Case 2.—Benj. Jordan, two and a half years old. Living in Philadelphia. Double, uncomplicated, congenital talipes equino-varus. April 5, 1894, operation of division of tendo Achillis and tendon of anterior tibial by open incision. Rectangular, posterior splints; dressed a week after operation. Feet in good position. Also division of flexors of all toes.

Case 3.—Orm Gantt, 5 years old; living at Island Heights, N. J. Admitted into the Orthopedic Hospital, Jan. 17, 1894, with the statement that he had been deformed since birth; having double talipes equino-varus; in walking his feet were turned in, so that he walked upon the dorsum of each foot. When eight months old he had been operated upon at the University Hospital. He then wore braces until 3 years of age. He did not remain in the Hospital after operation and the after treatment was probably neglected. After admission his feet were poulticed for three nights, in order to soften the callus on the dorsum of each foot. The operation was performed on January 25; Dr. Morton severed the flexor tendons of all the toes, the anterior tibial and the tendo Achillis of each foot. He also made an incision three inches in length on the outer aspect and dorsum of the feet through the callus, and simultaneously removed the astragalus and part of the cuboid bone of each foot. The rectangular, posterior tin splints were used as in the other cases. There was no rise in temperature after operation. Dressed for the first time on February 8. Wound well healed. He continued to wear the rectangular tin splint until March 3, when braces were applied which he is still wearing. Feet are now straight and in good position. Wounds entirely healed.

DR. G. G. DAVIS.—There are two things in regard to this case which occur to me: First, as a rule, I do not believe in open incision. The only advantage gained is when one cuts down upon bundles of contracted tissue; but in division of a healthy tendon, in an equally healthy patient, I do not think it necessary. In a case of torticollis where we have dangerous structures in the neighborhood, and where there are contracted tissues and a tendon that does not slide in a synovial sheath, then I would use an open incision.

Some time ago I showed at the County Medical Society several cases of wedge-shaped resection. As for myself, I have never seen a case at the age of 5 years on which I would operate upon the bones. In one case, which I showed at the College of Physicians, aged 6 or 7 years, the child walked

upon the dorsum of the feet, the toes pointed towards each other and the sole vertical, yet it was cured without operating upon the bones. The bones, in cases of this age, are soft. I showed an astragalus, removed by another surgeon, which was so soft that I could push a pin through it, with my finger, in all directions.

DR. G. G. DAVIS—I do not believe that excision of the astragalus alone, in cases which demand operation on the bones will straighten the foot; therefore where bone is required to be removed I believe the deformity can only be rectified by severe measures. In removing the astragalus, a portion only of the obstruction is removed and the external arch is left intact, and the deformity which remains is so great that it demands further procedures on the outer side of the foot, such as a removal of a portion of the cuboid or anterior portion of the calcaneum. A foot that can be straightened by removal of the astragalus alone is usually one which can be cured without operation on the bones.

DR. WOODBRIDGE—I thank the Section for the courtesy of allowing me to present these cases and as I have another engagement I will not enter into the discussion. I have only one word to say: I understand that Dr. Morton never removes an astragalus when it is in place; it is only when it is deformed.

DR. DEFORREST WILLARD—In tenotomy of the posterior tibial tendon, especially in fat infants, open incision is desirable. No surgeon, however, works in the dark in subcutaneous section of the tendo Achillis, and this method is just as exact as the open one since an amount of material will be thrown out, proportionate to the separation of the cut end.

Abstract of

REMARKS ON THE USE OF A BRACE IN LATERAL CURVATURE FROM EMPYEMA.

by DR. G. G. DAVIS. At a recent meeting of the Section when I exhibited a patient about 7 years of age wearing a brace for the correction of lateral curvature resulting from empyema, the views expressed by some present were so at variance with my own as to induce me to more carefully examine into the subject and ascertain whether the brace as ordered, was likely to be of service and desirable.

A discharging sinus, existing in the left chest wall of the child for more than a year, was only recently cured. Examination posteriorly showed the whole trunk, from the pelvis upward, inclined toward the right side with a slight lateral curvature in the upper dorsal region, the convexity being to the right. The right shoulder was higher than the left and the right scapula formed quite a prominent projection. Laterally, there was a slight forward inclination of the right shoulder which increased the prominence of the right scapula. On the left side there existed the scar and depressed cicatrix where the ribs were excised; and the contraction of the altered intra-thoracic tissue had taken place, accompanied by sinking in of the chest wall and lowering of the left shoulder.

As the general object in using braces and apparatus is to correct certain alterations in the form of the body, let me examine the mechanical problems suggested, and the means taken to solve them. First, then, as the deformity was confined to the upper portion of the body, therefore the means of correction were applied to that part. Again, as the lower portion of the body was normal, it furnished a fixed point of support for the application of the correcting force, consequently a steel band was made to encircle the pelvis between the great trochanters and the crests of the ilia, and fastened in front by a strap and buckle. To increase the hold of the band, a wide linen belt was attached to it, and reached from the trochanters to the ribs. It was secured

by two buckles in front. Four steel uprights were attached to the steel band, one under each axilla and one on each side of the medial line posteriorly. A transverse steel bar was fastened to the upper ends of the upright and curved so as to be high in the middle of the back and low under each axilla, forming a crutch.

Placing the child on his back and firmly strapping on the brace, corrected the lateral deviation of the trunk. Next to correct the elevation and forward inclination of the right shoulder and accompanying projection of the scapula, a strap was passed from the anterior end of the right crutch, over the shoulder and attached behind. This drew back the shoulder and corrected the tendency to stooping. Finally, to make lateral pressure over the projecting lump in the right upper thoracic region, a wide elastic band was fastened by straps to the right axillary upright, and to the upright on the left side of the spine. This made excellent pressure and completed the requirements of the brace. An apron had been attached by the mechanic, but as there was no necessity for it I removed it.

In another case, instead of fastening the elastic band to the axillary upright, I shall attach it to one running between the anterior extremity of the crutch to the pelvic band, and so obtain a more directly lateral force. This brace offers no hindrance to the free expansion of the contracted chest, and in no way prevents the patient from running, playing, or indulging in exercises and gymnastics, such as swinging from rings, or horizontal bars, etc. Morning and evening after removing the brace, he exercised by bending forward and backward and from side to side. The most important principle involved in the use of the brace in this class of cases is the means to be adopted to secure the expansion of the affected lung and chest wall. Is it better to allow a patient, with a recently healed wound and a marked deformity, to go without any attempt at correction on our part, or should we, by a portable brace, endeavor to maintain a gentle and persistent pressure on the distorted parts which will cause the contraction to gradually yield, yet not interfere with the expansion of the affected lung; while at the same time, the child is prevented from assuming any posture favoring persistence of the deformity? I have preferred the latter, with such exercises as he can take, believing it to be much more efficient than the spasmodic stretchings of intermittent exercises, interspersed with periods in which the body will be inclined to the affected side and every opportunity given for the contraction to take place. After the deformity has been partially reduced and the tendency to assume objectionable positions somewhat overcome, the brace may be discarded and therapeutic gymnastics alone employed.

DR. J. HENDRIE LLOYD—I have no set paper. I simply wish to make a few remarks and to show a few photographs. The subject of scoliosis is of great importance to the surgeon. I think the nervous origin of the disease is not sufficiently recognized by surgeons. It is important that it should be. It is seen especially as a complication of nervous diseases, as syringomyelia. In a recent monograph, Bruhe says that in 50 per cent. of cases of syringomyelia, scoliosis occurs. Some of these cases are also associated with marked kyphosis. One case of syringomyelia has come under my notice in which the deformity was similar to that shown by the skeleton here exhibited. One point in connection with scoliosis in syringomyelia is shown by this photograph. In some cases, when the patient is in the recumbent position, the deformity is obliterated. This case, seen in the photograph, simulates torticollis, because the scoliosis is high in the cervical region.

The second case with which scoliosis is associated is Freidrich's ataxia. It is a disease of the spinal cord seen in

childhood, and we are apt, again, too frequently to overlook it. It is allied to another form of disease which we may call disatropy. I have under my care at the Home for Crippled Children, a girl, aged 11 years, in whom there is marked muscular disatropy; there is secondary affection of the joint at the knee and ankle; and there is scoliosis. While not a typical case of Freidrich's ataxia, it is closely allied to it. There is probably some change in the tissue of the spinal cord. The photograph of the case shows the deformity at the knee and ankle, but even while lying in bed the twisting of the knee can be seen.

The last form of nervous disease which is confounded with scoliosis is shown by this photograph; the case had been under the care of a surgeon. When I went on duty at the Methodist Hospital, I found this woman with an affection of her knees; the surgeon had tapped them. As the case did not seem to progress it was turned over to the medical wards. I was struck by the peculiar deformity of the hand, which neurologists call *main en-griffe*. There was complete atrophy of the shoulder girdle. There was marked scoliosis. In short, the woman had muscular atrophy affecting the shoulders, arms and hands, with spastic symptoms in the legs, and with scoliosis and arthropathies. There were no sensory symptoms. The case was doubtless allied to syringomyelia. It is interesting to note that it had been regarded and treated as a surgical case.

A number of hypotheses could be advanced to account for scoliosis. One observer says that all cases of scoliosis are allied to arthropathies; for instance, it is identical, in the joints of the spine with arthropathies in the knee. Roth says it is due to muscular atrophy. Another hypothesis is that they are distinct trophic lesions, something like progressive atrophy.

When a case is of nervous origin the scoliosis, to a certain extent, is an evidence of Nature's effort to put the diseased spine in a better position. I never saw a case which would tolerate an apparatus. Most of the cases suffer great pain if attempt is made to straighten the spine. I recently admitted, to my ward in the Philadelphia Hospital, a young woman affected very similarly to some cases already mentioned; there is marked progressive muscular atrophy. She could not bear a brace of any sort. My remarks are entirely from the standpoint of a neurologist; I say nothing about the condition associated with empyema.

DR. C. K. MILLS—I have had two cases of syringomyelia in which spinal curvature was present. The cases of degenerative diseases, and syringomyelia in adults are not the ones most likely to show deformities, but these occur most frequently in Freidrich's ataxia and the affections closely allied to it pathologically, which show themselves early in life; but even in adults lateral curvatures do take place. I believe with Dr. Lloyd that little can be done with apparatus. In many other degenerative embryonal diseases, which are due to arrested development, my experience teaches me that little can be done either by operation or by apparatus, especially for the porencephalus cases. In spastic cases, either unilateral or bilateral, some advantage can be gained as to position, but nothing more.

DR. G. G. DAVIS—The orthopedists ought not to be too strictly called to account, because I think they would not put on an apparatus for an advanced case of pure nervous disease, except as a palliative measure. Much can be done by apparatus and it depends upon the nature of the case greatly. If an apparatus will give any additional comfort to the patient it is oftentimes advisable to order it. In regard to the cases referred to by Dr. Lloyd; in Freidrich's ataxia, a light brace might aid in supporting the body, and in Charcot's joints a mechanical appliance does, for a time, support and give at least some slight relief, which is more

than can be promised by medical treatment. I believe in the necessity for recognition of the points of the case, but I do not think that the application of apparatus is always useless.

DR. J. HENDRIE LLOYD—I should like to ask Dr. Davis if he would put an apparatus upon a Charcot joint? It is a matter of interest to me, as a surgical question, and I should like to hear it discussed. I think, in these cases, the surgeon, sometimes, does not recognize the exact nature of the difficulty. I know of one case, however, in which a surgeon operated on a spinal arthropathy, the exact nature of which he did not recognize, and in which marked benefit resulted from the operation.

DR. C. K. MILLS—The patient shown here to-night came to the Polyclinic Hospital last week. I have not full notes of the case, but the history is as follows: The man is 30 years of age, a painter by trade. The difficulty started slowly; at first he experienced trouble in holding his head still. When reading a paper, in spite of everything he could do, his head would turn slowly to the left. He has no pain, but this has persisted and is slowly growing worse. The case is one of a class somewhat common and, as we all know, most difficult to help. I have had considerable experience in what is termed spastic torticollis both of the tonic and clonic varieties; they are most obstinate and may resist treatment for years and forever. One case in particular occurs to me; a patient whom I showed at my clinic, and an account of which was reported in the *University Medical Magazine*. She had three surgical operations on the spinal accessory, and she had been burnt with a hot iron many times, but no help was obtained. I have brought this man here to-night, to obtain suggestions as to treatment. I have seen cases get well, but it is an affection difficult to cure because we do not recognize the underlying anatomic conditions.

DR. J. HENDRIE LLOYD—It is my opinion that torticollis involves a problem which we do not all understand. Prof. Ferrier and Mr. Horsley advanced the theory of a localizing torticollis center; at that time we were ready to localize anything and everything. But certainly we do not understand the condition.

A paper was next read by DR. RANDOLPH FARIES, on the
TREATMENT OF SCOLIOSIS BY FREE MOVEMENTS AND
APPARATUS,

in which he held that as the deformity is due to the concerted action of certain muscles or groups of muscles, therefore these should be kept inactive until their antagonists have been developed, by means of exercises and gymnastic apparatus, sufficiently to counteract the power exerted by the former ones. Also that the deformity, being compound, should be corrected in the same order as it occurred; that is, the rotation is first corrected, then the lateral curvature.

DR. WM. J. TAYLOR—I regret that I was not present at the reading of Dr. Faries' paper, as I am particularly interested in the treatment of spinal curvature by gymnastic exercises. I am glad to say, however, that such portion of the paper as I had the pleasure of listening to, meets my views entirely. But for the reason already given I am prevented from discussing the paper intelligently.

DR. C. K. MILLS—I quite agree with Dr. Faries as to his method of treating spinal curvatures, but the difficulties in the way are great. Little can be done in this direction until the colleges set the example, and until, in connection with every hospital, a room is set apart for this purpose and is put in charge of a competent assistant who can carry on the work year after year. It is essential that we should impress upon ourselves and our patients that this treatment should be carried out systematically for two or three years if necessary. One of the tendencies of modern medicine is

in this direction, and steps should be taken immediately to further and further advance the treatment.

DR. G. G. DAVIS—Lateral curvature is a subject much considered by the orthopedic surgeon, and for it much good can be done by gymnastics. There are two classes of such cases. In the mild ones, where the muscles are at fault and the spine itself comparatively healthy, therapeutic gymnastics are of no service. But there is another class in which the pathologic process is more profound and in which the bone and ligamentous tissues are likewise affected, and as the spine is the organ for keeping the body erect, the simple weight of the body which is supported by the spine will tend to cause curvature of it, and the tendency to distortion is increased by the efforts of the muscles on both sides of the spine. I believe that where this condition exists the spinal column will give way and deformity will occur rapidly; in these cases exercise is of little or no service. I believe that there are cases of lateral curvature which might be termed malignant. The deformity goes on increasing and in spite of most careful treatment the patient rapidly grows worse.

DR. RANDOLPH FARIES—The most essential point is the fact that we are ignorant of the compound action of the forces which are used. It is quite true that when one set of muscles is weakened, the corresponding set is strengthened and rotation takes place, after which deformity ensues; but just what forces are used, we do not know, and it is just this which seems to me the true scientific basis of the study of this condition. If this could be determined we should get at the rational method of treatment. The body of a vertebra may be made stretched by action, just as by action we make the tissues surrounding it more elastic. To my knowledge there is no medical book published which treats of the compound action of muscular force. Moreover, this seems to me the logical treatment of the disease, and until we treat scoliosis by the above method we are doing so empirically.

Medical Society of the State of Pennsylvania.

The Forty-fourth Annual Meeting was held May 15, 16 and 17, Philadelphia.

FIRST DAY—MORNING SESSION.

This was perhaps the largest meeting ever held, over 520 members being in attendance. The President, Dr. H. G. McCormick, of Williamsport, opened the proceedings at 10 A.M.

The Mayor of the city and Prof. E. Montgomery, Chairman of the Committee of Arrangements, delivered addresses of welcome.

Reports of delegates to the AMERICAN MEDICAL ASSOCIATION, and to the New Jersey State Medical Society were read. The Secretary, Dr. W. B. Atkinson, of Philadelphia, reported fifty-one county societies, with an aggregate membership of 2,400. The Treasurer reported a good balance in his hands. The Committee of Publication reported the publication and distribution of 2,500 copies of the Proceedings of 1893. The Legislative Committee reported their success in obtaining the passage of a bill by the Legislature creating an Examining and Licensing Board, and were discharged with thanks. The Committee on Contagious Ophthalmia reported the dangers of this disease, and need for its prevention, by legislation.

Dr. G. M. Gould, of Philadelphia, offered the following:

WHEREAS By all physicians it is admitted that a large proportion of the blindness of the world is due to the disease called ophthalmia neonatorum; and

WHEREAS, The well-known treatment of this disease by a physician, if at a sufficiently early period in its course, almost always results in preventing the blindness that would otherwise follow; and

WHEREAS, A committee appointed by the Ophthalmological Section of the AMERICAN MEDICAL ASSOCIATION at its last meeting has, after thorough consideration, drafted a blank form of a law and urged its passage by all State Legislatures, as well as advised all physicians to aid in securing the passage of such a law; and

WHEREAS, This blank form of a law drafted by the said Committee is as follows:

The People of the State of represented in Senate and Assembly, do enact as follows:

SECTION 1.—Should one or both eyes of an infant become inflamed, or swollen, or reddened at any time within two weeks after its birth, it shall be the duty of the midwife or nurse having charge of such infant to report in writing within six hours to the health officer or some legally qualified physician of the city, town or district in which the parents of the infant reside, the fact that such inflammation, or swelling, or redness of the eyes, exists.

SEC. 2.—Any failure to comply with the provisions of this Act shall be punished by a fine not to exceed two hundred dollars, or imprisonment not to exceed six months, or both.

