, and I therefore employed the negative pole for the cure of dysmenorrhea with the intention of thereby dilating the canal. But in looking over my cases in the light of the above words of Apostoli, I perceived that the pain had been equally well relieved in those cases in which the positive pole had been employed and with such high doses that stenosis was the result as were those cases which had been treated by moderate doses with the negative pole. This has led me to believe that they are

right who maintain that dysmenorrhea is rather due to endometritis than to stenosis of the canal. This view is still further borne out by the fact which has been observed by many others that rapid dilatation alone is not always followed by cure, while it sometimes requires repeating many times. I have also observed that the result of rapid dilatation was much more successful when it was accompanied by curetting and the application of iodized phenol to the endometrium followed by drainage with gauze; measures which are precisely among the most modern and most effective for the cure of endometritis. Then again, in making use of the sound we generally find that its passage over the internal os causes acute pain which after a few applications of the galvanic current invariably disappears. It now seems clear that this is due to the inflamed condition of the uterine mucosa, for in a healthy uterus the passage of the sound even with considerable pressure causes very little or no pain.

As I said in my paper above referred to, I quoted the report of a thousand cases of dysmenorrhea, in over nine hundred of which there was undoubted endometritis. My own experience, although much more limited fully bears out the correctness of this statement. In nearly all of my cases which required examination I have found the uterus sensitive to the touch; there was headache, very often trouble with the bladder and rectum, a uterine leucorrhœa diagnosed by means of the dry tampon of sublimated cotton left for twenty-four hours against the os, and in a great many there were reflex disturbances through the great sympathetic of such distant organs as the stomach, heart and eyes. On passing the sound I have invariably found that as soon as its extremity reached the level of the internal os, severe pain was caused which these patients stated was exactly similar to that which they suffered every month. On the other hand, I have seen so many cases of acute ante flexion without endometritis in which there was no dysmenorrhea that the opinion has been gradually growing in my mind that it is only when the above mentioned conditions are associated with endometritis that they cause dysmenorrhea. Moreover, my experience in the matter of treatment has been that in the majority of cases the most satisfactory results have followed the use of such measures as have been found to be most effective in curing endometritis, such as curing habitual constipation, removing other obstructions to the pelvic circulation, improving the circulation generally, improving the circulation in the pelvis by very hot douches and boro-glycerid tampons, rapid dilatation, curetting with and without the intra-uterine tampon, and with or without an intra-uterine stem and the application of the galvanic current.

With another year's experience, I can say the same thing even more positively. Since then we have constantly seen reports of cases of failure to cure dysmenorrhea by rapid dilatation alone. Even Winckel says that he had treated patients of his own, and had under his care patients of his colleagues who had been treated by rapid dilatation and even cutting of the cervical canal without avail.

Of the nine cases I reported a year ago I have seen or heard from seven who have all remained free from menstrual pain, and as far as I know so are the remaining two; and yet two of these cases have been treated by very thorough rapid dilatation. Since then I am sorry to say I have had other failures to cure by means of rapid dilatation alone. Two of these were followed by pelvic peritonitis in spite of the most rigorous antiseptic precautions, and probably owing to latent disease of the tubes, while the many cases which have been successful have at the same time been treated for endometritis by curetting and drainage. So that I am more than ever convinced that menstrual pain of uterine cause is, in the majority of cases, due to inflammation of the uterine mucosa, and can best be treated by the intra-uterine application of the galvanic current. The treatment, as I have already said, is almost painless, absolutely devoid of danger, only mild currents being employed and does not require the patient to lay up, or even to stop her usual work. She has only to come to the office twice a week for from three to six weeks, when as a rule her second period following the beginning of treatment will come on without pain so that in several of the cases I reported, the flow appeared while they were out walking and without their having made any preparations for it. In my paper above referred to, I stated that I employed the negative pole in the uterus in eight of the nine cases. It may be asked when should we employ the positive and when the negative pole? That depends upon the amount of flow and the size of the uterus. If the uterus is large and flabby or the flow profuse, I would use the contracting positive pole.

If, on the contrary, the uterus is undeveloped and the flow scanty, I would prefer the negative pole.

In case there may be some here who did not see my paper on the subject, I may be allowed to repeat the few brief directions for carrying it out:

After careful bimanual examination for the purpose of excluding pregnancy and of ascertaining the position and condition of the pelvic organs the vagina is disinfected by a douche, if this has not already been done at the patient's home. An ordinary Simpson's uterine sound of large size is then bent to the ascertained curve of the uterine canal, passed through the flame of the spirit lamp, cooled and insulated with a piece of clean rubber tubing to within two and a half inches of its extremity or less if we have reason to think that the uterus is undeveloped. In the handle of the sound a hole has been bored just large enough to hold the tip of the conducting cord from last zinc of the battery. The sound is then guided into the os uteri on the tip of the finger until it meets with some obstruction when a current of ten milliampères is turned on. In a minute or two the obstruction will seem to melt away and the sound will glide into the cavity of the uterus. The current is now gradually raised until the patient says she can feel it in the uterus, generally between twenty and fifty milliampères, being at once lowered on the appearance of the slightest pain. At the end of five minutes the current is gradually turned off again when the sound will be found to drop out almost of its own accord and very much easier than it entered.

This may complete the seance, or as an adjuvant and safeguard a boro-glycerid tampon may be inserted. The patient may return home and resume her duties forthwith, as such mild applications do not require any precautions in the way of resting, etc. The positive pole of the battery is attached to the ordinary clay abdominal electrode. When it is desired to attach the positive pole of the battery to the intra-uterine electrode, the latter must be made of platinum or carbon.

I can only say, in conclusion, that I have no hesitation in recommending a treatment which in my hands has given such good results.

DISCUSSION.

DR. MASSEY was glad the author was more positive now than formerly, in his use of the galvanic current in cases characterized by pain. It should not be forgotten, also, that his work originally was that of an operating gynecologist.

The speaker said he could corroborate everything which had been said in the paper about the ease of the treatment, and its freedom from risk in the hands of any one competent to make intra-uterine applications. He did not believe an application should be made to the interior of the uterus oftener than every two or three days. He rarely saw atresia unless very strong currents had been used, or the operator had omitted to insulate the portion near the os. It is for this reason that he preferred to insulate the instrument with shellac. The obstruction at the internal os is largely due to spasm.

He also wished to commend what had been said about painful menstruation being often of a neuralgic nature. He had called this condition "menorrhagia" instead of dysmenorrhea.

DR. SPRAGUE said he had had more satisfaction in this line of treatment than in any other; for he had very rarely failed to relieve dysmenorrhea by intra-uterine application of electricity. He had not tried the positive pole very much, but had not found it as good as the negative. He had used moderate currents, and he had not produced atresia, but on the contrary had relieved what atresia already existed. It is much more probable that the pain which is induced at the internal os is due to hypersensitiveness of the nerves than to endometritis, because it is relieved by a current so mild that it could hardly be expected to affect an endometritis. He never used over fifteen milliampères.

DR. HAYES wished to place himself on record as having the same clinical experience as Dr. Smith. The other day he had a case of dysmenorrhea which was supposed to be due to atresia, but he treated it with intra-uterine galvanization, and was much pleased to see it yield.

DR. CLEAVES said that after an experience of seven years she could corroborate what Dr. Smith had said. She thought dysmenorrhea was quite as often due to pelvic congestion as to endometritis; hence, it was relieved by quite mild currents. She could also corroborate what was said about this treatment not producing sterility, as a number of her patients had become pregnant within a few months after the treatment. She preferred mild currents, and gave the treatment not oftener than once in five days or a week.

One patient who had been formerly treated by several eminent specialists, and who had worn a glass stem after divulsion for several weeks without relief, was completely cured about seven months ago by mild applications of positive galvanism. She had remained perfectly well, and for the first time in her menstrual life is now absolutely free from pain.

DR. KELLOGG said that the use of the galvanic current for the relief of dysmenorrhea is its most important use; it is almost a specific for certain forms. In the great majority of cases, dysmenorrhea is not due to atresia, and this is why the surgeons have very largely abandoned the old method of dilatation advised by Dr. Peaslee. At one time he cured these cases after dilatation, because he found that in cases where there was no obstruction in the canal, there were vegetations present almost without exception. He thought these vegetations swell up at the menstrual period, and produce an obstruction only at this time. In these cases the use of ten to twenty milliampères with either pole—most commonly the positive—is very effective.

In another class the dysmenorrhea is due simply to hyperesthesia, and here he always uses the positive pole, as it destroys the sensitive nerve endings. He was very certain it did not prevent conception.

DR. DICKSON also wished to indorse the use of galvanism for this condition. He took great pleasure in saying that the surgeons and gynecologists in the hospital with which he was connected were now looking much more favorably on the electrical treatment. Cases in which the uterus is so irritable that uterine colic comes on, on the introduction of an instrument, yield very readily to galvanic treatment. He also believed with Dr. Cleaves that the condition is more often due to pelvic congestion than to endometritis.

His electrode for this work consists of an ordinary piece of copper wire, the size of a common uterine sound, the end of which is readily rounded. It is bent to the proper curve, and silver plated, and then insulated with hard rubber, for such tubing can not be easily procured to fit wire of various sizes.

DR. MAATIN expressed his appreciation of this paper. He thought as electricians we should not forget that we are speaking to the profession at large. Every case of dysmenorrhea is not by any means suitable for galvanic treatment. The treatment should be preceded by a thorough examination and the making of a careful diagnosis. We should not fall into the old-time quack practice of "giving" electricity. Occasionally dysmenorrhea is due to occlusion of the os or canal; sometimes it is due to non-development of the uterus, in which case the faradic current of slow vibration to develop the muscular tissue is more suitable than is the galvanic current. In another distressing form due to tubal and ovarian difficulty, we would get disastrous results from the galvanic current. A tubal or ovarian abscess, or the so-called cystic ovary will not yield to the galvanic current when it will frequently yield to a sedative current of high frequency. Even this should be used with great caution lest it cause the expulsion of the contents of such an abscess into the peritoneal cavity. For endometritis or stenosis of the canal, he agreed that galvanism should be used, and he preferred the positive pole with an electrode insulated beyond the os. He had devised an electrode specially for such work.

DR. WALKER said that galvanism is a failure if used as a specific. When the dysmenorrhea is more marked two or three days previous to the flow, he never gives galvanic treatment until after a careful examination of the appendages under chloroform.

DR. SMITH, in closing the discussion, said that several of the objections raised were really answered in the paper because he had expressly stated that the treatment is not to be begun until after a most careful and thorough examination for diagnostic purposes. Being an operating abdominal surgeon, he had forgotten to emphasize the fact that the treatment should only be employed by those competent to determine the existence of disease of the appendages. In the majority of cases he believed dysmenorrhea was due to spasm of the internal sphincter, the result of reflex irritation from an endometritis. It is for this reason, that he applies the current directly to the internal os, for it is well known that when there is a small ulcer in this situation, a mild cauterization of these terminal fibers will often temporarily give relief.

(To be continued.)

Blank Applications for membership in the Association, at the JOURNAL office.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE. \$5.00
SINGLE COPIES. 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

W. H. LOWDERMILK & CO., WASHINGTON, AGENTS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, MARCH 31, 1894.

THE FORTY-FIFTH ANNUAL MEETING.

The next annual meeting of the AMERICAN MEDICAL ASSOCIATION will be held in San Francisco, June 5, 1894. The programs of the Sections, so far as completed, show an amount of work that will not in any degree fall below the high standard of last year.

We are much pleased at the tendency to condense the papers, and in the interest of those who will read them, we hope that all Section officers will use their influence in inculcating the value of brevity as an aid to correct understanding. Redundancy of expression detracts from the merit of an article, and often renders the meaning obscure.

The enlargement of the JOURNAL made last July, will we trust be permanent, and will enable the early publication of the Transactions.

The revised list of members is now in preparation, and together with the report of the committee on the new Constitution, will be ready for distribution at the meeting. By the rules, this list must be published triennially, and few can imagine the labor involved in making the necessary changes.

We sincerely hope that the publication of this list will have the incidental effect of stimulating the members to renewed effort. We earnestly appeal to every member of our already great ASSOCIATION to use his personal influence to increase the membership. The ASSOCIATION has, to-day, more members than it ever had, but it has only about one-third as many as the British Medical Association. By a little more effort on the part of our members we might have twice as many members as that excellent organization.

The Committee of Arrangements have set about the task of bringing into fellowship the entire regular profession of the Pacific Coast, and these added to the existing list, will give the ASSOCIATION a greater impetus than has been given at any recent meeting.

One of the arguments used to bring them to this meeting, is that they will have an exceptional opportunity to meet their Eastern brethren. This demands from the old members that they make every reasonable sacrifice to benefit the ASSOCIATION by attending the meeting and taking part in its proceedings.

The trip itself promises to be most attractive; the stops among the Rocky Mountains of Colorado, the visit to Salt Lake and the scenery on the Sierras, will be remembered through life. By traveling on the regular ASSOCIATION train, there will be no extra fare of any kind required for the time taken up while inspecting Denver, Colorado Springs, Manitou, Glenwood Springs and Salt Lake. The itinerary will be published next week.

The rates promised are the excursion rates given to visitors to the Midwinter Fair which will be open until July. We are promised the benefit of any lower cut rate that may be prevailing at the time.

The return trip may be taken by way of the Northern Pacific Railroad, or may be taken by any of the direct lines.

Those desiring to see the Yellowstone Park and its natural wonders may return by way of the Northern Pacific.

We earnestly urge all who can, to make the excursion. Not only will the Doctor have an agreeable and pleasant journey but, on his return, the sick room of many a sufferer will hear the story of his eventful tour to the Golden Gate.

NEW JERSEY MEDICAL EXAMINING BOARD.

The State Board of Medical Examiners of New Jersey is now in the fourth year of its existence; and during this short time has demonstrated its importance and necessity. It has not alone elevated the standard of qualification of those who were licensed; prevented incompetents from practicing, and the influx of those who had fraudulent diplomas as was common before the law was passed, but exercised a decided influence upon medical education. The Medical Society of New Jersey, organized in 1776, was given authority to confer the degree of M.D. in 1866, but the Society did not often have an opportunity to exercise this privilege, for the reason that, as a rule, the medical colleges had far less rigid examinations. The law that was in force before the Medical Examining Board was created, simply required the registration of a diploma from a legally chartered medical college, in the office of the county clerk, in the county in which the party wished to practice. A similar law was in force in New York and Pennsylvania, before the present laws were enacted, but in these States the diplomas of schools outside of their respective States, had to be indorsed by one of the medical colleges of that State. This provision exercised some control, but in New Jersey

there was no medical college, and as a necessary consequence, many diplomas of disreputable and fraudulent colleges were registered; in fact this stimulated the sale of diplomas, and the organization of fraudulent diploma-granting institutions. We noticed for several years the diplomas that were annually registered in the different counties of the State, and among them were found diplomas the possessors of which had been driven from other States. We were much struck one year by finding the diplomas of the so-called "American Health College of Cincinnati, in which was taught in six weeks the great vitapathic system of medicine." This institution was incorporated under the laws of Ohio, "authorizing the holder of a diploma to practice the vitapathic system of medicine, and conferring power to solemnize marriages, preach the gospel, and perform all other duties as a minister."

The long-felt want was, however, soon supplied, by the establishment of the Medical and Surgical College of New Jersey, at Jersey City in 1888, under a charter obtained from the Legislature of that State in 1870. The character of the College was exposed by the writer early in 1890, and soon after was temporarily closed by injunction of the Hudson County Medical Society, and on Nov. 11, 1890, the State Board of Medical Examiners took action toward securing the repeal of its charter, at the next session of the Legislature, in which they were successful.

The present law, when it was enacted, May 12, 1890, was undoubtedly one of the best, and with a few amendments would be all that could be desired in the way of legislation. It differs from the laws of other States in dividing "the applicants for examination into three classes," to-wit: 1, persons graduated from a legally chartered medical school, not less than five years before date of application for a license; 2, all other persons graduated from a legally chartered medical school; and 3, medical students taking a regular course of medical instruction, the examinations all differing.

The Secretary, in the Third Annual Report, says that the law rather acts by exclusion than by rejection; "this is proven by the fact that during our three years' existence, we have examined only 397 candidates, including the preliminaries, and those previously rejected, and issued only 307 certificates to practice medicine, which only equals the number registered each year under the old law." Among the applicants examined, there were some who had been before the Board six times. The Board is composed of nine physicians, three of them being homeopaths and one eclectic, and is therefore what is called a "Mixed Board," the same as Illinois, Iowa, Missouri, Minnesota, Oregon, Washington, Virginia and Ontario. The Secretary closes his First and Third Annual Reports as follows: "Yet each member will

bear me witness when I say that we are a harmonious Board; we are there as nine men to see to it that the requirements of the laws are complied with; that the words 'school' or 'pathy,' are never mentioned in our deliberations; that we do not try to break down or build up any school, but we are determined that every physician who hereafter locates in New Jersey shall be an educated physician."

In 1892 the Board secured the passage of an "Act to Regulate the Practice of Midwifery," the first special legislation upon this subject in the United States. While it is true that Illinois, Iowa and Missouri under the general powers granted in the law creating these Boards, have taken the midwives under their supervision. This legislation was secured under the "belief that the health of a large number of the poorer classes, who employ midwives in confinement, should be and could be protected by securing better care of the lying-in women and their infants." The result has proven that the Board was right, and so far under this law 232 women have been licensed to practice as midwives. It means a decrease in all the ills and accidents incident to the lying-in chamber.

It is but just to call attention to the fact that all the benefits incident to this legislation have cost the State of New Jersey nothing, but that it has practically been carried on at the expense of the members of the Board. The fees received from candidates, after paying the stationery bills, printing, engraving and mailing certificates, printing laws, rules and regulations, and furnishing examination paper, etc., scarcely pay the traveling expenses of the Board, not to mention the loss sustained in their private business during their attendance upon the meetings of Board, and the time consumed while at home in the preparation of the questions for examination, and examining the answers to the same.

We understand that an effort will be made to secure amendments to the law, at this session of the Legislature, and it is to be hoped that provision will be made to relieve the burden of maintaining the Board from its members, and that they be properly compensated. It is not saying too much that a great deal that has been accomplished under these laws is owing to the efficient Secretary, DR. WM. PERRY WATSON.

THE LATE JOHN H. RAUCH, M.D.

The editor received a telegram on Saturday last, from DR. WM. GUILFORD of Lebanon, Pa., announcing that DR. RAUCH had been found dead in his bed that morning (March 24). Elsewhere we print his completed summary of the present smallpox epidemic in the United States; and a note from him written on Thursday stated that he would finish the article the next day. This article is therefore his last contribution to the literature of public hygiene. Since last

July, DR. RAUCH has edited the Public Health Department of this JOURNAL, and the leaders written on sanitary topics since that date, were most of them his production. Few men were better qualified to write with authority on sanitary subjects, and as a practical hygienist he had few superiors in any quarter of the globe.

The public park system of Chicago, the water supply, the drainage canal of the city, and a multitude of public works recommended by him, will perpetually remind the coming medical historian, that in this age lived a wonderfully energetic and capable sanitarian.

In the matter of higher medical education, no single man did more to elevate the standard than JOHN H. RAUCH. No one can doubt that it was almost solely due to the action of the Illinois Board of Health, under the Practice of Medicine Act suggested by him, that the medical colleges increased the length of their college terms, and required additional study as preliminary to graduation. The time was ripe for the movement. The AMERICAN MEDICAL ASSOCIATION had urged it repeatedly, and the general sentiment among medical men was tending toward higher medical education. The man to lead the work was found in DR. RAUCH, and within one year from the time the Illinois State Board gave public notice, the medical schools throughout the country had raised their admission standard, and lengthened their collegiate year. The movement thus started proved popular and still greater advances followed.

If few have had so great an opportunity, none have taken advantage of it as he did, to spring into leadership.

With the general acceptance of the four year system by the medical colleges, his work was finished, and he realized it. Worn and broken by the hardships of long and faithful service, and enfeebled by disease, he retired last autumn to his old home in Lebanon, for rest and recuperation.

His intense interest in everything relating to the AMERICAN MEDICAL ASSOCIATION, which organization he regarded as appealing in the strongest possible manner to the *esprit du corps* of the medical men of this country, led him to actively support this JOURNAL and too often work beyond his strength in its interest. As a member of the Board of Trustees, his advice was always conservative and useful. His place on the Board will not easily be filled.

CONSTRUCTION OF STATUTORY PROVISIONS FOR THE CARE OF INDIGENT SICK.

A statute providing for the care of the indigent sick, the Supreme Court of Idaho holds, in the case of Board of Commissioners v. McFALL, decided Feb. 9, 1894, is one of mercy and benevolence, and must be liberally construed, with a view to carry into effect

its beneficent objects and designs. The provisions of the Idaho statute, directing contracts to be made for the keeping of the indigent sick of a county, for a gross sum per year, the court holds are broad enough to include all such sick within the county. It does not require that they reside within the county any certain length of time, or that they possess any particular qualification, other than that of being indigent sick or otherwise dependent poor. A citizen of another State, who comes into this State and becomes sick, and is pecuniarily unable to provide for himself proper medical aid, attendance and support while so sick, comes within the purview of that statute. However, in a case of that kind it is the duty of the Board of County Commissioners to remove such sick person to the county or State of his residence as soon as practicable. One who has a contract for keeping all the indigent sick of a county, for a gross sum by the year, is not required to keep any who do not come within the terms of his contract. And he can not bind the county for the keeping and caring for any person who does not come within the provisions of the statute.

CHANGE OF OCCUPATION DOES NOT DISQUALIFY AN EXPERT WITNESS.

The competency of an alleged expert witness is a preliminary question of fact to be determined by the trial court, and its determination that the witness is competent will be generally regarded as conclusive, unless there is no evidence whatever, or no sufficient evidence, to support it, or the determination is contrary to the evidence. So says the General Term of the Court of Common Pleas of New York City and County, in its decision of the case of HAAS v. GREEN, rendered Feb. 5, 1894. That an expert witness has changed his employment, for example, has abandoned his studies as a chemist and devoted himself to the occupation of a druggist, vending drugs and toilet articles exclusively, this court further holds, does not render him any the less competent.

PUBLIC HEALTH.

The Smallpox Situation in the United States.

By JOHN H. RAUCH, M.D.

The following gives the smallpox status of the United States to March 17, obtained from official and reliable sources:

Two steamers have recently arrived with smallpox: One at the Delaware breakwater, from Rouen, France; and the other at Boston harbor from London. A young lady who arrived on the *Majestic* from Paris was taken sick after her arrival at Brattleboro Vt., and there was another case in Elk County, Pa.

No immigrants should be allowed to come to this country from Europe without being vaccinated before embarking, owing to the prevalence of smallpox in Europe.

The Health authorities should continue to press vaccination, as it will be found that the objections of many will be removed with the milder weather of the next three months.

With a more thorough sanitary investigation of the country than obtained twelve years ago, and the exclusion of unprotected immigrants, the epidemic should be stamped out by next December.

MASSACHUSETTS.—Dr. Abbott, the Secretary of the State Board of Health, reports under date of March 14, as follows:

Cases reported to the Board	October 1893,	3
“ “ “ “	November, 1893,	8
“ “ “ “	December, 1893,	19
“ “ “ “	January, 1894,	25
“ “ “ “	February, 1894,	27
“ “ “ “	March 1 to March 14,	14
		—96

Of this number 68 were in Boston, 8 in Lowell, 5 in Holyoke, 4 in Worcester, 2 each in Somerville, Brookline and Methuen, and 1 each in Marlboro, Yarmouth, Lawrence, Waltham and Lynn. There were 13 deaths and all unvaccinated. Can not give the vaccinal statistics at this time. The following, however, for the previous eight years (1885 to 1892 inclusive), is worthy of note:

Number of deaths from smallpox reported to the Board,	28
“ “ cases of “ “ “ “	124
“ “ deaths among the vaccinated,	3
“ “ cases “ “ “ “	50
“ “ Percentage,	6 per cent.
“ “ deaths among the unvaccinated,	17
“ “ cases “ “ “ “	49
“ “ Percentage,	34.7 per cent.
“ “ deaths among the doubtful or unknown (as to vaccination),	8
“ “ cases among the doubtful or unknown (as to vaccination),	25
“ “ Percentage,	32 per cent.

The only points in the State where cases exist are Lawrence, Yarmouth, Lynn, Waltham, and Boston. At the four first named there is only one case, and there are now in Boston only 17. In the latter part of February a number of cases were found in South Boston, and as there seemed to be a tendency to spread, the Board of Health promptly organized a vaccinating corps of fourteen physicians, who made a house-to-house inspection, in the infected districts, vaccinating all who were not protected by recent vaccination, and at this time it may be said that the disease is under control. Vaccination is compulsory in Massachusetts.

CONNECTICUT.—In December, 1893, there were 7 cases in the town of Winchester. Of these 5 were treated as chickenpox; the 2 following cases were recognized as smallpox. In January, 10 other cases occurred in the town, and then it spread to the adjoining towns of Norfolk where there were 3 cases, and to Canaan where there was 1 case. On January 3, a case was reported in New Haven. No spread from the three last points, so far as known. In Waterbury, a case was found on February 17 and another on the 26th. Last week a man suffering from smallpox took a New York train at South Norwalk. Much consternation was created on the train, and upon arrival at New York, the patient was taken in charge by the health authorities.

NEW YORK.—Smallpox now exists at Red Hook, Tivoli, College Point, Walworth, Manchester, Ontario, Yonkers, Utica, and Sing Sing Penitentiary.

NEW YORK CITY.—Cases in Hospital January 1, 18; February 1, 40; March 1, 64; March 3, 56; March 10, 50; March 17, 43. Cases reported for the week ending January 6, 11; January 13, 11; January 20, 22; January 27, 22; February 3, 22; February 10, 23; February 17, 23; February 24, 29; March 3, 30; March 10, 28; March 17, 26, making a total from January 1, to March 17, of 239 cases. From the foregoing it will be seen that the New York Board of Health has held the disease in check under very difficult circumstances, and it now looks as if it was under control, and that the number of cases will continue to decrease.

BROOKLYN.—In January there were 70 cases of smallpox reported, February 65, and to March 17, 71, making a total of 206 since the beginning of the year. This increase is mainly owing to a nest of smallpox found on March 1, and perhaps to the demoralization of the Health Department incident to a change of administration. The Health Commissioner is acting energetically and on the 10th inst. established eight vaccinating stations, where the poor can be vaccinated free of charge. Others will be opened as soon as possible, and we have no doubt, with the other precautions taken, that about April 1 the disease will begin to decrease. There are now about 60 cases in the city. There has been a slight increase during March in infected points throughout the State.

NEW JERSEY.—There is 1 case at Hoboken, and 3 at Jersey City, and several convalescents in the Hudson County pest house. In 1893 there were many cases in the State.

PENNSYLVANIA.—Since January 1, 1894, smallpox has existed and been found at the following places: Reading, Fritztown and West Leesport, Berks County; Mechanicsburg and Carlisle, Cumberland County; Oakdale, Allegheny County; Jeannette, Westmoreland County; Pittsburg, Tyrone Forges, Philadelphia, Pottstown, Bedford County; Williamsport, Wilkinsburg, Alleghany County; Shamokin. (An Italian direct from ship at New York died at Dagus Mines, Elk County) Riverside, near Danville, Danville, Jersey Town, near Danville, Mohn's Store, Berks County, and Pottsville.

Smallpox is now at Pittsburg (has been stamped out twice here in the last four months), Shamokin, Riverside, Danville, Jersey Town, Mohn's Store, Berks County, Maconaqu, Pottsville and Philadelphia. About a month ago a man died at Danville from what was called purpura hemorrhagica and chickenpox; soon after a case of smallpox occurred at Shamokin and then at Riverside. In both these cases the disease was traced to Danville. A bitter controversy ensued, but the State Board of Health very properly directed the Danville Board of Health to treat all cases of so-called chickenpox as smallpox, and on March 16 there were under treatment there, smallpox, 2 cases; varioloid, 3 cases; chickenpox, 10 cases. The case at Pottsville is traced to Danville.

A very disgraceful performance occurred during the week in which a smallpox case was compelled to walk forty-two miles before he was taken care of. How many cases will result from this case can not be told. There are now 27 cases in the State, a less number than at any time for the last six months. The vaccination of the public schools is progressing very satisfactorily.

PHILADELPHIA.—The Board of Health of this city at this time has a good smallpox record. In 1893, there were 43 cases reported and 5 deaths. There have been 3 cases since January 1, 2 importations from Connecticut and 1 from New York. There is only 1 case there now. Repeated introductions of the disease have occurred and it has been repeatedly stamped out. The President of the Board is fully warranted in his annual report in saying: "The comparative freedom of the city from the disease notwithstanding its prevalence in a number of places in Pennsylvania and adjoining cities, shows that among other things a most careful supervision and prompt application of prophylactic measures in all first cases and vaccination was successfully resorted to. There were twenty-four centers from which the disease might have spread, but notwithstanding this fact, the entire number of cases was only 13."

The steamship, *Eriuan*, from Rouen, France, arrived at the Delaware breakwater, March 3 with two of her crew suffering from smallpox.

OHIO.—Since February 1, smallpox has been reported at Springfield, Toledo, Columbus, Lima, Dayton, and Worthington. The Columbus case was two days in the General Hospital before character of disease was discovered, and the last week another case was found at that place. Since the first case was reported at Toledo three more have been found but no connection can be traced to the first case. Owing to the fact that a severe outbreak occurred in the State early in 1893, (introduced by immigrants) which resulted in the vaccinal protection of many, and the energetic efforts of the State Board of Health for the last four months, in pushing vaccination, it is believed that the disease will be prevented from spreading to a great extent. There are now in the State five points of infection and 8 cases.

ILLINOIS.—From October to March 8, there were outside of Chicago 5 cases in Mascoutah Township, Clinton County; Hull's, Pike County, 1; Cotton Hill Township, Sangamon County, 1; Manhattan, Will County, 1; Round Grove Township, Livingston County, 1; Joliet, 4; Peoria, 2; Spencer Station, Will County, 2; Jonesboro, 1; Edwards County, 15, all in county poorhouse. Of these there still remain at Joliet, 3; Jonesboro, 1; Edwardsville, 15, and at Spencer Station, 1, making 20 in all, a good record taking everything into consideration. It is said that only 5 cases occurred among the laborers on the Drainage Canal.

CHICAGO.—In December, 66 cases were reported; January, 180; February, 243; and to March, 17, 155, making a total of 578 since the beginning of the year. There are now in Hospital 153 cases. It will be seen that since January 1 there has been a very rapid increase, and that there are now in Chicago over one-third of all the cases in the United States. The conditions that obtain are peculiar, and while more

public vaccinations have been performed than in any other city in the United States, and a great deal of very excellent work done, the number of cases still continue to increase.

We are pleased to note that the clergy are interesting themselves in vaccination and through their assistance, whole congregations are being vaccinated; also that a house-to-house inspection is being inaugurated, and we have no doubt much good will be accomplished. With the elevation of temperature, the number of cases will begin to decrease.

The epidemic commencing in 1853, continued nearly through 1855, and was kept up by immigrants. We had another commencing in 1863, and continued to the end of June 1865. During this time immigration revived, and contributed to the keeping up of the disease, although some share of the cases were contributed from the large number of soldiers and prisoners of war at Camp Douglas. In 1871 smallpox was brought here a few days after the fire by immigrants, and in 1872 there was a marked increase of both foreign and domestic immigration into Chicago, attracted by the rebuilding of the city. This epidemic commenced in October 1871, and continued until May 1874. The next, commenced December, 1879, through an immigrant, and continued to the end of 1882.

After smallpox has obtained a foothold in a large city, it can only be stamped out by securing the vaccinal protection of all that may be liable to contract the disease, as no one can tell when they will come within the influence of the contagion.

WISCONSIN.—Under date of March 9, Dr. J. T. Reeve, Secretary of the State Board of Health reports as follows:

"Until January 20, last, our State had been almost entirely free from smallpox for years. On that date a case was reported from Milwaukee in the person of a little girl. The origin was not discovered. Very strict precautions were taken and the disease was confined to this case.

On January 27, the disease appeared in a prisoner in the county jail at Janesville. It was confined to the original case which proved fatal. Since that date it has appeared in the jails at the following named places, in the order and to the extent named, to-wit: Juneau, January 31, one case recovered; Sheboygan, February 1, one case, recovered; Portage, February 12, one case, recovered; Madison, February 14, one case, died; Jefferson, February 14, one case, followed February 21, by a second case; Waukesha, February 20, two cases, died; Elkhorn, February 23, one case. Several of these cases were in the persons of tramps arrested for vagrancy or crime, and some facts lead to the belief that the cases were closely connected in their origin. For example, the case appearing in the jail at Elkhorn, reported to this office February 23, the prisoner spent the night of February 8, in the jail at Jefferson from which smallpox was reported on the 14th.

The disease has also appeared in tramps in the following places, the tramps being at large at the time of their coming down with the disease: February 3, a report was received from Waukesha that a tramp was caught upon the street suffering with smallpox. He was confined to the pest house, and recovered. February 10, a tramp came to the police station at Fort Howard complaining of being sick. The Health Officer was called, and not diagnosing the case as smallpox sent the man to the Sanitarium of which he is the proprietor. It was soon manifest that he had the smallpox, but not until others had been exposed, and subsequently four inmates of the Sanitarium were stricken with the disease. The original case died; a second death followed. One of the attending physicians in these cases carried the disease to his seven weeks old babe. He then with wife and babe entered the Sanitarium. The child died, making six cases occurring at this institution with three deaths.

February 14, a case was reported from DePere. A girl working in the rag room of a paper mill—one case followed from exposure to the first case. March 4, another case was reported from DePere, a man employed in a paper-mill—apparently there was no connection with the former cases.

February 19, a case was reported from Camp Lake, Kenosha County, in the person of a laborer who came from Chicago the week previous. No cases followed.

February 22, a girl working in a paper-mill at Menasha was reported as having smallpox—the origin was supposed to be from the rags; the girl died. No cases followed.

Beloit reported February 24, a case in the person of a hotel girl—origin very doubtful. One case followed.

March 2 a case was reported from Lewisburg, Grant County. No additional cases reported.

On March 8, the last case reported, was at Neenah, in the

person of an infant six months old. No probable source of origin yet discovered, but some of the family had recently been traveling.

The cases outlined above make a total of 27, with 8 deaths, reported from 16 distinct communities. In all cases (with possibly one exception) the local Boards of Health and Health Officers were prompt and thoroughly effective in adopting stringent measures of quarantine, and the recommendation of general vaccination issued by the State Board of Health early in January, together with the rule of the Board requiring vaccination as a pre-requisite to admission to school, published January 31, caused vaccination to be very generally carried out throughout the State. There has since been reported a suspicious case at Milwaukee. This is a very instructive and interesting report.

MICHIGAN.—Dr. Baker, under date of March 16, says that since Jan. 1, 1894, there have been four jurisdictions in Michigan infected with smallpox. Otsego village 4 cases; Otsego township 2 cases; Menominee 4 cases; and Crystal Falls 1 case. In all 11 cases, and 3 deaths with no spread so far from the original cases. There are now in the State 4 cases. The vaccinal status of the State is good, and the sanitary organization of the State excellent.

IOWA.—Within the last four weeks Iowa had 7 points of infection, and in no instance did the disease spread beyond the first cases, all being importations from Chicago; smallpox now exists only at Tama City, where there is one case. This is a remarkably good record, and reflects great credit upon the local and State health authorities. Vaccination in spite of opposition has been very general.

MINNESOTA has had but one case, and there is no smallpox in that State now. The vaccinal protection of the State is very good, and with its complete and efficient health organization there is not much danger of the disease, if introduced, of spreading.

KENTUCKY.—Dr. McCormack says that we have only had 14 cases of smallpox in this State, during the present epidemic, 16 in Louisville, and 4 in Paducah. The disease was promptly stamped out in both cities.

INDIANA—There is at this time a case at South Bend, and 2 at Crown Point; both contracted the disease at Chicago. So far there has been no spread from the original number. The prevalence of the disease at Muncie, and other points in this State during the past summer, resulted in pretty general vaccination, and the State, generally speaking, is well protected from a vaccinal standpoint. The State Board of Health is, however, pushing vaccination, lest the disease obtain another foothold.

WEST VIRGINIA.—Last fall the disease appeared at Bridgeport, Harrison County, in the person of a young girl just returned from Chicago; six cases of varioloid developed from this case, but the disease was completely suppressed before Jan. 1, 1894. In November, 1893, smallpox was discovered in the town of Lewisburg, Greenbrier County. Three men contracted the disease from the first case, and from these after Jan. 1, 1894, 12 cases occurred, nearly all mild varioloid. The disease then disappeared.

VIRGINIA.—Since Dec. 1, 1893, there were 13 cases in Lunenburg County, 15 in Southwest Virginia, and 20 at Shendon near Luray. There is now only one case in the State.

MISSOURI.—Only three cases were sent to the hospital at St. Louis in eighteen months. One in January, and the others in February. They belonged to the tramp class of wanderers, and drifted here from other places. One unvaccinated patient died of confluent smallpox, the others recovered and the hospital is now closed. No cases have occurred throughout the State of Missouri. Dr. Homan, Health Commissioner, says: "Public vaccination has been practiced in St. Louis more diligently during the past six months than ever before, and this may account to some extent for the immunity enjoyed."

GEORGIA.—There are 5 cases of smallpox at Senoia and 1 case of smallpox and 4 of varioloid at Atlanta. Source of infection, Senoia. The Atlanta cases were thought to be chickenpox.

TENNESSEE.—Dr. J. D. Plunkett, under date of March 17, reports that since Nov. 7, 1893, there are 81 cases of smallpox in Tennessee. There are now in the State at Knoxville 4 cases, Chattanooga 2 and Nashville 2.

ONTARIO.—One case near Burgessville, Oxford County. Origin, Chicago.

There are now in Massachusetts 21 cases; of these 17 are in Boston. Connecticut 2; New York 123, distributed as follows: New York City 43, Brooklyn 60, and 20 cases throughout the State. New Jersey 4 cases; Pennsylvania 29, 12 of these being in Philadelphia. Ohio 7 cases, Indiana

3, Illinois 168 cases; of these there 15 in the State and 153 in Chicago. Wisconsin 10 cases, Michigan 4, Iowa 1, Virginia 1, Georgia 10, Vermont 1, and Tennessee 8 cases. Total in the United States 389 cases and less than there were on March 1.

From the foregoing, it will be seen that the effort of the health authorities, taken as a whole, have been successful, if not in stamping out the disease, in controlling it, as the only places where there is an increase are Chicago and Brooklyn.

A Petition to Establish a Department and a Secretary of Public Health.

To the Honorable the President of the Senate and the Speaker of the House of Representatives of the Congress of the United States of America.

The AMERICAN MEDICAL ASSOCIATION at its meeting at Washington in May, 1891, adopted unanimously this resolution:

"Resolved, That the President of the ASSOCIATION, W. T. Briggs of Tennessee, appoint a Committee to memorialize the next Congress to create a Department and a Secretary of Public Health."

At the meeting of the Fifty-second Congress in December, 1891, a petition and a bill to that effect were introduced in both Houses; in the Senate by the Hon. John Sherman and in the House by the Hon. John A. Caldwell, and they were referred to certain committees. No report has ever been made to either House on the subject.

At the annual meeting of said ASSOCIATION in the City of Detroit in June, 1892, the Committee reported the failure to secure any action of Congress on the petition; whereupon the ASSOCIATION again directed the select committee to renew its appeal for Congressional action; but no notice was taken of it, chiefly because the alarm at the approach of cholera from Europe led Congress at once to enlarge the existing quarantine system which it was supposed would answer all purposes.

The Chairman of the Committee addressed a communication to the Chairman of the Committee on Contagious Diseases in the Senate, which set forth that while the quarantine measures were very effective so far as the hindrance to transplanting the diseases of other lands was concerned; yet they did not include all the measures for the operation of preventive medicine which the AMERICAN MEDICAL ASSOCIATION was seeking to establish for the public welfare.

The only answer made at any time by this gentleman was merely verbal, and that it was his belief that Congress would not appropriate money that would increase public expenditure.

At the annual session in Milwaukee in June, 1893, these facts were reported, and the Special Committee was ordered to renew the appeal at the approaching Fifty-third Congress. Under this authority the undersigned beg your consideration of the whole subject anew.

In the Pan-American Medical Congress, which met in Washington in September, 1893, under the auspices of our Government, the most august assembly of medical men that ever met in this hemisphere, this question was carefully discussed and unanimously approved. Moreover, a large number of State Boards of Health, the National Board of Public Health and numerous medical societies in different cities and States have given their adhesion to this movement.

The AMERICAN MEDICAL ASSOCIATION is constituted of men of distinction in every part of the Union. For more than forty years its sessions have been held in the chief cities of the States lying between the Atlantic and Pacific coasts, and it represents nearly one hundred thousand intelligent and well-known citizens. The annual sessions have greatly promoted scientific research into the causes and treatment of diseases of every character, the formation of State Boards of Health, higher medical education and the publication of treatises on preventive medicine and medical practice, which form a continuous line of medical progress in the last half of this century.

The Government, through the operations of the Surgeons-General of the Army, Navy and Marine Hospital service has made liberal expenditures for the National Medical Library and its Index Catalogue, a Pathological Museum and some investigations on the origin, nature and spread of the fearful infectious germs that are brought to us by immigrant and other ships. But the medical profession believes that the Government can, in a wider way, promote the public welfare by creating a Department of Public Health, the head of which should be a physician, a member of the Cabinet

and on a parity with the heads of the Departments of War, Navy, Finance, Justice, Agriculture, etc. A fair investigation will show that no profession excels ours in positive efficiency to sustain public order, public comfort and public virtue.

Hygienic science, on the one hand, and the progress of the sciences and growth of the mind, on the other, have always been powerful factors in the evolution of humanity. In the first century, when Rome had reached her apogee in power and civilization, and had constructed great aqueducts, public fountains, public latrines, gymnasiae and a vast system of sewers, under the suggestions of physicians, Martial said that it was not merely a question of living, for the people, but to have good health; hence the maxim that has come down to us: "The health of the people is the supreme law."

Recently, the Lord Chancellor of England appointed Sir James Crichton Browne, M.D., L.L.D., as his visitor to make certain investigations in regard to the public health, and of the influence of certain employments upon the health and comfort of the laboring classes. We can only give a partial exhibit of his observations. He found, that while the decline in the death rate at all ages had been, within a certain period, 17.5 per cent. in those under 55 years of age, it had been reduced only 2.7 per cent. in those above 50 years old. The increased longevity has occurred under the age of 35. The decline in the death rate beyond the age of 45 had been insignificant, but from 65 to 75, the death rate was increased. He adds that it is not satisfactory to learn that while there has been enormous increase in the duration of life in babies and young people, the loss is alarming among those who are eminent in experience and judgment. The causes of this vital failure in the mature element of society was not difficult to find by his statistical studies. In three or four groups of diseases a marked increase in mortality has taken place; thus, in England and Wales, cancer in five years, from 1859 to 1863, carried off 35,654, while in five years from 1884 to 1889, the deaths by cancer were 81,620, an increase of 120 per cent. The increase in deaths by nervous diseases in the same period was 38 per cent.; in kidney diseases for the same period the increase in deaths was 164 per cent.; in heart diseases, the increase was 143 per cent. These affections, he continues, are of degenerative character and may largely be traced to vital abuse, overstrain and the increasing luxuriousness in our advancing civilization which establish premature senility. Moreover, the large increase in insanity is causing solicitude everywhere. It can not be questioned that this fearful increase in bodily and mental decay should be well understood by and placed before the people. There is another phase of this question of premature decay of great interest and it concerns a burning question of the day. Sir James says, that owing to the strain and drive in many manufactories where handicraft piecework prevails, the neuro-muscular systems of the shoulder, arm and hand which on the average attain maturity at 30 years, and should continue as much longer, begin to fail at 45 years, and while at 30 a man can earn 45 shillings a week, at 45, strive as he may, he can not earn over 38 shillings, and at 55 his earnings fall to 24 shillings, owing to the premature decay of the motor apparatus from overwork. In Sheffield he found that penknife makers aged 30 years, strike 28,000 blows a day with a hammer, but at 45, they find their celerity and skill have declined to nearly one-half, and a reduction in wages to the same extent ensues.

As we have no national office for the collection of such statistics, except perhaps the Bureau of Labor in a partial way, we must rely upon those furnished by other nations.

The telegraph operators, everywhere, sooner or later become the victims of scrivener's palsy of the fore-arm and fingers on account of the excessive use they are obliged to make of them, for, as their celerity fails their wages decline. The mail clerks on railroad trains are required to work many hours more than in other Government offices, and are besides compelled to memorize, with all the certainty of the multiplication table, the locality of eight to ten thousand postoffices in the vast districts of the country. The effect in numerous cases of this excessive use of the memory is insomnia and a mild form of dementia. It is, certainly, a function of statesmanship to investigate these serious evils. The Government has begun to investigate the exposure of employes on railroads who are often wounded and killed in the coupling of cars; and the investigation of the desperate use of young people in the "sweat shops" of clothing establishments has created a great outcry for their relief.

"In 1848 the Public Health bills in England went into operation. The annual death-rate which up to that time

was 22.5 per thousand diminished to 17.9 per thousand within twenty years; showing a saving in that time of 125,000 lives. The effect of hygienic measures in preventing sickness is well known in the State of Michigan. During the year 1889 there were 417 outbreaks of scarlet fever. In seventy-two of these outbreaks, isolation and disinfection were neglected and the number of cases, per outbreak, was 16.78 per cent. In fifty-two outbreaks, both isolation and disinfection were strictly enforced with the result of limiting the number of cases to 2.67 per cent. In many outbreaks only one restrictive measure was used and the other neglected, and in all such cases there was some reduction in cases, but never to the same extent as when both were enforced." (Dr. J. W. Brannan, *New York Medical Record*.)

Our census of 1890 shows that 524,000 deaths occurred in that year, and that 100,000 were from consumption. It is estimated that about one-half the whole number was due to diseases that could have been prevented.

It is now becoming generally known that infectious diseases and toxic elements are disseminated in food. An infectious disease in the family of a dairyman, or among his cattle, may be as widely spread as is the distribution of his milk. The pollution of streams supplying towns, cities, and wells of water at farmers' homes, we know, definitely, subject the people to tedious and fatal diseases which a wise sanitation would prevent. It is absolutely demonstrated that by the rigid application of hygienic measures the ravages of a pestilence may be stayed. Medical scientists speak of such destruction as a self-imposed curse of dying in the prime of life.

In primitive history we find that hygiene and therapy were the conservative and remedial agencies of afflicted peoples. We read with admiration of the wisdom which made sanitary measures a part of the religious codes of a nation. The hygienic laws of Moses, which undoubtedly embody fragments of his Egyptian training both as a physician and a priest, and the moral law, the Ten Commandments, received from the hand of God, have been kept together by the Jews in their sacred books and inculcated in their religious and social rites for thousands of years, which clearly accounts for their existence, physically and mentally, as one of the most vigorous races among the multitudes of the earth.

Physicians are held to be the guardians of the organs that concur for the maintenance of a healthy animal life, but it is not so generally understood that the great brain, the physical basis of the mind, is just as much an organ of their conservative regard; it is not so well known that the healthy brain is necessary to a free will—the function that places man in his supreme condition as master of created things.

The increased light which physiology and pathology have shed upon the relations of the brain and mind, has enabled us to locate the area in the brain where exists the capacity to think, where sensations are shaped into concepts, where ideas are symbolized in language, where memory holds its seat, the imagination displays its marvellous powers, and self-control is enthroned. All of the apparatus of our mere animal life—respiration, circulation of the blood, digestion and assimilation of food, excretions of waste tissues and the actions of the nervous and muscular systems are to maintain and develop in perfect health an area which we can cover with our two hands. It is the region of self-consciousness, the plane where spirit and matter are in impact and which enables a man to say: "I know that I know, I feel that I feel, I think that I think;" it is there, indeed, that consciousness feels itself to be coterminate with the cosmos. Who but the physician has the right to supervise this dread region? Closer than the minister of religion, or the rights of family, he stands as the guardian and interpreter of its illimitable faculties.

By prolonged physiologic and pathologic research, psychology has been lifted above the mere subtle reason of the schoolmen into the light of a new day, and is now comprehended as never before. Metaphysics is no longer a mere jugglery with words and phrases, but a function of consciousness only existing in the healthy area above described; it is the highest expression of reason, whereby the intuitional phenomena of thought and the phenomena derived from the senses, the ideal and the real, the subject and the object, the me and the not me, are brought by a free will into accord and the consciousness is freed from the baleful illusions, hallucinations and delusions which exist in the insane. The imperfect state of consciousness in unsound sleep, illustrates a mental state wherein ideas flow freely, regulated only by automatic association; we are led everywhere by the most grotesque and often fearful ideation, without any self-control; the metaphysical function is

in abeyance; there is no metaphysics in dreams, the consciousness is on too low a plane for any exercise of the will. This argument is legitimate and should be convincing, that medical men hold an indispensable relation to the social and political state.

All abuses of the appetite in any direction, all violence done to the brain by overwork, overstrain, the excitement of narcotics, and the delirious speculative ventures in the values of stocks and of the products of the crops; everything, indeed, that keeps up, unduly, mental excitement, deteriorates at length the organic structure of the brain, enfeebles the mind in judgment on any subject; in short, a condition of dementia supervenes. It is for the physician to warn teachers of the deleterious effects of overtaking scholars; to warn people against luxuriousness, indolence, and the habitual use of stimulants, and excess in any passion or appetite; for, while the organs of mere animal life are damaged the nutrition of the brain is changed, the will becomes so impaired that self-control is lost. It is appalling to contemplate the social destruction about us on account of the prevalence of the passions of avarice, speculation and lust which so greatly defile public virtue. These are evils the indulgence of which has ruined statesmen and empires. Luxury and vice in combination form the dynamite in the moral world.

The medical supervision should begin in the primary and intermediate schools, which are frequently in overcrowded, ill-lighted and ill-ventilated rooms; this has become so serious that in Germany, at least, it has brought about State interference, and physicians must be consulted in regard to the hygienic properties of a schoolhouse. The physical structure of the eye is most liable to evil changes, leading to shortsightedness; and the organic life of the brain substance is exposed to deterioration leading to lowering of the intellectual faculties. In the technological schools of France the use of tobacco is forbidden, because it has been ascertained that its abuse renders the student incapable of solving the highest problems in mathematics. It is also of great importance that the methods of teaching should not involve an excessive abuse of the memory—the *memoriter* plan. This it is thought is too greatly employed in American schools, but it seems to be a necessity so long as the rank of a pupil in his class depends upon the rate per cent. of correct answers. The abuse of the memory fatigues the brain as physicians well know, and impairs the power of the free will. Lessons are memorized, and not acquired by efforts of the understanding, hence they are not well retained and furnish a poor basis for intellectual ability. Not only so, but the emotional conditions so often encountered, and the startling phenomena of hysteria and hypnotism are thus often superinduced. There are no fortuitous conditions that concur for the production of the best moral and political circumstances of society; the whole is purposive intelligence existing in the individual and combined in the exigencies of the family and the State. Wherever the highest development of physical health exists, there will be found the surest basis of intellectual life. These are not abstract questions of philosophy but are the most practical questions of our times.

A candid and broad investigation of the medical profession shows that it appertains to the most important functions in the commonwealth. A distinguished English writer has said: "I think it will be well for the state when the medical profession is represented in the councils of the nation as weightily as can be assured by official places and conferred dignities." An eminent German economist has said: "We must look to the medical men to resuscitate society." There are no evils in society which physicians may not do much to avert; there are no foes of human happiness so widespread, miserable and despairing as those which underlie public health; and physicians are the only hope of public relief.

It is certainly a remarkable spectacle, the constant efforts of physicians to save the people from outbreaks of disease, when success will limit to the smallest dimensions our practice and incomes. But this arises from the nature of our studies whose tendencies are to render an unselfish service to humanity in the time of its calamities. The physician is bound to render service to the poor, especially. The amount of gratuitous service in great cities is a very large part of their practice. In all of our public general hospitals they serve without salaries.

If there were cruelties to prisoners on either side in our civil war, it was not perpetrated by the surgeons of the opposing armies. When the strife ceased they were the first to extend the fraternal hand across the red fields of conflict.

The progress of medical science establishes our increasing responsibility to place our medical schools on the highest plane of teaching. There is a very large aspect of medicine that renders it so commonplace as practically to degrade it, and this is a consideration that will be a great obstacle in the way to your adoption of our bill. I allude to the giving of drugs by everybody for the relief of symptoms of disease. It may be said all the people, young and old, not only offer general advice but specify the remedies to be used. If medicine has no other basis than prescribing, it would possess no autonomy, embody no science, nor philosophic spirit; it would only become an unstable empiricism and would be abandoned to a revolting charlatanism and its practitioners be mere vendors of secret, false remedies, and, as is now so largely done, would rob the sick not only of their money but of any hope of relief.

The human frame is said to be the Divine idea of mechanism, and nothing in all the works of creation so completely illustrates in its structure what is called by geometers the "principle of least action," that is, the greatest competency in function, with the least expenditure of material. Its figure, symmetry, mechanical, physical, chemical and biological forces are so correlated that it fulfills all the conditions of adjusting internal to external relations. Its organs of special sense, its area of consciousness wherein it is the equipose of the physical creation, justifies the ascription that man is the crown and flower of creation. Can any one doubt that it is only by a long and minute study that such an organism can be comprehended? Congress appropriates annually more than a million of dollars for the maintenance of military and naval schools, where the whole range of sciences are inculcated to ascertain the most approved methods of public defense and of killing our enemies. Can it be thought that any less science is needed to ascertain how to destroy myriads of enemies that provoke disease, and all the more terrible because invisible to common sight; and to save from death the most precious objects of human love and solicitude? Are there more scientific problems for solution in war by sea, or land, than those that exist in the grievances of our social life?

But we are not asking Congress to build a great medical school of instruction. Congress appropriates willingly large sums for the study of the diseases of cattle and plants, but comparatively nothing for the diseases of the people. But we show you that 522,000 inhabitants died in 1890, and that 250,000 of them at least, have perished by diseases which are preventable!

We ask for a Governmental Department of Public Health; one of whose functions would be the combination of the intelligence, feeling and force of all the schools and medical societies of the nation for collective investigation in order that physicians may become capable to the utmost, to relieve the woe and agony of suffering in individuals and families.

For the medical profession to be able to exert all its benign influences in society, it must have the same rank and dignity that is attached to other Departments in the President's Cabinet. The methods of research are the same as those employed by other scientists. The methods of the calculus that are employed to ascertain the cause of the perturbations of celestial bodies, are the same as those employed in the investigation of obscure diseases. The physician is guided in his investigations by the canons of logic, and hence it is that the opinions of well-trained doctors are as reliable and stable as those of jurists, statesmen, engineers, merchants, divines, lawyers and political economists. The same reproach applied to doctors because of their different opinions, applies equally well to all other callings.

At this time the success in medical practice surpasses any other period of its history. The death rate in our general hospitals was never as low. In surgery it is about 3 per cent.; thousands of successive births take place in maternity hospitals, without a single death; the mortality in typhoid fever is about 3 per cent. in hospital practice; in general medicine the rate is declining; but it is not as low as in surgery because of the increasing mortality, as before said, in such diseases as consumption, cancer, kidney, heart affections, and the continued bad hygienic conditions in the congested areas of our large cities, where one-half the children die under five years of age. (Cincinnati Hospital Report, 1893).

The influence of medical culture upon the progress of civilization as before said, both in ancient and modern times forms a great chapter in human history. The evolution of the mind and the achievements in philosophy are no more marvellous than what is seen in preventive and clinical medicine. The chief figure in the most brilliant era of Greek civilization was Aristotle. He was of the Esculapian caste

and took up the profession of his father, a practitioner of medicine; but his constant dissection of animals and plants aroused a philosophic spirit of seeking behind all the phenomena of nature by synthetic formula, the unity of all living beings and their indissoluble relation to the cosmos. We can not, in our space, point out all the achievements of his immense genius nor his specific work in detail that entered into his purpose of constructing the edifice of inductive philosophy. Mere fragments of his precious writings were the only intellectual food (excluding the canon of sacred Scripture and the liturgies of the Church) of the Dark Ages; but when at last the chief of his philosophic works were collected and translated into Latin, the dawn of the revival flushed the skies and the sun of a new mental life shone in full strength upon the scholastic world,—the church adopted his philosophy and the renaissance was complete. The influence of Aristotle has continued to direct modern thought, and though much of it has been laid aside, his inductive philosophy and logical methods are invincible.

In Europe, medical affairs have always had the watchful care of the state, and eminent practitioners are now more than ever before, receiving titles of distinction. In Italy a physician holds a Cabinet Secretaryship, and in the Parliaments, everywhere, distinguished practitioners are taking part in general statesmanship. Without the science of medicine, civilization could never be effective in semi-civilized and barbarous lands.

The conquest of India by Great Britain has been maintained by superior military power; but its present tranquillity is largely due to the beneficent work of medical practice. Since the last great rebellion there, the English and missionary societies of our own country have established fifteen hundred hospitals and dispensaries, and medical schools are increasing in numbers. The light of Christian benevolence is now carried into the hitherto closed doors of the homes of the people. In China the same benign work has taken deep root. Fifty years ago Dr. Parker of the American Presbyterian Church, opened a hospital in Canton, and an immense work has been accomplished in surgical and midwifery practice, for which the Chinese had no remedies at all. Now a large number of hospitals and dispensaries have been planted along the sea coasts and throughout the interior. Besides male, a large number of well-educated female practitioners, are employed in them. It is the most touching spectacle of human sympathy and relief the world has ever known. Were it not for their skill in medicine the American missionaries would be expelled. Japan, Korea, Java and Africa, are being advanced in civilization in the same manner. Dr. Mungo Park and Dr. David Livingston were the most venturesome explorers of Africa.

It is the belief of many physicians that if from the beginning of the settlements in this continent the medical office had been recognized as a Department of the State, on a parity with those of War, Justice and the rest, the great tribes of savage races could have been made friendly, and allies, and brought under the terms of a high civilization by the humane influence of our medical men.

Though Congress is voting vast sums for agricultural schools and experimental stations, yet these are above the reach of the great mass of farmers and their adult sons and daughters. They can not leave the fields and the household duties for at least nine months of the year, and they can not pay the expenses incident to college life; but schools of instruction, by means of lectures, demonstrations, drawings and experiments in physics, chemistry, and the structures and the functions of the chief organs of animals and plants, can be readily inculcated by the doctors in medicine who have themselves been taught in this manner. These lectures can be given by physicians during the winter seasons in the towns of the counties and within reach of the farmers' homes, and a central office, such as we propose, would aim to promote this without expense to the Government.

It will be the means of putting new life into the freshest and strongest minds of the people. Every farm would soon become an experimental station; Nature would be seen with new eyes, and the dull and monotonous lives of this most neglected class would become radiant with a new light. This may be counted one of the great influences that will follow the higher education of physicians.

The question may arise, whether such a Department in the Government would subserve the interests of any particular sect or school in medicine? We reply that, amid the apparent disparity in medical practice, there is one true unity and to attain this all true physicians are continually striving. It is evident that there can be but one anatomy, physiology, pathology, chemistry, physics or preventive

medicine. The difference among doctors lies in therapeutics or treatment of disease, and as in the past, so for the future, practitioners will use a variety of remedies and in varying quantities, and there will be different modes of management of sick and injured people. With the advance in medical education the modes of treatment will become more unified.

The organism which is called medicine, like every other product of man's constructive genius, is striving to attain perfection, and to accomplish this it must be sustained in all its scientific undertakings by the coöperation of national and state legislation.

We ask each member of Congress, who seeks relief for himself and his family in the times of their distress through the most accomplished practitioners of medicine, to consider that his mind is the type of that of millions who constitute the republic; and therefore we ask him to lend his influence to our effort to secure for the people the most highly trained persons in the science and art of medicine.

We hope that it is plain that a Secretary of Public Health would represent the medical consciousness of the nation, and that he would be one to whom we could all look for the exploitation of measures that will direct continuous scientific collective research in regard to epidemic and endemic diseases, and especially those of a degenerative character; and thus make his department the repository of the most important measures that concern the welfare and comfort of the people; and his duties will steadily grow broader and stronger in adaptability to public needs.

Respectfully submitted on the part of the Committee.

C. G. COMEY, Chairman.

A Bill to Establish a Department of Public Health.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled.

SECTION 1. That there shall be established a Department of Public Health. There shall be appointed by the President from the medical profession, by and with the advice and consent of the Senate, a Secretary of Public Health, who shall be entrusted with the management of the department herein established. He shall be paid an annual salary of \$8,000.

There shall be appointed by the President, with the approval of the Senate, an Assistant Secretary of Public Health, at an annual salary of \$5,000.

The Secretary of Public Health shall, with the approval of the President, provide suitable offices for the department, and shall employ such assistants and clerks as may be necessary.

SEC. 2. It shall be the duty of the Secretary of Public Health to obtain through all accessible sources, including State boards of health, municipal authorities, and the Surgeon-Generals of the Army, Navy and Marine Hospital Service of the United States, weekly reports of the sanitary condition of all ports and places within their territories and departments, and he shall publish weekly abstracts of the information thus obtained and other pertinent matters received by his department. The said department also shall, as far as possible, by means of the voluntary cooperation of State and municipal authorities, of various general and special hospitals, sanitariums, public associations and private persons, procure and tabulate statistics of marriage, births (noting those that are illegitimate), and deaths from epidemic, endemic and all other diseases, specifying those of a degenerative character, such as malignant growths, and affections of the nervous, circulatory, respiratory, secretory, digestive and reproductive organs, and from violence, accidents, suicide, murder, and data concerning the fruit of consanguineous marriages and the transmissibility of insane, alcoholic, syphilitic, nervous and malignant types of constitution to offspring, and to evils of race miscegenation. He shall also procure information relating to climatic and other conditions beneficial to health, and especially in reference to the most favorable regions in the United States for the cure or relief of chronic diseases, particularly tubercular consumption. He shall also procure information as to the prevalence and ruinous effects upon the body and mind of intemperance and prostitution. He shall endeavor to ascertain the extent, the origin and classification of insanity in the several States and territories of the country. He shall investigate the state of comfort of the laboring classes in respect to their lodgment, their trades, occupations, the healthfulness of their workshops and the contents of the atmosphere they habitually breathe, and the prevalence of premature degeneration of the nervous and muscular systems by the exactness of piece-work employment. He shall obtain information in regard to the soundness of their food and purity of water supply. He shall ascertain the ages at which the children of the poor are put to work, and its hindrance to their physical development, and their lack of common-school education. He shall seek through the State boards of health, information of the hygienic state of public school buildings respecting their illumination, ventilation, and presence of noxious elements in the circumambient air. He shall seek information in regard to the pollution of streams and navigable waters and public and private wells. He shall attempt, through the coöperation of the authorized medical schools in all the States, to promote the most extended and thorough training of students in order to fit them for the responsible duties that devolve upon practitioners of medicine. He shall, whenever an epidemic disease is spreading abroad, or in any country which by commercial or other relations may endanger the health of the inhabitants of the United States, have power to call a conference of the Surgeon-Generals of the Army, Navy and Marine Hospital Service, and the executive officer or officers of the various State boards of health throughout the country, to consider and advise with him in regard to the best methods to be pursued to protect the country against the invasion of any such epidemic disease, and the results of such conference shall be, by the Secretary of Public Health, communicated to the President and his Cabinet for such action as they may deem wise and expedient.

Besides the reports of the state of the public health which he shall make from time to time, the Secretary shall make an annual report to Congress, with such recommendations as he may deem important to

the public welfare, and the report, if ordered printed by Congress, shall be done under the direction of the department. The necessary printing of the department shall be done at the Government printing office upon the requisition of the Secretary, in the same manner and subject to the same provisions as that of other printing for the several departments of the Government.

SEC. 3. The President is authorized, when requested by the Secretary of Public Health, and when the same can be done without prejudice to the public service, to detail officers from the several departments of the Government for temporary duty, to act under the department of Public Health to carry out the provisions of this act, and such officers shall receive no additional compensation except for actual and necessary expenses incurred in the performance of such duties. When a detail of such officers can not be made, the Secretary, approved by the President, may employ such experts, and for such time and in such manner as the funds at the disposal of the department may warrant.

SEC. 4. That to defray the expenses in carrying out the provisions of this act, the sum of fifty thousand dollars (\$50,000.) or as much thereof as may be necessary, is hereby appropriated to be disbursed with the approval of the President, under the Secretary of said department.

This act shall take effect sixty days after its passage, within which time the Secretary and Assistant-Secretary may be appointed.

CORRESPONDENCE.

LETTER FROM BERMUDA.

WINTER DAYS IN SUMMER ISLANDS—NOTES FROM THE LAND OF THE LILY AND THE ROSE.

HAMILTON, BERMUDA, Feb. 28, 1894.

To the Editor:—Out of the gray and the gloom of a foggy February morning steamed the *Trinidad* to a summery land at sea, bearing the biggest boatload of tourists ever bound from New York to Bermuda.

The early advent of Lent doubtless had much to do with this unusual tide of travel, though the fashion still obtains of waiting till nearly the end of winter before coming here.

From the snow and the slush, the hail and the cold of New York and Brooklyn to the warm sunshine and balmy breezes of Bermuda—when life out of doors is a perennial pleasure—is a change so great that many fail to realize it, and nothing less than a personal experience will convince a doubting searcher for health or pleasure that here is a charming country, where the real rivals the ideal, and where fact touches fancy, in the picture painted after conning the story of these evergreen isles.

We sailed from the streets of Gotham, and the shores of Long Island heavily mantled in wintry garb, and though head winds and high seas delayed our coming and laid some of us low, the ills that betide a luckless traveler at sea were soon forgotten—for most troubles have an ending, and sea-sickness isn't bad after its over—in the gladsome sight of emerald hills, and white-walled, white-roofed houses in their rimming of green, glistening under a sunny sky.

The first thing noted by those who have not been here for a couple of seasons is the absence of the antiquated plan for getting ashore, which once so much amused newcomers. The water at the wharf not being deep enough to allow of anchoring alongside, and the city fathers refusing to build a proper pier, two huge poles were hauled on board by steamer windlass, and along these crawled several agile ebony athletes, with cross bars and rope, lashed the bars firmly, laid planks lengthwise, and on these passengers went ashore. Now, a spacious granite quay permits close coming of steamers, and the style of disembarking is quite up to date.

The march of improvement in Hamilton has been marked during the last year or two. The most notable advance, so far as concerns the Front Street pedestrian, is the fine granite pavement that now extends the whole length of that thoroughfare. The contrast in comfort with the ancient and disreputable brick sidewalk, is one that must be felt to be appreciated. Architecturally, the forward movement has been decided, both in public and private. Of the former, in Hamilton, the most prominent relates to the House of Parliament, which has been enlarged by the addition of a colonnade on the south front, handsome arcades on the other sides, and an ornate tower, of which the most striking ob-

ject is a handsome clock made by Gillert and Johnston, of Croydon, near London. These additions had been for several years in contemplation, but the project languished till 1887 when a joint committee of the Bermuda Council and Assembly reported in its favor as the most suitable Bermudian memorial of Victoria's fifty years reign, and though progress was slow the tower—which is built of the native coral with a mixture of red bricks and concrete, with terra cotta trimmings—was completed late last year, the clock put in position, and at midnight, 'twixt 1893 and 1894, the dials—each seven feet in diameter—were illuminated, and watched by a large crowd as the clock struck the closing hour and far well to the parting year. This clock—long waited for—is truly a timely addition to the attractions of Bermuda; and, topping the tall tower of Parliament House which is on one of the highest points in town, it makes a landmark noted for miles around. May its life be long and strikingly useful!

"All things come to him who waits," and history has repeated itself along this line to the Bermudian, native and visitor, who so long has been waiting for the finishing of the new Government House. In 1882, an Act was passed giving \$40,000 for its erection. Work was begun, but the money proved not enough, and when more was asked for, it was refused. Work ceased, was resumed, again ended, and this shuttlecock sort of business went on for years, till in 1890 it was decided to carry the work to completion, and in July, 1892, the present Governor became its occupant. It is a handsome structure, Spanish in style, of which the Bermudians may well be proud, and from the towers can be had charmingly varied views that compass almost the whole country. The approaches are not yet complete, and the opportunity for some superb landscape gardening by terracing the hillside and flowering the meadow between the House and Hamilton is such an exceptionally fine one that Bermudian enterprise should forge to the front and make it what it would surely be—a thing of beauty. The old House was razed in the autumn of 1892, and the garden with the semi-tropical flowers and foliage alone remains. The houses in Bermuda are almost without exception, built of coral composing the island structure, which is white and so soft that it can be cut and trimmed with saw and chisel, but hardens promptly on exposure. The roofs are thin slates of the same material. These are annually whitewashed, and rising 'mid their emerald surroundings—the Islands are always green—give a charm to the landscape that must be seen to be appreciated. Each dwelling is required by law to be provided with a tank for rain water taken from the roof, which, with the yearly whitening insures its purity. At various places, on hillside and elsewhere, are shallow basins leading to reservoirs cut in the coral; these catch and retain the rain. There are wells, but the water is too brackish to drink. Lately, the supply has been increased by several artesian wells, the water of which is good.

The drives in Bermuda are delightful. Smooth, coral roads, with ever-varying vistas of land and ocean make them specially attractive. The service is good and cheap—one dollar the first hour and half that each after hour. The fine roads give a special charm to cycling, and lovers of this sport find the wheel an added pleasure to the winter outing.

The health of these Islands is almost always good. A healthy October presages a healthful winter. There has been no epidemic in many years. The greatest mortality is under five, and among the blacks, is due largely to neglect. The leading death cause is consumption. Births and deaths are fully recorded. The former lead. Long lives, eighty-five to ninety-five years, are not uncommon. There are nine registered medical men, besides ten Army and five

Naval surgeons. There are two health officers—a post surgeon at St. George and a local one at Hamilton. A general Board of Health is composed of the Governor and Council—the latter, nine leading non-professional men. Quarantine regulations are careful and complete.

At the last session of Parliament, the question of sanitation and a remodeling of the Health Act of 1864 was debated, and the Attorney-General moved to introduce a new bill but, strange to say, the motion was lost. One of the features of the new bill was for the formation of a general Board of Health to consist of 'the Colonial Secretary, one member of the Council, two members of the Assembly, the senior medical officer of the Army and of the Navy, three civilian doctors and a resident physician who was to be sanitary inspector, clerk to the general board, adviser to the local boards, and also superintendent of the insane asylum, and health officer for Hamilton; not to engage in private practice, and to have a salary of \$2,000. Later in the session, a bill was introduced to import from England a portable steam disinfecting apparatus but this also failed. Quite likely another bill will be presented at the session of the Assembly next May.

La grippe has prevailed quite extensively in the south and west of the country since January, but few were fatal. The health of the troops stands high. The new army hospital—north of Camp Prospect on high ground, apart from the barracks—was completed and occupied towards the close of 1892. Every advanced sanitary appliance is to be found there, and there is a separate building for infectious diseases.

Through the efforts of Dr. Harvey—one of the leading medical men of Bermuda—a cottage hospital has been erected about a half mile from Hamilton and is now open, in charge of two women graduates of American training schools. Nine-tenths of its cost was given by Americans. It may prove of much value should contagious disease occur among visitors. The nurses are at command of any one in Bermuda, when not on duty at the hospital, and their skilled service may be a boon to many. Great credit is due Dr. Harvey for this good work. The Doctor who is also Medical Director of the Bermuda Insane Asylum, has been giving a course of lectures on sanitary subjects, and is now engaged in a scheme for promoting the sewerage system of Hamilton.

Bermudians assert their climate the most equable in the world and temperature tables support this claim; statistics prove the winter here more even than at Los Angeles, San Diego, Jacksonville or St. Augustine. The average for the season of 1888-1889, was sixty-three; for 1889-1890, sixty-three; for 1890-1891, sixty-four—a really remarkable record. As a rule, October, November, April, May and June are most agreeable. During December, January and February often the weather much of the time is charming. A clerical friend, convalescing from acute lung disease, who came to Bermuda by my advice, in December, returned in a month, delighted with his experience having added twenty pounds to his avoirdupois, and enjoyed the luxury of an ocean bath on Christmas. March is the worst month when east winds, low barometer and thermometer and frequent showers are apt to prevail. The porous soil admits of outings soon after a heavy rain. As in England, mornings often betoken a stormy day, but the clouds roll by to a beautiful afternoon. July and August, to the "outside barbarian" are too warm for his liking, and September, with its sultry breezeless days is most oppressive of all. May and June, as regards floral beauty of forest and field, offer special attractions, but Fashion at present has decreed that, during March the full tide of travel shall crowd steamers, hotels and boarding houses to discomfort. The highest pleasure

and good from a sojourn in this lovely little land will never be found till this senseless fad has had its day.

Twenty-four of the twenty-six who came with me are here for the first time, and all have reason to felicitate themselves, for the weather, fine on arrival has bettered till now it is truly ideal. A lucky lot, indeed, we are, for Jupiter Pluvius has been in one of his kindest moods, and only one day of the now nearing a dozen, has he showered upon us enough to prevent our usual daily outing.

And, too, what a charming contrast along thermal lines, for while you luckless mortals have been wrestling with the cold, and shivering and shaking in an effort to keep warm, we last Sunday went to the garrison service, at Camp Prospect in open carriages, and at its close sat in them with the sun streaming on us and listened to a delightful open air sacred concert, given by the regimental band of sixty pieces on the sward of a cedar grove near the Camp. Such a story—which may seem like a fairy tale—will give some idea of the changed conditions as regards winter comfort that obtain less than two days sail from New York, and which, well appreciated, must convince those seeking health or pleasure that Bermuda is one of the most charming winter marine resorts in the world, and as to ease of access for Americans without a peer.

The *Trinidad*, newly equipped, made her first trip from New York this year in forty-six and one-half hours. This will be welcome news to many, who, like the writer, enjoy an outing here, and must tend to make the travel tide hither higher than it has ever been; and when, as is expected, a still swifter steamer is put on the line, there is reason to think the voyage can be made in thirty-six to forty hours. Then, indeed, will those seeking surcease from toil with surroundings that tend quickly to rest and restore, find this boon almost at their doors; for to the writer—here for the fifth time, and who again and again has been abroad—Bermuda is the most restful place on earth. And where a people so much in need of such bounty as Americans? Where a folk, so many of whom are rushing along at "the pace that kills?" Almost tumbling over each other in their haste for fame or fortune, and so making themselves victims of tire and insomnia, who here might "throw physic to the dogs," and get that which, more than drugs or doctors, will give them a new lease of life and so add to happiness and length of days.

This is a typically Bermudian day. A gentle sou'west wind is blowing; bright sunshine, the balmy air laden with life's elixir, which blows so often over this favored isle, and song of birds blend to make alluring the matchless beauty of a land so unlike our own. A well-known man lately here, told a friend of ours that he had found the Garden of Eden. It is a Paradise for many—not all, for there are those who should keep well away from Bermuda. It is *not* the place for *consumptives*, or any far along in wasting disease. But for those battling with neuralgia, or coming back to health from acute illness or *narcotic disease*, it is, in truth, a happy land; and for many hapless mortals tossing in wakeful nights—it is a peerless place in which to woo and win the good angel of sleep. For the worn and weary, for tired pilgrims along any line, be it of brain or brawn, it is a Mecca to which they can come with high hopes of getting rest and relief.

It seems strange more do not come here. The fact is, few realize that forty-eight hours from New York is an elysium where frost and the white mantle of winter are unknown; where roses bloom the year round out of doors; and where the sleep-giving, health-bringing breezes, the panoramic beauty of sea and shore, and the quiet, restful, lotus-land alike combine to make halcyon days.

Bermuda is good, too, for those not ill. Let the busy

American doctor make a break in his over-active life, take a fortnight off and a ten days' sojourn in these sun-lit isles, and my word for it—if conditions favor—he will lay up a store of happy memories for many a time to come.

J. B. MATTISON, M.D.

In Opposition to Woman Doctors in Insane Asylums.

RICHMOND, VA., March 19, 1894.

To the Editor:—You refer in a late issue to the contest in our late Legislature on the "Woman Doctor Bill." Two years ago the lower House passed a bill unanimously compelling the Board of Directors of each insane asylum to put one woman doctor in office for each institution. This bill was defeated in the Senate, though every newspaper in this city and many in the country were heartily in favor of it. We had it "hot and heavy" in the newspapers. Men and women abused me pretty roundly for my opposition. I think I wrote a dozen letters in the papers against it. The asylum influence was very great against it, and but for this help I would have been badly whipped. In the last two years I have given this subject a great deal of thought and observation, wrote my pamphlet on "Woman's Place," published 1,000 copies of it and sent most of the members of the last Legislature copies, and I determined to go before the House Committee on Asylums this year and fight it at the start. My friend, Dr. Hunter McGuire, was on the other side of the question. As you know, he is a man of great influence here. He made as good a speech as any man could make on the wrong side of a question—spoke of the trained nurses in his Hospital (St. Luke's); what "deft fingers" the girls had, how readily they stopped hemorrhages, etc. In reply, I asked my friend: "What would St. Luke's be without Hunter McGuire?" He replied: "Nothing." The Committee was nine to one, and I hope this will end the question in Virginia for years, though the papers say not.

Before this meeting of the Committee I had been interviewing some of our best and most intelligent ladies on this question. To my surprise I found they took this ground, absurd as most intelligent *Christian* men would, at first sight, regard it. Said they: "If I were a doctor and a young girl, especially the daughter of a friend of mine, were to come to me and say: 'Doctor, I have been deceived by a young man and am in 'family way,' do relieve me for my dear mother and sisters' sake!' I would certainly relieve her." I said: "Madam, you would be sent to the penitentiary by the laws of Virginia, and would, in the eyes of God be committing murder." But they replied: "You men made these laws, and they are unjust. Men go *everywhere*, where they please, and don't lose caste; shall a girl for one offense, for trusting to one of you men whom she supposed had some regard for his oft-repeated oath of undying devotion, 'slip up,' be doomed to everlasting ruin and disgrace! Where is the sin? As to God's judgments, you are a poor teacher to warn women against them." You will see this argument has the semblance of truth in it, and I find it satisfies women of intelligence.

We are standing, Mr. Editor, upon the mouth of a volcano wider than Vesuvius. For years, in the North, married women have been using the *preventive* treatment against children, and I find it is spreading South. Two of my patients, both married women and pretty well to do, in the past month asked me to produce abortion; one upon the flimsy excuse that she had contemplated a visit to another State this summer. For promptly refusing she dismissed me. One lady I refused last year, went to Washington for the purpose, and came near losing her life. There may be o mestic, national sins more dire in the sight of God than

political offenses; and I want the medical profession throughout the whole Union to set their faces first, against the woman doctor, and against the God-defying and law-breaking male doctor who will sell his soul to the devil for five or twenty dollars.

In the "Institute" referred to in the sad Breckenridge scandal, we have a glimpse into what will happen in this country when it is filled with hospitals of this kind run by women doctors of the class named. A refuge for women of all kinds, and run in the interest, not of *science or humanity*, but of greed for gain.

By the way, I send you a clipping of a brief letter of mine published yesterday (the last shot, I hope) from one of our leading papers. The fair correspondent referred to abused me pretty roundly as selfish, jealous, etc.

"THE WOMAN DOCTOR'S BILL.

RICHMOND, VA., March 5, 1894.

"To the Editor of the Dispatch:

"A fair writer in the *Times* recently made quite a free use of my name, motives, intelligence, etc., in reference to the 'Woman Doctor' in the insane asylums.

The gentleman from whom she received her information of the night's session of the Committee on Asylums has done me injustice, of course not by design. I said: 'There were one or two mean, venal doctors (men, of course), in Richmond, I would like to send to the penitentiary for violating law, but if a woman doctor violated law it would not be for money, but from kind womanly sympathy.' I sent the fair correspondent a copy of my pamphlet on 'Woman's Place,' which I hope she will be kind enough to read, and I will be glad to have her criticism, either private or public. I also refer her to my letter to the State, in reference to my high respect for women. Perhaps, being her senior, I may be allowed to caution her lest she violate God's law in judging my motives.

Fully one-third of my past forty-five years' medical life has been given to the service of poor women and their children, without money or price. This regard for women runs through the lengthy pamphlet I send you. Since coming to my majority I have always and everywhere taught that a man is not worthy of the name, who would not willingly die for mother, wife, sister, daughter, aye for any woman, however poor or humble, who claimed his protection. This is not mere theory, as I can prove. On one occasion I nearly lost my life for a very poor woman, no kin to me. Can better evidence be given of my love and admiration?"

Respectfully,

W. W. PARKER.

He Very Properly Calls Medicus to Order.

MILWAUKEE, March 25, 1894.

To the Editor:—As a member of the AMERICAN MEDICAL ASSOCIATION and a Jew, I desire to enter an emphatic protest against the dragging of questions of race and religion into the discussion of a matter of business policy, as is done by "Medicus" in the JOURNAL of March 24. The fact that the gentlemen specified as Solomon and Isaac chose to differ from "Medicus" does not justify the wholesale and thinly veiled charge of hypocrisy and dishonesty, worthy only of a fifth rate political sheet, which is made in that letter.

Unless it is the policy of the JOURNAL to publish all communications sent to it, I fail to see the justification for publishing a gratuitous insult to a class of members who happen to differ from the majority in creed. A note suggests that the matter be settled on the floor of the ASSOCIATION. Surely no presiding officer, of any respectable body, would allow such language to be used in debate.

If the ASSOCIATION is not broad enough to cover all reputable medical men without reference to race or creed, the sooner we know it the better.

G. J. KAUNHEIMER, M.D.

[The right of every member to have his say is recognized, and the editor joins Dr. Kaunheimer in expressing the hope that all personalities may be eliminated from this discussion, as they will not be printed.]

Stands by Dr. Cohen.

BOSTON, March 26, 1894.

To the Editor:—I can not conceive how you permitted the publication of the contemptible, narrow and insulting letter signed "Medicus." He may well stay in the background by keeping his name away from the public—cowardice is de-

icted in every line. I am inclined to think that "Medicus" has ill feelings against Prof. Solomon Cohen for reasons known to himself—he was probably plucked by Dr. Cohen for deficiency in the subject that Dr. Cohen lectures on?

I will not attempt to discuss the "advertising question," for you have requested the matter to end.

The publication of the vile letter has, and will excite bitter criticism.

It is unnecessary for me to speak in defense of Dr. Cohen and the Hebrew race.

Hoping you will find space to publish this brief note, so that "Medicus" can see what repute he has gained by making a ferocious attack on many of the noble and leading physicians of our country.

S. GOODMAN, M.D.

Attacks Our Exchanges.

PHILADELPHIA, March 21, 1891.

To the Editor:—I write to endorse Dr. Cohen and the Code, but I go further: I would not receive or quote from any journal that publishes advertisements of the character condemned by Dr. Cohen. My proposition is that no ASSOCIATION money shall be paid for printing a journal to be given in exchange to any journal that prostitutes itself by publishing the vile advertisements in question. Let us fight this thing to the finish.

PRO-COHEN.

Endorses the Code and Dr. Cohen.

SAN JOSE, CAL., March 23, 1894.

To the Editor:—I write to endorse the article written sometime since, by Dr. N. S. Davis, of Chicago, on revision of the Code and the proposed changes in the constitution of the AMERICAN MEDICAL ASSOCIATION. Every word in that article is true, and it should be carefully read by every member of the ASSOCIATION. That article has not been answered, but I presume there will be an effort made to patch up the walls that have been knocked down by Dr. Davis just before the meeting in San Francisco.

I also endorse the remarks of Dr. S. Solis-Cohen and Dr. W. P. Howle.

JOHN WRIGHT, M.D.

BOOK NOTICES.

A Text-Book of Diseases of the Ear and Adjacent Organs. By DR. ADAM POLITZER, Imperial Royal Professor of Aural Therapeutics in the University of Vienna, Chief of the Imperial-Royal University Clinic for Diseases of the Ear in the General Hospital, Vienna. Translated into English from the third and revised German edition, by OSCAR DODD, M.D., Clinical Instructor in Diseases of the Eye and Ear, College of Physicians and Surgeons, Chicago. Edited by SIR WILLIAM DALBY, F. R. C. S., M.B., Consulting Aural Surgeon to St. George's Hospital, London. In one large octavo volume of 748 pages, with 330 original illustrations. Cloth, \$5.50. Philadelphia: Lea Brothers & Co. 1894.

The writings of Adam Politzer on the ear are held in high authority throughout the civilized world, and this text-book has for many years been considered his best. In this edition much space and attention have been given to intra-cranial diseases of otitic origin, such as subdural abscess, otitic meningitis, sinus-phlebitis, etc. The operative treatment of thrombosis of the transverse sinus is, according to the author much simpler than opening of intra-cranial abscess. The operation is thus performed: "After chiseling away the mastoid process, and carefully removing all diseased portions, the sinus is laid free. After this is done one should examine to see if the wall of the vein has the normal dark blue color, or if it is inflamed, thickened, covered with exudate, whether it pulsates or not, and whether it is soft or hard to the touch. Want of pulsation, and resistance leads

one to think of thrombus. Fluctuation with want of pulsation, should lead one to think of purulent or sanious degeneration."

He may then explore with a Pravaz or open the sinus by a vertical incision according to Lane's method. If the thrombus extend into the jugular, the author recommends the method of Rushton Parker, an incision through the skin into the jugular, and afterwards applying a ligature.

Lectures on Auto-Intoxication in Disease, or Self-Poisoning of the Individual. By CH. BOUCHARD, Professor of Pathology and Therapeutics, Member of the Academy of Medicine and Physician to the Hospitals, Paris. Translated, with a Preface, by THOMAS OLIVER, M.A., M.D., F.R.C.P., Professor of Physiology, University of Durham; Physician to the Royal Infirmary, Newcastle-upon-Tyne; and Examiner in Physiology, Conjoint Board of England. In one octavo volume; 302 pages. Extra cloth, \$1.75 net. Philadelphia and Chicago: The F. A. Davis Co., Publishers.

This volume deals with the toxines. Pathogenic processes generally; elimination of poisons; preliminaries to the study of the toxicity of emunctory products; intestinal antiseptics, and of various diseases due to bacillary products. The whole a series of lectures.

The author begins with the assertion that in this age Medicine has changed her attitude of observation. For a considerable time the chemical division of Bacteriology has been making great advances, and to-day the chemistry of the microbic products is the most important subject in connection with the subject. The author informs us that the healthy man is "both a receptacle and a laboratory of poisons. He receives them in his food, he creates them by disassimilation, and he forms them in his secretions. The human body is the theater of the toxic elaborations carried on by the normal microbes which constantly inhabit the alimentary canal."

The Dispensary of the United States of America. By DR. GEO. B. WOOD and DR. FRANKLIN BACHE. Seventeenth edition by H. C. WOOD, M.D., L.L.D., JOSEPH P. REMINGTON, Ph.M., F.C.S., and SAMUEL P. SADTLER, Ph.D., F.C.S. Pp. 1930. Bds. Philadelphia: J. B. Lippincott Company. 1894.

This well-known and standard treatise needs no introduction to the readers of the JOURNAL. When a book has passed to its seventeenth edition it has passed beyond the power of the reviewer to affect its standing. It therefore only remains to inquire how fully the last edition has kept pace with the advance of pharmacy since the issue of its immediate predecessors which have justly made the work famous. In this respect we can truly say that no pains have been spared to insure accuracy and completeness. It is somewhat unfortunate that the metric or decimal system should be given a secondary place in giving the doses of drugs, and this conservatism seems to have no reasonable excuse, inasmuch as the "National Dispensary" and the Pharmacopœia itself practically recognized no other system. Notwithstanding this defect, the book will continue to be as it has in the past the standard authority on this subject.

Transactions of the American Pediatric Society, 5th Session, held at West Point, N. Y., May 24, 25 and 26, 1893. Edited by M. CRANDALL, M.D. Vol. V. New York: Printed by Bailey & Fairchild. 1893.

This volume contains a list of the officers and members, and the papers read at the last meeting of the Society. Most of them have been printed elsewhere. Those interested in the diseases of children will find much that is interesting and instructive in this volume.

Congenital Affections of the Heart. By GEORGE CARPENTER. M.D. 16 mo., cl., pp. 103. London: John Bale & Sons. 1894.

This little volume is well written and handsomely printed in clear type, and includes the essentials of the subject,

which has not up to this time received very much attention. It will be found very instructive.

Tables and Notes on Human Osteology, for the Use of Students of Medicine. By SEDASTIAN J. WIMMER, M.A., M.D. With a preface by PROF. WILLIAM F. WAUGH, A.M., M.D. 16 mo., pp. 239. Philadelphia: Medical Publishing Company. 1894.

The author has compressed in a compact and convenient volume a careful compilation of the essentials of Osteology. In Dr. Waugh's preface he gives his opinion that this book is "the ideal help to the student in term time," and on examination we concur in his judgment. We find a tabulated summary of all the points to be memorized, arranged in such a way that it can not fail to be of service to the student.

Bulletin of the Harvard Medical Alumni Association, No. 5. Report of third annual meeting, held in Boston, June 27, 1893. Boston: Published by the Association. 1893.

This is a beautifully printed volume, gives the minutes of the last annual meeting and the speeches made at the annual dinner. On this occasion Dr. J. R. Chadwick presided. His presidential address contains valuable historical material. Drs. J. M. DaCosta, Abram Jacobi and W. S. Chaplin made speeches of interest.

NECROLOGY.

JOHN H. RAUCH, M.D., in Lebanon, Pa., March 24. Dr. Rauch was born in Lebanon, Pa., Sept. 4, 1828. He was graduated in medicine at the University of Pennsylvania in 1849. The following year he settled in Burlington, Iowa. His mind early turned toward natural sciences, and he became a private pupil of Prof. Louis Agassiz of Harvard College, and lived for some time in his family. In 1850, on the organization of the State Medical Society, he was appointed to report on the "Medical and Economic Botany of Iowa," and his report was published. He was an active member of the Iowa Historical and Geological Institute, and made a collection of material—especially ichthyologic—from the Upper Missouri and Mississippi Rivers for Prof. Agassiz, a description of which was published in *Silliman's Journal* in 1855. In 1857 he was appointed Professor of Materia Medica and Medical Botany in Rush Medical College, Chicago, which chair he filled for the next three years. In 1859 he was one of the organizers of the Chicago College of Pharmacy, and filled its chair of materia medica and medical botany. During the Civil War he served as Assistant Medical Director of the Army of Virginia and later in Louisiana. At the close of the war he was breveted Lieutenant-Colonel. On his return to Chicago, Dr. Rauch published a paper on "Intramural Intermittents and Their Influence on Health and Epidemics." He aided in reorganizing the health service of the city, and, in 1867, was appointed a member of the Board of Health and Sanitary Superintendent, which office he filled until 1873. During his incumbency the great fire occurred, and the task of organizing and enforcing the sanitary measures for the welfare of 112,000 homeless men, women and children devolved upon him. In 1876 he was elected President of the American Public Health Association, and delivered the annual address on the "Sanitary Problems of Chicago," at the 1877 meeting of the Association. When the Illinois State Board of Health was created in 1877, Dr. Rauch was appointed one of its members, and was elected its first President. In 1878-79 the yellow fever epidemic in the Southwest engaged his attention, resulting in the formation of the Sanitary Council of the Mississippi Valley and the establishment of the river inspection service of the National Board of Health. His investigations on the relations of smallpox to foreign immigration were embodied in an address delivered before the National Conference of the State Board of Health at St. Louis in 1884. In 1887 he published the preliminary results of his investigations into the character of the water supplies of Illinois. In 1888 he published a report on the quarantines of the Atlantic and Gulf coasts, and in 1892 he assisted ex-Surgeon-General Hamilton in the establishment and equipment of Camp Low, quarantine sta-

tion. Dr. Rauch was the author of monographs chiefly in the domain of sanitary science and preventive medicine. His chief work as a writer is embodied in the reports of the Illinois State Board of Health in eight volumes.

Frank P. Yetter, M.D., of Bowmansville, Pa., March 4.—John T. Liston, M.D., of Bunker Hill, Ind., aged 90. He is said to have built the first log cabin in the Wabash Valley.—James F. Bailey, M.D., of Cincinnati, March 16, aged 55. He was recently a member of the Ohio Legislature, and the author of the "Bailey Primary Election Law," which is a great improvement in securing purity in elections.—Geo. W. Norton, M.D., at Earlville, Ill., March 7, aged 90. He had resided in the vicinity since 1846.—F. G. Payn, M.D., of Bergen Point, N. J., March 5, aged 70. He was born in England, and practiced in Bayonne and Jersey City since 1856.—J. P. S. Roberts, M.D., of Bairdstown, Mo.—H. S. Cox, M.D., of Columbia, Tenn., March 8.—W. S. Irwin, M. D., of Louisville, Ky., March 8.—W. C. Hardin, M.D., of Louisiana, Mo., March 12, aged 88.—Anson Amesbury Ransom, M.D., of South Orange, N. J., March 11, aged 71. He was a graduate of the University of the City of New York.—J. P. Wallace, M.D., of Greeley, Col., a graduate of Bellevue (1875), March 11, aged 45.—G. H. Peebles, M.D., of Lincoln, Neb., March 15, aged 53 years. He was a graduate of Rush Medical College, class of 1863.—Reuben A. Vance, M.D., of Cleveland, Ohio, March 19.—Wm. C. Cole, M.D., of Fountain County, Ind., March 11.—Abram Sellers, M.D., of Lebanon, Ky., March 13, aged 87.—J. M. Bryan, M.D., of Philadelphia, March 14. He was a graduate of the University of Pennsylvania, class of 1892.—B. F. Hopkins, M.D., Rapatee, Ill., March 4, aged 43.—Eustace W. Fisher, M. D., of New York city, March 5, aged 51.—Charles Devol, M.D., of Albany, N. Y., March 5, aged 85. He was a graduate of Fairfield Medical College, class of 1831. Five years later he became a Methodist preacher but resumed the practice of medicine in 1855. He was devoted to the service of the poor.—Clarence E. Riggs, M.D., of New Orleans, March 14, aged 27. He was graduated at Tulane University.—H. J. Webb, M.D., of Pullman, Washington, March 4. He was one of the oldest and best-known physicians of Eastern Washington.

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Rio Grande Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville, Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland, thence east by way of the Northern Pacific R. R. to St. Paul. C. M. & St. P. R. St. Paul to Chicago. A stop over at Yellowstone National Park for those who desire it has been arranged, and it has been understood that at several places on the journey there will be short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentrating on this train should be effected at Chicago and St. Louis. For all information relating to this train, fares, etc., address J. M. Connell, 212 Clark st., Chicago, or any agent of Santa Fe line in other cities. Rates promised are the lowest excursion rates at time of departure.

This is the only route on which arrangements have been perfected by the Trustees.

Section on Physiology and Dietetics.—*To the Editor:*—I present to you the following announcement to the members of the Association apropos to the Section on Physiology and Dietetics prepared by the Secretary of the Section, Dr. Ephraim Cutter.

I earnestly commend the Section to all members of the Association interested in the subject, and indulge the personal hope that there will be a hearty response in the way of titles of papers sent immediately to Dr. Cutter. Very respectfully yours,

I. N. LOVE, M.D., Chairman.

NEW YORK, Feb. 10, 1894.

SECTION ON PHYSIOLOGY AND DIETETICS.

To the Members of the AMERICAN MEDICAL ASSOCIATION:—

This Section should be a mirror of your 1894 knowledge. It is believed there is something to mirror where American facts and ideas have precedence. Those who look for such facts and find foreign ones in their place, are disappointed. You must not say that there are no American facts. The number of medical ideas annually dying with their possessors is not small, as we judge. This Section is to rescue moritural and non-moritural dietetic and physiologic facts, no matter if they are little. A drop of water is a little thing. Yet vast oceans are made up of drops. To assist in this work you are hereby requested to give your contributions to any of the following subjects:

PHYSIOLOGY.

"Are the Eustachian Pharyngeal Orifices Closed or Open?" "Physiology of a Larynxless Voice." (Prof. S. Solis-Cohen invited); "Musical Action in Man and Animals;" "Love as Healthful Affection;" "Digestive Leucocytosis;" "Functions of an Undeveloped Clitoris;" "Physiologic Action of Hot Water Drafts;" "Impression of Traits of Character of the Father at the Time of Conception on the Offspring;" "Physiology of Dynamis; or: Life a Question of Expenditure of Vital Force;" "Physiologic Effects of Galvanism;" "Is the Seat of the Soul in the Lamina Terminalis?" "Physiologic Significance of Anencephalous Babies;" "Is the Unborn Babe at Term Capable of Thought or Knowledge?" "Penal Physiology;" "Fashion vs. Physiology among Women;"

DIETETICS.

"Relations of Food to Insanity; a, Fatty Degeneration; b, Embolism; c, Difficult Digestion;" "Is Cancer Caused by the want of Proper Feeding?" "Air as Food;" "Good Bread;" "Food vs. the Knife in the Treatment of Cancer of Breast;" "Is Cookery Drudgery and Degrading?" "Peanuts as Food in Fatty Degeneration;" "The Microscope and Food;" "Restaurants Fixed and Mobile;" "Voice and Food;" "Food vs. Resection of Ribs in Chronic Pleurisy;" "Dietetic and Cardiac Concretions sometimes called Polyphi and Food;" "Relations to Physicians of Cooking Schools;" "Are there not Close Relations of Food to Leprosy?" "A Poor Single Food may be better than many Good Foods Eaten at One Time Indiscriminately;" "The Formation of Alcohol in the Alimentary Canal from Fermenting Food;" "Distilled Water as Food;" "Cow's Milk as Sole Food for Adult Man;" "Dietetics and Epilepsy;" "Dietetics and Baldness;" "Dietetics and Teeth;" "Is Promiscuous and Hearty Feeding the best for Health?" "Living to Eat and Eating to Live;" "Dietetics changing Funerals to Weddings;" "Dietetics and Fibroid Strictures and Thickening of the Alimentary Canal;" "Ought the AMERICAN MEDICAL ASSOCIATION to Advertise Common Flour as a Royal Therapeutic Dietetic?" "Review of the Massachusetts State Board of Health Report, 1892;" "When Institutes of Technology and Schools of Mines Teach the Morphology of Foods, ought not Medical Colleges to do the Same?" "Foul Diseases that Masquerade under other Names;" "Does the Climate (Air Food) of San Diego Cure Bright's Disease of the Kidneys?" "Food and Calculi;" "Food and Atheroma;" "Food and Amyloid Degeneration;" "Food and Inflammation;" "Popular Food Ideas that have Slain Thousands;" "Dietetics and Religion;" "Dietetics and Male Neurasthenia;" "Why should not Government Protect the Food of Man as it does the Food of Plants?" "Watts, Applied to Food: 'Each pleasure has its poison too, and every sweet a snare;'" "Consumption of the Bowels and Food;" "Food and Colloid Feces or Amœba Coli;" "Food and Heart Disease;" "Food and Skin Diseases;" "Food and the Type of Disease;" "Food and the Exanthemata;" "A New Army and Navy Ration;" "Does Sea Air contain more Mineral Food than in Land Air?" "Diet and Scurvy;" "Diet and Defective Hearing;" "Diet and Ophthalmology;" "Oatmeal—Objections to as a Food for Man;" "Vegetable vs. Animal Food;" "Food and Nerve Diseases;" "Food and Nasal Catarrhs;" "Dietetic Importance of a National Secretary of Health;" "Importance of the Pure Food Bill now before Congress;" "Importance of Freshness in Food from the Botanic Kingdom;" "Impure Water for Ships;" "Why are Gruels Good Food?" "Diet Treatment of Bright's Disease." (Signed.)

I. N. LOVE, Chairman,
EPHRAIM CUTTER, Secretary.

SOCIETY NEWS.

International Medical Congress.—It is stated that about 200 American physicians will attend the International Medical Congress at Rome. There were over 600 at Berlin.

The Herkimer County (N. Y.) Medical Society has elected the following officers: President, Dr. Cyrus Kay, Jr.; Secretary, Dr. A. W. Suiter; Treasurer, Dr. Graves. The other officers of last year were reelected.

Have Societies Named for Them.—The Philadelphia brethren are having a mild epidemic of new medical societies, named for favorites; they now have medical societies respectively named for Prof. Hobart A. Hare, Prof. L. Webster Fox, Prof. Wm. E. Ashton and Prof. Jas. M. Anders.

Lancaster City and County Medical Society.—At the last meeting of the Lancaster (Pa.) City and County Medical Society an interesting paper was read by C. M. Franklyn, M.D. on "Fractures of the Skull." Cases were reported by Drs. Welchans, Brenholtz, Craig, Roebuck, Ziegler, and Miller.

An Old University.—Don Juan Ortega Rubia says in the *Revista Contemporanea*, Madrid, that "one of the oldest seats of learning in Europe, the University of Valladolid, celebrated recently its sixth centennial as an established university. In 1293 King Sancho IV of Castile and Leon gave charter to this school. But it had been in existence long before the Christian era."

Michigan Surgical and Pathological Society.—At the annual meeting of the Michigan Surgical and Pathological Society the following officers were elected: President, Dr. E. W. Jenks; Vice-President, George Kirker; Secretary, J. A. Patton; Treasurer, Dayton Parker. The latter was the retiring President, and he tendered the members a banquet at the conclusion of the meeting, which lasted until a late hour. Toasts were responded to by Drs. Jenks, Kirker, Hough, Hamlin, Milligan, Maier, Ahlborn, Ranpier, Leadbeater and Alderman.

The Northern District Medical Society met in Woodland, Cal., March 13. The Yolo Medical Society entertained the members at a banquet. Following is the program:

"A Case of Procrursive Epilepsy," A. W. Hoisholt, Stockton. Discussion opened by Elmer E. Stone, Marysville.

"Diphtheria," Oscar Stansbury, Chico. Discussion opened by C. H. Gibbons, Arbuckle.

"Gastric Ulcer," W. E. Bates, Davisville. Discussion opened by B. Caldwell, Biggs.

"The Decline of Maternity," David Powell, Marysville. Discussion opened by J. H. Parkinson, Sacramento.

"The Foothills of the Sierra Nevada Mountains in the Climatic Treatment of Bronchial and of Pulmonary Affections," R. F. Rooney, Auburn.

"The Causes and Treatment of Abortion," W. R. Cleveland, Biggs. Discussion opened by Thomas Ross, Sacramento.

"Some Peculiar Effects of La Grippe," H. D. Lawhead, Woodland.

"The Treatment of Venereal Diseases," W. J. Hanna, Sacramento.

The following are the present officers of the Society: President, Wallace A. Briggs; First Vice-President, J. R. Rooney; Second Vice-President, F. W. Benjamin; Third Vice-President, A. T. Hudson; Secretary, Elmer E. Stone; Treasurer, Oscar Stansbury. Board of Censors: W. A. Briggs, Chairman; G. W. Stratton, T. B. Reardan, W. E. Bates and Louis Melton.

The Indian Medical Congress.—The proposal to have a Medical Congress in India was considered at a meeting of the Council of the Calcutta Medical Society on January 24, when it was decided that an "Indian Medical Congress" shall be held in Calcutta at the beginning of January, 1895. The preliminary arrangements were discussed and a general plan sketched out. It was decided that in each province

local secretaries, native as well as European, should be asked to cooperate with the Calcutta secretaries, and it was further decided that the sections into which the Congress should be divided should be:

1. Medicine including Pathology.
2. Surgery.
3. Obstetrics and Diseases of Women and Children.
4. Public Health.
5. Medico-legal Medicine and allied subjects.

Further details will be given in a future issue. It was decided that the Congress should be widely advertised, and that all medical men practicing in every part of the world, but especially in India and the East, should be invited to take part in it and submit papers to be read in the different sections.—*Indian Medical Gazette*.

Medical Society of the Missouri Valley.—The sixth semi-annual convention of the Medical Society of the Missouri Valley met at Omaha March 16.

President Jonas of Omaha, called the meeting to order at 9:30 o'clock. The registration and payment of dues followed. The Committee on Credentials made its report, which was adopted. Secretary Thomas of Council Bluffs, read the minutes of the last meeting, which were approved without discussion. Miscellaneous business and reports of committees followed. Several new members were admitted.

Dr. F. M. Hiatt of Red Oak, Iowa, read an interesting paper on "Safe Anesthesia."

Dr. A. S. Mansfelde of Ashland, Neb., read a paper regarding "Brain Bruise—Contusion Without Hemorrhage;" Dr. Foote followed with "Cell Selections—Auto-infection"

Dr. Lanphear of Kansas City, who was on the program for a paper on "Vaginal Hysterectomy Without Clamps or Ligatures," asked for further time and he presented his paper in the afternoon.

Dr. J. M. Barstow of Council Bluffs, read an interesting paper on "Gasoline Poisoning," which was thoroughly discussed.

"Pulmonary Embolism" received the attention of Dr. Lowry of Lincoln.

The convention adjourned for lunch and reassembled at 2 o'clock, when the reading and discussion of papers was resumed.

The present Society was organized six years ago at Council Bluffs, and has 150 members, composed of the medical fraternity of Omaha, Council Bluffs, Sioux City, St. Joseph, Kansas City and other points in the Missouri Valley. The object of its organization was to foster acquaintance and meet semi-annually for the discussion of subjects of interest to the medical profession.

In the evening the doctors gave a banquet at the Commercial Club. Plates were laid for 100. The tables were artistically decorated with flowers and potted plants.

The following were the toasts: "The Doctor in Literature," Dr. Lowry of Lincoln; "Medical Education in the West," Dr. Bridges of Omaha; "Medical Charlatanry," Dr. Coulter of Omaha; "Post-Graduate Medical Education," Dr. Emmert of Atlantic, Iowa; "Women in Medicine," Dr. Van Mansfelde of Ashland; "The Physician and the Public," Dr. Gibbs of Omaha; "The Doctor in Politics," Dr. Macrae of Council Bluffs.

Association of American Physicians.—Preliminary program of the ninth annual meeting of the Association of American Physicians to be held in Hall No. 2, Columbian University, corner of Fifteenth and H Streets, Washington, D.C., on the mornings of May 29, 30, 31, and June 1, 1894.

President's Address, R. H. Fitz; "Some Researches in the Significance of Albumen and Casts, especially in those Past Middle Life," Fred'k C. Shattuck; "Some of the Chemic and Bacteriologic Characteristics of Milk," Thomas M. Rotch; "The Chemic Products of the Anaerobic Putrefaction of Pancreatic and Hepatic Tissues, and their Effects upon the Tests for Morphia," Victor C. Vaughan; "The Effect of Various Metals on the Growth of Pathogenic Bacteria," Meade Bolton; "Dr. S. C. Martin's Researches on the Bacteria, of Vaccinia," Harold C. Ernst; "Note on the Observation of Malarial Organisms in Connection with Typhoid Fever," W.

Gilman Thompson; "Experiments in Artificial Melanosis," George Dock; "The Mild Character and Diminished Prevalence of Syphilis and the Infrequency of Visceral Syphilis," John H. Musser; "A Case of Osteomalacia," George Dock; "The Treatment of Typhoid Fever," Samuel A. Fisk; "The Treatment of Certain Symptoms of Croupous Pneumonia, particularly in Adults," Beverly Robinson; "A Study of the Temperature in Cerebral Apoplexy," Charles L. Dana; "Traumatic Headache," Charles F. Folsom; "Tetany in America," J. P. Crozer Griffith; "Clinical Report of Two Cases of Reynaud's Disease," Frederick P. Henry; "A Case of Mitral Stenosis, with great Hypertrophy of the Right Ventricle; Death from Hemoptysis," A. McPhedran; "Stomatitis Neurotica," A. Jacobi; "Nocturnal Pain in Dyspepsia," Henry M. Lyman; "Lead Palsy in Children," Wharton Sinkler; "A Report on the Ultimate Results obtained on Experimental Eye Tuberculosis by Tubercular Treatment and Preventive Inoculation," E. L. Trudeau.

The Constitution provides that papers shall not exceed thirty minutes in the reading.

The Association will hold its sessions and these papers will be read only on the mornings of May 29, 30, 31, and June 1. On the afternoons of these days the Congress of American Physicians and Surgeons will hold its sessions.

The Association of American Medical Colleges.—The fifth annual meeting of the Association of American Medical Colleges will convene at Maple Hall, Grand Pacific Hotel, San Francisco, California, at 3 o'clock, p.m., Wednesday, June 6, 1894. Action will be taken at this meeting upon the following amendments, to-wit.:

Rush Medical College, by unanimous vote, submits the following amendment to Sec. V, Art. III, of the Constitution, "providing that students who intend to graduate in 1899, or in subsequent classes, four years of medical study and an attendance upon four annual courses of lectures of not less than six months duration each will be required. Provided, that graduates of literary colleges who have taken a course of scientific studies, graduates of schools of pharmacy that require three years study and adequate preliminary education, may be admitted to the second year's work or course of lectures in the college without examination."

The present wording of Sec. V, Art. III, is as follows: "Candidates for the degree of Doctor of Medicine shall have attended three courses of graded instruction of not less than six months' duration each, in separate years."

Subsequent to the above action by Rush Medical College, upon request of the Secretary, President N. S. Davis appointed the following named persons to act as an informal committee, to, in conjunction with such other colleges as could send delegates, hold a conference and prepare for submission a schedule of requirements adapted to a four years' course: E. L. Holmes, Chairman, Rush Medical College; Reginald H. Fitz, Harvard Medical College; Victor C. Vaughan, University of Michigan; Wm. Osler, Johns Hopkins University; Wm. E. Quine, College of Physicians and Surgeons, Chicago, Ill.; P. S. Conner, Medical College of Ohio; N. S. Davis, Jr., Chicago Medical College; Dudley S. Reynolds, Hospital College of Medicine; Perry H. Millard, University of Minnesota.

The meeting was held at Chicago, February 7, twenty colleges being represented. The representatives of the colleges present were unanimously of the opinion that the present requirements of the entrance examination were not sufficiently definite, and directed that the following amendment to Sec. I, Art. III, be submitted for consideration at the forthcoming session to be held June 6: "Colleges, members of this Association, shall require of all matriculates an examination as follows: 1, an English composition in the handwriting of the applicant, of not less than two hundred words, said composition to include construction, punctuation and spelling; 2, arithmetic—fundamental rules, common and decimal fractions and ratio and proportion; 3, algebra—through quadratics; 4, physics—elementary, Gage; 5, Latin—an amount equal to one year's study as indicated in Harkness' Latin Reader."

The present wording of Sec. I, Art. III, is as follows:

ARTICLE III, SECTION 1. Members of this Association shall require of all matriculates an English composition in the handwriting of the applicant, of not less than two hundred words, an examination by a Committee of the Faculty, or

other lawfully constituted Board of Examiners, in higher arithmetic, algebra, elementary physics and Latin prose.

As a result of prolonged discussion, and upon motion of Prof. Victor C. Vaughan, the committee, by vote recommended that Sec. V, Art. III, be amended to read as follows: "Colleges, members of this Association, shall require of all applicants for the degree of M.D., attendance upon three courses of lectures of not less than eight months each, or four courses of six months each, in separate years."

Upon motion the Chair appointed the following Committee to prepare a minimum of requirements suitable to a four years' course, with instruction to submit the same in time for action at the forthcoming session: P. S. Conner, Medical College of Ohio; Victor C. Vaughan, University of Michigan; Wm. E. Quine, College Physicians and Surgeons, Chicago; N. S. Davis, Jr., Chicago Medical College; C. B. Stemen, Fort Wayne Medical College, Ind.

The above Committee unanimously recommended that the Constitution be amended by the following addition: "Colleges, members of this Association, shall require at least an amount of work in each branch as follows, to-wit.:

	Hours didactic and recitation.	Hours Laboratory
History and Embryology	50	100
Anatomy and Physiological Chemistry	150	300
Physiology	200	75
Chemistry	125	125
Materia Medica and Therapeutics	125	
Practice	200	
Surgery	200	
Regional and Operative Surgery	50	50
Obstetrics and Gynecology	150	
Ophthalmology and Otolaryngology	25	
Mental and Nervous	25	
Dermatology	25	
Bacteriology	25	150
Pathology	50	100
Physical Diagnosis	75	
Pædology	25	
Medical Jurisprudence	15	
Hygienic and State Medicine	50	
Genito-Urinary	25	
Orthopedics	25	
Laryngology	25	
Clinical Instruction		

N. S. DAVIS, M.D., L.L.D., President.
PERRY H. MILLARD, Secretary.

MISCELLANY.

Personal Notes.

DR. JOSEPH A. WHITE of Richmond, Va., was seriously injured while riding in a fox hunt, March 6.

DR. VOGAN was appointed Health Officer of Lowellville, Ohio, March 12.

DRS. FORMENTO and HARNAN have been reelected to the Louisiana Board of Health.

DR. B. C. BRETT, the President of the Wisconsin State Medical Society, has received from the Honorable the Secretary of the Treasury, a formal request for his resignation as Acting Assistant Surgeon of the Marine Hospital Service and in response has addressed the following letter:

"Your letter of February 27, asking my resignation as Acting Assistant Surgeon of the Marine Hospital Service, is received. Regarding this request as the equivalent of an order from my superior officer, I herewith respectfully comply with it."

DR. A. W. SLAUGHTER has been appointed to succeed Dr. Brett in the position noted.

Medical College Notes.

THE ST. LOUIS MEDICAL COLLEGE held its commencement exercises March 16, and conferred the degree of M.D., on sixteen graduates.

THE MISSOURI DENTAL COLLEGE at its commencement March 16, conferred the degree of D.D.S. on twenty-one graduates.

THE BEAUMONT MEDICAL COLLEGE of St. Louis, at its seventh annual commencement March 15, awarded diplomas to thirteen graduates.

THE TOLEDO MEDICAL COLLEGE held its thirteenth annual

commencement March 12. There were nine graduates. This college will hereafter have a four years' course.

THE OHIO MEDICAL COLLEGE AT COLUMBUS held its second annual commencement March 13, and conferred the degree of M.D., on twelve graduates; there were also five graduates in pharmacy.

Hospital Notes.

NEW HOSPITAL.—A new hospital is to be built at Columbia, Pa.

NASHVILLE, TENN.—The report of Dr. Charles Brower shows that 1,117 patients were treated in the city hospital during the past year.

ISOLATION HOSPITAL.—Fond du Lac, Wis., stimulated by the appearance of smallpox in some Wisconsin towns will build an isolation hospital.

SELECTED A SITE.—The trustees of the Reuben Noble Hospital Fund at Westfield, Mass., have selected a site for that institution, which will cost \$20,000.

DIFFERENCES.—There is an interesting row between the regular, "homeopathic" and "eclectic" staff at the Cook County, Ill., Hospital.

ST. BONIFACE HOSPITAL, WINNIPEG, has been entirely reconstructed, and is now one of the best arranged Hospitals in the Dominion.

NORTH CAROLINA STATE HOSPITAL FOR THE INSANE.—The quarterly meeting of the North Carolina State Hospital at Morganton, was held March 1. The Hospital is overcrowded and needs enlargement.

CONTAGIOUS DISEASE HOSPITALS.—The Health Board of Detroit are unanimous in recommending the establishment of a contagious disease hospital. A pest house is to be built at Columbus, Ohio, on the county infirmary grounds.

HOSPITAL FOR INSANE, ROCHESTER, MINN.—Work on the rebuilding of the administration building at the State Hospital at Rochester, Minn., will begin shortly. It is to be a \$60,000 improvement and will greatly improve the appearance of the building.

THE OFFICERS AND MANAGERS of the Infants' Summer Hospital, Rochester, N. Y., held their annual meeting March 12. The debt of the lakeside institution has been reduced to \$1,500. The Hospital will be opened to patients at the usual time this summer. Among the officers were Dr. Edward M. Moore, Sr. and Dr. E. M. Moore, Jr.

THE FLAGLER HOSPITAL at Lockport, N. Y., has been made a general and emergency city hospital, the management being in the hands of a non-sectarian board of managers of twenty-one members, on which shall be represented the Mayor, the Board of Health and each of the religious denominations of the city.

THE "BIG FOUR" WILL HAVE NINE HOSPITALS.—The "Big Four" Railroad has finally decided to establish hospitals at Indianapolis, St. Louis, Cairo, Kankakee, Peoria, Sandusky, Cleveland, Columbus and Cincinnati, at a total cost of \$100,000. A hospital tax of 50 cents a month will be assessed on all employes receiving a monthly salary of more than \$50.

THE MEDICAL SOCIETY SELECT THE STAFF.—The Macon (Georgia) Hospital has been established, and the Macon Medical Society are to furnish the medical service of the Hospital. It is a great pity that the medical staff of municipal hospitals generally are not thus selected. The societies may well be trusted to recommend efficient and capable men.

MUNICIPAL HOSPITAL, PHILADELPHIA.—A movement to remove the Hospital to Petty's Island is doomed to failure, owing to the difficulty of reaching the Island in winter.

The Councilmen selected from the Twenty-eighth Ward where the Hospital is at present located were pledged to work for its removal, but the other councilmen object to its removal to the vicinity of their respective constituents, and so the Hospital is likely to remain where it is.

NEW HOSPITAL AT BALTIMORE.—The Faculty of Baltimore Medical College will build a new hospital this summer on the site of the Maryland General Hospital, which is to be torn down. The hospital will have a capacity of 150 beds and 20 private rooms and it is designed to be completed in December. The committee in charge of the new building are Drs. R. H. P. Ellis, R. W. Johnson, J. D. Blake and Wilmer Brinton. The physicians and surgeons composing the hospital staff are Drs. C. G. Hill, R. H. P. Ellis, David Streett, Wilmer Brinton S. K. Merrick, John D. Blake, A. C. Pole, George Reuling, R. W. Johnson, T. A. Ashby, W. T. Howard, Jr., S. T. Earle and R. B. Warfield.

MILWAUKEE is to have a Children's Hospital. It will be opened May 1. The following will be the medical staff:

Attending Physicians—Dr. Bennett, Dr. R. C. Brown, Dr. H. V. Ogden and Dr. S. Friend.

Surgical Staff—Dr. Ralph W. Chandler, Dr. Bryant Smith, Dr. F. Rogers and Dr. Frank Munkwitz.

Attending Oculists—Dr. Edgar H. Neyman and Dr. H. V. Würdemann.

Consulting Staff—Dr. William Fox, Dr. T. E. Wallbridge, Dr. Thomas Hay, Dr. Louis Frank (dermatologist), and Dr. Franklyn J. Tower (pathologist).

Miss Louise King, a graduate of the Illinois Training School for Nurses, will be the Superintendent of the Hospital.

WINNIPEG GENERAL HOSPITAL.—At a meeting held March 11, the attending medical staff of last year was re-appointed for the ensuing year, viz:

For the general wards—Doctors R. J. Blanchard, Jas. Patterson, J. R. Jones, H. H. Chown, H. A. Higginson and J. S. Gray.

For the isolated wards—Doctors W. J. Neilson and N. B. Gillies.

For the maternity wards—Doctors A. J. McDonnell and R. M. Simpson.

Specialist for diseases of the eye, ear and throat—Doctor J. W. Good.

A communication was received from the attending medical staff with reference to the terms and conditions on which patients should be received into the private wards of the Hospital. A committee of the Board was appointed to meet and confer with the medical staff in reference to this matter.

THE FIRST HOSPITAL CAR.—The Central Railroad of New Jersey has just fitted out and put into service the first hospital car in the history of railroading. It was turned out of the Ashley shops a few days and is now stationed at Mauch Chunk, Pa., ready for use. It is divided into two compartments, both of which are fitted up for hospital use. There are cots for the patients, seats, a good supply of medicines and lintels and other necessary articles for the care of the injured. The car is painted a light cream on the interior, and is made bright and cheerful. Maimed and injured patients can now be tenderly cared for, and rest as well as at home. The car was constructed at the suggestion of Mrs. Dr. Erwin of Mauch Chunk.

KANSAS STATE BOARD OF HEALTH.—Dr. H. W. Roby of Topeka, (Homeop.) has been appointed a member of the Kansas State Board of Health to succeed Dr. J. P. Stewart.

BOARD OF HEALTH OF MANITOBA.—The following appointments have been made to constitute the Provincial Board of Health as re-organized at the last session of the House; James Patterson, M.D., Winnipeg; John Mackie, M.D., Portage la Prairie; Alex. Flemming, M.D., Brandon; George Riddell, M.D., Crystal City; S. J. Thompson, V. S., provincial veterinarian. Dr. Patterson has been selected Chairman. The first four gentlemen are also the District Inspectors for the province. E. M. Wood has been appointed Secretary of the Board.

A Mexican Pest House.—Five American sailors have returned to this city, after an experience in a Mexican pest house that has convinced them, at least, that the Mexican quarantine officials have much to learn of sanitary regulations, as well as of the laws of humanity.

Isolated for eight days, deprived not only of liberty but of food, drink and medical attendance, to say nothing of comfort, it was fortunate that these mariners had no serious illness, otherwise the mistaken vigilance of the Mexican health officials and the indifference of the steamship company's agents might have been responsible for their deaths from exposure. The steamship *Vigilancia*, of the New York and Cuba Mail Steamship Company, more generally known as the Ward line, on February 3 last left her pier at the foot of Wall Street bound for Vera Cruz, Mexico. The *Vigilancia* had formerly been in the Rio trade, and this was her first voyage to the Mexican ports.

Shortly after the *Vigilancia* sailed, some sort of skin disease broke out among the crew and became general. It was merely an annoying rash, and is attributed to the bad condition of the bedding. Among the crew of the steamer was Albert C. Barrett of 170 East Seventy-sixth Street, who was rated on the ship's books as electrician and ice engineer. He related his experience to a reporter as follows:

"Not one of the Ward line steamers," said Mr. Barrett, "carries a doctor. They only have medicine chests, and when any of the crew is sick one of the officers prepares a dose from the chest. When this skin disease broke out, there was no one to attend to the men. When we anchored at Progreso, Mexico, on the morning of February 10, about forty men were suffering slightly with this complaint, and when the Mexican quarantine officers boarded the *Vigilancia* they were greatly scared at the thought of smallpox. The ship was quarantined for twenty-four hours, and the captain was very anxious to get away. It was finally arranged to send ashore five men as sick, and then give the ship a clean bill of health. Men were selected who could best be spared. I was one, and the others were E. T. Stilling, William Hamm, R. Caccia, cadets, and Patrick Coyle, oiler.

"We were landed on the beach over a mile from the city, and escorted to an old, tumble-down, adobe hut, with a leaky and dilapidated roof, and without doors. Here we were met by an individual who informed us in broken English that he was the Chief of Police, and that we were not to be allowed to leave the hut under any circumstances. He then left us in charge of two policemen, armed with sabres and revolvers.

"For twenty-six hours we remained in this hovel without food or water or bedding of any kind, and our repeated requests to be allowed to go to the city to see the United States Consul were refused by the guards. On the second night Coyle and myself stole away and reached Progreso without detection, and sought Mr. John Waddle, the acting United States Consular Agent. Mr. Waddle is the English Consul also, and befriended us in every way possible. He told us he could not visit our quarters without the consent of the Mexican authorities. He promised to attend to our case and we returned to the hut.

"We sent an appeal to the United States Consul and got a few things in return. We were kept in the pest-hole until February 18. Mr. Waddle saw that we were properly cared for, and February 28 we got away on our own ship, which had returned. But for the efforts of Mr. Davis and Mr. Waddle we might still be in that awful place."—*New York World*.

THE PUBLIC SERVICES.

Examinations U. S. Army Medical Corps.—In view of the possibility of the reduction of the Medical Corps of the Army from one hundred and twenty-five to ninety Assistant Surgeons, by action of Congress at its present session, and to save possible loss of time and expense to candidates if such action be taken, the examinations appointed for March and April, 1894, will, by order of the Secretary of War, not be held until further notice.

It is probable that if the Corps should not be reduced, the Examining Board will be convened in the fall of 1894. Of this, notice as early as possible will be given.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from March 18, 1894, to March 28, 1894.

Major HENRY M. CRONKHITE, Surgeon U. S. A., is relieved from duty at Ft. Clark, Texas, and ordered to report in person to the commanding officer, Ft. Reno, Oklahoma Ter., for duty at that post, relieving Capt. WILLIAM C. GORGAS, Asst. Surgeon. Capt. GORGAS, on being thus relieved, will report in person to the commanding officer, Ft. Barancas, Fla., for duty at that post, relieving First Lieut. ROBERT S. WOODSON, Asst. Surgeon. First Lieut. ROBERT S. WOODSON, Asst. Surgeon, on being relieved by Capt. GORGAS, will report in person to the commanding officer, Ft. McIntosh, Texas, for duty at that post-

and for field duty in the Dept. of Texas, relieving First Lieut. BENJA. MIN L. TEN EYCK, Asst. Surgeon. Lieut. TEN EYCK, on being thus relieved, will report to the commanding officer, Ft. Clark, Texas, for temporary duty at that post.

First Lieut. HAARLAN E. McVAY, Asst. Surgeon, so much of par. 8, S. O. 60, from A. G. O., March 12, 1894, as relates to him, is amended to direct him, on being relieved from duty at San Carlos, Ariz., by First Lieut. STRAUB, Asst. Surgeon, to report in person to the commanding officer, F. Huachuca, instead of Whipple Bks., Ariz.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending March 24, 1894.

Surgeon B. S. MACKIE, ordered to the U. S. R. S. "Franklin." P. A. Surgeon W. C. BRAISTED, from Naval Hospital, New York, and to the U. S. S. "Columbia."

P. A. Surgeon S. G. EVANS, from the Naval Hospital, Philadelphia, and to the Naval Hospital, New York.

Surgeon W. G. FARWELL, ordered to the U. S. S. "Columbia."

Marine Hospital Changes. Official list of changes of stations and duties of medical officers of the U. S. Marine Hospital Service, for the four weeks ended March 17, 1894.

Surgeon C. S. D. FESSENDEN, detailed as chairman of board for physical examination of Asst. Surgeon L. E. COFER, March 6, 1894.

Surgeon GEORGE PURVIANCE, detailed as chairman of board to inspect Reedy Island Quarantine, Feb. 20, 1894. To report at Bureau for temporary duty, March 2, 1894.

Surgeon W. H. H. HUTTON, detailed as chairman of board for physical examination of Inspector of Hulls, March 9, 1894.

Surgeon J. M. GASSAWAY, detailed as recorder of board for physical examination of Asst. Surgeon L. E. COFER, March 6, 1894.

Surgeon JOHN GODFREY, detailed as chairman of board for physical examination of candidate, Revenue Marine Service, March 6, 1894.

Surgeon FAIRFAX IRWIN, to proceed to Paris, France, for special duty, Feb. 24, 1894.

Surgeon F. H. MEAD, detailed as chairman of board for physical examination of candidates, Revenue Marine Service, March 10, 1894.

Surgeon H. K. CARTEB, to report at Bureau for special duty, March 14, 1894.

P. A. Surgeon C. E. BANKS, to proceed to Portsmouth, N. H., as Inspector, March 12, 1894.

P. A. Surgeon P. C. KALLOCH, granted leave of absence for thirty days, March 12, 1894.

P. A. Surgeon A. H. GLENNAN, detailed as member of board to inspect Reedy Island Quarantine, Feb. 20, 1894.

P. A. Surgeon EUGENE WASHIN, granted leave of absence for sixteen days, March 3, 1894.

P. A. Surgeon J. J. KINYOUN, to report to chairman of Committee on Ventilation and Acoustics, House of Representatives, for special duty, Feb. 21, 1894.

P. A. Surgeon R. M. WOODWARD, to report at Bureau for special duty, March 14, 1894.

P. A. Surgeon G. M. GUITERAS, granted leave of absence for twenty days, Feb. 19, 1894.

Asst. Surgeon W. G. STIMPSON, granted leave of absence for twenty-five days, March 5, 1894. Detailed as recorder of board for physical examination of Inspector of Hulls, March 9, 1894.

Asst. Surgeon E. R. HOUGHTON, ordered to examination for promotion, March 8, 1894.

Asst. Surgeon M. J. ROSENAU, ordered to examination for promotion, March 6, 1894.

Asst. Surgeon L. E. COFER, to report to board for physical examination, March 6, 1894. Placed on waiting orders, March 15, 1894.

Asst. Surgeon C. H. GARDNER, detailed as recorder of board for physical examination of candidates, Revenue Marine Service, March 10, 1894.

Asst. Surgeon W. J. S. STEWART, detailed as recorder of board for physical examination of candidates, Revenue Marine Service, March 10, 1894.

LECTURE.

OÖPHORECTOMY AND UTERINE CURETTAGE UPON THE SAME PATIENT—INTERSTI- TIAL SALPINGITIS—HEMATOMA OF THE OVARY, AND PELVIC PERI- TONITIS—DIAGNOSIS UN- DER ANESTHESIA.

A Clinical Lecture delivered at St. Luke's Hospital.

BY HENRY T. BYFORD, M.D.

CHICAGO.

PROFESSOR OF GYNECOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS; PRO-
FESSOR OF GYNECOLOGY, CHICAGO POST-GRADUATE MEDICAL SCHOOL;
PROFESSOR OF CLINICAL GYNECOLOGY, WOMAN'S MEDICAL
COLLEGE; GYNECOLOGIST TO ST. LUKE'S HOSPITAL;
SURGEON TO WOMAN'S HOSPITAL OF CHICAGO;
CONSULTING GYNECOLOGIST TO MICHAEL
REESE, CHARITY, CHICAGO, AND
PROVIDENT HOSPITALS.

Diagnosis:—The case represented by the patient now being anesthetized might, in the slang phraseology of the past decade, be called a "chestnut"—it is a case of oöphorectomy for diseased uterine appendages. We have lately had a case of oöphorectomy at almost every weekly gynecologic clinic. You might justly make the criticism that were I a man of parts I would ring a few changes in these cases, and do something for them besides eternally taking out the ovaries, more particularly since it is now the fashion to treat the endometrium and even to remove the uterus and let the diseased ovaries and tubes remain. Yet I expect to find something interesting and instructive even about this every-day case.

The young lady is a nulliparous grass widow 25 years old, who has made me promise to leave one ovary. She has been up and down with slight attacks of peritonitis for five months. She has been faithfully but unavailingly treated, and demands a cure. She has also a muco-purulent endometritis which, with other facts, suggests a possible gonorrhoeal origin. There is a profuse menorrhagia for a week of each month and a moderate metrorrhagia coming and going from one to two weeks thereafter.

I first proceed to curette the uterus. I find the cervix purplish and the internal os soft and dilatable to the slightest pressure of the blades of Goodell's dilator. The uterine walls are flabby and the mucous and submucous tissues infiltrated. The blades of the dilator being separated three-fourths of an inch I scrape out the softened mucous membrane until I can get no more, being careful not to injure the softened muscular tissue. Having washed out the uterine cavity with a 1-2000 solution of bichlorid of mercury, I swab it out with a 95 per cent. carbolic acid, and consider that we have relieved the uterus of its portion of the sepsis.

I disinfect my hands again, while the nurses are arranging the patient for an abdominal section.

A small low incision in the linea alba reveals some

frail adhesions of an almost normal ovary and tube on the right side, which I have broken up before lifting the parts to the surface for inspection. On the left side the omentum is firmly adherent to the horn of the uterus. The adhesions are recent, for the tissues are still blackish with unabsorbed minute extravasations of blood. This blackened appearance of the omentum does not denote rottenness, as many hasty observers are apt to infer. I tie it off only far enough to head off the oozing, and shall expect the tissues to present a normal appearance within a few weeks, as I have verified by secondary operations in other cases. The tube is the size of the finger and with its adhesions presents a typical case of an interstitial salpingitis. The ovary is the size of a small egg, and is embraced by the tube and so firmly adherent to the posterior surface of the broad ligament that I can separate it only with the greatest difficulty. I have walled off the intestines by sponges, for fear that pus may be present and that it might escape as the adherent tissues separate. The mass comes up without rupture, however, and I proceed to ligature the appendages as close to the uterus as possible, in order not to leave a septic focus at the uterine horn. The adhesions were not very old, the oozing is therefore mostly by capillary and is ceasing so rapidly that I can close the abdominal cavity without drainage.

We have now cleaned and disinfected the uterus, removed all of the remaining tissue that contained the septic material and "saved the other ovary and tube harmless" from all liability to infection.

An incision into the thickened and yellowish walls of the tube shows it to be filled with thickened mucous membrane and luxuriant vegetations, rather than pus and granulation tissue. The fimbriated end is contracted and apparently closed, although not firmly. Undoubtedly some fluid had escaped into the abdominal cavity, causing the inflammation and adhesion of the ovary. The uterine end admits a large probe and has allowed of drainage; and had it not been for the ovaritis and peritonitis, the patient might, after a long time, have recovered sufficiently without the peritoneal section. From the ovary I turn out an organized blood clot the size of a large English walnut. The ovarian stroma appears to be pretty well destroyed by interstitial inflammation.

This case illustrates in an interesting way the progress of gynecologic surgery. Ten years ago this progress was largely made up by the invention and perfection of new operations; during the past five years, however, quite a little of this advance towards perfection has been due to the combination of operations. Fifteen years ago we were taught not to perform trachelorrhaphy and perineorrhaphy at the same time, because hemorrhage might take place from the cervix, or the cervical stitches might become infected, and we could not then get at the

wound. Pretty soon, however, we began to perform both operations at one sitting, and before long added curetting and the ligature of hemorrhoids to them,—and now this combination (the so-called *big four*) is one of the common procedures in this clinic. Later, Alexander's operation was added to this combination, and still later abdominal section. Five or six years ago I was afraid to touch the endometrium when I opened the abdomen, and did not dare to open the abdomen immediately after curetting the uterus. But antisepsis has taught us that we can do all things in surgery. We now operate all over the patient, and her system does not seem to be at all inconvenienced by it.

In a month I will make a speculum examination in this case, and see to it that the cervix does not subsequently contract so as to prevent uterine drainage. If necessary I will dilate the cervix and apply disinfectants and alteratives to the endometrium until no trace of endometritis shall be left. If that is not enough I will again curette, for the only way to "save the other ovary harmless" is to cure the endometritis.

Our other patient, who is a virgin, 17 years old, has been sent to me with the supposition that she has serious pelvic trouble. Abdominal enlargement, iliac dullness, swelled feet, amenorrhea for a year, cough and palpitation, are the signs and symptoms reported. She is anemic, yet quite fleshy and hearty in appearance. By pressing over the pubes I bring the abdominal walls well down into the pelvis, and will press upward from the vagina and rectum, and thus bimanually palpate all that is in the pelvis. The vagina is small and does not allow of satisfactory palpation of the deeper parts. With two fingers in the rectum passed up behind the cul-de-sac of Douglas I penetrate, as it were, right into the pelvic peritoneal cavity and can feel everything. But I feel nothing worthy of note. The uterus is small and normal, the tubes feel like folds of membrane, the ovaries are a trifle large, but movable and evidently not seriously diseased. Instead of diagnosing the case I must undiagnose it. The abdominal enlargement was due to intestinal gas, the iliac dullness to feces in the sigmoid flexure, and the amenorrhea, swelled feet and palpitation to cardiac complications and anemia. We will turn the patient over to the medical department. The medical attendant will examine her heart, urinary secretions and other functions, inquire into the diseases of her infancy, etc., and will undoubtedly find something to do for her besides removing the ovaries.

When you go out to practice I hope that before sending in cases for gynecologic operations you will examine into general conditions, and not send patients suffering with mitral regurgitation or chronic nephritis to a gynecologist to run the risk of having their unoffending ovaries removed. Remember, also, that if it is necessary for me to give an anesthetic to clear up a diagnosis of pelvic trouble, that you yourselves might profit by adopting the same procedure.

DELAYED DELEGATION.—Dr. A. Jacobi, of New York, chairman of the American delegation to the Rome International Medical Congress, has telegraphed that his departure was delayed, and in consequence he and a number of other American physicians were unable to be present at the opening of the Congress. Dr. Jacobi added that he and his party expected to arrive in Rome before the final adjournment of the Congress.—*N. Y. Herald.*

POSTERIOR PROSTATO-CYSTOTOMY.

BY WILLIAM T. BELFIELD, M.D.

CHICAGO.

Of the various operations that have been practiced for reaching the bladder and prostate, only the median perineal and supra-pubic continue in general favor; and since the usefulness of the former is for anatomical reasons greatly restricted, the supra-pubic almost monopolizes the field.

The operation of Kraske for extirpation of the cancerous rectum has suggested to various surgeons a method for reaching important structures at the posterior surface of the bladder. Ullmann removed a tuberculous seminal vesicle; Dittel proposed and Küster executed the post-urethral excision of lateral masses of the enlarged prostate; Cabot suggested the extraction of ureteral calculi; and the present writer drained a suppurating prostatic utricle. As the result chiefly of anatomical studies, I now venture to call attention to an operation that may be described as *posterior prostates-cystotomy*.

The anesthetized patient is placed upon the left side, thighs flexed to a right angle, hips elevated eight inches or more, rectum empty and bladder moderately distended with air; a broad grooved staff is introduced. From a point midway between the tip of the coccyx and the right tuber ischii a superficial incision is carried forward, curving toward the raphé which it reaches one and a half inches in front of the anus. Guided by a finger in the rectum and the staff, blunt instruments carefully dissect the rectum from the membranous urethra, prostate and bladder-wall between the lower extremities of the vesicles. The rectum being held out of the way by a retractor (it would be desirable here to ligate on each side the prostatic venous plexus, if unusually large) the point of a knife is made to enter the groove of the staff exactly in the median line half an inch above, and is carried downward to a point the same distance below, the upper border of the prostate, dividing the trigone, the so-called "middle lobe" of the prostate, and the prostatic utricle, and terminating just above the orifices of the ejaculatory ducts. If required, the incision can be safely extended in the median line upward half an inch and downward through the thin commissure joining the lateral lobes of the prostate.

When the divided edges are drawn apart, the entire prostatic surface is accessible to eye and finger; the bladder can be drawn downward and the ureteral orifices exposed (on the cadaver). Complete suturing of the wound in bladder and prostate, while practicable, would probably be less desirable than partial suturing and drainage through the upper angle of the wound, which corresponds with the lowest point of the contracted bladder.¹

This incision seems to have two decided advantages over the supra-pubic: 1, perfect command of the entire prostate and base of bladder and; 2, perfect drainage and consequent reduction to a minimum of the dangers of urinary infiltration; it is also practicable in cases of contracted bladder to which the supra-pubic is not adapted. Incidentally it affords access to structures whose intimate clinical relations with bladder and prostate are becoming better understood—prostatic utricle, seminal vesicles and extremities of ureters; for reaching the fundus of the bladder, however, it seems inferior to the high incision.

The proper field of this operation must be shown by extensive clinical experience; I have used it in one case, removing a calculus and lateral masses of

¹ It might be found possible to introduce suitable catheters into the ureters and thus prevent contact of the urine with the wound; whether this difficult measure would have any practical advantage over the perfect low-level drainage afforded by the tube seems doubtful.

the enlarged prostate, the latter being far more accessible than I have ever found them through the supra-pubic incision. Complete healing followed in fifteen days.

A New Method for Drainage of the Bladder.—Perfect drainage of the bladder is obtained by a simpler incision along the same route: A tenotome is made to enter the perineum—blade horizontal—an inch or more in front of the anal margin, passed between prostate and rectum, and enters the bladder between the upper extremities of the prostatic lobes (it is well to have the bladder partly filled and its floor depressed by the beak of a sound); a slender forceps is carried along the blade into the bladder, the knife removed and the channel dilated by separation of the branches of the forceps for the introduction of the drainage tube. This incision opens and drains the prostatic utricle—which appears to be an important factor in prostatic cystitis from any cause. I have used this method of drainage in two cases with entire satisfaction. The perfection of such drainage was well shown in a third case, operated by Dr. Wishard, of Indianapolis, concerning which the writer was consulted. To prevent urinary contamination of a plastic operation for remedying a complete epispadias in a man 22 years old who had absolutely no vesical sphincter and consequently complete incontinence, a soft catheter was introduced through this incision. The bladder was kept so thoroughly empty that the flaps ingeniously made to cover the deep urethra healed by primary union.