SEC. 3.—This Act shall take effect on the—day of—eighteen hundred and ninety—; and

WHEREAS, Five States have already placed upon their statute books, laws similar to or identical with the foregoing law, while in other States the same measure is under consideration; and

WHEREAS, The Philadelphia County Medical Society on May 9 unanimously passed a resolution indorsing the law recommended by the Committee of the Ophthalmological Section of the AMERICAN MEDICAL ASSOCIATION, and appointed a Committee to devise means and methods of securing the enactment of such a law by the Pennsylvania State Legislature; therefore be it

Resolved, 1. That in the opinion of the Medical Society of the State of Pennsylvania, it is of the most vital importance to the welfare and happiness of the community, and to the good name of the State of Pennsylvania, which has always been foremost in matters pertaining to the health of her citizens, that the law recommended by the Committee of the Ophthalmological Section of the AMERICAN MEDICAL ASSOCIATION should be enacted by the Legislature of the State, and the Medical Society of Pennsylvania respectfully requests the Honorable Representatives of the State at Harrisburg to do all in their power toward placing such a law upon the statute books of the State.

2. That a committee of three be appointed to cooperate with the other Committees to devise means and methods of securing this law.

The whole was adopted.

Committee: Drs. Edward Jackson, H. F. Hansell and J. A. Lippincott.

On motion of Dr. Hiram Corson, Conshohocken, it was

Resolved, That a legislative committee of five be appointed, and that they be instructed to present the subject of the care and treatment of the insane and the organization of hospitals for the insane, as expressed by this Society two years ago.

Committee: Drs. J. C. Gable, York County; R. B. Watson, Clinton County; H. L. Orth, Dauphin County; Alex. Craig, Lancaster County, and C. W. Youngman, Lycoming County.

On motion of Dr. J. C. Gable, it was

Resolved, That a committee of seven be appointed to consider and suggest the appointment of an inspector whose duty it shall be to aid the Board of Examiners of Pennsylvania to carry out the medical legislation of this Commonwealth, to report tomorrow.

Committee: Drs. Gable, S. S. Towler, of Forest County; F. P. Ball, Clinton County; T. C. Detweiler, Lancaster County; T. P. Simpson, Beaver County; W. Murray Weidman, Berks County; F. D. Davis, Allegheny County.

The Luzerne County Medical Society invited the State Society to meet in Wilkesbarre in 1895. It also protested against the use of the term, "allopathic" by daily papers.

On motion of Dr. S. Solis-Cohen, the following was taken up:

The respective State medical societies entitled to representation in the American Medical Association, and through them their affiliated local societies, having been requested to consider the matter of revision of the Code of Ethics and

report to the Association at its next annual meeting; and if any alteration be deemed advisable, each State so deciding to specially indicate the part to be changed and write out in full the new form proposed; therefore be it

Resolved, That it is the sense of the Medical Society of the State of Pennsylvania that the Code of Ethics be not changed in any way.

On motion of Dr. Cohen, the Secretary and delegation to the American Medical Association were instructed to present this action of the Society in relation to the Code of Ethics.

FIRST DAY—AFTERNOON SESSION.

DR. G. D. NUTT, of Williamsport, read the

ADDRESS IN SURGERY.

He gave a review of progress made in this branch. The mortality in major operations had been reduced about one-half. Prevention of disease should be the aim of the profession. In difficult operations, success or failure depend greatly upon the action of the general practitioner in deciding to call in aid before the case has passed the safety point. Too frequently, failure is due to want of appreciation of danger sufficiently early.

DR. E. LAPLACE, of Philadelphia, read a paper on "Radical Cure of Hernia." Radical cure meant non-return of hernia in that place. To secure this, after alluding to the various methods of operating, he detailed his own which was to completely obliterate the canal by a slow healing by means of the production of a burn. The cicatrix thus closed the canal so that it remained closed. Hernia might recur but it could not pass down the canal which had been destroyed. It must then be a direct hernia and retained by suitable mechanical appliances.

DR. E. S. LEMOYNE, of Pittsburg, read a paper on a "Modification of Pirogoff's Amputation" which he asserted gave a better stump, and was more easy of applying an artificial foot, etc.

DR. J. C. McALISTER, of Driftwood, on the "Treatment of Puerperal Eclampsia chiefly by Hypodermic Use of Veratrum Viride." He alluded to the great advantage of chloral; in addition he had found the veratrum hypodermically to act most powerfully. He detailed a number of cases in all of which his results had far exceeded those he had obtained from any other form of treatment.

DR. J. V. SHOEMAKER, of Philadelphia, read a paper on
PSORIASIS WITH SPECIAL REMARKS UPON ETIOLOGY AND TREATMENT.

He exhibited a series of five well-marked cases of psoriasis, and called attention particularly to certain important points concerning the origin and treatment of the disease:

Case 1.—The first patient has for many years been subject to recurrent attacks of rheumatism. This constitutional dyscrasia gradually gave rise to the disease of the integument and also affected the heart, which is hypertrophied. The mitral valve is likewise implicated. This man had been treated in vain by many methods. He has been in the Medico-Chirurgical Hospital for a week, during which time his diet had been restricted to one thyroid gland daily—one-half being taken, lightly fried, at noon and the remainder in the evening. As a consequence the eruption has become paler, less prominent and there has been less shedding of scales. This treatment will be continued for the present and his regimen will be gradually enlarged to include plain and easily digested articles of food. For cardiac symptoms, he was given 15 minims of strophanthus three times a day.

Case 2.—A man, 35 years of age, has had psoriasis for twelve or thirteen years. The disease began at nearly the same time upon both legs just in front of the knees. Until recently the patches had, for the most part, existed only upon the leg and at the back of the elbows but lately they have attacked nearly every portion of the body. A sister and a brother are also affected by the same disease. The patient has occasionally suffered from rheumatoid pains but he has never had a decided attack of inflammatory rheumatism. He believes that there is a rheumatic tendency in his family. His case is furthermore interesting by the coexistence

of sycosis, which began three years ago upon the chin and now involves in addition the cheeks and upper lip.

The treatment of the psoriasis was by means of a capsule containing tartar emetic, sulphide of calcium, and salol.

Case 3.—A coachman came under observation sixteen years ago, covered with psoriatic patches. The lesions differ from those of the first patient in being brighter, more infiltrated and more abundantly provided with scales. The man is an old rheumatic subject. When the rheumatic symptoms disappeared under appropriate treatment the psoriasis vanished. Now, after the lapse of so long a period, the rheumatism has returned and with it the eruptions upon the skin. The lesions are especially marked upon the exterior surfaces. He has been given 10 grains of sublimed sulphur with a grain of cream of tartar in capsules three times a day in the hope of overcoming the constitutional condition upon which the disease of the skin depends. Both sulphur and cream of tartar are admirable remedies in the treatment of rheumatism and both have a decidedly beneficial effect upon the glands of the skin.

Case 4.—This man, 32 years of age, sent by Dr. Whitesides, of Philadelphia, entered the hospital but a few moments before I started for this meeting. In the brief conversation which I had with him I learn that he is an old sufferer from gastro-intestinal catarrh. Three years ago this condition was relieved and the psoriasis disappeared. Lately they have both returned. You will perceive that the whole surface is more or less studded with large and small spots of infiltration and that these are particularly marked upon the extensor surface. Here and there the skin is fissured. I wish in this instance, to direct the attention of the members to the cause of the eruption, viz., an alteration in the mucous membrane of the gastro-intestinal tract. If we can correct this condition by suitable remedies it will not be necessary to make local applications in order to remove the infiltrations. I will order in this case 2 drachms of liquor pepsini with 10 minims of dilute hydrochloric acid before meals and one-fiftieth grain of sulphate of strychnin after meals. The diet must be restricted.

Case 5.—This patient is likewise affected by spots and patches of psoriasis, especially upon the elbows and knees. The disease is of long standing, the infiltration is marked and numerous fissures are present. As the man only speaks Hungarian I have been unable to obtain a detailed history of his case. I will, on general principles, assume that the skin disease is associated with the gouty or rheumatic diathesis. He shall be placed upon the iodid of potassium in 15 or 20 grain doses three times a day.

"These cases are excellent illustrations of the etiology of psoriasis. Two of the patients are frankly rheumatic, two are probably of arthritic tendency, while the fifth is the subject of chronic gastro-enteritis.

"Psoriasis is often excited by the presence of rheumatism or gout. In other cases it depends upon chronic disturbance of the digestive organs, disease of the liver, disorders of the blood and maladies of the nervous system. The appearance of the papules, patches, and scales is characteristic and typical, whatever the cause. The facts relating to its etiology are most significant guides to treatment. In each case we must endeavor to ascertain the origin. Though the lesions present precisely the same appearance the therapy must obviously differ in accordance with the etiology. A routine treatment of psoriasis is an impossibility. Defects of digestion and nutrition must be corrected, constitutional and—approximately—specific remedies must be administered or the state of the nervous system must be improved. The habits and the diet must be regulated or changed. Ingestion of thyroid glands is a mode of therapy which may well prove of service in certain cases. The grand principle of treatment is to determine the origin of each case. Acting upon this belief, I lay comparatively little stress upon topical treatment. Increasing experience convinces me that accuracy in tracing the genesis of the disease points to an internal therapy upon which we may place our reliance more firmly than upon local measures."

DR. ORVILLE HORWITZ, of Philadelphia, read a paper on "Treatment of Stricture of the Urethra," which elicited a discussion by Drs. J. B. Deaver, Prof. Brinton and H. O. Walker, of Detroit.

Dr. O. H. ALLIS, of Philadelphia, spoke on "Cramming in Medical Schools," as making it impossible for the student to digest the immense amount of educational food forced upon him. His remarks produced quite a marked impression upon the members who were attentive listeners.

The time growing short, a large number of apparently interesting and valuable papers were declared as "read by title," and business was then called up.

The report on the Rush Monument Fund showed but one additional subscription for the year, of only \$3, but the Committee was continued.

A resolution by Dr. P. D. Keyser, of Philadelphia, urging the striking out from the bill before Congress, relative to the Army, that portion reducing the number of Assistant Surgeons to ninety, was considered and unanimously adopted and ordered to be sent at once to Congress.

SECOND DAY—MORNING SESSION.

The Nominating Committee was announced and retired to deliberate upon choice of officers, etc., for 1895.

Dr. W. S. FOSTER, of Pittsburg, read the "Address in Medicine," giving a concise *résumé* of the advances in that line. He reviewed each point in a conservative manner, showing the absurdity of certain claims which had been made for the antipyretics, the animal extracts, etc. He counseled slower progress rather than the so frequent announcement of wonderful remedies soon to follow the foolish exhibition of past years.

Dr. HILDEGARDE H. LONGSDORF, of Dickinson, Cumberland County, read a paper on "Christian Science in Its Relation to the Medical Profession." This ably exhibited the follies of this class of so-called healers, detailing at length their plans and the dangerous results which so frequently followed in real cases of disease. The paper was well received, and a motion was adopted to ask the Publishing Committee to print one thousand copies for distribution to the community.

Dr. S. SOLIS-COHEN made some remarks on the subject, "Should the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION be Used to Promote Quackery?" He called up recent action of the Philadelphia County Medical Society, as follows:

"WHEREAS, The Code of Ethics of the American Medical Association declares it derogatory to professional character for a physician to dispense or in any way promote the use of a secret nostrum; and the Association by a resolution unanimously at its meeting, in 1892, forbade the advertising of such in its JOURNAL, and

"WHEREAS, The JOURNAL has continued to advertise such nostrums, and in defense of its course in this particular, has published an anonymous personal attack on a member of the American Medical Association and of this Society,

"Resolved, That the Philadelphia County Medical Society respectfully demands that the Trustees of the JOURNAL of the American Medical Association shall in their public official acts respect the spirit and the letter of the Code of Ethics; and that the columns of its JOURNAL shall not be used for the anonymous personal abuse of its members in good standing.

"Resolved, That a copy of these resolutions be transmitted to the Medical Society of the State of Pennsylvania and to the American Medical Association and to the weekly medical journals."

After full discussion, a substitute and changes were unanimously adopted as follows:

Resolved, That the Medical Society of the State of Pennsylvania hereby indorses the resolutions concerning the conduct of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION transmitted from the Philadelphia County Medical Society.

Resolved, That it is the opinion of this Society that if the finances of the American Medical Association do not permit the publication of a journal that does not violate the Code of Ethics by the insertion of notices of secret nostrums and other objectionable advertisements, the Trustees should be instructed to cease publication.

Resolved, That these resolutions, together with the resolu-

tions of the Philadelphia County Medical Society, be officially transmitted to each Trustee of the American Medical Association, and that the delegates to the Association elected at this meeting be instructed to present the same to the meeting of the American Medical Association at San Francisco, and to use every honorable endeavor to secure such action as shall effectually remedy the matter complained of.

Papers were then read by Dr. J. M. BALDY, of Philadelphia, on "Acute Endometritis;" by Dr. B. H. DETWEILER, Lancaster, on "Croup and Diphtheria," discussed by Dr. S. S. COHEN, who pointed out the difference between croup and diphtheria; by Dr. C. H. THOMAS, Philadelphia, on the OPERATIVE TREATMENT OF MUSCULAR ASTHENOPHIA (HETERO-PHORIA).

A number of illustrative cases were reported which showed the extremely varied character of the symptoms and the favorable results of operation. The subjective symptoms of asthenopia show almost no distinct characteristics pointing to their origin, whether refractive or muscular; the same headaches and the same sense of eye-strain are complained of under both conditions. Graduated tenotomy (partial) is practicable and efficient because of the elasticity of the margins of the tendons. Muscular asthenopia may present symptoms of all grades of importance, from the slightest to the most serious. As in refractive, so in muscular, asthenopia, the gravity of the symptoms bears no constant relation to the amount of the physical defect. It is impossible to predict with any considerable definiteness the result of correction of either refractive or muscular error. As much—and very much the same kind of—relief is to be expected from the correction of muscular anomalies as from the correction of errors of refraction and accommodation; as might be expected from the similarity in the symptoms. The muscular conditions in every case should, as a matter of routine, be as carefully investigated as are the media, eye-ground, the refraction, and the amplitude of accommodation.

A large number of most valuable papers were declared read by title.

The Committee to aid the Board of Medical Examiners reported:

Resolved, That the secretary of each county society is requested to forward at once to the Secretary of the State Board of Medical Examiners a correct list of the registration of doctors under the last Act, on and from the first day of March last, and quarterly thereafter; and in counties without a society the President of this Society shall appoint a member living in such county to procure such list, and in any case of neglect the Secretary of the State Board of Medical Examiners of this Society shall be empowered to procure the same.

Five hundred dollars were appropriated to carry this out.

Resolutions from the Allegheny County Medical Society in favor of epileptic colonies, and asking the authorities to aid in this matter, were presented and adopted.

An amendment to the rules governing the presentation of papers was laid over under the laws. This was in favor of short ten-minute papers and the interchange of personal experiences. Discussion to be limited to five minutes each speaker. This was caused by the unavoidable omission of many papers, owing to the great length of many that were read.

SECOND DAY—AFTERNOON SESSION.

The Nominating Committee reported these officers for 1895: President, John B. Roberts, Philadelphia; Vice-Presidents, S. C. Stewart, Clearfield County, J. A. Lippincott, Allegheny County, J. H. Wilson, Beaver County, R. Armstrong, Clinton County; Secretary, Wm. B. Atkinson, Philadelphia County; and the usual number of Censors, etc.

Next place of meeting, Chambersburg.

Dr. T. McKENNAN, Pittsburg, read the "Address in Mental

Disorders," reviewing the current treatment and the use of hypnotics, etc.

Dr. C. W. DULLES, Philadelphia, read a

REPORT ON HYDROPHOBIA,

which was a continuation of his former account presented six years ago. He reported 78 cases of nervous diseases recurring in the United States since his former communication was read, which turned out to be tetanus or cerebro-meningitis, which formerly would have been erroneously classed as rabies. Eighty per cent. of these were in States in the immediate vicinity of the Pasteur Institute in New York city, and this preponderance he ascribed to the agitation of this subject in the public mind by publications emanating from the said Institute. He was very conservative in his diagnosis and did not believe that hydrophobia is more apt to occur in the young.

Dr. C. K. MILLS, Philadelphia, in discussing the paper agreed much with Dr. Dulles, but was not quite ready to say that hydrophobia did not exist. He was glad to know that the investigation was to be continued.

In a "Brief Review of the Therapeutics of Whooping Cough" Dr. W. C. Hollopeter, of Philadelphia, advocated antiseptic gargles especially containing hydrogen peroxid. He thought that a specific is yet to be discovered.

Dr. MACCUEEN SMITH, of Philadelphia, discussed the treatment of "Simple Inflammation of the Middle Ear and their Sequelæ." He insisted upon the routine examination of the ears of new-born children by the attending physician. Should there be accumulations in the meatus, they should be removed by the syringe. If on examination, the membrane be reddened, Politzenization or inflation of the middle ear should be performed to remove inflammatory exudates from the tympanum. Deaf-mutism is frequently produced by neglected inflammatory middle ear disease, either catarrhal or infectious in origin. Dr. Burnett thought that inflammation of babies' ears is due to too much swabbing and urged that meddling interference be forbidden.

Dr. L. TURNBULL, Philadelphia, discussed the subject, objecting to the practice of inserting all sorts of home remedies in the ears of children.

A paper on "Dietetics" was read by Dr. H. F. SLIFER, of North Wales, reviewing the forms of treatment by diet and digestives. A number of others were read by title. Dr. G. G. DAVIS, Philadelphia, exhibited five cases of amputation near the ankle. These cases were shown to combat the theory that in injuries to the foot and its vicinity amputation, in order to give a good stump for the application of an artificial leg, must be done above near the knee. These men walked without difficulty, showing little halt, and each was engaged in work demanding much walking; one was a night watchman at a large establishment. The exhibition was accorded a round of applause.

Dr. E. E. MONTGOMERY'S "Address in Obstetrics" followed, and under the call for new business the following was unanimously agreed to:

WHEREAS, The Library of the Surgeon-General's office of the U. S. Army, has grown to be the second or third in importance in the world, and has become the most important center of medical culture in the United States; and

WHEREAS, Any curtailing would be a national disaster to the medical profession of the United States, and to the people to whom they minister; therefore

Resolved, That the Medical Society of the State of Pennsylvania, respectfully and most earnestly petition the Appropriation Committee of the United States Senate to restore the annual appropriation to \$10,000, as the minimum possible sum with which the usefulness of the Library can be kept up.

THIRD DAY—MORNING SESSION.

The "Address in Hygiene" was read by Dr. J. H. WILSON, of Beaver. He alluded to the great need of attention to

cleanliness, fresh air, sunshine, pure water, etc. He referred to the way by which contagious diseases are propagated by books, papers and slate pencils which are not only handled but placed in the mouths by children, requiring disinfection in some way as by heat, etc. Some school boards compel a child who appears with dirty face and hands to go to the wash room and there be cleansed by the janitor. It is the duty of physicians to instruct patients in all points of hygiene; as the entire change of clothing at night, the regular washing of the feet, keeping the finger nails clean, etc. Back yards and cellars should receive as much attention as any other part of the premises. The care of consumptives to prevent the spread of tuberculosis was now being properly understood and handled by boards of health. This paper was discussed by Dr. W. P. Munn, of Colorado, who was present, who alluded to the house-to-house method of inspection now practiced in Denver. Contagious disease is reported, the officials inquire into the habits and work of the people; the plumbing, sewerage, etc., all is tabulated, kept in the public libraries and thus becomes the property of the public. When a person is about to rent a house, he goes to the health bureau, examines the records and knows the previous condition of that house, and its sanitary condition. Landlords are thus compelled to keep their properties in the best possible sanitary state.

Tuberculosis was the subject of several papers and much animated discussion. DR. A. M. COOPER read one on "Psychical Phases in Tubercular Folks." As he was located in a country district he had a good opportunity of following such cases, and after an experience of forty years was inclined to great skeptical belief as to the contagiousness of the disease, especially in the married state. In fifty-five cases where fifteen husbands died, the wives were still alive and well, while in twenty-five where wives died, the husbands were all alive and in good health. He regarded heredity as more potent than contagion in consumption.

Papers were read by DR. J. M. TAYLOR, Philadelphia, on "Contagious Aspect of Tuberculosis of the Lungs;" by DR. L. F. FLICK, Philadelphia, on "Prophylaxis" in this disease, in which he urged most earnestly the need of quarantine; he believed this was required, owing to the presence of the bacillus, though he admitted that its transplantation successfully demanded a proper soil. The disease is a constitutional one with a local auto-inoculation, and you can cure the case. It can be controlled in two ways; by building up the system and preventing the re-introduction of microorganisms into the system; by increasing the body weight, rest, sleep, etc. The reëntrance of disease by the sputum is specially to be prevented; all sputum must be received into vessels loaded with a germicide. This should be devitalized at the earliest possible moment. Houses where consumptives live should be thoroughly cleansed and bedding, etc., disinfected.

DR. T. J. MAYS, Philadelphia, spoke on "Strychnin Treatment." He detailed cases in which the most marked results followed positive doses of strychnin. Especially was it valuable in weak heart, and exhausted nervous system. DR. D. LONGAKER gave the notes of an "Autopsy in a Case of Tubercular Meningitis."

DR. W. P. MUNN, Colorado, spoke on the "Colorado Climate for Consumptives." Cure and rest should receive as much attention as prevention. The most effective factors against the disease are those of environment, occupation, clothing, personal habits and the correction of faulty conditions; without these climatic changes are useless. Inhabitants of high dry altitudes do not acquire the disease. Such altitudes are fatal to the bacilli. The children of tuberculous parents born in such altitudes are usually exempt. The conditions for a cure are dryness, sunshine, pure air, rare

atmosphere within certain limits and an equable moderate temperature. All these are found on the western slope of the mountains in Colorado. Of forty physicians in Denver, 30 per cent. were consumptives when they went to Colorado but are now in vigorous health. Five remain on account of consumptive wives, who are now in good health, and a large number of former consumptives are enjoying most excellent health. One-fourth of the people went there, originally, because of pulmonary disease in their families. He believed that outdoor life was essential in the cure, and to be cooped up in a room was no better in the West than any where else. Dr. S. Solis-Cohen spoke of the curability of the disease. He agreed with Dr. Munn that this must not be recognized among the curable diseases. Though some forms as the very acute—which is called "galloping consumption" on account of the general diffusion of the infection—left no hope of a return to health. The only reason why the chronic form is not curable is that the patient is so situated that he is unable to avail himself of therapeutic measures, or because the disease comes under intelligent treatment at too late a time. Generally, the patient is so placed pecuniarily as to be able to obtain the proper hygienic measures to procure improvement, and as in certain cases, while too far gone for a cure, can have the life prolonged and made very comfortable. He did not under-rate the use of drugs, but if a choice must be made, would prefer to know how to live rather than to employ drugs. Proper breathing is a most important desideratum.

Papers were read by Dr. J. M. Anders, Philadelphia, and the discussion continued by Drs. Jas. C. Wilson, Philadelphia, J. Solis-Cohen, W. E. Hughes and others. During these debates Dr. W. T. Bishop, Harrisburg, obtained the floor and on his motion it was agreed that the elective officers should form a committee to carry out the suggestions in the address of the President to secure the membership in the county societies of all members of the regular profession, that thus the entire profession of the State should be more fully represented.

On motion of Dr. Towler, it was

Resolved, That the Medical Society of Pennsylvania presents the following facts to the Judicial Council of the American Medical Association and asks its action thereon:

The Trustees of the JOURNAL of the Association in 1892, at Detroit, were directed to abstain from publishing in the advertising columns, advertisements of secret nostrums. Such advertisements are, however, still published in defiance of the resolution.

In the JOURNAL of April 7, 1894, there is advertised a Sanitarium Association which openly offers stock to those physicians who will send patients to it for treatment. In the opinion of the Medical Society of Pennsylvania these advertisements are improper and unethical, according to the letter and spirit of the Code of Ethics.

The Medical Society of the State of Pennsylvania therefore asks the Judicial Council to take such action in regard to the said Trustees as is demanded to sustain the integrity of the Association and enforce the provisions of the Code of Ethics.

On motion of Dr. Frank Woodbury, Philadelphia, the following was unanimously adopted:

WHEREAS, Medical science and practice at the present day is securely founded upon demonstrable facts of chemistry, physics and biology, and is independent of and superior to the restrictions of any dogma, creed or so-called school of practice; and

WHEREAS, A title indicating sectarian distinction or restriction is inapplicable to scientific physicians and tends to mislead the public and therefore is highly objectionable; therefore be it

Resolved, That the Medical Society of the State of Pennsylvania respectfully directs the attention of the State Medical Council and State Board of Medical Examiners and Licensers to this subject, and requests the said Council in all its publications to refrain from the use of any sectarian title, as applied to the representatives of this Society constituting one of the Examining Boards; also

Resolved, That in classifying candidates for examination and applicants for license, the said Board of Medical Examiners use its influence and authority to prevent the said objectionable sectarian epithets from being applied to regular physicians, who by training and education are qualified to employ all proper means for the relief of the afflicted, without restriction or prejudice, and who are independent of allegiance, either implied or avowed, to any sect, dogma or school.

On motion of Dr. S. Birdsall, Susquehanna, the following was adopted:

WHEREAS, A bill for the establishment of a National Bureau of Health in the Department of the Interior is now pending in Congress; therefore

Resolved, That the Medical Society of the State of Pennsylvania desires hereby to express its entire and cordial approval of said bill, and to record its opinion that the sanitary interests and general welfare of our country will be greatly promoted by the enactment of the proposed law.

Resolved, That we hereby respectfully request the representatives of our State in the National Legislature to aid the passage of said bill by their earnest and active support.

Resolved, That our Secretary forward a copy of these resolutions to each United States Senator and Member of the House of Representatives from the State of Pennsylvania.

THIRD DAY—AFTERNOON SESSION.

DR. G. DE SCHWEINITZ, Philadelphia, read the "Address in Ophthalmology." He strongly indorsed the action of the Ophthalmological Section of the American Medical Association, in urging the passage of a law, making it the duty of a midwife or nurse having charge of infants, to report all cases of ophthalmia neonatorum or sore eyes to the health officer or other qualified person in each city, town, etc.; 70 per cent. of blindness in infants is caused by this disease and it should be prevented. The well-known treatment by a physician at a sufficiently early period rarely fails to result in a cure so that blindness is prevented. He alluded in detail to other forms of eye trouble and the appropriate remedies.

A paper was read by DR. S. L. ZEIGLER ON

CORNEAL ULCERS TREATED BY THE GENERAL PRACTITIONER.

Simple corneal ulcer is not necessarily dangerous, but may seriously affect vision; especially when central. Lacrymo-nasal lesions are the immediate cause. Gastro-intestinal disorders from errors in diet are the remote cause. Constitutional dyscrasias may be the predisposing cause. If septic materials are present in the ocular cul-de-sac a break in the corneal epithelium will court infection and subsequent ulceration. To summarize: Simple corneal ulcer is a purely local inflammatory process, arising chiefly from infection by septic secretions, and originating in lacrymo-nasal lesions. The treatment is: 1, use a mild, antiseptic eye-wash in the eye, a mydriatic if necessary, and hot applications when indicated; 2, treat the nose locally with tr. benzoin comp., and the use of a cleansing spray; 3, improve the hygiene, regulate the diet and give salt water baths.

A paper was read by DR. HORACE FOX, ON

SYMPHYSEOTOMY AND VARIOUS OTHER PROCEDURES IN THE DELIVERY OF PREGNANT WOMEN WHEN THE PELVIS IS CONTRACTED AND DEFORMED.

Symphyseotomy, as performed by its present adherents, is not based on sound theoretical and practical grounds, nor is it confined to the limits of its *demonstrable use*. When the sacro-pubic diameter measures three and three-fourths inches or above and we have *any* of the various presentations or positions, other measures besides symphyseotomy will relieve the jeopardous condition of the lives of the mother and child. When the sacro-pubic diameter measures between two and three-fourths inches and three and three-fourths inches and the woman is in the active stage of labor, symphyseotomy should be performed, but should such a pelvic contraction be discovered before the setting in of labor, premature labor has many greater advantages, and

should unhesitatingly be performed in preference to permitting the woman to go to full term and then performing symphyseotomy. When the sacro-pubic diameter measures under two and three-fourths inches, Cæsarean section or the Porro operation should be preferred.

DR. CHARLES H. BURNETT, of Philadelphia, read a paper entitled:

CHRONIC TYMPANIC VERTIGO; ITS RELIEF BY REMOVAL OF THE INCUS,

in which he showed that the vertigo so often attending chronic catarrh of the middle ear, is due to impaction of the stapes in the oval window, and pressure thence through the labyrinth-fluid upon the motor filament of the auditory nerve. Impaction of the stapes is due to the retraction of the membrana tympani and the auditory ossicles, brought about by sclerosis and synechiæ, and *not* to disease of the semicircular canals. Hence the name, "Ménière's disease," for this malady is a misnomer, since it was applied by Ménière to an affection of the semicircular canals. As the vertigo from chronic catarrh of the middle ear is due to a lesion of that cavity, Dr. Burnett suggests for this form of aural vertigo, the name of "chronic tympanic vertigo," as being more accurate and more distinctive. In fact, Ménière's disease is something like hydrophobia, rarely if ever occurring, but being confused with some other disease, whereas chronic tympanic vertigo is of frequent occurrence and, though easily diagnosed by the aurist, is often mistaken by the general practitioner for "biliousness," "epilepsy," "neurasthenia" and even apoplexy.

As this form of ear-vertigo is due to impaction of the stapes in the oval window, surgical liberation of this ossicle, by removal of the incus, is the only means of cure. The tinnitus and deafness always accompanying chronic tympanic vertigo are also relieved by this operation, which can be performed only upon the patient under a general anesthetic, when the ear is to be illuminated by an electric forehead-lamp.

Four cases, the latest in a series of twenty operated upon recently by Dr. Burnett were then given, showing the satisfactory results of this operation, which is unattended by any inflammatory reaction.

On motion of DR. J. MONTGOMERY, Chambersburg, it was

Resolved, That no physician or surgeon shall be compelled to give testimony against his patient in cases where he has received confidential communications from said patient, unless the same shall be raised by the patient.

On motion, this was referred to the Legislative Committee.

The following officers were elected for the ensuing year: President, John B. Roberts, of Philadelphia; Vice-Presidents, Drs. S. C. Stewart, of Clearfield County; J. A. Lippincott, of Allegheny County; J. H. Wilson, of Beaver County; R. Armstrong, of Clinton County; Secretary, W. B. Atkinson, of Philadelphia; Assistant Secretary, H. G. Kreutzman, of Franklin County; Treasurer, G. B. Dunmire, of Philadelphia. George S. Hull, of Chambersburg, Chairman Committee on Arrangements.

J. W. Groff, of Montgomery County, is delegate to the New York State Medical Society; C. A. Rather, of Dauphin County, to the New Jersey Medical Society, and A. C. Wentz, of York, and P. R. Koons, of Cumberland, to the Maryland Medical Society.

President Roberts made the following appointments for next meeting: Dr. C. L. Stevens, of Athens, Bradford County, to read Address on Surgery; Dr. Isaac C. Gable, of York, Address on Medicine; Dr. Van B. Ulrich, of Chester, Obstetrics; Dr. F. X. Dercum, of Philadelphia, Mental Disorders; Dr. Hildegard H. Longsdorf, of Carlisle, Address on Hygiene; Dr. Lewis H. Taylor, of Wilkesbarre, Address on Otology.

The entertainments provided consisted of luncheon given daily in succession by the Medico-Chirurgical College, the Polyclinic and the University of Pennsylvania. A reception was given by the Medical Club at the Hotel Bellevue, one by the Faculty of the Jefferson at the Academy of Fine Arts, and a theater party followed by a reception by the Philadelphia County Medical Society. On the Saturday following adjournment, the members of the Society and their friends were tendered a complimentary excursion to Asbury Park, where they were handsomely entertained at the Hotel Brunswick by the Mayor and citizens of this charming city by the sea. The visitors were delighted with the location and great facilities for entertainment, and went away fully prepared to indorse the invitation which will be presented at San Francisco for the next meeting of the American Medical Association to be held at this place in June, 1895.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, JUNE 2, 1894.

THE DUTIES OF MEDICAL MISSIONARIES IN THE ORIENT.

The following autobiographical paragraphs have been selected from several such published in *Medical Missions* for March, 1894, in answer to questions by a society of London medical students. That society contains not a few young men who are fitting themselves for the foreign field and is known as the "Medical Missionary Association of the London Hospital." In answer to the question, What sort of work does the missionary get? DR. SIDNEY HODGE, of the Hankow Hospital, replies that he gets every kind of work that he would get at home.

I am family doctor to a large mission; general practitioner to the Chinese public; specialist in every department, and have a wide operative field. I have not done as much as many out here, but if I mention some operations I have done you will have an idea. Amputations—leg, arm, breast, etc. Excisions—knee, elbow, upper jaw. Removal of malignant tumors in various situations. Eye operations innumerable, iridectomies, entropia, etc. And while I am writing there is an amputation at the knee joint, one at the shoulder, and an ovariectomy awaiting me. You will see, therefore, that our work is no child's play. There is an equally wide field in medicine: Fevers, chiefly malarial, always a fair sprinkling of nervous cases, phthisis, pneumonia, rheumatism, with an occasional epidemic of Asiatic cholera, just to keep you awake. Then there is midwifery, always difficult, either version or forceps. The Chinese are difficult and disappointing patients, and any one who comes out here must lay in a large stock of divine patience. The people are ignorant and suspicious. Anything chronic requiring long treatment has a poor chance. They are, however, on the whole grateful patients, and there is splendid opportunity to reach them by conversation when resident in a hospital."

DR. W. P. MEARS, of Foochow, has been largely engaged in training and teaching native students preparatory to their going out as dressers and assistants to the mission hospitals. Writing to the Lon-

don Hospital students, he shows in a sentence or two the power of the medical missionary element in Chinese mission work:

"Lately a traveling native evangelist has asked that a medical student may be allowed to accompany him, and for this reason—he finds that often after a long day he is refused lodging for the night in village after village, because he is a preacher of strange doctrine, and he must, therefore, walk, three, four, five or more miles further, when he is wearied out, before he can find shelter. On the other hand, he says that he and a medical man together would be willingly received anywhere. I find that this is not a solitary case and that the same difficulty is experienced elsewhere. In time we hope to have men for such itinerant medical work, but at present we have none."

DR. R. L. SCUDDER, of the Arcot Mission, S. India, says of the Ranipet Hospital, of which he has charge:

"Government has placed at our disposal, free of all cost to the mission, a large hospital, where we can administer to the spiritual as well as physical diseases of the people. All that they require is that the medical officer in charge shall give a reasonable attention to his work."

DR. GRACE MACKINNON, of Patna, had in the ten months from November, 1892, to September, 1893, new patients, 3,022; dispensary attendance, 10,156; hospital in-patients, 12; major operations, 11; minor operations, 81; visits to homes, 304.