THREE CASES OF CARCINOMA DEVELOPED ON LUPUS VULGARIS.

Read before the Chicago Pathological Society Feb. 13, 1894.

BY EMANUEL FRIEND, M.D.

CHICAGO.

CHIEF ATTENDING PHYSICIAN TO DEPARTMENT OF SKIN AND GENITO-URINARY DISEASES UNITED HEBREW CHARITY DISPENSARY; ATTENDING PHYSICIAN TO CENTRAL FREE DISPENSARY.

It is a well-known fact that when two or more ulcerating affections of the external skin of different etiologic relations, involve the same region, they often give rise to great difficulty in making a diagnosis.

Such cases, for instance, as the combination of syphilis and carcinoma reported by Lang and Doutrelepon; others again as lupus and carcinoma first reported by O. Weber in 1859, and following him came Esmark, Hebra, Lang and numerous others.

Having been afforded during my last year's stay in Vienna, of seeing at least three cases of carcinoma developed upon the site of lupus vulgaris of the face, I take the liberty of giving you a brief *résumé* of the scanty literature of the subject, and at the same time demonstrating a few histologic specimens relating to the subject. The one which I have at present under the microscope, having been used by Prof. Kaposi while lecturing on this subject last winter; the others I prepared since my return home.

Ziegler, *Allgemeine und Specielle Pathologische Anatomie*, page 465, under "Epithelial New Growths" states: "The epithelial hyperplasia may take place in the epidermis, as well as the epithelium of the sebaceous glands and the hair follicles, probably also the sweat glands."

In the epithelial papillæ of many of the cancers involving the skin, there are found lamellated nodules of horny epithelium, and in consequence they

have received the name of horn cancers. Occasionally calcification takes place in such cancers.

Page 466: "The epithelial cancers, that is those growing out from the *rête malphigii*, develop with preference at the junction of the external skin and the mucous membranes, on the lower lip, nose, eyelids, preputium, anus, external female genitals, etc. Sometimes they start from warts, cornu cutanæ, scars, pustules and ulcers, and arise not seldom upon the base of a lupus ulcer or scar."

Neisser, *Ziemssen Pathologie and Therapy*, Vol. xiv, page 606, in his "Differential Diagnosis" between lupus vulgaris and carcinoma, says, "one ought not to forget that complications of carcinoma and lupus occur, and in these cases owing to lack of resistance, in part, of the lupus tissue against the encroaching cancer papillæ, it is advisable to adopt early therapeutic measures."

Lesser, *Lehrbuch der Haut und geschlechts Krankheiten*, page 201, states: "Occasionally pathologic changes in tissue are the seat of epithelial carcinoma, which are in no way directly responsible for the origin of same, such as ulcers of foot, syphilitic ulcerations, lupus, etc."

The probabilities are that the pathologic epithelial proliferations in connection with the diminished resistance of the connective tissue are responsible for this atypical hyperplasia, the formation of cancer.

The technique of preparation of the specimens was as follows: The excised piece of tissue was hardened in alcohol, beginning at 60 per cent. and increasing gradually to absolute alcohol. Then put in equal parts of ether and alcohol for two or three days and, finally, from a thin solution of celloidin to a thicker one and then mounted and cut; the sections being about fifteen micromill. thick. Hamatoxylin and eosin used as stains. A number of sections I stained by both Ziehl and Kühne's method for tubercle bacilli with negative results, which did not surprise me, as you all know how rarely the bacillus is found in lupus tissue, possibly once in 90 or 100 sections; and on this very ground is largely based the argument for the non-tuberculous nature of lupus vulgaris, by a few of the leading dermatologists and pathologists of Europe.

Microscopic Picture.—Zeiss A. Ocular No. 3. One sees deep in the corium, isolated tissue masses called by Leloir, "Lupome." They lie irregularly and at different depths in the corium, while the upper and papillary layer, and *rête malphigii* appear normal; and at the same time one sees, below and interspersed in these so-called lupome nodules, are some round, others elliptical bodies, which have taken the eosin stain more readily than the surrounding tissue; the extreme vascularity of the part is very noticeable.

Zeiss E. Ocular 3, shows how well defined the borders of the lupus nodules are from the surrounding connective tissue; although slightly more irregular in their arrangement they are made up of the same constituents as the miliary tubercle, namely granulation tissue, epitheloid and giant cells. The main difference between the lupus nodule and the tubercle, being the retrograde metamorphosis which they undergo; while in the tubercle we get a typical cheesy degeneration in the lupus nodule we get more an atypical or fatty degeneration, while the interstitial connective tissue becomes hyperplastic and contracts.

The difference in the retrograde metamorphosis is said by some to be due to the vascularity of lupus in contra-distinction to the tubercle; while others again believe the relative number of tubercle bacilli responsible for the difference.

undergone a kerato-hyaline degeneration. These are undoubtedly epithelial nests; some cut diagonally, others cut square across.

In the three cases, which I saw in Prof. Kaposi's wards, the face was the seat of the affection; whether

The round and elliptical bodies previously mentioned are now seen to be made up of concentric layers of cells, with few nuclei, the whole or rather the more central parts with the appearance of having

or not this is the most common seat, I have been unable to determine, but judging from the fact that the face is the most common seat of lupus vulgaris, it would be plausible to consider the face as the most

common seat of this complication, with carcinoma. In conclusion, I wish to thank Prof. Paltauf, as well as Docent Riehl for their liberality in supplying me with material, as well as for the many other kind favors shown me during my studies in Vienna.

PRACTICAL POINTS IN TREATING DISEASES OF THE EYE, EAR, NOSE AND THROAT.

Read before the Dauphin County, Pennsylvania, Medical Society, March 6, 1894.

BY J. WALTER PARK, M.D.

HARRISBURG, PA.

OPHTHALMIC SURGEON TO THE HARRISBURG HOSPITAL, CHILDREN'S INDUSTRIAL HOME AND HOME OF THE FRIENDLESS; LATE CLINICAL ASSISTANT ROYAL LONDON OPHTHALMIC HOSPITAL, LONDON, ENGLAND.

The professional relationship existing between the general practitioner and the one who confines himself to special branches of medicine, is one of such a character that the constant interchanging of views upon practical points, gained by experience in the various branches of medicine, is of so much importance that I will endeavor to present for your consideration to-day, a few practical points, of such a character as will interest the general profession more than it will my esteemed colleagues, who limit their work the same as I do. We will consider them in the following order: 1, the eye; 2, the ear; 3, the nose; 4, the pharynx and larynx.

1. *The Eye.*—It is well that there should be some methodical way in examining a patient when he presents himself for examination; it is therefore your first duty to take a general view of the eyes to be examined, observing the movability of the eyeballs in their various meridians; to see with what freedom and to what extent he can move the various recti muscles in all directions, the condition of the eyelids, lachrymal puncta, ocular and palpebral conjunctivæ, the transparency of the cornea and the movability of the iris. In an inflamed eye always be sure to look for a foreign body, either in the cornea or under the lids; this can not well be done without the aid of a lens to concentrate the rays of light upon the parts to be examined by artificial light and an ophthalmoscope. The latter are often imperative to examine the movability of the iris. Occasionally you will find a short, inverted, white cilia on the upper or lower lid near the inner canthus, and seemingly protruding into the caruncle, which if removed will remedy the entire inflammatory condition. Next of importance to foreign bodies in the eye, is the movability of the pupillary border of the iris. Generally you will find a change in its color when any inflammatory condition exists, but quite frequently in the early stages this change has not taken place sufficiently to be visible to the eye, hence the necessity of depending entirely upon the contraction and dilatation of the pupil by artificial light concentrated upon the cornea, by the aid of which you can readily discern its movability. If immobile, or acting sluggishly, you should instill a mydriatic at once to cause dilatation and prevent adhesions of the iris to the anterior capsule of the lense, for once permanent adhesions form, your chances for good vision are very few indeed. To know when and how long to skilfully use a mydriatic, can only be acquired by a long and continued use of the same in diseases of the iris. A safe rule to be governed by in the use of atropin, is to never use it in adults over 40 years of age, except

in inflammatory diseases of the iris, and then carefully watch the tension of the eyeball for fear that much dreaded disease, glaucoma, may be brought on by its use. Use it sparingly and only long enough to keep your pupil dilated.

One of the most serious diseases of the eyes to which I can call your attention, is ophthalmia neonatorum. When called to see a case of this kind, or one simulating it, the first step taken in examining your case is the most important, that is to examine the child's eyes carefully so as to see the exact condition of the cornea. Do not be satisfied with merely trying to see its cornea, but be sure you do see it. Every physician should have a pair of small lid retractors, for without them you can not get a good view, on account of the severe blepharospasm, and the cornea always rolling up under the lids, out of sight. Thorough antiseptics in every particular is necessary. A detailed account of its treatment in this paper would consume too much of your time, but a few words as regards the use of atropin, I think, are necessary. Atropin should always be used if you have an ulcer in the center of the cornea, and eserine in its stead for the marginal ring ulcer. This ulcer often starts at the sclero-corneal junction, and in forty-eight hours has traversed the entire border of the cornea. The eserine contracts the pupil, and by its tension on the iris prevents prolapse into the perforating ulcer, while a *similar condition* is prevented, by *dilatation* of the pupil, when the ulcer is central. Phlyctenular keratitis, or the small and multiple ulcer of the cornea is another frequent disease of children, and one of the most common diseases of childhood. Photophobia, the almost constant and contracted condition of the eyelids, often a papular eruption around the eyes, and an acute or chronic rhinitis are its chief symptoms. Note this fact, that most cases are preceded by a running nose, or in other words, an acute or chronic rhinitis, bad sanitary condition of their habitations, an insufficiency of the proper kind of food; and that if you treat the nose, administer good food, the daily bath, etc., in conjunction with the treatment of the eyes; your patient will get well in half the time that is required if you only treat the eyes, and neglect the nasal complication.

If you only treat the eyes, and neglect the nose, you will generally have successive crops of phlyctenular ulcers return, and the result will be that you have your patients on your hands for a long time, and perhaps lose them, by their getting into other hands.

Atropin and yellow oxide of mercury are the best remedies for these cases. Boracic acid solution injected into the nostrils will generally remedy the rhinitis in children. Persistent treatment, however, must be enjoined upon the patients even after they are seemingly well. The general health, as well, must be attended to in all cases, as a rule.

2. *The Ear.*—Next of importance is the organ of hearing. Quite an advancement in the treatment of diseases of the ear has been made within the past five to ten years. The most satisfactory, however, has been the removal of the ossicles and tympanic membrane for chronic suppuration of the middle ear. Where there are no mastoid complications, eight out of every ten cases of from six months' to three years' standing, that have resisted all other forms of treatment, get well after this operation, if it

is well and properly done. The removal of the stapes is rarely required. Quite frequently, in old or chronic cases, there are no ossicles to be found, they having been entirely destroyed by suppurative processes. Where the hearing in suppurative cases is defective, about 50 per cent. of the cases are improved. Tinnitus aurium is also most always greatly relieved and generally entirely stopped.

I have lately been using Dr. Doench's middle ear apparatus for the purpose of applying medicated vapors in the middle ear for chronic catarrhal deafness, and find that when menthol vapor is thus introduced through the Eustachian catheter, I can invariably improve cases of from six months' to two years' standing, who hear the tick of an ordinary loud ticking watch at three inches, to fifteen and twenty inches by actual measurement. The tinnitus aurium is also almost entirely relieved in a majority of the cases. The operation for the removal of the ossicles is very simple, and usually does not confine your patient to bed over forty-eight hours, almost *always* unattended with any danger, and usually in four or five days is attending to business again. When you have a chronic, fetid suppurating ear, with tenderness over the mastoid process, there is generally mastoid complication, and the earlier you establish free drainage by either opening it up through the attic of the tympanic cavity, or the mastoid process, the sooner your patient will get well. Chronic suppurating ears, sooner or later, become dangerous to the patient, and contrary to the advice of some physicians, should not be encouraged, but stopped as soon as possible. In all acute and chronic suppurating ears, pyoktannin will often arrest the discharge quicker than boracic acid if it is always used in fresh solutions, not over three to five days old. I use it in 1 to 500 strength solutions, and find it to have a more *lasting effect* in the destruction of pus germs, than peroxid of hydrogen. Wherever there are unhealthy granulations, or symptoms of polypi, there is nothing so efficacious as the curette, followed by equal parts of iodoform and boracic acid blown into the ear twice daily. In all acute or chronic suppurating ears, never forget that in a *majority of the cases*, they originate from some acute or chronic pharyngeal or nasal inflammation, that they need watching, and in most instances treatment, before the ear complication will get well. Furuncle of the meatus is a very painful and often stubborn disease to treat. There is very frequently a tendency to recurrence, and my experience has been that a 40 grain to the ounce solution of menthol in olive oil, generally prevents the recurrence of a second one.

3. *The Nose.*—There is no doubt that the nose is one of the most abused organs of the human body. Its functions of breathing, smelling, warming and sifting the respiratory air from microorganisms previous to its entering the lungs is very frequently interfered with and imperfectly performed owing to the few *perfectly* formed noses, as well as the *few* which are not diseased in some manner. Always be sure to make a careful examination before expressing an opinion. In the so-called "mouth breathers," you will generally find one of the five following causes for this defect, viz: Hypertrophied tonsils, adenoid vegetations in the vault of the pharynx, hypertrophy of Luschka's tonsil, hypertrophy of the turbinated bodies, or nasal polypi. If either of these defects exist, the earlier you remedy the cause,

the sooner you relieve your patient, and save many complications which may arise by continuous delay. The relationship existing between aural and nasal diseases are such that I never think of examining the one without the other. Influenzas and catarrhal diseases of the nose and naso-pharynx are the causes of three-fourths of all aural diseases.

Stenosis of either nostril, when due to hypertrophied conditions of the turbinated bodies, to exostoses or enchondromas, should always be remedied by operative measures, for it is the only sure way to remedy such defects, restore the natural respiratory functions of the nose, and thereby save many laryngeal and pharyngeal complications which are sooner or later sure to occur. Thorough cleanliness of the nose and naso-pharynx, the early recognition and treatment of acute and chronic rhinitis, will generally prevent the hypertrophic conditions, as well as all the aural complications, of which there are so many. The early treatment of the hypertrophic form, generally prevents the atrophic variety, which so often follows if this is not done; and once this form is thoroughly established, prevention of its further progress is all that can be done in the way of treatment. To even remedy the stench that accompanies atrophic rhinitis requires the constant and close attention of the physician, as well as the patient. Of all the various cleansing lotions which I have tried, the boracic acid, sodium chlorid, acid carb. and water solution is the best. This should be used in all fetid catarrhal conditions, as well as acute and chronic rhinitis, by spraying the nose and naso-pharynx, both anteriorly through the nose and posteriorly through the mouth. Fluid petroleum, combined with the various antiseptics, are excellent for the prevention of crust formations, and to allay the stench in most all cases. My experience has been that the fluid petroleum for constant use is better adapted for the mucous membrane of the nose than albolene or benzoinol. The two latter, after long and continued use, seem to leave a dry condition of the mucous membrane, which the former does not do so much after its discontinued use. The fluid petroleum and its combinations should always be used after the cleansing lotion has been used. Nasal polypi should always be removed by the snare, and *not* twisted off as is so frequently done. After their removal the bases of each one should be thoroughly cauterized, and quite frequently you will not have any return of them; if not done, they will be sure to grow again.

Dull headaches and pains in the region of the frontal sinuses, especially when accompanied by dullness of the mental faculties, are generally caused by an extension of the inflammatory conditions in the nose to the frontal sinuses. By treating the nasal cavities and establishing free drainage through the ethmoid cells you remedy all the pains, and restore the stunted memory. I remember two cases of that nature, whose minds were bordering on insanity, entirely restored by relieving the pent up secretion in the frontal sinuses, caused by immense hypertrophies of the superior and inferior turbinated bodies. *Remember*, that a constant dull pain at the base of the nose, and a stunted memory are its chief symptoms. If you are not careful you will attribute this pain to some ocular trouble, when in fact it is entirely nasal. I have had cases referred to me quite frequently to treat the ocular trouble, when I found it nasal.

4. *Pharynx and Larynx.*—In examining the pharynx and larynx, considerable skill and dexterity in the manipulation of instruments is required, in order to see and examine the parts well. Practice alone, will bring about these results. There are plenty of ordinary cases which would never get into the hands of the specialist if you were to devote more time to skilfully handling the laryngoscope and post nasal mirrors. A chronic follicular disease of the tonsils, which is generally recognized by small, white, cheesy masses imbedded or protruding from the follicles of the tonsils, and which invariably taints the breath, is best remedied by puncturing each follicle with the galvano-cautery point. There is no other treatment so effectual as this. Where hemophilia exists, the treatment of hypertrophy of the tonsils is also best done by the galvano-cautery point. It is really dangerous to practice excision in such cases, while in others where no idiosyncrasy exists, it is the quickest, and equally as effective as the galvano-cautery point. In all so-called "mouth breathers," look for enlarged tonsils, and adenoid vegetations in the vault of the pharynx. Specific ulcers of the tonsils, arches of the palate or the walls of the pharynx, yield best to applications of chromic acid, in conjunction with your constitutional treatment.

I have used various cauterizing applications, but find none so efficacious as chromic acid. In acute and chronic pharyngitis a solution of from 20 to 60 grains to the ounce of nitrate of silver applied twice a week, for awhile, acts admirably. Do not be afraid to use strong solutions, for they are generally well borne, and you accomplish in a week's time what would otherwise require a month's treatment. In tubercular ulcerations of the pharynx and larynx, the application of the curette and lactic acid, when applied in the early stages of the disease, prolong the life of your patient materially, and in quite a number of cases the ulcerations will heal up, and when your patient dies it is generally by the lung complications, which exist in almost all of these cases.

Acute and chronic laryngitis are among our most frequent diseases of the larynx, and are generally concomitant with, or a sequela of, a severe influenza. In acute laryngitis, inhalations of hot steam impregnated with comp. tr. benzoin, eucalyptol and camphor, are very soothing to the inflamed parts, and promote resolution and free expectoration quicker than any other remedy I know. In all such cases, remember to keep the secretions open, especially free diaphoresis. After the stage of resolution has set in, expectorant treatment accompanied by inhalations of the vapor of terebene, eucalyptol, and camphor will soon get your patient well. You must also not forget to treat any existing laryngeal or nasal complications at the same time. Counter-irritants are generally condemned, but I have found them act very well in the majority of cases. Inhalations of menthol will ease the pain and dysphagia accompanying the acute stages, and should be used through a curved glass inhaler. In chronic laryngitis, I have obtained the best results from direct applications of nitrate of silver, mentholin oil, and creosote inhalations. The creosote should be used in hot water at a temperature of from 140 to 160 degrees. The aphonia which so often accompanies slight attacks of acute or subacute laryngitis, caused by a congested condition of the vocal cords, generally yield nicely to a 10 grain solution of alum or sulpho earbolate of zinc sprayed into the

larynx. All applications of whatever character must be prolonged, and applied regularly to get good results. In most pharyngeal and laryngeal diseases do not depend too much on your patients to carry out your instructions, for all those cases requiring direct applications to the diseased parts *must* be done by yourself. If you do not do it yourself, you will very often fail in accomplishing the good results you desire.

In the preceding remarks I have confined myself entirely to practical points, gained by personal experience, and have only touched upon those which I considered most important, and such as you meet in your daily routine of practice. If I have mentioned but one point which may in the future be of some service to you in relieving suffering humanity, I shall feel as though I have accomplished *some good*.

32 North Second Street.

THE PSYCHO-PHYSICAL RELATIONS OF MAN, CONSIDERED FROM THE STANDPOINT OF A PRACTITIONER OF MEDICINE.

Read before the Binghamton Academy of Medicine Oct. 19, 1893.

BY JOHN M. FARRINGTON, M.D.

BINGHAMTON, N.Y.

(Continued from page 450).

Excessive fright has often been productive of grave results, and in many instances, of sudden death. Among the grave diseases induced by fright are mentioned typhus, epilepsy and apoplexy. Fear excites especially enuresis, diarrhea and generally produces a relaxation of the sphincters of the mucous passages, causes abortion and predisposes to attacks of contagious and miasmatic disease, while it aggravates every disorder and often renders them fatal. We might, if time would permit, refer to many recorded cases of positive and even fatal illness being induced by the imagination only, but one instance or illustration must suffice. Lord Stanhope relates the following: "An English physician while walking with a friend and conversing with him upon the power of the imagination in its effect upon the health observed a robust and healthy laborer approaching; to prove to his friend the truth of his opinion he accosted the man and inquired after his health, to which he gave satisfactory answers, which seemed to excite much surprise to the physician, and the laborer was gravely and with a sort of affectionate interest told that he was certainly in a state of disease which required great care. The laborer immediately returned home and went to bed declaring that he was really ill. As soon as the physician learned the ill effects of his experiment he called on the man and apologized, assuring him that he was in perfect health, and that what he had previously said to him was merely to show the influence of the imagination. Nothing that he could urge was of any avail. The laborer persisted that he was very sick, refused to leave his bed and died in a few days."

But fear has been used with curative effect. Various imitative diseases have been arrested by the use of it. Boerhave tells us that he once had several patients with epileptiform convulsions from sympathy with a person who fell down before them in an epileptic fit. He was puzzled at first how to act, but reflecting that the attacks were produced by a mental impression, he resolved to try the effect of a still stronger impression to check them. He ordered, in the hearing of the patients, hot irons to be prepared

and applied to the first person who was seized with a convulsion. The consequence was that no more fits occurred afterward. Instances are recorded of a prompt cure of gout, asthma and hysteria being accomplished by sudden fright. Hildanus relates that a man disguised as a ghost took another laboring under severe gout, carried him down stairs and then left him. The terrified invalid quickly found his way up stairs and never afterward was troubled with gout. Violent agitation of the mind from indignation, vexation or mortification has a decided effect upon the organism. The former inducing at first an excitation of the circulation, while if protracted it has an undermining effect upon all the functions. While vexation and mortification induce an interference with the digestive function, nausea and vertigo. The effects of melancholy are strikingly exhibited in those who suffer from loneliness or from great misfortune; a general derangement and languid condition of the functions are produced, thus causing a wasting of the tissues. But the most obvious effect of a psychical cause is the sudden changing of the color of the hair from dark or gray to white induced by sudden fright or extreme grief. "It indicates," says one author, "an extreme sinking in the process of vegetation, because by the perishing of the vascular r te, nothing but the gray or white outer covering remains." Terror will cause the hair to stand on end. A state of mind or feeling continually acting upon the body will, usually, in the course of time induce a characteristic change or effect upon the individual's form, gait or expression. So marked are these effects we are continually making use of them to aid us in diagnosing the character and disposition of every person we meet. They are signs hung as it were about a man by nature, through the silent yet certain operations of the mind upon the organism.

On this influence of the thoughts affecting the features and the character of the expression rest, we believe, the science or art of physiognomy. A person who is ever absorbed in mathematical calculations will eventually have traced upon his features an expression indicative of his mind's pursuit. One constantly depressed in spirits will wear a "long face" as foreign to mirthfulness as warmth is to an iceberg; his features in time will become so fixed that he will ever exhibit a melancholic air, no matter how much his feelings may change. The lineaments of care are indelible. We might, did time permit, multiply instances of the same certain results, but it is unnecessary to dwell upon the illustrations to prove that which we every day may witness. We are ever making a practical application of the knowledge we have obtained by personal observation, by affixing a character to every face we meet, from the sharp visage of the miser, to the broad benevolent features of the philanthropist; from the bright and cheerful countenance of the contented man to the careworn features of one whose life has been a struggle with misfortune; from the empty expression of the thoughtless to the sedate and thoughtful brow of the philosopher.

The passions have a marked effect upon the functions, especially upon the secretions, rendering them greater or less in quantity and of an irritative or perverted character. Thus fits of anger in the mother are said to produce a very irritating milk, followed by griping in the infant and green stools, and Dr. Van Ammon relates the case of a woman who, while

furiously from excitement, put her child to the breast and by so doing caused its sudden death; it sank lifeless upon her bosom in a few moments. Rage is believed by many physiologists to be capable of generating a most virulent poison in the saliva. The effect of anger upon the physical system is most apparent. The violent tension of the muscles, and the disordered breathing, disturbing the free circulation of the blood causes it to be thrown back upon the heart and this organ labors with inordinate force to propel it onward. Hence a rupture of the heart or large blood vessels sometimes occurs in a fit of anger. John Hunter attributed the commencement of his heart disease to a fit of passion. Jealousy is thought to act upon the biliary secretion and no doubt does indirectly, by first inducing a disordered condition of the digestive function. A variety of colors, present in the different cachexia are attributed to the influence of the passions; thus we have "yellow envy, pale unhappy love and black insatiate hate." A frequent or intense fixation of the attention upon some tragic event described by another may induce the same excitement or agitation of the system as though the tragedy were really witnessed. The frequent imitation of the manifestations of certain passions, or the feigning of them may give rise to the real presence of the sensations they were intended to counterfeit. Thus actors have died upon the stage, and we once saw an actress brought home from a theatrical rehearsal at which she had swooned, and after her return to consciousness she remained for some time in a high state of nervous excitement and agitation.

Perception, as we have heretofore noticed, comes originally from the senses; from the latter as from a starting point or alphabet do the thoughts and fancy branch out, as it were, and incessantly form new data and increased sources of thought, of imagination and perception, which also are subject to corporeal conditions. Should the senses be unduly exercised, the organs thus overworked become weakened and injured, and through them the whole system suffers. The strain produces an over excitement and perhaps a degree of inflammation of the organs involved, followed by disturbance of the general system. Too little employment of the senses, by not assisting the vital process of innervation, occasions a state of general weakness and imbecility. Excess of imagination produces the same result as a strain upon the senses only in a higher degree. It causes an excitement which is followed by a corresponding depression of all the functions of somatic life. Too little exercise of the imagination, like too little use of the senses, induces a low state of the general system and of innervation. The same may be said of the redundant or inadequate exercise of the thinking powers. Thought has an influence over the vital processes, because of the use it makes of the vital power in its operations and manifestations; its excessive action interferes with the organic functions by abstracting too much of the vital power from the bodily organs, which in consequence of this deprivation are unable to perform properly their functions. As thought impedes digestion so as before stated does digestion impede thought. This applies with special force to abstract or continued meditation after a meal, or a moderate intensity of thought with a "plenus venter." We have previously alluded to the influence that dyspepsia has upon the mental

condition; we will now notice how the latter may produce the former. It is a well-known fact that a large class of dyspeptics are individuals who are giving more or less attention to intellectual pursuits. Two reasons have been assigned why such persons are most subject to this disease:

1. Because of the sedentary habits which these pursuits or occupations usually involve.

2. On account of the well-known sympathy existing between the stomach and the brain.

Here, then, is an important point leading to therapeutics or the treatment of the disease in question. If dyspepsia has been induced through the operation of mental causes, the mind is the chief channel for the induction of remedies. The physician here must exercise tact to determine the cause of the functional derangement and then with a nice discrimination select the proper course of procedure to remove it. It is unfortunately too common for medical men to pay but little regard to the mental aberrations peculiar to this disease. To examine them with attention and, if possible, to afford relief, should be embraced within that philanthropy which ought to be inseparable from our profession. The medical adviser should recommend such stimuli to the patient's intellectual and moral powers as seem most demanded to excite a healthy influence upon the organism. Profound thought impedes the action of the senses. A person may be so buried in his own thoughts as to be, as it were, dead to surrounding stimuli, and utterly unconscious of what is passing about him; thus Archimedes at the storming of Syracuse, remained absorbed in thought, and thus do we observe results often extremely ludicrous from absence of mind; the mind being intent upon something abstract or remote, is not cognizant of corporeal acts. Maniacs in their ravings will often inflict ghastly wounds upon themselves without feeling them; the soldier, when comes the "tug of war," is unconscious of his wounds, and the brutal pugilist will bear a multitude of tremendous blows when in the ring but afterwards, when put to bed, becomes sorely conscious of his thumpings and bruises and gives way to groans of agony and exhibits the weakness of a child. The power of the prepared mind to resist impressions upon the body is a well-known fact. The most courageous man is a coward when taken by surprise, and the bold Indian who laughs at fear, will start like an antelope at a sudden sound.

This mental power over bodily pain is also an observed fact; let the mind be prepared for the occurrence and the body is as it were insensible to injury as a marble bust. This we have seen in the flagellation of proud-hearted school boys who received the blows from the pedagogue with perfect indifference, or, better still, in the operations at our hospitals, where enfeebled sufferers will sometimes endure a severe operation without a groan. The influence of attention upon the bodily organs has been carefully noted by many physicians. Dr. Brigham in his work on the brain, published in 1840, alluded to this subject. He asserts that he has seen tumors, ulcers and eruptive diseases increased and perpetuated by mental attention directed to the diseased part. In fact there is scarcely a disease but that may be aggravated by constant anxious thought in reference to it. But the important fact to draw from the phenomenon is that not only will mental attention aggravate disease but it will also relieve it. Kant

was able to forget by the strength of thought, the pain of gout and other diseases, and it is a well-observed fact that calling off the attention of the patient from his disease and fixing it intently upon other matters will have the effect of greatly relieving the suffering from a disordered organism. We see frequently, the effects of mental influence in preventing or removing the feeling of fatigue. Dr. Darwin happily illustrates this influence by reminding us of what we often witness in the child. Although heartily tired we have only to give the little fellow our walking stick; he straightway plants it between his legs and rides off as merry as a lark. The *modus operandi* of the mind in this case is explained as follows: A temporary energy is imparted by the mere effort of the will to the nervous system, and the immediate effect of this is to invigorate the exercise of the respiratory and circulatory systems on the state of which the feeling of fatigue so much depends. Many instances are on record where a complete cure has been effected by the influence of mental impressions. A humorous anecdote is related of Lord Chief Justice Holt which will illustrate the point under consideration: When a young man, Holt was a wild fellow full of jokes and humor. On one occasion, with some companions he stopped at an inn in the country where they contracted a debt of such an amount that they were unable to defray it. In this dilemma they appealed to Holt to get them out of the scrape. Holt observed that the innkeeper's daughter looked remarkably ill and was told by her father that she had the ague. Hereupon he gathered several plants and mixed them together with a great deal of ceremony, afterward wrapping them in a piece of parchment upon which he had scrawled certain letters and marks. He then hung the ball around the young woman's neck and the ague did not return. After this, Holt offered to discharge the bill, but the gratitude of the landlord refused any remuneration and the company left. When he became Lord Chief Justice a woman was brought before him accused of being a witch. She was the last person tried in England for witchcraft. She made no other defense than that she was in possession of a ball which infallibly cured ague. The ball was handed to the Judge who found it to be the very one which he had made years before to cure the landlord's daughter and to pay his own bill.

I presume every physician present might relate a parallel instance of cases that have come under his own observation, or that of some of his friends, where the mental attention alone upon physical ailments has wrought remarkable results. This influence is one of exceeding interest, for by it are we able to explain many phenomena otherwise inexplicable. To this is due the apparent success of the legions of charlatans who pose under many different titles such as Faith Curers, Christian Scientists, Spiritualists, etc., and perform such "miraculous cures." They impress the ignorant or superstitious with the fullest and most confident expectation of certain results taking place within their organism, and the power of mental attention thus directed often induces the anticipated result or some approximation to it. To our mind this is the true explanation of most of the phenomena produced by animal magnetism. The subject must be one of nervous temperament or one who has confidence in the power of the manipulator to induce the mesmeric state or hypnotism,

else the operator fails. This power of expectant attention is one that might be used with advantage by physicians in the treatment of disease, and not be left in the hands of the ignorant and the knavish to prey upon and delude those whose ignorance or superstition render them fit victims for this class of mountebanks. We all have recognized the effect of expectant attention in some subjects over the action of medicine, so that it is the custom of many physicians to tell the patient what result is expected from the remedy administered. We have read of instances where emesis, purgation, diuresis, etc., have been produced by bread pills, the respective patients having been told in advance that the medicine would operate thus. The power of expectant attention will induce phenomena without the subject being aware of any voluntary effort to cause their production. It is to us a source of satisfaction to know the power that produces the otherwise mysterious phenomena, yet in what manner that influence operates upon the corporeal system we can not tell. It is but another of the manifestations of the psycho-physical relations of man; it is a proximate fact, and we can not as yet go further. We have previously in this paper referred to the influence of the passions upon the secretions, but there are other mental states that affect the action of the secretory glands, e. g., the thought of a luscious fruit or of food may be sufficient to excite an abundant flow of saliva; the maternal affection of the mother for her babe induces a prompt and copious flow of milk at the time of nursing, and excessive feelings of joy or sorrow excite a flow of tears. Having thus briefly considered some of the psycho-physical relations, it remains for us to make the same remark which we previously did in reference to the physico-physical relations, to-wit: That they do not manifest themselves alike in all individuals. They exhibit themselves most in tender and pliable nervous systems. Sex, age and education all have an influence. The woman, the child and the prematurely developed are the best subjects for their manifestations. Premature development and premature education are the causes of a train of both mental and physical diseases. As the relations of the mind and the body are affected by too early development of the one and the too early culture of the other, so will they be affected by retarded development of the body and delayed training of the mind. Likewise will these relations be disturbed and abnormal where culture of the mind or exercise of the body or both be inordinate or excessive, or if either or both be neglected.

Here enter the principles of hygienics, and we are led to appreciate the influence of study and exercise or their opposite, indolence, upon the health of the individual.

As before observed we are the subjects of a higher and lower existence—spiritual and animal; two systems of perceptive faculties, one of the body, the other of the mind. As we have seen a reciprocal relation exists between them, and our highest happiness in this life will be to so develop the one by exercise and the other by culture as to produce the most perfect state of the intellectual and moral powers that the corporeal frame will permit, without injury to itself, either by inducing disease or shortening life. Harmony of the development of the body and mind is essential to harmony of their

mutual relations. It is a matter of deep regret and humiliating to our civilization to witness the unequal development of these two systems in the inhabitants of our country. While some overtax the mind, others overwork the body. How sadly the physico-psychical relations are ignored, not only by many parents and teachers in the education of the child, but by adults in their own conduct. The body is left to care for itself while the mind is spurred on as long as the poor, pale mortal frame can endure the strain, when death comes to claim the victim of a parent's folly and to lessen the number of the sickly "pale faces" of the nineteenth century. Surely we have well earned the title which the Indians gave to our forefathers.

"If the mind be overworked by excessive culture, while Nature is engaged in perfecting the body, the demand upon the energies of the system is too great; the one becomes exhausted, while the other is stunted of its fair proportions and dies." We are not, however, one of those who consider that studious habits and intellectual pursuits tend necessarily to injure the health or abbreviate the term of life—that mental labors are ever prosecuted at the expense of the body and must consequently hasten its decay. Such a result need not occur if attention be given to the welfare of the corporeal system and the mind be not exerted to an injudicious and excessive extent. We have numerous instances of men who have attained great intellectual prominence, and distinguished themselves by the profundity and multiplicity of their mental achievements who by temperate habits and systematic exercise have enjoyed firm health and attained a protracted existence, of which number Wm. E. Gladstone furnishes us to-day a notable example. Yet the inclination of ambitious and intellectual minds is to carry their mental labors to an inordinate and injudicious extent, so that those who possess the highest powers of mind seldom attain great age. Sinclair, in his "Code of Health and Longevity," states that in the long list of persons who had lived above a century there is but one individual, Fontanelle (who lived to within a few days of 100 years) at all distinguished for his intellectual powers, while there are above 1,700 others remarkable for little else than the number of their years. A well-developed and properly exercised body is especially adapted for the proper performance of the mental functions; at the same time a mind duly occupied is essential to the highest enjoyment of health. Great advantage accrues from varying the kind of mental exercise so that the mind does not become wearied with any subject and thus render its further pursuit irksome. To what extent the mind may be exercised without an ill effect upon the body is a question difficult of solution, and each individual must estimate this point as well as he can from his own experience. We have thought very much upon this topic, especially during our student life, and wished that we were able to draw the proper estimate of physical and mental exercise so as to secure harmony of the relations existing between the body and mind and thus obtain the most perfect development of the one, with the highest possible culture of the other. We can most feelingly quote Baron Von Swieten (1776) on this subject who says: "There is no state on all sides happy; for of all men, those who give themselves up to the study of wisdom might live the most happy if they were not obnoxious to disease from

that very cause. Happy are they who can so conduct the healthy exercise of the body together with the improvement of the mind!"

"Tis the great art of life to manage well
The restless mind."

"At no time," remarks Dr. Bell, of Philadelphia, "before or since, has the salutary union between mental and bodily exercise been so fully recognized as in ancient Greece and Rome, where the gymnasia and baths were resorted to alike by the philosopher, and the soldier, the youthful aspirant for fame and the staid citizen. Often the same person might be seen passing from the instructions of the professed athlete to the lessons of the sages and orators in the lyceum and the academy; thus while they secured to themselves health and bodily vigor, which should enhance their personal enjoyments and civic usefulness as defenders of the state, they acquired also those accomplishments that give virtue and dignity to the individual, and by reflection to his country and his age. However much we may choose to overlook this connection between mental and bodily purity and health, it is not less a portion of natural law; and if true of the one is equally so of the many, and if true in private it is *à futuri*, more valid still in public hygiene. When the historian speaks of fermentation among the masses, the poor, the dissolute and the reckless in a city or state, his language is scarcely figurative and he may very appropriately add that this tendency to outbreak and disorder is kept up, if it be not in a great degree produced, by physical deterioration and taint; by impure air causing bad blood and disordered brain; added to filth and bad food continually irritating the nervous system and giving rise to a host of abnormal sensations. It is no straining in causation to say that sickness or disorder in the body politic is often the manifestation, as it is the effect, of a neglect of public hygiene. So, also, beyond all doubt, have nations been driven into war, with its ever attendant horrors and atrocities, owing to the dyspeptic condition or splenic humors of princes and ministers of state."

We have already given many illustrations of the influence of the interior life upon the body, and though we may be charged with repetition we can not close our remarks on this influence better than in the words of Newnham: "Witness the suffusion of the countenance in blushing; the shrunk features and the pale gooskin produced by alarm; the chattering of the teeth under fear; the increase of various secretions under mental emotions, as of the tears in sorrow or the bile in anger; the palpitation of the heart under almost every sudden emotion; the short and quickened breathing of expectation; the oppressed and stifled respiration of intense and harrowing emotion; the arrested and almost imperceptible action of breathless anxiety and expectancy; the influence upon the muscles of expression of the countenance, alternately lighted up with joy or worn with anxiety and suffering, and the thousand varied emotions which they are capable of expressing; the plump portliness of the man at ease and the extreme thinness of the victim of deep disappointment, or of any long continued devouring passion; so that to be dried by grief, to be devoured by remorse, to be consumed by sorrow are not only common expressions but literal representations of actual bodily conditions."

We have yet to speak of the psycho-physical relations in the solemn moment of death. The phenomena which occur differ with different individuals, depending as they do upon the direct cause of, and the parts or organs which are first affected by death. Bichât has stated that death commences from the heart, the lungs or the brain. In the first case, the psychical functions would be the latest and slowest in ceasing their manifestations. In the second case, the functions of the brain are early impeded and the mind would the more quickly cease to manifest itself, while in the third case the nervous center being primarily affected, a cessation of mental manifestations are the first to occur, consciousness being lost several hours before somatic death occurs. Of the senses, observation proves that hearing is the last to expire. Again, the mental operations at the hour of death vary in different individuals, seeming often to partake of the quality of those that were most prominent during life and often as has been remarked, "the ruling passion is strong in death."

But however much these relations of body and mind may be modified in the solemn hour of death, here our investigation must cease; the subject of them no longer exists; the relations are sundered; the body is no longer sensible to the excitement of the mind and our eyes are veiled from the spirit's departure, and we are to seek further knowledge of its relations elsewhere than in this life. "If no mortal lifts the veil we must seek to be immortal."²

We have thus far considered our subject sufficiently, we trust, to prove it not only to be one of profound interest to every thoughtful individual, but of much practical importance to the physician. By a knowledge of these relations he may frequently be greatly aided, not only in making a correct diagnosis, but fitted for a more successful treatment of disease. From physical signs he may determine psychical causes and from psychical may infer somewhat of somatic. Though a single sign may be of little import taken alone, yet if it coincides with others it is often of great value in determining the character of a disease. Constitutions differ so materially that we can not mark out an invariable law that will govern all cases, but can only make an approximation in our description of what may be expected from certain psychical or somatic conditions. In lively active individuals we may expect a replete and brisk action of the vessels, while in phlegmatic persons the contrary conditions will be present. Intense anxiety and melancholy will indicate, with other symptoms, organic disease of the heart or large vessels: Thus we might present a long list of psychical or physical signs which are of special interest to the medical practitioner but our limits forbid. The physiognomy of the human countenance in sickness is an open book to the medical attendant; to his eye is presented a mirror of many morbid conditions as the countenance changes with the varying stages of the malady, assuming every shade of expression from that indicative of trifling functional derangement, to that which characterizes grave disease. The positions that we have taken we do not assume or affirm

² Origin of man and of life.—Gen. II, 7. "And the Lord God formed man of the dust of the ground, and breathed into his nostrils the breath of life; and man became a living soul."

The decree of punishment.—Gen. III, 19. "In the sweat of thy face shalt thou eat bread, till thou return unto the ground; for out of it wast thou taken; for dust thou art and unto dust shalt thou return."

Man's final separation of body and soul.—Ecc. XII, 7. "Then shall the dust return to the earth as it was; and the spirit shall return unto God who gave it."

to be immutable laws; they are but general principles founded upon the observation and experience of many writers.

Our paper has acquired great length, although we have only taken a very brief survey of this important subject. These facts we are to use as points collected for our study, test, and possibly modification, and also as nuclei around which we are to add others as our careful observation or experience shall enable us to do. And in our investigations we should remember, as Dr. Feuchtersleben has wisely remarked, that, "in all human research and endeavors, it is indispensably necessary carefully to avoid every partial mode of consideration, to hold fast every problem as an enlightening point of instruction; the radii are to be sought and traced everywhere to their origin, but that this process is most especially to be held sacred in our profession, which in every concrete instance presents a countless number of circumstances all equally worthy of attention to every one who has learned, not merely to spell, but to read the book of life." Would time permit we might next consider the changes in the psycho-physical relations which occur in the phenomena of somnambulism and delirium. It would also be interesting to sum up the diseases in which these relations specially depart from their normal action. Proceeding with our investigations into the pathology of the psycho-physical relations we would next consider the various forms of insanity and amentia, but this is a subject too extensive to allow us to examine at this time. As we have found many diseases to be more or less compound, neither purely somatic or purely psychical, but in which both body and mind are more or less involved, we at once appreciate how important a knowledge of the physiology, pathology and therapeutics of the psycho-physical relations are to the physician in the practice of his profession, especially in treating the various psychopathies. The psychological physician should possess in a high degree the quality of self-command, and must be able by his personal demeanor to obtain influence over the minds of others. He is to be the physician not only, but combine in his person the physician, remedy and vehicle. Remedies may be applied through the senses, especially sight and hearing. "Light acts as an excitant, twilight as a calmant; darkness according to circumstances acts as both. The positive colors act as stimulants, the negative as sedatives."

The mind may be excited by noise, soothed by silence, and cheered by harmony and melody. The effect of music is exceedingly pleasant in some cases. Bishop Beveridge makes the following observation descriptive of its effects upon him: "It calls in my spirit, composes my thoughts, delights my ear, recreates my mind, and so not only fits me for after business, but fills my heart at the present with pure and useful thoughts, so that when the music sounds the sweetest in my ears, truth commonly flows the clearest into my mind, and hence it is that I find my soul is become more harmonious by being accustomed so much to harmony." But an enthusiastic pursuit of the study of music has induced insanity, and it is said that mad musicians are the maddest of the mad.

Hope is a most important coefficient to the physician. He is often an observer of its guardian power in sustaining the victim during the ravages of dire disease. It is a power that every physician should avail himself of, if possible, though it should be used

wisely and with a strict adherence to truth, else the confidence that was reposed in him will be lost, and the confidence of the patient in his physician and the remedies employed are as essential to his recovery as hope itself, and even more so, for it can not be inspired if the power be wanting. The patient must not be deceived if his illness is to have a fatal termination. The rule being, "to speak the truth yet cheer the sufferer." The affections are to be acted upon; the physician should seek to obtain not only the respect but the affections of his patients by bestowing his with a warm and generous heart.

In closing my remarks upon the psycho-physical relations of man, I have to regret my inability to do justice to this most momentous subject. Yet I trust, however, that my feeble attempt to impress its importance has not been entirely unsuccessful. I have tried to illustrate these relations from a medical point of view, and to show that to no one is a true understanding of these relations more valuable and necessary than to the physician, while fortunately to him are presented the most ample opportunities for their study. Not a day passes but that he is called to witness illustrations of these reciprocal relations of mind and body. No age is exempt from their influence, no profession can fully hide them. A fit of indigestion or an aching tooth levels the philosopher with the common herd of mankind. All the passions, thoughts, and emotions are at work in a greater or less degree in modifying the physical condition; while every derangement of function or abnormal condition of the bodily organs is exerting an influence upon the mental state.

But the interest of the subject does not stop here. The fact of man's spiritual nature being involved in all his conditions, whether they be healthy or diseased, gives, as we have before stated, sublimity to our science. The accomplished physician has a *medecina mentis* as well as a *medecina corporis*. His mission is higher than that of a mere prescriber of the articles of the materia medica. To him, alone, does the province belong to treat the entire man. The body is not the only object of his care. Mind and matter are in man too intimately connected to be studied or treated apart. What more need be said of the ennobling influence of the study and practice of medicine? And what is there that gives it such an interest and moral grandeur, unless it be the Psycho-Physical Relation of Man!

CLINICAL HISTORY OF THE CASE OF PRESIDENT JAMES ABRAM GARFIELD.

BY ROBERT REYBURN, A.M., M.D.

PROFESSOR OF PHYSIOLOGY AND CLINICAL SURGERY MEDICAL DEPARTMENT HOWARD UNIVERSITY, WASHINGTON, D. C., AND ONE OF THE ATTENDING SURGEONS IN THE CASE OF PRESIDENT GARFIELD.

(Continued from page 417).

III.

July 24, 8 A.M. The President's skin is drenched with a profuse perspiration. His skin is cool, with a somewhat anxious expression of countenance. An examination of the wound was made by the consulting and attending surgeons, and a small pus sac was found about three inches from the external wound (in a downward direction). After consultation it was deemed advisable to make a counter opening three inches below the wound for the purpose of drainage.

The skin was sprayed with sulphuric ether to diminish the sensibility of the parts, and the opening was made by Dr. Agnew assisted by Dr. Hamilton. A large drainage tube was tied in communicating with both openings. The wound was then dressed, and he was given one ounce of Liebig's extract of beef, and afterwards three ounces of milk and one teaspoonful of rum.

July 24, 12 M. The President feels much more comfortable since the operation. His skin is much more natural in hue. He is still sweating profusely but there is no evidence of rigors. He has vomited once slightly this morning, but has taken and retained some nourishment.

July 24, 12 M. Temperature 99.8; pulse 118; respirations 24. July 24, 7 P.M. Temperature 99.2; pulse 104; respirations 23. July 24, 5 P.M. The President is much more comfortable to-day than yesterday. He has slept a good deal at intervals during the day, and has retained all the beef essence given. To-day Professors Bell and Newcomb came to the President's room with Mr. Tainter and demonstrated the use of the induction balance for discovering bullets in the human body. Professor Agnew returned to Philadelphia in the 5:40 P.M. train, but Professor Hamilton remained over during the night in Washington. July 24, 6 P.M. The wound was dressed, and thoroughly washed out with a weak solution of carbolic acid (one-fourth of 1 per cent). He received a hypodermatic injection of one-eighth of a grain of sulphate of morphia at 7 P.M., and slept tolerably well during the early part of the night. He vomited once at about 10:30 P.M. He took small quantities of beef juice and milk during the night. At 3:30 A.M. he had a profuse sweat. He was rubbed off with a solution of alum and then with alcohol.

July 25, 8 A.M. The President seems quite cheerful this morning, and takes his liquid food freely and with relish. He passed a comfortable night, and has had no rigor since yesterday. July 25, 8:39 A.M. Temperature 98.4; pulse 96; respirations 18. July 25, 12 M. Temperature 98.4; pulse 106; respirations 20. July 25, 7 P.M. Temperature 101.8; pulse 110; respirations 24. At 12 M. he took six grains of quinia (bisulphate) and at 3:30 P.M. he complained of feeling cold. Bottles of hot water were placed at his feet, and he was well rubbed. He vomited once, and after the vomiting he had a profuse sweat. He was quiet but did not take much nourishment during the day with the exception of beef essence. He had a hypodermatic injection of one-eighth of a grain of morphia at 7 P.M. He slept for an hour or two, and at 11:30 P.M. had another slight rigor. He complained of chilliness which was followed by fever and sweat during the night. Professor Agnew arrived at 12 (midnight). The President was somewhat restless during the night, and the fever which had subsided during the evening rose again about midnight, and continued until 3 A.M. after which it again subsided.

July 26, 8:30 A.M. Temperature 98.4; pulse 102; respirations 18. July 26, 12 M. Temperature 98.4; pulse 106; respirations 19. July 26, 7 P.M. Temperature 100.7; pulse 104; respirations 22. July 26, 8 A.M. The President is quiet and does not complain of pain.

July 26, 8 A.M. The wound was dressed, and Dr. Agnew enlarged the opening over the rib, and extracted therefrom a fragment of bone, which had been driven in by the bullet, and was lying loose in the inner

track of the wound. Some fragments of muscle and connective tissue were also removed. The largest piece of bone removed was about an inch in length. There were also small particles of bone taken out. The wound was well irrigated with the quarter per cent. solution of carbolic acid, and two drainage tubes were fastened in the lower wound, one entering the cavity, and one draining the lower opening of the wound. The President bore the operation remarkably well, and in fact his condition seemed much more comfortable after the dressing and operation than it was before.

July 26, 12 M. He took six grains of bisulphate of quinia. During the afternoon he had several good naps, and took liquid nourishment quite freely. At 3:39 P.M. the President had a slight sweat. 5:30 P.M. He was given six grains of bisulphate of quinia. 11 P.M. The President had his hypodermatic injection of one-quarter of a grain of sulphate of morphia at 7:30 P.M.; after a short time he went to sleep and slept until 11 P.M. when he awoke, and after a little while he went to sleep again, and slept soundly until 5 A.M.

July 27, 7:30 A.M. This morning he took beef essence, and four ounces of koumiss. July 27, 8 A.M. Temperature 98.4; pulse 94; respirations 18. July 27, 12:30 P.M. Temperature 98.4; pulse 90; respirations 18. July 27, 7 P.M. Temperature 98.8; pulse 96; respirations 20.

July 27, 8:30 A.M. The President's wound was dressed and looked well. There were no rigors nor febrile rise of temperature during the day. He took his liquid nourishment freely and without any apparent disorder of the stomach. He received his hypodermatic injection of one-fourth of a grain of sulphate of morphia at 7:40 P.M. and slept well during the night, sleeping at one time three hours without interruption.

July 28, 8 A.M. The President was very cheerful this morning, and seemed to feel comfortable. July 28, 8 A.M. Temperature 98.4; pulse 92; respirations 18. July 28, 12:30 P.M. Temperature 98.5; pulse 94; respirations 18. July 28, 7 P.M. Temperature 100.5; pulse 104; respirations 20.

Professor Hamilton was present at the morning dressing of the wound. During the morning the patient took bouillon, beef juice, milk, with an egg beaten up in it, and one teaspoonful of rum. At 10:18 A.M. he took six grains of bisulphate of quinia. During the morning the President's room was thoroughly aired and cleaned, and all the carpets and upholstered furniture were removed. He took a good deal of liquid food to-day, and had no febrile rise until 4 P.M. when he complained of feeling a little feverish. The wound was again dressed at 6 P.M. and the drainage tube being found to be obstructed was removed, and a larger tube inserted. At 7:40 P.M. he received a hypodermatic injection of one-eighth of a grain of sulphate of morphia, and went to sleep at 9 P.M. At 10:30 P.M. he complained of a sharp pain over the region of the bladder; this was relieved by hot fomentations and he went to sleep again at 11:30 P.M. At 11:30 P.M. his temperature was 99.8; pulse 98; respirations 19.

July 29, 7 A.M. The President slept well, and awoke feeling refreshed. The wound was dressed at 8:15 A.M. and was found to be in an excellent condition. He is still taking liquid food only, consisting of milk and egg with a little rum alternating with

koumiss and beef juice. July 29, 8:30 A.M. Temperature 98.4; pulse 92; respirations 18. July 29, 12:30 P.M. Temperature 98.4; pulse 98; respirations 19. July 29, 7 P.M. Temperature 100; pulse 98; respirations 20.

July 29, 8:30 A.M. Immediately after the evening dressing yesterday the President's afternoon fever began to subside. He bore the dressing of his wound well, and exhibited very little fatigue after its completion. 7 P.M. The President has been cheerful during the day. His wound was dressed the second time at 1:30 P.M. The febrile rise came on later and was not so marked as yesterday. He received his usual hypodermatic injection of one-eighth of a grain of sulphate of morphia about 8 P.M. and slept well during the night taking liquid nourishment at 1, 3 and 6 A.M.

July 30 8:30 A.M. The slight febrile rise of yesterday afternoon had subsided by midnight, and this morning his temperature is again normal. July 30, 8:30 A.M. Temperature 98.5; pulse 92; respirations 18. July 30, 1 P.M. Temperature 98.5; pulse 98; respirations 20. July 30, 7 P.M. Temperature 100.2; pulse 104; respirations 20.

July 30, 8:30 A.M. The President slept well until 8:40 A.M. His wound was then dressed, and found to be discharging freely. At 9:10 A.M. he took some rare beefsteak and scraped beef for breakfast, following this with six ounces of koumiss. At 10 A.M. he took six grains of bisulphate of quinia. During the day he received a good share of liquid food, had several naps, and expressed himself as feeling quite comfortable. A head rest elevating the upper portion of his body was placed under the mattress of his bed, by means of which his head and shoulders have been somewhat raised, and he expressed himself as much pleased by the change of position. The afternoon rise of temperature was moderate and did not commence until 5 P.M. Professor Agnew arrived to-day, and was present at the evening dressing along with Professor Hamilton. (Professor Hamilton has remained continuously on duty with the attending surgeons since July 27). A small drainage tube was passed farther into the cavity of the wound than heretofore, and the wound was thoroughly washed out with the quarter per cent. solution of carbolic acid. He received a hypodermatic injection of one-twelfth of a grain of sulphate of morphia, and went to sleep at 8:15 P.M.

July 31, 8:39 A.M. The President slept well during the night, and expressed a desire for solid food. After his wound was dressed he took a lamb chop for breakfast. Professor Hamilton returned to New York this morning while Professor Agnew remained in Washington. The afternoon fever of yesterday subsided earlier than the night before, and had quite disappeared by 10 P.M.

July 31, 8:30 A.M. Temperature 98.4; pulse 94; respirations 19. July 31, 12:30 P.M. Temperature 98.5; pulse 94; respirations 19. July 31, 7 P.M. Temperature 99; pulse 104; respirations 20.

The President bore the morning dressing of his wound well. He took and retained an ample supply of nourishment to-day, and seems to improve in his general condition. An enema was given him this afternoon. The wound looks well, and the secretion from it is quite abundant. The wound was dressed the second time at 6 P.M. At 7:30 P.M. he received his hypodermatic injection of one-twelfth of a grain of

sulphate of morphia, and slept well during the night.

August 1, 8 A.M. The President awoke quite refreshed this morning and said he had spent the best night since his injury. His wound was dressed at 8:35 A.M. and quite a free flow of pus came from it. After the dressing Professor A. G. Bell and Mr. Tainter tried for the second time the induction balance, for the purpose of endeavoring to locate the bullet in the President's body. This was an apparatus composed of a series of induction coils, so arranged that on being brought near a metallic body the electric balance would be disturbed, and a sound produced. Both Professor Bell and Mr. Tainter from these experiments located the ball in a space about two inches in diameter, somewhat to the right, and four and a half inches below the umbilicus. As will be seen hereafter this localization of the bullet was an error, and aided in confirming the erroneous diagnosis, which had been previously made by the consulting and attending surgeons as to the location of the bullet. The pus from the wound (though it was thoroughly washed out twice, and sometimes three times a day, and allowed free exit by means of drainage tubes) gradually formed a sinus or false passage in a downward direction from the wound. The transverse wound through the body of the first lumbar vertebra, from its irregular and rough character entirely prevented the passage of any probe in that direction; hence from all the means of information at our disposal, we were led to the belief that the bullet was located in the right side of the abdomen below the point of entrance. After the testing of the induction balance the President took some beefsteak, toast and gravy and a cup of coffee. At 11 A.M. he was given six grains of bisulphate of quinia, and this dose was repeated at 4:30 P.M. During the day the President seemed somewhat tired, and took several naps. He was given the usual amount of liquid food including koumiss. He complained during the afternoon that the koumiss had seemed to disagree with his stomach. Food was withheld from him for a short time with the effect of relieving him.

August 1, 8:30 A.M. After the slight rise of temperature yesterday afternoon it became normal early in the evening, and so continued during the greater part of the day. August 1, 8:30 A.M. Temperature 98.4; pulse 94; respirations 18. August 1, 12:30 P.M. Temperature 98.4; pulse 100; respirations 19. August 1, 7 P.M. Temperature 99.5; pulse 104; respirations 20. August 1, 7:45 P.M. He received one-eighth of a grain of sulphate of morphia hypodermatically, and slept well during the night.

August 2, A.M. The President slept well until 8 A.M., when his wound was dressed as usual. A new soft long catheter (No. 8) was passed into the opening of the eleventh rib, and passed downward into the abdominal cavity between three and one-half and four inches, and allowed to remain. Another drainage tube was put into the external lower wound (the one made by the incision) and both were kept in place by strips of adhesive plaster. Discharge of pus from wound was free.

August 2, 8:30 A.M. Temperature 98.4; pulse 94; respirations 18. August 2, 12:30 P.M. Temperature 98.4; pulse 99; respirations 19. August 2, 7 P.M. Temperature 100; pulse 104; respirations 20.

August 2. The President had an enema at 2:30 P.M. The wound was dressed at 6 P.M. and he complained of darting pains during the evening radiat-

ing from wound. The discharge from the wound was quite profuse. He had at 7:45 P.M. one-eighth of a grain of sulphate of morphia hypodermatically, and slept well during the night.

August 3, 8 A.M. The President passed a comfortable night and this morning the long, soft rubber tube was removed from the wound (it seeming to cause irritation), and a short, wide drainage tube was inserted in its place. Dilute solution of permanganate of potash was used to wash out the wound instead of the dilute solution of carbolic acid. The strength of the solution of permanganate used was eight grains to two pints of water at the temperature of 100 F. Professor Agnew (who had been on duty with the attending surgeons since July 30) returned to Philadelphia at 9:30 A.M. At 5:30 A.M. the President took six ounces of koumiss, at 7:30 four ounces of bouillon and two teaspoonfuls of beef juice, and at 9 A.M. six ounces of milk and two teaspoonfuls of rum. He went to sleep at 9:45 A.M. and slept until 10:45 A.M. when he took six grains of bisulphate of quinia, and the same dose at 5:40 P.M. At 11:30 A.M. he breakfasted and took a little steak, toast and potato. He passed a very comfortable day. The discharge from the wound was profuse and laudable in character. During the afternoon he had scarcely any pain, and his temperature remained normal until the evening, when it was one degree above. During the day he took a good supply of liquid food.

August 3, 8:30 A.M. Temperature 98.4; pulse 96; respirations 18. August 3, 12:39 P.M. Temperature 98.4; pulse 100; respirations 19. August 3, 7 P.M. Temperature 99.4; pulse 102; respirations 19.

He received his hypodermatic injection of one-sixteenth of a grain of sulphate of morphia at 8 P.M. and went to sleep at 9 P.M. He slept well during the night, waking at 3 A.M. for a short time. He then slept until 8 A.M. of August 4. Professor Hamilton arrived last night (August 3) and will remain until Professor Agnew returns. August 4. Wound was dressed at 8 A.M. The drainage tube was removed and a smaller tube inserted. Diet the same as yesterday. 12:30 P.M. He was given six grains of bisulphate of quinia. At 12 M. Professor Hamilton made a careful examination of the President, and found a small point of induration, one and a quarter inches to the left of anterior superior spinous of right ilium, and about the center of a line drawn from one anterior superior spinous process to the other. The President had an enema at 4 P.M. and at 6 P.M. he took six grains of bisulphate of quinia.

August 4, 8:30 A.M. Temperature 98.4; pulse 90; respirations 18. August 4, 7 P.M. Temperature 100.2; pulse 102; respirations 19.

The President passed a good day without drawbacks of any kind. He took his nourishment well, and has shown little fatigue after his dressings, and changes of position. The wound looks well. The President took a fair amount of liquid food during the day, and went to sleep at 9 P.M. and slept well during the night. He received no morphia at bedtime to-night.

August 5, 8:30 A.M. The President slept naturally during the greater part of the night, though he has taken no morphia for the past twenty-four hours. His improved condition warranted several days ago a diminution in the quantity of morphia administered hypodermatically at bedtime, and it was reduced at first to one-twelfth, and then to one-sixteenth

of a grain in the twenty-four hours without any unpleasant results, and finally has been altogether dispensed with. Yesterday and to-day only two bulletins have been issued, in place of three as heretofore. August 5, 8:30 A.M. Temperature 98.4; pulse 88; respirations 18. August 5, 7 P.M. Temperature 100.4; pulse 102; respirations 19. August 5, 6 A.M. He took seven ounces of koumiss. At 9:10 A.M. seven ounces of milk with two teaspoonfuls of rum. At 11:40 A.M. he breakfasted on toast, beef-steak and potatoes in small quantities. At 9:30 A.M. he was given six grains of bisulphate of quinia. At 12 M. he took four ounces of koumiss. At 1 P.M. he took six ounces of milk and two teaspoonfuls of rum. At 3:10 P.M. he had three and a half ounces of chicken jelly. At 5 P.M. he took beef juice and bouillon, and at 7:30 P.M. he took six ounces of milk and two teaspoonfuls of rum. Wound was dressed at 6 P.M. and the discharge was abundant. No hypodermatic injection of morphia was given this evening. The President did not get to sleep until after 9 P.M. and awoke at 11:15 P.M. for a short time and then slept through the night until 6:30 A.M. August 6.

August 6, 3 A.M. The President took three ounces of Valentine beef juice, and two and a half ounces of bouillon. At 7 A.M. he took six ounces of milk with two teaspoonfuls of rum. 8 A.M. Dressed the wound as usual. The cavity of the wound was measured and found to contain two ounces of fluid. To-day it was deemed best to suspend the administration of the bisulphate of quinia, and to give instead two teaspoonfuls of compound tincture of gentian three times a day. Claret was also directed to be given as a beverage. He took during the morning four ounces of the claret. Breakfast consisted of a small quantity of steak, toast and potatoes.

August 6, 8:30 A.M. Temperature 98.4; pulse 92; respirations 18. August 6, 12:30 P.M. Temperature 98.5; pulse 100; respirations 19.

The President passed a comfortable morning but towards the afternoon he complained very much of exhaustion from the excessive heat. The external temperature was such that it was found impossible to keep the temperature of his room below 90 degrees F. without closing the doors and windows, which was not thought prudent. During the day the President took a good deal of liquid, but scarcely any solid food. Towards the afternoon his febrile symptoms seemed to become more aggravated, and he was greatly exhausted by the evening dressing. No quinia was given to-day, and his tongue seemed to clear off. At 8 P.M. Professor Agnew arrived. At 10 P.M. the President took seven ounces of milk with three teaspoonfuls of rum. He soon afterwards went to sleep, and slept the greater part of the night.

August 7. From 1 to 5 A.M. the President had a slight febrile rise which passed off by 8 A.M. At that hour his temperature was 98.7. At 6 A.M. he took six ounces of koumiss, at 8:15 six ounces of milk, and two teaspoonfuls of rum. At 11 A.M. he breakfasted on a little steak, toast and potatoes. At 11:15 A.M. he had four ounces of koumiss. At 1 P.M. he had seven ounces of milk. At 3:20 P.M. he took four ounces of claret. The President complained so much of the compound tincture of gentian that it was stopped, and six grains of bisulphate of quinia given instead. The President complained to-day of slight chilliness, and of pain in the region of the wound and in the limbs.

August 7, 8:30 A.M. Temperature 98.7; pulse 96; respirations 18. August 7, 12 M. Temperature 100; pulse 104; respirations 20. August 7, 7 P.M. Temperature 101.2; pulse 104; respirations 20.

August 7. The President was fairly comfortable during the day, although his temperature began to rise earlier than yesterday, and rose almost as high. At the morning dressing it was found that the entrance of wound through the eleventh rib was apparently obstructed by the drainage tube with accumulation of pus in the cavity of the wound. At 6 P.M. the wound was dressed as usual. The drainage tube was temporarily removed, and the President was placed on his right side for the purpose of promoting drainage from the wound, for about an hour during the afternoon and evening. The President passed a quiet night, and slept well without the use of any anodyne. The rise of temperature of the afternoon subsided during the evening and did not recur at any time in the night.

(To be continued.)

Report of the Committee on Revision of Constitution, By-Laws and Code of Ethics of the American Medical Association, with Amendments.

To the President and Members of the American Medical Association:

Gentlemen: Your Committee, to which was committed the task of studying the Constitution and By-Laws of the AMERICAN MEDICAL ASSOCIATION, with a view of determining whether they could be changed in any manner so as better to promote the development of the Association, and better to advance the interests which it represents, have had the same under most careful consideration, and submit the following, which has already been published in the JOURNAL of the Association and other medical periodicals.

AMERICAN MEDICAL ASSOCIATION.

CONSTITUTION AND BY-LAWS.

HISTORY.

In May, 1846, a medical convention was held in the city of New York to consider measures for the elevation of the medical profession in all its constituent elements, and for the promotion of its organic unity. After much discussion this convention declared that a National organization of every State and interest was demanded. Committees were appointed to draft a Constitution, By-Laws and a Code of Ethics, and to report at a meeting to be held the following year. Accordingly, in May, 1847, representatives of the profession of the United States met in Philadelphia, heard and discussed reports of the committees, organized under the name of the AMERICAN MEDICAL ASSOCIATION, and adopted a Code of Ethics, a Constitution and By-laws, which, with slight alterations, have continued to direct the organized movements of the profession until the present time. In compliance with the instruction of the Association in June, 1892, the following Constitution and By-Laws, are formulated for the purpose of promoting the best activity of a general medical organization of the profession in North America:

CONSTITUTION.

Name.—This organization shall be known as THE AMERICAN MEDICAL ASSOCIATION.

MEMBERS.

Members.—Membership shall be limited to the members of the several affiliated State medical societies recognized thereby or represented therein. As membership in these societies is open to all reputable practitioners in each State, the membership in the AMERICAN MEDICAL ASSOCIATION is open to all reputable physicians in North America.

All persons now members of the Association shall continue such so long as they remain in good standing in their State society, and pay their annual dues. If they desire to participate in any annual meeting, they shall present to the Committee of Arrangements of said meeting a certificate from the officers of their State or local society to the effect that their standing is good, and one from the Treasurer of the Association showing that all dues are fully paid. To all presenting such certificates, the Committee of Arrangements shall issue the credentials necessary for active participation in the annual meeting.

All members of recognized State or local medical societies may become members of the Association by presenting to the Committee of Arrangements at any annual meeting a certificate from the officers of their society showing that they are in good standing therein, and a certificate from the Treasurer of this Association showing that they have paid their annual dues.

All members of the recognized State or local medical societies who are unable to attend the annual meeting may become members of the Association by sending to its Treasurer, at any time, a certificate from the officers of their society of their good standing, and remitting the annual dues.

All members who have fulfilled these two conditions shall have equal rights and equal responsibilities in the Association, and shall regularly receive the Association JOURNAL.

All State medical societies, with their constituent local societies, shall be recognized by the AMERICAN MEDICAL ASSOCIATION if they accept its Code of Ethics.

Members of Canadian and Mexican medical societies shall be admitted to membership upon the same terms as those in the United States. The regular graduates of such schools and colleges of dentistry as require of their students a standard of general education and a term of professional study equal to those of the best class of medical colleges in this country, and embrace in their curriculum all the fundamental branches of medicine, differing chiefly by submitting practical and clinical instruction in oral and dental surgery in place of practical and clinical instruction in general medicine and surgery, shall be recognized as members of the regular profession, and shall be eligible to membership upon the same terms as other members.

No persons shall be permitted to take part in any annual meeting until they have completed the conditions of membership at that meeting, and can exhibit certificates to this effect from the Committee of Arrangements. But suitable persons may be introduced as guests either at the general session or the Section sessions, and be invited to engage in the scientific and social exercises of the meeting without taking part in the transaction of business.

MEETINGS.

Meetings.—The regular meetings shall be held an-

nually at such time and place as may be advised by the Business Committee and ordered by the Association. The details of these meetings are stated in the By-Laws.

OFFICERS.

Officers.—The officers of this Association shall be a President, four Vice-Presidents, one Secretary, one Assistant Secretary, a Treasurer and a Librarian. These officers shall hold office during one year or until their successors are elected, and shall enter upon their duties immediately after election.

The President shall preside at the meetings, preserve order and decorum in debate, giving a casting vote when necessary, and perform all the other duties that custom and parliamentary usage may require. At the opening session he shall deliver an address to the general meeting, not to exceed thirty minutes in length.

The Vice-Presidents may be called upon to assist the President in the performance of his duties, and during his absence, or at the request of the President, one of them shall officiate in his place.

The Secretary shall record the minutes of the general sessions and authenticate the proceedings; give due notice of the time and place of the next annual meeting; notify all members of committees of their appointment and the duties assigned to them; hold correspondence with other organized medical societies, both domestic and foreign, and carefully preserve the archives and unpublished transactions of the Association.