The foundation stone of the new Medical Mission Hospital at Patna was laid on July 29, 1893, by the Lieutenant-Governor of Bengal.

A French missionary, DR. LIENGME, has his field among the Zulus of Gazaland, a lot of wild and bloodthirsty heathen. He went, on invitation, to visit one of the "kings," and was called upon to practice in the royal family. One of the queens was treated for pneumonia and recovered, fortunately for the missionary. Then the king came forward for treatment for the complications arising from too much "sope" or alcoholic drink. The king entreated the missionary to give him a medicine to have many children. The missionary proceeds to say:

"Medical skill in the Lord's hands has been one of the great means in attracting the king's and his people's favor. When I was known, the sick people came from great distances. One day I cured a deaf man by extracting a cork of wax from his ear. In a few days a number of people with ear diseases came from different parts of the country. The same thing occurred with eye diseases. Many doctors would have envied my opportunities. The consultation and operating room consisted of a tree under whose shade a small bench was fastened on the ground, and two trunks were reserved for the patient's use. Near by was a small tent containing the medicines, and that was all. The patient knelt, lay or sat down. A piece of paper was spread on the ground for the instruments, and the operation was proceeded with. Generally a crowd of natives looked on, unable to conceal their astonishment, and very often their fear.

When a patient after three days was quite restored, only the scar to tell of the tumor, their admiration had no end. 'You are the king of the white men! hé! hé! hé! that man, that is a surgeon!' they would exclaim. I have already told you that sick people came to live near us. At the end of our stay there were over sixty. If I hadn't been obliged to send them away, the number would have speedily increased. I was very sorry to have to send them away. Those poor people couldn't be comforted when they saw that they had come too late. A poor old blind woman had made a five days' journey, and I was obliged to send her home without having done anything to relieve her. Many others who excited our compassion had thus to be sent away. All my medicines were gone; I could not satisfy their entreaties for 'just a little, very little medicine to drink.'

"Some figures will give you an idea of what has been done during our short stay in Gazaland: I had thirty-three operations, of which eight were cataracts, three other eye operations, and four for hydrocele. I removed an inferior maxilla, with necrosis caused by a bad tooth, which a native doctor had tried to extract. The patient appeared in a fearful state; he believed a 'molye' (witch) had put a rotten bone in his mouth. I operated also on five cases of tumor, which healed by first intention."

He had over 1,400 consultations under the tree or in some neighboring hut.

LIABILITY OF VARIOUS CLASSES OF HOSPITALS AND THEIR PATRONS.

The United States Circuit Court of Appeals, Eighth Circuit, has rendered an exceedingly important decision in the case of the Union Pacific Railway Company v. Artist, decided Feb. 12, 1894, and just reported in the advance sheets of 60 *Federal Reporter*, 365. The Court says that if one contracts to treat a patient in a hospital—or out of it, for that matter—for any disease or injury, he undoubtedly becomes liable for any injury suffered by the patient through the carelessness of the physicians or attendants he employs to carry out his contract. If one undertakes to treat such a patient for the purpose of making profit thereby, the law implies the contract to treat him carefully and skilfully, and holds him liable for the carelessness of the physicians and attendants he furnishes.

But this doctrine has no just application where one voluntarily aids in establishing or maintaining a hospital without expectation of pecuniary profit. If one, out of charity, with no purpose of making profit, sends a physician to a sick neighbor or to an injured servant, or furnishes him with hospital accommodations and medical attendance, he is not liable for the carelessness of the physicians or of the attendants. The doctrine of holding the principal responsible no longer applies, because, by fair implication, he simply undertakes to exercise ordinary care in the selection of physicians and attendants who

are reasonably competent and skilful, and does not agree to become personally responsible for their negligence or mistakes. The same rule applies to corporations and to individuals, whether they are engaged in dispensing their own charities, or in dispensing the charitable gifts of others intrusted to them to administer.

One reason why corporations and individuals conducting hospitals supported by charitable endowments and contributions, and operated to heal the sick and injured, but not for profit, are not liable for the negligence of their employes, is, that the moneys in their hands constitute a trust fund devoted to a charitable purpose, and the courts refuse to permit it to be diverted to the very different purpose of paying for the malpractice of their physicians or the negligence of their attendants. Moreover, the corporations or individuals that administer such trust must, after all, leave the treatment of the patients to the superior knowledge and skill of the physicians. They can not direct the latter, as the master may ordinarily direct the servant what to do, and how to do it. If they did do so, the physicians would be bound to exercise their own superior skill and better judgment, and to disobey their employers, if, in their opinion, the welfare of the patients required it. And, finally, the patient is not required to accept the proffered accommodations and attendance. They are but freely offered to him. He may refuse to accept them, and seek other physicians and other accommodations.

What those who charitably furnish hospital accommodations and medical attendance are responsible for is only the exercise of ordinary care in the selecting of the physicians and attendants whom they employ.

Following this statement of principles, the Court of Appeals reverses a judgment rendered by the Circuit Court against the Union Pacific Railway Company for the malpractice of physicians and the negligence of attendants in a hospital maintained by it, for the benefit of its employes. The evidence tended to show that the Company required each of its employes to contribute from his wages twenty-five cents a month towards the support of a medical department, the Company contributing the amount required in addition to the sum thus raised to pay the expenses of this department. The Circuit Court charged the jury that the hospital was not a charitable institution, in any sense that those words are used in law, and that the Company was bound to use reasonable care to see that the treatment given to patients in such hospital was such as was ordinarily given in hospitals of this kind to such patients. This, it is held, was wrong.

The test which determines whether such an enterprise is charitable or otherwise, the Court of Appeals holds, is its purpose. If its purpose is to make profit,

it is not a charitable enterprise. If it is to heal the sick and relieve the suffering, without hope or purpose of getting gain from its operation, it is charitable. Tried by this test, the hospitals and medical department of this Company are a great public charity. They are supported by the voluntary contributions of this great corporation and its employes, without the purpose of profit thereby. And the court says that it does not speak of their "voluntary contributions" unadvisedly. If the individual contribution of twenty-five cents a month was a part of the pay of the employe, the Company could not lawfully take it out without his consent. If he did not consent, then he did not contribute, and the Company still owed him the amount of this assessment. If he did consent, he voluntarily contributed the amount of his assessment. Moreover, it was shown that besides these contributions of twenty-five cents per month from each employe, the Company contributed from \$2,000 to \$4,000 per month for the purpose of furnishing these hospital accommodations. If it be urged that this gift may have been prompted by an ulterior and selfish motive,—that the Company may have thought that the operation of its medical department would protect it from excessive claims for injuries resulting to its servants—the answer is that the true test of a public charity is not the motive of the donor, but the purpose to which the money given is to be applied.

If a dozen of the employes of this Company had contributed a fund, out of charity, to furnish one of their number, who was injured, with hospital accommodations and medical attendance, they certainly would not have been liable to him for the malpractice of the physicians or the negligence of the attendants they employed. If they had intrusted such a fund to a third person to administer, who, out of charity, contributed to it more largely, and he furnished the accommodations and attendance by the use of this fund, it goes without saying that he would not be liable for the negligence of the physicians or attendants he employed. That the party to whom this charitable gift is intrusted, the party that contributes most liberally to it, and the party that can not by any possibility derive any direct profit or benefit from it, since it is not subject to bodily ailments and injuries, is a corporation, can not extend the limits of legal liability here.

The result is, the Court holds, that the only contract the law implies in such a case as this, is an agreement on the part of the Company to use reasonable care to select and obtain skilful physicians and careful attendants, and if the Company performed that contract it was responsible no further. In other words, it was responsible for the discharge of its own personal duty, and not for the performance of the duties of its employes.

SMOKE AND THE STRIKES.

At first blush the connection between a labor strike and the public health and comfort may not seem very obvious. But the coal famine, which has resulted from the widespread disturbances among the miners, has certainly led to a material abatement of the smoke nuisance and its injurious effect upon the health and happiness of several millions of people. The consequent pressure for economy in the use of coal for fuel has taught a great object-lesson in the value of careful stoking, and the consumer has learned that he can get more heat out of a given quantity of coal, if this is so fed to the furnace as to secure its perfect combustion instead of allowing a large percentage of it to pass off through the chimney in unconsumed carbon and gases.

Experts estimate that a smoky chimney indicates a loss of from 10 to 25 per cent. of the fuel used—the amount varying with the density of the volume of smoke poured out into the atmosphere to poison it with noxious gases, which produce or aggravate many affections of the respiratory apparatus; to settle down on all subjects, animate and inanimate, in a shower of inky, grimy, oily "blacks," destructive alike of good clothes, good looks and good morals; and to shut out the health-giving sunlight, to the injury of eyesight and to the causation of mental and nervous depression and gloomy views on all mundane subjects.

But it is not in the education of the fireman or stoker alone that there is improvement. The value of many mechanical devices for the smokeless combustion of the bituminous coals has been demonstrated, with claimed results of saving in coal bills that remind one of the Celtic logic which induced Pat to buy two stoves instead of one, on the representation of the dealer that one would save half its cost in the year's coal account.

Stationary "plants," locomotives and even tug-boats are being fitted with smokeless furnaces which increase boiler capacity and reduce fuel bills; and a Hamburg-American steamer recently arrived at New York, "fitted with furnaces that so completely burn the coal and all the products of its combustion that it requires 30 per cent. less fuel to run it than would be required with ordinary furnaces, and no black clouds pour from the funnels and no cinders fall upon the decks."

Promise of further minimizing of the smoke evil is also to be found in the increasing utilization of the petroleum oils, hydraulic power, compressed air, electricity and gas for manufacturing and even domestic purposes. "Petroleum bricks" are manufactured in France, concerning which DR. C. W. CHANCELLOR, formerly Secretary of the Maryland State Board of Health, now U. S. Consul at Havre, reports that: "Trials of these bricks as fuel have been made at

Marseilles on several tugs, and it is found that, weight for weight, they develop three times as much heat as the ordinary coal and leave no ashes. It is expected, with some slight change in the furnace, to arrive at still more perfect results, not only in the increased heat, but in the entire suppression of smoke and on the most economical basis, one kilogram of the bricks being equal to four kilograms of coal."

Railroad companies, driven thereto by the coal famine, are equipping their locomotives with petroleum-burning devices; hydraulic power on the most stupendous scale is being developed for the production of electricity, and the use of this agent and of gas for household cooking and heating is daily becoming more common. It is, probably, to these that we must look for our greatest measure of relief from the evils to health and happiness which the smoke nuisance now inflicts.

The beginning of the twentieth century should be ushered in with a total absence of the fuliginous canopy which hangs over these closing years of the nineteenth.

CORRESPONDENCE.

Editorial Correspondence.

GALESBURG, ILL., May 28, 11 P.M.

The ASSOCIATION train left Chicago via Santa Fe line promptly at 5 P.M., May 28. There were ninety persons on board bound for San Francisco, as follows:

J. A. Work and wife, Elkhart, Ind.; Dr. L. Duncan Butkley, New York; J. B. Roberts, Philadelphia; C. C. Roberts and wife, Philadelphia; Miss Roberts, Philadelphia; Mrs. A. L. Massey, Philadelphia; Miss Massey, Philadelphia; Miss Willard, Philadelphia; Alonzo Garcelon and J. A. Donovan and wife, Lewiston, Me.; Allen Pierson and wife, Spencer, Ind.; Mrs. C. A. Garcelon, Chicago; H. McColl, Lapeer, Mich.; Geo. Davenport, East Randolph, Vt.; C. S. Talbot, Chicago; G. W. Jenkins, wife and daughter, Kilbourn City, Wis.; John L. Crofts, Little Falls, N. Y.; Mrs. Katherine E. Evans and Miss S. E. Clark, West Brattleboro, Vt.; H. D. Holton and wife, Brattleboro, Vt.; C. F. Jenne and wife, Brattleboro, Vt.; Joseph Eastman and daughter, Indianapolis, Ind.; C. W. Foster and wife, Deering, Me.; Ellis Phillips, wife and daughter, New Haven, Pa.; E. B. Lyon and wife, New Britain, Conn.; G. A. Shelton and wife, Shelton, Conn.; Jos. E. Root and wife, Hartford, Conn.; John P. Sharer, Little Falls, N. Y.; B. O. Reynolds, Lake Geneva, Wis.; Foster Pratt, Kalamazoo, Wis.; A. E. Remick, Chicago; F. C. Echeiman and wife, Elkhart, Ind.; E. J. Senn, Chicago; Geo. Perkins and wife, Somers, Ky.; H. M. McKenzie, Elwood, Iowa; L. C. Stephens, Blackville, S. C.; H. M. Starkey and wife, Chicago; E. F. Ingals, wife and two children, Chicago; John B. Hamilton, Chicago; W. E. Quine and wife, Chicago; H. O. Worden, Pittsburg; G. W. McNeill, Pittsburg; Thomas J. Gallaher, Pittsburg; E. H. Small, Pittsburg; D. W. Graham and wife, Chicago; Thos. E. Cunningham, Cambridge, Mass.; Jerome Cochran, Montgomery, Ala.; A. H. Cook, Chicago; E. E. Montgomery, Philadelphia; H. V. Würdemann and wife, Milwaukee; G. Benson Dunmire and wife, Philadelphia; D. R. Brower, Chicago; S. S. Bishop and wife, Chicago; Edmond C. Ingalls, Oak Park, Ill.; E. Willa Kellogg, Milwaukee; E. J. Bush and wife, Platteville; Mark Rowe and wife, Redmon, Ill.; C. E. Cook and wife, Mendota, Ill.; Frank Woodbury, Philadelphia; Harriet Garrison, Dixon, Ill.; J. D. Cotton, Marietta, Ohio; J. T. Cotton, Charleston, W. Va.

Thanks to the thoughtful care of Superintendent Garcelon, of the Pullman Palace Car Company, every comfort was provided. Handsome cars, elegant equipment, and a magnificent Santa Fe dining car, made up one of the finest trains ever pulled out of Chicago. Dr. Donald McLain's special car with a party from Detroit, were at the Chicago depot when we left. Dr. Mulheron, Dr. Stoner, M. H. S., and others were of this party. All regretted it when our train left the depot without them, but as two more Pullmans with delegates from the Southeast were expected to join our train at Burrton, Kan., the railway officers announced that they could not take them, but they may join us at Kansas City. The weather is fine, and so far the trip has been without incident. All were happy in anticipation of a pleasant journey.

JOHN B. HAMILTON.

The Difference between the Copyrights on Medical Books and the Patents on Mechanical Appliances.

DETROIT, MICH., May, 1894.

To the Editor:—In the *Medical News* for May 19, our esteemed friend, Dr. Gould, states his view of the difference between the copyrighting of medical books and the patenting of mechanical appliances. Thus he says, "one is payment for instruction, while the other is tribute for permission to use a certain instrument."

The fallacy of this statement is evident. Granted that the book instructs, does not the instrument also instruct? The buyer of the book pays for the brain work of the author, and in like manner the buyer of the mechanical appliance pays for the brain work of the inventor. If both are good articles they will both instruct the profession who use them. Both are teachers. Most medical books introduce into their pages the work of inventors of mechanical appliances, and even introduce cuts of the same. It is said that the book copyright does not set up a monopoly. It is well that this is not believed, else some person would have to pay damages for publishing books without the permission of the person who copyrighted the same. Every physician knows that a medical book is a monopoly to the full extent of the protecting law under which it is issued.

We are surprised that the claim is made that the patenting of an instrument prevents the buyer from being instructed by the same. Every person knows that the sale of such mechanical appliances depends upon the instruction of the profession respecting their uses. Every mechanical appliance of merit is a great educator to the entire profession, even in lines outside of its especial adaptation. It seems perfectly evident that both good books and good mechanical appliances alike teach the medical profession new ideas or old ones in new applications. Bad books and bad instruments also teach by their negative qualities. We are of the belief that the giving of both author and inventor the right to avail themselves of their rights as citizens, in the matter of copyrighting and patenting the products of their brain activities, would promote equity between physicians and advance the general prosperity of the entire profession.

We have searched in vain in all directions for reasons for denying the inventor of mechanical appliances what is granted the medical book writer. We can find absolutely none. It were tardy justice to grant the former his legal rights at this late day, but tardy justice were better than continued injustice.

LEARTUS CONNOR, M.D.

NECROLOGY.

E. S. ELDER, A.M., M.D., President-elect of the Indiana State Medical Society, and for fourteen years past its Secretary; Dean of the Medical College of Indiana and Professor of Practice and Principles of Medicine in the same college; late member of the State and of the City Boards of Health; member for ten years past of the Clinical Staff of the City Hospital and City Dispensary; member of the Indiana Academy of Science; member of the American Medical Association; late President of the Mitchell District Medical Society, and of the Shelby County and Rush County Medical Societies; a Knight Templar and a thirty-second degree Scottish Rite Mason, Steward and Elder in the Central Avenue M. E. Church of Indianapolis; Business Manager of the *Indiana Medical Journal* and examiner for various insurance companies, died in Indianapolis May 19, 1894, of peritonitis following intestinal obstruction. Dr. Elder, it will be seen, filled a large place in Indiana medicine. He was a self-

a second circular be sent out warning ladies against long dresses and advising them to have their skirts cut sufficiently short to avoid all danger of contagion. These gentleman, the son of a physician, Dr. S. F. Elder, of Hillsborough, Ind., where Dr. Elder was born in 1841, of English ancestry. At 18 years of age, Dr. Elder was a school teacher. During the war he was Provost Marshal for the 6th District. He graduated from the Medical College of Ohio in 1867, practiced in Morristown until 1875, when he attended lectures in Bellevue Medical College, New York, taking the degree in 1876. He then located in Indianapolis where he practiced to within two weeks of his death. Dr. Elder was a born organizer and so became a valued member of every society and enterprise with which he was connected. He was particularly prominent in the State Medical Society and knew by name and sight nearly every one of its 1,200 members.

ALFRED A. LUTKINS, M.D., of Jersey City, died May 9, aged 68 years. He was a retired practitioner of wealth and social prominence. He was a licentiate of the New Jersey State Medical Society of 1848, and an M.D. of the University Medical College in 1878. During recent years he gave up practice except among his oldest clients.

GEORGE W. BROWN, M.D., Secretary of the New Jersey State Medical Board, and whose home is at Long Branch, died on May 12 of consumption, at the Trenton House, Trenton, N. J., where he had been a guest since January 22, last. He was 36 years old, and was graduated at the College of Physicians and Surgeons in the class of 1879.

WILLIAM B. DOOSON, M.D., who for several years has been known as the oldest living graduate of Jefferson Medical College in Philadelphia, died in that city on May 11. He was 93 years old. Although the greater part of his practice was in the South, where he had lived since his graduation from college, he was recognized by physicians generally as an authority in operative surgery. The date of his diploma was the year 1834.

ROBERT FULLER, M.D., of Schenectady, N. Y., died May 9, of pulmonary tuberculosis. He was 72 years of age, a graduate from the Albany Medical College, dating from about fifteen years ago. He was a graduate in arts at Union College, class of 1840.

W. C. WILLIAMS, M.D. of Cheshire, Conn., May 21.—Thomas Wilkinson, M.D., of Ann Arbor, May 26. He was a graduate of the Vermont Medical College, and served in the War of 1812. He was 95 years of age.

BOOK NOTICES.

Medico-Chirurgical Transactions.—Published by the Royal Medical and Chirurgical Society of London. Vol. vii, (second series) London: Longmans, Green & Co. 1893.

The transactions of this Society, always of interest, have this year a melancholy attraction in the last presidential address of the late Sir Andrew Clark. A curious custom of the Society is one which condemns its President each year to read in full the biographical notices of the deaths of members. This year, Sir Andrew objected to the custom, which he notwithstanding complied with. In America the duties of preparing necrology reports are relegated to a special committee, whose report, the reviewer is bound to add, is usually read by title, and the members read the notices in the Transactions. The papers in this volume include: I, Amputation for Diabetic Gangrene, by Rickman J. Godlee; II, on The Advantages of an Amputation Through the Thigh, either as a Preliminary Operation to, or in some Cases, instead of, Amputation through the Hip, where the Joint is itself Diseased and the Patient in very bad Condi-

tion, by H. G. Howse; V, The Radical Treatment of Severe Talipes Equino-Varus, by Edmund Owen; XX, Use of Atropin in Cholera, by T. Lander Brunton; and XXI, A Case of Malignant Disease of the Thyroid Gland with most Unusual Course, by Felix Semon. All the papers are interesting, and the volume as a whole most instructive.

Transactions of the Forty-eighth Annual Meeting of the Ohio State Medical Society held at Put-in-Bay, June 28, 29 and 30, 1893. Cincinnati, 1893.

The particular feature of interest in this report is the address of the President Dudley P. Allen, M.D., on the History of Early Legislation and Societies in Ohio. From this report it is learned that the first State Society of Ohio was "the result of an Act of Assembly," passed January 14, 1811. A medical practice Act was also passed at that session, and in 1812 an Act to incorporate medical societies was passed and the State divided into seven medical districts. The chief function of the State Society was to regulate the practice of medicine and to supervise the district societies. An interesting account of the work of the societies is given in the paper, and at the meeting of 1837 is a paper by Dr. Willard Parker, then of Cincinnati. The present Society was formally chartered on Washington's birthday, 1848, although for some years it had been in existence. The paper contains much of historical interest. There are many interesting papers on medical and surgical topics, and the volume is highly creditable to a Society already distinguished by the high scientific value of its papers and discussions.

The Diseases of the Will. By TH. RIBOT, Professor of Comparative and Experimental Psychology in the College of France, translated by Merwin-Marie Snell. Pp. 134. Chicago: The Open Court Publishing Co. 1894. Price 75 cents.

This interesting little book will be of interest to all alienists. There are five chapters. Chapter I is on Impairments of the Will—Defect of Impulse; Chapter 2, on Excess of Impulse; Chapter 3, on Impairment of Voluntary Attention; Chapter 4, The Realm of Caprices; Chapter 5, The Extinction of the Will, and a Conclusion. The book is interesting, original and scientific. The translation is an excellent one.

Essentials of Anatomy, including the anatomy of the viscera, arranged in the form of questions and answers, prepared especially for students of medicine. By CHAS. B. NANCREDE, M.D. Pp. 388. Fifth edition. Philadelphia: W. B. Saunders.

When a book has passed to its fifth edition, it has passed beyond the reach of the reviewer, for it is then evident that it has found an appreciative public.

PUBLIC HEALTH.

Contagion of Influenza.—Investigations of the epidemic of influenza, or "grip," which has prevailed during the last four years, have adduced an overwhelming mass of evidence in proof of the contagiousness of the disease. The English commission concludes that it is not infectious in the sense that it is conveyed through the atmosphere, although the contagion is carried in the breath of the patient; but, like some of the exanthemata, it requires contact or intimate proximity with those afflicted, for its spread. The preventive lesson is obvious.

Osculatory Contagion.—The Sanitary Committee of the Orange, N. J., Board of Health, has recommended that a circular be issued to the people "urging every one to desist as much as possible from kissing, as the touching of lips is likely to convey contagion; one of the persons might have disease germs in the throat and communicate them to the other." It was also proposed by the same Committee that

men are inviting destruction. The exercise of sanitary authority is none too well liked at best; when it excites ridicule its days are numbered. The advice against long dresses might be defensible if it were necessary; as a matter of fact, women whose health is worth preserving don't sweep the streets with their dresses. As for the other proposition—that may be safely left with the young people of both sexes.

Epidemic Diseases.—The usual seasonal lull has set in with respect to smallpox. There are still occasional new cases in the infected districts, as there will probably continue to be in diminishing numbers, during the summer months. To what extent the contagion has been destroyed in the cities and places thus far visited and what amount of vaccinal protection has been secured as a result of the recent "smallpox scare," will be learned upon the advent of cold weather next fall. For whatever the figures are worth, reports show an enormous amount of vaccination performed during the past few months. The Chicago Health Department, for instance, reports: Number of vaccine points used between Dec. 1, 1893, and April 30, 1894, 321,400; number used between May 1 and May 31, 1894, 449,000; total used between Dec. 1, 1893, and May 31, 1894, 770,400. At present the Department is using an average of 14,500 points per day, and attributes the recent reduction in the number of new cases to this work. For the first seventeen days of May the daily average of new cases in the city was 30; during the rest of the month, and notwithstanding the low temperature, the daily average was 11—a reduction of 61.7 per cent.

Asiatic cholera seems to be still spreading in Western Russia, but elsewhere in Europe there are no authentic accounts of its existence. It is now exceedingly doubtful if the Lisbon outbreak was really Asiatic cholera. Drs. Pestana and Bettencourt have presented their report to the Portuguese government, in which they assert that the bacillus which they discover in the discharges of the patients is identical with that found in the Lisbon drinking water, but is not the same as that to which Prof. Koch and other bacteriologists ascribe Asiatic cholera. It is certain that the low rate of mortality reported in the Lisbon epidemic is not that of the fatal Indian pestilence. The Spanish government, whose commission unhesitatingly pronounced the disease to be Asiatic cholera, still continues quarantine precautions, not only on the Portuguese frontier but against certain French ports, the latest being the town of St. Nizaire at the mouth of the Loire, a port doing considerable business with Mexico and the West Indies. The existence of cholera at Villa Real is officially denied.

Yellow fever, which has been epidemic at Rio de Janeiro during the past three months, is reported decreasing in the number of cases and in virulence. A steamer from Rio, April 13, arrived at Trieste, Austria, May 26, having lost her captain and four other officers from yellow fever during the voyage.

Railway Sanitation.—Recent investigations, both in this country and abroad, into the contagiousness of the dust and atmosphere in railway coaches, have awakened new interest in the subject of the sanitation of railway travel, first agitated by the late Dr. Rauch many years ago. In this country many State Boards of Health now exercise a supervision of railways in this direction, and enforce cleanliness about stations, the proper disposal of excreta, a pure water supply and frequent inspections of depots, buildings, outhouses, grounds, feed yards, cattle pens, etc., in order to discover and correct unsanitary conditions.

In the sanitation of trains the following points are insisted upon:

"Purity of water furnished passengers for drinking; not only should its source be closely scrutinized, but the after care of it should be kept in mind. In this connection attention is called to the disgusting and dangerous method in vogue for supplying water tanks with ice. Where these tanks are charged from the top, the ice, after it is broken to suitable size, is handled at least twice by men with dirty, begrimed and possibly infected hands; where the ice is

brought into the cars, by the dirty hands of at least one workman. This practice should be broken up, not only for the sake of cleanliness, but because there is real danger of infecting the water supply of trains. Water tanks should be thoroughly cleaned at frequent intervals, and scalded inside.

"Passenger cars should be kept in the cleanest possible condition. The practice of sweeping and dusting cars en route when occupied is reprehensible; it is most disagreeable to passengers, and should be stopped, as the dust so raised may oftentimes be infected. Instead, they should be cleaned by damp mops and cloths.

"Each car should be provided with a reliable thermometer, and conductors should be instructed to keep their cars heated in winter or cool weather not above 70 degrees nor below 60 degrees F. Conductors should also be required to pay special attention to the ventilation of their cars. Urinals and water-closets should be thoroughly cleaned, and flushed with a disinfectant solution at the end of each trip. The floors of water-closets should be mopped with a disinfectant solution."

Causes of Smallpox Epidemics.—In answer to a request from one of the editors of the local press, for information concerning the smallpox epidemic, Dr. A. R. Reynolds, Health Commissioner of Chicago, has furnished a lengthy paper, which is, in effect, an argument and an appeal for continuous and general vaccination, as applicable to the country at large as to the city of Chicago.

The questions which Dr. Reynolds essays to answer are as follows: "What were the causes of this outbreak? Were they avoidable? Have the proper measures been enforced to arrest the progress of the outbreak? What is necessary to prevent a recurrence of such outbreaks? What are the prospects for the immediate future?"

Such passages in the answers to these questions as are of general interest are here given:

1. As to causes: It is unfortunately the fact that in this country general vaccination is secured only through the immediate dread of smallpox, as during a widespread outbreak of the disease—a so-called "epidemic." The last general vaccination, not only in Chicago, but throughout the United States, was during the epidemic of 1881-3. About ten years prior to that—namely, during the epidemic of 1871-4—vaccination was also general, as it was during the epidemic following the close of the civil war. In the intervals between these periods smallpox occurred only sporadically and caused little or no alarm. In the absence of this menace, vaccination was neglected until another general outbreak caused it to be resorted to.

While it is incontestably true that vaccination secures immunity from smallpox in an immense majority of cases, it is also true that the degree of susceptibility of the smallpox contagion varies with the individual. This is shown by the fact, observed long before the days of Jenner, that while, as a rule, one attack of smallpox secures against a subsequent attack, nevertheless there are persons so susceptible to the contagion that they are attacked a second or third time or even oftener.

What is true of these exceptions to the rule that one attack of smallpox is a preventive of a subsequent attack is also true of vaccination—with this additional limitation: That the protective power of vaccination is impaired by the lapse of time in a large number of individuals. As the result of experience and observation the best authorities have fixed the period of five years as the practical limit beyond which it is not safe to rely upon a given vaccination.

During the intervals between these general vaccinations there is a steadily increasing number of individuals susceptible to smallpox, made up of those born during the interval and not vaccinated, of those in whom vaccination has lost its protective power and of unvaccinated immigrants and others coming into the community. Added to these are the hypersusceptible individuals whom neither repeated vaccinations nor a previous attack of smallpox will protect.

The first cause, then, of the present outbreak, was a ten years' aggregation of individuals susceptible to the smallpox contagion and the second cause was the introduction of the contagion—the application of the spark to the magazine.

2. Were these causes avoidable? In the absence of general and continuous vaccination—no. Without such stringent governmental control of the individual as obtains in some European countries, vaccination can not be made com-

pulsory, except during an alarming prevalence of smallpox—when, indeed, vaccination becomes voluntary and not compulsory.

In this country the extent of the vaccinal protection of a community is the measure of its intelligence. It is not the better sanitary environment of our best residence districts alone that secures practical immunity from smallpox to their inhabitants; it is their active appreciation of the virtue of vaccination. The disease is as virulent and as deadly to-day among the vaccinally unprotected of all classes as it was before the discovery of Jenner, when the pock-marked face, the hideous deformity of eye and nose, and every feature, was as common among the nobility as among the denizens of the slums.

And here lies a duty of the public press: To exploit the value of vaccination and to urge its general and continuous enforcement. If it is not generally and continuously enforced, there is only one other method of preventing the recurrence of smallpox outbreaks whenever the aggregation of unprotected is great enough. That method consists in the maintenance of a non-intercourse quarantine against any infected place when the disease appears in this country. This is impracticable. There have been, since this epidemic began, a total of twenty-five States affected, exclusive of Canada and Mexico. . . . Under the circumstances and conditions the outlook was clearly unavoidable. . . .

4. What is necessary to prevent a recurrence of such outbreaks? . . . Only by general and continuous vaccination can any community hope to escape outbreaks of smallpox. It is one of the oldest known diseases afflicting mankind; it is one of the most widely diffused, being epidemic in Africa and thence carried by commerce to every quarter of the globe; it is one of the most virulent and one of the most persistently contagious of diseases. Therefore we are likely to have its contagion, like the poor, always with us; and wherever the contagion finds a sufficient number of susceptibles there will be set up an epidemic outbreak.

The only known means to prevent such a disaster is by preventing the aggregation of susceptibles, and that this can be done by general and continuous vaccination is a demonstrated fact. It has been abundantly proven that just in proportion as vaccination is efficiently and properly performed—which implies its necessary repetition—it markedly diminishes mortality from smallpox; it renders smallpox a mild disease as compared with the disease in the unprotected; it is an almost absolute security against death from smallpox. And, on the other hand, it is just as incontestably proven that (in the words of the eminent English sanitarian, John Simon): "Wherever vaccination falls into neglect, smallpox tends to become again the same frightful pestilence it was in the days before Jenner's discovery; that wherever vaccination is universally and properly performed smallpox tends to be of as little effect as any extinct epidemic of the Middle Ages."

MISCELLANY.

The Board of Health of Dubuque, Iowa, have decided to burn the present building used as a pest house and to establish a new one on a boat in the river.

Gifts to Hospitals.—The will of William F. Sayles, of Pawtucket, R. I., includes bequests of \$16,000 each to the Rhode Island Hospital and to the Rhode Island Homeopathic Hospital. These donations are to take the form of endowments of free beds, which will in perpetuity bear the names of the members of his immediate family.

The Red Parasol.—The fashionable "fad" of the red parasol is now defended on the ground that it is an efficient freckle preventer—the actinic rays of the sun, which it is claimed are the cause of the pigmentation, being intercepted in passing through a red medium. The swell practitioner will not neglect this obvious hint; he will see to it that the ephelidal disfiguration is duly prevented—whenever the ruddy hue suits the complexion.

Every Soldier His Own Surgeon.—It is now predicted that the wounded in the next war will be largely left to their own resources, because the surgical service has become so unwieldy that it must be greatly reduced. Archibald

Forbes, the famous war correspondent, grimly sums it all up in the phrase: "Væ vulneratis!" Color is lent to this view by the fact that the British war office is considering a proposition that all soldiers be instructed in the elements of anatomy and physiology in order that they may be able promptly to stop the flow of blood from a leading artery. The proposer of the scheme also offers the suggestion that every soldier shall have the leading arteries mapped out on his body by dotted lines tattooed in India ink.

Scientific Cooking.—Not content with her activity in other directions, the advanced woman is invading the doctor's realm by efforts which, in the measure of their success, must rob the profession of a lucrative class of practice. She proposes to abolish dyspepsia by substituting scientific cooking for the ignorance which now rules the American kitchen, and is setting up "Rumfords" in universities, colleges and academies all over the land. In Boston, which is, as usual the center of this new crystallization of social forces, she has just held an exhibition of household economics, of which a feature was the practical demonstration, as given at the World's Fair last summer, of cooking by electricity, the plant consisting of oven, chafing dish, coffee pot, tea kettle, broiler, saucepan and hot plate. At this exhibition Edward Atkinson's Aladdin oven—the oven of the lamp—was also exploited as an instrument that the cook of to-morrow will not be able to do without.

Journalistic Enterprise.—Under this heading the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION says: "We congratulate our esteemed contemporary, the *New York Medical Record*, on its cable reports of the Eleventh International Medical Congress. The first instance of the kind, we believe, attempted in American medical journalism." While thanking our esteemed contemporary for these kind words of appreciation, we beg leave to say that is not the first instance of the kind, for a reference to the files of the *Medical Record* will show that cabled reports of the Copenhagen meeting in 1884, and of that in Berlin in 1890, were also presented to our readers.—*N. Y. Medical Record*.

A New Device.—Dr. Byron Robinson, of Chicago, announces a new device for intestinal anastomoses. It consists of two metal discs around whose circumference there is a groove. In the groove is placed a hollow rubber tube. The two discs are clamped together with a ratchet or spiral screw. The principle on which the device works is the same as Denny's cylinders. The gut is gradually necrosed through by slow elastic pressure. The rubber, tube and pressure can be so controlled that the circular line of union may be of determined width. The elastic pressure avoids lateral fistula from too rapid or too violent force. The device is called the "rubber-faced disc."