For his personal expenses in attending the annual meetings the Secretary shall draw upon the Treasurer of the Association.

The Assistant Secretary shall aid in recording and authenticating the proceedings of the Association; serve as a member of the Committee of Arrangements, and perform all the duties of the Secretary temporarily, whenever that office shall be vacant by death, resignation or removal.

The Treasurer shall have the charge and management of the funds of the Association. He shall give the Board of Trustees bonds for the safe keeping and proper use and disposal of his trust. Through the same Board he shall present his accounts, duly authenticated, at each regular meeting. He shall each month furnish the President of the Board of Trustees with a statement of accounts for the guidance of the Board in its expenditures. For his personal expenses in attending the annual meetings, he shall draw upon the treasury through the President of the Board of Trustees.

The Librarian shall receive and preserve all property in books, pamphlets, journals and manuscripts presented to or acquired by the Association, record their titles in a book prepared for this purpose, and acknowledge the receipt of the same. He shall deposit these documents in such place and manner as the Association may direct, after advising with the Board of Trustees.

STANDING COMMITTEES.

The Committee of Arrangements shall be composed of at least seven members, of whom the Assistant Secretary shall be one, all residing in the place at which the Association is to hold its next annual meeting. It shall provide suitable accommodations for the meeting; shall verify and report upon the credentials of membership; shall issue credentials of

membership to such as fulfill the conditions; shall publish the rules governing the reading and discussion of papers and the order to be observed in the business of the general and sectional meetings; shall receive and announce all papers communicated, and, with the several Section Secretaries determine the order in which the papers shall be read and discussed; shall prepare a list of members present on a separate roll for convenience in calling the ayes and nays, when these are demanded; and shall cause all members to register their names, residences and temporary addresses during the annual meeting, and the name of the Section in which they will severally vote for Section officers. The expenses of a hall for the general meeting, of rooms for the Sections, and of cards of membership, shall be met by the Association. Should the Committee incur other expenses, it must meet them from its own resources.

This Committee shall be nominated by the Business Committee, and elected by the Association.

The Board of Trustees shall consist of nine members, three of whom shall be elected annually on nomination of the Business Committee, and serve for three years. This Board shall manage all matters relating to finance and publication. It must provide for and superintend the publication and distribution of all such proceedings of the Association as may be ordered to be published, in such manner as the Association may direct. In doing this it shall have authority to appoint an editor and such assistants as may be necessary, and to determine their salaries. It shall procure and control such materials as may be necessary for the performing of the duties assigned it. To the Board or its representatives must be delivered, during the annual meeting, or as soon thereafter as is possible, by the Secretary of the Association and by the Section Secretaries or Executive Committees, all records of meetings, papers or discussions, and such other documents as were ordered published by the Association.

All money received by the Board of Trustees or its agents, resulting from the discharge of the duties assigned them, must be paid to the Treasurer of the Association, and all orders for disbursements of money, in any way connected with the work of publication, must be indorsed by the President of the Board of Trustees. It shall further be the duty of the Board of Trustees to hold the official bond of the Treasurer for the faithful execution of his office; to annually audit and authenticate his accounts, and present a statement of the same to the Association. This report must specify the character and cost of all publications of the Association during the year; the number of copies still on hand, and the amount of all other property belonging to the Association, under its control, with such suggestions as it may deem necessary. It shall yearly publish a list of members, their addresses in full, year of admission, the Constitution and By-Laws and Code of Ethics, and such other information as may be deemed useful, for distribution to the members at each meeting.

At the opening of each volume it shall publish a disclaimer by the Association for any responsibility for opinions expressed in the volume.

To this Board must be referred all propositions for the appropriation of money, to be considered and reported upon before the final action on the same by the Association.

The General Business Committee shall be com-

posed of the several Section Executive Committees, selected as hereafter described. It shall hold daily meetings during the sessions of the Association, and such other meetings as may be deemed necessary for the performance of its duties. All matters of business not provided for by the Committee of Arrangements, the Board of Trustees, the Judicial Council and Special Committees, shall be referred to it without debate, for consideration and report to the Association. In general, this Business Committee shall give especial attention to the interests of the Association as a whole, and through these interests shall seek the development of the Sections; it shall consider all matters of business referred to it by the Association, and report upon them at the earliest possible moment, when the Association may accept or reject said report, as it may deem best.

It shall be the duty of this Committee to seek the removal of such obstacles as interfere with the cordial coöperation in the Association of all competent, honest practitioners of rational medicine throughout this continent, and to promote every means by which coöperation shall be effected and maintained.

The General Business Committee shall make and present the nominations for officers of the Association and its Standing Committees, and recommend the time and place of the ensuing meeting. It shall appoint its own officers, and adopt rules for the orderly performance of its duties. Finally, it is expected that it will perform all its duties in the interests of the advancement of scientific medicine.

The Judicial Council shall consist of twenty-one members, whose duty it shall be to take cognizance of and decide all questions of an ethical or judicial character which may arise in connection with the Association, and the Association will accept such decision as final.

Of the twenty-one members first appointed, the first seven named upon the list shall hold office one year, and the second seven two years. With these exceptions, the term of office of the members of the Judicial Council shall be three years, seven being nominated by the Business Committee yearly, and elected by the Association. The Council shall organize by choosing a President and Secretary, and shall keep a permanent record of its proceedings. The decisions of said Council shall be final upon all ethical questions referred to it by the Association, and must be accepted without debate. Such decisions shall be reported to the Association as soon as practicable.

All questions of a personal character, including complaints and protests, and all questions on the ethical standing of medical societies shall be referred at once, when presented to the Association, to the Judicial Council, and without debate.

INCOME AND EXPENSES.

The income of the Association shall be derived from subscriptions to its journal and advertisements therein, from specific publications and voluntary contributions for specific objects.

Its funds may be appropriated for the expenses of halls, for general sessions and Section meetings, and for cards of membership, and such other expenses of the annual meeting as are essential for the conduct of the routine work; for meeting the necessary personal expenses of the Secretary and Treasurer while attending the annual meetings and in conducting the neces-

sary correspondence; for publications; for enabling standing committees to fulfill their respective duties and conduct their correspondence; for the encouragement of scientific investigation by prizes, and for defraying the expenses of scientific investigation under the instruction of the Association, where such investigation has been accompanied with an order upon the Treasurer to supply the funds necessary for carrying it into effect.

AMENDMENT.

No amendment or alteration shall be made in any of these rules except at an annual meeting next subsequent to that at which such amendment or alteration may have been proposed, and then only by the voice of three-fourths of all the members present. Provided, however, that when an amendment is properly under consideration, and an amendment thereto is offered germane to the subject, it shall be in order, and if adopted, shall have the same standing and force as if proposed at the preceding meeting of the Association.

BY-LAWS.

1. *Order of Business.*—The order of business at the annual meetings of the AMERICAN MEDICAL ASSOCIATION shall be subject to the vote of three-fourths of all the members in attendance. Until thus altered, except when suspended, it shall be as follows:

1. Calling the meeting to order by the President.
2. The report of the Committee of Arrangements on the credentials of members, after the latter have registered their names and addresses; and on such other matters as it desires to present to the Association.
3. The reception of guests of the Association.
4. The annual address of the President.
5. The reception of reports from all special committees.
6. The reading and consideration of reports of standing committees, the Board of Trustees, Business Committee and Judicial Council.
7. New business and instructions to standing committees.
8. The report of the Business Committee and the election of officers of the Association; the selection of next place of meeting.
9. Reports from the Executive Committees of the Sections.
10. Reading of the minutes by the Secretary.
11. Unfinished and miscellaneous business.
12. Adjournment.

MEETINGS.

The Annual Meetings of the AMERICAN MEDICAL ASSOCIATION shall be held in May if the place be in the South, and in June if the place be in the North. The day of opening of the general sessions shall be the first Tuesday after the first Monday of the month selected. The hour of opening on the first day shall be 10 A.M., and on the following days 4:30 P.M.

SECTIONS.

The several Sections shall hold their first meeting at 1:30 P.M., on the first day, and at 9 A.M. and 1:30 P.M. thereafter daily.

The several Sections are as follows:

1. Practical Medicine and Physiology.
2. Obstetrics and Diseases of Women.
3. Surgery and Anatomy.
4. Orthopedic Surgery.

5. State Medicine.
6. Ophthalmology.
7. Diseases of Children.
8. Dental and Oral Surgery.
9. Medical Jurisprudence and Neurology.
10. Dermatology and Syphilis.
11. Laryngology and Otology.
12. Materia Medica and Pharmacy.

Officers of Sections.—The officers of each Section shall consist of a Chairman, Secretary and Executive Committee. The Chairman and Secretary shall be elected annually immediately after the Section is called to order on the afternoon of the second day. During the session of the first day, the Chairman shall appoint a Nominating Committee, consisting, if practicable, of ex-chairmen of the Section, to report at the opening of the afternoon session of the second day. Election shall be by ballot.

The Executive Committee of each Section shall, when first appointed, consist of three members from among those who have been in attendance at the sessions of the Section for at least two years, to serve for one, two and three years respectively; and thereafter the retiring Chairman of the Section shall take the place upon the committee of the retiring member. It shall be the duty of the Executive Committee, in conjunction with the Chairman and Secretary, to give special attention to the interests of their own Section. Thus they shall secure the annual republication from the JOURNAL of the work of the Section, its papers and discussions, list of officers, lists of all members of the Section, with their addresses, and rules adopted by the Section for the conduct of its work, securing from the Section the funds needful for the performance of this purpose. They shall carefully edit all publications of the Section, and secure a creditable mechanical execution of the same. They shall also take such measures as in their judgment will secure the cordial coöperation of all reputable workers in their special fields in North America.

The several Executive Committees of the Sections shall meet together and form a General Business Committee of the Association, with powers and duties described under the head of the General Business Committee.

The Chairman of each Section, in addition to his duties as a presiding officer and a member of the Executive Committee, shall read a short address at the opening of the session on the first day. In conjunction with the Secretary, he shall secure from members papers to be read, and arrange for the discussion of the same. This order of Section work he shall communicate to the Chairman of the Committee of Arrangements at least one month before the annual meeting.

No paper read before the Sections shall occupy more than twenty minutes. If it be longer, the writer should make such an abstract as will bring it within the limit, and present it for discussion. No person shall discuss any paper more than once, or speak longer than fifteen minutes without unanimous consent.

No paper shall be read before any Section that is not in such condition as to pass at once from the reader's hands to the Executive Committee of the Section. Within thirty days, said Committee must forward the entire work of the Section to the Board of Trustees, with such recommendations as it deems proper. But no paper shall thus be sent by an Exec-

utive Committee that does not fall under one of the following heads:

1. Such as may contain and establish new facts, new modes of practice or new principles of real value.

2. Such as may contain the results of well-devised original experimental research.

3. Such as present so complete a review of the facts on any particular subject as to enable the writer to deduce therefrom legitimate conclusions of importance.

Other papers containing material of more or less value shall be returned to their authors, to be published as they may desire, with the statement that they were read before said Section of the AMERICAN MEDICAL ASSOCIATION.

In general it is expected that each Executive Committee will make every effort to secure for its special Section, papers and discussions which will fairly represent the active workers in their department of medicine, and to promote cordial good will among the several workers therein.

PUBLICATION OF PAPERS AND REPORTS.

All papers and reports must be so prepared as to require no material alteration or addition at the hands of authors. All Section work must be in the hands of the Trustees within thirty days after the annual meeting. Proofs will be sent authors, but they should be returned at the earliest possible moment, and unless returned within two weeks, the paper may be omitted from the JOURNAL. Every paper requiring it shall be illustrated at the expense of the Association, should it accept the same for publication. Every paper accepted is understood to be contributed exclusively to the Association JOURNAL, though brief extracts of the same may be published elsewhere. In case of an article that is of especial value, the result of expensive research or experimentation, the Trustees, at their discretion, may compensate the writer in accord with the usual price of such work.

The Board of Trustees has the power to reject any paper referred to it, unless especially instructed to the contrary by the Association.

DUES.

Each member of the Association shall pay the annual subscription to the JOURNAL of five dollars before receiving from the Committee of Arrangements the membership ticket to the annual meeting. The evidence of this shall be the Treasurer's receipt for the five dollars. Any member failing for one year to pay this subscription shall be dropped from the rolls.

DELEGATES.

The President of the AMERICAN MEDICAL ASSOCIATION is authorized to appoint members, desiring such appointment, as delegates to the several medical and scientific bodies that are in sympathy with the Association.

DUTIES OF MEMBERS.

No members shall be permitted to address the Association unless they shall first have given their name and address, which shall be distinctly announced from the chair. If desirable, the member may be required to go forward and speak from the platform.

Failure to do special committee work shall cause the offender to forfeit a continuance of the same ap-

pointment, or a place upon any other, unless satisfactory excuse is offered.

It is expected that every member will, in every available way, promote the interests of the medical profession as represented in the Association, and will conform to all its regulations in spirit and letter until they may be altered by the action of the body which formulated them.

CONDITIONS EXCLUDING FROM MEMBERSHIP.

All societies that reject the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION, or intentionally violate or disregard any article of the same, are thereby of their own choice debarred from membership.

THE PREVIOUS QUESTION.

When the previous question is demanded, it shall take at least twenty members to second it. When the main question is put under force of the previous question and negatived, the question shall remain under consideration, the same as if the previous question had not been enforced.

NEW BUSINESS.

No new business, or resolutions by members, shall be introduced at the general session of the Association, except on the first and fourth days of the meetings.

ELIGIBILITY TO OFFICE.

In the election of officers and the appointing of committees by the Association and its President, they shall be confined to members present at the meeting, except in the Committee of Arrangements.

MEDICAL AND SURGICAL EXHIBIT.

There shall be no medical and surgical exhibit, under the authority or recognition of the AMERICAN MEDICAL ASSOCIATION, other than that made before the several Sections under the supervision of the Business Committee. All that is new and of value to the scientific or practical physician can thus find an appreciative audience. Experience has shown that all other exhibits detract from the work in Sections, and so lessen the attractiveness of the annual meetings to those whose presence is desirable.

Signed: H. D. HOLTON, *Chairman.*

BENJAMIN LEE.

AMENDMENTS PROPOSED BY A MAJORITY OF THE COMMITTEE ON REVISION TO THE REPORT AS MADE BY THEM LAST YEAR AT MILWAUKEE.

Amendment to be inserted between lines 28 and 29.¹

Any Commissioned Officer of the Medical Staffs of the Army, Navy and Marine-Hospital Service may become a member of the ASSOCIATION by presenting to the Committee of Arrangements at any annual meeting his commission in that branch of service of which he is a member or a certificate that he holds such commission from the Surgeon-General, or officer authorized to act for him, and a receipt from the Treasurer of this ASSOCIATION showing that he has paid the annual dues.

Amendment to be inserted in line 31 after the words "their society."¹

Or if a member of the Public Service from the Surgeon-General or Officer authorized to act for him of the corps to which he belongs.

Amendment to be inserted in line 134 after the word Committee.¹

With one person appointed by each of the State Medical Societies, and from each branch of the aforesaid Public Service.

EXPLANATORY NOTE.—It will facilitate understanding the proposed Constitution and By-Laws if the following considerations are kept in mind:

1. The key-note to all the changes suggested is "the advancement of scientific medicine as represented in the Sections." The Sections include all the ASSOCIATION. Hence, the elevation of the Sections to a more active participation in the conduct of affairs simply locates responsibility differently and, it is believed, more satisfactorily. It will be noted that the Sections are given no power to act independently of the ASSOCIATION. No act or recommendation of their representatives becomes binding upon the ASSOCIATION until the general body has so voted. The Business Committee from the Sections simply thinks over the problems committed to it, and advises the ASSOCIATION in accordance therewith. It is believed that this Business Committee is so constituted as to fairly represent the entire ASSOCIATION and the interests of the Sections. The only additional duty imposed upon this Committee beyond that it already possesses is the nominating of the officers of the ASSOCIATION and recommending the place of meeting. The officers and the place of meeting so obviously affect the prosperity of the Sections that it seems wise for them to make recommendations. It is believed that the fact that all questions will hereafter be fully studied by representative committees of such character as to command confidence, will attract to the ASSOCIATION thousands who have hitherto stood aloof; will promote the feeling of fair play between individuals, and give assurance to all that hereafter no ill-considered action will be taken by this great body.

2. Radical changes are made in the conditions of membership. It will be seen that but one kind of members is provided for. To discriminate between the worthy and unworthy has been referred to the several State societies. If these societies or the proper officer of one of the specified Medical Corps indorse an individual as worthy in their several States or respective Medical Corps, then the AMERICAN MEDICAL ASSOCIATION accepts them without question, and enrolls them among its members on their payment of the annual dues. This membership can be retained indefinitely by the annual presenting of a certificate of good standing in the State society of which the individual is a member, and paying the annual dues. Thus it is possible for every member of the profession in the North American continent to become and remain an active member of the ASSOCIATION. No person can become a member of the ASSOCIATION who does not become a member of a State society or Medical Corps and retain his active membership therein. It will be noted that the term, "State society," is made to include the Territories and the District of Columbia. It also includes Mexico and Canada upon the same conditions as the States. Distinguished gentlemen from other countries are cared for as guests either of a Section or the general ASSOCIATION.

3. The general meetings of the ASSOCIATION are reduced to the shortest space possible consistent with the doing of the necessary routine work. On the other hand, the Section meetings are lengthened to the greatest possible extent. The reputation of the ASSOCIATION, its power to advance the bounds of medicine, its attractiveness to the tens of thousands of doctors, must lie in the Section activities. Only here can be obtained adequate compensation for absence from active practice, with its necessary financial losses; for long and tiresome journeys; and for expenditure of a considerable sum from the scanty surplus of the average doctor's income.

Meanwhile, it is believed that the new features provide for the more satisfactory transaction of all business that may come before the ASSOCIATION. By adopting the document as presented, the ASSOCIATION will have provided for the study of every question by experts previous to its consideration by the ASSOCIATION. It thus will be able to act with more fact and wisdom.

It is believed that the adoption of the proposed organic laws will promote the best interests of the ASSOCIATION, of its Sections, of scientific medicine, of the several State societies, and of every intelligent practitioner of medicine, and hasten the organic unity of the profession of the entire North American continent. As such, it is commended to the consideration of the ASSOCIATION.

¹ The numbering of lines is necessarily omitted in the JOURNAL; they will be printed in the official document to be used at the meeting.

CODE OF MEDICAL ETHICS AND ETIQUETTE OF THE AMERICAN MEDICAL ASSOCIATION.

Report of Majority of Committee.

PROEM.

A code may be either penal or ideal. A penal code is an authoritative compilation of laws and is enforced by the infliction of penalties. Such are the civil and criminal codes of national, state and municipal governments.

An ideal code is the crystallization of the best thought and sentiment of any considerable body of men who have for long periods been associated with a common purpose, with reference to the regulation of their conduct in their relations to one another and to society in general.

Such a code forms an ideal standard, to the requirements of which each individual should strive to attain—a lamp to the feet of the young and inexperienced—a mirror into which the more mature, glancing, may be able to judge whether or not they are swerving from the paths of rectitude and honor.

Ethics is that science which treats of human actions and mental affections considered as virtuous or vicious, right or wrong. A code of ethics therefore takes cognizance of, and formulates, rules of action of the most exalted character, founded on eternal principles of justice, as applicable to the special conditions of the class for which and the time at which it is formed. Hence it follows that, from time to time, certain of its non-essential details may be modified without in any way impairing the solidity of its fundamental teaching. Obviously the code adopted by a learned profession must be ideal rather than penal, as it would be beneath the dignity of its members to bind themselves by penal restrictions. On the other hand, those who become obnoxious to the punishment of the penal code of any existing government are *ipso facto*, unworthy of association with the members of such a profession. Medical Ethics, as a science, is well worthy the study of all physicians, and should be included in the curriculum of every medical college. The code which springs from its teachings is based upon the actual experience of the noblest members of the profession, from the earliest times down to the present, and contains the essentials for the successful and honored conduct of a medical career.

Etiquette consists in the observance of a certain form of ceremonial between two or more persons in the conduct of affairs of frequent occurrence. Unlike ethics it involves no distinct question of morals, but, as by due conformity to its requirements the prosecution of affairs is facilitated, friction diminished, misunderstandings obviated and intercourse rendered more agreeable, it can not be neglected by physicians any more than by other classes of society. The peculiarly delicate and personal character of the relations of physicians to their patients naturally involves conditions which call for especial provision in this respect.

PART I.—MEDICAL ETHICS.

CHAPTER I.

OF THE OBLIGATIONS RESTING UPON PHYSICIANS.

ARTICLE I.—Of the Education of Physicians.

Of the momentous nature of the responsibilities devolving upon physicians there can be no question. The issues of life and death hang upon the proper performance of their duties. These responsibilities are only the graver and more enduring because there is no tribunal other than their own consciences to adjudge penalties for ignorance or neglect. On this ark none should venture to lay presumptuous hands. Manifestly the first duty of those who assume such responsibilities is to prepare themselves by a long, laborious and faithful course of study for the practice of this difficult and recondite art.

This course of study should be:

1. *Preliminary.*—This should include the ordinary branches of a liberal education, such as are taught in collegiate institutions which confer degrees in the arts, so-called, among which may be named languages, mathematics, literature, history, philosophy and logic. Not until the memory has been thus stored with essential preparatory knowledge, and the mental faculties have been trained to processes of correct reasoning, will the individual be in a position to comprehend the more abstruse science of medicine in all its branches, and to assimilate and utilize the immense amount of facts thrust upon the mind in the crowded curriculum of

a medical school. Not the least among the advantages of such an education in the humanities in preparation for purely technical study, is the ennobling and refining effect of intercourse with the cultured and learned, on the character and manners, by virtue of which that courtesy, propriety and dignity of demeanor, which are essential to the character of the true physician, as depicted in every code that has ever been written, become a second nature, requiring no enforcement by rule.

2. *Technical.*—This should embrace such earnest and prolonged study of medicine in all its departments as will render the student reasonably familiar, not only theoretically but practically, with the universally recognized fundamental branches of the science and art.

Equipped with this degree of mental furnishment and technical skill, and with nothing short of this, is the physician ready to enter, with a clear conscience and a proper self-confidence, upon the discharge of the responsible duties of a practitioner of medicine.

ARTICLE II.—Of the Duties of Physicians to Their Patients.

SECTION 1.—Being thus possessed of the requisite knowledge and skill for the treatment of disease, and also of the sanction of government for their employment, physicians should consider these acquisitions as sacred talents committed to their trust, and should use them diligently, honestly and solely for the benefit of their patients. It should be manifest to all that they do not suffer their own ease, comfort, pleasure, profit, advancement or dignity even, to interfere with the discharge of this primal fundamental duty.

SEC. 2.—The authority of the physician in the sick room is absolute and autocratic. Like all powers its possession carries with it the obligation not to abuse it, but rather to exercise it as gently and unobtrusively as is consistent with the good of the patient.

SEC. 3.—The familiar and confidential intercourse to which physicians are admitted in their professional visits, should be used with discretion and with the most scrupulous regard to fidelity and honor. The obligation of secrecy extends beyond the period of professional services; none of the privacies of personal and domestic life, no infirmity of disposition or flaw of character observed during the professional attendance should ever be divulged by the physician except when he is imperatively required to do so. The force and necessity of this obligation are indeed so great, that professional men have, under certain circumstances been protected in their observance of secrecy by courts of justice. Physicians should discourage as much as possible, however, the needless disclosure of family concerns, the knowledge of which is not essential to successful treatment.

SEC. 4.—Physicians should not be forward to make gloomy prognostications, because they savor of empiricism, by magnifying the importance of their services in the treatment or cure of the disease. But they should not fail on proper occasions, to give to the friends of the patient timely notice of danger when it really occurs; and even to the patient himself if absolutely necessary. This office, however, is so peculiarly alarming when executed by them, that it ought to be declined whenever it can be assigned to any other person of sufficient judgment and delicacy.

SEC. 5.—Physicians ought not to abandon a patient because the case is deemed incurable; for their attendance may continue to be highly useful to the patient, and comforting to the relatives, even in the last period of a fatal malady, by alleviating pain and distress, and by soothing mental anguish.

ARTICLE III.—Circumstances under which Physicians may properly decline to render Their Services.

SECTION 1.—While the duties of physicians to their patients are thus imperative, there are, on the other hand, reciprocal obligations of patients to their physicians of so obvious a character, that their studied neglect will justify the latter in declining to continue attendance on a family or a case.

SEC. 3.—Such are: The habitual refusal or neglect, on the part of those who can not plead poverty as an excuse, to remunerate a physician for services rendered; the refusal or studied neglect on the part of a patient, or the family of a patient, to carry out the instructions which the attendant deems essential; the surreptitious use by the patient of remedies not prescribed by, or disapproved of, by the attendant; and the surreptitious introduction of another physician, either as the family adviser, or during the progress of a case.

CHAPTER II.

OF THE RELATION OF PHYSICIANS TO THE PROFESSION AND TO THEIR COLLEAGUES.

ARTICLE I.—*Duties for the Support of Professional Character.*

SECTION 1.—The possession of the privileges and immunities appertaining to membership in the medical profession imposes the obligation to maintain its dignity and honor, to exalt its standing and to extend the bounds of its usefulness. It is incumbent, therefore, upon its members to make themselves familiar with this and similar treatises in which are epitomized the views of the best and noblest of its votaries in all the ages, and to shape their conduct in accordance with the settled principles therein laid down. It must be constantly borne in mind, however, that the profession exists not for the maintenance of its own dignity and honor, but for the benefit of humanity. Its true dignity will therefore be best promoted by an unsullied life and by the strict observance of the requirements of the opening articles of this Code, namely, the acquirement of such an education as shall make its members at least the peers of those of the other learned professions, and single-hearted devotion to the welfare of those who seek their services. Frequent and fulsome allusions to this subject, however, as well as claims of unusual self-sacrifice and beneficence on the part of the profession, especially in print, are in bad taste, and only subject those who make them to the ridicule of thoughtful men.

SEC. 2.—It is derogatory to the dignity of the profession to resort to public advertisements, or private cards or handbills inviting the attention of individuals affected with particular diseases—publicly offering advice and medicine to the poor gratis, or promising cures; or to publish cases and operations in daily prints, or suffer such publications to be made; to invite laymen to be present at operations, to boast of cures and remedies, to adduce certificates of skill and success, or to perform any other similar acts. These are the ordinary practices of empirics, and are highly reprehensible in physicians. It shall not be considered as a violation of the spirit of this section, however, for physicians engaged in the work of medical education, either singly or associated in colleges, or for physicians practicing in hospitals, whether private or public, general or special, to announce the fact or allow it to be announced to the profession in the advertising pages of strictly medical journals, or for physicians devoting special attention to one of the recognized special departments of medical practice to note the fact on their signs or private cards.

SEC. 3.—Equally derogatory to professional character is it for physicians to hold patents for secret nostrums. For, if such nostrums be of real efficacy, any concealment regarding them is inconsistent with beneficence and professional liberality; and if mystery alone give them value and importance, such craft implies either disgraceful ignorance or fraudulent avarice. It is also reprehensible for physicians to give certificates attesting the efficacy of secret remedies.

ARTICLE II.—*Of Consultations.*

SECTION 1.—Consultations should be promoted in difficult or protracted cases as they give rise to confidence, energy and more enlarged views in practice. A request for a consultation by patients or their friends should not be considered as implying distrust of or dissatisfaction with the attendant. Nor should it be assumed that the consultant is called in because he is the superior in knowledge or skill of the attendant, or that it is his function to pass judgment on the treatment which has been pursued. The true ground is simply the benefit which may accrue to the patient by bringing the judgment of two or more minds to bear upon the case.

SEC. 2.—A consultation being requested either by the physician or by the family or patient, it is the right of the former to select the consultant. It is equally the right of the physician thus called upon to decline the consultation, unless in exceptional emergencies where life is immediately at stake. A thorough education, preliminary, scientific and technical, furnishes the only presumptive evidence of professional abilities and acquirements, and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless, as in consultations, the good of the patient is the sole object in view, and as this is often dependent on personal confidence, no intelligent practitioner, who has a license to practice from some medical board of known and acknowledged legal authority, and who is in good moral and professional standing in the place in

which he resides, should be refused consultation, when it is requested by the patient.

SEC. 3.—Consultants should observe the most scrupulous regard for the character and standing of practitioners in attendance, carefully avoiding any insinuation which could impair the confidence reposed in them or injure their reputation.

CHAPTER III.

OF SPECIAL DEPARTMENTS IN MEDICAL PRACTICE.

ARTICLE I.—*Of the Necessity for Specialties.*

SECTION 1.—The advantages which have accrued to the science and, in a still more marked degree, to the art of medicine, and hence to humanity, from the division of its practice into a number of departments can not be gainsaid. Differentiation in study and labor of whatever kind is the test of civilization. The field of medical knowledge is now so vast that no one mind can compass it in all its details. Nor can any one hand obtain the dexterity essential for the successful performance of all the delicate and daring operations of modern surgery.

ARTICLE II.—*Of the Education of Specialists.*

SECTION 1.—Specialists should not be something less than general practitioners, but general practitioners and something more. Without omitting one jot or one tittle either of the preliminary or of the technical education insisted upon as essential for the physician, they should superadd to this a period of general practice, and then, upon this broad foundation of theoretical and practical knowledge, should build the superstructure of the special art for which they feel themselves best qualified by natural ability.

ARTICLE III.—*Of Specialists as Consultants.*

SECTION 1.—As a consultation is the conjoint investigation of a case by several practitioners with a view to its conjoint treatment, the responsibility being equally divided between them—they equally sharing the credit of success as well as the blame of failure—the mere introduction of a patient to a specialist by the attendant, with the communication of such facts in regard to the personal or family history as may assist in deciding whether it is for the best interests of the patient that the specialist shall assume entire control and management of the case, does not, in any true sense, constitute a consultation, and should not therefore be subject to the same limitations.

SEC. 2.—It is the obvious duty of general practitioners, when cases come under their care for the successful management of which they have not had the requisite training, or do not possess the necessary facilities and appliances, to recommend and introduce such cases to a competent and reputable specialist, and thus prevent them from drifting into the hands of charlatans.

CHAPTER IV.

OF THE COMPENSATION OF PHYSICIANS.

ARTICLE I.—*Of Fees.*

SECTION 1.—Under existing conditions, physicians are dependent for their livelihood on fees received from their patients. The attempt to gloss over this fact under the pleasing fiction of the voluntary *honorarium* savors rather of charlatanism than of professional dignity. In justice to themselves and their fellow-practitioners, therefore, physicians should present their claims for remuneration at stated and frequent intervals, and, if payment is refused or unreasonably delayed, should not hesitate to take legal measures to compel the same.

SEC. 2.—A fee-bill may properly be adopted by the physician of any circumscribed locality as a general guide in regard to the standard of charges, but should be considered simply as establishing a *minimum* rate for patients in good circumstances.

ARTICLE II.—*Of the Business Relations of Physicians.*

SECTION 1.—It should never be forgotten, however, that the relation of practitioners of medicine to their patients is not that of tradesmen to their customers. Such competition as is considered honorable in business can not exist between physicians without diminishing their usefulness and lowering the standard of the profession. Equally unprofessional is a resort to the devices of the trades-union and the boycott.

The attempt to obtain the practice of others by underbidding is extremely disreputable. It especially behooves

physicians of large means to be on their guard against the temptation from personal motives, to remit or diminish fees in the case of prosperous patients, as great hardship may thus be worked to their less fortunate brethren. Physicians should exercise care in entering into contracts with corporations, companies or societies, that the compensation agreed upon is such as to elevate rather than depress the local standard of remuneration for similar medical services.

SEC. 2.—As in consultations the conditions are such as involve unusual responsibilities, at least a double fee should be charged by both attendant and consultant.

SEC. 3.—Poverty and professional brotherhood should always be recognized as presenting valid claims for gratuitous services; but neither institutions endowed by the public or by individuals, societies for mutual benefit, for the insurance of lives or for analogous purposes, nor any profession or occupation can be admitted to possess such privileges. Nor can it be justly expected of physicians to furnish certificates of disability to serve on juries, or perform military duty, or to testify to the state of health of persons wishing to insure their lives, to obtain pensions, or the like, without a pecuniary acknowledgment.

ARTICLE III.—Of Fees in Vicarious and Casual Attendance.

SECTION 1.—In the event of the enforced absence or disability of physicians for brief periods, their colleagues should cheerfully and gratuitously attend to their practice, and, on their return, should furnish a statement of services rendered in order that they may collect the fees therefor. A physician, however, contemplating a protracted absence can not reasonably expect the extension of such a courtesy.

SEC. 2.—In obstetrical and important surgical cases, which give rise to unusual fatigue, anxiety and responsibility, it is just that the fee should be awarded to the physician who actually renders the service. If, in a case of confinement, the physician who has been engaged arrives after the birth of the child under the management of a casual attendant, but before the delivery of the placenta, the fee should be equally shared by the two physicians.

CHAPTER V.

OF THE DUTY OF PHYSICIANS TO THE STATE.

ARTICLE I.—Of General Duties.

SECTION 1.—As good citizens it is the duty of physicians to be ever vigilant for the welfare of the community, and to bear their part in sustaining its institutions and burdens; they should also be ever ready to give counsel to the public in relation to matters especially pertaining to the profession, as on subjects of medical police, public hygiene and legal medicine.

SEC. 2.—It is their province to enlighten the public in regard to quarantine regulations; the location, arrangement and dietaries of hospitals, asylums, schools, prisons and similar institutions; the protection of water supplies; the medical police of towns; sewerage and drainage; and the prevention of epidemic and contagious diseases. When pestilence prevails, it is their duty to face the danger, and to continue their labors for the alleviation of suffering and saving of life, even at the jeopardy of their own lives.

ARTICLE II.—Of Special Duties of Physicians as Experts.

SECTION 1.—Medical men should also be always ready, when called on by the legally constituted authorities, to enlighten coroner's inquests and courts of justice on subjects strictly medical, such as are embraced in the science of medical jurisprudence. But, in these cases, and especially where they are required to make a postmortem, it is just, in consequence of the time, labor and skill required, and the responsibility and risk which they incur, that the public should award them adequate compensation.

SEC. 2.—Physicians have a right to expect pecuniary acknowledgment from the State for the time and labor which they expend in making out returns for sanitary and statistical purposes, but they should not consider the neglect of the State to recognize the justice of this claim a ground for refusing to make this important contribution to the public weal.

PART II.—MEDICAL ETIQUETTE.

CHAPTER I.

OF COURTESY BETWEEN PHYSICIANS.

ARTICLE I.—Of the Nature of Etiquette.

SECTION 1.—The etiquette which should prevail between physicians in their professional intercourse and contact is

founded upon the dictates of common sense and the requirements of common courtesy.

Its strict observance will not fail to command the respect and goodwill of other members of the profession, and to promote that sense of mutual confidence and brotherhood which is so eminently desirable.

ARTICLE II.—Of Professional Services of Physicians to Each Other.

SECTION 1.—Practitioners of medicine are entitled to the gratuitous services of any one or more of the faculty residing near them whose assistance may be desired.

Physicians when ill are usually incompetent judges of their own cases, and the natural anxiety and solicitude which they experience at the sickness of those who are peculiarly dear to them tend to obscure their judgment, and to produce timidity and irresolution in practice. Under such circumstances, medical men are especially dependent upon each other, and kind offices and professional aid should always be cheerfully afforded, whether to themselves or to those members of their families who are immediately dependent upon them for support.

SEC. 2.—In many instances, however, a substantial recognition of such services may be both offered and accepted without violation of professional courtesy on either side.

SEC. 3.—Physicians should select some one member of the faculty as their family attendant, to whom the same loyalty, confidence and respect should be accorded as they expect from their own patients.

ARTICLE III.—The Etiquette of Consultations.

SECTION 1.—A consultation having been decided on, the attendant or a member of the patient's family should convey to the physician selected the request for the meeting, leaving the determination of the hour to the consultant.

SEC. 2.—The attendant should endeavor to reach the house in advance of the consultant in order to prepare the mind of the patient for the ordeal, as well as to receive the consultant and briefly to communicate such salient facts as may save the time of both in the sick room.

SEC. 3.—The attendant should precede the consultant in entering the patient's room, and should briefly examine the case in order to restore confidence to the patient so that questions may be the more intelligently answered, as well as to inform himself of the progress of the case since his last visit. The consultant should then be requested to make a full and satisfactory examination of the case, the attendant calling attention to any noteworthy or perplexing features which may have escaped the notice of the consultant. On the conclusion of the examination, they should retire to a private place for deliberation, the attendant being the last to leave the room.

SEC. 4.—The opinion of the attendant should be delivered first. When there are several consultants they should deliver their opinions in the order in which they have been called. No decision, however, should restrain the attending physician from making such variations in the mode of treatment as any subsequent unexpected change in the character of the case may demand. Such variation and the reason for it should be carefully detailed at the next meeting in consultation. The same privilege and obligation belong also to the consultant if sent for in an emergency, when the regular attendant can not be obtained.

SEC. 5.—The attendant should communicate the directions agreed upon to the patient or his friends. Any opinions which it may be thought proper to express to the family may be communicated by the consultant. But no statement or discussion should take place before the patient or his friends, except in the presence of all the faculty attending, and by their common consent; and no opinions or prognostication; should be delivered which are not the result of previous deliberation and concurrence.

SEC. 6.—In case of the unavoidable delay of one of the parties to a consultation, custom does not require the physician present to wait more than fifteen minutes after the time fixed. At the expiration of that period it will be the duty of the attendant, if present, to see the patient and prescribe; but, under similar circumstances the consultant should retire, unless informed that the condition of the patient is so alarming as to require instant attention, or in case the consultant is at a considerable distance from home, when the patient may be seen, and the immediate emergency met, or such examination made as may be deemed requisite. Information of such action, with a statement of conditions found and opinions arrived at, should be left for the attendant in writing and under seal. Otherwise, the consultant should await another appointment.

ARTICLE IV.—*The Etiquette of Occasional and Accidental Attendance.*

SECTION 1.—The same scrupulous regard for the reputation and feelings of their brethren which is binding in consultations should regulate the conduct of practitioners; when in a sudden emergency or for any reason, professional or otherwise, they are brought into confidential relations with the patients of other physicians.

SEC. 2.—A physician should not take charge of or prescribe for a patient who has recently been under the care of another member of the faculty in the same illness, except in the case of sudden emergency, or when the latter has relinquished the case, or has been formally dismissed and properly compensated.

SEC. 3.—A physician called to an urgent case, because the family attendant is not at hand, should resign the care of the patient immediately on the arrival of the latter.

SEC. 4.—A physician called to the patient of another practitioner in consequence of the sickness or absence of the latter, should on the return or recovery of the regular attendant and with the consent of the patient, surrender the case.

SEC. 5.—When, in the case of sudden illness, or of recent accident, several physicians are simultaneously summoned, the patient or family should indicate which one they prefer. Otherwise, courtesy should assign the patient to the first who arrives, who should select from those present such additional assistance as may be needed. In all such instances, however, the practitioner who assumes the management should insist that the family physician be called, and, unless further attendance be requested should, with the others present, resign the case on the arrival of the latter.

SEC. 6.—A physician called to a case of sudden or accidental death not occurring in his own practice, should direct that the usual attendant be at once informed thereof, in order that the latter may arrange for an autopsy, if advisable, and perform any other professional services required in such circumstances.

CHAPTER II.

OF DIFFERENCES BETWEEN PHYSICIANS.

ARTICLE I.—*Of Avoidance of Misunderstandings.*

SECTION 1.—A physician should always be slow to suspect a colleague of intentional slight, injury or wrongdoing, inasmuch as a full knowledge of the facts and circumstances may satisfactorily explain conduct which at first seems offensive or selfish.

ARTICLE II.—*Of Arbitration.*

SECTION 1.—Should diversity of opinion or opposition of interest, however, unfortunately lead to disagreement and estrangement between individual members of the profession, the case should not be left to create or to foster prolonged animosity but should be referred at once, privately, to the arbitration of a suitable number of physicians or a court-medical, whose decision should be final.

SECTION 2.—As, in consequence of the intimate and confidential character of the relation of physicians to their patients there exist numerous points in medical etiquette through which the feelings of medical men may be wounded in their intercourse with each other, which can not be understood or appreciated by general society, neither the subject matter of such differences nor the decision of the arbitrators should be made public.

ARTICLE III.—*Of Seniority.*

SECTION 1.—Seniority among the practitioners of any city, town or district is determined not by age, but by the period of public and acknowledged residence as a practicing physician in the same.

SEC. 2.—At informal meetings and on public occasions, courtesy accords the position of prominence to the senior.

SEC. 3.—Physicians newly establishing themselves in practice in any place should, as soon as practicable, call upon the resident physicians, or otherwise notify them of their arrival, and of their desire to cultivate fraternal relations with them.

SOCIETY PROCEEDINGS.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 148).

AFTERNOON SESSION—THIRD DAY—SEPTEMBER 14.

The meeting was called to order at 2:30 P.M.

CHAS. G. CANNADAY, M.D., of Roanoke, Va., Member of AMERICAN MEDICAL ASSOCIATION, American Electro-Therapeutic Association, British Gynecological Association, London, Pan-American Medical Congress, etc., read a paper on

THE TREATMENT OF SUBINVOLUTION BY ELECTRICITY.

Sir James Simpson's "Subinvolution", Scanzon's "Chronic Parenchymatous Metritis," Klob's "Habitual Hyperemia, with Profuse Proliferation of Connective Tissue," Edis' "Metritis," Hodges' "Irritable Uterus," Lisfranc's "Engorgement," Kiwisch's "Infarctus," and Noeggerath's "Diffuse Interstitial Metritis," or any other name that may describe the enlarged and engorged condition of the uterus only recalls to the practitioner, up to a few years since, the stubborn and unyielding condition he has to treat. To Sir James Simpson we are more indebted than to any other for accurately defining and calling attention to its frequency and treatment. One of the first to describe its macroscopic and microscopic appearance was Snow Beck, in 1851.

Its etiology is interesting in the extreme. Everything that could have been credited with producing a pathologic condition of the pelvic organs has been claimed as an exciting cause, but it seems that a large number of those cases coming under observation have followed abortions, lacerations, twin-pregnancies, and similarly enlarged pregnant uteri (viz: large children, hydramnios, etc.), and in those delicately constituted as to uterine development. This will cover a wide field; and to this might be added another very frequent cause, viz: The practice of using ergot at some time during labor, which stimulates the contraction of the unstriped muscular fiber, producing a quasi-tetanoid spasm of the uterus, which subsequently fails to contract sufficiently to induce involution. As to histology: The bulk of the investigators concede that the uterus consists of unstriped muscular fibers in the highest state of development, varying in length from one one-hundred-and-tenth to one-fortieth of an inch, as it is found in the unimpregnated or gravid state, also yellow elastic, fibrillar and homogeneous connective tissue, round, spindle-shaped, and irregular cells (Thomas' elementary fusiform fiber cells) serous membrane, mucous membrane, nerves, blood vessels and lymphatics.

During gestation, the muscle cells enlarge to ten times their size in the unimpregnated uterus. All the remaining anatomic structures of the uterus during gestation are enlarged. After parturition, the uterus should rapidly decrease, until in four to six weeks it has attained its normal size. This change is the result of the fatty degeneration of the muscular fiber, with the subsequent absorption of this fatty material, and its removal from the uterus. This is brought about by the impaired nutrition, the result of the chronic contraction of the unstriped muscular fiber, which contraction should be immediate and permanent after delivery, otherwise, the nutrition of the cells is not impaired, foundation for excessive amount of connective tissue is laid and normal involution can not obtain. As all writers recently have occasion to regret, our pathology is very scanty on a disease which has had a recognized position in gynecology for the last forty-five years. It is evident to all observers that there is an excessive amount of tissue present and that there is also quite a defective condition of both the vascular and lymphatic systems. No clear and concise limits can be definitely fixed between the pathology of some forms of chronic metritis and subinvolution.

Mary Putnam Jacobi, who, under a very careful study of the subject, found the muscular fibers enlarged, with nuclei disappearing, and smaller fibers with indistinct central nuclei; others still smaller in which the nuclei were distinct, while in another variety no nuclei were discovered, but granular and oil globules were found, and that the wasting of the cell began in the protoplasm and ended in the nucleus. She found among these fibers nucleated connective tissue cells and amorphous tissue. The blood vessels and lymphatics were very much enlarged and intimately connected

with the muscular tissue, which she considers a strong diagnostic point from chronic metritis; as herself and De Siney have shown, in the latter, a peri-vascular condition is present. Its diagnosis is generally easy, when we remember that an abortion or pregnancy must be present as a starting point. Hansen finds that involution extends over a period of twelve weeks, but that in two-thirds of the cases the uterus has returned to normal in from six to ten weeks. Weakness of the back, excessive lochial discharge, or the appearance of menorrhagia may be the most important symptoms found during the puerperium. Evidently, in the first stage, we have hyperemia and congestion. A large flabby uterus, with thickness of walls increased, and the sound reveals an enlarged uterine cavity; the mucous membrane bleeds freely. Whether this be chronic metritis or subinvolution uteri, following abortion or confinement, matters little in the treatment.

As to treatment: That, other than electricity, will only lightly be touched upon. As prophylactic clearing well the uterus of clots, the use of weak antiseptic vaginal injections, refraining from use of ergot, or any of its kindred drugs at any time in labor, or, if used during labor, to be continued for several days after labor at suitable times to induce and maintain contraction of unstripped muscular fiber, and to induce physiologic malnutrition, so necessary for the fatty degenerative process common in normal involution. Tonics, baths and drugs, hastening absorption, with nutritious diet will accomplish much in building up the system. Vaginal injections of hot water 110 or 115 degrees, using three or four gallons once daily, with pledgets of cotton every third night, inserted up the vagina, saturated with anhydrous glycerin and boro-glycerid, with the application of iodized phenol on a cotton wrapped probe, or better still, by a few drops injected into the cavity of the uterus with an intra-uterine syringe, provided the os is patulous, will all hasten the cure. If the os is very much congested, a Buttle's scarificator plunged into the cervix and the congestion relieved in this way will do much good toward aiding a cure. But the greatest amount of good can be accomplished in the least time by the proper application of electricity. The detection of subinvolution is generally not accomplished as early as the tenth day, from the fact that any symptom referable to this is not generally attributed to this cause, but if it is detected at so early a stage, that is, at ten days, and the intra-uterine dimensions is found to be ten centimeters, and much tenderness does not exist, we should use the medium Engleman coil, having a length of 200 meters and a diameter of seven-tenth millimeters, with the bipolar vaginal electrode, after the manner suggested by Apostoli, using as powerful current as the patient is able to stand to accomplish the object. This to be continued for five minutes, then to be discontinued for ten minutes, with the electrode in same position, when the current should be re-applied for a period corresponding for same time, when the electrode should be removed. If a more powerful effect is desired, the intra-uterine bipolar method should be tried, having the proximal pole of the intra-uterine electrode stop at the os and the distal as far toward the fundus as it will reach, pressing it alternately to posterior, anterior and lateral portions of uterus. This to be used with Engleman's coarse coil, having a diameter of one and four-tenths millimeters and a length of sixty-six meters, with a strong current. But in failing to effect involution in this manner, as will often be the case, owing to such a sensitive condition of parts, or to the infiltration of tissue being so abundant and so organized as to preclude any certain results from the treatment, we must adopt another. The writer is mainly influenced by Hansen's observations as to diagnosis of subinvolution, and if he finds at the second week a uterus varying from eight to thirteen centimeters, at third week from seven and five-tenths to ten and five-tenths, and at the fourth week from seven to nine centimeters, and fifth week from six to nine centimeters, it is concluded he has subinvolution to deal with; and, provided symptoms are present as above described, the case is treated on a different plan, by aiming, first, to reduce the engorged and congested condition; secondly, to absorb hyperplastic elements, and thirdly, to restore tone to muscular and vascular structures. This consists of, first positive galvanic intra-uterine application of at least thirty milliampères from eight to ten minutes, and if much tenderness exists and pain is induced, to be followed by the vaginal bipolar application of the faradic current from a coil having a diameter of .225 millimeters, and having a length of 600 meters, after the method as described by Engleman. By this means the uterus is relieved of engorgement, the unstripped muscular tissue composing the uterine

walls are strengthened, and the walls of the blood vessels are restored to their normal contractile powers. The capillaries are relieved of their hyperemic condition, and the process of involution is in every way aided. Bipolar intra-uterine faradization must be carried out to be effective in this instance by the bipolar intra-uterine sound.

If the subinvolution has passed the stage of active congestion we may hasten involution by using the negative pole of the galvanic current—intra-uterine—especially if the uterus presents a hardened condition. In several instances in which ergot was freely used during labor, there has been used the daily application of the faradic current to uterus for seven or eight days, as used by Trippier and Apostoli of Paris, and in each instance with the happiest results, and I am of the opinion that this should be used in all cases where ergot has been freely used during labor; strict antisepsis being carried out in each instance.

By this method described, I am satisfied that subinvolution uteri can be cured in one-half of the time consumed by any other means than electrical.

DISCUSSION.

DR. DICKSON said he had had good results from the faradic current in the treatment of subinvolution.

DR. HAYES felt that galvanism did more towards starting up a new retrograde metamorphosis than the faradic current, although both are beneficial. But in subinvolution, there is an arrest of that physiologic change by which the organ is reduced from a weight of about three pounds at the time of confinement to a weight of about three ounces, as it is in the unimpregnated condition. In his estimation, no agent is superior to electricity in starting anew this process, and clinical experience shows that this has accomplished more than curetting or the surgeon's knife. He would employ the positive pole because there is frequently an increased menstrual flow, and there is also a flabbiness and a condition of undue moisture which seems to indicate this pole. He rarely employed over forty or fifty milliampères, given from five to eight minutes at intervals of four or five days.

DR. SPRAGUE thought it made very little difference whether intra-uterine galvanic treatment or bipolar faradization was employed; we can depend upon both to give relief. His results had been more rapid when he had given sittings of fifteen minutes on alternate days.

DR. MASSEY strongly commended the method. He saw many acute cases of this kind in consultation, but very few in private practice unless they had lasted for many years. At present, he was disposed to return to the former belief that the relaxed uterus is the cause of very many of the reflex symptoms observed in women. He uses the faradic current chiefly in cases which have existed not over six months. If there be such a thing as a specific, it is electricity for subinvolution—the faradic current in recent cases, and the galvanic current for the more chronic ones. Ergot frequently causes irritation and aggravates the condition. Subinvolution, he thought, was almost always due to a microbic invasion of the uterus at the puerperal period. If it be due to the gonorrhœal germ, the case will prove most obstinate, but other cases will be found quite amenable to this treatment.

DR. A. LAPHORN SMITH added his testimony to the value of the continuous current in subinvolution. He had not employed the interrupted current very much, although no doubt by the contraction of the muscular tissue which it produces, the uterus could be made to contract firmly upon the nutrient arteries, thus leading to fatty degeneration and absorption. He agreed with the preceding speaker that subinvolution was very largely due to septic infection occurring at miscarriages or at full term. We are especially apt to have this after abortions, because Nature is not prepared to carry out this retrograde process as she is at the completion of the normal period of gestation.

He had had more experience with the treatment in alveolar hyperplasia, viz.: Where the uterus is too deep, owing to a deposit of fibrous tissue between the layers of muscles. In such cases, faradism is not effective; the continuous current is necessary. It acts as calomel does when applied to the cornea, i. e., by exciting the activity of the absorbents. No matter how performed, he was certain the depth of the uterus could be reduced from day to day by negative galvanization.

DR. CANNADAY, in closing the discussion, said that if the subinvolution had existed for a year or more, the congestion will have in large measure subsided, and therefore greater benefit is likely to accrue from the use of negative galvanization.

zation. He wished to emphasize the fact that he thought ergot had much to do with the production of subinvolution, owing to the tetanoid condition it produces in the muscular fiber. In recent cases, faradization is more active, but later on, it is of little avail except the current be from the fine coil.

DR. PLYM. S. HAYES of Chicago, then demonstrated by means of a eudiometer the amount of gas evolved from water during electrolysis. This amount is somewhat in excess of that occurring in the uterus because a portion of the current is expended in decomposing the salts found in the tissues.

This demonstration served as an introduction to Dr. Hayes' description of

A NEW INTRA-UTERINE ELECTRODE.

By PLYM. S. HAYES, M.D., Professor of Electro-Therapeutics, Chicago Polyclinic.

I had employed the Apostoli method of the intra-uterine use of galvanic electricity for but a short time when my attention was called to the amount of gas liberated around the intra-uterine electrode, and that the presence of the electrode in the cervical canal served as an obturator, preventing the escape of the gas which is formed.

In one of my cases, that of a multipara, who, by repeated childbearing, had so large and patulous a cervical canal that the intra-uterine electrode did not fully occlude it, I noticed the escape of gas by the side of the electrode in the form of a froth. I also repeatedly noted the fact that the removal of the intra-uterine electrode was followed by the same froth, either with or without color, according as the introduction and removal of the electrode had been attended with sufficient traumatism to produce a slight hemorrhage or not. Occasionally the escape of the gas was attended with a slight sound, such as would have attended the forcing of soap suds through a small orifice. The escape of the gas with sufficient force to produce a noise suggested to me the probability of the presence of gas under pressure within the uterine cavity. In order to demonstrate this, I have at times, after the employment of Apostoli's method, introduced the blades of a uterine dilator and opened them slightly and have seen as much as a drachm of bloody froth escape from the uterine cavity. Experience soon demonstrated that when the gas was allowed to escape from the uterine cavity by means of the dilator or a uterine irrigator, the post-operative pain was decidedly lessened. My experience in this regard, with report of case, was embodied in a paper which was read before the Tri-State Medical Society at their meeting at Chattanooga two years since.

The method of providing a way for the gas to escape after electrolysis was an improvement on the method as described by Apostoli unless, perchance, it may be proven, that the post-operative pain is mainly due to uterine contractions excited by the gas which acts as a foreign body within the uterus and these contractions produce a decidedly therapeutic action on the uterine tumor. That this claim has been made by any electro-therapist who has made use of this method is unknown to me, for I have failed to see any mention of it in the literature bearing on the subject. Granted that the post-operative contraction is of therapeutic value, the query remains, Is the benefit derived from such contractions excited by the presence of gas of sufficient value to run the risk of forcing the contents of possibly diseased tubes or even uterine mucus into the abdominal cavity?

That the galvanic current causes gas to be liberated—hydrogen from the negative pole and oxygen and chlorine from the positive pole—when the fluids and tissues of the body are subjected to electrolysis, is an undisputed fact. The amount of gas liberated from either pole by means of 100 milliampères of current passing for a definite period of time through water can readily be determined by means of a properly constructed eudiometer, which instrument becomes then a coulombmeter; 100 milliampères passing for five minutes through acidulated water will liberate 7.5 cubic centimeters of the mixed gases. This is somewhat in excess of the amount that would be liberated in intra-uterine electrolysis, because here we have a portion of the electrolytic energy exerted in decomposing the salts and organic compounds found in the tissues. Even if the gas liberated should be but one-half of the amount liberated in our eudiometer with acidulated water, it would still give us 1.25 cubic centimeters of oxygen in five minutes, which time is frequently consumed in intra-uterine electrolysis.

The removal of gas after the electrolysis has been completed has been proven, by clinical experience, to be of value,

but there remains the fact of a rapid evolution of gas within a muscular cavity that has three openings—the Fallopian tubes and the cervical canal, the last of which may be quite thoroughly occluded by the intra-uterine electrode, so the accident which we wish to avoid by the removal of the gas is quite likely to have occurred during electrolysis and before the method above described for the removal of the gas could have possibly been employed. These considerations, in connection with the desire to produce an electrode that could readily be rendered aseptic, that would be comparatively easy of introduction, and that could be made to act within the uterine cavity and at the same time be without action on the cervical canal, caused me to formulate the following as the ideal of an intra-uterine electrode:

The active part of the electrode should be of platinum and flexible. There should be a means of exit for the gas generated around the active part of the electrode and it should be so constructed as to sustain a boiling temperature, or be uninjured by being subjected to the action of an antiseptic solution. Should the electrode become clogged with blood or mucus so as to prevent the exit of the gas, a means should be provided for clearing it while in situ while the current is passing, and should be so insulated that the cervical canal should not be subjected to the action of the current.

The electrode I now present to you is the attempt at the embodiment of this ideal. This electrode has now been in use for over a year and has proven to be of value in meeting the indications herein detailed. It consists of a straight or slightly curved metal tube covered with hard rubber. To the end of the tube is soldered a spiral of especially tempered platinum ribbon which terminates in a bulb of platinum. The spirals of the platinum ribbon are separated so as to allow the entrance of liquids and gases into the interior of the spiral, which is continuous with the tube. An oblong fenestra is made in the tube at the point that will be just external to the cervix, when the electrode is introduced. The proximal extremity of the electrode is bent at an obtuse angle and is arranged for attachment to the battery. An opening at the angle permits the introduction of a stylette, by means of which the tube can be cleared of accumulated mucus. The stylette may also be used to maintain the form and give rigidity to the electrode during introduction. The edges of the platinum spiral are made smooth and slightly rounded so as not to inflict injury on the soft parts. The screw-like arrangement of the spiral aids materially in the introduction of the electrode, for as soon as the electrode is engaged in the cervical canal a rotation of the instrument causes it to advance. The material of which the electrode is constructed allows of its being boiled, or being placed in alcohol, or some like aseptic solution.

After using the electrode, I remove the mucus, blood, etc., which adheres to the spiral, by switching it rapidly through water and allowing the water from a faucet to run through the tube. After this, the electrode is put into a test tube partly filled with water, with the platinum point down and the water brought to the boiling temperature and kept there for some minutes. Then it is placed in another test tube containing alcohol and allowed to remain till needed. To Mr. Warner of the McIntosh Company, whose technical skill and perseverance has aided materially in the production of this electrode, much praise is due.

I have entered thus fully into the details which prompted the construction of this electrode because it attempts to accomplish that which is entirely new, viz., the elimination of gas as it is generated by electrolysis into the uterine cavity. In this particular, the electrode is a pioneer in a new field.

The testimony of those who have used it, is that while it does not wholly prevent the post-operative pain in every case, it does so in a great degree in the majority of cases.

Intra-uterine electrolysis is not without danger, even in the hands of the most conservative, and any instrument that will lessen the danger of setting up a peritonitis or of relighting the fires of an old one, should find a permanent place in our armamentarium.

DISCUSSION.

DR. GEHRUNG said that when he began to use the Apostoli method at the time it was first promulgated, he made the same observation regarding the accumulation of gas within the uterus. He employed puncture at that time, and found that the gases accumulated within the tumors, and formed the basis of future abscesses. He had seen this also in the practice of others. At that time he constructed a hollow electrode, which is illustrated in Dr. Massey's book, and which consists of a trocar needle in a silver tube, open

at both extremities, and perforated with holes so that when the electrolysis has been applied through the trocar, the trocar may be removed, and the accumulated gas in the tumor allowed to escape through the cannula which is retained in position as long as deemed advisable. It was found that fluids sometimes escaped for days after the operation, showing that the effect of the electrolysis lasts for some time after the application. In one case, the cannula was left in for twenty-one days. The same method he used afterwards in the uterus in a similar way to that described in this paper.

DR. MASSEY said the instrument just exhibited is undoubtedly a novelty as regards the question of providing for the escape of the gas. In puncturing a large fibro-cyst in one case, he employed Gehrung's instrument, and was astonished at the very large quantity of gas aspirated, although a current of not over 150 to 200 milliampères was applied for two or three minutes. He thought much of the irritation ordinarily observed is due to the use of inflexible instruments. About a year after the description of Dr. Gehrung's instrument was published in his book, he learned from Dr. Goelet that he had devised a similar instrument in ignorance of Dr. Gehrung's work.

DR. DICKSON thought it would be better to have the tip of the instrument protected when used with strong currents. He also thought the folds of mucous membrane might catch in the grooves of the spiral and lead to hemorrhage, and that when the positive pole was used, the withdrawal of the instrument might be attended with much difficulty. The cleaning of the instrument after certain cases could hardly be effected by anything short of passing it through a flame.

DR. MASSEY remarked that this instrument was an improvement on his, only in having a hollow handle.

DR. GEHRUNG said that without intending to advocate the puncturing method in the treatment of fibroids, he desired to mention that one of the great advantages of the instrument to which he had alluded was that it could be left *in situ* and electrolysis repeated without resorting to another puncture. He also made use of the stylette by which the instrument could be introduced or withdrawn.

THE PRESIDENT remarked that it had been claimed that much of the good effect of electrical treatment is due to the action of the liberated gases. If this be so why should instruments be devised to allow its escape?

DR. HAYES, in closing the discussion, said that about eighteen or nineteen years ago he had constructed an instrument which would allow of the escape of gas, but he had not published it. The introduction of his instrument is not nearly so difficult as one might suppose, although of course it is not so easily effected as with the ordinary instruments. The tip can be readily coated with shellac, but if the electrode be introduced and allowed to remain stationary, there is very little danger in having the tip made of solid metal. Even though the positive pole be used, there is no great difficulty in removing the instrument, the operation being facilitated by gently rotating it. The evolution of gas is so great when strong currents are used as to prevent in a measure the adherence of the tissues to the electrode.

W. B. SPRAGUE, M.D., of Detroit read a paper on

A CONTRIBUTION TO THE ELECTRO-THERAPEUSIS OF SALPINGITIS.

The pathology of tubal troubles has been so recently evolved that the therapeusis is still in the embryonic stage. Many of our leading lights declare that there can be no rational therapeusis—that there can be no remedy but extirpation—as if decapitation were a cure for cephalalgia!

Yet many men have a firmer faith in Nature's economy, and are seeking to aid her efforts at repair by, at least so far as possible, removing the cause. Nearly all cases are accompanied by and most of them caused by endometritis, either acute or chronic, specific or non-specific. Since this has been established our first duty is plainly to relieve the endometritis. To this end many forms of treatment have been advised, but Polk's revival of Sims' conception of depletion and drainage seems to be the only one which has brought satisfactory results, and the relation of parts is such that the application of this principle to the womb produces a direct as well as an indirect influence upon the tubes—it removes the cause and relieves the chronic congestion in those cases which bear the treatment well.

Now the severity of the measure by which it is accomplished, as taught by its author and the profession at large, has limited its applicability in the hands of even its warmest advocates. Divulsion, and curetting of an inflamed womb with inflamed adnexæ has often aggravated the inflammation, making extirpation necessary. This has seemed to the

surgeon good ground for the argument that extirpation should be the first and only resort.

But Apostoli has taught us that the same results may be attained by a milder and more rational means. The intra-uterine application of the negative pole of the constant current of electricity is the most reliable method we have for treating endometritis to-day, the rationale of which is this same principle of depletion and drainage, by the cathartetic action of the current, aided by the trophic influence and by its caustic action. Goelet has shown that the influence extends to salpingitis and, if carefully and judiciously used, is the safest and best treatment yet advocated for this affection. He says that many cases of simple inflammation of the lining membrane of the tubes will subside with the endometritis, if free drainage through the uterine canal is established and maintained, and if protection is afforded against such influences as would tend to irritate the sexual organs.

My experience leads me to indorse the foregoing most heartily, but the object of this contribution is to call attention to a modification of Goelet's treatment which has been quite successful, in a few cases, in my hands, by reporting some illustrative cases. At the Michigan State Medical Society meeting held at Grand Rapids in 1890, I reported a case as follows:

"Mrs. H., aged 32, has had one miscarriage, but for several years previously she had suffered from a pain in the right iliac region, at frequent intervals. A year ago last April she began to suffer more than ever before, and she came to me for relief. She told me, in describing her symptoms, that she had an enlargement in the side with pain. I found this enlargement to be considerable, but the abdominal muscles were strong and I could not distinctly outline it. I diagnosed an ovarian tumor, and felt that my diagnosis was confirmed as I watched its growth in after days. But one day she came to tell me that she had had a free discharge of yellow matter after a sensation as of something giving way the night before, and the swelling was subsiding. An examination proved the correctness of her statement, and I changed my diagnosis to pyosalpinx. My treatment to this time had been merely palliative, principally faradism, to relieve the pain. She was now comfortable, and I suspended treatment a few weeks, when the tube began to fill again. I resumed the faradism, and soon after added galvanism. On June 15, I gave twenty-five milliampères, intra-uterine, negative. After three intra-uterine applications, the last one sixty-five milliampères, I changed to the vaginal electrode, placed against the tube, sixty-five milliampères, June 29. Soon after this there was a second discharge of pus, and relief from pain. I gave twenty-one more applications similar to the last described, before March 29, 1890, when the tube had again filled, and was giving considerable trouble. I now determined to try to effect an entrance into the tube. I therefore converted my graduated uterine sound into an electrode, insulating it with small rubber tubing, and passed it into the womb. I then connected it with the negative pole of the battery, and turned on ten milliampères. Turning the end of my sound toward the right cornu, I exerted gentle pressure against the point that I thought to be the proximal end of the tube. Suddenly, within five minutes, my sound slipped onward about an inch. I was startled, and thought of perforation of the uterine wall, but perceiving my patient undisturbed, I decided that I had really been more fortunate than I had expected, and accomplished my purpose. So I passed the electrode still further in and raised the current to twenty-five milliampères for seven minutes. There was free discharge of pus for several days following, and renewed relief from all the symptoms. I have since introduced the sound into the tube on May 12 and 25, and on June 12, the last time in the presence of Dr. Manton, who kindly came in to confirm my diagnosis. The tube seemed quite empty of pus at the last sitting. The sound has passed more readily at each subsequent sitting, and enters to a depth of more than five inches. The patient, who is a seamstress, has not lost an hour's work from treatment, and her general health is much better than a year ago." (*Trans. Michigan State Medical Society, 1890.*)

I administered two or three treatments to this patient soon after the above report, and have been agreeably surprised to find that she is completely cured. There has not been a drop of pus discharged since, nor has there been any trouble with the uterus or adnexæ. Except for a chronic pharyngitis the patient's health is perfect and she pursues her avocation without interruption.

Another interesting case of pyosalpinx is as follows:

In the spring of 1889 I was called to a case of acute gon-

orrhœa in the person of Mrs. D., aged 33 years. The result was what is ordinarily called a cure, without any apparent involvement of the uterus or adnexæ at the time. The uterus had been badly lacerated at a previous confinement and trachelorrhaphy was performed a little later. In a short time the menstrual flow became scant and painful, and there was enlargement of the tubes, followed in a few days by a free discharge of pus and relief to pelvic distress and headache which she had suffered. In the summer of 1890, the distress at the periods growing monthly more severe and prolonged, I began intra-uterine applications of galvanism, and found one day that I could pass my electrode into both tubes by a manipulation which I will describe later. I have continued this treatment since at intervals varying from three days to four months, the longer intervals being later. After every treatment (which is applied only when the patient is suffering from distension of the tubes), there is discharge of pus and relief to all the symptoms. For the past twenty-two months I have made only twenty-six applications, only five of which were given during the present year, 1893, and my patient is able to do her own housework and wait upon an invalid husband, suffering only occasional serious discomfort, whereas she had at first been able to do very little and suffered much of the time.

In 1891 I reported a case of hematosalpinx before the above-mentioned Society. The case was as follows:

Miss C., aged 30 years, a seamstress by occupation, had undergone a not unusual history of retroversion, endometritis, prolapse of the ovaries and salpingitis previous to the summer of 1890. She spent this summer on the New England coast and was much improved in general health when she returned to Detroit in the autumn. But the menses became scant and irregular and began to usher in a very severe headache and backache which were very slow in subsiding after the menses ceased. These phenomena developed with increasing severity and regularity, and I was called to see her suffering in an unusually severe recurrence, Jan. 27, 1891. I found a retroversion and enlargement of the womb with an abnormal swelling in the left vaginal fornix. I replaced the womb and gave internal remedies which afforded very little relief, but the headache, backache and swelling in the fornix subsided coincidentally during the following several days. She came to my office by my request on February 5, 22 and 25, and I made intra-uterine applications *a la* Apostoli for the endometritis. On the last named date I made the following notes: Left tube distended, probably by catarrhal secretions. Has had much vertical headache for the past week, and a sensation of water trickling over her forehead. I seemed to succeed in passing the electrode into the distended tube—at least it passed about four inches beyond the os by turning it to the left side and gave pain in the region of the left ovary. Gave twenty-five milliamperes negative current for ten minutes. On March 1 she returned and I again noted as follows: She reports that her headache was relieved soon after last treatment, and that she discharged a brown viscid material from the vagina for two days following. I find the distension nearly gone from the tube and have again passed the electrode into it, beyond question, feeling its point through the abdominal wall near the ovary. I gave twenty milliamperes ten minutes, negative current. My diagnosis now changed from that of hydrosalpinx to hematosalpinx, but I determined to try what a persistence in this line of treatment might do for her. On March 16 I again recorded: I repeated the intra-tubal treatment March 9, but did not succeed in entering the tube so far. This treatment was followed by menses next day, which were free from pain, normal in quantity, and followed by no headache. She reported these facts yesterday, March 15, when I gave another treatment, introducing the electrode probably more than an inch into the tube. She says she is "perfectly well."

I repeated the treatments twice more in March and her menses recurred April 4, quite normal and freer than formerly. She reported another menstrual period ushered in May 30 which was the most normal in all respects that she had experienced for many months. I continued to maintain the patency of the tube by occasional treatments for a few months and there has never been a recurrence of the hematosalpinx. I reported the case in June of the same year, when I wrote as follows: "My patient is very comfortable unless she runs a sewing-machine or takes a long walk, in spite of the abnormalities in her pelvis. From my experience in treatment, by electrolysis, of stenosis of the cervical canal, I expect to obtain a permanently patent uterine orifice in the diseased tube, and to have cured my hematosalpinx." This patient was married the following

spring and on July 14, 1892, I was called in haste, but too late to prevent the loss of a two months fetus, due to a recurrence of the retroversion which she had endured for several days without reporting. Her menses again ceased March 1 of the present year and on the 26th of July she felt motion. By careful watching the womb was kept in position until the danger of abortion was passed.