The Nuisance of Carpet Beating in Populous Sections.—One of our contemporaries has the following suggestion as to carpet-beating in cities: "We have often been asked by citizens how articles to be cleaned should be treated without beating, and we beg to suggest that if they were spread upon the grass and thoroughly swept with a stiff broom moistened with water with which a little ammonia has been mixed, the object would be most thoroughly accomplished and one of the most dangerous and disagreeable nuisances to which our citizens are now subjected entirely abated. Articles of clothing should be hung upon a line and brushed with a hand-broom treated in a similar manner." In the country, it matters not about the shaking out of household filth, such as is deposited by myriad footsteps, but in cities the matter becomes a nuisance, dangerous and detrimental to the public health. This latter statement is embodied in the sanitary code of more than one of our cities many years ago, and long prior to the introduction of bacteriologic considerations. From the point of view of the bacteriologist, the wisdom of having a distinct prohibition against the reckless distribution of house-dust is undoubted. There is no record yet made up as to the exact numerical proportion of pathogenic germs, but we are prepared to take sides with those who hold that one of the filthiest things in nature is the dirt beaten out of a dirty carpet.

Royal Invalids.—So momentous are the events, affecting the lives of millions, that hinge upon the state of health of a few personages in Europe, it is no wonder that the condition of a royal larynx, the neuralgia of an imperial tympanum, or the sequelæ of an attack of grip in a monarch should be the perennial themes of speculation and the occasions for sensational utterances. "Caligula, a Study of the Madness of a Roman Cæsar," is the latest contribution to the literature of sick royalty. Claimed now to be a purely historical study, it has been denounced in Berlin as a scandalous document, intended to prove the Emperor William insane, and journals have been confiscated for attempting to give it publicity.

In the pamphlet, Caligula had inherited epilepsy from Germanicus, his father, a Crown Prince and popular soldier who suffered from an insidious disease that eventually carried him off. This is intended, it is asserted, for Emperor Frederick, while the grandfather, King William, is depicted under another pseudonym, and Bismarck figures as Marcus, a great statesman who had served Caligula's father and grandfather successfully and faithfully in building up a great empire only to be banished when Caligula ascended the throne. "The Emperor's traits are accurately portrayed—his deformity of limb, his affection of the middle ear, his attacks of *petit mal*, his insomnia, feverish activity, fondness for military and naval display, even to his peculiarities of speech and drastic paraphrases of classical quotations.

While the pamphlet has not been seized and its author has not, as yet, been molested, the publication has caused such a profound sensation that an authoritative statement is made that "Emperor William is in better health, mentally and physically, than ever before; that for eighteen months he has not suffered pain in his neuralgic ear, and for a year he has not been troubled with insomnia; that his face is fuller and browner than ever, his stride is quick and springy, and his greetings to the people always betray good spirits." Whereupon the *quid nuncs* murmur:

"Methinks the lady doth protest too much."

Meanwhile, it is well known that King Humbert, of Italy is afflicted with cancer of the larynx, almost identical, as to location and character, with that of the late Emperor Frederick, William's father,—the disease of which Gen. Grant died and which carried off the British Ambassador at Rome last year. And as a sequela to his recent attack of the grip, Alexander III, Emperor of Russia, has developed symptoms of a permanent affection of the lungs so serious in its nature as to render necessary a change of the imperial residence to Kiev, where the climate is more favorable than at St. Petersburg.

Philadelphia Notes.

THE TRUSTEES of the Jefferson Medical College held a meeting May 21, when they discussed the question of re-organization, and the appointment of a Provost, as proposed by the Alumni Association, and decided to postpone further consideration to a subsequent meeting. The next regular meeting will be held in September when final action will probably be taken. The impression is that the Trustees are averse to making this change of management. Dr. S. MacCuen Smith was elected Clinical Professor of Otolaryngology; W. Joseph Hearn, Clinical Professor of Surgery; and E. P. Davis, Clinical Professor of Obstetrics.

EXPEDITIOUS EXAMINATION OF SPUTUM FOR TUBERCLE BACILLI.—The following method is followed in the laboratory of the Medico-Chirurgical College, by Prof. Laplace:

1. Apply a small speck of recent sputum to a cover-glass, spread it out thin, and let it dry by waving it to and fro in the air.
2. Slightly heat the cover by passing it through the flame of an alcohol lamp, three times, rather slowly.
3. Stain the portion of now thoroughly dried sputum by

pouring upon it a few drops of the red stain (Ziehl's solution, composed of fuchsin, 1 part; carbolic acid, 5 parts; alcohol 10 parts; water, q. s. to make 100 parts). While the solution is on the cover-glass, hold it in the flame of the lamp and heat until the vapor rises.

4. Decolorize at once, by immersion in water acidulated with nitric acid.
5. Pour some alcohol over it, and finish decolorizing by repeated immersions in the acidulated water, if required.
6. Pour some distilled water over the specimen and wash it until clear and apparently colorless.
7. Color the background by staining with methylene blue solution.
8. Dry the specimen.
9. Apply to slide and mount in Canada balsam.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from May 19, 1894, to May 25, 1894.

- Major PETER J. A. CLEARY, Surgeon, is granted leave of absence for four months.
- Capt. WILLIAM G. SPENCER, Asst. Surgeon, having been found by an Army retiring board incapacitated for active service, will proceed to his home.
- Lieut.-Col. FRANCIS L. TOWN, Deputy Surgeon-General, is relieved from temporary duty in the office of the Medical Director, Department of the Missouri, and will report in person to the Commanding General, Department of Texas, for duty as Medical Director of that Department.
- Capt. ALONZO R. CHAPIN, Asst. Surgeon, is relieved from duty at Ft. Hancock, Texas, and ordered to new Ft. Bliss, Texas, for duty.
- First Lieut. FRANCIS A. WINTER, Asst. Surgeon, is relieved from duty at new Ft. Bliss, and from temporary duty at old Ft. Bliss, Texas, and ordered to Ft. Hancock, Texas, for duty at that post.
- Capt. GEORGE MCCREERY, Asst. Surgeon, will, upon the abandonment of Ft. Sidney, Neb., report in person to the commanding officer, Ft. D. A. Russell, Wyo., for duty at that post.
- Capt. ROBERT R. BALL, Asst. Surgeon, is relieved from temporary duty at Ft. Monroe, Va., and ordered to Ft. Adams, R. I., for duty, relieving Capt. WILLIAM C. BORDEN, Asst. Surgeon. Capt. BORDEN, on being thus relieved, is ordered to Ft. Snelling, Minn., for duty at that post, relieving Capt. CHARLES F. MASON, Asst. Surgeon. Capt. MASON, on being thus relieved, will report in person to the Superintendent of the U. S. Military Academy, West Point, N. Y., for duty at that post.

CASUALTY.

Col. JOSEPH C. BAILY, Asst. Surgeon-General, died May 16, 1894, while en route from El Paso to San Antonio, Texas, in the line of duty.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending May 26, 1894.

- Asst. Surgeon B. R. WARD, from the Bureau of Medicine and Surgery, and to the "Vermont."
- Surgeon C. A. SIEGFRIED, ordered to the "Cincinnati."

VOL. XXII.

CHICAGO, JUNE 9, 1894.

No. 23.

ADDRESS.

PRESIDENT'S ADDRESS.

Delivered before the American Medical Association at the Forty-fifth Annual Meeting held at San Francisco, June 5, 1894.

BY JAMES F. HIBBERD, M.D., LL.D.
RICHMOND, IND.

Members of the American Medical Association:

A year ago in the great city of Milwaukee, on the shore of the inland sea, it was my privilege to express my surprise and to offer my thanks to the members of the AMERICAN MEDICAL ASSOCIATION for the distinguished honor conferred by elevating me to the Presidency of this paramount Medical Society of the United States, and to-day, in the greater city of San Francisco, within sound of the surf on the eastern shore of the wide Pacific Ocean, I rise to iterate the expression of my appreciation of the honor bestowed and again to extend thanks therefor.

We are assembled here this morning to open the forty-fifth annual meeting and celebrate the forty-seventh anniversary of the organization of the American Medical Association; to continue the noble work it has successfully prosecuted all the years of its existence; to commune professionally and declare the progress of medicine during the association year just ending; to fulfil the service of the present Association program and to arrange for a fresh one for our successors; to greet old friends and to make new acquaintances. And we come to our duty this morning with buoyant spirits, invigorated by the inspiring scenery we have traversed since leaving our homes, our stay here made prospectively profitable by the scientific menu our program presents, and our social and scenic enjoyment of richest promise through the thoughtful labor and esthetic taste of our efficient Committee of Arrangements, the nature and extent of which has just been rehearsed by its Chairman.

We are not here at the time nominated at Milwaukee. Soon after the adjournment last year, the statement was made that if the meeting this year should be held on May 1, as ordered, time would not be offered State societies to act on the question of the revision of the Code of Ethics as has been recommended by the Association, and change of the date of this meeting was suggested. This sentiment increased and other reasons for the change were added. The pressure growing stronger and more urgent, conferences were held in Washington during the session of the Pan-American Medical Congress. Many consultations were held at other times and places, and much correspondence was had without finding any opposition to the change and accordingly it was made, and published in the JOURNAL of the Association, Nov. 11, 1893.

At every annual meeting the officers of the Association, particularly the Permanent Secretary and the Treasurer, have difficulty in appeasing delegates

who are not received because the credentials presented by them have not been issued by a society entitled to representation in the Association. The law regulating this matter is plain, to-wit: "The delegates shall receive their appointment from permanently organized State medical societies, and such county and district medical societies as are recognized by representation in their respective State societies."

The difficulty lies in the fact that some of the State societies are not representative bodies, and consequently this constitutional provision cuts off all delegates from such States except those commissioned by the State society itself. While this is the letter of the law it is not the spirit that animates the organization of the Association. The Constitution should be revised in this particular at least. There are two ways of overcoming the trouble: 1, strike out the words, "representation in" from the Constitution where it prescribes the qualifications of delegates, leaving all such county and district medical societies as are recognized by their respective State societies fully authorized to commission delegates to this Association. The other and better plan would be for every county society in each State to be represented in its State society. Facile methods of accomplishing this can readily be selected; perhaps the plan of organization so long in successful and satisfactory operation in Indiana might serve as a paradigm. There each county has its society, known by the name of the county, and the State society is composed of all the members of all the county societies. Annually each county society selects delegates to the State society, and at the same time nominate delegates to the American Medical Association who are commissioned by the State society. This simple plan secures substantial autonomy to the county societies and provides for equal representation to the Association from every part of the State. Every member of every county society can attend the meetings of the State society and participate in all business except voting. This seems to me both theoretically and practically adapted to a complete organization of the profession in every part of the Union, and if this Association at this session would formulate a scheme similar in spirit and in terms and recommend it to the consideration of such State societies as do not now have an equally serviceable organization, it would in my judgment be doing a good work, sowing seed that would bring forth sound fruit in the future. In Indiana the State society and each county society is a legal corporation, and while this is not essential to its method of organization of the profession of the State, it is to my mind desirable.

In this connection I desire to lay before you some thoughts touching the arrangement of subordinate medical societies in their relation to the American Medical Association. Every medical man who belongs to any medical society should belong to a

county, or an equivalent medical society, and every member of a county society should be *ipso facto* a member of his State society, and this an *open sesame* to the American Medical Association. By this arrangement all reputable physicians in the United States would be brought together in a common guild, whose power to do good within its legitimate sphere would be limited only by its aggregate wit and energy. Such a consummation would place this Association in a position to fulfill the mission hopefully anticipated for it by its earnest and patriotic founders, and would elevate the American profession to a plane for useful work the highest conceivable for the disciples of scientific medicine.

This would in no wise interfere with the organization of medical men devoted to special lines of practice or investigation; indeed the more of these, and the more special their fields of labor and inquiry, the more rapid will be the development of medical knowledge, the nearer will expert art approach to perfection and the greater will be the blessing to humankind. In these special and limited societies there will be a concentration of thought and labor that will yield results advanced and true to a degree beyond hope from a more promiscuous assembly.

All the adherents of the special organizations will be members of county societies and thereby of their respective State societies, whence, for the asking, they can step through the portals of this Association and find in our Sections a department already organized and at work into which they can enter, each according to his tastes or qualifications, and feel at home among fellow laborers.

A member of either of these special organizations entering the appropriate Section will find himself in the midst of all the members of the Association whose tastes run parallel with his own, whether specialist or general practitioner, and it is this mingling of these sundry classes of investigators and practitioners, exchanging views and detailing experience, that creates the vast stores of profit and pleasure so much enjoyed at our annual meetings. In this scheme for the organization of the American medical profession is there not promise enough to make us hope and labor for its early consummation?

A sentiment was expressed last year at Milwaukee by a member and has, I think, some currency among other members, that indicated a misconception of the character and *personnel* of the Sections as I view them. The sentiment was uttered in a private discussion of the propriety of conferring on the Business Committee the functions of the Nominating Committee, and was substantially this: My colloquist said: "The Business Committee is made up of ex-chairmen of Sections; the Sections are in the hands of specialists; the specialists reside in the greater cities and consequently the Business Committee will be constituted of special practitioners who hail from the greater cities, and some of the cities are great enough to furnish half a dozen chairmen at once. This will not only exclude general practitioners from a voice in the selection of officers of the Association, but may by chance or design place the general business of the Association under the management of specialists from a few of the more important cities of the country." The error of this representation lies in the fact that its entertainers fail to recognize that the aggregate membership of the Sections at each annual session is the total membership of the Association in

attendance. True, in each Section there will be members of the special society whose work is the same as that to which the Section is devoted, and there will be others whose engagements are limited to the same line of practice, but these combined, except in two or three Sections, will not number more than a small minority, probably not a tenth, of those enrolled in the Section; the other nine-tenths will be general practitioners whose professional proclivities have directed them to the Section, and these general practitioners have the power by their votes, the right by virtue of their membership, and the obligation under their duty to the Association, to elect the best man in the Section to its chairmanship without inquiry whether he lives in a big city, a little city or a hamlet, and in so doing will make it patent to every thoughtful mind that the *personnel* of the Business Committee will be selected under conditions to insure as intelligent, as well distributed, and trustworthy a committee as the Association can secure. And moreover the function of a nominating committee is to nominate, not elect; confirmation or substitution is in the authority of, and always exercised by the Association. I am led to present this subject in this light and to this extent, because I feel that a majority of the members recognize the imperfections of our present mode of selecting the Nominating Committee, and realize that the welfare of the Association calls for a committee which has elements of permanence in its organization and whose *personnel* has been selected with something of deliberation.

When Dr. Geo. M. Sternberg was appointed Surgeon-General of the Army in May last, he made two innovations in the administration of the affairs of the office: 1, in establishing an Army Medical School to give passed candidates for appointment to the Army, laboratory practice in bacteriology, sanitary chemistry and other essential instructions for military service; 2, the position of attending surgeon in cities having good facilities for medical improvement be filled with young men who are preparing for promotion.

These changes did an excellent work that was accomplished without additional expense to the Government; the Museum and Library Building furnished the rooms, and the medical officers on duty in Washington did the teaching in addition to their regular work. But the number of active young surgeons about Washington and other cities attracted observation, and led the Chairman of the Committee on Military Affairs to conclude there was a surplus of Assistant Surgeons, and in his report to the House he reduced the number from 125 to 90, thus inhibiting fresh appointments until the number shall be reduced. This recommendation has passed the House, and if it should be approved by the Senate will greatly embarrass the medical service of the Army, and in the end be a serious detriment to the country, because many military posts will have to depend on civil physicians for medical attendance, and in case of war these would not take the field, and the Army would be without trained medical officers, which would be as serious an evil as unskilled officers in any other department. When these facts were pointed out to the Chairman of the Committee by other members with better knowledge of practical military affairs, the Chairman replied that no one outside the Army surgeons had complained, not a single medical society had claimed that any injury would result. Let the American Medical Association at once call

the attention of Congress to the mistake threatened.

Many of you may remember that the last Congress of the United States was about to refuse an appropriation to continue and complete the publication of the Index Catalogue of the Library of the Surgeon-General's office, the venerable Chairman of the House Appropriation Committee alleging that the medical fraternity were demanding too much, in fact had already received more than the lawyers or any other professional guild. This state of affairs becoming a matter of common fame, some physicians interested their representatives in the House by presenting to them the true state of affairs, with the result of a concerted effort being made in the House to enlighten the assembly to the extent of convincing the members that this was not an appropriation for the benefit of medical men, but to complete a great educational work for the benefit of the whole people, the doctors' relation to it being that they must do the work because no other class of men were trained to the service. The appropriation was saved and the catalogue is nearing completion.

But there is still a point in connection with the appropriation for the Library that needs attention, that can probably be better given by this Association than otherwise, and that is the restoration of a part of the appropriation for the support of the Library which was dropped by the last Congress, and the cut continued in the military bill before the present House. For twelve years the appropriation was \$10,000, but the last Congress reduced it to \$7,000, and the present Congress proposes to continue the reduction. Doubtless most Congressmen, and possibly some physicians, regard the Library of the Surgeon-General's office as an ordinary department library intended mainly for the use of the medical officers of the Army, but in truth it is the National Medical Library, open to, and used by, physicians from all parts of the country, and the possibility of finding at one place in this country the greater part of the literature on any medical subject has exercised a powerful influence on American medical literature and education.

The Library aims to obtain every medical book, periodical and report published in any country or language as soon as possible after it is issued, and have it at once catalogued and indexed and made available for use. This requires about \$7,500 annually. There are still between twenty and thirty thousand volumes of medical books, published years ago, required to complete its equipment to meet all calls made upon it. These volumes are out of print and only to be had from second-hand booksellers and auction sales as opportunity offers, and will involve say \$2,500 spent annually for perhaps ten years. Does not this condition of the Library and its support make a demand on this Association for aid, either as an organization or through the influence of its individual members on their respective members of Congress?