During the discussion which followed the report of this case in 1891, I took occasion to argue for greater conservatism in these cases, in answer to which Detroit's leading extirpationist spoke as follows:

"I don't know how many children Dr. Sprague's patient has, or how many she will get in the future. I think she is unsexed. I think her generative organs, as far as propagation of species is concerned, are of no more use to her, and I believe with Dr. Manton, that very serious irritation is likely to take place and subject her to great danger in the future." (*Trans. Mich. State Med. Soc. 1891.*)

Thus, incidentally, the case has developed an unanswerable reply to the plea for immediate extirpation in such cases.

I have not been able to find that any one else has advocated seriously or practiced intra-tubal electrolysis for any form of salpingitis. I am aware that the possibility of entering the tubes in these cases is discredited, and I have found many cases in which I have been balked in my efforts, but I have good reason to believe that I have succeeded in several cases besides these that I have reported, and I have had no untoward results following my efforts in any instance. Even where I am convinced that I failed, I have frequently given great relief to the patient and sometimes caused free discharge of catarrhal or purulent secretion, as the case might be. It seemed to me, therefore, that after three years of careful effort and observation in this direction it was desirable to lay the matter before this, the only body of men in our country competent to pass upon and approve or condemn a continuation of effort in the same line.

I have believed that the number of cases in which we could apply the treatment is necessarily limited, but that in many cases, where it is possible, the direct application of the current to the diseased membrane would be far more beneficial than to depend upon the remote and secondary effects of applying it to the endometrium. I do not ignore the danger of careless manipulation in this region, and most earnestly warn tyros in electro-therapy from making the attempt to enter the tubes with any electrode. The strictest asepsis should be observed before, during and after the séance.

I use an insulated Simpson sound with the normal curve a little accentuated at the extremity. As soon as I have passed the internal os uteri, I turn the point of the instrument to the side which I wish to enter and gently follow along the bottom of the fossa until I reach the os uterinum of the tube, which is indicated by the points sliding into a slight depression. I then attach the negative conductor, turning on slowly, ten to thirty milliamperes, according to the nature of the case. I exert just sufficient leverage to hold the bulbous point in firm contact with the ostium. I usually notice evidence of the cataphoretic action by oozing of fluid from the os uteri. In those cases where I have succeeded in entering the tube, I have felt the point of the electrode suddenly advance, and have immediately found it fixed, as if in a narrow canal. In some instances I have then been able to advance it from one to two inches farther, and then have felt the point in the ovarian region, with the other hand, through the abdominal wall, in several instances. After the first one or more treatments, the point does not always stop at the fornix, but enters the tube readily, as was the case in the instance where Dr. Manton verified my observations. I have always exercised great care to avoid force, simply guiding the electrode, with my hand supported at the forearm. With this precaution, and the low current used, I do not think the danger of perforation is as great as is sometimes represented.

(To be continued.)

Philadelphia Pathological Society.—The semi-annual conversational meeting of the Philadelphia Pathological Society will be held in the upper hall of the College of Physicians Building, Thirteenth and Locust Streets, on Thursday, April 26, 1894, at 8 P.M. Dr. Simon Flexner, Associate in Pathology in the Johns Hopkins Medical School, will deliver an address entitled, "An Experimental Study of the Nature and Action of Certain So-called Toxalbumins." Members of the medical profession are cordially invited to be present.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, APRIL 7, 1894.

THE DEPARTMENT OF PUBLIC HEALTH.

The AMERICAN MEDICAL ASSOCIATION four years ago set about the task of securing at the hands of Congress a Department of Public Health, and the committee appointed for that work has been steadily at work. Much has been done to clear the way to united action, and but for the hasty and ill-judged action of the New York Academy of Medicine, the matter would already be far advanced. That the bill proposed by that body to establish a "Bureau" of Public Health, was singularly defective they now admit, and have withdrawn the original bill providing for sanitary districts and have substituted a much better one. It is, however, far inferior to the broad plan of a Department of Public Health.

The bill of the AMERICAN MEDICAL ASSOCIATION Committee, contents itself by forming the Department, and leaves the details of subsequent organization and development to the Department itself. It is not reasonable to suppose that Congress will ever create such a Department unless it means to be guided somewhat by its advice in rendering its work effective, so then at present there is only one thing to do, and that is to work earnestly to secure the passage of the AMERICAN MEDICAL ASSOCIATION bill, which we understand will be introduced in the Senate by the Honorable JOHN SHERMAN, of Ohio, and in the House by the Honorable JAMES B. McCREARY, of Kentucky.

We earnestly hope that the New York Academy of Medicine will cease to urge its "Bureau" scheme against the great measure now proposed by the ASSOCIATION.

It is said that the reason for holding back is that there is immediate probability of its passage, for certain very distinguished persons in authority are against another Cabinet office. In other words our legal brethren are so well entrenched in what they

now seem to regard as a right inherent in their profession, that the welfare of the country forms no part of the argument.

We know we are right in making this request for a substantial recognition of our profession. A first class sanitarian in the Cabinet would be one of its most useful members; let us therefore make no halt in our efforts toward securing this result. Our ASSOCIATION reaches every Congressional district; let every member write to his member of Congress and ask his unqualified support of the AMERICAN MEDICAL ASSOCIATION bill, "to establish a Department of Public Health;" and to oppose any bill having for its purpose the establishment of any alleged "Bureau of Health."

It may not and very likely can not be passed at this session, but let us make the attempt, and if we fail, let us obtain from the candidates who will be nominated for Congress during the coming summer, a categorical and definite answer to the question, Will you, if elected, favor the bill to create a Department of Public Health? Let us put this question to every candidate this summer and we will have some definite result from the next Congress. In a free country with ballots in our hands, we are not helpless if we make organized effort. Medical societies in affiliation with the AMERICAN MEDICAL ASSOCIATION, and those in sympathy with the movement should lose no time in passing resolutions favoring the establishment of a Department of Public Health, and copies of these resolutions should be forwarded by the secretary of the society to the members of Congress from the district in which the society is located.

The petition framed by the committee, which was published last week, while rather lengthy, furnishes in proper form the most cogent reasons for the passage of the bill: The prevention of disease; the amelioration of suffering; the improvement of the condition of the poor, and the lengthening of human life are objects sought to be attained by the proper utilization of the powers and forces of our Government. To this beneficent and patriotic work our noble ASSOCIATION joining the American Public Health Association, has set its hand, and let us see to it that when we ask for this great establishment we are not given a petty Bureau.

Let us also insist that whoever of our profession shall be entrusted with this great work, after the formation of the Department, shall be clothed with such rank as shall make his office equal in dignity to those held by the members of the legal profession.

THE ASSOCIATION TRAIN.

We respectfully urge upon members who intend going to San Francisco to concentrate on the Association Train wherever possible; by that means we

shall go to California in a body and give a more favorable impression of the ASSOCIATION, than to scatter and travel singly or in squads.

The following is the itinerary: The train will arrive at Colorado Springs May 30, 8 A.M. Visit the Springs and Manitou, if desired take a ride through the "Garden of the Gods." Leave Colorado Springs 1 P.M., for Denver, where there will probably be a reception by a resident committee of the Colorado Medical Society. From Denver the schedule is so arranged as to make a daylight ride through the heart of the Rockies to Glenwood Springs, at which point a stop of several hours will be made, the baths can be taken, and then proceed to Salt Lake City; arrive there early in the morning, remain all day, which will give an opportunity to visit all points of interest, and leave that night for San Francisco direct, arriving on the morning of June 3.

The early start guards against all possible contingencies of delays or accidents.

There are several side trains which have been managed by medical gentlemen in the interest of opposition lines to the one selected by the Trustees,—we regret extremely that we could accept but one line, but we were compelled to travel by one route. By the arrangement as consummated there are no free passes on account of the ASSOCIATION. Those traveling on passes would travel in that way whether there were an officially designated train or not.

The arrangement with the respective companies is, that our Treasurer pays at current excursion rates for the transportation of all officers for whom the ASSOCIATION treasury regularly pays the transportation, and the respective railroad lines pay at current rates for the advertising in the JOURNAL. By this arrangement the ASSOCIATION treasury, and not any particular individual is the beneficiary.

The cash expense of transportation, (which is no trifling matter) at a meeting so long a distance, has thus been prevented, and we feel sure that when this fact is known to the ASSOCIATION there will be but one mind as to the way of travel. The rates promised are, for the present, the Midwinter excursion rates, without extra charges for the delays in Colorado and Salt Lake. Should at the last moment any reduction in rates be offered by any other line, the line selected by the ASSOCIATION, the Santa Fé, has agreed to meet it.

THE DEATH OF BROWN-SEQUARD.

The newspaper notices of the death of this eminent physician afford a singular example of the difference between notoriety and fame. The largest and oldest morning paper in Chicago in its announcement says:

"PARIS, April 2.—PROF. BROWN-SEQUARD, the eminent physician and physiologist, known chiefly to the world at large as the discoverer of the so-called 'elixir of life,' died here to-day."

Thus apparently in the eye of the public, his long

and useful life, full as it was of the record of painstaking physiologic and therapeutic research, was overshadowed at one stroke by a single ill-advised and faulty publication written in old age. His experiments on the physiology of the nervous system, and his able deductions therefrom, are the scientific works by which his friends will choose to remember him, and to have his name transmitted to posterity. They will refer with admiration to his published works, and to the story of the prizes granted him by the Academy for original discoveries. They will wish to blot out from the record that last act in the drama of his life, whereby he very nearly caused his professional brethren of the entire world to palm off on the public a pretentious fraud. Let this be forgotten as the vagary of an old man, undergoing senile cerebral changes. Let the medical historian, like the Recording Angel who wrote down the oath of UNCLE TOBY, blot out the record of the "elixir" with a pitying tear.

In the Necrology column we give a summary of the life and professional services of this truly great man; a record which few have surpassed, and which will endure as a monument to his patient industry and powers of research.

ANOTHER WELL-INTENDED LAW IS FOUND INVALID.

Whatever may be the personal estimates placed by different individuals upon the doubtless well-intended Michigan Act, No. 207, of 1893, popularly known as the "Jag Cure Act," the Supreme Court of that State has pronounced it unconstitutional. This it has done in the case of the Senate of the Happy Home Club v. Board of Supervisors of Alpena County, decided Feb. 20, 1894. The statute in question provided that from any person charged or complained against as being a disorderly person on account of drunkenness or intoxication, the court, or justice, might accept a recognizance conditioned that such person would take treatment for the cure of such drunkenness or intoxication, of some corporation organized within the State for administering such cure and required by law to make and file reports in reference thereto, within a time specified, and conform to the rules and regulations of the corporation administering such cure, and that he would not drink intoxicating liquor for the period of three months, and upon his appearing before the justice at the end of sixty days, and showing that he had conformed to the conditions of the recognizance up to that time, he should be acquitted and discharged. This, in effect, the Court says, would permit unofficial persons to prescribe rules which should acquit persons charged with crime. The rules of the corporation referred to might be lax or stringent; but, whatever they were, the justice had only to acquit if

they were shown to have been complied with. They might be as variable as the corporations prescribing them were numerous. But it was not within the province of the Legislature to delegate to private corporations the power to make laws for the discharge of offenders. And therefore, this statute was invalid.

THE ARMY HOSPITAL STEWARDS.

The Hospital Stewards of the Army are urging their claims to recognition as one of the educated army classes, by endeavoring to procure such legislation as will give them rank and special commissions in the Medical Department.

In the old Army any bright soldier was likely to be selected by a Surgeon and detailed as Acting Hospital Steward by the Commanding Officer. In the hospital he picks up the names of the more common drugs, learns after a while to compound simple prescriptions, and perhaps to apply a bandage.

If the same conditions were now present there would be little reason in their claim, but the practice now is to secure registered pharmacists whenever possible for such appointments. They must enlist as soldiers, but it is with the distinct understanding that they will be appointed to the non-commissioned staff as Hospital Stewards immediately after enlistment.

These Stewards are clearly entitled to whatever improved standing the later and more exacting requirements should bring them, and whatever consideration is due the modern educated pharmacist is due the Hospital Steward. He is or should be a chemist, a botanist, a pharmacist, a bookkeeper and correspondent, acquainted with the details of hospital administration, and become an expert drill master in the Hospital Corps drill.

That the Government should demand all this and withhold recognition either in adequate pay or military honor, seems a pity.

PHYSICIANS' AND SURGEONS' INSTRUMENTS ARE MECHANICAL IMPLEMENTS.

The Board of U. S. General Appraisers at New York hold, in a decision of theirs rendered Dec. 30, 1893, that, following a fair construction of the language of the Supreme Court, instruments used by the physicians and surgeons of a hospital for the purpose of carrying on their professions, are mechanical implements—implements for carrying on the professions of medicine and surgery—and can not be classed as either philosophical or scientific instruments or apparatus, for the assessment of duties, when imported, and can not be admitted free.

Blank Applications for membership in the ASSOCIATION at the JOURNAL office.

CORRESPONDENCE.

Rates to the Association Meeting.

ROCKFORD, ILL., March 22, 1894.

To the Editor:—The encouragement being promulgated through the JOURNAL and the Pacific Coast medical press to members of the ASSOCIATION to turn out and make the June meeting a grand success is in every way very commendable and proper; but to the large body of the rank and file of the medical profession—those who do not hold office in the ASSOCIATION; those who do not hold office under the United States Government, or under the government of some one of the larger transportation companies; for all the members living east of the Rockies or the Mississippi, the serious question confronting them is *transportation*. Distance makes this a very important factor toward securing an attendance. Time will be consumed in transit and attendance, to say nothing of sightseeing; and absence from home to most of us means arrest of income; which added to the ordinary expense of travel, consumes a large share of the hard accumulated wealth of the busy domestic, or house-to-house visiting physician of the smaller towns and country surrounding. These are the men whom it is the alleged object of the ASSOCIATION to benefit. They are not dispensers of drugs, but faithful conveyors of the current knowledge of medicine to the people, where the *higher* lessons of the ASSOCIATION teachers find a fertile soil for propagation and successful growth. But, unless cheap rates are guaranteed, the combined arguments of the ASSOCIATION and Pacific Coast journals will *not* secure an attendance worthy of being called an AMERICAN MEDICAL ASSOCIATION. Cut rates will have been, by the time of the meeting, abolished, regular rates established, and with the question of transportation for the editors of influential journals and officers of the ASSOCIATION settled, some of the "members" will recognize the financial necessity of remaining at home and taking their medical nutriment from the soup-houses of the enterprising dailies or advertising medicals.

At the Detroit meeting we had "one fare" from Chicago; at Milwaukee "one and one-third," while last winter for the occasion of the winter holidays the students of the Michigan University had a round trip of four dollars, Detroit to Chicago. The last meeting at Washington gave us a "one and one-third" and two weeks later gave the Tunkers—an unimportant society—"one rate" to a small town in Maryland near Washington, with *two* stop over privileges each way. If distillers' or brewers' or millers' or grocers' associations want to meet in national convention for acknowledged purposes of private gain, they can invariably secure better rates of transportation than the AMERICAN MEDICAL ASSOCIATION does. Ministers, active or retired; high church and low church—some so low as to solicit life assurance or peddle homeopathic pellets—have half fare permits freely urged upon them at the beginning of every year over *all* lines in their territory. Yet who does more for the care of unemployed and unfortunate wrecks that railroad corporations every year make and cast adrift upon our communities than the local doctors? Who do they call upon for earliest aid and forget to pay when they have disasters like Kankakee, Chatsworth or Ashtabula? Who averts for them the conveyance of contagion and avoidance of sickness and accident in incidental travel so much as the doctor, whose keen and trained habits of observation turn on every train to aid some unfortunate, delirious with headache, ready to plunge from the platform; or suggests to the superintendent a sanitary precaution at station or on board that increases the pleasure of travel as well as revenue of stockholders? And yet when we meet in annual convention they usually

exact the outside limit of fare for transportation from us. Please say a word for us. We are as eager to learn as your city *confrères*; we work hard and conscientiously, and would appreciate the favor of a low rate of transportation for ourselves and families across the continent as much as the most exalted officer of the ASSOCIATION.

DANIEL LICHTY, M.D.

Twenty-one years a member of the ASSOCIATION.

More Trouble for Medicus.

BOSTON, March 26, 1894.

To the Editor:—It was with great regret that I saw the article signed by "Medicus" which appeared in your JOURNAL of this week's issue. Whether or not the Code was violated in accepting the advertisements referred to, I will not discuss, but it appears to me that "Medicus" lacks very much in ethics and you, Mr. Editor, showed a great lack of discretion in allowing such an abusive article to appear. "Medicus" does not show very much logic in being personally abusive and bringing up the race question in a purely medical discussion. A physician and a gentleman ought not to resort to such methods. Why does not "Medicus" sign his name to his article? Is he afraid—or perhaps he has some interest in those new and wonderful remedies? Or perhaps he is a boomer to the syrup of figs cure. I shall be obliged to you if you spare a little space in your JOURNAL for this article.

Yours respectfully,

J. W. ELKINS, M.D.

Baltimore Medical College—A Correction.

BALTIMORE, March 28, 1894.

To the Editor:—In your issue of the JOURNAL of March 17, 1894, I observe in your editorial, p. 394, you state the Baltimore Medical College is a two-year school, *i. e.*, graduates students after attendance upon a two-year course of lectures.

This school *is* and *has* been a member of the AMERICAN MEDICAL ASSOCIATION since its organization in Nashville four years ago. Its name will be found among the schools primarily suggesting a convention for the three-year movement.

The American Medical College Association permits all students who matriculated prior to July 1, 1892, to apply for graduation at the end of two courses of lectures. The only students therefore that can possibly apply for graduation at end of second course in any school, a member of the Association, are those who so matriculated. All other *must* be and *are* pursuing a three-year graded course.

Our school is a three-year school, *precisely* as are other schools in the Association, governed by the same laws. I trust you will make the necessary correction in the next issue of the JOURNAL, as the editorial in question, in stating the matter is in error.

Yours very truly,

DAVID STREETT, M.D., Dean.

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Rio Grande Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville, Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland, thence east by way of the Northern Pacific R. R. to St. Paul. C. M. & St. P. R. St. Paul to Chicago. A stop over at Yellowstone National Park for those

who desire it has been arranged, and it has been understood that at several places on the journey there will be short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentrating on this train should be effected at Chicago and St. Louis. For all information relating to this train, fares, etc., address J. M. Connell, 212 Clark st., Chicago, or any agent of Santa Fe line in other cities. Rates promised are the lowest excursion rates at time of departure.

This is the only route on which arrangements have been perfected by the Trustees.

Transportation Rates.—The Committee of Arrangements has worked indefatigably on the matter of transportation rates, trying to get a round trip for a single fare.

By advice of Mr. T. H. Goodman, General Passenger Agent of the S. P. Co., who furnished addresses, we sent out circulars to agents of all roads interested in the matter.

About one-half of those replying favored our petition and promised to advocate it before their respective associations, through which all such matters must be arranged.

The following communications from Mr. Goodman place the matter as it now stands, in a clear light:

"SAN FRANCISCO, March 16, 1894.

"Dr. R. H. Plummer, Chairman Committee of Arrangements, American Medical Association, 652 Mission Street, San Francisco.

"Dear Sir:—This morning's mail brings us your yesterday's letter, handing for our perusal three letters from Eastern railway officials. Having read the letters you sent, we return them herein and beg to emphasize our previous statements to you in person and by letter, that the Trans-Continental roads have virtually done what you ask, namely: accorded a one-way rate.

"In other words, the rate for a thirty-day ticket from Missouri River points to San Francisco is \$60. Excursion, that is round-trip, tickets, Missouri River points to San Francisco and return, are being sold to-day at a rate of \$65.50. Such tickets require the going trip to be made within fifteen days from date of sale, and the return trip within fifteen days after the day upon which the ticket is signed here in presence of a railroad agent, but in no event later than July 15 next.

"We have told you that within the State of California we ignore the fifteen-day limit on both going and returning trips; in other words, that the holders of the tickets are at liberty to move at will within the State of California within the life of the ticket, and that the fifteen-day limit returning is not enforced west of our terminals at Portland, Ogden and El Paso.

"You have asked our permission to state positively that these Midwinter Fair rates would be in force at the time attendants at your convention will want to move westward. We have replied that the traffic is west bound traffic, and that we do not control the matter. You will doubtless, however, recollect our telling you that this rate would, in all probability, hold until after that period. We gave you our reason for that statement, namely: that one of the roads had announced that it would continue the sales up to June 30.

"We appreciate your desire for an authoritative statement in this regard. As we can not make it, we will write you that we feel you are quite safe in stating the fact that such rates have been announced, and that the sale would continue until that date.

"We beg to again call your attention to one point, which is quite material in this matter: The Trans-Continental roads having virtually done what you asked, you should bring all the influence to bear that you can upon the roads east of the Trans-Continental roads. Those roads are, for the most part the ones forming the Western Passenger Association, the Central Traffic Association and the Trunk Line Association. The Western Passenger Association roads lie between the Missouri River and Chicago and St. Louis. You should go to them for a rate similar to our Midwinter Fair rate. They tell you their rate will be \$20, Chicago to Missouri River and back, and \$12 St. Louis to Missouri River and back. As the single-trip rate, Chicago to Missouri River, is \$12.50, and from St. Louis \$7.50, you will see that their rates are not reduced nearly as much as the Trans-Continental road rates. Can you not through some of your

profession at Chicago approach the General Passenger Agents of the lines leading from Chicago whose names we have given you? We think they will appreciate the importance of the occasion.

"One of our assistants has in hand the matter of reduced rates locally, and you will be shortly advised.

Respectfully yours,

T. H. GOODMAN."

Extracts from letter of Feb. 12, 1894:

"The rates thus continued are as follows: \$65.50 from Missouri River points, being Sioux City, Council Bluffs, Omaha, Pacific Junction, St. Joseph, Atchison, Leavenworth and Kansas City; \$77.50 from St. Louis, Cairo, Memphis and New Orleans.

"The rates mentioned to you exceed the one-way, thirty-day rates as follows:

"That from the Missouri River by \$5.50; that from St. Louis, Cairo, Memphis and New Orleans, by \$10, and that from Chicago (\$85.50), by \$13.

"We deem it but proper to here mention that if our Shasta Route between San Francisco and Portland is passed over on either going or returning trip from Missouri River, St. Louis or Chicago, the rate will be \$15 greater.

"As on this occasion passenger movement is from the East to the West, it is but proper that the question of rates should be taken up with officials of Eastern roads. We suggest, therefore, that you correspond first with those who have charge of the passenger traffic of the so-called Trans-Continental Association roads. They are as follows:

"For rates from the territory lying beyond the Missouri and Mississippi Rivers, you should address Mr. B. D. Caldwell, Chairman Western Passenger Association, Chicago; Mr. F. C. Donald, Commissioner Passenger Department Central Traffic Association, Chicago; Mr. L. P. Farmer, Commissioner Passenger Department Trunk Line Association, New York; Mr. M. Slaughter, Assistant Commissioner Southern Passenger Association, Atlanta, Ga."

From the foregoing communications it will appear that, while we have not been wholly successful, if the roads between the Missouri River and Chicago, and between Chicago and Atlantic points where local travel far exceeds that over the Rocky Mountains, will give the same reductions as the roads from the Missouri River points to San Francisco, we will practically have a single fare for a round trip.

Can not the profession in the East, by united efforts, secure these concessions?

The time is growing short, and Chairmen of the several Sections should send in their reports, etc., for insertion in the program.

R. H. PLUMMER, Chairman.

San Francisco, March 25, 1894.

SOCIETY NEWS.

The Lucas County Medical Society of Toledo, Ohio, held its regular meeting March 19. The following officers were elected for the ensuing year: President, Dr. Wright; Vice-President, Dr. Foster; Secretary, Dr. Hunt; Treasurer, Dr. Waddick; the Executive Committee: Drs. McVety, Watson, and Heltman.

Academy of Medicine.—At the regular meeting of the Academy of Medicine of Cincinnati, held March 19, a resolution was introduced by Dr. P. S. Conner, protesting against the bill now pending in Congress to reduce the Medical Corps in the United States Army. The resolution was adopted by practically a unanimous majority.

Officers Elected.—At the meeting of the Chicago Medical Society April 2, the following were elected: Nicholas Senn, M.D., President; L. L. McArthur, M.D., First Vice-President; Harold N. Moyer, M.D., Second Vice-President; Arthur R. Reynolds, M.D., Treasurer and J. C. Hoag, M.D., Secretary.

Resolutions were also adopted expressing the deep sense of obligation of the Society to Prof. Senn for his donation to the Newberry Library.

Chicago Medical Society.—At its meeting, April 2, the Chicago Medical Society unanimously adopted a resolution indorsing the bill prepared and approved by the AMERICAN MEDICAL ASSOCIATION and the American Public Health Association for the creation of a Department of Public Health with a secretary who shall be a member of the Cabinet. The sentiment of the Society is that a Bureau of an existing Department, under the charge of a subordinate officer, as proposed by the New York Academy of Medicine, is not broad enough for the importance and magnitude of the interests involved.

The Illinois Army and Navy Medical Association.—The next meeting of the Association will be held in Decatur, Thursday and Friday, May 17 and 18, 1894.

It is the general desire that this shall be the best attended and most interesting meeting in the history of the Association. It will follow the meeting of the State Medical Society, which will convene in Decatur, Tuesday, May 15; thus the members of our Association who may be interested in the State Society will have an opportunity of attending both.

It is to be regretted that heretofore the attendance has not been such as it should have been; while all of the members are more or less responsible for that, still the failure in the past to gather the members of the Association is no reason why we should not now make a greater effort than ever before to have a well attended and good meeting. A meeting that shall bring together most if not all of the members who can possibly attend.

The old reaper, Death, is decimating our ranks from year to year; he is charging upon our lines and here and there our comrades are falling—bravely falling in the line of duty with their faces to the foe. They whose work it was, and who in the discharge of duty did so much in relieving suffering—and prolonging the lives of our brave boys—the heroes of 1861-'65—are themselves passing away rapidly. Many fell while in active duty during the struggle, many since then have surrendered to the common foe. Should not those of us who survive endeavor to meet annually; not only for the social pleasure and professional reunion; but to present papers, discuss them, compare the present with the past, the progress in surgery—especially military surgery—and topics akin to those which in times of war entered daily into the routine of our work, as well as those of later date which have been uppermost in our thoughts as we have been engaged in our life work. Is it not also our duty in fitting manner at our gatherings to honor the memory of those of our number who as years go by complete their work and become enrolled with the *Immortals*?

That an interesting program may be provided for our next meeting, we earnestly solicit a contribution from every member of the Association whether they can be present at the meeting or not. Will you not, dear doctor, at your first opportunity (and if one does not come by spontaneous generation, make one yourself) sit down—think awhile—arouse memory—stir up your cerebration, if need be—do it several times—and with pen, ink and paper, prepare a contribution, long or short, at your pleasure, that shall embrace some personal recollections of the part you had or observed while in the service as a surgeon or a soldier. It may be a story of some deed of heroism, on land or sea, by surgeon or soldier. It may be the history of a case of gunshot wound of more than ordinary interest. It may be a comparison of the then and present methods of treatment of wounds or diseases. But so many things will suggest themselves of interest, not only to yourself but associates also, and worthy of presentation. We will ask you to be guided by your own suggestions.

It is our further desire that what you do, you do quickly and transmit your paper to us if possible by April 15th prox. Also that you inform us at the same time, that you will, if possible, attend the Decatur meeting. The latter is important in order that we may know what calculations and preparations should be made for entertainment, and especially one evening when we think all would be pleased to gather around the festal board—a surgeon's campfire—for a pleasant social and intellectual time.

If there should be a general response from the members of the Association it will be possible for us to have material of such quality and quantity as not only to make our meet-

ing a very pleasant and profitable one but also of historic interest, worthy of preservation in the records or transactions of the Association.

We await with much interest your reply to this letter, for the success of our next meeting and the future of the Association is in your hands.

The party receiving this circular letter is requested to inform us of any death or change of residence among the membership of the Association during the year.

Please acknowledge the receipt of this letter. Address the President of this Association,

E. P. COOK, President, Mendota, Ill.

EDWARD P. BARTLETT, Secretary, Springfield, Ill.

Association of Military Surgeons of the United States.—The program of the fourth annual meeting of this Association has been issued. The Association will convene at 10 A.M. in Albaugh's Opera House, Washington, D. C. The President of the United States is expected to be present and to make an address. The Association of Military Surgeons of the National Guard of the United States was organized in September, 1891, at Chicago, Ill., by a corps of representative members of the Guard from more than half of the States of the Union and several officers of the Medical Department of the U. S. Army, with many veteran surgeons, ex-officers of our volunteer army during the Civil War. The objects in view were announced as: The bringing of military medical officers in closer personal relations, and the development of a department *esprit de corps*, for the discussion of matters relating to the medical department of the militia, for the discussion of military matters from a medical and scientific point of view, for the reading of papers on military medicine and surgery, hygiene and equipment, and for the advancement and welfare of our civilian soldiers, whether in the field or at home. The Association was reorganized in August, 1893, under its present title. The roster includes active, honorary and contributing members. The active members are commissioned medical officers of the Army, Navy, Marine-Hospital Service and National Guard or Volunteer Militia of the United States. To honorary membership are elected men who have been in the medical service of the National Guard or in the medical department of the Regular Army or Navy and Marine-Hospital Service, or in that of the National Homes for Disabled Volunteers and any distinguished military or naval surgeons from any part of the world. Any person may become a contributing member by assisting in furthering the objects of the Association. At the present time there are 185 active, 42 honorary and 3 contributing members. The President is Colonel Nicholas Senn, Surgeon-General of Illinois National Guard; Vice-President, Colonel B. J. D. Irwin, Assistant Surgeon-General U. S. Army; Second Vice-President, Colonel Louis W. Read, Surgeon-General Pennsylvania National Guard; Secretary, Lieutenant-Colonel E. Chancellor, Missouri National Guard; Assistant Secretary, Captain J. M. Cabell, Assistant Surgeon U. S. Army; Treasurer, Major L. C. Carr, Ohio National Guard; Chairman Committee of Arrangements, 1894, Major George Henderson, Surgeon-General District Columbia National Guard.

It is earnestly requested that the Surgeon-Generals of the States send samples of "litters" for exhibition at this meeting, such as they now use, of anything peculiar or novel in them. The Army and Navy will show the different patterns of litters they have in use, and it is surmised that much profit and practical good will result from this interchange of views. It is estimated that the expense of sending litters to Washington will be comparatively small.

An exhibition of the field appliances and work of the Medical Department of the United States Army will take place at one of the morning sessions, and it is expected that a competitive Ambulance Corps Drill will be one of the many attractions at this meeting.

On the evening of the first day there will be an informal reception and collation at the Ebbitt House.

On the evening of the second day a reception by the President at the White House is anticipated.

The afternoon and evening of the third day the Committee has planned an enjoyable trip on a palatial steamer, down the historic Potomac, making a landing at Mount Vernon for an hour, and then speed on down the river to

Marshall Hall, the home of Chief Justice John Marshall, and there partake of a popular and elegant "plank shad bake," and return before midnight.

A committee of ladies will look after the comfort and welfare of all ladies in attendance on this occasion.

It is very important that the Committee of Arrangements should know as early as possible if you will attend this meeting, and how many will form your party, and the hotel accommodations desired.

The fatigue uniform will be worn during the day and full dress with side arms at all evening entertainments; otherwise, the civilian *full dress*, with the Association button must be worn.

The following are the papers expected to be presented at the meeting:

President's address, "Abdominal Surgery on the Battlefield," Col. Nicholas Senn, Surgeon-General Ill. N. G., Chicago, Ill.

SYMPOSIUM ON TRANSPORTATION OF THE SICK AND WOUNDED.

"History," Col. Chas. H. Alden, Ass't Surgeon-General U. S. A., Washington, D. C.

"Litter," Major Valery Havard, Surgeon U. S. A., Fort D. A. Russell, Wyo.

"Travois," Major John Van R. Hoff, Surgeon U. S. A., Governor's Island, N. Y.

"Railway," Col. Louis W. Read, Surgeon-General N. G. Pa., Norristown, Pa.

"On Board Ship," Albert L. Gihon, Medical Director U. S. Navy, Washington, D. C.

"Ambulance," First-Lt. Myles Standish, Surgeon Mass. V. M., Boston, Mass.

"Notes on the Introduction of Tent Field Hospitals in War," showing the advantages of treating military invalids under canvas on the battlefield, instead of buildings improvised for hospitals, by Col. B. J. D. Irwin, Ass't Surgeon-General U. S. A., Chicago, Ill.

"The Medical Officer at the Summer Encampments," by Lient-Col. Chas. R. Greenleaf, Deputy Surgeon-General U. S. A., San Francisco, Cal.

"Easy Methods of Carrying Out the Principles of Aseptic Surgery," by Col. Robt. Reyburn, Late Surgeon and Bvt. Lt-Col. U. S. Vols., Washington, D. C.

"Equipment and Instruction of Sanitary Soldiers," by Capt. Chas. F. Mason, Ass't Surgeon U. S. A., Ft. Snelling, Minn.

"A Field Kitchen Wagon." For cooking food and sterilizing dressings at dressing stations and on the march, by Capt. H. O. Perley, Ass't Surgeon U. S. A., Plattsburg Barracks, N. Y.

"The Personal Equipment of the Sanitary Soldier," by First-Lt. Geo. D. DeShon, Ass't Surgeon U. S. A., Fort D. A. Russell, Wyo.

"The Action of Rattlesnake Venom upon the Bactericidal Power of the Blood Serum," by Capt. Chas. B. Ewing, Ass't Surgeon U. S. A., Fort McHenry, Maryland.

"The Relation of the National Guard Surgeon to the Medical Profession and to the Community," by Capt. T. C. Clark, Ass't Surgeon N. G. Minn., Stillwater, Minn.

"Sabre Wounds," by Col. R. E. Giffen, Surgeon-General N. G. Neb., Lincoln, Neb.

PUBLIC HEALTH.

Cholera in Constantinople.—The Greek Government announces the receipt of a dispatch from Constantinople stating that nine cases of Asiatic cholera, three of which proved fatal, occurred in that city within the few days prior to March 23.

Leprosy in Kentucky.—Dr. D. B. Schoolfield, of Dayton, Ky., reports a case of leprosy at that place. The patient is a 14-year old boy whose father says the disease was contracted at Key West, Fla., where the family formerly lived. The premises have been put in quarantine by the local health officer.

Scarlet Fever in Schools.—Students in the college at Winnebago City, Minn., and in the Union Theological Seminary, New York City, have been taken down with scarlet fever, and at the former place the college, churches and schools have been closed by the authorities. The theological student is believed to have contracted the disease in a horse car.

Typhoid from Cow's Milk.—An apparently well-authenticated outbreak of enteric fever from typhoid-infected milk is reported from Montclair, N. J. Some thirty families had been affected up to date. These, it is claimed, were all supplied with milk by a dairyman in whose family two children had been ill with typhoid fever for some weeks before the outbreak.

A Dangerous Nostrum.—Health Commissioner Reynolds, of Chicago, has analyzed a sample of a nostrum called "Birney's Catarrh Cure," sold indiscriminately by many druggists. He found 4 per cent. of cocain in the sample and adds that "the indiscriminate use of such a remedy is dangerous in that it may be used to excess, and then the dangerous properties of the contained remedy will become apparent. The amount of cocain in Birney's Cure is sufficient to develop the cocain habit when it is used persistently and in quantities."

New York State Board of Health.—The inquiry into the management of the New York State Board of Health, by a special committee of the State Senate, still drags its slow length along. At a recent session Dr. Lewis Balch, the Secretary, recalled to the witness stand, said he had some time ago intended to resign, but on being informed that charges were to be preferred against him he had postponed handing in his resignation. In answer to a direct inquiry he said he now intended to resign his office in the coming May.

Smallpox having appeared in two almshouses in Illinois, to-wit: at Libertyville, Lake County, one case, and at Edwardsville, Madison County, fifteen cases, the State Board of Health has renewed its order for the summary vaccination of all inmates of such institutions throughout the State. Secretary Scott has also urged the immediate vaccination of all employes of railway companies. Secretary Probst of the Ohio State Board and Secretary Metcalf of the Indiana State Board have taken similar action. Responses from the railways indicate a general compliance and some companies have made recent vaccination a condition of employment.

A Boycotted Water Supply.—The typhoid epidemic at Ashland, Wis., has been ascribed to the Ashland Water Company and, as a result, the use of the water furnished by

the Company has been almost entirely abandoned—its place being taken by spring water from driven wells and from the Weber Mineral Springs near the town. The Water Company insists that the water it supplies is pure and its proposition to pay the expense of analyses, to be made at frequent intervals by experts whom the Ashland Medical Society shall designate, has been accepted by the Society. Meantime, and incidentally with the boycotting of the Water Company's supply, the epidemic is abating.

Sanitation of the Cholera Centers.—In accordance with the agreement made at the recent International Sanitary Conference at Paris, heretofore referred to in the JOURNAL, the Sultan of Turkey has sent a special mission to the Yemen under Marshal Assaf Pacha, to superintend the sanitation of the "holy places." Various establishments for the accommodation, boarding and medical treatment of the pilgrims are being constructed; asylums, hospitals and dispensaries are being built; the wells are being cleansed and disinfected; the tanks are being increased in number and a large and competent staff of physicians is stationed at Mecca—the shrine of the Prophet—Medina, El Thor and at the Red Sea ports where the pilgrims land.

Typhoid in Buffalo.—The epidemic of enteric fever in Buffalo, N. Y., which the late Dr. Rauch was investigating for the JOURNAL at the time of his death, seems to have attained its maximum about March 21, up to which date 414 cases with 21 deaths had been reported from the beginning of the outbreak, March 6. A few additional cases and deaths have since been reported from day to day up to the close of the month, but the epidemic, as such, is substantially ended. The cause of the outbreak is not yet decided, but investigations are in progress which, it is hoped will determine this important point. Bacteriologic examinations of the Niagara River water, taken at the Bird Island inlet, point to typhoid contamination of the water supply.

State Hospital for Consumptives.—A short time ago the Secretary of the Michigan State Board of Health read a paper in which he advocated special hospitals for certain classes of consumptives. Now he is being inquired of relative to a *State Hospital for Consumptives*. One letter is as follows:

"Now suffering from consumption, I write for what advice you may give me that will be of use to me in taking care of myself and preventing its spread. I had the grippe over two years ago, and a severe cold, and my left lung has troubled me ever since. I have been told that there is a building being erected to be used as a hospital for the care of consumption, free to all those that are not able to pay—the State of Michigan to stand the expense. If there is such a place, I would like to be treated as soon as they are ready. Hoping to hear from you soon, I am, very respectfully," etc.

Undoubtedly many lives could be saved in Michigan if poor persons suffering from this most dangerous communicable disease could be placed in a special hospital, where under well-planned rules and trained attendants the danger of spreading the disease shall be reduced to the minimum. The disease is spread in several ways, one of the chief being by the dust from the dried matter which is coughed up and expectorated, such infectious dust being breathed in by whoever comes within the area of the infection.

A letter from a Health Officer reads as follows:

"Inasmuch as you have decided to put consumption in the category of contagious diseases (which ought to have been done long ago), I write for a little advice. We have a pauper of the township who has been afflicted with consumption for a year or two. The supervisor boards him at one of the hotels in the village of —, where he has the use of the sitting-room, office and bar-room, as he is yet able to be around. Besides using the floors and cuspidors he is in the

habit, most every morning, of standing on the porch and coughing up a half teacup or more of sputa and expectorating it upon the sidewalk. I have labored with him, the proprietors, and the supervisor to prevent such an exposure to others, but of no avail. I have tried to get the supervisor to send him to the county house, but don't succeed. What am I to do?"

The Secretary of the State Board of Health estimates that there are in Michigan in every year about three thousand *new cases* of consumption, and that in each year about that number of persons die in Michigan from consumption. He believes that in each year possibly hundreds of these *new cases* might be prevented by such provision by the State as would care for a few hundreds of poor persons having consumption of the lungs, and who are now expectorating and scattering the seeds of consumption broadcast, to rich and poor alike, through hundreds of communities.

If the State Legislature does not soon make such provision, perhaps some philanthropic millionaire may see in this proposition a useful service which he may easily do for the welfare and happiness of the people. The establishment of such a hospital for the *prevention*, as well as for the cure, of this disease which now causes the most deaths, would indeed be a noble act, and a grand monument to the memory of the founder.

HENRY B. BAKER, Secretary.

Office of the Secretary of the State Board of Health, Lansing, March 24, 1894.

Legal Sequelæ of Vaccination.—In refusing an injunction to restrain the school directors of Williamsport, Pa., from excluding unvaccinated pupils from the public schools, Judge Metzger held that the directors have the power, delegated to them by the Legislature, "to exercise a general supervision over the public schools of their district" and that with the exercise of this power no court has authority to interfere. This "general supervision" implies the power to make any rule, or regulation, which may be deemed necessary for the prevention of the spread of disease among the pupils attending school. "Vaccination," said the Judge, "is a sanitary regulation, intended to protect the health of the pupils. No one would doubt their power to exclude a pupil from school if its parents or any member of the family in which it resided was afflicted with smallpox, or any other malignant disease that was contagious. A rule excluding all such would be regarded as reasonable and proper. Why then should an order excluding all not vaccinated, and who refuse to be vaccinated, be held unreasonable and beyond the power of the directors to enforce?" . . . In some States the Legislature have provided by statute for the exclusion from school of persons not vaccinated, although otherwise entitled to admission. This is so in Maine and in Massachusetts. And in *Abell vs. Clark*, 84, Cal. 226, it is held to be competent for the Legislature to require pupils of the public schools to be vaccinated. If the Legislature can do so, then it is also competent for the body to whom it has delegated its power over the public schools to do likewise. It has delegated to the school boards of the respective districts the power of general supervision over public schools. This power in controversy contravenes no law and violates no principle of morality or public policy. On the contrary, the welfare of the public demands that at particular times such orders should be enforced."

In a suit to restrain the principal of a public school from enforcing the vaccination order of the Terre Haute, Ind., local Board of Health, the court decided to hear testimony as to the efficacy of vaccination, notwithstanding the opinion of the Supreme Court of California, in a similar case, that vaccination having been accepted by the world of science it is no longer an open question. The Indiana State Association of Anti-Vaccinationists is backing up this suit as a test

case. Among the witnesses was one, 70 years of age, who testified that he "had suffered from the bad effects of being vaccinated at 2 years of age." Had he not been then vaccinated there is no telling how old he might now be. Dr. Caldwell, a Terre Haute physician, testified that he knew of two deaths which he attributed to vaccination, but he said he would not treat a smallpox patient unless he had himself been vaccinated. A man named Rhodes testified that he was vaccinated in 1881 and that six years afterward a running sore came on his leg and that he has suffered ever since. Mr. and Mrs. Tusche testified to having had the smallpox after being vaccinated, one thirteen years and the other twenty years afterward—the inference being: No vaccination, no smallpox. And such are the end-of-the-century arguments against vaccination in Indiana—and elsewhere.

The school board of Utica, N. Y., having disregarded the advice of the local board of health on the enforcement of vaccination of public school children—replying to such advice that it would enforce vaccination when it "got good and ready" and threatening the health board with legal action to make it keep "hands off"—the health authorities cite the following sections of the New York statutes:

"No child or person not vaccinated shall be admitted or received into any of the public schools of the State, and the trustees or other officers having the charge, management or control of such schools shall cause this provision of law to be enforced."

"A person who wilfully violates any provision of the health laws, the punishment for violating which is not otherwise prescribed by those laws or by this code; and a person who wilfully violates or refuses or omits to comply with any lawful order or regulation prescribed by any Board of Health or health officer, or any regulation lawfully made or established by any public officer under authority of the health laws, is punishable by imprisonment not exceeding one year, or by a fine not exceeding \$2,000, or both."

Based upon these the Board of Health orders that no child shall be admitted into any school, public or private, in Utica unless vaccinated within four years prior to date of admission; and formally notifies the school board and the superintendent of public schools to comply with and enforce this order under penalties authorized by the statutes.

At Mt. Erie, Wayne County, Ill., a criminal suit was brought against the school directors for enforcing the school-vaccination order of the State Board of Health. Justice Dogberry—it could have been none other than he who delivered the famous charge to the watch—fined the school board \$1 for the first offense and, on a second suit, imposed a fine of \$2—under what provision of what statute has not yet been discovered. The State Board of Health had the cases appealed to the circuit court where they were promptly dismissed, the prosecution abandoning them. A civil suit for \$2,000 damages has been brought by parents of school children against the St. Francisville, Lawrence County, Ill., school board on the same ground as in the Mt. Erie cases. The State Board of Health will defend in this suit, which is still pending.

BOOK NOTICES.

Essentials of Physics. By FRED. J. BROCKWAY, M.D. Second Edition. Crown 8vo, 320 pages, 155 fine illustrations. Price, cloth, \$1.00 net. Interleaved for Notes, \$1.25 net. Philadelphia: W. B. Saunders, 1894.

This book, which only claims to be a compilation, will be found extremely useful to students preparing for entrance examinations, and as well to seniors wishing to refresh their minds on the subject of physics. The various attributes of matter: light, heat, electricity and sound, are concisely and carefully stated. It is especially full on the subject of electricity.

Anomalies of Refraction and of the Muscles of the Eye. By FLAVEL B. TIFFANY, M.D. Author's Edition. Kansas City: Hudson-Kimberly Publishing Company, 1894

In this neat little illustrated volume of about 300 pages, the author has included the physics of vision, the methods of physical examination of the eye, and the anomalies of refraction, as well as of muscular balance. The subject is presented in the most elementary and easily comprehended

manner, and any one who does not have access to the larger text-books on ophthalmology can get condensed and well-digested information from its contents. But the topics are not treated extensively enough for the practicing oculist. The indispensable mathematical formulæ are omitted and the therapeutic directions are not sufficiently precise for application in practice. On various pages, views are presented (for instance on presbyopia and heterophoria) which do not correspond to what is generally known of these subjects. The work contains no literary references of any kind.

NECROLOGY.

Wm. Howe Harris, M.D., of Louisville, March 20, aged 60 years.—Geo. W. Stone, M.D., of Rome, Pa., March 14, aged 80.—J. Knox Thompson, M.D., of Petersburg, Va., March 19. Dr. Thompson was serving his second term in the Virginia Legislature.—Almon Lull, M.D., of Berkeley, Cal., March 16, aged 89.—J. W. Lambert, M.D., of Peoria, Ill., March 20.—John R. Logan, M.D., of Grand Forks, N. D., March 18. He was born at Fenelon, Ont., and graduated at Trinity College, Toronto.—A. P. Edgar, M.D., of Collins, Iowa, March 15, aged 40. He was a graduate of the Medical Department of the State University of Iowa.

CHARLES B. EDOUARD BROWN-SEQUARD.—The Island of Mauritius was the birthplace of Charles B. Edouard Brown-Sequard, who first saw the light there in 1818. His father, a Philadelphia sea captain, lost his vessel in an attempt to carry provisions to the people of the Island during a famine. The captain remained on Mauritius and married a lady named Sequard, and their son took both their names. He was partly educated in Mauritius, finishing his studies in Paris, where he received the degree of M.D. in 1846. He made radical discoveries in connection with the blood, and was awarded five prizes by the French Academy and twice received the Queen's grant for the encouragement of science, from the British Royal Society. His experiments with regard to the nervous system were also interesting and worked complete changes in the theories and practice of medicine. In 1858 he delivered lectures in London before the Royal College of Physicians and Surgeons. In 1864 he was appointed Professor of the Pathology and Physiology of the nervous system at Harvard University and held the chair four years, after which he returned to France and was given the Chair of Experimental and Comparative Pathology in the School of Medicine in Paris, which place he kept till 1871. In 1873 he came to New York and took up the practice of medicine. Five years later he returned to Paris and was given the Chair of Experimental Medicine in the College of France. He published many works of great value, and was in constant demand as consulting physician in important cases of nervous diseases. He considered himself an American, and was proud of the country of his father.

THE LEBANON COUNTY, PA., MEDICAL ASSOCIATION ADOPTS RESOLUTIONS ON THE DEATH OF DR. J. H. RAUCH.—A meeting of the physicians of Lebanon County was convened at the office of Dr. A. B. Gloninger, in Lebanon, March 27, at 11:25 A.M., attended by Drs. W. M. Guilford, H. H. Roedel, S. P. Heilman, J. W. Trabert, J. C. Bucher, G. L. Weiss, A. B. Gloninger, John Walter, W. F. Kline, J. A. Biever and C. W. Schmehl, to take action relative to the death of Dr. John H. Rauch. Dr. Guilford was called to the chair and Dr. Heilman was appointed Secretary. Dr. Guilford then gave verbally an interesting sketch of the career of Dr. Rauch, referring to his service to the medical profession in elevating its standard, and to the country and world at large in sanitary work, to his mission to various important foreign scientific and medical assemblages, his unselfish character his constant activity and his useful life in its entirety.

On motion it was ordered that a committee of three, to

include the President and Secretary of the meeting and Dr. Roedel, be appointed to draw up a suitable minute relative to Dr. Rauch, that the press of this city be requested to give publicity to the same, that a copy of said minute be furnished to the brothers and sisters of the deceased, that the members of the profession in Lebanon County be notified of this action, that they be requested to proceed in a body to the house from whence the funeral is to proceed, and also attend the service in a body.

W. M. GUILFORD, President,

Attest:—S. P. HEILMAN, Secretary.

At this meeting it was unanimously

Resolved, That by the death of Dr. John H. Rauch, the medical profession in the United States as well as in the whole civilized world, has lost an eminent sanitarian, who has devoted the most of his active life to the interests of public health; in many cases imperiling his own life in infected camps and cities to ward off the dread infectious diseases, cholera and yellow fever, and prevent their entrance into this country, or to limit their spread. His interest in the higher medical education and the elevation of his chosen profession was earnest and has resulted in great good.

Resolved, That the medical profession and the cause of science at home and abroad has sustained in the death of Dr. John H. Rauch an almost irreparable loss.

Resolved, That as a kind Providence decreed that he should return to the home of his youth to meet the last great event, we, his fellow physicians of Lebanon County, will honor his memory and pay the last tribute by attending his funeral in a body.

Resolved, That a copy of these transactions and resolutions be given to the public press of this city and an engrossed copy be sent to the bereaved family.

W. M. GUILFORD, }
S. P. HEILMAN, } Committee.
H. H. ROEDEL, }

MISCELLANY.

Has Practiced Half a Century.—Dr. Benj. F. Hart, of Marietta, Ohio, celebrated the fiftieth anniversary of his professional life, March 24.

The late Professor John Tyndall, the eminent British scientist, gave to Harvard, in 1885, the sum of \$10,000 to found scholarships for one or more students who may show decided talent in physics. This sum was part of the proceeds of lectures delivered by Professor Tyndall in America in 1872.

Hospital Notes.

THE GENERAL ASSEMBLY of Iowa has voted to locate the new northwest insane asylum at Cherokee, Iowa.

ROCHESTER STATE HOSPITAL.—The managers of the Rochester State Hospital are making preparations for rebuilding that portion of the institution which was recently destroyed by fire. The probable cost of the repairs will be \$65,000.

AN OVERCROWDED HOSPITAL.—The Presbyterian Eye, Ear and Throat Charity Hospital of Baltimore, has such a following that the building is now overcrowded. New patients admitted for treatment in the Free Dispensary exceed 1,200 each month since Jan. 1, 1894, and the attendance during this period has exceeded 10,000 persons. The Board of Governors have recently purchased contiguous property 150x30 feet for Hospital extension. This charity has become one of the largest special hospitals in the country.

Medical College Notes.

THE MEDICAL DEPARTMENT of the University of Wooster, Cleveland, Ohio, held its commencement exercises March 21, and conferred the degree of M.D. on ten graduates.

THE UNIVERSITY MEDICAL COLLEGE, of Kansas City, held its commencement March 20. There were nineteen graduates.

THE CLEVELAND UNIVERSITY held its commencement

March 20, and conferred the degree of M.D. on thirty graduates. Four graduates received the degree of D.D.S.

THE KANSAS CITY MEDICAL COLLEGE at its twenty-fifth annual commencement March 22, awarded diplomas to thirty-two graduates.

THE BARNES MEDICAL COLLEGE, of St. Louis, Mo., held its commencement March 20, and forty-two graduates received the degree of M.D.

THE LONG ISLAND COLLEGE HOSPITAL held its thirty-fifth annual commencement March 21. There were fifty-four graduates.

BEAUMONT HOSPITAL MEDICAL COLLEGE.—It is unofficially reported that the Beaumont Hospital Medical College of St. Louis, will be closed, and that the faculty will be consolidated with the College of Physicians and Surgeons.

ITS FIRST COMMENCEMENT.—The Wisconsin College of Physicians and Surgeons at Milwaukee graduated two students March 26.

STIRRING UP THE COLLEGES.—The Missouri State Board of Health is inspecting the medical Colleges of that State as to equipment, laboratory facilities and curricula of instruction. It has already examined eight St. Louis institutions and is this week examining the colleges in Kansas City, where there is trouble in the faculty of the Homeopathic College. As a result of the St. Louis inspections, the Deans of the St. Louis Hygienic College of Physicians and Surgeons, the Woman's Medical College and the American ("Eclectic") Medical College have been notified that they do not conform to the requirements of the Board and that, therefore, their diplomas will not be recognized as entitling their possessors to practice in Missouri.

The Hygienic College was notified to the same effect by the Illinois Board last winter, and the Dean of the American ("Eclectic") Medical College has been notified by Secretary Scott that an adverse report will be made at the next meeting of the Board by the committee which recently investigated that institution.

The Toledo (Ohio) Medical College has been restored to "good standing" by the Illinois Board.

RUSSIAN MEDICAL QUALIFICATIONS.—What is known as the "feldscher certificate"—a Russian medical qualification—is frequently offered in the United States as the equivalent of a diploma of the degree of Doctor of Medicine, and has been commonly accepted as such in States where the laws require a medical diploma as the basis for license to practice. Some time since the Illinois Board of Health undertook to determine the value of these certificates for the purposes of the Illinois medical practice act. An authoritative statement of the character of Russian medical qualifications has just been received by Secretary Scott from the foreign office of the Russian Imperial Government through the Hon. G. Creighton Webb, Secretary of the United States Legation at St. Petersburg. Following is a translation of the statement:

Note of the Medical Department to the Department of the Interior, dated Feb. 10, 1894, No. 1020.

Referring to the despatch of February 5, the Medical Department has the honor to inform the Department of the Interior that, according to the existing laws, (Articles 93, 94, 95, 116, 587, Medical Statutes, Vol. XIII, Code of Law, edited in 1892) no one, be he Russian subject or foreigner, not possessing a diploma or a certificate from a Russian university or from the Imperial Military Medical Academy, has a right to practice any branch of medicine in Russia. Foreign physicians possessing foreign diplomas and desiring to practice medicine in Russia are obliged, besides receiving a diploma of their profession from a Russian university or from the Imperial Military Medical Academy, to know the Russian language. Foreign physicians, however, who are well known, or who have made themselves acquainted to the learned world by their works or by successful and eminent practice, or who have occupied professorial chairs or impor-

tant medical positions in some other country, are allowed to practice in Russia after only a verbal examination (colloquium) in the Medical Council or without any examination whatever, subject to the decision of the Medical Council, confirmed by the Minister of the Interior. The names of all physicians who have the right to practice in Russia are entered on the General Medical List issued annually by the Medical Department.

Midwives are also obliged to possess diplomas from medical faculties or from the Military Medical Academy.

Feldschers are not allowed to treat independently in Russia, but are allowed to give preliminary help in illness before the arrival of the doctor and under his control and also to perform all the feldscher functions, viz.: to nurse the sick, to make ordinary simple bandagings, to let blood (by order of the doctor), to revive unconscious persons, to vaccinate, to extract teeth, to set bones, to write prescriptions under the dictation of the doctor, to prepare medicines, etc.; they are also allowed to use medicines in their treatments, but only such as are considered absolutely innocent house remedies, and by no means strongly acting medicines. (No. 100, Code of Regulations and Statutes of the Government, Dec. 3, 1875, Article 2015.)

(Signed)

CONSTANTINOV.

It is not probable that the "feldscher certificate" will hereafter be accepted, in Illinois at least, as the equivalent of the diploma required by law.

THE PUBLIC SERVICE.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from March 24, 1894, to March 30, 1894.

Lieut.-Col. SAMUEL M. HORTON, Deputy Surgeon-General, will report in person to the President of the Army Retiring Board, at San Francisco, Cal., for examination by the Board. By direction of the President.

Capt. WILLIAM R. HALL, Aast. Surgeon, is relieved from duty as attending surgeon and examiner of recruits at San Francisco, Cal., to take effect upon the completion of his examination for promotion, and will report in person to the commanding officer, Whipple Bks., Ariz., for duty at that post.

LECTURE.

SOME RECENT ADVANCES IN SURGERY OF THE HEAD.¹

A Lecture delivered before the Medico School of the United States Army, Washington, D. C., Jan. 18, 1894.

BY W. W. KEEN, M.D.

PROFESSOR OF THE PRINCIPLES OF SURGERY AND OF CLINICAL SURGERY, JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

"Gentlemen of the Army Medical School and friends:—It is a very peculiar pleasure to me to be present to-day for two reasons. One is because I feel the very greatest interest in such a medical school. Having visited a good many years ago the English Army Medical School at Netley, and observing the very great advantages that were presented for the medical officers of the Army and Navy there, I have beheld with the greatest delight the broad-minded policy which has established this school here. It is also a great delight to me to renew an old acquaintance with the President of the Faculty whose acquaintance I first made as a fellow student in Brown University. Subsequently this friendship was cemented during the war when Drs. Mitchell, Morehouse and I were associated with him in the hospital for wounds and injuries of the nervous system.

I want to say a few words in reference to some points as to two topics in connection with recent progress in intracranial surgery. Time will only allow me to speak of:

1. Those infective diseases of the brain arising from diseases of the ear.
2. Intracranial hemorrhage.

First then, infective diseases of the brain, extending sometimes even to the spinal cord, principally arising from infective diseases of the ear. These may be four in number: 1, we may have a pachymeningitis. This is generally limited to the brain, but it may extend occasionally, though rarely, to the cord. It gives rise, also, not uncommonly, to "extradural" abscess; 2, leptomenigitis, or inflammation of the soft membranes of the pia mater, which causes either a diffused inflammation or a localized "subdural" abscess; 3, abscess proper; that is abscess in the structure of the cerebrum or the cerebellum; 4, thrombosis of the sinuses, more especially in the sigmoid portion of the lateral sinus.

If any of you will examine an open skull you will notice that the petrous bone forms a water-shed between the posterior and middle fossæ of the skull, in which lie respectively the cerebellum and the temporo-sphenoidal lobe of the cerebrum. Moreover, if you will examine the petrous bone, especially in sections, you will be struck very much by the thinness of the bone, in some parts not thicker than a sheet of paper, so that by its ready caries or necrosis inflammation may easily extend from the cavity of

the tympanum to the intracranial cavity. Moreover, a large number of veins pass through the bone and afford a ready path from one cavity to the other. It will be seen therefore, that these infective diseases very frequently will attack those portions either of the brain or its envelopes which lie immediately in juxtaposition with the anterior or the posterior surface of this petrous bone. Given then, this easy mode of access, what is the ordinary course of such a disease? It is important to remember that these diseases of the brain very rarely arise from acute middle ear disease; they are almost invariably the result of chronic otitis media. They are occasionally the result of disease of the nasal cavities or of the soft parts of the face; but in ninety-five cases out of one hundred, perhaps, they arise from infective disease of the middle ear.

First of all, if such a suppurating otitis media has produced caries or necrosis, the process naturally extends to the dura mater and a pachymeningitis results. Fortunately in the majority of cases this is a localized inflammation producing either a slight layer of pus between the dura and the bone, or a considerable layer amounting, in fact, to an extradural abscess. The course of such an abscess varies. Sometimes, though rarely, a spontaneous cure results. If so the pus accumulates between the dura and the squamous portion of the temporal bone and the bone being very thin here (for you see it is translucent), it bores its way through the squamous portion and in this manner obtains an exit.

I have here two photographs, from a case in which I assisted Dr. MacCuen Smith in the Jefferson College Hospital, which well illustrate two different stages in the course of such a disease. The first shows the large incision that was made, the ear falling downward and forward to such an extent that it seemed impossible for it ever to regain its normal position, and the extensive removal of the bone. The large incision especially forward was required to obtain access to the aperture in the squamous bone by which the pus had escaped from the cavity of the skull,—an aperture through which the pulsating dura was easily seen. The second shows very well indeed that the ear has been practically, permanently restored to its proper position. The patient recovered without a bad symptom.

2. Instead of limiting its ravages to the hard membranes of the brain, it may produce a leptomenigitis, which will be followed either by diffusion of pus upon the surface of the brain extending even to the cord occasionally, or it may accumulate at one point thus producing a subdural abscess.

3. Instead of limiting itself to the exterior of the brain it may attack the interior and, strange to say, in not a few cases there will be an inch or even more than an inch of apparently perfectly healthy brain between the petrous bone and the abscess.

¹ Stenographically reported for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Now as to the symptoms of these various lesions. I need scarcely detain you with these because I am not speaking to a body of students hearing this for the first time, but to gentlemen who are familiar with most of the diseases I describe and the means of diagnosis. It is more especially to the matter of treatment that I wish to call your attention, though incidentally I will say a word or two in reference to symptoms. Abscesses external to the brain, extradural and subdural abscesses, are very apt to be associated, as are abscesses elsewhere, with elevation of temperature. You will have a temperature of 101, 102 or 103 degrees with the ordinary signs of intracranial inflammation, such as mental dullness, intense headache, and in some instances valuable localizing symptoms; but in contra-distinction to this,—and it is especially to this one point I want to call your attention, for we may make great mistakes in diagnosis,—in intracerebral abscesses, and not uncommonly in cerebellar cases, you will have a temperature either normal or subnormal. There may be a slight initial rise and then a fall to the normal or even below. Therefore, in any case of chronic ear disease in which when the discharge ceases intense headache and mental dullness comes on and a depressed or normal temperature occurs, especially if to these be added any localizing symptoms, you may be almost certain that you will have to deal with an intracerebral abscess. Now, what is the proper treatment for all three of these, because they may be grouped together very well in the matter of treatment? The first thing to do is to open the mastoid antrum, and, if need be, the mastoid cells, to search for the abscess in the cerebrum or cerebellum. Where will you open the mastoid antrum? You will notice that at the upper part, the base of the mastoid, lies the mastoid antrum. Between it and the apex there may be developed a certain number of spaces known as the mastoid cells. The mastoid antrum is the part you want to aim for: 1, because it has a direct connection with the middle ear and therefore will be the first part invaded by the pus; and 2, because from it you can readily reach the cells which will often be filled with pus. This pus is loaded with microorganisms of the most virulent kind even when there is no odor to the discharge; and this point is important in the matter of diagnosis. It is not the discharges which have bad odors that are necessarily fatal; those in which there is almost no odor are often more dangerous than those which are very foul.

In a capital book just issued, entitled, "Pyogenic Infective Diseases of the Brain and Spinal Cord," Dr. Macewen, of Glasgow, has called attention to a little anatomic point in connection with the anatomy of the temporal bone, viz.: The suprameatal triangle. Its boundaries are the root of the zygomatic process above, the posterior border of the meatus in front and a line joining the two behind. The value of the suprameatal triangle is two-fold. Just at the base of the triangle lies the antrum, and therefore, if you perforate at that point you will reach the mastoid antrum. The second point of value of the triangle is that the sigmoid portion of the lateral sinus always lies back of it and is therefore out of danger. Moreover, if, back of the triangle, you draw a line parallel to its posterior border from the posterior inferior angle of the parietal bone to the apex of the mastoid process; this line will correspond to the axis

of the sigmoid portion of the lateral sinus, or as it is better called the "sigmoid sinus." These bony points can always be recognized when exposed in an operation. The axis of the lateral sinus proper is a line drawn from the junction of the mastoid parietal and occipital bones to the middle of the meatus. To perforate into the mastoid antrum, I very frequently use the ordinary carpenter's counter-sink. Macewen recommends the rotating burr with the ordinary surgical engine, such as dentists use. He very properly, I think, condemns the use of chisel and mallet, for the reason not only that the blows of the mallet produce a disturbance within the skull that might diffuse the pus and do harm to a diseased brain, but because, in more than one instance the chisel has been driven wider and deeper than was intended and has wounded even the lateral sinus. He refers to four such cases, in three of which death occurred. Either the burr or the gouge, rarely the trephine, still more rarely the chisel should be used. The external incision is from the base to the apex of the mastoid directly down to the bone, the ear is then drawn forward and the antrum perforated in the suprameatal triangle. But you must beware of two points of danger. The first is that already alluded to, viz.: The lateral sinus. When operating in the cavity of the antrum you discover any little mass of granulations it is of the greatest importance before touching it with burr or gouge that you investigate it by means of a probe to see whether or not there is a perforation exposing the sinus,—because not uncommonly there is already a perforation from the mastoid antrum into the groove for the sigmoid sinus, and if you rudely destroy this you may very easily puncture the sinus and place yourself in a very embarrassing position. Then, you must be extremely careful to cleanse the antrum and to stanch the blood, so that you can see the next source of danger, viz.: The canal of Fallopius, in which runs the seventh or facial nerve. This runs just underneath the further part of the floor of the mastoid antrum. You must be careful, therefore, if you espy the little ridge which often marks the line of the canal, to avoid puncturing it lest you injure or destroy the seventh nerve and so paralyze the face. If this ridge is not visible there is another means of avoiding the seventh nerve. Expose the face and have one of your assistants watch its muscles. If your burr or gouge approaches the nerve you will produce a twitching of the face, and that, on a warning from your assistant, should be the signal for you to stop. Having opened the antrum, how will you cleanse it? Merely to wash it out as I have seen it done is most inefficient. And more than this,—when we do inefficient operations we simply expose our patient to greater danger, for this reason, that the microorganisms of the inspissated pus of the antrum are shut up and inert; but they are ready to reënter upon a vigorous and baleful life if you give them blood, blood serum and plenty of oxygen. So long as they are confined they will do little harm; but break down the barrier of granulating tissue which, like a wall of defense shuts them off and you open the door for their infective influences. Hence the rule should be thoroughness or don't touch it at all. Therefore after smoothing off the interior of the antrum and cells, take small bits of gauze or sponge and wipe out the cavity with your antiseptic solutions thoroughly and completely. Thoroughness, and thorough drainage afterward, are essential to success.

Supposing now that you find you have to deal with more than a mere mastoid case; that the brain is involved either from an extradural abscess, a subdural abscess or it may be even an abscess in the brain itself, you will naturally do one of two things: Either enlarge the opening already made and so get access to the deeper abscess, or else make an independent opening. As a general rule the latter is the better course to pursue. In doing so the best point for the trephine opening is that indicated by Barker, viz.: One and a quarter inches behind and one and a quarter inches above the middle of the external meatus, because the vast majority of abscesses of the brain will lie within what Mr. Barker has well called, "the dangerous area," which is a circle having a radius of an inch and a quarter, and for its center the point I have mentioned. The trephine opening should not be a large one—a half-inch is all that is usually needed. In many cerebral operations large openings, one and a half or two inches, or sometimes even larger than that are needed; but in abscess of the brain, a small opening only large enough to give access, is all that is necessary. Whenever the brain substance is lacerated there is always a tendency to the formation of a fungus cerebri—a most dangerous complication. Hence my caution in this respect.

I am quite persuaded that in a case of infective disease of this sort, in a young lad at Jefferson College Hospital, I lately made just this mistake myself; and a very natural one it was I am sure. Fortunately no ultimate evil resulted from it. The boy last 4th of July went in swimming, and in diving got a quantity of cold water in his nostril. This produced an invasion of the frontal sinus. The boy entered a hospital soon after, toward the end of July, and had a little abscess opened over the eyebrow and was soon discharged from the hospital as well. Not long after this, great headache and mental dullness came on but without any rise in his temperature. He entered the Jefferson Hospital and I diagnosed abscess in the frontal lobe. The diagnosis was facilitated in this case and made very certain by the fact that just over the eyebrow was a soft swelling. The moment an incision was made and the parts raised, I found a small aperture already existing in the skull. The dura was protruding through the little opening which was surrounded by an area of necrosed bone. The bone was not yet loose. Then followed my mistake. I should have been content with that small opening, through which I could perfectly well have reached the abscess; but the tendency is whenever we see dead bone, to get rid of it, and I took my forceps and cut away the bone until I had an aperture about an inch and a half in diameter. Through this I introduced a grooved director and at a depth of two inches I reached the abscess. He was a different boy in twenty-four hours; clear in mind and free from headache. From that time to this he has gone on improving and I hope before long will be entirely well, except that his sight, I fear, will be nearly lost from atrophy of the optic nerves following optic neuritis. But the result of removing so much bone was that it was followed by fungus cerebri. This has gradually healed over but there is still some dead bone to come away. Now, had I let the bone alone I could have reached the abscess and have put my drainage tube in. There would have been no such opening through which a fungus cerebri would

have protruded, and the dead bone would have come away just as it is going to come away now.

Make therefore a small opening not over half an inch in diameter. If there is neither an extradural nor a subdural abscess, the abscess will be usually at one of two points, either in the temporo-sphenoidal lobe which occupies the middle fossa of the skull, or in the cerebellum.

How will you reach such abscesses? The first can be reached by puncture in the axis of the temporo-sphenoidal lobe, that is in a line from the opening towards the wing of the opposite nostril. This is far more exact than the direction generally given to puncture in a direction "downward, forward and inward." As a rule I use the director, the groove of which facilitates the escape of the pus and its blunt point avoids any vessels. I do not like the knife; it may wound a large vessel difficult to control especially with a small opening. Suppose you do not find the abscess. Withdraw your probe exactly in the line in which you introduced it, and pass it in another direction. Never sweep it round, for if you do you cut off large numbers of fibers in the substance of the brain. Do as little harm as you can.