The desirability of supervision of public health by the general government has been recognized by this Association for many years and manifested in various ways. Four years ago a committee with Dr. C. G. Comegys, chairman, was appointed to prepare a bill, and petition Congress on behalf of the Association to establish a Department of Public Health with a Secretary for its chief who should be a member of the President's Cabinet. This committee has done

much earnest work, drafted a bill and presented it to Congress, devoted labor and time personally to its advocacy before committees and members of Congress. The committee has been continued, somewhat modified, and has reported annually to the Association and will present an interesting report to this meeting to which I invite your thoughtful attention. Last year the Association appointed another committee with Dr. U. O. B. Wingate as chairman, to consult with a like committee of the American Public Health Association which has for several years been engaged in an effort to induce Congress to enact a law placing the supervision of the public health in charge of the general government. This committee will also submit a report for your consideration.

Other organizations have likewise entered Congress with petitions asking that the general government be clothed with authority to execute such measures as to assist in protecting public health. Much good may be anticipated from the attention these several sanitary organizations will excite, both in the congressional and public mind, and I doubt not that when the agitation has accomplished the valuable result of cultivating a knowledge of what is essential to the public welfare it will lead to a union of effort on the part of all workers that will insure satisfactory results.

My interest in the premises is such that during the year I have sought through personal intercourse and a wide range of correspondence to ferret out the best plan for supervision of public health that we can hope to have Congress crystallize into a working law. Without rehearsing details, I feel free to declare my conviction that enough has been ascertained of the sentiment of the Executive and Legislative Department of the Government to rob us of all hope of the establishment of a Department of Public Health within the remainder of the nineteenth century.

A Bureau of Public Health with a Commissioner as its chief, within one of the existing Departments of the Government was apparently within reach of a united, harmonious, aggressive effort of the profession for a year or two previous to the enlargement of the power of the Marine-Hospital service by the last preceding Congress, but the excellent work of that service at home and abroad since its increase of authority and means, has lessened the anxiety of the Government and the apprehension of the public in such degree as to make those in power less attentive to appeals to do what should yet be accomplished.

The outlook at this time for securing a Bureau of Public Health during this session of Congress is not encouraging, but if the problems in silver, tariff and national revenue should be speedily and satisfactorily solved there might appear a ray of hope for a Bureau within the life of the present Congress, provided the medical and sanitary professions would make common and joint effort in demanding it.

At present there is no measure formulated in this behalf so worthy of support as the New York Academy bill now in the hands of Congress, and in making this declaration I by no means ignore the fact that strong opposition to that bill has been made by strong men; I well know that no important measure like that can be inaugurated without challenging adverse criticism, but my abiding faith in the fitness

of sanitary human nature for great things is such that I harbor no doubt that if the opposition to this bill present a better than it, its friends will accept, and if this bill sustains its present status under severest scrutiny, its opponents will join in urging its enactment into a law and thereby vindicate characters at once wise and patriotic.

While a century of experience has convinced the great body of intelligent people that vaccination is the true and only prophylactic for smallpox, it has not carried conviction to the extent its merits deserve and the welfare of the people demands. The causes of this are not difficult to discern; vaccination and other forms of sanitation have prevented a visitation of the epidemic of smallpox in this country for a generation and the people have lost the fear of its contagion through ignorance of its nature while progressing, and its sequels if its victims survive. Add to this the disorders that sometimes follow the insertion of pure vaccine in a cachectic system and the greater evils arising from the use of spurious or imperfect vaccine and careless vaccination, all open to the observation of the public and subject to amplification by cranks and the maliciously ignorant, and we can not marvel that there is a positive distaste for vaccination among a considerable portion of our population, and a carelessness about securing it on the part of a much larger number. A knowledge of these facts should only inspire physicians and other sanitarians who are the custodians of the knowledge of the value of vaccination to protect from smallpox, as much so as smallpox itself, and that with pure vaccine inserted under proper conditions into the tissues of a person fit to receive it there is positively no shadow of evil, but a promise of good not surpassed by any other single measure of preventive medicine.

Evidence accumulates that the undetermined conditions that conduce to the propagation of smallpox are now, and for at least two years have been, prevalent in this country, resulting in outbreaks of the disease more or less serious in various parts of the country and too often leaving foci from which fresh infection is distributed. Under these circumstances it seems to me the reasonable duty of this Association, at this time, to declare and proclaim its unabated faith in the virtue of vaccine to protect from smallpox, to render persons as immune against variola as an attack of variola itself, and that it is innocent of all mischief when the vaccination is done by a vaccinator who is a competent judge of both the purity of the vaccine and the fitness of the vaccinee.

Let us abide in the hope that the Jenner centennial celebration provided by this Association and to be a part of its exercise at the annual meeting in 1896, may bring out the boundless blessing of the discovery of the immortal Jenner in such wise that all men shall see and acknowledge its protecting power, and even the wayfaring man, though a fool, may not err by further causeless cavil.

Two leading purposes the fathers of this Association had in view at its organization, demanding its serious consideration, were the elevation of the standard of medical education, and that the authority to decide upon the sufficiency of the qualification of a candidate for a diploma should not rest with his teachers.

Much has been done in advancing the extent and character of the collegiate instruction of medical

students; the examination of candidates for diplomas is still conducted by teachers who instructed them as was done then, and is no more satisfactory to the thoughtful minority of the profession now than it was then. Forty-eight years ago, seven professors was the conventional number of the faculty for medical colleges, and the annual term was twenty weeks, and in the two terms required for graduation the students heard the same lectures each year. Now there are medical colleges requiring attendance four years, of seven months each, on graded courses under, in some instances, as many as forty-eight instructors. This for the equipment for graduation, while one post-graduate school announces one hundred and sixty-four instructors. Certainly the Association has ground to congratulate itself on the fruits of its persevering labor to secure more thorough medical education, but this has been the theme of so much of the literature of the Association that I drop the general subject and confine my remarks to one suggestion as to a particular line of instruction.

The progress of medicine in the immediate future must be along biologic lines, and it seems to me desirable that every medical college should have a chair devoted specially to instruction in biology. Within the current year, responding to an invitation to make some remarks on matters pertinent to a lecture on bacteria which had just been delivered, a gentleman of superior culture, of extensive travel and acute observation, a lawyer by profession and a statesman by practice, said that the status of physicians had within comparatively a few years undergone a marked change. In earlier historical times the priests were accounted of highest rank and worth in the civil professions, then came a period when the devotees of statecraft received highest honor and exercised most potent influence in the affairs of men. Physicians held subordinate rank and positions both in war and in peace, but in the last few decades the relations of these professions among themselves, and in their standing before the world, had been undergoing significant change until, from being the lowest, physicians were now rising above the other liberal professions and would steadily move forward until they were accorded the first place among honored people of the world, and this for the reason that they have devoted themselves by rigid scientific investigations to make patent the causes of disease and to determine exact measures for emasculating these causes, and for neutralizing their effects when they had eluded detection or escaped emasculation. My own sentiments accord entirely with the spirit of the views enunciated by the learned gentleman, and my estimate is based on the result of the more exact method applied to the investigation of the laws by which the omnipotent Creator has fashioned the world and continues its government. The microscope in skilled hands, and its revelations compared and classified with scientific acumen, have revolutionized our knowledge of the world of living things below the world of microscopic living things, and in this minor, and, to us, newly revealed world, has been discovered the generators of the most extensive, persistent and malignant epidemics that periodically decimate the earth, as well as many of the most frequent and intractable, and fatal disorders that we have always with us. All this knowledge has been wrought out by the devotees of one branch of biology; and an-

other line of biologic workers have carried us back through the morphology of organs, tissues and cells to the origin of vital activity in protoplasm, and, still more important, in doing so have given us glimpses of the origin and development of the somatic mind that will, when the scheme of nervous organization and function shall be clearly portrayed, dissolve the mystery that has in the past obscured our realization of the true nature of hypnotism, Christian science, and other anomalous neuroses which the sciolists, and in an especial manner those claiming to be doctors, are promulgating and practicing to the discredit of true scientists and the injuring of the ignorant and weak-minded classes.

We should apotheosize protoplasm, the dividing line between inorganic and organized matter, itself at once the result of the law of perpetual motion with which the Creator endowed the atoms of elemental matter, and the beginning of that phase of energy known as vital activity, which, in its development as now presented to us, constitutes the entire vegetal and animal kingdom.

No one people or class of people can claim exclusively to have opened the way into this more primitive arcana of nature. The physicists of all nations, botanists, zoölogists, anatomists, physiologists, and their congeners have all participated in this progress. Schwann and Virchow and Ferrier and Jackson and Pasteur and Kock and Sternberg may be mentioned, without prejudice to the labor, name or fame of their many coadjutors, as examples of what benefactors to our race scientists may become, whose genius lifts them to a plane of investigation not covered by the curricula practiced in the medical school of their day, and their distinction is due to their advanced study of biology.

This review impresses me with the importance of establishing in each of our medical colleges where a finished education is intended, a chair especially devoted to teaching the principles and practice of biology on the lines and to the extent herein indicated, from whose alumni we shall have more quickly arise neophyte Virchows, Pasteurs, Jacksons and Sternbergs, whose labors, when further advanced, shall hasten the day when the world shall recognize the medical profession as the paramount benefactors of the human race, by virtue of suppressing the causes of all preventable diseases and alleviating the suffering, shortening the duration, and lessening the ravages of such as can not be prevented, and with this higher estate of the disciples of Esculapius will come such insignia of real knowledge, such fruit of expert skill, that he who runs may read the lines that broadly separate the true position from ignorant or unscrupulous pretenders.

Amendments to the Constitution are always pending; sometimes many, sometimes few; those submitted the preceding year are disposed of at each annual session, but others take their place for consideration at the succeeding meeting. Few of these are approved by the Association, being lost through failure to receive the support of three-fourths of the delegates present or by not being called up by their authors or others.

Last year a special committee appointed at the last preceding meeting made a report remodeling the entire Constitution which necessarily laid over until this meeting and the committee, being continued, will make further report here and the whole subject

will come up for final disposition at this session. It is apparent to all who have given attention to this matter that there is much feeling among the members who have been active in working up the changes that will be offered as a substitute for the Constitution as it now exists, and also among those who regard the innovation as an evil instead of a benefit. But while these feelings are right and proper in themselves they need not claim other than watchful attention to secure a fair and unbiased expression of the will of the Association, according to the method prescribed by our laws, and in so doing there is nothing to excite passion or interfere with that deliberation that should distinguish the proceedings of an assembly composed of cultured and refined people seeking the welfare of the guild to which they belong. This may readily be done by taking a vote to determine whether the voters present desire any change in the existing Constitution. If this decision is against any change, that is conclusive for the nonce. If the decision of expressing this satisfaction with the Constitution as it is, the next question should be, Is the report of the committee of revision precisely what the voters want as a substitute? An affirmative vote here settles the matter, and a negative will call for amendments that will adjust either the existing Constitution or the committee's substitute until it conforms to the wish of the delegates. Is it not palpable to every considerate mind that all this may be done without excitement of any kind and with a minimum waste of time of the Association?

And so, too, with our Code of Ethics. For many years there has been a feeling among many most excellent and intelligent working members of our guild that the Code did not fairly accord with the demands of the advanced profession in their intercourse with each other, nor with the proper reciprocal relation between the profession and the public. While on the other hand, many members equally intelligent and devoted to the Association, have felt that the Code of Ethics that has guided the Association through nearly half a century prosperously and honorably, and still is a reliable guide in every advanced thought and action, can not be bettered for our present status, and should not be disturbed. At Detroit, in 1892, this agitation culminated in the appointment of a committee to inquire into the expediency of revising the Code. This committee last year submitted two reports, the majority recommending an amended Code, and indicating the lines on which emanation should precede. The committee was continued to complete its labor, and the fruit of its service will be before you in an extended report. The minority report claimed the sufficiency of the Code as it is, and recommended that it be left intact. Here also, even more than with remodeling the Constitution, there is much warmth of feeling, and as in that case a little calm forethought will convince that a primary vote involving the question whether or not the voters want any alteration of the Code may end the consideration of the subject without excitement, confusion or overwarmth of feeling, by a decision to let the Code stand as it is, and the contrary decision will call for such further procedure as recited for the completion of an amended Constitution, and in this as in that, the work should be done as intelligent and fair-minded citizens transact important business, with decorum and without waste of time.

Touching the sufficiency of the Constitution and Code of Ethics of the American Medical Association, as they are now, I have well-settled convictions, the result of many years of observation, experience and reflection, but I am not here to proselyte to my opinions; as I interpret my mission on this occasion it is to exercise my influence and use my authority to secure to those here entitled to vote, a clear, untrammelled judgment, and to encourage a cheerful acquiescence of all parties in whatever conclusion may be thus reached. Shall I not have the cooperation of every friend of the American Medical Association present in this laudable effort?

ORIGINAL ARTICLES.

A CLINICAL STUDY OF THE SO-CALLED REFLEX NEUROSES.

Read before the Chicago Medical Society, June 4, 1894.

BY H. GRADLE, M.D.
CHICAGO.

Observations gathered mainly during the last fifteen to twenty years by numerous authors have shown that there are many nervous ailments which owe their origin to a minor local disease or anomaly in some part of the body. Yet this subject of reflex neuroses has neither received adequate recognition in general text-books, nor has it been fully appreciated by the profession at large. The interest of such a subject to the general practitioner depends upon the frequency of these ailments. In this respect views differ widely.

Ophthalmic and rhinologic observers have, perhaps more than any other, contributed to this subject and their reports abound in instances of this kind. Indeed some specialists no doubt exaggerate by including under the head of reflex neuroses, conditions, the reflex origin of which is not yet established nor even probable. Many text-books on nervous diseases, on the other hand, slight the subject, or like the treatise of L. C. Gray state that reflex neuroses are rare occurrences. Yet even widely different views as to the frequency of reflex neuroses are not wholly irreconcilable, if we but use the term with strict definition of its meaning. According to gradual usage the name, "reflex neuroses," is at present applied to any *abnormal* nervous process started by the irritation of some peripheral sensory area. This definition by itself enables us to distinguish between mere symptoms which are the *normal* and invariable consequences of disease of a given sensory part, and the reflex neuroses proper which are brought on by such irritation only under certain circumstances. In fact, characteristic of reflex neuroses is their apparent capriciousness. The same peripheral lesion which leads to a reflex neurosis in some patients may exist in others without producing such disturbances.

It is evident that if we accept this definition, very many headaches, neuralgias and motor disturbances come under the head of reflex neuroses, and that this nosological group hence includes many of the ailments daily met with. On the other hand, it may be admitted that epilepsy, chorea and other types of nervous disease of graver significance are probably but rarely of reflex origin.

The term "reflex" is used by the clinician in this connection in a wider than its true physiologic significance. As the physiologist speaks of the act of

winking as a reflex induced by conjunctival irritation, so the clinician may call a blepharospasm a reflex neurosis, if it is maintained by conjunctival disease. But to speak of a neuralgia due to a diseased tooth as a "reflex" occurrence is not warranted by physiologic nomenclature. We must either intentionally enlarge the significance of the term "reflex," or we may call these nervous disturbances, *neuroses of peripheral origin*, and subdivide them into motor, secretory, vaso-motor, sensory, (and possibly inhibitory) neuroses of peripheral origin. Even the motor "reflex" neuroses are not always reflex in the sense of the physiologist. Some of them, it is true, are but types of normal reflex action morbidly exaggerated. As such might be mentioned sneezing fits from nasal disturbances and blepharospasm from ocular irritation. In other instances, however, such as asthma and reflex epileptiform convulsions, the nervous disturbance has no physiologic prototype. Unlike the normal reflexes, these motor phenomena are not the immediate consequence of the irritation to which they owe their origin. The peripheral excitation does not lead at once to a reflex action, but its continuance influences the nervous centers so that *periodic* discharges occur in the nerve channels which are normally not open to impulses of such origin. *Periodicity* is also a feature of some sensory neuroses like migraine and the so-called visceral neuralgias. Other sensory neuroses, however, such as many forms of headache and neuralgia are either constantly present or recur with every increase of the peripheral irritation.

In order to have a definite basis for further discussion of the subject I will now tabulate the neuroses of peripheral origin, the existence of which has been satisfactorily established by the observations of more than one author. Without attempting any full review of the literature I will only quote as authorities some of the writers who reported either the first or the most conclusive instances of such neuroses, or who have summarized the literature. I may add that I have personally seen illustrations of nearly all the quoted neuroses of ocular and nasal origin.

STARTING POINT.	NEUROSIS.
Anomalies of refraction and accommodation of the eye ¹ and some instances of anomalies of the external muscles. ²	Headaches, continuous or periodic. Vertigo. Nausea. Ciliary spasm. Blepharospasm and chorea of facial muscles. Epilepsy (rare).
Diploplia from insufficiency of one of the external muscles of the eye.	Deviation of the head simulating wry-neck. ³
Nasal disease ⁴ and suppuration of maxillary sinus. ⁵	Lachrymation. Discomfort in eyes and lids. ⁶ Scotoma fugax (blind headache). ⁴ Vaso-motor disturbances of lids and face. ⁴ Headaches. ⁴ Neuralgia of branches of trigemini. Vertigo. Facial spasm. ⁷ Cough. ⁸ Spasm of glottis. ⁴ Asthma. ^{4, 9} Nightmare. Epileptiform convulsions. ¹⁰ Functional cardiac disturbances. ¹¹ The symptoms of exophthalmic goitre. ¹²

STARTING POINT.	NEUROSIS.
Ears.	Vertigo. Nystagmus. ¹³ Cough (rare).
Pharynx and faucial region. ⁴	Cough. Epilepsy. ¹⁴ Spasm of glottis. Morning vomiting. ¹⁴
Teeth. ¹⁵	Neuralgia of Trigemimus. Otaglia. Headaches. Facial spasm. Epileptiform convulsions. ¹⁶
Stomach ¹⁷ and Intestinal tract.	Headache. Vertigo. Trigemimus neuralgia. ¹⁸ Visceral neuralgias. Cardiac and circulatory disturbances. Epileptiform convulsions.
Painful peripheral cicatrices.	Epilepsy. ¹⁹

This list would be incomplete without reference to neuroses originating from disease of the pelvic organs²⁰ and the male genitals (especially adherence of the prepuce).²¹ But since I have no personal experience in this line, and since authors on these subjects are neither as precise in their statements nor as harmonious among themselves as in the instances tabulated, I will base my comments principally on the other topics.