Having explored sufficiently and ineffectually, leave that point and go to the cerebellum. It may be very possibly, that you will look on your patient and say: "I wonder if his condition will bear it?" I remember well a case of this kind. The child was in such a condition that I decided not to do a second operation; and what was the result? The child died; and I found an abscess in the cerebellum containing one and a half or two ounces of pus. The child could not have lived, even if I had found the abscess; but surgically it was none the less a mistake. The additional danger of a second slight operation, for it is really a slight operation to expose and puncture the cerebellum, is as nothing compared with the absolute certainty of death if the abscess be not found.

To attack the cerebellum with safety you must avoid the lateral sinus. This runs in a line drawn from the meatus to the external occipital protuberance. The trephine should therefore be applied well below this line and midway between the mastoid and the middle line. A few turns of the trephine will penetrate the bone, or, if the patient is a child, a simple gouge will quickly make an opening. Through this you can not only puncture the cerebellum on the same side but by an oblique puncture can reach the opposite lobe. Having found the abscess it is evacuated and then drained, the after treatment being that with which you are all familiar.

This whole matter of cerebral abscesses is very recent, especially in connection with cerebral localization, which I have not touched on but shall presently in connection with hemorrhage. So late as in 1886 the first case of cerebral abscess was diagnosed and properly treated. You see therefore, how recent all of this surgery is; eight years covers practically the whole of it.

There may be, however, a fourth result, viz.: Thrombosis of the lateral sinus, especially the sigmoid sinus. This disorder is frequently misinterpreted or overlooked, and patients are allowed to die when they might be saved. What, first, is the reason for this condition? Why, nothing is easier you see than to pass through the thin lamella of bone which separates the petrous bone from the sigmoid sinus.

There is nothing easier than here, inside of the ear, to have necrosis, with infective invasion from this through the veins into the sigmoid sinus. It is common to find pus in the sigmoid groove, not uncommon to find it in the sinus itself in cases of thrombosis. The evil unfortunately is not restricted to the sigmoid sinus. The disease comes in contact not only directly with the current of the blood from the sinus into the jugular vein, but may pass all the way down this vein to the clavicle. More than this, fragments of the thrombus may be carried down or the thrombosis be extended until the lungs become involved. You will have then, first, expectoration, later, in twenty-four or forty-eight hours, discolored by the admixture of pus. When it extends as far as the lungs it is deadly. I know of only one case of such extension in which recovery was achieved; and that one case of recovery, in an infective disease of this kind is an extraordinary thing.

That sinus thrombosis, which formerly was considered so fatal, is not so fatal as it was supposed to be, is proved by the fact that I have gathered from different surgeons thirty-two cases that have been operated upon, of which nineteen recovered and only thirteen died. You will find in Dr. Macewen's book, thrombosis of the longitudinal sinus, of the cavernous sinus and of the sigmoid sinus. He mentions twenty-seven cases in his own practice of which twenty were treated and sixteen recovered. More than this, thrombosis of the sigmoid sinus was formerly thought to be absolutely inaccessible and absolutely fatal. Of the cases of thrombosis of the sigmoid sinus in his practice, there were eighteen cases, of which seventeen came to operation and thirteen recovered.

Now what are the symptoms of thrombosis of the sigmoid sinus and what should be its treatment? First of all you will have a patient with an old otorrhea, from chronic disease of the middle ear. It is very common, especially of late, to think that a chronic disease of the middle ear does not amount to anything. This may be true in a great many cases, but we know now far better than to think it true in all. Such a case may go on for fifteen or twenty years but the day of reckoning may at last come, and when it does come it comes like a whirlwind.

Take a case of old otorrhea. The discharge will stop and your patient will complain of headache. The headache is intense. Along with it will not come that dulling of the intellect as in cases of abscess; but on the contrary the intellect will be clear and you will find that there is post-mastoid tenderness even in the bone, though no tenderness in the mastoid process itself. Follow the line of the sinus from the mastoid back, and the post-mastoid tenderness will almost always be found. Now examine the neck, and if you have a case in which the extension of the clot has been intrajugular, you will feel a hard cord just posterior to the carotid artery or you will find a matting of all the tissues, because not uncommonly there is inflammation around the jugular vein and carotid artery. If there has been any escape of pus externally you will have it in the supræmeatal triangle. You will expect also other symptoms. What is this but a pyemia? We know perfectly well that the common cause of a pyemic condition is an infective clot that forms in a vein; and what is this but an infective clot in a large vein, peculiarly situated and unfortunately, to us peculiarly inaccessible.

You will expect, with the symptoms I have indicated, that the temperature will go up. There will be violent fluctuations of temperature; high at night and comparatively low in the morning, but only comparatively. Given, then, these conditions, you will be pretty sure that you have to deal with sinus thrombosis. First of all the mastoid operation. Sometimes you will have just these symptoms without any thrombosis, simply from the mastoid disease, but unfortunately this is rare. When it exists, if you see no reason to go further than the simple mastoid operation, stop there, but watch your patient. Stand over him with knife in hand ready instantly to interfere. A few hours may carry that patient just beyond the safety line into absolute danger and death. Watch carefully, and unless he is better within twenty-four or forty-eight hours do the second operation, viz.: expose the sinus.

I have already told you of the lines that mark the supræmeatal triangle. You will carry your incision down here as before. It will have already been made and you will simply have to re-open your old incision. It is sometimes necessary to make the incision posteriorly. Examine most carefully the little mastoid vein that runs in the sinus between the squamous and the occipital bone. Always examine this vein that makes its entrance here into the sinus, because if there is pus in the groove of the sinus very likely you will find it working its way out along the length of the vein and you will see a small portion of a drop of pus at this point. Then from your old incision work backward and upward. You will observe that you have punctured the antrum there. You will then work upward and backward and uncover one inch of the lateral sigmoid sinus. This is easily done. There is not a man in this room who can not do this operation if he will be gentle and careful.

Your gouge and your sharp spoon, or Rozier forceps, will enable you to uncover the sinus entirely. See whether it is hard or soft; see what is its color. This will likely give you all the information you want as to whether or not you have a clot. If you have reason to suspect clot, or if the symptoms, even without clot, are such as to justify it, you must open the sinus. You say to me at once: "That will give a fearful hemorrhage and expose the patient to the greatest danger of death." There is nothing outside the sinus as dangerous as the pus inside. There is nothing outside of it or that you can do outside of it that can possibly be as dangerous as the infection that will be carried from suppurating sinus down to the lungs. Therefore do not hesitate, for you can do it with perfect safety.

Have beside you in that case two or three strips of iodoform gauze and a pair of forceps immediately alongside of them. Make your incision and if blood comes out there is no clot; your finger will be a sufficient plug. If you find no clot you can plug perfectly well and prevent a clot extending further backward at least. Supposing you find a clot then you will have no bleeding, for a clot acts as a cork or plug. What will you do then? Clean it out until you get free hemorrhage. You will find cases reported in which the sinus was cleaned out and in which even a slough of the sinus escaped afterward and the patient got well. If you are going to interfere at all your interference must be thorough.

Having opened the sinus, cleaned it out, and

plugged it, what then? If the jugular vein is involved you must make an incision instantly in the neck and open that vein. Tie it between two ligatures, or tie one ligature only because often one end is entirely plugged by clot. In some cases that I did some years ago this vein was entirely destroyed and I had the greatest difficulty in defining it. It was collapsed entirely and surrounded by an immense amount of inflammatory tissue. Tie the vein, especially go below the clot. Go down below the level of the clavicle and tie below the clot in order to prevent its extension toward the lung; there is the great danger. Having done so, wash it out with an antiseptic solution, plug it with iodoform gauze, and you will get, in a large majority of cases a most satisfactory result.

I had not expected to take up so much time with this; but I always feel that in such matters there is a sort of modern surgical romance, and when one gets to talking upon a subject to which he is much attached it runs away with him.

I will only have a very few minutes, therefore, to say a few words in reference to the important matter of cerebral hemorrhage and at the close I will show you the means of detecting a bullet by Dr. Girdner's telephone probe.

As in matters of abscess there are three positions in which hemorrhage may occur in the cranium. It may occur between the dura and the skull,—extradural hemorrhage, corresponding to extradural abscess; under the dura, between it and the brain,—subdural hemorrhage; in the brain, more frequently in the cerebrum than in the cerebellum, making cerebral hemorrhage.

Extradural hemorrhage is due in the vast majority of cases, one may say almost without exception, to rupture of the middle meningeal artery. Now to show what a fatal disease this is: In a paper published a little while ago by Giesin he states that he collected 147 cases that were not operated on, and 131 or 89 per cent. of these died. Of 110 cases operated on, 36 died, a mortality of 33 per cent. Nothing could speak more strongly than these figures.

The middle meningeal artery comes up, as you know, through the foramen spinosum and soon divides into an anterior and posterior branch. A man falls or receives a blow on the head. He is stunned by it. In the course of a minute or five minutes, it may be half an hour, he comes to himself; there may be only a few seconds of unconsciousness. He comes to himself but unfortunately the artery has been ruptured. What happens then? While he is conscious, a little leakage of blood, which goes on increasing. After a while, or if the rent is a large one, in a short time you will have extravasation of blood with the formation of a clot. The moment that this clot becomes large enough to produce symptoms of compression the man will become unconscious, and this unconsciousness will deepen into coma, and finally into death. This symptom is the one worth all the others. It behooves you therefore, in cases of injury of the head in which there is any suspicion of intracranial hemorrhage, to investigate the witnesses. The patient himself will be unconscious, but investigate the witnesses to see whether he had a stunning, secondly, a recovery of consciousness, and then a recurrence of coma; and if he had, and other symptoms go along with it, your diagnosis is an assured one.

What will be the symptoms? In the first place the patient's pulse will be accelerated. In the next place his temperature will not rise remarkably. It takes time, but it will rise later. Next, the pupil on one side, the side of the clot, will be dilated, and if the clot has gone downward to the base of the brain it may be that preceding the second unconsciousness you will have anesthesia. More than this as it creeps up from this or from the centers along the fissure of Rolando, you will get first the face paralyzed, then the arm, and, if it extends widely enough, the leg.

I remember a case of gunshot wound reported some time since in which this very progressive history occurred. By the time the ambulance reached the patient the ambulance surgeon found that his face was paralyzed, and in a short time the arm. By the time the hospital was reached his leg was paralyzed, and he was unconscious. Now there could be nothing, no cause that would be progressive, and rapidly progressive—there would be no possible pathologic cause for such conditions, excepting hemorrhage.

I remember a case I had two years ago at St. Agnes' Hospital in which the diagnosis hung by a more slender thread. A man going to his stable about 6 o'clock in the morning, lost his footing on the top of a haymow and fell directly to the stable floor, striking on the top of his head and inflicting two slight wounds in the scalp, one in the middle and the other a little way from it. He was picked up unconscious and was absolutely unconscious from the moment he was found, apparently until he reached the Hospital and I saw him at about half past seven o'clock. As I looked at him there, he lay extended on the couch, perfectly motionless, with the ordinary stertorous breathing and hot perspiration that you find in a case of ordinary concussion of the brain. There was absolutely nothing to indicate to me where the damage was, or even what it was. No anesthetic was necessary, and I first made a little incision from each of the wounds to determine if there was a fracture, but found none. What then could account for this man's comatose condition? There was only one thing and that was a large clot, because it was too sudden, too profound, to originate in a little rupture. It must be a source of the greatest compression that would produce such profound coma. Then came the question as to which side it was on. He had no hemiplegia, but absolute paralysis, except the muscles of respiration. I examined the eyes and found that he had on the left side a slightly more dilated and less mobile pupil than on the right. I then thought that in all probability there was a clot on the left side of the man's brain, and I need scarcely tell you the satisfaction I had when I removed a half inch button of bone from that man's temple. The instant the bone came away there was a clot welling up, and I found a clot inside of his head that was one and one-half times the size of my first. I found four rents in the artery, and it is needless to say that in a case of that kind the damage done to the brain by the primary injury was such that it was impossible for him to survive. I quote this case merely as one instructive in diagnosis.

Where will you trephine? Not by the symptoms of injury, but according to the doctrines of cerebral localization. If it is a blow on the posterior part of the occiput by falling backward, and the patient has the right side paralyzed, hemiplegia, or his right arm alone is paralyzed, monoplegia, will you trephine on

the side of the injury? Never. Trephine over the left motor area. Trephine by the doctrines of cerebral localization.

Three or four weeks ago a woman who had been subject to attacks of vertigo, was going up stairs and suddenly cried out for help as she fell over backward; she was taken up unconscious, not completely so but semi-conscious. Dr. Cross, when examining her pupils, found this one little peculiarity, which was a beautiful instance of exact observation: When he took a candle and passed it to the left, the woman followed it with her eyes, but when he passed the candle to the right she paid absolutely no attention to it. He judged, therefore, that the right field was blind. Now, blindness of the right field, from the crossing of the optic fibers, means injury of the left side.

I did no operation, because when I saw the woman, three days after the accident, she was dying and in fact lived only a few minutes after I saw her. The postmortem examination showed that the fibers between the left cuneus and the eye were caught by a blood clot, and, therefore, if I had made my trephine opening as I had intended I would have come directly upon it. To this point I want particularly to call your attention. The evidence at the time was that the woman struck on the right occiput. There was a place where she winced when you touched it, and in her unconsciousness carried her hand to the point, and had we operated by the doctrines of the locality of the injury we should have been far afield and would never have found the clot, for it was on the side opposite to that which received the injury.

Only one word, gentlemen, and I am done. Middle cerebral hemorrhage, which will be commonly a subdural clot, can not be distinguished from meningeal clot, and it is not necessary that it should, for the treatment is precisely the same. Apoplectic clots in the brain must necessarily be let alone; but if the clots be traumatic they may sometimes, as in the case just narrated, be accessible.

I wish to call attention to two points: How to reach the anterior branch and the posterior branch of the middle meningeal artery. The anterior branch finally reaches, as you know, that anterior inferior angle of parietal bone where it is situated in a groove or canal. Take one inch and a quarter behind the external angular process on a level with the eyebrow, and open at that point, and you will almost certainly come on the anterior branch. If you do not find the clot there, are you going to fold your hands and say: "I can not find the clot," and let the patient die. This was done in a good many cases of the 110 of which 36 died. The clot was not found and the patient died. Never let a patient die hereafter from intracranial clot any more than from intracranial abscess. The posterior branch is just below the parietal boss, at the same level as before. There is the parietal boss, a point very easily found, and just below it, on a level with the eyebrow, will be found the posterior branch. Having found the clot, drain it, wash it out, secure the bleeding vessels, and then ordinary care for such a case is all that is necessary.

I am greatly obliged for your patience on which I have trespassed much more than I intended; my excuse must be the importance of the subject.

ORIGINAL ARTICLES.

CAN TYPHOID FEVER BE ABORTED?

Third paper read before the Mahoning County, Ohio, Medical Society, March 12, 1894, with the Records of the Reported Cases Continued to Date of Recovery; also of three other Members of the Family who were attacked after the Reading of this Paper.

BY J. E. WOODBRIDGE, M.D.

YOUNGSTOWN, OHIO.

As a preface to my paper, I wish to acknowledge my indebtedness to the President of this Society, to our last ex-President, to the ex-President of the Ohio State Medical Society present, to Dr. Thomas, Dr. Barnes, Dr. Dickson and all others who have confirmed my diagnoses, watched the results of treatment, or in any way have aided me in my work; and to thank them for their very complimentary remarks in the discussion of my previous papers. Having my work characterized as the greatest discovery of the age by one member, my name associated with that of Jenner by another, and another give expression to his pride that a member of this Society had done what I have; would be exceedingly gratifying to me at any time, but especially just now when I am promulgating ideas which must arouse the indignation of every great medical professor in the world, because they, if true, convict him of teaching errors that have not only cost hundreds of thousands of lives, but have discouraged all investigation in this most important field, and must incur the bitter hostility of a large class of physicians who not daring to adopt my treatment, or failing to secure the results I claim, will lay all the blame to my method, rather than upon their application of it. I wish, too, to thank the editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, for so promptly defending me from the spiteful attacks of the editors of two or three medical journals.

I wish too, to say to the members of this Society that I fully appreciate their courtesy in giving up most of their last meeting to my second paper on the same subject. And when they by a unanimous vote gave me the floor again this evening, I could not help wishing that my work were enough advanced to enable me to make my third paper something more than a mere effort to inaugurate a new era in the diagnosis, prognosis and treatment of typhoid fever, the subject which for more than twenty years has lain nearest my heart, and to which all the best years of my life have been devoted. To the strictly scientific part of my work I need not even call your attention. Most of it has been better done by abler workers, and some of it is in too chaotic a state to be even alluded to amongst scientific men, since we know so little of the cause of typhoid fever that we can not say positively that any one germ invariably produces it. And so little of the real action of the remedies exhibited that we are unable to say whether eucalyptol and guaiacol, or creosote, or calomel, or any one agent is essential, or how or why a cure has invariably followed their exhibition.

The importance of the subject to you, to all American and Canadian physicians, and indeed to practitioners of medicine all over the world, wherever typhoid fever prevails, can not be overestimated, because of its terrible mortality.—(The death rate in Pittsburg in 1892 was 23 per cent.); because of the broken constitutions of the more than 100,000 who recover from the disease in the United States annu-

ally; because the king upon his throne, the statesman wielding the destinies of the greatest nation, the merchant with his princely wealth, and the most brilliant physician, with all their resources, and all their power can not escape it, and because, last but not least, aside from the method of treatment I have given you, there is no known means of aborting the disease or of saving the life of every case.

That I can do this, the charts shown you at the last meeting of this Society (a few of which have been published), and which represent only cases that I have treated since the 25th day of June, 1893, and of the cases I have treated since that time only such as presented absolutely pathognomonic symptoms of typhoid fever, in nearly every one of which the diagnosis was confirmed by from one to five of the ablest diagnosticians in the country, are unquestionably

ing of this Society, I condemned all of the published methods of treatment of typhoid fever; gave in detail my treatment and foreshadowed in some measure the important results I expected to follow its adoption, by telling the essayist of the evening that if he would abandon his own, and all known methods of treatment, and pursue the course I had indicated he would have better results, but he, while expressing his respect for me as a careful practitioner condemned my theories and the remedies I proposed, as did every other member who joined in the discussion.

In 1882 I addressed the Society on the subject of intestinal hemorrhage in typhoid fever, saying that it would be unknown if the disease were properly treated, and that it would be a safe rule to send to State's prison any physician who ever had such a case, presupposing that he was called in due season, admitting such a law might occasionally do injustice, but claiming that its general effect would be beneficent. Some of you will remember

Case No. 55-A. Name, T. M. Diagnosis confirmed by Drs. McCurdy, Dickson and Robert Gibson. This patient not seen again until March 3.

Case No. 55-B. Name, T. M. March 2.

conclusive evidence. At least you must accept them as such, until you can produce an instance where I have had a case which had been sick less than eight days when I was called, and lost by death, or failed to abort, or to so modify the disease as to cause it to run an exceedingly mild course (unless complicated by preëxisting or co-existing disease).

A bold assertion after reading Osler's statement, ("The Principles and Practice of Medicine," 1892, page 33): "The profession was long in learning that typhoid fever is not a disease to be treated by medicines;" also on page 531, he says: "We are still without an agent which can counteract the gradual influence of the poisons which develop in the course of acute febrile diseases, such as typhoid fever, pneumonia and diphtheria."

And yet twelve years before this book was published (in 1880) at an unusually largely attended meet-

ing on Nov. 13, 1884, in the discussion of a paper by Dr. Thomas on the use of the term, "typho-malarial fever," I condemned its misapplication to cases of true typhoid fever with no malarial taint, and took occasion to say at the same time that the term, "malarial fever," was misapplied when used to designate a fever that runs three or four weeks without intermission or distinct remissions, and ends in death from intestinal hemorrhage or exhaustion. That again in 1890 I spoke in condemnation of the use of the coal tar derivatives in the treatment of the disease, saying that I believed that a very large percentage of the deaths from heart-failure were due to their exhibition, and that in 1891 I again spoke to the Society on the subject, saying that I believed typhoid fever could be aborted. Thus the fact that I have regarded typhoid fever as a curable disease has been no secret since 1880; and that when called

before the sixth or eighth day of sickness I invariably give a prognosis of ten or twelve days sickness, or if longer, so mildly sick as to cause no uneasiness—no danger—is also well known; and the medical profession abroad will understand that if I had failed in a single instance to make my prognosis good, both the people and the profession here would have held me responsible years ago.

During all these years I had made every possible effort to prove the correctness of my theories, so that when I appeared before my Society, claiming the ability to do what all of the great teachers have taught and believe is impossible, I might have the means, not alone of proving my assertions, but also of defining the principles governing the proper treatment of the disease. But my claims were too absurd for belief, even by the most credulous, and although the author-

their former selves emerge from their sick-room and creep about more dead than alive, often for months, when they might just as well have sat up and eaten beefsteak or bread and butter after the sixth or seventh day of treatment.

A few years since when Dr. McCurdy was President of the Ohio State Medical Society, and by virtue of his office was the highest representative of the profession of the State, we had several interviews on the subject of publishing my claim that typhoid fever could be aborted, and the method of treatment that seemed best calculated to produce this result, and we

Case No. 60. Diagnosis, Typhoid fever. Name, Mrs. A. McF. Diagnosis confirmed by Drs. McCurdy and Dickson. Complicated with inflammation of both lungs and hemorrhage from the right lung.

ities in some hospitals would permit me to see their patients or make dissections, it was long an utter impossibility for me to secure an opportunity to treat even a few patients in a public way, under the observation of a skilled diagnostician, notwithstanding the fact that my applications were supported by the highest credentials.

I met with so many discouragements that lack of money alone prevented me from opening a hospital for typhoid fever in which to demonstrate to the world how to abort the disease, and a few thousand dollars placed at my disposal in 1880 would long ago have resulted in the saving of many thousands of lives annually, as well as the great amelioration of those other thousands who languish weeks in a burning fever, then suffer the horrible pangs of hunger (I have felt them), and finally as mere shadows of

Case No. 62. Name, Miss A. M. Diagnosis confirmed by Drs. McCurdy and Dickson.

both felt that without more conclusive evidence than I could then adduce of my ability to abort the disease that no possible good would result from such publication; and although he has done me the honor to pronounce my method of treating typhoid fever a wonderful discovery, yet he expressed the belief that such premature publication would greatly imperil my professional career. I believe the Doctor still thinks, and I am sure the opinion is correct, that it would have been better to have waited a few years longer, before making any public announcement on the sub-

ject, because my cases are yet too few to carry conviction to the mind of every member of the profession that it is possible to abort typhoid fever, and twelve years of active private practice, without a death, is not long enough to convince every one that death is a wholly unnecessary consequence of the disease. Had I waited until I could have reported the cases of twenty years, without a death from typhoid fever, and a proportionately increased number of aborted cases; waited, too, until I had completed my investigations so far as to enable me to state with exactness the laws upon which the scientific treatment of typhoid fever depend, instead of detailing the treatment which I gave individual cases, and giving formulæ which, while acting admirably, may and probably do, contain ingredients which add little, if any to their efficiency, enough of thinking men in the profession would then have accepted my theories to aid me in convincing the unthinking, and the treatment of typhoid fever would have been revolutionized. Now what will the result be? We must wait and see. How long? Who can tell? The lessons of the past must be unlearned before the lessons of the future can be understood. All of the great teachers of the past and the present have so iterated and reiterated the statement that typhoid fever can not be aborted, that it will take long to unlearn that one lesson, especially while the very best and latest text-books, and all of the leading medical professors of the world are teaching the contrary; and until this lesson has been learned it is useless to expect physicians to succeed with the abortive treatment of typhoid fever, for only to the most careful watching and the most skilful use of the remedies at our disposal will this treatment yield its happiest results. How can he succeed in such a work who firmly believes in the impossibility of success, or how can he be expected to give due energy to a work in which he has no faith?

Another lesson which will be difficult to unlearn and which is taught by the great teachers with as much unanimity as the other, is, not to treat symptoms. Beginning at any given day early in the disease, one should treat a patient with a temperature of 105 or 106 degrees exactly as one would were the temperature 101 or 102 degrees. The physician who says that the important object to be attained is to bring the temperature down, is like the man who would attempt to resuscitate a drowning man without first taking him out of the water, and the end would probably be the same in either instance. It is not the symptom which kills the patient, and one patient with a temperature of 105 degrees may be on the high road to recovery, while another with a temperature of 101 degrees or even lower may be rapidly approaching the grave. Watch the temperature, the pulse and all other symptoms as matters of scientific interest, and as showing the results of treatment given hours or even days before, but not as giving any indication for treatment in the future. This rule applies only in cases which have been properly treated prior to the eighth day of sickness. Last month, I gave in detail the treatment of three typical cases of typhoid fever. Two were treated regardless of symptoms, and one which I did not see until the sixteenth day of his illness, and for that reason, was treated almost entirely by the symptoms. All recovered, but while one was not allowed any solid food for ten days after his temperature was normal, the others ate

solid food all of the time. Two were never sponged at all; the other thoroughly. The one was not allowed even to rise to stool; the others sat up and walked about and one of them went out of doors during his illness. The detailed treatment of these individual cases was given because to them I gave nearly, if not quite, every remedy that I regard as essential to the abortive treatment of the disease, in all of its various stages, and because I wished to make more careful observations before attempting to publish a thesis on the treatment of typhoid fever. In future, as my investigations result in improved methods, I shall give the profession further details, and I hope to be able to go much more fully into this part of my subject in a paper which I propose to read at the San Francisco meeting.

Admitting that typhoid fever can be aborted, it becomes a matter of prime importance to decide how to abort every case and save every life. This will be impossible as long as the people buy and use patent medicines, take domestic remedies or for any reason neglect to send for a physician in season, and they will never realize the importance of sending for a

Case No. 63. Diagnosis, Typhoid fever. Name, Miss M. McF. Diagnosis confirmed by Dr. Dickson.

physician in due time so long as he fails to make a diagnosis and institute proper treatment promptly when called.

Typhoid fever is man's most insidious enemy; having a long period of incubation its early diagnosis becomes a matter of the greatest importance, and should invariably be made the first time the patient is seen, with sufficient accuracy to warrant the institution of proper treatment. I readily concede the impossibility of always making a correct or positive diagnosis at the first visit, but every case in which the temperature is ever so slightly elevated and the pulse ever so little accelerated, in which no contra-indications can be discovered should be prescribed for as a case of typhoid fever, thus giving the patient the benefit of every possible doubt, since I know of no disease or condition which under this rule would be unfavorably influenced; on the con-

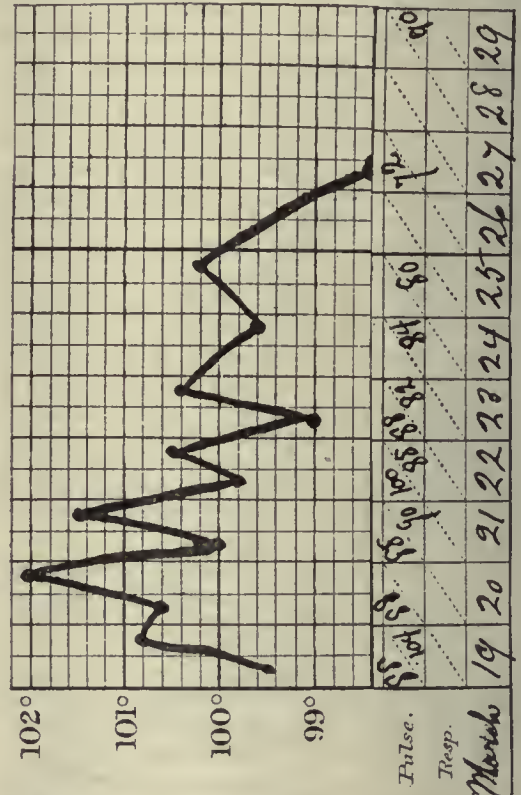

trary the diseases in which this course would be ideal treatment are too many to be even mentioned in one short paper. In diphtheria, in measles, in variola, in malarial fever, in pneumonia, in influenza and all catarrhal troubles you have given your patient the best possible initial treatment. You will remember that I was assigned the duty of presenting a paper on "La Grippe" at our annual banquet, after its visitation in 1889, and that I then said that I accredited the fact that I had had no deaths from la grippe or any of its sequelæ to the treatment I had invariably pursued. I might have added that although I made no mistake in diagnosis, I regarded for purposes of treatment, every case of la grippe as a case of typhoid fever, except that I usually gave the remedies in larger doses. Thus, while la grippe and typhoid fever differ so widely that I do not think any careful physician would be likely to make a mistake in diagnosis, they are best treated in almost identically the same way, at least, in their

diagnosis, a false report, or the medicine and not the disease killed those twelve patients. In this conclusion I am ably sustained by Dr. Eliot, of New Haven, who says:

"When typhoid fever really exists but is not correctly diagnosed it is, in this vicinity most frequently called malarial fever, and at a later stage, typho-malarial fever. This mistake generally depends upon a mixture of ignorance and carelessness. I do not care to maintain at the present time that typho-malarial fever never occurs. I presume that every one is aware, however, that this term should be limited to cases of disease which are due to the simultaneous action of the typhoid and of the malarial poisons. I am thoroughly convinced that most cases of so-called typho-malarial fever are in reality cases of typhoid fever. If a malarial element is present in some of them it is possible to remove it

Case No. 65. Diagnosis, Typhoid fever. Name, F. McF. Diagnosis confirmed by Dr. C. C. Booth.

Case No. 66. Name, Mrs. H. McF.

earlier stages, and the same is true of all of the malarial fevers and of the so-called "typho-malarial fever," if there be such a thing.

During my long and intimate association with my uncle, Dr. Timothy Dwight Woodbridge, whose well-stored mind and brilliant intellect enriched by the observations of more than fifty years of active practice, made him not only a pleasant companion but always a wise guide in all matters relating to our profession, he often said that there was no malarial fever in this locality which would ever cause death, even if left without medical treatment, and yet our Health Officer's report for last year (1893) shows twelve deaths from malarial fever and only nine deaths from typhoid fever. If Dr. Woodbridge, Sr., were right, and my experience certainly sustains his opinions, then there are three horns, and three only, to the dilemma of the physicians who made these reports. Every one of these cases was a mistake of

promptly by appropriate treatment. With regard to cases of so-called malarial fever it should be remembered that most fevers which are caused by malarial poison are of a distinctly intermittent or remittent type. If, therefore, a case of continuous fever occurs which is uninfluenced by adequate doses of the ordinarily used anti-periodics, there is good reason for challenging the diagnostic accuracy of any one who pronounces such a case malarial fever. In most cases of this kind the disease is enteric fever. The vital statistics of our city and State show a number of deaths as due to malarial and typho-malarial fever which is almost equal to the mortality reported from typhoid fever. There is little doubt that the majority of these cases reported represent mistakes in diagnosis, where enteric fever has been overlooked and called by another name."

The above quotation is perfectly applicable to this locality, except that our statistics are worse than

those of New Haven, and would have been even worse than they are had not some diagnoses of malarial fever been corrected to typhoid fever by consulting physicians before death, sometimes even in the third or fourth week, corrections that came too late to benefit the patient. There can be no doubt if these reports could be analyzed and autopsies made, there would be found a large number of deaths due to typhoid fever which have been reported under other names. Osler, than whom there is perhaps no better authority, says, in "Principles and Practice," page 30, that "cases coming on with severe headache, photophobia, delirium, twitching of the muscles and retraction of the head are almost invariably regarded as cerebro-spinal meningitis;" that he has thrice performed autopsies on cases of this kind in which no suspicion of typhoid fever had been present, and adds: "Cerebro-spinal meningitis is, however, a rare disease, typhoid fever a very common one, and the onset with severe nervous symptoms is by no means infrequent. Fully one-half of the cases of so-called brain fever belong to this category."

Some of you may object to my method of making a diagnosis; may say that I reach conclusions from insufficient data. But you are reminded that this is a diagnosis for treatment only, and to be verified or corrected by future observations and at the earliest possible moment, and that it can be justified only on the premise that the physician's most important duty is to cure his patient rather than strive for the unattainable absolute accuracy of diagnosis. I am aware that you can approach very close to an absolutely exact diagnosis in typhoid fever if you await the development of all the characteristic symptoms of the disease, but you will purchase your *exact* diagnosis at far too high a price, and it will come too late to benefit your patient. It is strange, too, what a varied value different members of the profession place upon the symptoms ordinarily supposed to be pathognomonic of typhoid fever. One will pin his faith to rose spots, another to tenderness in the right iliac-fossæ, another attaches much importance to tympanites and dullness over the spleen; while one old physician who actually believes he is something of an authority, says he never saw a case of typhoid fever in which there was not diarrhea with little black specks through it. He is on a par with those who fail to make a correct diagnosis until their wits are awakened by the appearance of rose spots or the supervention of an intestinal hemorrhage. Their diagnoses may be exact, indeed, but so far as any benefit to be derived from treatment is concerned they might almost as well have been made in the dead house. A diagnosis of typhoid fever based on such slight evidence as two symptoms only, and those common to many other pathologic conditions might and probably would occasionally require future correction, but could never result in harm to the patient, because the remedies administered in the doses advised could do no possible harm in any condition which could be mistaken for typhoid fever; and while the best possible treatment for any stage of this disease would be almost equally beneficial in the early stages of any acute fever, and a very large majority of these, including mild cases of typhoid fever, or typhoid fever taken very early, would be cured long before a positive diagnosis would ordinarily be made in typhoid fever, or indeed before the development of pathognomonic symptoms would

render such diagnosis possible. If you await the appearance of these, you will rarely succeed in aborting the fever; and unless you are an exceedingly expert diagnostician you will sacrifice a very large percentage of this class of patients.

I hand you the completed chart of Angus McFee, No. 51, which was shown up to date at our last meeting, and in whose case a fatal end was so confidently predicted by a member who had examined him in the afternoon. You will please observe the rapid fall of temperature after each application of large doses of the eucalyptol-guaiacol mixture to the abdomen. He had two or three small hemorrhages of the bowels. (Dr. McCurdy, who saw Mr. McFee with me immediately after I was first called, during the discussion of this paper said that he considered this the worst case of typhoid fever he had ever seen.)

I was called to-day to see his wife, Mrs. Angus McFee, Chart 60, who undoubtedly has typhoid fever. If so hers will be an exceedingly interesting case, since it will be complicated from the beginning, she having had extensive pelvic trouble since the birth of her child. On the night of ——— she was called up and stood on a cold oil cloth, contracting a severe cold to which she accredited her violent headache and backache, cough and the agonizing pains in the region of the right nipple, and for this reason did not send for me until to-day.

Dr. Dickson and Dr. McCurdy confirmed this diagnosis. The abdominal symptoms yielded promptly to treatment, but the trouble of the lungs grew rapidly worse and culminated in a profuse hemorrhage of the right lung. The temperature to-day, March 29, as you will see, is in the morning 97.8 degrees, and this evening 99.6 degrees; cough still troublesome, but otherwise she is quite well, has eaten a little beefsteak yesterday and to-day, and her diet is left unrestricted hereafter.

A brother, sister, and sister-in-law who aided in nursing A. McFee have each had an attack of typhoid fever since Mrs. McFee was taken sick, and all are well. See Charts No. 63, No. 65 and No. 66.

One of the charts published in my last paper as complete is reproduced.

T. Murdock (Chart No. 55), whose temperature and pulse were normal, who sat up and ate beefsteak on the tenth day, who took no medicine after the thirteenth day of treatment, and whose temperature and pulse were still normal to the eighteenth day, after which he was not seen until March 3, which was the twenty-seventh day. He was therefore, with the exception that he did not regain his strength, apparently entirely well for fifteen days; ate such food as he wished, walked out of doors and up stairs every night to bed until March 3, when I was recalled and found morning temperature 102.6 degrees; afternoon temperature 104.8 degrees, with pulse 112 to 116; although there were no rose spots, much abdominal tenderness, nor tympanites, it was unquestionably a relapse of true typhoid fever, from which he recovered more slowly than from the first attack; his temperature first touching normal on the fourteenth day of treatment. Of cases that I have seen early in the disease this is the first relapse I have ever had.

His sister, Miss A. M., No. 62, residing in the same house, consulted me March 12, 1894. She presented fairly well-marked symptoms of typhoid fever, except that the tenderness and pain in the right iliac fossæ seemed to justify a graver disease. She had been

attended during last summer for what her physician diagnosed as inflammation of the bowels. The development of well-marked swelling in the painful and tender right iliac fossæ prompted me to call in consultation two eminent abdominal surgeons, Dr. McCurdy and Dr. Dickson, who both expressed the opinion that she had typhoid fever complicated with grave pelvic trouble. She recovered in fourteen days. (See clinical chart.)

If in these preliminary papers I have convinced you that it is possible to cure typhoid fever; that in the future a death from the disease will be *prima facie* evidence of culpable ignorance or criminal carelessness, either on the part of the patient, his friends or his medical attendant; that the long weeks of burning fever followed by a shattered constitution and sometimes clouded intellect, need no longer be feared; if I have impressed upon your minds the importance of making an early diagnosis and promptly acting upon it; have shown you the danger of mistaking typhoid for malarial fever or any of the milder diseases, and have clearly indicated that the scientific treatment of typhoid fever in its earliest stages is also the best possible initial treatment for any disease for which it is likely to be mistaken, then your time and mine, and the space these pages will occupy in the JOURNAL, could hardly have been put to better use.

AN INTERESTING CASE [MORPHIA HABIT].

Read before the Shelby County Medical Society at Shelbyville, Ind.,
March 12, 1894.

BY H. O. PANTZER, M.D.

INDIANAPOLIS, IND.

PROFESSOR OF CLINICAL GYNECOLOGY AND SURGICAL PATHOLOGY, CENTRAL COLLEGE OF PHYSICIANS AND SURGEONS; GYNECOLOGIST TO CITY HOSPITAL AND CITY DISPENSARY, ETC.

An irritable stomach from stenosis of the esophagus is treated long time for cancer of the stomach, when the morphia habit is formed. Exploratory laparotomy leads to a correct diagnosis. Cure by bougies and irrigation of the stomach. The morphia habit is cured by the restitutation of the moral powers. Discussion of the essentials underlying the cure from vice of habit of any kind. Subsequent development of cancer in the right ovary. Cure by cello-salpingo-oophorectomia duplex.

Mrs. M. L., American, aged 42 years, is married and the mother of four children. I was called to see her in consultation with her family physician, Dr. R. F. Bigger, in April of 1892. Then she had been an invalid of four years, being confined to bed continuously of late. The disease began with an irritable stomach and indigestion. She frequently vomited after eating, and retching at times was quite persistent. At times, food after swallowing seemed not to go down well. She suffered sharp deep-seated pains in the epigastric region, seemingly irrespective of meals taken. She soon lost appetite, and became emaciated. She was much troubled with sour eructations, and felt sore in her stomach at all times. Different medicines given for these conditions, and careful dieting were of no avail. In the start the diagnosis of indigestion was made; later on the persistence of the trouble and its increasing severity, together with the emaciation and a discolored skin, led to the diagnosis of cancer of the stomach situated near the cardiac orifice.

Three eminent physicians, singly, in turn, had seen the case in consultation with Dr. Bigger, and all concurred in his diagnosis. One of these, a famous abdominal surgeon, gave it as his opinion that the walls of the stomach were infiltrated to an extent making any operative venture without prospective good, though he offered to make an exploratory incision in consideration of a doubt that always pertains to intra-abdominal diagnosis. The ordinary remedies for cancer and indigestion were given; and for the relief of pain various drugs were tried in turn until morphia was settled upon. This drug, at the time I saw her, was being given in 5 grain doses hypodermically every morning and evening.

I found the patient feeble and emaciated, having a dry and shriveled skin of a pale, somewhat sallow color. The color of the skin, to me, rather than cancer, suggested tuber-

culosis. The tongue was swelled and flabby, coated and foul; it was distinctly malarial in character, though seemingly showing more, besides. The temperature ranged between 98 and 100 degrees F., without any regularity in its rise and fall. The pulse was weak, 80 to 100 beats per minute. Latterly, she had at times showed symptoms of hydrops, expressed in edema of the extremities and face. The heart and lungs showed nothing abnormal. The abdomen was considerably distended, tympanitic, tender to light touch, sore and even painful to pressure in the epigastric region. There was increased hepatic and splenic dullness and tenderness. The subcutaneous glands nowhere were found enlarged. With the patient on her back, there seemed to exist a low area of dullness, like that from ascites, but this could not be verified in any other position of the body. The menstrual function was reported to have been normal until the present trouble had existed one year; then the flow became sparse and painful. The examination of the pelvic organs revealed nothing abnormal, excepting local tenderness. This and the dysmenorrhœa and sparse flow were ascribed to the frequent vomiting and retching, and to the great general debility. The patient complained of great pain in her stomach and, though less in degree, throughout her abdomen. I was informed that her bowels were constipated and sluggish to act; that she could eat little and retain hardly anything; and, whereas her normal weight was from 140 to 150 pounds, that now she weighed about 90 pounds.

I inflated the stomach with carbonic acid gas water for purpose of diagnosis, but failed to distend this organ very much. I attributed, at the time, this failure to her slow drinking of the aerated water, and the immediate eructations following its ingestion. I found no evidence of tumor, nor of thickening of the wall of the stomach anywhere. An examination of the dorsal region showed nothing unusual; no area of dullness which might exist were cancerous tumefaction present about the esophagus.

I made no definite diagnosis. I felt I should have to accept the opinion that there was no cancer; at most this could only be of very recent development, and then it was not yet clinically manifest. I suggested the possibility of a peritoneal tuberculosis developing in the region of the cardiac end of the stomach; say from post-mediastinal glands or diaphragm. This seemed the most tenable supposition by the clinical history. The personal history of the patient contained nothing suggestive of the pathology further than her dark skin and that tuberculosis had occurred in the family. Undoubtedly the morphia habit was much to blame for her present trouble. I reasoned that possibly the disease for which the morphia was originally given, might have been long passed, and that the drug habit, contracted meanwhile, perpetuated the suffering. Stricture of the esophagus was thought of, but easily dismissed from mind. There was nothing given in the history of the life of the patient to inculcate this organ and besides, the trouble seemed beyond the esophagus, inasmuch as she could swallow food well enough, only that she had trouble in keeping it down. I advised to fathom the theory of cancer by an exploratory incision, and if no cancer were found, nor anything else that afforded therapeutic indications, to first withdraw the morphia, and subsequently to act on the clinical indications present. Even by this procedure there was little hope held out to either the patient or doctor, owing to the great decrepitude of the patient. Yet, seemingly, this plan included all hope left after four years of invalidism, confirmed by the vice of a most indomitable habit. The patient, however, was willing to submit to any procedure promising a change for better or worse. She was brought to my sanitarium on May 24, 1892. Previously, for a period of about six weeks, at my direction she was put on a liquid and semi-solid diet of the most digestible nature. This was given in small quantities at a time. During periods of great irritability of the stomach, food was withheld, often for half a day and longer. Copious injections of hot salt water (6 per cent.) into the rectum, and peptonized milk, and milk-and-whisky enemata were regularly given every four to six hours. This plan of feeding was adhered to throughout her stay at my house. Quinin was given for the cure of malaria and in small doses together with strychnia as a tonic.

The patient was operated on May 26, two days after her arrival, in the presence of Drs. R. F. and R. G. Bigger, Wm. Karstetter and E. C. Reyer, the latter giving the anesthetic, chloroform. Incision in the median line above the umbilicus. A careful search of the entire abdominal cavity was made, organ after organ being sought out and examined systematically, without detecting anything particularly

amiss. The liver was somewhat enlarged; the gall bladder was free of stones or enlargement; the spleen was moderately enlarged; nothing abnormal about the stomach *except its small size*, like the stomach of a child of 6 or 8 years, however, without any more than a slight thickening of its walls; no tumefaction, nor evidence of inflammatory disease or adhesions anywhere; nothing abnormal about the kidneys, intestines, appendix, omentum, peritoneum; no enlarged mesenteric glands. The incision was enlarged downward slightly at this juncture to examine the pelvis, and this exploration too was of negative result.

The size of the stomach, however, proved sufficiently suggestive. In considering what conditions might have given rise to this state the question of esophageal stenosis again came up, and the introduction of bougies into the esophagus a few days afterward, revealed a stricture of wide caliber near its cardiac end. The bougie at the stricture imparted the sense of being held by a pouch, and this obstacle, a few days later, when the bougie had caught in it, was forced to yield. Very likely a small cicatricial band across the lumen of the esophagus had existed and now was broken through. The recovery from the laparotomy was uneventful. The stomach was daily irrigated with a mild solution of hot soda water, which for a long time in the return flow yielded great quantities of mucus and a tenacious and shreddy matter, indicative of a chronic, deep-seated catarrhal inflammation of the stomach. Gradually, though not evenly, the stomach function and the appetite improved.

When the patient was domiciled with me, I desired to begin at once limiting the quantity of morphia taken. Heretofore it was given by injection every morning and evening, 5 to 6 grains at a dose. I proposed to divide this dose, giving it only as needed and in the smallest quantity effective. I am convinced that all cures of the morphia habit are temporary, deceptive or farcical, except where they are based on the regeneration and development of the moral force in man; this, quite irrespective of drugs or all other adjuvants employed. The moral feature is the essential etiologic condition in producing a vice of habit of any sort, be it addiction to morphia, alcohol, cocain, tobacco or what not; and the therapy must be selected and employed with regard to this. It is true this is in absolute contradiction and condemnation of the gold cure, and kindred procedures. Unfortunately, we can not satisfactorily investigate, for the purpose of negation, the real virtue of these methods. Thus we can not compute with sufficient accuracy their percentage of relapses in advertised cures, and we know nothing of the number of their absolute failures. The men interested in these methods stand, necessarily, in a position hostile to the exposure of their failures. Certain is it, that some cures are deceptions from the start; that many of the others are of short duration; and that the number cured permanently is small. The permanent cures, it may be argued, may fitly be ascribed to the revival of the moral powers residual in the respective individuals, almost regardless of other therapeutic means and measures employed.

We must accept the Biblical doctrine that man is built in the image of God; and hence, that his capability of development is infinite. The meaning of the passage in the Lord's prayer, pertaining to the evil of temptation, certainly is oftentimes too narrowly construed, when it is made to read that man is absolutely unable to meet temptation, and to withstand it. This construction is in antagonism to the doctrine that man is built in the image of God, and in its pedagogic application it is of disastrous effect on the moral development of man. Man shall not seek out temptation anywhere. But equally shall he not evade it when it meets him in the regular path of his daily presence and mission among men. Of the two ex-

tremes, it is much better that we purposely seek temptation, to merit by qualification the divine heritage, than that we hide away in abject fear, and suffer degradation, degeneration and demerit.

For the purpose of illustration imagine the individual from infancy reared in the ever-present consciousness of this godly attribute by which he may meet temptation and withstand it! Add to this the legacy by hereditary transmission of the moral wealth accumulated through hundreds of generations reared and strengthened by such doctrine and its strife! Or, on the other side, by the same activity and duration of forces, compute the moral loss to mankind in consequence of the pedagogical mistake mentioned!

Prohibition and refuge from temptation beside their direct degenerating effect, ultimately develop deception and hypocrisy. We must admit, as being logical, that we can not trust to extrinsic conditions for the support of a moral failing in man. The ordinary environment of man is ever changing, inconstant and, hence, fickle and unreliable.

Prohibition and refuge from temptation do service, but only while they are present; they impart no lasting property, no power. Thus the ordinary asylum for the morphia habitué is inseparably connected for the inmate with conditions which withhold from him his coveted drug; here are no ways, nor friends by which morphia can be procured; and everything is arranged to abolish temptation. Exchange this environment for the ordinary conveniences and attractions offered as soon as the patient is returned to society and freedom, and, because the provisions and restrictions of the institute are wanting, early the consciousness of this want is felt. It soon befalls the victim of habit like a frightful darkness, from which rescue seems possible only over paths heretofore wandered and recognized even by the blinded senses. An improvement, a cure is possible only by the constancy of an adequate support. This support is constantly present only where it rests within the individual. Where, however, the degeneration of moral power and where the neglect of its function has not annihilated this faculty, we have truthful cause to hope for its redemption and resuscitation: This moral basis of a cure is true, and it gives the best possible and only assurance of its duration. I am led to this discourse by reason of the credence commonly given to the virtue of drugs; to the retirement of the patient for the purpose of effectually withdrawing the coveted drug; to the seductive effect of large numbers seeking the same end; to the swaying properties of public mentioning for like purpose, and to other measures. This credence is bestowed, owing to an erroneous conception of the relation of things. Never, nowhere, does a drug replace a moral want or deficiency in man. Such methods are subterfuges, deceptions and snares. They lack truth and they lack the desired effect. They must be relegated to the division of mere auxiliaries, if they be not entirely banished from therapeutic consideration.

My patient was informed of the negative result of the exploratory incision. She was told that her case included nothing requiring the continued use of the morphia; that the morphia was a positive harm without any redeeming feature in it for her; that all her varied interests as an individual, as a mother, as a wife, and as a member of society demanded the disuse of the drug. That she must quit it for her salva-

tion; that she could do this; that she must and could do so alone by her own effort, and that her effort alone would suffice; that she had best begin at once. She was to be her own judge of what she needed; she was to have what quantity and whenever she asked for it. My nurses were instructed accordingly; they were bid to give the patient morphia whenever this was called for by her, as freely as when she called for food or drink, *aye*, even more, without any restriction. The patient was impressed with the sincerity of my conviction that her habit was an unfortunate fault acquired; that during the time of her cure from this habit she could not do entirely without morphia; that as her condition would vary, so would she require more and less; and that I relied entirely on her to guide me in giving the drug. Obviously this step was preceded by her fullest conviction of the disastrous consequences of her habit: That the morphia to her was really a curse and a detriment.

I here append an extract from the clinical record giving the daily dosage of the morphia taken during all the time to its complete abandonment on the twenty-ninth day.

First day, 24 hours	3	grains.
Second day, till time of operation . . .	1 $\frac{1}{4}$	"
Third day	6 $\frac{1}{2}$	"
Fourth day	3	"
Fifth day	3 $\frac{1}{2}$	"
Sixth day	1 $\frac{1}{2}$	"
Seventh day	1 $\frac{1}{4}$	"
Eighth day	$\frac{3}{4}$	"
Ninth day	$\frac{2}{3}$	"
Tenth day	$\frac{3}{8}$	"
Eleventh day	$\frac{3}{8}$	"
Twelfth day	$\frac{1}{8}$	"
Thirteenth day	$\frac{1}{4}$	"
Fourteenth day	$\frac{1}{2}$	"
Fifteenth day	$\frac{1}{4}$	"
Sixteenth, seventeenth and eighteenth days, each	$\frac{1}{2}$	"
Nineteenth day	$\frac{1}{4}$	"
Twentieth and twenty-first days, each . . .	$\frac{1}{2}$	"
Twenty-second day	7-12	"
Twenty-third day	0	"
Twenty-fourth day	$\frac{1}{4}$	"
Twenty-fifth day	$\frac{1}{2}$	"
Twenty-sixth day	$\frac{1}{4}$	"
Twenty-seventh and twenty-eighth days 0		"
Twenty-ninth day, last dose	$\frac{1}{4}$	"

The single doses varied between one-eighth grain and one grain; the former dose being given once only; one-quarter grain was the ordinary quantity asked for, excepting during the first five days, when one grain doses were administered quite often. The morphia was given all by hypodermic injection. The entire quantity given during the twenty-nine days was twenty-eight and one-half grains. No attempt to deceive the patient as to the quantity given was ever made. The last one-quarter grain dose was given toward morning, after almost three days' abstinence. The patient was restless and sleepless, and tired out, when she rang the bell for the nurse and asked for one-quarter grain of morphia. It was given without a plea or remonstrance on the part of the nurse. But it had hardly been injected, before the patient grew angry with the nurse, rebuking her for giving it, and saying she had no need of it. She made a wild effort to withdraw it from her arm with the clutched hand of the other arm. This was the last time she took morphia by her own wishes. Very nearly two years have passed since then, and to her they were years of much suffering and distress from various causes. During this

time she underwent another laparotomy, eight months after the former, to which I shall refer again in the regular narration of this case. During the first twenty-four hours following this operation, I ordered the injection of two one-quarter grain injections of morphia, and another on the second day. These were taken by the patient with a sense of revulsion. I distinctly recall her pleading look when first the drug was proposed. It was as though asking anxiously and imploringly: "Can't I do without it? Don't you fear to give it to me again?" My decision was firm and well founded; it did no harm, as the consequence proved. I have this patient where I can observe her, and I am convinced that she is cured permanently. After three months the patient could not be recognized as the same woman. She had become rejuvenated, and gained in flesh, vying with her grown daughter in plumpness and vivacity. Subsequently the patient recalled once having eaten, two years before the beginning of her stomach trouble, a hot morsel of meat, which became lodged in the lower end of the esophagus, and which for the want of any fluid at hand she could displace neither upward nor downward for some minutes. She suffered pain in this region for a week or so afterward. She had never thought of connecting this event with her ailment, nor even thought of it at all again until now. Undoubtedly this was the cause of her esophageal stricture. Since her cure the patient has had repeated attacks of neuralgia, and of articular rheumatism, which each time revived the irritability of her stomach. At such times she resumed the daily irrigation of her stomach, which she had learned to do herself, and at no time again did these symptoms give rise to much trouble.

About this time her menstrual periods grew successively more painful, and they were accompanied and followed by great tenderness throughout the lower abdomen. The flow returned every three weeks, continued longer than normal and was clotted and dark. She had whites between the periods. She suffered at all times from sharp pains radiating from the right inguinal region and great weakness in the loins and limbs. Her bowels again were costive and required urging by medicine or rectal injection. Her stomach, too, became irritable, and her appetite failed her. An examination on Dec. 14, 1892, revealed the womb normal in size, congested, twisted on itself from a point in front to the right; its fundus was drawn to the right and descended and somewhat fixed there. The right ovary was found prolapsed, adherent, enlarged and painful. The left ovary was slightly enlarged and tender, and its tube thickened and pulsating. A small nodule was left on the posterior surface of the womb, near the left horn. Hot douches, ichthylol tampons, bromids, rest in bed and other remedies were tried in vain. The pains steadily grew worse, and their darting character became more pronounced; the swelling of the right ovary reduced none under treatment, if anything seemed larger, while the clinical symptoms seemed to indicate the existence of cancer. Naturally I felt chary of pronouncing it such, owing to the precedent in this case. However, I concluded to operate.

Operation at my sanitarium Jan. 20, 1893. Present Drs. R. F. Bigger, F. Harrison and R. Hessler, the latter giving chloroform. The operation consisted of a double salpingo-oophorectomy and a myomectomy by laparotomy. I found a non-adherent left ovary, showing small cystic degeneration, its tube tortuous, thickened and highly vascular, and studded with white, glossy tumors like little pearls. The right ovary was enlarged by small cystic developments; on its free surface was a tumor the size of a large hazelnut, and of gelatinous contents; its walls were highly vascular, with a yellowish tint in some parts. The ovary and tube were studded with little excrescences as on the left side. The nodule on the posterior surface of the uterus was excised by an incision right through to its base and

each half turned out separately; the opening was sutured with a catgut suture. The microscopic examination by Dr. R. Hessler, professor of microscopical pathology in the Indiana Medical College, verified the diagnosis of cancer of the right ovary, and of fibroma of the uterus. The recovery was uneventful but for the formation of a hematocle in the left lateral ligament, probably produced by the retraction within the broad ligament of a cut vessel within the stump. This gave rise to a painful swelling in the right side, from which she fully and speedily recovered.

Since that time the patient has had no special trouble, further than occasional attacks of malaria. The examination of the pelvis within a week of this writing discovered a painlessly movable uterus and no thickening or tenderness in either broad ligament.

This case is interesting primarily because of the difficulties attending diagnosis. When once, the first time, the fatal diagnosis of cancer was made it naturally entailed the free administration of morphia. The history of this case warns us to be more careful in obscure cases to eliminate all sources of error. The case demonstrates the value and judiciousness of an exploratory incision in every case of doubtful grave abdominal disease. The comparative innocuousness of the measure, where it is carried out by skilled hands, in a properly appointed surrounding, marks the point of its legitimacy. The method of overcoming the morphia habit as pursued here commends itself by the result obtained. The principle of this method has a wide application in human effort, and should have more attention than heretofore given to it. The subsequent development of cancer in this case is an interesting clinical casualty.

The impression from the foregoing might be that the writer has not duly emphasized the importance of a sanitarium provision for the cure from such vice; or even that he stands in an attitude hostile to an institution purposely and solely conducted for the cure of this affection. Obviously, the sanitarium can readily be appointed to include all the requisites that are necessary and to banish all untoward influences that are objectionable in attempting this cure. Such appointments can hardly be attained with the patient in his or her own home. During the recovery from such vice, the patient is beset with tribulations and suffering which need and should be met effectively at once, and this can only be given by competent and authoritative presence, i. e., the doctor or nurse. It hardly needs repetition that this domicile in a sanitarium must exclude the elements or appearances of refuge and prohibition. The patient of this disease should enter upon such a course in exactly the same spirit as when undertaking the cure of a purely medical disease.

NEURASTHENIA.

Read before the St. Louis Medical Society, Jan. 20, 1894.

BY I. N. LOVE, M.D.

PROFESSOR CLINICAL MEDICINE AND DISEASES OF CHILDREN, MARION-SIMS COLLEGE OF MEDICINE, ST. LOUIS; VICE-PRESIDENT AMERICAN MEDICAL ASSOCIATION.

Since Beard's time, the well-posted physician, whether in the general field or a special line, has recognized neurasthenia "as a legitimate and well circumscribed morbid entity." Our own Dr. C. H. Hughes, of St. Louis, recognized the world over as a high authority upon neurological subjects, in a paper read before the Missouri State Medical Association

fully twelve years ago, suggested as a name for the disease, general functional neurotrophia as preferable to neurasthenia. He expressed the thought at the time that the disease was a more or less general failure of the normal nutrition appropriating power in the higher nerve centers, especially the psychical, leading to consequences short of appreciable structural change—a pure neurotrophia—which is only functional in its effects and confined, in expression, to an altered and lowered functioning in the nervous system itself.

A synonym for the disease is nervous prostration, and the name which Beard himself gave to it was nervous exhaustion, but all the names are objectionable, for they suggest symptoms rather than a definite pathological condition.

The cause of this disease, like all others, may be hereditary or acquired. The medical man who is brought in close relations to the family as family physician should be fully impressed with the thought that his advice will be of value in the securing of nerve capital and a good general equipment for at least the rising generation of the family. Truly many individuals are put into the world and have crowded upon them the battles of life when they are so poorly equipped with nerve force as to be almost considered nervous bankrupts.

The child which has a tubercular inheritance can be built up and away from it; so, too, if heredity is against it from the standpoint of the nervous system, the child may be fed up and out of it.

In these modern days of specialism, while admitting that the expansion of knowledge in every department of life has largely put an end to that ideal of "knowing something about everything, and everything about something," yet the members of the medical profession should guard themselves strenuously against the danger of automatic specialism. As was recently remarked by the *Medical Record*: "The glory of modern specialism is that it has unraveled difficult questions in the etiology of disease, and its crowning work must lie in its ability to meet the demands which this new pathological inquiry makes with adequate therapeutic measures. To do this requires mental expansion in every direction, and not alone in any one."

As was well said by Dr. Hughes in his recent essay before this Society upon this subject: "Physicians may become specialists in practice, but they should never cease to be generalists as students."

The family physician, other things being equal, is well equipped for coping with the disease under consideration within certain limits, on account of his personal knowledge into the habits, manner of life and general physical make-up of the patient as well as his temperament. Hutchinson defines temperament as the sum of physical peculiarities of the man exclusive of his tendency to disease, and it has tersely been expressed as being the "peculiar way in which the individual reacts to the stimuli of his environment." Temperament has been too much neglected in these latter days. There was a time in professional and institutional circles when much more stress was laid upon this subject and an ability to recognize and know temperament used to be considered part of a sound medical training. There are many things in man which the test tube and the microscope can not discover, and in our work as bacteriological delvers and in our desire to be

superlatively scientific, we should not lose sight of this fact.

While by no means maintaining that leisure and wealth are the only conditions favorable to neurasthenia, so-called, I still urge with Beard that it is seldom found among those who live below the upper crust of the social world; that its habitat is rather in Fifth Avenue than the Five Points. The manual laborers of the world, however little they may know, generally know enough to rest when they are tired, and they have the advantage of fewer superheated and poorly ventilated homes, besides their muscular development holds down their emotional centers to a safe level. Neither are they as a rule disturbed by the trinity of A's which confront a large proportion of those in the higher walks of life, viz: Ambition, Avarice and Anxiety, and the trio of L's which environ the rest, viz: Laziness, Luxury and Lust.

The writer desires to be placed upon record in favor of the position that in spite of the fact that cases of neurasthenia are overlooked by the family physician, yet the number that are labelled nervous exhaustion, by neurologists, which do not properly come under that head, is very greatly in excess; in other words, to a certain degree it has become the fad on the part of the American public to elect to be placed under the head of neurasthenics, and neurasthenia is the chief hobby ridden by the nerve specialist of to-day. I take the position that 90 per cent. of the so-called cases of nervous exhaustion are spurious. That they are the victims of nervous weariness may be admitted, but weariness and exhaustion are two different things. Physical weariness may occur in three ways: The muscles may be affected, the nerves may become fatigued, the brain may become weary; all or any of the three may become tired out, and this tiring out may occur time and again without exhaustion resulting; and the classical symptoms as given by Beard and corroborated by so many other observers the world over which apply to nerve exhaustion, may appear in a modified form in the victim of nerve weariness, and suggest to the alarmist or he who is given to forming extreme conclusions that the case before him is one of exhaustion.

Michael Foster, the great physiologist, in a recent address delivered before the members of the University of Cambridge, apropos to this subject of weariness, says:

"Observations and reasonings, into the details of which I can not enter now, have led physiologists to the conclusion that a muscle not only in the body but also for a measurable time out of the body, is continually undergoing change of substance; that the complex groupings of atoms, molecules and particles by virtue of which it is alive are continually being made and as continually being unmade; the living complex muscle is always being built up out of, and always breaking down again into simpler substances. Did we possess some optic aid which should overcome the grossness of our vision, so that we might watch the dance of atoms in this double process of making and unmaking in the living body, we should see the commonplace lifeless things which are brought by the blood, and which we call food, caught up into and made part of the molecular whorls of the living muscle, linked together for a while in the intricate figures of the dance of life, giving and tak-

ing energy as they dance, and then we should see how, loosing hands, they slip back into the blood as dead, inert, used-up matter. In every tiny block of muscle there is a part which is really alive, there are parts which are becoming alive, there are parts which have been alive, but are now dying or dead; there is an upward rush from the lifeless to the living, a downward rush from the living to the dead. This is always going on, whether the muscle be quiet and at rest or be moving; some of the capital of living material is always being spent, changed into dead waste, some of the new food is always being raised into living capital. But when the muscle is called upon to do work, when it is put into movement, the expenditure is quickened, there is a run upon the living capital, the greater, the more urgent the call for action. Moreover, under ordinary circumstances, the capital is during the action spent so quickly that it can not be renewed at the same rate; the movement leaves the muscle with an impoverished capital of potential stuff, and a period of rest is indeed in order so that the dance of atoms of which I just now spoke may make good the loss of capital and restore the muscle to its former power.

"In considering muscular weariness, we at the same time must keep in mind weariness of the nerve centers, for after all the weariness of the whole body from muscular work is to a very great degree in fact chiefly a weariness, speaking broadly, of the brain.

"When we have excessive muscular exertion, the weariness may take a form of distress and if the effort be continued the distress may become so great as to occasion such complete exhaustion that even death may result. In excessive work of whatever kind it may be, in order for the work to be accomplished, there is made a greater demand upon the blood for oxygen. Difficult breathing or panting results from the changing quality of the blood. There are many things besides carbonic acid which are swept into the blood as the result of the activities of the body; in other words, the product of work in the human body is a poison which must needs be eliminated through the medium of the lungs and the other excretory organs."

Foster again well expresses it, "as the breath of man is poison to his fellow-man, so the outcome of the life of each part of the body, each tissue, be it muscle, brain or what not, is a poison to that part and its fellows, and may be a poison to yet other parts. Of each member, while it may be said that the blood is the life thereof, it may with equal truth be said that the blood is the death thereof; the blood is the channel for food but it is also a pathway for poison."

It would seem superfluous to draw attention to these well-known physiologic facts, but I do so only to emphasize the point which I make, and that is that by neglect upon the part of the individual of certain necessary laws involving rest, opportunities for oxygenation, proper attention to elimination through the various draining channels of the body, excessive work whether bodily or mental in repeated cases produces such a degree of weariness and poisoning of the nerve centers as to mislead us in the direction of interpreting the symptoms present as those of neurasthenia.

The same author in his admirable paper referred to says: "The loss of living capital, or the presence of the products of work which would have no ap-

preciable effect on a muscle, may wholly annul the work of a piece of nervous machinery. If an adequate stream of pure blood, of blood made pure by the efficient coöperation of organs of low degree, be necessary for the life of the muscle, in order that the working capital may be rapidly renewed and the harmful products rapidly washed away, equally true, perhaps even more true, is that of the brain. As physical and mental efforts are continued, the eliminating capacity unless carefully guarded is marred, the resulting poisons are more and more heaped up in the system, poison the muscles, poison the brain, poison the heart, poison at last the blood itself, starting in the intricate machinery of the body, new poisons in addition to themselves. The hunted hare run to death dies not because he is choked for want of breath, not because his heart stands still, its store of energy having given out, but because the poisoned blood poisons his brain, poisons his whole body. So also the schoolboy urged by pride to go on running beyond the earliest symptoms of distress, the mere loss of wind, struggles on until the heaped up poison deadens the brain and he falls dazed and giddy as in a fit, rising again it may be, and stumbling unconscious, or half conscious only, by mere mechanical inertia of his nervous system, only to fall once more, poisoned by poisons of his own making."

I quote liberally from the thoughts of the physiologist, Foster, for the purpose of making more clear the position taken. If continued effort without rest will poison to the extent of producing death, surely many repeated efforts which are not so much in excess with conditions favorable to accumulation of leucomaines, namely, only a tied up state of the secretions, inattention to the proper diet, accumulations of undigested and unassimilated food which undergoes fermentation and decomposition, developing ptomaines, thus adding to the reserve of poison in the system; keeping in mind the fact that the neglect of hygienic laws, failure to secure proper ventilation of rooms and the proper clearing out of the alimentary canal at proper times; surely we may have weariness and poisoning to the point of distress and even to that point which would suggest nervous exhaustion. Men who are greatly absorbed in their work have no time to think about the laws of health, but the family physician and the neurologist, as well, should realize in these cases the importance of "clearing the decks for action." They should promptly turn on the batteries which will scatter the accumulated poisons, open the windows, put the patient outdoors, anywhere so that the purest air may be breathed and elimination of the accumulated poisons hastened. In his essay read before this Society a few weeks ago, Dr. Bremer said:

"There is no class of sufferers more persistently and vigorously maltreated than the neurasthenic. The cause of this lies in the fact that there is no organ, member or tissue in the body, which has not been held up as the chief offender in neurasthenia by some or another specialist. The worst of it is that since specialism is still on the increase, the number of offending parts of the body is steadily multiplying, and however much legitimate specialism may have done for the advancement of the medical sciences, it must be admitted that the abuse of specialism has assumed the proportions and significance of a nuisance. There is to-day no specialist but does not consider neurasthenia a legitimate and fruitful

field for its work, in a few instances to the advantage, but much more frequently to the detriment of the patient. Broadly stated the medical profession of to-day may be divided into two classes; the peripherists, comprising almost all specialists, and the centralists, found principally among the general practitioners and the neurologists. It has been said of the latter that whenever they do make a right diagnosis, as a rule nothing can be done for the patient. This is unfortunately true in a measure, but in this sense, that the patient has already gone the round of the peripherists, the specialists of the various organs, who mistook the case for a local trouble causing general symptoms, and tinkered at irrelevant symptoms, until the precious time for rational general therapeutics was gone. Had they looked upon the disorder of the various organs with a "central" light, interpreting the local trouble as being due to a general central disturbance, the result of their therapeutic efforts would probably have been entirely different.

"As a matter of fact it must be stated, that social strata do not make any difference in the frequency of Beard's disease. Rich and poor are indiscriminately affected by it. The only difference is in name, not in fact. For while the well-to-do neurasthenic, especially he that has an inkling of the ailment from his reading on the subject, is apt to apply to a neurologist for relief and get from him the true name of the disease, the poor man has to be satisfied with the diagnosis of biliousness, dyspepsia, catarrh and similar diagnostic incongruities, and is allowed to worry through his collapses as best he can, with the aid of quinin, calomel and tonics."

It is fortunate for humanity that the general pathologists and other specialists of the world have had this note of warning given them by a neurologist. Possibly they will in future leave the domain referred to entirely to those who look upon all the disorders of the various organs with a "central" light and interpret all local troubles as being due to a general central disturbance. However positive this dictum may seem, practitioners and specialists will more than likely still go on recognizing the fact that over-eating with too little defecation and accumulated leucomaines and ptomaines, and peripheral irritation, a figurative thorn in the flesh, all may if left unrelieved, create all of the symptoms of so-called neurasthenia, and that the cause being removed, the symptoms will disappear as if by magic.

Commencing with the teething child which is thrown into reflex convulsions as the result of an erupting tooth, all along the line to the second childhood when an unrelieved pruritis or eczema drives its victim mad with discomfort, we have evidences in favor of the thought that peripheral irritations are the prime cause in many cases of so-called neurasthenia.

Every general worker and specialist in diseases of the rectum has found patients on the border line of nervous exhaustion and almost madness, all produced by a fissure of the anus. There are probably those within the sound of my voice who have seen numerous cases presenting many of the symptoms of neurasthenia, caused by an obstructing spur upon one side or the other of the nasal septum, occasioning accumulations above up to the frontal sinuses, and at times the sufferings approaching the agonies of the damned. These cases, together with others which might be mentioned, the offending organs never having been interrogated, have run the

gauntlet of neurological treatment for months and even years, and are finally relieved quickly and precisely by the removal of the peripheral disturbance. We all know that excruciating pain borne even for a short time or pain of any kind wherever located, if long continued, will beget a general demoralization of the nervous centers simulating nervous exhaustion. Surely all of us, whether specialists or workers in the general field, should try to save our patients pain, with a view to the husbandment of their nerve force. From infancy, the growing child should have its teeth guarded with a view to prevent toothache and the consequent nerve disturbance. The mothers of the world should be placed in the best possible condition for the pangs of maternity, remembering the element of poisoning, how susceptible the nervous centers are to being poisoned. Thus elimination, cleansing of all the emunctories, should be the rule, particularly during the pregnant period, and then every possible pain should be prevented. More rapid recoveries would follow and parturition would result in less loss of nerve force.

Indeed, there is no special line of study which the worker in general medicine or the family physician should apply himself to more assiduously than the nervous system. Just in so far as he can, this particular laborer in the medical vineyard should be a neurologist, for it is a fact that all will admit that after all the nervous system represents our main capital. All that will develop it and maintain it and prolong its usefulness, should be known and made a part of the armamentarium of the general practitioner. The neurological author of "Current Fallacies" about neurasthenia, previously quoted, read a tirade in this Society a few years ago against gynecology (which by the way, was never answered), but may we not say that the criticism which may justly be directed toward the specialist who runs too much in grooves, will apply in a most pronounced way to the neurologist who dwells too much upon his particular line of thought.

In the language of the present President of this Society, the brainy and brilliant Outten, "the psychiatrist, whose curious art is oft too finely wrought, syllogizes mind oft while his own is pathologized by thought." In other words, the neurologist is in danger of laying too great stress upon his particular part of the anatomy and is tempted to misinterpret symptoms and dislocate disease. To him, unless he have a care, every victim of suffering or discomfort is a bundle of nerves gone wrong. The most successful workers in this field are those whose emotional centers have been kept in reserve and whose intellectual centers have been most strongly developed from the beginning and they base their work upon a foundation of broad general practice. The neurologists, like all the rest of us, should remember that every man becomes largely the crystallized result of all that he has seen, of that which he has associated with, and of that with which he has been brought most closely in contact. The psychiatrist then should constantly guard himself against exaggerating the neurological phenomena which present themselves to his view. He and the rest of us should remember that it is all very well to declaim against the specialist who interprets all headaches as being due to a necessity for eye-glasses, or the one who prefers to glide ever and always only in gynecic grooves, but some of our neurological brethren, God bless them,

have often been known to misinterpret and exaggerate symptoms. Admitting for the sake of argument that many a woman suffering from a sore brain or a sorrowing heart has received treatment for a sore womb, that the womb of the world has been twisted and twirled in excess, that the docile, gentle and inoffensive ovary has not often enough been permitted to blush unseen and waste its sweetness upon the silent air, but all too oft has been rudely snatched from its sacred lair when it never had been guilty of doing anybody harm, still the fact remains that gynecology has relieved more sorrows, brightened more homes, saved more precious lives, and will go on saving more millions of lives that exist now only in the womb of the future than all of the other surgical specialties combined. It is the novices only who rush in where angels fear to tread, and act upon the idea that a woman's anatomic, physiologic and pathologic world is her womb. We should none of us, however, throw stones at each other, for the bulk of those in the medical profession (and out of it, too, for that matter) this side of Heaven, have their houses composed chiefly of glass.

I have in my records a half dozen cases of men of affairs approaching the fair, fat and forty age, where success had come to them after many weary years of labor; leisure, responsibility, over-eating and constipation followed; then came headaches, brain pressure, anxiety, insomnia, morbid fears followed by neurological opinion suggesting nervous exhaustion, which in its turn was followed by a frenzy of anxiety and dread of the future, all relieved within a few weeks by brisk purging, flushing of the kidneys, diaphoretics, fresh air, proper diet, a few nights of good sleep, and last but not least the instruction to buy and wear No. 16 collars instead of 14½ size which had been worn for years. Busy men when nearing the middle mile post of life as they increase in weight, often fail to realize that their necks grow more rapidly than their girth, and as a result they suffer from plain, everyday, tight collar headaches.

In a discussion of this subject at a recent meeting of this Society, a prominent member cited his own case of neurasthenia as one produced by prolonged loss of sleep and anxiety on account of sickness in his household, and that he was practically cured by many long continued hours of sleep. Here was a case of extreme fatigue diagnosticated nervous exhaustion, which was relieved by hours of sleep. Fancy, if you can, any one, the picture of intellectual health and animal vigor, as having had neurasthenia and been cured of it inside of a few weeks.

Constipation, excessive eating, lack of exercise and absence of proper exposure to fresh air upon the part of one of the strongest, most healthy looking and most robust members of our profession, resulted in a collapse which was interpreted as neurasthenia and treated as such, and kept under treatment for several years and the victim is not well yet, and the question may well be asked whether he ever will be. His neurologist flattered his vanity by telling him that he had neurasthenia as the result of overwork. Overwork forsooth! A practical all around physician would have inquired into his habits of life and ascertained the fact that he was a gourmand, that he ate as much of the richest food, being possessed of epicurean tastes, as would have been sufficient for three men. Being a specialist, with his work confined almost entirely to ill-ventilated offices in an old

styled, illy plumbed house on one of the prominent thoroughfares of the downtown portion of the city, the conditions were favorable to accumulation of poisons. He was in the position of a furnace supplying force to a mechanism wherein the fuel was shoveled in, in enormous quantities, a poor draft was given, the amount of oxygen was not sufficient, the ashes of combustion and clinkers were not properly removed and as a result there was an explosion upon the part of the outfit. Had the doctor referred to, fallen into the hands of an all-around many-sided physician, he would probably have been purged early and often for at least a week, for it would have taken that length of time however energetic his doctor might have been, to have cleared out the accumulations in that alimentary canal. At the same time his kidneys would have been flushed with a view to the more complete removal of poisons which are eliminated through this channel. The activity of the skin would have been encouraged, and during this time the poisoned nerve centers having unfitted him for exercise, he would have been furnished muscular exercise through the medium of massage. I venture the opinion that he would have been rid of his leucomaine and ptomaine poisoning within a very short time, and having been placed upon proper diet and instructed to take proper exercise both in walking and horseback riding, he would have been in shape for work promptly.

Malaria, cold and rheumatic conditions are often potent factors of so-called cases of neurasthenia. Chilling of the surfaces even if malaria be ruled out, and certainly where the system is depressed, no matter what the case we may have under our care, malaria can not often be ruled out of our philosophy, particularly in the Mississippi Valley. But even though it be not considered, with the nervous system, (which after all is our power of resistance against disease) below par, the susceptibility to cold so-called, is great. Chilling of the surfaces, driving the blood inwardly and interrupting the equilibrium of the circulation, still further adds to the difficulties which confront us, and begets a condition of disease which has been long considered under the term of rheumatic, to which Dr. Hans Froelich in a paper recently presented to the profession, has given the name of lymphostasis (*Medical Mirror*, January, 1894).

Dr. Froelich says that with such patients there is always too rich a supply of food with too little combustion, caused by insufficient peristaltic and voluntary motion. These circumstances, single or combined, then cause an engorgement of the concentrated lymph, which condition is first noticed in the fissures and tissue spaces, the source of the lymph system.

It will thus be seen that the rheumatic and gouty elements, the presence of uric acid and the deposit of fibrinous materials along the track of nerves, in other words, a lymphostasis should be constantly kept in mind, and so too the fact that in proper regulation of diet, massage and flushing of eliminative organs lies relief.

In closing, I desire to emphasize the following points:

1. The majority of cases of so-called neurasthenia are either victims of (a) nerve weariness dependent upon misdirected energy without proper rest at proper intervals; and (b) nerve poisoning, the result of

constipation, improper food and accumulation of the ashes of combustion, leucomaines and ptomaines—a disposition to use the stomach too much and the rectum too little, and a failure to appreciate the importance of pure air as a rejuvenator of tired and poisoned nature; or else (c) nerve demoralization resulting from unrelieved peripheral irritations.

2. There is less harm in the victim of disease directing his attention to special organs and peripheral points as the offenders of his comfort, than there is in having his mind absorbed in the contemplation of his nervous apparatus. In other words, it is an evil day for any one, man, woman or child, when the attention is concentrated upon the nerve centers, when the energies are directed toward watching nervous symptoms; in fact, it would be well for them if they never had a knowledge of the anatomy and functions of their nervous system, and this knowledge should be the last presented to them for consideration.

The best way to cure the discomforts occasioned by nerve weariness and nerve poisoning, and even those of nervous exhaustion, which are far more serious, is to prevent them; and it should be our constant desire to impress upon the families with which we come in contact the importance of building up the nerve capital of the child from the day of its birth and even before its birth, indirectly through the mother. We should endeavor to teach the burden bearers and battle wagers of the world that the fruit bearers have a nervous system more easily fatigued and more easily put on edge than their own. Then will we help them to realize that marriage is not a failure. With a view to the building up and maintainment of nerve force and guarding against nervous bankruptcy, both on the part of parents and children, we should teach them the importance of proper food, proper clothing and a properly opened condition of the animated system of sewerage. We should impress them with the fact that the daily visit to the Temple of Cloaca, with satisfactory results, is quite as important as the morning and evening prayer. When we recall the fact that 90 per cent. of the women of the world are much more constipated than the traditional owl, we will realize what room there is for improvement in this direction. A special missionary work should be entered into on the part of the profession among the teachers of our schools, for they need not only to know the importance of the flushing out of the alimentary canal, so far as they themselves are concerned, but its importance as a stimulator of the wit and the ability of the young idea in the direction of shooting properly. All along the line we are safe in keeping in mind the cardinal principles both as preventers and curers of the conditions mentioned, namely, elimination, disinfection, nutrition, tranquilization and oxygenation. Large quantities of pure water serve, whether preceded by medicament or not, as excellent stimulators of the eliminative organs.

Food that is easily digested and readily assimilated is important, and in this connection the fats, hydrocarbons, are more valuable even as nerve builders than as enemies to tuberculosis, and that is saying a great deal. Under this head, butter and milk stand preëminent.

Sleep is indeed "tired nature's sweet restorer," and it represents the life of the individual. Mothers should be impressed with the fact that children who

are poor sleepers run the chance of growing up with wrecked nervous systems. The average mother, as well as the average child, does not sleep enough.

The limits of this paper will permit of but a few points in the way of treatment. As a sleep producer, I believe that trional in 10, 20 or 30 grain doses, is the best remedy we have at hand. No exaltation, no depression and no bad effects follow its use. I observe in a recent number of one of my exchanges, a very pronounced tribute to this remedy by Dr. J. B. Mattison, of Brooklyn, N. Y., a high authority. His experience is entirely in harmony with my own.

The digestion should be helped in order to secure nutrition in better form in every way possible. I have no sympathy with those who inveigh against the general aids to digestion. Just as well say that when a man's leg is broken or injured he should not wear a crutch as to say that when the digestive powers are crippled, crutches are not indicated. Pepsin which assists in the digestion of albuminous foods, and diastase which directs its energies toward the digestion of starchy foods are of value. Papoid is also an excellent helper of digestion. Remembering that we have a condition of general debility all along the line, tonics are certainly indicated, and there is none better in all the world as a toner up of digestive and general nerve activity than strychnia.

For long, arsenic in the form of Fowler's solution has been a sheet anchor in the treatment of chorea and allied conditions, and believing as I do that in neurasthenia, which is a disease of adult life, that the conditions are almost identical to those which are present during childhood when chorea prevails, (hysteria, chorea and neurasthenia are all a species of physical insanity) I consider arsenic of great value. Within the past few months I have administered to these cases a preparation which was introduced to the medical profession by Dr. Wm. F. Barclay, of Pittsburg (one of the most reputable physicians in the State of Pennsylvania, a man who is an expert chemist and a thoroughly reliable observer) and to which has been given the name of arsenauro, which is in fact a beautiful and attractive liquor of the bromid of gold and arsenic. (Every 10 drops, the ordinary dose, contains one thirty-second grain of gold bromid and one thirty-second grain of arsenic bromid. I have a very large number of patients using this compound in 10 drop doses three or four times a day and uniformly with good effect.

Let us not forget that the majority of these cases, whether spurious or bonafide neurasthenia, have usually a rotten, crowded condition of the alimentary canal, a long history of constipation leading up to leucomaine and ptomaine poisoning and that the entire system of secretory glands is deficient and perverted in activity, and that flushing out of the emunctory system is called for. As an all around excellent stimulator of elimination, tongalin (Liq. tong. salicylat—Mellier) is indicated. Pains which are present are well met by the salicylic acid contained in the compound and which is of the best form, being made from the oil of wintergreen. The pilocarpin, cimicifuga and colchicin which it contains are all stimulators of elimination. I usually administer from a teaspoonful to a tablespoonful at bedtime and oftener if necessary in order to clear out the bowels thoroughly.

In cases of la grippe which are accompanied by so-called rheumatic symptoms and great nervous

prostration, the tongalin is particularly indicated as a flusher of the sewerage system.

Change of scene and air are often indicated, and to my mind, no better place in all America can present itself than Hot Springs, Arkansas. Here we have the elevated mountainous atmosphere, the ideal water and facilities furnished for drinking it in large quantities, and being hot it is all the more promptly eliminated, and at the same time the bathing in the hot water is very beneficial in the direction of relieving the pains which so frequently accompany these conditions.

The judicious administration of electricity is certainly indicated, but I am strong in the belief that more are benefited by judicious massage, both manual and mechanical, than by electricity.

WHAT THE GENERAL PRACTITIONER SHOULD KNOW ABOUT DISEASES OF THE EYE.

BY FRANK TRESTER SMITH, A.M., M.D.

CHATTANOOGA, TENN.

SECRETARY OF THE TRI-STATE MEDICAL SOCIETY OF ALABAMA, GEORGIA
AND TENNESSEE.

In the issue of the JOURNAL of February 3 Dr. W. A. Fisher reviews an article of mine on the above subject read before the Tennessee State Medical Society.¹ In the article I stated that it was not expected that every doctor should become a specialist but that he should understand enough to know his ignorance; that it was not necessary for him to be able to fit glasses but he should understand the main indications for the use of spectacles, viz.: Presbyopia, diminished vision, asthenopia, headache, functional nervous diseases, etc.; he should be able to diagnose between cataract and glaucoma as a cause of poor vision, and also be familiar with the diagnosis of inflammations of the conjunctiva, cornea and iris; he should be informed on the indications and contra-indications for the use of atropin, eserine and similar drugs. My article was an endeavor to outline a statement of the *minimum* amount of knowledge which a general practitioner should possess who desires to practice medicine conscientiously. More information on these subjects might be useful, but the above seemed to me to be indispensable. I advocated, further, that the doctor should not attempt to use the ophthalmoscope. It is on this latter point that Dr. Fisher takes issue with me, and he truly states that my position is different from that of most of the teachers of the day.

To this I can reply that it accords with the practice of the day. The great mass of practitioners have decided that it is not best that they should attempt to use the ophthalmoscope. It has seemed to me that one of the main causes that the doctors know so little of this branch is that their teachers try to cover too much ground and the medical student gets a working knowledge of very little in most of our colleges.

The Doctor is unfortunate in the examples he presents in advocating the use of the ophthalmoscope by the general practitioner. He asks: "It is of importance to diagnose glaucoma early, but if he is barred from the use of the ophthalmoscope how can he make the early diagnosis?"

¹ Alabama Medical and Surgical Age, June, 1893. Virginia Medical Monthly, July, 1893. Atlanta Medical and Surgical Journal, August, 1893. American Practitioner and News, December, 1893.

The diagnosis can certainly be made by the increased tension which does not require a great amount of skill if it be at all marked. The diagnosis with the ophthalmoscope depends on the excavation of the optic nerve mainly and this does not occur *early*. In the case of glaucoma cited, the pain and diminished vision would suggest glaucoma. Confirming this there would have been an anesthetic hazy cornea, a shallow anterior chamber, a dilated pupil, enlarged episcleral veins, a history of halos and increased presbyopia, although some of these symptoms would have been wanting.

The case of Dr. Shinn was one of amblyopia from tobacco or alcohol, and could have been diagnosed by the central scotoma for red more certainly than by the ophthalmoscope. The Doctor relates a case of cataract and asks why the ophthalmoscope should be ignored. Practically no one makes a diagnosis of cataract with the ophthalmoscope except it be in incipient cataract. A general practitioner ought to be able to diagnose a cataract which was so far developed as to cause the sufferer to be sent to the asylum, especially if he should dilate the pupil. The gradually failing vision without inflammation and the age of the patient would indicate the trouble which would be confirmed by the appearance of the pupil. As to fitting glasses, I said the practitioner need not do this work. So far as the specialist is concerned it would be better if spectacles were fitted by doctors than by jewelers and traveling charlatans. Many defects of the eye would be discovered which are now unnoticed. The more the profession know of the eye the better for the competent oculist. From a theoretical standpoint it might be better for all practitioners of medicine to master the ophthalmoscope, but I believe the student would better spend the time in studying the diagnosis of glaucoma and cataract by other means or with physical diagnosis and kindred studies. The graduate should be required to be informed on the matter indicated in the article but it is not necessary for him to handle the ophthalmoscope nor is it expedient as a rule that he should do so.

CLINICAL HISTORY OF THE CASE OF PRESIDENT JAMES ABRAM GARFIELD.

BY ROBERT REYBURN, A.M., M.D.

PROFESSOR OF PHYSIOLOGY AND CLINICAL SURGERY MEDICAL DEPARTMENT HOWARD UNIVERSITY, WASHINGTON, D. C., AND ONE OF THE ATTENDING SURGEONS IN THE CASE OF PRESIDENT GARFIELD.

(Continued from page 502).

IV.

August 8, 6 A.M. He had five ounces of koumiss. At 8 A.M. seven ounces of koumiss. At 8:40 A.M. he took five ounces of claret. August 8, 8:30 A.M. Temperature 98.4; pulse 94; respirations 18. August 8, 12 M. Temperature 100.2; pulse 104; respirations 20. August 8, 7 P.M. Temperature 101.2; pulse 108; respirations 19.

The President's wound was dressed at 8 A.M. and it being evidently necessary to make a more free opening in the wound to facilitate the escape of pus, he was etherized this morning, and the operation performed. Dr. Reyburn administered the ether, and it acted very quickly and pleasantly. The incision was extended downwards and forwards, and a

counter-opening was made into the track of the bullet below the margin of the twelfth rib; this was done by Dr. Agnew. Two drainage tubes were then inserted. The President bore the operation well. He was given some claret at 12 M. At 1 P.M. he took seven ounces of koumiss which he vomited soon afterwards. He took no nourishment until 5 P.M. and then only small doses of milk and lime water were given him during the evening until his stomach recovered from the nausea resulting from the etherization. The wound was dressed as usual at 6 P.M.; it looked well, but had a profuse discharge of pus and bloody serum. The President slept well during the night, but had fever which partially abated towards morning.

August 9, 8:30 A.M. The President has a higher temperature than he has had for a number of days at this hour of the morning. At 8 A.M. his wound was dressed, and it was found that the pus was being freely discharged through the counter opening made yesterday. August 9, 8:30 A.M. Temperature 99.8; pulse 98; respirations 19. August 9, 12:30 P.M. Temperature 99.7; pulse 104; respirations 19. August 9, 7 P.M. Temperature 101.9; pulse 106; respirations 19.

Since yesterday afternoon small quantities of liquid food given at short intervals have been retained, and during the day larger quantities were administered without gastric disturbance. He had an enema at 5 P.M. The wound was dressed at 6 P.M. The track of the new wound was found to be closed evidently causing some irritation. The President slept well (without the use of any anodynes) but sweat a good deal during the night, and complained of weakness this morning (August 10). Professor Agnew left at 2 P.M. August 9.

August 10, 5:30 A.M. He was given five ounces of milk with half an ounce of lime water. At 8 A.M. the wound was dressed, and a profuse discharge of pus came from the new opening, which evidently relieved him very much. His temperature fell to normal this morning. August 10, 8 A.M. Temperature 98.5; pulse 104; respirations 19. August 10, 12:30 P.M. Temperature 98.6; pulse 110; respirations 18. August 10, 7 P.M. Temperature 101; pulse 108; respirations 19.

August 10, 8:15 A.M. He took half an ounce of brandy. At 9 A.M. he took breakfast, a little chicken toast, potatoes and strawberries. At 11:15 A.M. he had half an ounce of brandy. At 12:15 P.M. he had six ounces of milk with half an ounce of lime water. At 3 P.M. he had six ounces of koumiss. At 4:15 P.M. he had half an ounce of brandy. At 5:15 P.M. The President has passed quite a comfortable day, and had no rise of temperature until the evening. The wound was dressed at 6 P.M. and was much improved in appearance, and with a free discharge from the deeper parts of the wound. He has taken half an ounce of brandy four times during the past twenty-four hours and an adequate supply of liquid food.

August 11. The President slept well during the night only awaking once. At 4:30 A.M. he had six ounces of milk. At 6:30 A.M. he had six ounces of koumiss. At 8:30 A.M. he had three ounces of bouillon, and two teaspoonfuls of meat juice. At 10:40 A.M. he had for breakfast the same as yesterday. The wound drained well, and there was not such an accumulation of pus as usual, in the deeper parts of the wound. Granulations are showing themselves on

the edges of the wound. August 11, 8 A.M. Temperature 98.5; pulse 104; respirations 19. August 11, 12:30 P.M. Temperature 98.6; pulse 110; respirations 19. August 11, 7 P.M. Temperature 101.2; pulse 108; respirations 19.

At 12 M. he had six ounces of milk. At 2 P.M. he had four ounces of bouillon, and two teaspoonfuls of meat juice. At 4:10 P.M. he had six ounces of koumiss. During the day he had four doses (of half an ounce each) of brandy, at intervals of four hours. The President had an excellent day until 4 P.M. when the febrile rise took (101.2). On dressing the wound at 6 P.M. the flow of pus not as abundant as usual. After dressing the wound the President seemed to feel relieved, and fell asleep about 6 P.M. Professor Hamilton arrived at 10 P.M.

August 12, 1:15 A.M. he had six ounces of koumiss, and the same at 6 A.M. At 8 A.M. he was given half an ounce of brandy. During the night he was somewhat restless, and awoke at 5:30 A.M. After being sponged off with alcohol he went to sleep again and slept until 7:30 A.M. At 8:40 A.M. he took two ounces of bouillon, and two teaspoonfuls of beef juice. He breakfasted at 10:50 A.M. on a raw beef sandwich, and milk toast and seemed to enjoy it. No brandy was given at noon at the request of Professor Hamilton. At 1 P.M. he had six ounces of koumiss, and at 3 P.M. he had six ounces of milk. At 5:30 P.M. he had six ounces of koumiss. Dr. Bliss was compelled to go home to-day at 1:30 P.M. as he was suffering from septic poisoning received through a cut in his hand while dressing the wound of the President on August 8.

August 12, 8:30 A.M. Temperature 98.6; pulse 100; respirations 19. August 12, 12:30 P.M. Temperature 99.3; pulse 100; respirations 19. August 12, 7 P.M. Temperature 101.2; pulse 108; respirations 19.

The President has been doing fairly well to-day, though slightly feverish. It was determined to abstain from giving the President any brandy or other stimulants for the term of twenty-four hours. The wound was dressed as usual, and the discharge at both morning and evening dressings was not as abundant as customary. He had the same febrile rise (101.2) that he had last evening.

August 13, 8:30 A.M. The President did not sleep as well as usual during the early part of the night. After midnight, however, his sleep was more refreshing, and only broken at long intervals. This morning his temperature did not fall to the normal point (as it has done for several days past) and remained at 100.8 during the morning dressing. After the morning dressing he improved, and his temperature fell to 99.2. August 13, 8:30 A.M. Temperature 100.8; pulse 104; respirations 19. August 13, 12:30 P.M. Temperature 99.2; pulse 102; respirations 19. August 13, 7 P.M. Temperature 100.7; pulse 104; respirations 19.

August 13, 2 P.M. The fever indicated in the morning bulletin has gradually receded and the President is in good spirits and expresses himself as feeling very comfortable. The day is extremely oppressive, over 90 F. in the shade; but the President's room is kept comparatively comfortable by means of the cooled air, which is forced into it, the temperature being kept about 80 F. Early this morning at 3 A.M. he awoke and took six ounces of milk; at 6:45 A.M. he had six ounces of koumiss; at 8 A.M. he had three and one-half ounces of bouillon, and two drachms of

meat juice. The stimulants which had been suspended during the past twenty-four hours were resumed to-day. The President showed such exhaustion after their suspension that the unanimous opinion of the surgeons was in favor of their resumption. Professor Hamilton left for New York at 10:15 P.M. At 8 A.M. the President was given half an ounce of brandy; at 10:30 A.M. he breakfasted on a little stewed dried beef, toast, potatoes and a little onion. At 11 A.M. he had six ounces of milk. At 1:10 A.M. he had three ounces of chicken jelly, and half an ounce of brandy. At 4 P.M. he had six ounces of milk and at 5 P.M. he had an ounce of brandy and three grains of bisulphate of quinia. At 5:45 P.M. he had four ounces of bouillon, and two drachms of meat juice. The President's wound was dressed as usual this morning and evening, and a free discharge of pus came from it at both dressings.

August 14. The President slept fairly well during the night, but was slightly feverish, though he said that he felt quite comfortable. The morning dressing seemed to tire him, and there was a good deal of irritability of the stomach. At 2:15 A.M. he had six ounces of milk; at 5 A.M. six ounces of koumiss; at 8 A.M. half an ounce of brandy in six ounces of milk, and three grains of bisulphate of quinia. He breakfasted at 10:15 A.M. on a little steak, potatoes, and a few blackberries. At 12 M. he was given three grains of bisulphate of quinia with half an ounce of brandy; soon after this he vomited. His temperature this morning at 8 was one degree less than at the same hour yesterday morning. His temperature at the evening dressing of the wound was about the same as that of last evening.

August 14, 8:30 A.M. Temperature 99.8; pulse 100; respirations 18. August 14, 12:30 P.M. Temperature 99.8; pulse 100; respirations 18. August 14, 7 P.M. Temperature 100.8; pulse 108; respirations 19.

August 14, 12:30 P.M. He was given three drachms of beef juice, which he retained. He then went to sleep until 3 P.M. when he awoke and shortly afterwards vomited. At 5:30 P.M. he again vomited about four ounces of sour liquid tinged with bile. All nourishment was suspended, and he was given a teaspoonful of the following mixture in water every four hours:

R Tincture lavandulæ comp aaj drachm.
 et tincturæ cardamoni comp: aaj drachm.
 Acidi carbonici grs. iv.
 Alcohol: diluti jss uncia.
 Mscce.

At 9:45 P.M. he vomited again, and at 9:50 P.M. he was given one drachm of aromatic mixture. At 11:30 P.M. he vomited six ounces of greenish biliary fluid. He complained of pain in the epigastrium, had considerable restlessness with fever. His pulse reached 120 per minute.

August 15, 3 A.M. The President has awakened at intervals of about half an hour, and complains a good deal of the pains and distress in the stomach. He has retained two teaspoonfuls of milk and lime water, which have been given every half hour since 11 P.M. (of August 14). His pulse is still 120 and very weak. After consultation with Drs. Bliss and Woodward, Dr. Reyburn gave the President three-sixteenths of a grain of sulphate of morphia hypodermatically. After receiving the injection he went to sleep in a short time and slept soundly until 7:30 A.M.

August 15, 8:30 A.M. Temperature 100.2; pulse 108; respirations 20. August 15, 12:30 P.M. Temperature 99; pulse 118; respirations 19. August 15, 7:30 P.M. Temperature 99.6; pulse 130; respirations 22.

During the morning the President's stomach was very irritable, and he was given only three teaspoonfuls of milk and lime water at 7:30 A.M. which was all the nourishment he was able to retain. For the irritability of the stomach he was given twelve powders each containing one-twelfth of a grain of calomel with one grain of subnitrate of bismuth. He took one of these every hour until seven were taken.

The condition of the President at this time excited very grave apprehensions in the minds of the attending surgeons. His stomach could not assimilate food and just as soon as this occurred he rapidly developed symptoms of exhaustion. During the afternoon and evening his pulse went up to 130 per minute, whilst his temperature kept falling. After consultation, alimentation by the rectum was determined on, and there is every reason to believe that our doing so saved the President from rapidly impending death. The following was the formula used, viz: The yolk of one egg, one ounce of bouillon, one and a half ounces of milk, one half ounce of whisky, and ten drops of deodorized tincture of opium. Mix and administer at the temperature of 100 F. as an enema per rectum. The administration of these enemas was highly beneficial to the President, and he showed the restorative and invigorating effect of their use almost immediately. From August 15 until August 18 he was unable to take any food whatever (except three teaspoonfuls of beef essence) and in fact for about one week subsequent to that date he was nourished almost exclusively in the same way. At 10:30 A.M. he had nutritive enema (see formula given above). At 9:15 and at 11 P.M. the vomiting again recurred, and very hot water in teaspoonful doses was given; this seemed to relieve the nausea.

August 16. During the night the President suffered from nausea until 3 A.M. when a nutritive enema was given him, which he retained. After this he went to sleep, and slept until 7:30 A.M. At 8 A.M. the wound was dressed as usual. There was a free discharge of pus from the wound, and the President was much exhausted by the dressing. Had nutritive enemas at 3:15 A.M., at 8 A.M., at 12 M., at 4 P.M. and at 8 P.M. During the afternoon the President reacted a good deal, and seemed to be much better. At 5:30 P.M. he vomited about three ounces of a greenish brown fluid with but little odor. The wound was dressed at 6 P.M. It seemed rather dry, but there was a fair amount of discharge from it.

August 16, 8:30 A.M. Temperature 98.6; pulse 110; respirations 18. August 16, 12:30 P.M. Temperature 98.3; pulse 114; respirations 18. August 16, 7 P.M. Temperature 98.9; pulse 120; respirations 18.

August 16, 7 P.M. Temperature 98.9; pulse 120; respirations 19.

August 17. At 3 A.M. the President had nutritive enema, and again at 8 A.M. He slept well during the night, and looks better this morning. August 17, 8:30 A.M. Temperature 98.3; pulse 110; respirations 18.

August 17, 12:30 P.M. Temperature 98.7; pulse 112; respirations 18. August 17, 6:30 P.M. Temperature 98.8; pulse 112; respirations 18.

At 10 A.M. he fell asleep, slept soundly and awoke

refreshed at 11:15 A.M. He did not vomit during the day, and the nutritive enemas were well retained, and seemed to nourish him sufficiently. Professor Agnew has been here continuously on duty since 11 A.M. of August 14, and as the grave symptoms presented by the President seemed to demand the presence of all the surgeons, Professor Hamilton was sent for and arrived at 10 P.M., August 16. During the afternoon a teaspoonful of beef extract was twice administered by the mouth, and was retained. Small quantities of cold water and cracked ice were also given without causing nausea. At 12:30 P.M. the President was given the nutritive enema; at 12:40 P.M. one drachm of extract of beef; at 1:45 P.M. another drachm of extract of beef; at 5 P.M. a second nutritive enema, and at 11:45 P.M. a third drachm of extract of beef. During the day the President seemed quite comfortable until about 9 P.M., when he complained of pain and slight swelling of the right parotid gland. The wound was dressed as usual night and morning. The inner track of the wound seems to be closing up, and the eleventh rib at the seat of the fracture is covered with granulations.

August 18. The President slept well almost all the night, and awoke at 6:30 A.M. apparently much refreshed. He was then washed and sponged with alcohol, and his position changed. During the night the swelling of the right parotid gland had increased very rapidly, and the following local application was applied:

R. Iodoformi
Et balsam Peru aa drachm j.
Collodii uncia j.
Misce.

At 7 A. M. he had nutritive enema, and also at 1:30 P.M. At 9:30 A.M. he had half an ounce of koumiss, and the same at 10 A.M. and at 11 A.M. At 2:30 P.M. he had two ounces of koumiss, and two tablespoonfuls of milk gruel. At 4:30 P.M. he had nutritive enema. At 7 P.M. he was given three tablespoonfuls of milk gruel and at 11:30 P.M. he had nutritive enema.

August 18, 8:30 A.M. Temperature 98.8; pulse 104; respirations 17. August 18, 12:30 P.M. Temperature 98.4; pulse 108; respirations 18. August 18, 6:30 P.M. Temperature 100; pulse 108; respirations 18.

The President asked for and retained several small portions of liquid nourishment during the day and evening. He bore the evening dressing fairly, but complained a good deal of the pain in the parotid gland. Professor Agnew left this evening for Philadelphia.

August 19. The President was somewhat restless and slightly feverish from 10 P.M. last night to 2 A.M. this morning. At that hour he began to perspire, and then fell asleep, and slept until 7:30 A.M. At 8 A.M. the wound was dressed, and the soft catheter used to wash out the wound was passed along the lower track of the wound twelve and a half inches, and quite a free discharge of pus came from the wound.

At 7 A.M. he had four ounces of koumiss; at 7:30 A.M. nutritive enema; at 8:30 A.M. four ounces of koumiss; at 10:15 A.M. two ounces of milk gruel. At 11:20 A.M. he began to perspire, having had a slight rigor. He was rubbed dry, and wrapped in warm woollen cloths, with heat applied to his extremities. There is a slight swelling of the right side of the face, around the right eye, but the pain

and swelling of the right parotid gland has much diminished. There being a tendency to diarrhea one drachm of subcarbonate of bismuth was given to the President at one dose. At 1 P.M. he had nutritive enema; at 3:30 P.M. three ounces of milk gruel; at 4 P.M. six ounces of koumiss; at 6:30 P.M. nutritive enema and at 7:20 P.M. three ounces of milk gruel. At 7:30 P.M. the bowels were moved.

August 19, 8:30 A.M. Temperature 98.4; pulse 106; respirations 17. August 19, 2:30 P.M. Temperature 98; pulse 106; respirations 17. August 19, 2:30 P.M. Temperature 100; pulse 106; respirations 18.

Professor Hamilton left for New York in the 2:10 P.M. train to-day. Professor Agnew came from Philadelphia to Washington to-night (August 19).

August 20. The President slept tolerably well, but wakened several times during the night. He stood the dressing of the wound very well this morning. The President has slightly relaxed; he had two loose passages, one at 1 A.M. and one at 12:15 P.M. At 1:30 A.M. he had nutritive enema; at 3 A.M. three ounces of milk gruel; at 8:30 A.M. five ounces of koumiss; at 10:20 A.M. nutritive enema; at 12:20 P.M. three drachms of beefsteak juice; at 2 P.M. three ounces of milk gruel; at 4 P.M. three ounces of koumiss, and at 6:30 P.M. three ounces of milk gruel. During the day the President took in all nine ounces of milk gruel, and eight ounces of koumiss, by the mouth. At the morning dressing the wound looked well, and the pus was laudable in character.

After the operation of August 8 the flexible tube used to wash out the wound at each dressing readily followed the track of the ball to the depth of three and a half or four inches. At the dressings, however, a small quantity of pus came, as was believed from the deeper parts of the wound, from the part of the track beyond the above mentioned point. The pus flowed either spontaneously or after gentle pressure had been applied over the anterior surface of the right ilium. This deeper part of the track was not reached by the tube until yesterday morning, when the separation of a small slough permitted the tube to pass downwards and forwards for the distance of twelve and a half inches from the external opening of the last incision.

August 20, 6:30 P.M. The President was somewhat exhausted by the evening dressing, and has a little more fever this evening. To-day the following ointment was ordered for application to the inflamed parotid gland:

R. Unguenti belladonnæ.
Iodoformi.
Balsam: Peruvian.
Miscæ.

The swelling of the right parotid gland appears to be unchanged.

August 20, 8:30 A.M. Temperature 98.4; pulse 98; respirations 18. August 20, 12:30 P.M. Temperature 98.4; pulse 107; respirations 18. August 20, 6:30 P.M. Temperature 100; pulse 110; respirations 19. At 10 P.M. he was given nutritive enema.

August 21. The President awoke more frequently than usual during the night. At 3:40 A.M. he fell asleep, and slept soundly until daybreak. He took liquid nourishment in small quantities during the night. The wound was dressed as usual at 8:20 A.M. The secretion from the outer surface of the wound was rather scanty, and there was not so much secretion as usual from the deeper track of the wound.

August 21. At 3:30 A.M. he was given four ounces of koumiss; at 4:50 A.M. three ounces of milk gruel; at 7 A.M. nutritive enema; at 7:45 A.M. four ounces of koumiss; at 10:10 A.M. three ounces of koumiss; at 12:45 P.M. four ounces of milk gruel. At 1:30 P.M., in endeavoring to hawk up the secretion from the right parotid gland, which was very tenacious, he brought on an attack of vomiting. At 3:20 P.M. he was given the nutritive enema. At 5:15 P.M. he vomited six ounces of biliary fluid of a greenish yellow color. The President having vomited three times during the afternoon, the administration of food by the mouth was temporarily suspended. The parotid swelling is painless but stationary. August 21, 8:30 A.M. Temperature 98.8; pulse 106; respirations 18. August 21, 12:30 P.M. Temperature 99.4; pulse 108; respirations 18. August 21, 3:30 P.M. Temperature 99.2; pulse 108; respirations 18.

President Garfield was some of the time entirely, and all of the time very largely, sustained by rectal feeding from the 14th of August until his death on September 19. The value of this method of supplying waste in grave disease has never been more strikingly shown than in this instance, because in all probability there was never a patient more closely observed by his medical attendants, and because the quantity and quality of the rectal diet were most carefully regulated, both as to mode and time of administration. During the stage of inflammation of the parotid gland (eight days) this mode of sustenance was entirely relied upon, he being unable to take any food by the mouth and stomach, and only very small quantities of cracked ice and water, which were frequently rejected.

The quantities carefully measured, were prepared at the dispensary of the Surgeon-General by Hospital Steward W. F. Crusor, U. S. A., in accordance with the following formula:

"Beef Extract.—Directions: Infuse a third of a pound of fresh beef, finely minced, in fourteen ounces of cold soft water, to which a few drops (four or five) of muriatic acid and a little salt (from ten to eighteen grains) have been added. After digesting from an hour to an hour and a quarter, strain it through a sieve and wash the residue with five ounces of cold water, pressing it to remove all soluble matter. The mixed liquid will contain the whole of the soluble constituents of the meat (albumen, creatin, etc.), and it may be drank cold or slightly warmed. The temperature should not be raised above 100 F.; as at the temperature of 113 F., a considerable portion of the albumen, a very important constituent, will be coagulated."

Two ounces of beef extract, two drachms of beef peptonoids, and five drachms of whisky were given with scrupulous regularity every four hours, day and night. Occasionally five to fifteen drops of deodorized tinct. opii were added as an additional nerve stimulant and anodyne, and also to secure retention of the enema. They were usually retained without causing any discomfort on the part of the patient, and, as a rule, once in twenty-four hours a discharge of healthy feces occurred, generally of such consistency and form as would justify the belief that digestion had taken place in the small intestine. For the first five or six days the yolk of an egg was added to the injections, but in the judgment of the surgeons was the cause of annoying and offensive flatus. This symptom was promptly relieved by discontinuing the egg, and temporarily adding about a drachm of willow charcoal to the enema. Charcoal tablets by the mouth were also occasionally used.

There was a strong desire on the part of the physi-

cians to discontinue the use of stimulants, but on each occasion when the attempt was made the pulse became more frequent and feeble, so that we were forced to resume their use. Later in the history of the case, after the removal to Elberon, alimentation both by the rectum and the mouth was found to be borne without evidence of peristaltic antagonism.

August 22, 8:30 A.M. Temperature 98.4; pulse 104; respirations 18. August 22, 12:30 P.M. Temperature 98.4; pulse 104; respirations 18. August 22, 6:30 P.M. Temperature 100.1; pulse 110; respirations 19.

A feeling of uneasiness prevailed to-day among the medical attendants in consequence of the unfavorable condition of the President. He is greatly troubled by the tenacious mucus which accumulates in the back of the throat, and in the effort to free his mouth and throat he twice brought on attacks of vomiting yesterday. Happily after midnight the President who had been restless, fell into a sound sleep. He slept more quietly during the after part of the night, and has been able to retain liquid nourishment when taken by the mouth, as well as the nutritive enemata. During the day there was no recurrence of the vomiting and nausea. The parotid swelling is not materially smaller but is painless, and there is less of the accumulation of mucus in the mouth and throat. During the morning he took about twelve ounces of milk gruel and koumiss, and at 7 A.M. an enema of beef extract was administered. During the day for the first time was noticed a slight incoherence of speech, immediately after awaking from sleep. This seemed to disappear as soon as the senses became fully under control. The heat of the weather has somewhat moderated to-day, and it was not considered necessary to use the cooling apparatus for the President's room.

August 22, 2:10 P.M. The President has passed a quiet afternoon, and sleeps a good deal of the time. Up to the present time he has taken and retained twenty-four ounces of liquid nourishment consisting of milk porridge and koumiss. He also continued to take at stated intervals small quantities of the same kind of food during the evening without disturbance of the stomach. The wound was dressed as usual, and the process of repair seems to be going on in all parts of the wound exposed to view.

August 23, 8:30 A.M. Temperature 98.4; pulse 100; respirations 18. August 23, 12:30 P.M. Temperature 98.9; pulse 104; respirations 18. August 23, 6:30 P.M. Temperature 99.2; pulse 104; respirations 19.

August 23, 8:30 A.M. The President slept during the greater part of the night but awoke at intervals. He has taken since last night a larger quantity of liquid food by the mouth than in the corresponding hours of any day during the past week. During the night he received two nutrient enemata, and the use of the nutrient enemata was continued at longer intervals during the day. He continued to take liquid food during the afternoon and evening, and had no recurrence of gastric disorder. The parotid swelling remains unchanged, but the mucus which accumulates in the back part of the mouth is less viscid, and now gives but little trouble. This morning in addition to his koumiss and milk porridge, he was given the juice of a steak, which he took with relish. Professor Agnew, who has remained on duty since August 20, returned to Philadelphia to-day, having been relieved by Professor Hamilton. In spite of all our efforts to nourish the President he is emaciating

so rapidly that it is distressing to look at him. His weight when he was wounded was 210 pounds, and his weight now is probably not more than 130 or 135 pounds. This emaciation is accompanied by such great exhaustion as to give rise to the most gloomy forebodings on the part of his medical attendants. During the last three or four weeks the President has often expressed the wish to be in his old home; he longed to be back in Ohio, "on the old sod once more; to walk down the streets of Cleveland, meeting and greeting familiar friends."

(To be continued.)

SOCIETY PROCEEDINGS.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOBLET, M.D., President.

(Continued from page 514).

A CONTRIBUTION TO THE ELECTRO-THERAPEUSIS OF SALPINGITIS.

DISCUSSION.

DR. A. LAPHORN SMITH said that if this paper had been read before the Philadelphia Obstetrical Society, the author would be glad to escape from the room with his life. At the same time, he quite agreed with the author in his statements. He felt quite sure that the tubes can be catheterized. Dr. Wallace showed him in his Liverpool hospital six cases at one time, in which he had introduced a uterine sound into the tubes. Again, he had himself frequently had cases in which fluid accumulations in the tubes were discharged spontaneously. The source of the discharge had been proven by the use of clean, dry, cotton tampons. In view of these facts, why can not we empty the tubes in the natural way through the uterus? A few more papers of this kind, he thought, would stem the tide and control the present operating furor.

DR. N. W. WEBER, of Detroit, said that if there are no other triumphs to be ascribed to electricity than those achieved in the relief of ovarian neuralgia, and the great distress attendant upon pyosalpinx, and various pelvic adhesions, it certainly has accomplished a great deal. He could recall the sneering doubt with which the report of Dr. Sprague's second case was received in their State Society; yet he felt satisfied from what he had seen that the author was doing a great work. We should endeavor to suppress this great tendency to perform severe abdominal operations on all sorts of slight pretexts.

DR. MASSEY said that while appreciating this conservative surgery, it should not be forgotten that this work is for experts only. In 1888 he had himself brought the subject of treating such conditions by intra-uterine negative galvanization up before the Philadelphia Obstetrical Society. He succeeded at that time in emptying a number of tubes.

DR. SARAH A. STEVENSON, of Chicago, said that notwithstanding the law which has been laid down that electricity is contra-indicated whenever there is pus present, she had for a long time employed it in such conditions. Studying Bozeman's experiments in catheterization of the ureters, she had become convinced that it was entirely feasible to drain the Fallopian tubes in a similar way, but she had hesitated hitherto to employ it herself. She was therefore pleased to learn of Dr. Sprague's results.

DR. GEHRUNG remarked that as electricity is known to cause dilatation of various apertures, it would seem that this agent would greatly facilitate the catheterization of the tubes.

DR. SPRAGUE, in closing the discussion, said he had been agreeably disappointed at the way his paper had been received, for he expected it would be very severely criticized. It was the report of the very discussion to which Dr. Massey had referred that first led his thoughts in this direction.

DISCUSSION.

"WHAT ARE THE POSSIBILITIES OF ELECTRICITY IN THE TREATMENT OF FIRROID GROWTHS?"

The disputants were requested to confine their remarks to the special points presented in the following synopsis:

- a. Symptomatic Cure. (Hemorrhage, pain, pressure symptoms, strength and nutrition.)
- b. The Growth. (Arrest, retrogression, disappearance, recurrence.)
- c. Kind of current.
- d. Properties of the Current. (Electrolytic, cataphoric.)
- e. Action of the Current: 1, nerve (vaso-motor, motor innervation, sensory); 2, muscle (irritability of, structural changes in.)
- f. Contra-indications.
- g. Change of method, current strength, polarity, length of sances, frequency of application and duration of treatment.

DR. J. H. KELLOGG read a paper on

WHAT ARE THE POSSIBILITIES OF ELECTRICITY IN THE TREATMENT OF FIBROID GROWTHS?

I began the treatment of fibroid growths by the electrolytic method something more than five years ago, and am still employing this method of treatment with confidence and satisfaction, although, as I am willing to confess, with more moderate expectations respecting the possibility of a radical cure of the disease. The Secretary has arranged this subject under convenient headings for discussion, and this synopsis, I believe, covers practically the whole ground. In opening the discussion I will touch briefly upon each point.

1. *What are the possibilities of electricity as regards a symptomatic cure?* One of the most prominent and serious symptoms connected with fibroid growths of the uterus is hemorrhage. Certainly, every physician who has had any considerable degree of experience must have been convinced of the value of electricity, especially the constant current employed after the method of Apostoli, in the control of the hemorrhage which usually accompanies fibroid growths. That electricity is capable of controlling this hemorrhage, I think is generally admitted among gynecologists, even those who do not consider the remedy of value in relation to other symptoms.

That local applications of electricity are of value as a means of relieving the pain which frequently accompanies the development of uterine fibromata, is also equally well attested. In my own experience I have found it a very valuable measure.

Symptoms, such as the interference with the functions of the bladder and other adjacent organs are relieved in cases in which the growth is diminished in size and perhaps, also to some extent in other cases.

The general strength and nutrition of the patient are as a rule, I think, from my experience and that of others who have had an extensive use of this remedy, improved in a very marked degree under the influence of the galvanic current. This improvement may be due in part to the suppression of the hemorrhage, but I think it is in many cases due to the influence of the galvanic current upon the abdominal sympathetic. The great sympathetic centers, located in the abdomen, have charge of the most important processes of nutrition. These are incidentally brought under the influence of the galvanic current in the treatment of fibroids, and it is, I believe, very largely through this means that the patient's nutrition, blood quality and general strength are improved.

2. *What are the effects of electricity in relation to the growth and development of uterine fibroids?*—That the electrical current will arrest the growth of fibroid tumors is a question which is still contested by many gynecologists, but the statistics which have been published by Keith, Apostoli, Massey, the writer and various other electro-therapeutists, it seems to me, must be accepted as evidence that fibroid growths, at least in certain cases, may be arrested by proper applications of the constant current. In my own experience, arrest of the growth has been secured in 75 per cent. of the cases treated, and in 55 per cent. there has been a diminution in the size of the tumor. In a few cases the tumor has entirely disappeared, but usually, even in the most favorable cases, some small evidence of the tumor remains behind. I think this will be the rule, except in cases in which the treatment is applied near the menopause and continued long enough to secure a decided retrograde change in the tumor, when the treatment may be so thoroughly successful that the growth may be made to disappear entirely. I have seen this occur in two patients who remained but a few months under treatment.

3. *What kind of current shall be employed?*—I think there is at the present time no question among electro-therapeutists as to what form of current has the most decided effect

upon uterine fibroids. I am certain that no experienced electro-therapeutist would think of employing any other than the constant current for the purpose of antagonizing the growth of a uterine fibroid. The effects required are such as can not be obtained from the faradic or any other form of current than the galvanic.

4. *What properties of the constant current are useful in its application to the treatment of uterine fibroids?*—This portion of the subject is one which, perhaps, requires more elucidation. I have made no original experiments which will enable me to throw any new light upon this part of the question. My own belief is that the electrolytic action of the current, the action which occurs in the vicinity of the electrodes, is that which is of the greatest service in the treatment of the class of morbid conditions under consideration. This belief has led me to employ in connection with my treatment a coulombmeter by the reading of which I obtain directly the measure of the actual amount of electrolytic work done. In experiments which I have made upon living rabbits and thick portions of fresh beefsteak, I find that there is a definite relation between the amount of work indicated by the coulombmeter and the work done in the tissues; but it is necessary, also, to take into consideration the indications of the milliamperemeter. I do not wish to be understood as saying that the same amount of work will be done by one milliamperè of current in ten minutes, as will be done by ten milliamperès in one minute; but I am sure more uniform dosage may be obtained by the employment of the coulombmeter in connection with the milliamperemeter than by the use of the milliamperemeter alone. It is possible to obtain the number of coulombmeters by multiplying the number of milliamperès by the time of the application; but the coulombmeter saves the trouble of this computation, giving the results by direct reading.

5. *What is the action of the constant current when applied to fibroid growths of the uterus?*—It is evident that not only the tissues of the uterus, but all the other organs intervening between the electrodes are brought under the influence of the electrical current. But it is doubtless through the influence of the current upon the nerves, muscles and vascular structures of the uterus and the morbid growths connected with it that the beneficial results observed are obtained. Through the influence of the current upon the vaso-motor nerves, the current produces contraction of the arterioles such as is seen when it is applied to the skin, and thus diminishes the blood supply of the tumor and cuts off to some degree its nutrition. The motor nerves of the uterus are powerfully stimulated by the current, and this must also exercise some favorable influence upon the growth. The anesthetic effect of the positive pole, well recognized in electrical applications to other parts of the body, is here of great service in the relief of pain. The effect of mild galvanic applications is to increase muscular irritability. This is one of its physiologic effects. The large current necessary for the most satisfactory results in the treatment of these growths may have the effect to set up degenerative changes in the morbid structures of the growths.

I am convinced, however, that the most important effect of the current is that upon the vascular structures of the uterus. I have frequently noticed after the application of the current, especially when I employed a large quantity, as from 200 to 300 milliamperès, that slight evidences of inflammatory reaction have appeared, as evidenced by increased tenderness, slight swelling and other evidence of a circumscribed phlebitis. In two or three such instances the phlebitis has extended to the vessels of one leg. In one case, that of a woman having a very large fibroid reaching two or three inches above the umbilicus, in which I applied a very strong current, probably about 350 milliamperès, the patient became very ill and was confined to her bed for several weeks. Both limbs were enormously swollen with phlebitis. The patient had a high fever for several days and I despaired of her life; but she made a good recovery and at the end of three months the tumor had decreased greatly in size and at the present time, five years since the treatment was applied, the patient is hard at work every day in a laundry. She has been able to engage in this laborious employment for the last four years. I believe that the amount of blood supply is diminished by the succession of inflammatory processes set up in the vicinity of the internal electrode by means of which the vessels are plugged up and that this is the principal means by which the constant current is of use in the treatment of fibroid tumors.

6. *Contra-indications for the employment of electrolysis for uterine fibroids.*—According to my experience, electrolysis is

not properly applicable to the treatment of uterine fibroids in the following cases:

a. Rapidly growing tumors not accompanied by hemorrhage. These tumors are either fibro-cystic or soft edematous myomata; and experience shows that neither class is amenable to treatment by electrolysis. Soft edematous tumors are not benefited even by the removal of the appendages. Hysterectomy is the only remedy in these cases.

b. Rapidly growing tumors which make their appearance after the menopause, or which take on rapid growth at this period, are not favorably impressed by any mode of applying the constant current with which I am familiar; although Dr. Massey has reported some success by means of abdominal puncture.

c. In cases in which an ovarian cyst exists as a complication of uterine fibroids, the use of electricity is inadvisable, as it is likely to increase the growth of the cyst; and as an operation must ultimately be performed for the removal of the cyst, it is better to remove the appendages completely with the cyst, or perform hysterectomy, than to depend upon the uncertain and possibly injurious results of an application of the constant current.

d. The constant current is also of doubtful value in cases in which the uterine fibroid is complicated by serious disease of the appendages. In these cases, applications even of a very mild character are often followed by inflammatory reaction, so that the current can not be tolerated in doses of sufficient strength to accomplish positive results.

e. It is also evidently useless to continue applications of the current in cases in which no good results are obtained after thorough trial for several months. Some cases will prove rebellious to this, as well as to all other non-surgical measures of treatment. Such cases require removal of the appendages or hysterectomy. I have secured excellent results in a considerable number of such cases by the removal of the appendages only. I prefer this method to hysterectomy in cases in which it is applicable, but have performed hysterectomy in a considerable number of cases with satisfactory results.

f. I mention, lastly, still another class of cases in which I consider surgical measures preferable to the use of the constant current; namely, cases in which the patient is unable for any reason to submit to the use of the constant current for a sufficient length of time to secure satisfactory results. The patient may reside at a distance and be unable on account of poverty to remain under treatment for six months or a year, the shortest length of time in which any very marked results can reasonably be expected. In such cases, and in various other circumstances, I think the patient should be allowed to decide whether the slow and less certain, but also less dangerous, method of electrolysis shall be employed or the more radical, though also somewhat more hazardous surgical method.

7. *Methods of employing electricity in the treatment of uterine fibroids.*—The strength, polarity, time, frequency, duration, and after care are questions of great practical importance for consideration in the discussion of this subject. Briefly, my own experience is this as regards the strength of the current. I am inclined to use a current of less quantity than when I first began the employment of the constant current in the treatment of uterine fibroids. Instead of using 250 to 300 milliampères, I now ordinarily employ 100 to 200. My usual rule is to make the current as strong as the patient can bear without too great discomfort. I endeavor to lessen the pain, and hence increase the current by employing with the constant the sinusoidal current with very rapid alternations. As previously stated, I use a coulombmeter in connection with the milliampèremeter as a measure of the work done. If I use a weak current I make the application for a longer time, applying as a rule from 80 to 100 coulombs of current, sometimes more. A weak current does not produce so strong an effect as a strong current, even although the number of coulombs may be made the same in each case by increasing the time for which the weak current is used. On this account, I use a larger number of coulombs when I employ a weak current, so as to approximate as nearly as possible the results obtained by a stronger current. The coulombmeter is not, like the milliampèremeter, a necessity, but is a very convenient instrument.

I almost invariably employ the positive pole for the internal electrode, on account of its hemostatic properties. One of the greatest drawbacks in these cases is the fact that at the beginning hemorrhage or menorrhagia is frequently excited, resulting in the discouragement of the patient and interference with the treatment. The positive pole may be

slower in its action, but it is certainly less painful, and its use is more convenient than the use of the negative pole.

As regards the time of the application, I give little attention to the matter of time. As I have said, the amount of work done, as indicated by the coulombmeter, gives more useful information than any timepiece can give.

The frequency of the application must be regulated by the patient's toleration of the treatment. My usual practice is to make the application once or twice a week—rarely more than twice, and frequently but once.

The duration of the treatment is necessarily long. I have never been able to continue the treatment more than a year in any case. Dr. Apostoli reports success in cases after three years of treatment. I have seldom been able to continue treatment more than four to eight months, as my patients are almost all from a distance, so that I can not keep them under treatment for an indefinite length of time. I usually see decided indications of improvement after three to six months' treatment.

The after care in these cases is a matter which, in my opinion, receives too little attention. My usual custom is to give the application in the afternoon or evening and then send the patient to bed with instruction to remain twenty-four hours, or even forty-eight hours if there is any tendency to inflammatory reaction. Immediately after the application the patient receives a vaginal douche consisting of boiled water or a solution of bichlorid 1 to 10,000. The day following the application, two or three vaginal douches are administered. In case of painful symptoms, fomentations over the lower abdomen or a hot hip pack is applied. If there is a tendency to flowing, the alum vaginal pack, or packing the vagina with equal parts of alum and subcarbonate of bismuth is employed.

I tabulated a year or two ago the results of sixty-two cases. I found that 82 per cent. were very greatly benefited. Seventy-five per cent. of the entire number were symptomatically cured. In 55 per cent. the tumors were reduced; and in 14 per cent. the tumors disappeared entirely. In the cases in which the tumors disappeared, the growths were interstitial or submucous, and were in most cases small or moderate in size. A study of my cases led me to observe a marked difference in the results obtained in the different classes of fibroid tumors according as they were subperitoneal, submucous, or interstitial in character. In all the cases in which the tumors were greatly reduced in size or disappeared entirely, the growths were submucous or interstitial in character.

Another condition which favors good results in the treatment is the approach of the menopause. In my experience, the treatment unquestionably hastened the development of the menopause. My personal belief is that the constant current operates as a curative agent in these cases in precisely the same manner as does the menopause; namely, by causing shrinking of the blood vessels, thus cutting off the nutritive supply of the growth. The cicatricial tissue formed as the result of the repeated applications of the current closes up the small vessels, in this respect operating as does the retrograde change by which a withering of all the blood vessels of the uterus and appendages takes place at the menopause.

DR. FELICE LA TORRE, Privat-docent in Obstetrics at the University of Rome and member of the Society of Obstetrics and Gynecology of Paris, sent a contribution to the discussion which was read by the Secretary,

ON THE ACTION OF ELECTRICITY ON UTERINE FIBROMATA.

To establish in an exact manner, in the present state of our knowledge, the action of electricity on uterine fibromata, is in my opinion a problem whose solution is rather difficult; for we do not know yet in what the current consists, and what the electric phenomena are that it produces on the tissues. Nevertheless, since in these later times certain modifications in the tissues by means of the galvanic current (Apostoli's method) have been determined we may, however, by analogy, arrive at some hypotheses.

In reference to this, the American Electro-Therapeutic Association has done well to put on the program of their discussions, the action of electricity on uterine fibromata.

I am not just now in the best condition to take part in the debate, being absent from Rome; if I permit myself to do it by this paper it is to respond to the amiable and flattering invitation of our illustrious President to whom I tender my heartfelt thanks, and to submit to the Congress a new point of view in the study of the action of electricity on uterine fibromata.

The effects of electrical treatment of uterine fibromata

manifest themselves in two ways: 1, arrest of hemorrhage—an effect almost constant; 2, diminution in size of tumor—rare effect. How does this happen?

Every one knows that the action of the continued current is threefold, viz: polar, interpolar and extrapolar action. We understand each other as regards the signification of these terms; I shall not dwell on it. The extrapolar action has no direct influence on the fibromata; I do not take this into account here.

Let us now see what the principal modifications are from the polar and interpolar action on the tissues, and how they exert their influence in the arrest of hemorrhage and in the reduction of the fibroid tumor.

1. *Polar Action.*—One can say in general that the result of the polar action of the continued current, positive pole, according to the researches of Ciniselli, Klein, J. Parson, Villes, Apostoli, Piccinini, MacGinnis, La Torre, etc., is as follows:

a. A chemic caustic action with hard eschar.

b. An alteration (sclerotic at positive pole, imbibition at negative) a macroscopic and microscopic alteration of the tissues in general and of the vessels and blood in particular.

c. An energetic contraction of the uterine muscle.

2. *Interpolar Action.*—This exists, as shown by the experiments of Ciniselli, Dorsey, Shaw, Steavenson, Willis, Witte, Decio, etc. We have:

3. *Its Electrotonic Action.*—Exaggerated function—circulation and nutritive processes with increased activity.

4. *Its Cataphoric Action.*—Transmission of substances from the positive to the negative pole.

5. *Its Catalytic Action.*—Decomposition of complex bodies into their constituent elements.

We can from this conceive how the hemostatic effect of the galvanic current may be sought for in the polar action of the positive pole, and the reducing effect in the interpolar action aided by the polar action.

In what way does the polar action arrest hemorrhage?

In the beginning, it was thought that it was the galvanocaustic eschar which arrested the hemorrhage, but no one thinks it any longer; especially when the case is that of a large uterus where the cauterization is limited to a small surface. This is true in so far as arrest of hemorrhage has been obtained without introducing the electrode into the cavity of the uterus, by simply resting it against the cervix. I have had a few of these cases. It is evident that in these cases there is no question of intra-uterine chemic-cauterization and eschar.

On the contrary, it is much more probable that the arrest of hemorrhage is due to the contraction of the muscular elements. We know, in fact, that the continued current causes contraction of muscular fiber more easily than any other form of electrization, and that the unstriped fibers respond more promptly than the striped. In favor of these facts is the frequent expulsion of polypi from the uterine cavity after application of the continued current. Now the continued current causes the muscular fibers to contract energetically in every direction, thus compressing the vessels which penetrate the uterine walls transversely and in this way hindering an abundant afflux of blood to the organ whence the arrest of the flow.

In what way does the interpolar action reduce the fibroma?

This is a more difficult question, but I shall try to note the principal points. I shall not mention in this case all the opinions and all the theories advanced; I shall only touch upon the most plausible of these.

Milne Murray believes that the vessels of the capsule of the fibroma lose their function, whether by the interpolar action or by the polar contraction as well; the tumor consequently deprived of its nutrition must necessarily begin a regressive course.

Shaw, having observed that in some fibromata, subjected for a long time to electrical treatment, the weight diminished at the same time that the quantity of albuminous substances increased, believes that the current acts by producing direct electrolytic modification in the tissues of the tumor and still more in the liquids of the tumor.

Willis E. Ford believes also that it is in the liquids of the tumor, in the interpolar space, that the principal modifications take place; these are supposed to be chemic decompositions, resolution of complex bodies into others more simple, and to the elimination of products of these decompositions could be attributed probably, certain general disorders of the patients subjected to electrical treatment.

Ciniselli, on the other hand, finds it probable that the current produces a permanent modification on the nutrition of the tumors. This hypothesis is proved by the fact that

there is found in the urine of patients treated by the galvanic current a greater quantity of sediments after the treatment than before, and an increase in the specific gravity.

These were the theories until quite recently, when Decio of Milan, in a remarkable work: "The Galvanic Current in the Cure of Uterine Fibro-Myomata" (*Annali di ost. e di gin. Milano*, 1893, No. 3 e 4), offered a new theory which seems to me quite plausible, studying from a new point of view the reducible power of fibromata. He believes one of the modifications to be a disturbance in the molecular interchange, due without doubt to electrolytic phenomena; that is, to certain special movements of molecular interchange among the elements. In what this consists is not yet well known, but an approximate idea is given by the theory of Grothius, on liquids subjected to electrolytic interpolation. Now it is precisely in these disturbances in the molecular interchange of the elements of the tumor that Decio finds a new cause of atrophy of the fibromata. He has in fact found in the urine of women with uterine fibromata, submitted to electrical treatment (Apostoli's method) a constant peptonuria, and in direct proportion with the diminution in size of the fibromata. Decio finds this analogous to that which takes place in puerperal peptonuria. And in fact we find that the transformation of the albuminoid substance of the uterine muscle into peptone after labor is always *pari passu*, with the regressive process of involution of the uterus. It is, reasoning thus, precisely in a rapid absorption of this soluble product and in a successive elimination by the kidneys, that we find the cause of the reduction in size of the uterus the first days of the postpartum state. Besides this regressive movement of involution, Fischel attaches great importance to uterine contractions; these destroy by their rapid succession the cellular elements; it is these which by their compression of the nutritive vessels diminish the afflux of oxygenated protoplasm; it is these, finally, which hasten the metamorphosis of the proteid substances of the uterine parenchyma.

According to Fischel, it is especially to the slight uterine contractions during pregnancy that we may attribute the transient peptonuria of some pregnant women.

Now we have the same compression with the same effects in the fibromatous uteri submitted to the action of the galvanic current.

We have, then, the same causes and the same effects in the regressive changes of the puerperal uterus as in the myomatous uterus. Here we have a physiologic peptonuria. Decio says: "Here an artificial, electrical peptonuria." Decio has moreover observed that the electrical peptonuria was very manifest in cases of large tumors which had a great tendency to regressive metamorphosis; that the peptonuria was little or none where the regressive process of the tumor was doubtful, and that it was lacking altogether in the case of small uteri; a fact which he explains by the small quantity of elements causing either no peptonuria or very little. This fact has still another analogy, viz.: That the puerperal peptonuria is very insignificant or nothing at all in abortions or premature deliveries; this Truzzi explains by the moderate development of the uterine parenchyma and by the small contractile power at the moment of delivery.

Decio, then, having his views on the increase of soluble albuminous substances found by Shaw, considers that, as a result of special chemic modifications caused by the current (as Willis E. Ford has also shown by experiments on nutritive fluids), there can be a partial transformation of these juices into peptone, which, penetrating into the circulatory current—herein aided by uterine contractions—shows itself in the urine. Hence, evidently, the reduction of the fibroma.

This is a theory which I find very plausible.

Wishing to draw a conclusion, after what I have just said, we can say with much probability that electrical treatment acts on fibromata in two ways. We have:

1. The energetic contraction of the uterus under the positive polar action of the continued current, which, producing a compression of the organ, hinders an abundant afflux of blood and arrests the hemorrhage.

2. Special chemic modifications in the tissues, disturbance in the molecular interchange among the elements of the tumor under the interpolar action of electricity, causing a transformation of nutritive juices into peptones or into other sediments which are absorbed and eliminated by the kidneys, whence the atrophy and reduction of the fibromatous tumor.

(To be continued.)

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
F. J. REBMAN, LONDON AGENT, 11 Adam Street, STRAND, LONDON.
W. H. LOWDERMILK & CO., WASHINGTON, AGENTS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duuglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, APRIL 14, 1894.

"CHARTERED BY THE STATE."

One of the most interesting sections of the report on medical education by the Illinois State Board of Health is that concerning fraudulent medical institutions, some excerpts from which have already been given in the JOURNAL.¹ The history of these "diploma mills" furnishes a pretty conclusive argument for reform in the legislation which empowers any three or more individuals, who can "put up" between them the sum of three dollars with the Secretary of State, to flock together, start a "college" or "university" and confer degrees in medicine and issue diplomas with or without other consideration than that *ad pecuniam*.

The report furnishes the data of some fifty fraudulent diploma-selling concerns that have been started in the United States since 1833. Of this number twenty-nine have become extinct through agencies among which the Illinois Board itself has been one of the most effective, although the Board admits with some chagrin that it has been less successful in Illinois than in other States in breaking up these institutions "chartered by the State."

Its investigation and exposure in 1882, of a batch of four Boston concerns which were selling medical diplomas for \$50 each, "C. O. D.," is a notable instance of the work of the Board in this direction. These concerns were organized and operated under Massachusetts legislation, similar to that of Illinois, for the incorporation of associations, universities, colleges and academies "for charitable, educational and other purposes;" and one of their most valued trade-marks was the legend, "Chartered by the State." As a result of the work of the Illinois Board and the publicity attendant thereon the Massachusetts Legislature passed an act, May 30, 1883, forbidding such incorporations from conferring medical degrees and

issuing medical diplomas without special authorization from the General Assembly, and the sanction of the commonwealth has thus been withdrawn from the "diploma mills" of Massachusetts.

They still, however, continue to be chartered by the State of Illinois—as witness the "Malok brood," the Harkins' "universities" and other "colleges" and "institutes" started in Chicago during the last half-dozen years.

Early in the existence of the Illinois Board a protest was entered with the Secretary of State against the further issue of charters to this class of institutions and a demand was made for the revocation of those in existence upon proof of the fraudulent nature of the operations thereunder. The reply was, in substance, a request to be informed what the Board was going to do about it—that the law provided for the issue of the charter upon the payment of the fee, and if the Board did not like it, it had better get the law changed. Whereupon the Board asked the Legislature to except from the act concerning corporations the incorporation of medical colleges and institutions, even as corporations for banking purposes, the insurance business, the operation of railroads, real estate brokerage and the business of loaning money were excepted. But the law of 1872 still stands on the statute books and the Maloks and the Harkins profit by it.

In the latter part of the last century the Supreme Court of Pennsylvania was empowered by the General Assembly of that State to issue certificates of incorporation to organizations for charitable, benevolent or educational purposes. But when, some forty years later, an application was made for a certificate of incorporation for a medical college, the Court refused to issue the certificate on the broad ground that the General Assembly could not have contemplated putting into the hands of a bench of lawyers the power to determine the qualifications of a faculty of teachers of medicine. And the wise and witty judge who delivered the opinion of the Court took occasion to point out that, to act upon the assumption that the General Assembly, in empowering the Court to issue certificates of incorporation, intended that any three men in any town of the State, however illiterate or irresponsible, might organize and demand of the Court a certificate—in effect, a charter—under which they might flood the State with medical diplomas, would be to place the degree of Doctor of Medicine in a situation similar to that which a celebrated Minister of France once threatened as to another kind of title—namely: That he would "create so many dukes that, while it would be no honor to be a duke, it would be no shame not to be a duke."

In the closing years of the nineteenth century a single State officer—not necessarily even a lawyer—

¹ JOURNAL AMERICAN MEDICAL ASSOCIATION, March 31, 1894.

is, apparently, accounted wiser by many State Legislatures than the entire Supreme Bench of Pennsylvania deemed itself fifty years ago.

STATE CARE OF THE INSANE IN NEW YORK.

On Oct. 1, 1893, the new system, known as "the State care" system, went into operation, by the assumption on the part of the State Commission in Lunacy, of the financial responsibility of caring for 8,700 insane poor. This number is about half the total poor insane in the State; there are 8,800 others supported in the asylums of New York and Kings Counties. An editorial paragraph in the *New York Tribune* sums up the present condition of these latter asylums in the following terms:

"The management of the New York asylums has always been excellent, and there is no pressing need of the transfer of the institutions to the State. In Kings County the institutions have been brought under political influence, and their management has been fraught with incompetence and scandal. The asylums at St. Johnland and Flatbush ought to be turned over to the State. The insane patients would receive more scientific treatment and more humane care; and a heavy financial burden now borne exclusively by Brooklyn taxpayers would be distributed among the counties."

These remarks indicate a true diagnosis and prognosis in respect of asylum management. There are already indications, on the part of certain "ring" politicians in Kings County, that the insane poor of that region will be passed over to the care of the State Commission, provided that the sums of money that have lately been expended on certain large asylum buildings in Suffolk County, can be repaid by the State. The insane poor would probably hail the change of custodians, if they could vote on the question, inasmuch as their dietary has been such that not a few of their number have been patient, under attacks of scurvy as well as under mental alienation.

A long letter from Albany, in the newspaper above named, states that the question of dietary of the insane is a foremost one, at the present time, with the State Commission. To this end, DR. AUSTIN FLINT has been invited to frame a "generous diet" for the State's 8,000 lunatics. The first recommendation of DR. FLINT was the almost unheard-of suggestion—in any State charity or "pauper" institution—to get good cooks for each and every asylum. DR. FLINT takes the position that good cooking subserves the physical welfare of the sick, not only, but also the pocket-book of the administration. "A good cook," says he, "is an important element in economical management." He then narrates some of his earlier experience in relation to the public institutions of New York City:

"In 1867 I was appointed by the Commissioners of Public Charities and Correction of the City of New York, to inspect the methods of cooking and serving food to the inmates, numbering then more than 10,000, of the institutions under their charge. After a careful inspection, as requested, I proposed certain changes in the dietaries, and at my suggestion an accomplished professional cook, at a liberal salary, was put in charge of the kitchens at Bellevue Hospital. As

a result of this, not only did the cook save to the institution the sum of his salary, but the cost of maintenance of the patients per capita was materially reduced. At that time the number of patients in Bellevue Hospital was between 500 and 600. I suggest at the beginning that a thoroughly competent male cook be put in charge of the kitchens in all institutions with 500 or more inmates, and that he be required to personally supervise all the cooking, and not the cooking for the medical staff only. While it may be proper to provide for ordinary paupers and criminals little more than enough to keep them in fair physical condition, the insane poor, though a charge upon the State, should receive better consideration. Again, a most important part of the treatment of the insane relates to general nutrition, and many patients suffering from mental diseases require a great abundance of nutritious food, which contributes very largely to their cure, and thereby tends to relieve the State from their care and maintenance for a long period."

Writing in the line of this suggestion, DR. FLINT recommended the following quantities of supplies for 100 persons for thirty days:

Meat with bone, including salt meat, fresh and salted fish, and poultry (lb)	2,250
Flour (may be in part substituted by cornmeal and macaroni) (lb)	3,000
Potatoes (lb)	1,500
Milk (quarts)	750
Eggs (dozen)	493
Sugar (lb)	429
Butter (lb)	429
Cheese (lb)	429
Rice (lb)	108
Hominy (lb)	108
Oatmeal (lb)	108
Coffee	215
Tea (lb)	26

The large purchases of food-stuffs to support a population of nearly 9,000 souls, will enable the Commission to obtain very low rates. The asylums, for example, will consume 6,000 barrels of flour and 250 tons of sugar in a year. The Commission aims to supply the same quality and relative quantity to the inmates of each hospital—whereas under the old system there were frequent departures from impartial treatment, at least, so it has been charged.

The Commissioners report that for the month of October they have effected an aggregate cutting down of the estimates of the trustees of the various asylums by \$55,000, and for November \$35,000. The inmates of the asylums will make all their own clothing. The inmates of New York's asylum on Blackwell's Island do so, and it is perfectly feasible in all the State hospitals. All farm work also ought to be done by the inmates of the hospitals. It will be good for the health of the patients to have them work out of doors. All the vegetables and farm products, hay and the like, thus can be raised by the inmates of the hospitals, and large sums saved. The inmates of the hospitals also ought to make the mattresses of these institutions, and by degrees these mattresses, made of hair, will be substituted for the old straw ones.

One of the novel features of the new *regimé* will be the discontinuance of the tobacco ration. On this subject DR. MACDONALD is reported as saying:

"It is highly unwise to give insane patients, who are peculiarly nervous class of people, tobacco either to chew or to smoke. We found upon investigation that the supplying of tobacco to the inmates of the hospitals was costing the State the large sum of \$15,000 annually. But that was not the worst of it; the health of the patients is seriously affected, and when smoking is permitted there is danger of fire. One hospital has had four fires in the last year, all, there is reason to think, the result of tobacco. Why, on Ward's Island there are 2,000 men patients who have not used tobacco in any form since 1877, and they are in excellent health. We

have, therefore, refused to allow any money in the hospital estimates for the use of tobacco."

A great saving has been made by cutting off a long dead-head "family" list, by reducing the equestrian stock, and by dismissing fancy help. One institution formerly governed by four florists, now must get along with one only. The amount of the current appropriation for the State insane is \$1,300,000, all of which must be strictly accounted for by the three Commissioners, at the head of whom is DR. CARLOS F. MACDONALD. The hospital trustees are not permitted to spend a dollar without estimate and consent, and all expenditures must be submitted monthly for audit.

The unfortunate lunatics will, under the new *regime*, have a more generous diet—minus the nicotine element—with a greater amount of that occupational exercise that is salutary to the mind diseased. The work in which the State Commission is engaged is one worthy the best minds of the State, and we would feel more hopeful of good results if another medical man had a place on the Commission.

MEDICAL EXAMINING AND LICENSING BOARDS.

The next annual meeting of the National Conference of State Medical Examining and Licensing Boards will be held in the city of San Francisco, June 5, 1894, during the session of the AMERICAN MEDICAL ASSOCIATION. DR. CHARLES K. COLE, of Helena, Mont., the Secretary of the Conference, has issued a circular calling for reports on the various subjects with which these Boards are concerned, and proposes to tabulate and present to the Conference the information received in continuation of the work in this connection previously done by the late DR. RAUCH, the founder of the Conference and its President at the time of his death.

Each Board is asked to report the period of its existence; the number of candidates examined during such period, by years, and the number passed and furnished license to practice; its organization with reference to schools of practice; its judgment upon the advantages and disadvantages of mixed Boards and of separate Boards for each school of practice—regular, "homeopathic," "eclectic;" its judgment as to the number of members which should constitute a Board and the proper appointing power; "should teachers in medical schools be eligible to membership on State Examining Boards?" Should certificates be interchanged between State Boards? The leading defects in the laws concerning such Boards; the requirements as to period of study and curriculum which should entitle colleges to recognition as in "good standing" for purposes of registration; the litigation had by the Board and its results; the number of practitioners in the State, by schools of practice, in the Army, Navy and Marine-Hospital Services, and those practicing illegally; all legislation con-

cerning medical practice within the jurisdiction of the Board.

This list of subjects embraces many of direct interest to every member of the profession, and the session of the Conference is likely to attract attention.

VITAL STATISTICS IN NORTH CAROLINA.

DR. R. H. LEWIS, of Raleigh, Secretary of his State Board of Health, is earnestly engaged in promoting an improved system of vital registration in North Carolina. The last *Bulletin* contains his statement regarding the chief obstacles in the way of the proper collection of statistics in the rural and urban populations under his charge. We quote a portion of his article:

"One of the most important functions of a sanitary bureau is the collection of vital statistics. Section six of our law says: 'Monthly returns of vital statistics, upon a plan to be made by the State Board of Health, or their Secretary acting under their instructions, shall be made by the County Superintendent to the Secretary of the State Board.' The plan devised by the late Secretary, the lamented Dr. Wood, and still in vogue as the best available, is not calculated to secure complete and accurate statistics, but merely a general idea of the prevalence of particular diseases, especially those of a communicable character, in the counties, and the number and causes of death in the cities and towns. Indeed, the conditions with us are such—an extremely conservative and rather sparsely settled rural population in the main—that obtaining reliable statistics from the State at large is simply out of the question at present and we fear will be for many years to come. And yet it is of peculiar importance to our State, inasmuch as immigration is greatly desired, that we should have accurate and reliable statistics, especially in mortuary matters.

"Even in cities and towns it is not possible to obtain full and reliable mortuary statistics except under a strict enforcement of ordinances imposing a decided penalty for the burial or removal from the corporate limits, of a dead body except upon a burial permit issued by a designated official, based upon a death certificate, giving, chief among other things, the cause of death signed by the attending physician, or cases where there was no attending physician, by the nearest friend, and sworn to by him before a magistrate. The authorities should impress this ordinance particularly upon the undertakers in such a manner as to effectually prevent their undertaking the preparations for burial until the burial permit is produced. Something less than a year ago we sent to every town in the State having five hundred or more inhabitants, and to all county-seats of less population, a model ordinance with sample blanks, in which the regulations suggested above were set forth, in the hope that it might be generally adopted and mortuary statistics collected in every place on the same plan. While only two towns have formally adopted the ordinance as a whole, a number have it essentially, and the statistics sent in we believe to be generally reliable. But we can not help feeling when we note a death rate very much smaller in one town than in another of about the same sanitary conditions, that the former either has an imperfect ordinance or does not enforce a good one. We are not willing to admit, that any municipality would deliberately 'fudge,' as we used to say in marbles, on its sisters.

"We have brought forward this subject because of its importance and in the hope that those of our readers living in cities and towns will interest themselves in the matter sufficiently to inquire as to the ordinance on the subject and as to the enforcement of the same. The display of such an interest on the part of the medical men of any city or town would surely have its effect upon the authorities and make for the perfecting of the returns."

Whatever of influence this JOURNAL may have with the medical men of the "old North State" is unhesitatingly thrown in favor of the difficult but necessary task that has been assumed by DR. LEWIS. We trust he will be heartily supported.

WHAT ARE PRIVILEGED COMMUNICATIONS?

At common law, confidential communications made by a patient to a physician are not privileged. By statute they are, however, rendered otherwise in most of the States. In Indiana, for example, physicians are prohibited from testifying as to matter communicated to them, as such, by patients, in the course of their professional business, or advice given in such cases. With this for a basis, the Supreme Court of Indiana has, in the case of *SPRINGER v. BYRAM*, decided Feb. 15, 1894, examined quite a number of authorities and summarized the law as follows: The privilege may attach, notwithstanding the presence of third persons in the sick-room, where the consultation is had. If the attending physician calls in another physician for consultation, the communications made to the latter are privileged. Where there are two physicians, the patient does not, by calling one of his physicians as a witness, waive his privilege to object to the testimony of the other. Communications made by a patient to his physician, for the purpose of professional aid and advice, are privileged, because intended to be private and confidential, and can never be divulged without the consent of the patient; it being the privilege of the patient, and not of the physician. The privilege of exemption from testifying to declarations made and facts actually known is extended to a physician who derives his knowledge from the communications of a patient who applies and makes disclosures to him in his professional character. The immunity extends to all such facts, whether learned directly from the patient, or acquired by the physician through his own observation or examination. Neither can disclosures be made by other persons whose intervention is strictly necessary to enable the parties to communicate with each other. But if parties sustaining confidential relations to each other hold their conversation in the presence and hearing of third persons, whether they be necessarily present as officers, or indifferent bystanders, such third persons are not prohibited from testifying as to what they heard. Thus, the court holds, in this case, that persons in charge of an ambulance sent by a stranger to take an injured party home after an accident, are not forbidden to testify as to what such party then said to a physician as to the cause of the accident.

CORRESPONDENCE.

Proposed Revision of the Code of Ethics of the American Medical Association—Report of the Committee on Revision.

To the Editor:—After more than ten months of the year have passed since the last annual meeting of the AMERICAN MEDICAL ASSOCIATION, the majority of the Committee appointed nearly two years since to inquire whether any

revision of the Code of Medical Ethics was desirable, have made their report in the JOURNAL OF THE ASSOCIATION of the 7th inst. As less than half of the State and Territorial medical societies will have regular meetings between this time and the meeting of the ASSOCIATION in San Francisco, it is apparent that no proper consideration can be given to this report by the several State medical societies for the purpose of instructing their delegates regarding it, as was contemplated by action taken at the annual meeting in Milwaukee. And but few readers of the JOURNAL will fully comprehend the changes contained in the revised Code and their real import, unless they read it in direct comparison with the present Code, item by item. For the majority of the Committee, instead of pointing out such sections or parts of the Code as they deemed wrong or defective, and presenting such substitutes as they believed necessary, as such committees usually do, have simply re-written the whole Code, preserving so much of the language of the present Code as to make the casual reader think that no very important or radical changes had been made in the revised document.

A closer examination, however, will show that by silently omitting several whole sections relating to some topics; dropping a word here and a line there from other sections, and introducing new sections ostensibly for better covering the so-called progressive changes in the profession itself, the Committee have placed their revised Code on a radically different basis, and have so constructed some of its details as to violate the plainest principles of equality and justice. The character of the revised Code plainly shows that its authors have had for their chief objects: 1, the elimination from the Code of every item that tended to make a distinction between regular and irregular practice, between modern scientific medical education and the metaphysical dogmas of past centuries; 2, the careful introduction and recognition of class distinctions in the profession; and 3, the actual substitution of the license from some board or tribunal legally authorized to grant it, in the place of a regular medical education, as the test of recognition, both in consultation and professional fellowship.

In the work of *elimination*, the majority of the Committee have entirely omitted the sections relating to the "obligations of patients to their physicians" and of the "public to the profession;" and also of Sections 2 and 3 under the head of "Duties for the Support of Professional Character." By these omissions they have destroyed the completeness of the Code, for it is just as important for the physician to know what are the just obligations of his patients to him, as it is to know his obligations to his patients.

And if it is important that the members of the profession should be taught their obligations to the public, they should be equally informed of the just obligations of the public to them. It is no just excuse for these omissions to say that the Code was not intended for the perusal of patients or the public, for it was really intended for both; and if physicians were more diligent in placing copies of the Code in the hands of their more intelligent patrons it would greatly benefit all parties. By omitting from the Article on "Duties for the Support of Professional Character," Section 3, they have erased from the Code the only rule directly enjoining a high standard of moral excellence and purity of character on the part of the physician; a rule which in substance, first appeared in the celebrated oath of Hippocrates and has been retained in every code of ethics since. If, as is said in the "Proem" or Introduction to the revised Code, "Ethics is that science which treats of human actions and mental affections considered as virtuous or vicious, right or wrong," why omit from a code of ethics all precepts relating to the maintenance of a noble, vir-

tuous and temperate life as essential to a truly successful professional career?

Under the same heading, "Duties for the Support of Professional Character," the revised Code reproduces as Section 2, Section 4, of the present Code in full as follows: "It is derogatory to the dignity of the profession to resort to public advertisements or private cards or handbills inviting the attention of individuals affected with particular diseases—publicly offering advice and medicine to the poor gratis, or promising cures; or to publish cases and operations in daily prints, or suffer such publications to be made; to invite laymen to be present at operations, to boast of cures and remedies, to adduce certificates of skill and success, or to perform any other similar acts. These are the ordinary practices of empirics, and are highly reprehensible in physicians." But to this well-recognized section the revising Committee make the following remarkable addition: "It shall not be considered as a violation of the spirit of this section, however, for physicians engaged in the work of medical education, either singly or associated in colleges, or for physicians practicing in hospitals, whether private or public, general or special, to announce the fact or allow it to be announced to the profession in the advertising pages of strictly medical journals, or for physicians devoting special attention to one of the recognized special departments of medical practice to note the fact on their signs or private cards." Read in plain direct language, this means that every physician who claims to give "special attention" to some particular class of diseases may "invite the attention" of those affected by such diseases by advertising the same on his door plate, sign board, and private cards as much as he pleases, while the first half of the section makes the doing of the same thing by the general practitioner not only "derogatory to the dignity of the profession," but "highly reprehensible." Will the members of the Committee of Revision inform us on which of the "eternal principles of justice" alluded to in their "Proem" this distinction is founded? The next section, which relates to the holding of patents is so far emasculated as to make it prohibit only the holding of patents for *secret nostrums*.

By omitting all mention of surgical instruments and appliances, and also of the prescribing of *secret nostrums*, the inference necessarily follows that if this Revised Code should be adopted it would be no longer "derogatory to professional character" to hold patents for all kinds of instruments and appliances used in medical and surgical practice, and to prescribe *secret nostrums* and trade-mark medicines, *ad libitum*. Surely this would be progress, but in what direction—that of science and honor, or that of mammon and dishonor?

It was doubtless the same train of thought leading to the proposed changes in the two sections last noticed, that prompted the Committee to introduce into the Revised Code a new chapter on "Special Departments in Medical Practice," with three Articles: 1, on the Necessity for Specialties; 2, on the Education of Specialists; and 3, on Specialists as Consultants.

Under the first head, the necessity for specialists is made to rest on the broad assertion that "the field of medical knowledge is now so vast that no one mind can compass it in all its details. Nor can any one hand attain the dexterity essential for the successful performance of all the delicate and daring operations of modern surgery." And it is added that, "differentiation in study and labor of whatever kind is the test of civilization." Yet in the very next Article, on the education of the specialist, it is stated that they must not "omit one jot or one tittle, either of the preliminary or the technical education insisted upon as essential for the physician," and consequently "specialists should not be

something less than general practitioners, but general practitioners and *something more*." In other words, the present field of medical knowledge is so vast that no one mind can compass it, and therefore differentiation in study and labor, the very test of civilization, necessitates division into specialties; nevertheless, the specialists must not differentiate or abate one jot or one tittle, but barbarously struggle to cover the whole field, that they may be "general practitioners and something more." That is something more than the whole. What kind of philosophy or logic is this?

In the third Article of this remarkable chapter it is declared to be "the obvious duty of general practitioners, when cases come under their care for the successful management of which they have not had the requisite training, or do not possess the necessary facilities and appliances, to recommend and introduce such cases to a competent and reputable specialist, and thus prevent them from drifting into the hands of charlatans." Now is it not equally the "obvious duty" of the specialists, when cases come to them not embraced in their specialty, to recommend and introduce such cases to a reputable general practitioner, and if so, why not incorporate it in the Code? Why put the ethical injunctions all on one side? Is there not the same danger that the unfortunate patients might drift into the hands of charlatans in the one case as in the other? Perhaps, however, the members of the Committee regarded every case safe that reached the hands of a specialist, inasmuch as they had declared him to be both "general practitioner" and specialist or "something more." If it is really desirable to introduce into the Code any mention of particular grades or classes of practitioners, instead of this illogical chapter, the Committee on revision might have properly incorporated the substance of the resolutions adopted by the Association in 1869, which simply declare that specialties are "recognized as proper and legitimate fields of labor," and that "specialists shall be governed by the same rules of ethics and professional etiquette as have been laid down for general practitioners." This would have kept the Code in harmony with, instead of in violation of, that "eternal principle of justice" which accords to every member of a profession equal rights and privileges.

But the climax of degradation is reached in this Revised Code in its Chapter II, Article II, Of Consultations, Section 2, where it is declared that, "a thorough education, preliminary, scientific and technical, furnishes the only presumptive evidence of professional abilities and acquirements, and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless, as in consultations the good of the patient is the sole object in view, and as this is often dependent on personal confidence, no intelligent practitioner, who has a license to practice from some medical board of known and acknowledged legal authority, and who is in good moral and professional standing in the place where he resides, should be refused consultation, when it is requested by the patient." Here, after the usual flourish about "a thorough education," etc., we have a complete abandonment of the authority of the profession to decide what shall be the character and qualifications of those who are to be recognized in consultations and fellowship, and its transference to any medical board of known "legal authority," to grant a license to practice.

This is done by simply omitting from the corresponding section in the present Code the word "regular" at its beginning, and from between the words, "intelligent," and "practitioner" further on; and the omission of the words, "recognized by the Association," directly following the words, "acknowledged legal authority." Also the omission of all of the last paragraph of the section as it is in the present Code. By these omissions they have removed from this Revised Code, every vestige of authority for the profession to

decide what shall be the education and qualification of those who are to be admitted to its own fellowship and consultation, and have given that authority directly to an indefinite number of medical schools and medical boards of every *ic* and *ism*, regular, homeopathic, eclectic, physiopathic, etc., all possessing "acknowledged legal authority" to grant degrees or licenses. Consequently no one holding a license from any of these sources should be refused consultation and fellowship by the members of a great and beneficent profession. Yet it is well known that there is scarcely a medical impostor or charlatan in the country who does not hold a license or diploma from some one of these schools or boards having legal authority to grant the same.

It seems to me the learned and highly esteemed members of the profession who constitute the majority of the Committee on Revision of the Code, in their anxiety to free the Code from all allusions to regular or irregular practice, to genuine or bogus systems of medical education, and to ethically recognize special privileges for specialists, have so far obscured their own mental vision with an almost tiresome protestation in favor of "education, preliminary, scientific and technical," that they have not clearly seen the abyss of incongruities into which they have drifted. If the time ever comes when each State shall have only one board of medical examiners, before which all candidates for admission into the profession shall be examined on all branches alike, and with substantial uniformity in their standards, it will then be easy to adjust the details of the Code to the legal requirements. But until that time does come it is hoped that the great body of the medical profession in this country will adhere to the present Code, which has met with the unqualified approval of the profession of all other enlightened countries. And even then let those who are on the stage of action be careful to make the changed conditions or relations of the profession conform ethically to the "eternal principles of justice," instead of trying to make the "eternal principles of justice" conform to the professional requirements.

Yours truly, N. S. DAVIS.

Chicago, Ill., April 9, 1894.

In Favor of the Old Code.

To the Editor:—If there were any argument required to prove that the Code as it now stands is a masterpiece in dignified statement of what constitutes professional conduct, that argument in most convincing power would be furnished by placing the alleged "old," "obsolete," Code side by side with the productions of the would-be revisers of it.

The Code has been sneered at as a meaningless wordy-make-up hundreds of times, and yet somehow, notwithstanding that it is meaningless, just as soon as a man does an unprofessional thing the old Code tells him of it. The Code appeals to the highest principles in man. Anything which antagonizes the Code is something which is of a lower order than the highest principles in man. Mr. Editor, there are a great many men in the world who enjoy being members of an honorable profession, and who never do anything toward maintaining the honor of the profession. These men are anxious to share in the profits, financial profits too, which such an organization carries with it, and if you have never done so before, turn to the proposed revision as published in the last JOURNAL, and see how "carefully" the old Code has been "studied," along lines which affect consultation fees.

It will be vastly more to the honor of the profession to throw the Code overboard and openly indorse tomfoolery and quackery, than to do the humiliating thing of subscribing to a silly apology for doing for money what everybody knows to be a disgraceful thing.

J. L. TRACY, M.D.

Professor John Tyndall.

MT. CARMEL, ILL., April, 1894.

To the Editor:—Your notice, on page 523 of the JOURNAL of April 7, of Prof. John Tyndall's donation to Harvard, does very meager justice to his noble acts. He came to this country in October, 1872, and delivered lectures in Boston, Philadelphia, Baltimore, Washington, New York, Brooklyn and New Haven—thirty-six in all; the total receipts for which were \$23,100. After deducting his actual expenses there was left \$13,033. This he placed in the care of a board of trustees, consisting of Prof. Joseph Henry, Dr. E. L. Youmans and Gen. Hector Tyndale, with a request that the interest on the same be used to send two especially promising American pupils to one of the European universities. The trustees found considerable difficulty in carrying out the instructions, and did not use all the interest as it accrued. At the end of thirteen years the fund had increased to \$32,400. Prof. Tyndall then decided to divide this into three equal parts; and gave one part to Columbia College, one to Harvard University, and one to the University of Pennsylvania, to be used in the establishment of three permanent fellowships in physical science.

J. SCHNECK, M.D.

Is After Medicus.

SEATTLE, WASHINGTON, April 4, 1894.

To the Editor:—Every reader of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and especially every member of the ASSOCIATION who ranks himself a gentleman, will indorse the remarks of Dr. S. Solis-Cohen and treat "Medicus" with contempt.

Very truly, EMIL BORIES, M.D.

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Rio Grande Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville, Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland, thence east by way of the Northern Pacific R. R. to St. Paul. C. M. & St. P. R. St. Paul to Chicago. A stop over at Yellowstone National Park for those who desire it has been arranged, and it has been understood that at several places on the journey there will be short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentrating on this train should be effected at Chicago and St. Louis. For all information relating to this train, fares, etc., address J. M. Connell, 212 Clark st., Chicago, or any agent of Santa Fe line in other cities. Rates promised are the lowest excursion rates at time of departure.

This is the only route on which arrangements have been perfected by the Trustees.

SOCIETY NEWS.

The North Philadelphia Medical Society was organized April 2, Dr. William G. Howell was elected President, and Dr. J. B. Brackbank Secretary.

The Chicago Medical Society.—The Publication Committee, on behalf of the *Chicago Medical Recorder*, will give two prizes of \$100 each for the best papers submitted before the Chicago Medical Society during the year 1894-5. The editor, Dr. Church, must be notified of each paper entering the contest at the time it is read before the Society. It is intended to increase the amount and number of these prizes

as the profits from the *Recorder* may justify, and all members of the Society are urged to continue their cordial support of the journal and, other things being equal, to give our advertisers the preference when prescribing. It is also suggested that whenever a worthy article for physicians' use is presented by agents, the advice be given to advertise in the *Recorder*. The *Medical Recorder* is now self-sustaining, and will require no further financial aid from the Society, but in the way suggested much can be done toward increasing the fund for prizes, which will secure original and valuable work and add greatly to the importance of the Society.

(Signed) E. J. DOERING,
JOHN A. ROBISON,
ARCHIBALD CHURCH,
Committee on Publication.

April 2, 1894.

Association of American Anatomists.—The sixth annual meeting of this Association will be held in connection with the Congress of American Physicians and Surgeons, May 29 to June 1, 1894, in the city of Washington, D. C. This will be the first meeting since that of December 27 to 29, 1892, at Princeton, N. J. The sessions will be held in the Preparatory Department of the Columbian University, H Street, between Thirteenth and Fourteenth, within a few steps of three lines of street cars, and only a few blocks from the principal hotels and Government Departments.

Members who expect to attend will please notify the Secretary and forward to him the titles of papers, etc., which they expect to contribute. The final program will be issued about May 1.

Thus far the following titles have been received:

Dr. Harrison Allen, University of Pennsylvania, "Morphology as a Factor in the Study of Disease." This paper will be read at the general meeting of the Congress on the afternoon of May 29. The discussion will be led by Dr. Thomas Dwight, of Harvard, Dr. Fred H. Gerrish, of Bowdoin, Dr. Frank Baker, of the University of Georgetown, and Dr. Burt G. Wilder, of Cornell.

Also by Dr. Allen two papers: "The Study of the Human Cranium," and "On the Shortening of the Face-axis in the Evolution of the Mammalia."

Dr. Carl Heitzmann, of New York City, "Identity of Structure of Protoplasm with that of Striped Muscle."

Dr. B. G. Wilder, of Cornell, "Relation of the Olfactory to the Cerebral Portion of the Brain." Also "Notes on the Anatomy of the Orang."

Dr. D. K. Shute, of Columbian University, Washington, "Perineum and Perineal Body."

Dr. Wm. P. Carr, of Columbian University, Washington, "Theoretical Anatomy of the Sympathetic System."

Papers are also promised by Dr. Thomas Dwight, of Harvard; Dr. Frank Baker, of Georgetown University, and Dr. D. S. Lamb, of the Army Medical Museum. The titles have not yet been reported.

It is requested that nominations and recommendations for membership be sent to the Secretary before the time of meeting. D. S. LAMB, M.D., Secretary and Treasurer,
800 10th Street, Washington.

March 31, 1894.

Texas State Medical Society.—The twenty-sixth annual meeting of the Texas State Medical Society will be held in the Senate Chamber, Capitol Building, Austin, Texas, April 24, 25, 26 and 27, 1894. The following papers are announced:

Bacteriologic Aspects of Croupous Pneumonia. H. A. West, M.D., Galveston.

The Therapeutic Uses of Spartein. David Cerna, M.D., Galveston.

Hydrotherapy. D. R. Wallace, M.D., Waco.

The Relation of Pharmacy to Medicine. James Kennedy, M.D., Galveston.

Introducing the Subjects of Dosimetry and Subcutaneous Medication. D. R. Wallace, M.D., Waco.

The Present Status of Symphyseotomy, and its Relation to other Obstetrical Operations. J. F. Y. Paine, M.D., Galveston.

Report of a Monstrosity without Limbs or Sexual Organs. Matthew M. Smith, B.Sc., M.A., M.D., Austin.

Tuberculosis of the Joints; its Etiology and Treatment.

Wm. M. Cunningham, M.D., of Bastrop. Discussed by Drs. W. F. Starley of Tyler, and I. E. Clark of Schulenberg.

Diseased Joints in Children. Samuel E. Milliken, M.D., New York.

The Treatment of Neglected Cases of Hip Joint Disease. J. E. Thompson, M.D., Galveston.

Removal of Female Breast and Axillary Glands for Malignant Disease. B. F. Britain, M.D., of Arlington.

A Report of Six Cases of Depressed Fracture of Frontal Region of Skull, with Two Deaths. J. S. Price, M.D., of Beaumont. Discussed by Drs. A. F. Sampson, Galveston, and Matthew M. Smith, Austin.

Brain Surgery of To-Day. Matthew M. Smith, M.D., Austin.

Concussion and Contusion of the Brain. T. F. Wynn, M.D., Pittsburg.

A Contribution to the Study of the Action of Chloroform. Drs. Edward Randall and David Cerna, Galveston.

Chloroform Anesthesia. Q. C. Smith, M.D., Austin. Discussed by Drs. H. K. Leake, Dallas, and H. C. Nott, Goliad.

Irrigation and Drainage for Peritonitis. Joseph Price, M.D., Philadelphia, Pa. Discussed by Drs. B. E. Hadra, San Antonio, and C. A. Smith, Tyler.

The Modern Treatment of Wounds. Russell A. Hibbs, M.D., New York City. Discussed by Drs. T. J. Bennett, Austin, and George W. Christian, Houston.

Report of a Case of Injury to the Chest. August Schenk, M.D., Kennedy.

Appendicitis; also Report of a Case of Congenital Displaced Enlarged Liver, Mistaken for Tumor; Operation. J. E. Gilcrest, M.D., Gainesville. Discussed by Drs. B. E. Hadra, San Antonio, and A. Sims, Weatherford.

The Operative and Mechanical Treatment of Club-Foot, with Report of Cases. T. W. Shearer, M.D., Wallisville.

A Case of Incomplete Dislocation of the Head of Tibia Inwards, with Complete Outward Vertical Luxation of the Patella. William J. Bever, M.D., Creek.

On Perineorrhaphy by Duke's Method. Thos. More Maden, M.D., Honorary Member, Dublin, Ireland.

Abscess of Spleen in Child Three Months Old; Recovery. W. A. Watkins, M.D., Kemp. Discussed by Drs. Q. C. Smith, Austin, and J. D. Burch, Aurora.

The Fitness of the Climate of Texas for Operative Surgery, Demonstrated by Results in Recent Capital Cases. By Drs. Beall, Walker and Capps, Fort Worth.

Increase of Mental Unsoundness. D. R. Wallace, M.D., LL.D., Waco.

Morphin Suicides. Prevention. Treatment of Opium Poisoning. E. D. Capps, M.D., Fort Worth.

Mind Cure. D. R. Wallace, M.D., LL.D., Waco.

Dysmenorrhea with Sterility, and its Treatment. Sam Cunningham, M.D., Elgin. Discussed by Drs. Hibbs, of New York, and G. B. Foscoe, of Waco.

An Original Method of Disposing of the Ligatures after Laparotomies in the Pelvic Region, Effecting Perfect Vaginal Drainage, with Report of Cases. James Cummings, M.D., Austin. Discussed by Drs. W. J. Mathews, of Austin, and H. H. Thorpe, of Liberty Hill.

Intra-Uterine Manipulations in Pelvic Inflammation. J. F. Y. Paine, M.D., Galveston.

Placenta Previa Treated by Cesarean Section. G. A. Moses, M.D., St. Louis, Mo. Discussed by Drs. T. D. Wooten and G. A. Cupples.

The After Treatment of Celiotomies. G. D. Parker, M.D., Houston. Discussed by Drs. A. C. Scott, of Temple, and Q. C. Smith, of Austin.

Some Clinical Observations on Hematozoa Malariae. Wm. Gammon, M.D., Galveston.

Embarrassments of Medicine. James H. Bell, M.D., Philadelphia, Pa.

H. A. WEST, M.D., Secretary, Galveston.

Wisconsin State Medical Society.—The forty-eighth annual meeting of the Wisconsin State Medical Society will be held at the Plankinton House, Milwaukee, May 2, 3 and 4, 1894. The sessions will be held in the Casino Hall of the Plankinton House, beginning at 11 o'clock on Wednesday forenoon, May 2. The reading of papers and discussions will be continued Wednesday afternoon and evening, as well as during the entire day of Thursday.

The literary exercises will be resumed at 8:30 o'clock Friday morning, and the annual election of officers has been set down for 10 o'clock. At 11:45 A.M. business will be sus-

pended for a recess of fifteen minutes, when, at 12:00 m., the President of the Society will deliver the Annual Address.

The Anniversary Dinner will be served at the Plankinton House at 1:00 P.M. The members of the Society will meet in the Club Room and be called in seniority of graduation, and, preceded by the invited guests, will march in procession to the banquet hall. Tickets to the dinner, for which there is no extra charge, should be procured of the Treasurer, Dr. S. S. Hall, as early as possible—preferably when registering at the beginning of the meeting—that the Committee on Arrangements may know the number to provide for. The Committee announces that no person will be admitted to the dinner without a ticket. It is expected that the Anniversary Banquet will be one of the very pleasantest features of the session, as it surely was last year, and every member is urgently requested to be present.

The following is a partial list of papers which will be presented at the meeting:

- Annual Address by the President, Dr. B. C. Brett, Green Bay.
 Address in Surgery, Dr. H. Reineking.
 Knee Joint Disease, Dr. Wm. Mackie, Dr. H. M. Brown.
 Injuries of the Cranium and Contents: Diagnosis, Dr. B. G. Gudden; Treatment, Dr. W. H. Earles; Medico-Legal Aspects, Dr. J. A. Jackson.
 Hernia—Anatomical Considerations, Dr. F. W. Epley.
 Treatment of Reducible Hernia, Dr. B. T. Phillips.
 Treatment of Strangulated Hernia and Radical Cure of Same, Dr. A. H. Levings.
 Splints, Dr. G. D. Ladd.
 Varicose Veins and Their Treatment, Dr. J. R. Minahan.
 Local Treatment of Acute Follicular Tonsillitis, Dr. A. B. Farnham.
 Internal Treatment of Acute Follicular Tonsillitis, Dr. W. H. Neilson.
 Removal of the Tonsils, Dr. Joseph Szoldrski.
 Etiology, Pathology and Symptomatology of Tonsillar Hypertrophy, Dr. F. C. Rogers.
 Tumors of the Tonsils, Dr. O. M. Waterman.
 Discussion by Dr. J. S. Walbridge, Dr. F. C. Rogers, Dr. A. B. Farnham, Dr. H. V. Würdemann, Dr. B. Bantly.
 The Pathology of Granular Conjunctivitis, Dr. H. V. Würdemann.
 The Medical Treatment of Granular Conjunctivitis, Dr. C. Zimmermann.
 The Surgical Treatment of Granular Conjunctivitis, Dr. J. A. Bach.
 The Complications of Granular Conjunctivitis and their Treatment, Dr. E. H. Neymann.
 Acromegalia, Dr. E. L. Bullard.
 Pyrexia, Dr. W. H. Washburn.
 Antipyretics and Their Modus Operandi, Dr. T. H. Hay.
 The Present Status of the Treatment of Acute Febrile Diseases by means of Antipyretic Drugs, Dr. H. B. Sears.
 Hyperpyrexia and its Management, Dr. G. M. Steele.
 The Ephemeral Pyrexia of Childhood, Dr. H. B. Tanner.
 The Pathology of Uremia, Dr. B. J. Bill.
 The Clinical Aspects of Uremia, Dr. E. H. Townsend.
 The Therapeutics of Uremia, Dr. C. H. Lemon.
 The Principles and Ruts of the Practice of Medicine, Dr. J. R. Currens.
 Waiting, Dr. S. W. French.
 The Country Doctor in Obstetrics, Dr. W. T. Sarles.
 Myomectomies, Dr. A. J. Puls.
 Observations on Seventy Recently Performed Laparotomies, Dr. F. B. Robinson.
 Complications in Abdominal Surgery, Dr. A. J. Burgess.
 Perineal Repair, Dr. P. O'Keefe.
 Strophanthus, Dr. D. Mereness.
 The Use of Heart and Respiratory Stimulants in Anesthesia, Dr. M. H. Fisk.
 The Use of Heart Tonics and Stimulants in Acute Febrile Diseases, Dr. C. M. Gould.
 The Treatment of Malignant Diphtheria, Dr. S. P. Deahofe.
 Belladonna, Dr. S. B. Sperry.
 House Disinfection, Dr. O. T. Hougén.
 The Duty of the State Toward the Inebriate, Dr. R. M. Wigginton.
 Hygiene of Villages, Dr. L. H. Pelton.
 Heredity and the Wards of the State, Dr. E. H. Townsend.
 Five Minutes With the Typhoid Bacillus, Dr. F. J. Tower.

- Provision for the Insane Awaiting Commitment, Dr. M. J. White.
 Functional Nervous Diseases, Dr. Irving D. Wiltrout.
 Treatment of Epilepsy, Dr. W. F. Wegge.
 Report of Two Cases of Unusual Parasitic Intestinal Disease, Dr. E. F. Woods.
 Stomach Catarrh and Stomach Lavage, Dr. A. F. Heising.
 Broncho-Pneumonia in Children, Dr. J. Noer.
 Catarrhal Pneumonia, Dr. Julia P. Kelley.
 Cerebral Signs and Simulations in Pneumonia, Dr. J. R. Barnett.
 Gouty Deposits of the Testicle, Dr. F. J. Tower.
 Infantile Cynosis From Bismuth Poisoning, Dr. A. S. Maxson.
 Treatment of Opium Poisoning, Dr. W. H. Hulburt.

It may not be practicable to follow the program in the order of time as given above, and precedence in the reading of papers will be given to members of Standing Committees.

Communications relating to any changes in the provisional program should be addressed to Chairman of Program Committee, Dr. W. H. Washburn, prior to April 23.

W. H. WASHBURN, Chairman Program Committee.
 U. O. B. WINGATE, Anniversary Chairman.
 ERNEST COPELAND,
 J. R. McDILL,
 H. P. WENZEL,

Committee of Arrangements.

B. C. BRETT, President,
 CHARLES S. SHELDON, General Secretary.

BOOK NOTICES.

A Manual of Therapeutics. By A. A. STEVENS, A.M., M.D. 16 mo. cl. pp. 435. Philadelphia: W. B. Saunders. 1894. Price \$2.25.

This Manual has been prepared for students, and is a concise abridgement of the greater treatises, but the author uses the old English system of weights and measures throughout instead of the modern decimal system, even in the dose table at the end of the book; an unfortunate thing for a book that aspires to be in harmony with recent textbooks. Many of the unofficial drugs are briefly commented on, and with the exception noted the book is an excellent one of its kind.

Syllabus of the Obstetrical Lectures in the Medical Department of the University of Pennsylvania. By RICHARD C. NORRIS, A.M., M.D., Demonstrator of Obstetrics, University of Pennsylvania, etc. Third edition. Philadelphia: W. B. Saunders. 1894. Price \$2.00.

The popularity of this Syllabus is well attested by the fact of its having passed to the third edition. It is one of the most complete of its class. In this edition the changes that have taken place in the University course have been incorporated. The copious index adds to the value of the volume.

Transactions of the third annual meeting of the Association of Military Surgeons of the National Guard of the United States, held at Rush Medical College on August 8, and at the United States Government Building, Jackson Block, August 9 and 10, 1893, Chicago, Illinois. St. Louis: Buxton & Skinner Stationery Company. 1894.

The volume opens with a transcript of the minutes of the meeting, an account of the clinics and entertainments. The papers and addresses read at the meeting then follow. The magnificent historical paper of President Senn on "Enterorrhaphy" (published at the time in this JOURNAL), will always give a permanent value to this volume of the Transactions, if there were no other reason. The name of the organization has been changed to the less cumbersome one of "The Association of Military Surgeons of the United States."

Clinical Diagnosis. By ALBERT ABRAMS, M.D. 16 mo. cl. pp. 273. Twenty-eight illustrations. New York: E. B. Treat & Company. 1894. Price \$2.75.

This book is a manual of medical diagnosis from a clinical

standpoint and is generally well written, but there is an occasional lapse. On page 110, the following title arrests attention: "The Chemical Analysis of the Stomach as a Means of Diagnosing Gastric Disturbances." On reading the text it is seen that it is the *contents* of the stomach, that are to be analyzed, and not that organ itself as the title states. The table on bacteriologic diagnosis is excellent, but the directions for demonstrating the presence of bacteria in specimens, is not given at that place but scattered through the volume. The typography is singularly unattractive, but there is much useful information in the work—a jewel which deserves a better setting.

Transactions of the American Orthopedic Association. Seventh Session held at St. Louis, Mo., Sept. 19, 20 and 21, 1893. Vol. VI. Published by the Association. Philadelphia. 1894.

This volume contains the list of officers, list of presidents, honorary members, corresponding members, minutes of the seventh annual meeting; the constitution and by-laws, the President's address and the papers read at the annual meeting.

Most of these papers have been printed in the medical journals and some of them in this JOURNAL. They do not therefore require separate mention. The volume is well printed, amply illustrated and carefully edited. There is, however, no index. A. M. Phelps, M.D., of New York, is President, and John Ridlon, M.D., of Chicago, is Secretary.

An Illustrated Encyclopædic Medical Dictionary: Being a Dictionary of the Technical Terms used by Writers on Medicine and the Collateral Sciences, in the Latin, English, French and German languages. By FRANK P. FOSTER, M.D. Vol. IV. Illustrated. Pp. 775. New York: D. Appleton & Company. 1894.

This magnificent Dictionary is now completed with the volume under consideration. We have before mentioned the receipt of former volumes, and commented upon the work. No work approaches it in completeness, and none shows more painstaking labor. The vast research required to collect and define with accuracy the medical terms used in four languages, is something that makes most men shrink from such a task, and it is not likely that the present generation will see another work of this character. The sale is necessarily limited on account of the expensive nature of the book and its extent, and every member of the profession who can afford it should lend encouragement to the publishers by adding it to his collection. No money can be expended to better advantage in enlarging a medical library, than that invested in Foster's Dictionary.

The classical training of the author leads him to great conservatism in the spelling of medical terms, and we fear that those who agreed to the spelling reform at the last annual meeting of the American Medical Editors, will meet with no encouragement in this Dictionary. That reform will come quite surely, but we must remember that the lexicographer's function is not to reform, abbreviate or alter, but to record the existing condition. It is a pleasure to once more refer to the author's remarks on pronunciation: "The Roman method, strange as it may seem to those who are unaccustomed to it, and who now see it for the first time in a medical dictionary, is the one now taught in the leading universities of this country and it will doubtless be adopted everywhere within a very few years." "The value of a dictionary," says the distinguished author, "seems to me to depend upon its accuracy, the convenience of its arrangement, and its comprehensiveness; and in the preparation of this work those qualities have been esteemed in the order in which they are here enumerated." A supplement at the end of the fourth volume contains the words omitted from the preceding volumes.

We congratulate Dr. Foster and his collaborators upon the happy completion of this book, the result of his thirteen years' unremitting labor, and congratulate the medical profession upon the acquisition of this newest and greatest monument to American scholarship.

NECROLOGY.

PETER BOWMAN, M.D., of New York city, April 5.—T. H. Rucker, M.D., formerly of New Albany, died at his home in Evansville, Ind., March 31, aged 79.—B. St. George Tucker, M.D., of Colorado Springs, March 30, aged 55. He was a son of Hon. Beverly Tucker, of Virginia, and a descendant of John Randolph, of Roanoke. He was a surgeon in the Confederate Army.—E. A. Clark, M.D., of San José, Cal., March 30, aged 65. He was a native of Tiffin, Ohio, resided in California since 1850, and had taken an active interest in political as well as medical affairs.—Charles A. Cooper, M.D., of Oil City, Pa., March 26, aged 70.—David Watson, M.D., of Bellefontaine, Iowa, March 31, aged 75.—George A. Watts, M.D., at Tripoli, Iowa, April 9, aged 94.

ON THE DEATH OF DR. RAUCH.—At a meeting of the Philadelphia County Medical Society held March 28, the following resolutions were adopted:

Resolved, That the Philadelphia County Medical Society has heard with great sorrow of the sudden death at Lebanon in this State, of Dr. John H. Rauch, of Chicago, lately Secretary of the Illinois State Board of Health; a man whose interest in the cause of medical education, and whose efforts in increasing the efficiency of the medical profession and maintaining its dignity and honor, have rendered incalculable service to the public.

Resolved, That this resolution be published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and in the medical journals of Philadelphia.

T. B. SCHNEIDEMAN, Secretary.

PUBLIC HEALTH.

Leprosy in Texas.—A case of leprosy is reported to have been discovered in Dallas, Texas. The patient is a West Indian negro, who claims to have escaped from that country two years ago.

International Sanitary Conference.—Articles of convention were signed by the delegates to the International Sanitary Conference in Paris on the 4th inst., the United States and Great Britain making reservations as to details. A copy of the articles has not yet, April 12, reached this country, but it is claimed that if the decisions of the Conference are carried out they will prove an effectual check to the importation and spread of Asiatic cholera into Europe and thence to the United States.

Typhoid Fever.—The outbreak from typhoid-infected milk at Montclair, N. J., has been clearly traced to a dairy in Verona, where the milk cans were washed in water from a well in close proximity to the vault used by the dairyman's family in which there had been two cases of typhoid fever. Milk from this dairy was also supplied to families in Bloomfield, where eleven cases have occurred besides the sixty cases at Montclair and others at Glen Ridge and Verona—in all a total of some eighty cases up to date. The Verona dairy is quarantined and an inspection is being made of dairies on neighboring farms.

Louisiana State Board of Health.—Governor Foster, of Louisiana, has reappointed Dr. S. R. Oliphant and Mr. S. Odenheimer to succeed themselves as members of the State Board of Health. Dr. Oliphant will probably be reelected President at the annual meeting, which takes place on the 12th inst. Dr. Lucien F. Salomon, who has for many years

acceptably filled the office of Secretary of the Board, will not accept a reelection, his practice requiring more attention than is compatible with the duties of the office. Dr. Salomon's retirement is a distinct loss to sanitary interests in the South.

Asiatic Cholera.—Cholera of a virulent type was reported, April 5, to be "raging" in Czenstochov, a place of about 5,000 inhabitants on the Prussian frontier of Poland. The town has been quarantined.

The disease is reported, April 9, to be rapidly spreading in Constantinople, having extended from the poorer and more congested districts, to which it was at first confined, to portions of the city where the better classes live. Councillor Calliadi Bey and a servant of one of the members of the Greek legation died on the 8th inst., after an illness of only a few hours in each case. The Greek legation has been since removed and other foreign representatives are seeking temporary refuge outside the city. It was the Greek government which first announced, March 23, the existence of cholera in Constantinople.

The Smallpox Situation.—Smallpox continued to increase up to the close of March, but with the approach of warm weather it is probable that it has reached its height for the present season. New points of infection, developed since the close of Dr. Rauch's summary, and new cases in the then infected localities, have been reported as follows:

MASSACHUSETTS—In South Boston, where the disease was believed to have been "stamped out" in February, there were found four cases, March 20, and a fifth on the following day. In Springfield, March 20, "patients in the pesthouse appear to be doing well"; this is the first intimation received of smallpox at Springfield.

NEW YORK—In New York city from four to ten new cases a day are reported; on the 18th a case was removed from a house where four other cases had occurred since March 13; on the 20th a case was found among 100 boys confined in the House of Refuge; on the 22d a family, quarantined for refusing to submit to vaccination, escaped by cutting a hole through the party wall of their flat; on the 25th a policeman was found ill with the disease—judging by newspaper comments on this case it would appear that the New York police force is not vaccinated; on the 26th a cook in a fashionable bachelor's apartment house, who had been treated for a week in the house for malarial fever, was sent to a hospital by an ambulance surgeon who diagnosed his disease as typhoid fever; at the hospital he was found to be in the eruptive stage of smallpox; on the 29th, eleven cases were found in a large crowded, double tenement house in Harlem; one was dying and two others died during removal; April 4, Dr. Balch, Secretary of the State Board of Health, reports ninety-one cases with twenty deaths in New York city, during the week ended March 31; April 8, the steamer, *Obdam*, from Rotterdam, was taken in charge at quarantine with one case of smallpox on board.

In Brooklyn smallpox was declared epidemic by Health Commissioner Emery, March 26; there were eighty cases reported in January and sixty-five in February; the spread of the disease is attributed to neglect of vaccination and the concealment of cases by parents and physicians; vigorous efforts are being made to suppress the outbreak and the State is cooperating; tents furnished by Gov. Flower are used for the overflow from the crowded pesthouse; April 4, Dr. Balch, Secretary of the State Board of Health, reports 167 cases with 20 deaths in Brooklyn during March. At Utica, a new case occurred on the 26th. Cases were reported on the 19th at Manchester, Walworth and Palmyra, villages in the suburbs of Rochester. Cases were reported at Geneva and Ithaca on the 20th. A case was reported on the 23d at Mt. Vernon.

NEW JERSEY.—Another case was found in Hoboken on the 29th, after it was believed that the disease had been suppressed.

PENNSYLVANIA.—On the 23d the local board of health at Danville issued a proclamation declaring smallpox to be epidemic at that place and ordering schools and places of amusement to be closed. The usual local excitement followed, with villification of the board and its action, but the board was sustained by Dr. Atkinson, President of the State Board of Health, who visited Danville on the 28th and expressed great surprise that the Danville physicians let the epidemic get such headway while they were quibbling about names—whether a disease which was spreading day by day and causing numerous deaths should be called smallpox or chickenpox." Early in March the corpse of a child was taken from Danville, where the physicians were disputing over smallpox and chickenpox, to Lewisburg by the father for burial; on the 20th the father was taken down with smallpox. On the 28th, "for the first time in a number of years," a case of smallpox was found in Harrisburg; the patient had just returned from Bridgeport, Conn., and was sick on his arrival. Another case was reported in Pittsburg on the 27th, after it was believed the disease had been "stamped out;" the patient had never been vaccinated; seventeen cases in hospital April 4.

ILLINOIS.—In Chicago the disease continued to spread without abatement during the month; the total number of cases reported during March was 305; cases having developed in the Cook County Hospital, wards 17 and 26 were put in quarantine; April 9, a prisoner at the Harrison Street police station died of hemorrhagic smallpox in his cell; 108 new cases were removed to the pesthouse during the first ten days of April; smallpox corpses were discovered by the inspectors; April 6 one, April 9 two, April 10 one.—March 26 a case was reported at Alton, Madison County, a tramp.—On the 27th, one case and one "suspect" at Hoopston, Vermillion County.—On the 29th, one case at Greenbush, Warren County, supposed to have been contracted from tramps from Joliet; April 4 three new cases developed in this family.—April 2, two cases reported at Maywood, Cook County, contracted in Chicago.—April 5, two cases in the Grundy County poorhouse, origin, a tramp, supposed to have chickenpox, discharged April 2, before the true nature of his disease was detected.—April 5, one case in Freeport, Winnebago County.

SMALLPOX was discovered March 24 among seventy-seven Chinese detained in the bonded warehouse at Vancouver, B. C., destined for Portland, Seattle, San Francisco, New York and other points in the United States.

Solid Sanitary Gains from the World's Fair.—The following paragraphs are taken from an article in the *Independent*, reviewing in a sanitary way the results of the Fair at Chicago. The article opens with a statement as to the prevalence of typhoid fever in that city before the Fair began. The writer shows that in 1891 there was an average daily mortality of 5.4, chiefly young lives. This vital drain was serious, and a betterment was observed in 1892 as a result of some sanitary attempts as to water supply and sewerage, especially the former. "At the outset the daily press of the city in blind devotion to the supposed 'interests' of the city, studiously ignored the frightful facts; but the Health-Board and the medical periodicals refused to be hoodwinked, and would not keep silence. They stated that in 1891 the percentage of typhoid deaths was 16.6 in 10,000, making a total of 1,997 (only three short of 2,000), and each death is justly presumed to represent ten cases which recover. It is no wonder that cautious people hesitated before planning to visit the Fair. Nobody doubted that the cause of the trouble was a polluted water supply. The London *Lancet* sent forth competent envoys to make a thorough, impartial, scientific investigation, and no doubt their report influenced many Englishmen to remain away. Matters had considerably mended in 1892, but then the mortality rate was equal to that of Philadelphia in the Centen-

nial year—it had fallen to 6.74, while in Philadelphia it was 2.22; Boston, 1.22; New York only .90; Brooklyn, .80; London .49, and in Berlin .42; these last two cities use only filtered water. It will perhaps present a more vivid picture, if we say that in the month of January, 1892, there were 311 deaths from typhoid in Chicago, and in the much more compact city of Brooklyn but 8. In May of the year 1891 half as many people died, as in the whole State of Massachusetts during the entire twelve months of the year; two-thirds as many as died in London with its 4,000,000 of people, in the entire previous year.

In Dr. John H. Rauch, Chicago has had for years a fearless and aggressive sanitarian, whose *fiat-justitia-ruat-celum* ideas have impressed themselves on an able and energetic set of younger men, who dared to know the worst, to show the worst, and to push forward remedial measures, and then to show to all the world as far as possible, what intelligently directed effort had accomplished.

Profs. William T. Sedgewick and Allen Hazen, of the Massachusetts Institute of Technology, had prepared a paper for the American Statistical Association called "Statistics of Typhoid Fever in Chicago," accompanied by a diagram showing at a glance the bad eminence of Chicago when compared with Philadelphia, Boston, New York and London. Every once in a little distance the line that represented that city shot up into one of those sharp peaks that tell the practiced eye that things are going badly, and the peak for 1890-'91 went many squares above the worst that had ever been known before, even in Chicago. The paper and diagram made an incisive impression far and wide, and the Secretary of the Illinois State Board of Health called a conference, at which the city, the Sanitary Department and the canal authorities—these being the parties in interest—were represented; and Dr. Reilly pointed out the coincidence between heavy rainfalls that flush out the sewage from the canal into the lake and a rapid rise in the death rate, and he also indicated the only remedy then possible—a greater pumping power; but "nothing of practical value" resulted from this conference, and it is only charitable to suppose that the explanation of what seems a criminal apathy was in the fact that the four-mile tunnel was then in process of construction and would soon be finished, and other tunnels were in process of extension.

Toward the end of 1892 it became possible to shut off the most polluted of the water intakes and begin using the extended tunnels, so that December of 1892 shows 47 deaths from typhoid against 311 in January. On May 1, 1893, the four-mile tunnel was completed; and when the American Public Health Association held its meeting in October it was found that, reckoning from Sept. 30, 1892, to Sept. 30, 1893, the mortality had gone down to a percentage of 2.64 as against 6.72 for the year before, and part of this time the old dangerous intakes were in use. The figures told their own story, and the State Board of Health of Illinois evolved a most instructive "exhibit" from this and other experiences; so that maps, charts, diagrams and statistics demonstrated conclusively that it must have been the bad water that caused the great destruction of life originally; for it was confined to no locality, and was but little aggravated in the overcrowded sections, and the amendment was equally universal.

The ventilation of the subject previous to the Fair put everybody on his guard; the Fair managers became alarmed and welcomed the "piping" of a pure supply on to the grounds from twenty-five miles away, and the principal hotels distilled their drinking and cooking water; but, in spite of all, we hear that a considerable number of people had the fever after returning from Chicago.

Somber as the picture is, it has its bright, redeeming side; everybody's attention was arrested, the eminently practical Chicagoans began to study, not only pure water supply but every phase of sanitation. They saw how innocuously all the wastes of the Fair were disposed of. Especially the women came and saw, and forthwith began to conquer. They organized sanitary associations in every part of the city, whose duty was to cleanse some special district; they mounted one of the smokeless crematories on wheels, and showed how the garbage could be destroyed without offense, by just destroying it; and now we learn that the municipal authorities have five of them at work. The whole community has been educated by the sanitary necessities of the situation. The women have been awakened, and there need be no fear that they will relax their demands for pure air and pure water, and these will be echoed all over the land by intelligent women. Score one for the solid benefits conferred by the Fair.

MISCELLANY.

Hospital Notes.

Bids have been opened for the erection of a new pathological building on the City Hospital grounds of Boston, Mass.

AT THE monthly meeting of the Board of Directors of the Pennsylvania Hospital, the resignation of Dr. W. H. Harrison, assistant physician of the department for insane men, was received and accepted. Dr. Horace Phillips, an ex-resident physician, was elected to succeed him.

THE dedication of the new hospital in Newcastle, Ohio, took place April 3.

THE annual meeting of the medical staff of Saginaw Hospital was held April 4. The election resulted in choice of Dr. W. C. Conroy, President, and Dr. W. S. Connery, Secretary.

Medical College Notes.

THE AMPHITHEATER of the new medical building of the Tulane University in New Orleans was destroyed by fire March 31. The loss will not exceed \$12,000.

THE SOUTHERN MEDICAL COLLEGE of Atlanta, Ga., held its annual commencement April 2, and awarded diplomas to forty-two graduates.

THE MIAMI MEDICAL COLLEGE (Cincinnati) held its annual commencement April 4, and awarded diplomas to twenty-two graduates.

THE MCGILL UNIVERSITY of Montreal, Quebec, held its commencement exercises April 5. Fifty-five graduates received the degree of M.D.

THE FIFTEENTH annual commencement of the St. Louis College of Medicine was held March 27. Twenty graduates were awarded diplomas.

THE FOURTH annual commencement of the Kansas Medical College (Topeka) was held March 28. There were seven graduates.

THE MEDICAL COLLEGE OF INDIANA, at Indianapolis, held its twenty-fourth annual commencement March 26, and awarded diplomas to fifty-two graduates.

THE WOMAN'S MEDICAL COLLEGE of Cincinnati held its commencement exercises April 2. Fifteen received the degree of M.D.

AT THE thirteenth annual commencement of the Omaha Medical College seventeen graduates received their diplomas.

THE ANNUAL COMMENCEMENT of the medical department of the University of Oregon (Portland,) was held April 2. There were fourteen graduates.

NOT IN "GOOD STANDING."—As a result of its investigations of the St. Joseph medical colleges the Missouri State Board of Health has declared the Northwestern Medical College to be not "in good standing," and has refused to recognize the diplomas recently issued to the graduating class of fourteen. If these young gentlemen desire to practice in Missouri they must pass a satisfactory examination before the Board. Among the reasons given for "slating" the College is the want of proper laboratory facilities for instruction in chemistry and bacteriology.

EVIDENCE OF PRELIMINARY EDUCATION.—At the January meeting of the Illinois State Board of Health, the rule concerning the evidences of preliminary education, required of applicants for matriculation in colleges of "good standing," was amended so as to read:

2. Diplomas of graduation from a good literary and scientific college or high school, or at least a second-grade teacher's certificate.

The amendment consists in striking out the alternative of an examination by the faculty of the college, and the argument advanced was that such examinations were "too often a farce, very few colleges ever finding an applicant too ignorant to be matriculated."

But now comes Dr. S. J. Talbot, Dean of the Boston University School of Medicine, who points out that there are no second-grade teachers' certificates in New England, and that this action of the Illinois Board seems to "place all Eastern schools, including Harvard as well as our own, in an embarrassing position, inasmuch as, however well educated a man may be after having spent one, two or even three years in a literary and scientific college, if he has not fully completed his course and received a diploma he could not gain admission to any medical college that the Illinois Board would recognize."

This contention gains added force from a recent utterance of Dr. Bowditch, of Harvard, who finds an increasing number of medical students who have left literary and scientific colleges before completing the course, in order to devote more time to the increasing demands of the medical curriculum.

It would seem that the Illinois Board will find it necessary to revise its recent action, and the subject is important enough to receive the attention of the Conference of Examining and Licensing Boards at its forthcoming meeting.

THE MICHIGAN COLLEGE OF MEDICINE AND SURGERY, (Detroit,) held its annual commencement March 29. Addresses were given by Rev. Samuel Plantz and Prof. Edward W. Jenks, M.D., L.L.D., of the faculty. Dr. Hal C. Wyman administered the Hippocratic oath and presented the diplomas to twenty-seven graduates. The exercises were followed in the evening by a banquet.

American College of Dental Surgery.—A class of forty-three, including two women, was graduated with the degree of D.D.S., by the American College of Dental Surgery of Chicago, April 2.

Pneumatic Tires for ambulances are being strongly urged by the local health authorities of many cities, on the ground that they will materially reduce the jar, jolting and other injurious effects of these rapidly driven vehicles.

Disposal of Garbage.—New Orleans is trying the experiment of disposing of its garbage by the Simonin process, which consists in the extraction of all fatty matter by treatment with naphtha or gasoline, after which the residue is dried and ground; the products have a commercial value as lubricating oils and fertilizers, and the process is claimed to be free from nuisance in the matter of offensive odors.

The Missouri State Board of Health unanimously passed a resolution which will have the effect of excluding female physicians as assistants at the city institutions. It provides that the assistants at the Female Hospital for the ensuing year be selected from the corps of assistants at the City Hospital, and that it is not expedient to employ female physicians at the City Hospital.

Quacks in Kansas.—County attorneys and local health officers throughout the State of Kansas have been instructed by the State Board of Health to begin an active crusade against the quacks and itinerants, the "disreputable conscienceless medical swindlers," to quote Secretary Dyker's vigorous language, "who have made Kansas their favorite haunt." Prosecutions are to be at once begun against all violators of the medical practice laws, and it is hoped thus to purge the State of its quacks and to relieve the community and the qualified practitioner of their presence.

The "Medicine Man" of Male-Kula, New Hebrides.—A large island, of the name given above, is now being rescued from savagery by missionaries going to that island from Australia. The position of woman is that of a slave and burden-bearer. An evident symbol of male tyranny is the fact that before any female on Male-kula becomes a wife her two upper front teeth are knocked out by the "medicine man," aided by half a dozen old women, who hold the girl's arms and legs while the cruel operation is being performed. This has been done to hundreds of these poor women, giving them a most hideous looking appearance when grinning at a stranger. The tide has now begun to turn, and the meetings for church and school have females in orderly attendance, as well as men and boys, a condition that was formerly quite out of the question.

THE PUBLIC SERVICE.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from March 31, 1894, to April 6, 1894.

Capt. EDWARD C. CARTER, Asst. Surgeon, will proceed at once to Ft. Spokane, Washington, and report to the commanding officer for temporary duty.

Major CHARLES L. HEIZMANN, Surgeon U. S. A., is granted leave of absence for twenty-one days, to take effect on or about April 14, 1894.

First Lieut. EDWARD L. MUNSON, Asst. Surgeon, will proceed without delay to Camp Merritt, Mont., and report to the commanding officer, for temporary duty at that post.

First Lieut. CHARLES F. KIEFFER, Asst. Surgeon, having reported at Hdqrs. Dept. of Dakota, is assigned to temporary duty at St. Paul, Minn., and will report to the Medical Director of the Dept. for instructions.

First Lieut. HENRY D. SNYDER, Asst. Surgeon, is relieved from duty at Ft. Reno, Oklahoma Terr., and ordered to Ft. DuChesne, Utah, for duty at that post, relieving Capt. SAMUEL Q. ROBINSON, Asst. Surgeon. Capt. ROBINSON, on being relieved by Lieut. SNYDER, will report in person to the commanding officer, Davida Island, New York, for duty at that post.

Major PETER J. A. CLEARY, Surgeon, will be relieved from duty at Ft. McPherson, Ga., by the commanding officer of that post, on the receipt by him of this order, and will report in person to the commanding officer, Ft. Custer, Mont., for duty at that post.

The following named officers are detailed to represent the Medical Department of the Army as delegates to the Association of Military Surgeons of the United States, to meet in Washington May 1, 1894: Lieut. Col. WILLIAM H. FORWOOD, Deputy Surgeon-General; Major ROBERT M. O'REILLY, Surgeon; Major JOSEPH K. CORSON, Surgeon; Major WALTER REED, Surgeon; Capt. JOHN L. PHILLIPS, Asst. Surgeon; Capt. G. L. EDIE, Asst. Surgeon.

PNEUMONIC FEVER—ITS SYMPTOMATOLOGY.

BY EDWARD F. WELLS, M.D.

CHICAGO.

DIGESTIVE SYSTEM.

During the chill or rigor there may be chattering of the teeth, and this usually augurs a severe attack. In one of my cases incessant and prolonged chattering occurred without the presence of a chill or general rigor, but this is rare.

A man, aged 65, was awakened at midnight with uncontrollable chattering of the teeth. I saw him within an hour and found him in a great state of nervous excitement and alarm. His subjective symptoms were a feeling of uneasiness and an indefinite dread of impending evil. The skin was pale, pinched and cool; pulse 96, respirations 20, and temperature 99 degrees. He was restless, tossed about in bed, passed his urine frequently, and his teeth chattered incessantly and uncontrollably. This latter continued for more than two hours, subsiding gradually. Although the skin was cool, yet there was neither chilliness nor rigors. The ordinary symptoms of severe pneumonic fever were developed and the patient died on the eighth day.

Grinding of the teeth is not infrequent in children, and is sometimes met with in adults. It usually indicates a cerebral complication and is of evil import. When present in children, together with brightness of the eyes, contraction or dilatation of the pupils, startings in sleep, etc., convulsions may be feared.

Extraordinary sensitiveness of the teeth was present in one of my cases.

A lady, aged 37, of nervous temperament, suffered an attack of pneumonic fever, locally affecting the base of the left lung. During the first twenty-four hours she had excessive vomiting, followed by intense headache and low delirium. Convalescence began on the eighth day. During convalescence and for some time afterward the teeth were so sensitive that she could scarcely bear them in contact and was compelled to subsist solely upon liquid foods.

Patients suffering with pneumonic fever, in common with other severe acute diseases, are seldom troubled with toothache, and its appearance may be viewed as an indication that convalescence is approaching.

The teeth—especially the upper ones—are usually covered with a soft, grayish deposit, although in the very mildest cases they may remain clean. In the cases of greatest severity—those accompanied by low, adynamic or typhoid symptoms—the teeth always, and often the gums¹ and lips also, are covered with dark-colored sordes. The extent, amount and color of this deposit is a pretty accurate gauge of the gravity of the case. Its disappearance is an unerring harbinger of improvement.

Bowling² has called attention to the occurrence, in some cases, of a peculiar deposition on the teeth, just along the margins of the gums, of matters of various shades of color, ranging from a light orange to a dull vermilion, the tint being always deepest near the gums and shading off as the

distance is increased. The line of deposit is about one-sixteenth of an inch in width and can usually be removed, although a permanent stain sometimes results. Bowling considers it an exudation from the gums and not a deposit from the expectoration or the ordinary secretions of the mouth, and that it differs from ordinary sordes. He noted this peculiar line in about one-third of his cases.

Although I have diligently searched for this line in a large number of cases, yet I have been able to recognize nothing answering the above description, except in a few cases, and in these I could not eliminate from my mind the belief that it was merely ordinary sordes, colored by blood from the expectoration, or from bleeding gums.

This line must not be confounded with the discoloration of the gingival margins due to the presence in the system of the compounds of lead,³ mercury, iodine, etc., nor with the line in the same locality found in some cases of phthisis.⁴

The tongue is usually protruded in a natural manner, unless there is great prostration, cerebral excitement or coma; under which circumstances it will be extended with difficulty, excitedly, tremblingly,⁵ hesitatingly, slowly or not at all. In some low and dangerous cases it may be retracted or laterally contracted, giving it a short and blunted, or a narrow and pointed appearance.

During the progress of the disease and in different patients the tongue may present almost every imaginable appearance, ranging from the normal to one covered with a foul mucus coating or a most luxuriant fur; or denuded of epithelium, deeply fissured and as dry as a board. It may remain clean and moist—not to be distinguished from its healthy condition—not only in a few mild cases, but also in rare cases of the utmost severity, and I have even seen patients perish with such tongues.

When I first witnessed such cases I was greatly surprised, but I soon discovered that others had noticed the same fact, Louis,⁶ long ago, found the tongue normal in sixteen of thirty-five fatal, and in nineteen of fifty-six non-fatal cases. I am not aware, however, that any other observer has noticed this condition in so large a proportion of cases,—I certainly have not.

In general a natural appearance of this organ, or, having departed more or less from this state, a return to such a condition, is a favorable indication.

During the early days of the attack, and in some of the milder cases throughout its entire course, the tongue is lightly coated⁶ with a cream or yellowish colored mucus secretion, borne upon a more or less luxuriant fur. In the milder cases this continues to the beginning of convalescence, when the coating gradually disappears, leaving the tongue clean and of a normal appearance. In the severe cases this coating takes on a dark color and becomes dry, hard and fissured.⁷ This is especially the case in those persons who breathe through the mouth. If this condition is developed it always denotes danger,⁸ and if there is no accompanying thirst it is often a fatal indication. In those successful cases in which the coating becomes dry and hard the tongue sheds its epithelium and presents a scalded appearance. In this state it is very sensitive and quickly becomes

dry and glazed when exposed to the air, but is easily moistened by keeping the mouth closed or by taking a drink of water. Although a dry state of the tongue always indicates a grave case,⁹ yet we should not base our prognosis exclusively upon this fact. I have seen pneumonic patients recover whose tongues were so dry, hard and fissured as to almost prevent articulation.

Returning humidity and softness, when the tongue has been dry and hard, or disappearance of the fur and coating when these have been present, are reassuring signs. A return to a natural appearance is first seen along the margins of the tongue, gradually extending towards the center. Sometimes this change occurs in irregularly distributed patches, giving the organ a very peculiar appearance. As a rule, to which there are exceptions, as before indicated, a favorable opinion as to the issue of the attack may be entertained so long as the tongue and mouth remain moist.