The coexistence of a peripheral anomaly and of a functional nervous ailment is not sufficient by itself to base upon it the conclusion that the latter is dependent upon the former. The reflex origin of a given neurosis can, however, be proven by various methods. In many instances it is suggested by the patient's history if carefully examined. Whenever the nervous disturbance follows regularly any intensification of preëxisting local ailments, a relationship between the two phenomena is highly probable in the light of our present information. If the patient states that his headache is brought on by the use of his eyes, or in another case that his attack of asthma is always preceded by sneezing and stuffiness of the nose, there can be little doubt as to the relation of cause and effect. In other instances, however, the cause is persistently present, while the nervous disturbances are of periodic occurrence, for instance, in migraine dependent on astigmatism, and in the few rare cases of epilepsy which have been traced to nasal irritation. Under these circumstances, the examination of the patient can only lead to a tentative diagnosis of the origin of the nervous trouble. The experimental production or exaggeration of reflex neuroses in patients subject to them is possible only in some instances. Thus sneezing fits, spells of nasal cough, more rarely headaches, and occasionally asthma and attacks of syncope may be induced by irritating with a probe the sensitive nasal area of patients suffering from such nasal neuroses, but this experiment is not always successful. Occasionally, too, periodic attacks of the existing neurosis follow intra-nasal cauterization. In various instances of

epilepsy due to sensitive cicatrices, the reporters were able to bring on the attacks by pressure upon the scars.

As a rule, however, the reflex origin of a neurosis can only be proven by its cessation after eliminating the cause, a test which constitutes the principle of treatment. If the refraction of the eye is suspected as the cause, absolute rest of the eyes, if necessary, combined with the use of a cycloplegic drug, and finally appropriate glasses, decide the correctness of the diagnosis. If heterophoria, a strain of the ocular muscle during the maintenance of binocular vision, seems to account for the nervous disturbance, the exclusion of one eye by a shade will obviate the immediate consequences of this strain. The nasal neuroses are often checked at the beginning of an attack by the thorough application of cocain to the sensitive area, although this test is not always positive. And finally, in those instances in which fecal retention or irritation of the bowels by parasites can be suspected as the cause of the neurosis present, systematic intestinal evacuation is the test of the correctness of this view.

In other instances the therapeutic test can not be as decisive concerning the origin of the neurosis as in those just quoted. Whenever the peripheral lesion is of such a nature that persistent treatment is required for its removal and that some time must elapse before its consequences can be expected to cease, good judgment is necessary to determine whether the neurosis is really of peripheral origin or simply a coincidence. If the interests of the patient demand general hygienic direction besides the elimination of the local disease, the decision is particularly difficult. This explains why our knowledge of intestinal and uterine "reflexes" is so much less positive than the doctrine of ocular and nasal neuroses. Under such conditions, it is only the accumulation of similar well observed cases upon which reliable conclusions can be based.

It might seem as if the most conclusive evidence could be obtained by the surgical removal of the cause of irritation whenever this is feasible. Indeed, the most brilliant cures of nasal reflexes and of epilepsy due to painful cicatrices come under this head. But here also judgment and neurologic training are required to avoid sources of fallacy. It has been said that some of these cases, for instance asthma of nasal origin, were really cured by counter-irritation, and that the galvano-caustic destruction of the sensory area in the nose acted as a "derivative." This objection could be entertained only if it had been shown that "counter-irritation" anywhere else yielded equally positive results, which has never been done. The validity of the reflex theory has also been assailed on the ground that relapses have occurred after such operative cures. But whenever such relapses were examined by competent observers (Hack quotes such cases), it was found that they depended on relapses of the local disorders, which the surgical treatment had failed to eradicate thoroughly. Such coincidences are really but an additional proof of the correctness of the "reflex theory."

The real source of fallacy in conclusions based upon the results of operative treatment is, in my judgment, the difficulty of distinguishing between the influence of the operation itself and the influence of the mental impression made by the operation. It is well known to neurologists that emotional impres-

sions and "expectation" may stop for a time, or even dissipate permanently, choreic movements, but more especially hysterical pains and spells, even when they had existed for a long time. It is equally a matter of experience that some cases of epilepsy are temporarily benefited by any new treatment of an impressive nature. For this reason, much familiarity with the clinical history of functional nervous disorders is requisite to enable the observer to decide whether the disappearance of the symptoms could be properly attributed to the operation, or whether the cure depended rather on mental "suggestion."

The less we know about the pathologic significance of the alleged peripheral cause, the less reliable will be any conclusions as to its relation to coexisting neuroses. Hence skepticism is in place when for instance, Scheinmann²² seeks the cause of some nervous condition in sensitive areas wandering from place to place in the nose and reappearing after the operation in another spot. Judgment might also be held in reserve as to the relation of neuroses to low degrees of heterophoria. No doubt there are cases where the strain of eye muscles working under disadvantage leads to nervous disturbances. But to what extent the lower degrees of insufficiencies of ocular muscles—almost normal occurrences—are resented by the nervous system is still an open question. Any oculist who has learned by experience how little the muscular balance of the eye-ball is at times changed by extensive tenotomies in well-marked cases of ocular deviations of the latent type can not but doubt whether the mere nicking of muscles in low degrees of heterophoria cures the patient by influencing the muscular tension or the patient's mind. Indeed the question is a proper one, whether many instances of heterophoria are not by themselves hysterical manifestations, and such a view would be supported by the frequent experience of complete relapses of the ocular deviations after temporary cures by operations on the muscles.

More than mere skepticism, however, is called for, when attempts are made to cure neuroses by muscle-cutting—that is to say, by removing the alleged muscle-strain in the forced effort at binocular vision, in cases which present manifest strabismus and hence have no binocular vision.²³

When, however, persistent and well-defined nervous symptoms disappear promptly and permanently after the surgical removal of some demonstrable peripheral lesion, or return only if their starting cause relapses on account of insufficient treatment, there can be no logical doubt that the neurosis has been maintained by the peripheral anomaly in question.

In all discussions on "neuroses" it must be clearly kept in view that the manifestations of a disordered nervous system are but symptoms, and that these symptoms may depend on different remote causes in different instances. Similar symptoms may be of "reflex" origin from one organ or another in one case, but may be due to actual lesions in the nervous system in another patient. Hence there is no contradiction in admitting that epilepsy and chorea are sometimes of peripheral origin, although in most instances they depend on disease of the nerve centers.

The peripheral irritation which can induce nervous disturbances in certain patients is not necessarily

and indeed but rarely felt as pain. It may even give rise to so little conscious sensation that inattentive patients overlook it, or at least do not connect it with the neurosis started by it. When, for instance, ametropia causes headaches or other neurotic symptoms, the patient may or may not complain of discomfort in the eyes. Personally, however, I have never seen a case in which close questioning did not elicit at least the admission that the eyes did give rise to some slight annoyance when used steadily. Similarly in the case of nasal and pharyngeal disorders. While in some instances the patients may not complain directly, still I was always able to learn by proper questioning that some local disturbance could be felt, though perhaps not enough to suggest it as the cause of the neurosis. But there are also many instances of physiologic reflexes started by an excitation of sensory nerves of which the individual does not become conscious. As illustrations might be mentioned the regulation of the act of accommodation by the blurring of retinal images, the coördination of the external muscles of the eye under the influence of diplopia, the self-regulation of the breathing movements by means of the distension of the pulmonary tissue, the changes in the cardiac rhythm and in the size of the arterioles according to local conditions of rest or activity, and many other instances.

A clear insight into the pathogenesis of reflex neuroses can only be obtained by an analysis of all the factors concerned in their production. For evidently the peripheral anomaly starting the neurosis is but one of the factors, or why should a patient with nasal polypi have asthma when so many others suffering from the same nasal condition escape the secondary affection? Why should but a small number of hypermetropic people get headaches while the majority of eyes with this deficiency cause only disturbed vision and nothing else? If an irritation alike qualitatively and quantitatively produces disturbances in the nervous system of but one person out of many, there must be special reasons for this exceptional result. Unfortunately our knowledge of the conditions determining neuroses is as yet but very meager.

The history of patients shows often that the nervous trouble began after some special increment in the intensity of the peripheral irritation. Thus very frequently headaches from eyestrain date back to the time of unusually severe use of the eyes. Again, in other instances, nasal neuroses begin when the chronic nasal condition is intensified by an acute coryza or when the nose has been irritated by exposure to dust. But these observations, important as they are, do not solve the question why such peripheral irritation will only cause neuroses in some persons and not in others.

In a fair proportion of these sufferers we can recognize hereditary influences. In my inquiries into the family histories in cases of ocular and nasal neuroses, I have very often found similar affections in different members of the family. While it is in no sense an explanation to state that neuroses are more liable to occur in a person predisposed by heredity still the fact as such is worth noting.

In the sensory neuroses, and especially those of ocular origin, I have learned to regard as important factors the pernicious results of indoor confinement in cities. My case-book contains numerous records of school children and young clerks whose headaches or dizziness or other sensory discomforts were for

²² Berl. Klin. Wochenschrift, 1889, Nos. 14 to 21.

²³ Ranney, New York Med. Jour., 1894, pp. 80 and 113.

the time being checked by glasses of moderate strength, but who were equally comfortable without their glasses after a thorough vacation. It is especially during the growing period of life that want of out-door exercise and close confinement increase the liability to reflex disturbances. Chlorosis also has its share in the etiology of these affections, and where the history shows that the nervous disturbances although clearly of peripheral origin have only begun since anemia was manifested, iron and hygienic directions are often as serviceable as the correction of the peripheral cause.

The history of some cases shows that the sensory neurosis dates back to the time of recovery from some acute fever—measles, more often in my experience than any other. I have also noticed relatively often that headaches of refractive origin began during the lactation of mothers. In two instances of nasal neuroses, observed by myself, excessive smoking seemed to be a predisposing condition, and moderation of this habit relieved the intensity and frequency of the attacks. One of the patients had short attacks of dyspnea with palpitation of the heart and was ultimately cured by operations restoring the patency of the nose. The other one had periods of cardiac irregularity and acceleration presumably due to papillomata in the nose, but the diagnosis was not made certain, by his refusal to the operation.

A factor to which but little attention has yet been called is the coexistence of several sources of irritation in the system. I. N. MacKenzie (*Am. Jour. Med. Sci.*, April, 1884,) has observed that nasal neuroses are often most pronounced during menstruation and that they can be exaggerated by sexual excesses. It is well known that migraine accompanies the menstruation of some women. In a few instances of migraine especially accentuated during such times I have proven the ocular origin by successful correction with glasses. Several cases of asthma, the nasal origin of which was shown by the ultimate relief given by nasal surgery, have given me the history of attacks induced particularly during times of intestinal distress and in these patients dietetic management had a distinct influence on the frequency of the asthmatic attacks. It is common experience, too, that pregnancy predisposes some women to serious nervous symptoms. In some instances of facial neuralgia, of scotoma fugax and of circulatory disturbances in pregnant women, the nasal origin was strongly suggested by the history of the nasal distress, although I have only twice demonstrated the relationship by the success of intra-nasal operations. It should be remembered in this connection, that nasal operations have several times been followed by miscarriages.

It must finally be admitted that in many instances of neuroses of peripheral origin no accessory influences, no disturbances of nutrition, in fact no deviation from perfect health of the nervous system can be detected. Indeed this seems to be the case in many of the more typical instances in which the elimination of the starting point stops at once all nervous symptoms. On the other hand, whenever the history shows fluctuation in the intensity of the nervous troubles and periods of intermission, it is more likely that the peripheral cause has been aided in its influence upon the nervous system by accessory baneful circumstances without which it would not

have sufficed to induce the neurosis. These considerations explain also why some neuroses cease spontaneously, in spite of the persistence of the peripheral cause, while others never stop until the starting point is removed.

Finally it is proper to ask, What is the relation of reflex neuroses to hysteria? While hysterical persons are not exempt from these troubles, I have neither found in my experience nor in the reports in literature, any large proportion of cases of neuroses of well established peripheral origin in patients with manifest hysteria. I might almost say that where the history of hysteria is clear, the therapeutic test is apt to fail in establishing the peripheral origin of the symptoms. No doubt some of the hysterical complaints, for instance some forms of headache and the globus hystericus are really of peripheral origin. But it seems as if in their production it were not so much the inferior centers as the cerebral hemispheres in which the disturbances are induced. For hysterical manifestations when once established are apt to persist, even after the influence which started them has been eliminated.

THE EMPLOYMENT OF THE ELECTRO-MAGNET IN OPHTHALMIC PRACTICE.

Read before the Annual Meeting of the State Medical Society of Michigan.

BY ROBERT WINTHROP GILLMAN, M.D.

DETROIT, MICH.

Ophthalmic Surgeon to St. Mary's Hospital; Ophthalmologist to the Woman's Hospital and Foundlings' Home; etc.

The employment of the magnet in ophthalmic practice dates back barely twenty years; though, as "there is nothing new under the sun," the magnet was probably known to the ancients; and, at least two thousand years ago, the Brahmins were well acquainted with its use in surgery, as we find it mentioned in this relation in their sacred writings.

The first description of its use in connection with the eye was reported by Fabricius Hildanus in 1656. But Dr. McKeown, of Belfast, Ireland, has the honor of having been the first to effectively employ the magnet in an operation in the deep structures of the eye, extracting, by this means, in the year 1874, a chip of iron from the vitreous humor.

In 1877, Hirschberg constructed his electro-magnet, which on account of the large size of the tips, and the nice balance of the instrument has become the most desirable for general practice. The instrument, in simple terms, may be described as consisting of a core of soft iron, of cylindrical shape, around which is coiled insulated copper wire; the entire instrument being protected by a neat case of ebonite. There are two screws to receive the battery connection at one end, while at the other end the core projects, so that tips of different sizes can be attached to it. One large zinc-carbon cell will give a sufficiently strong current; but the storage battery is altogether more satisfactory, as it will generally be found in good working order, and giving off a much stronger current—decided advantages.

Before attempting the insertion of the magnet, it is most important that there should be a positive diagnosis of the presence of a piece of iron or steel in the eye; and, if possible, its exact location should be determined. Then, in recent cases, no time must be lost in deciding on its removal.

In doubtful cases, where an object in the vitreous with the ophthalmoscope, or by focal illumination is observed, the magnet brought in contact with the globe will sometimes clear up the diagnosis of a particle of iron, by making it alter its position; and, then often the patient will experience pain, owing to the movements of the object within the eye. When there is suspicion that a foreign body has penetrated the eye-ball, thorough examination with the ophthalmoscope should at once be made; for, if the media are clear there will be no difficulty in tracing the track of the intrusive substance. Air bubbles in the vitreous are sometimes to be seen, giving strong evidence of a foreign body having invaded the eye. Small rents in the iris, which perhaps would escape detection by a mere ocular examination, can readily be seen by the aid of the mirror.

The chips of iron or steel which penetrate the eye-ball are usually splinters from hammers or other tools requiring considerable force to operate them. Boiler makers, from the fact that they are constantly using the hammer upon iron plates and rivets, would perhaps be found to form the majority of those meeting with this class of injury. But such accidents would seldom happen if the operatives wore mica spectacles as a protection to the eyes while at work; a precaution which, I believe, many manufacturers in Germany insist on their employes adopting.

Metallic chips seldom pass completely through the eyeball; they usually embed themselves in the background of the eye or fall below in the vitreous. Small particles of iron implanted in the tunics of the eye may remain a lifetime without exciting inflammatory action or interfering with vision. Hirschberg removed with the magnet a piece of iron from the eye after a residence therein of thirty years. But when a foreign body lies in the vitreous, it nearly always creates a disturbance, as well mechanically as chemically; so that the eye, almost without exception, would be lost unless the offending body was removed.

The operation can be performed with or without the aid of an anesthetic; preferably without, as the pain is not great, and often the patient can assist the operator by controlling the movements of the eye. There is but slight danger of a prolapse of the vitreous; and where it does occur only a drop or two appears in the wound and can be easily dealt with.

Splinters of iron embedded deep in the corneal tissue, and threatening to pierce into the anterior chamber, can often be readily removed by the magnet. When they have penetrated through the cornea, and lie in the anterior chamber, or rest in the iris, the tip of the magnet, introduced through the wound and brought in contact with the particle, will succeed in its removal without producing as much disturbance, or as greatly endangering the wounding of any of the delicate structures related to the aqueous humor, as would the employment of the forceps.

If the particle lies in the crystalline lens, the safest and best plan of dealing with it is to extract the lens by the ordinary operation for cataract. When the chip has pierced the deeper structures of the eye it is important to locate its site if possible; but hemorrhages into the vitreous may cloud this medium. As a rule the tip of the magnet may be guided in the path left by the foreign body, except where the wound leads through the cornea, iris and lens, when it may be best to make an incision through the sclera. Or

where the wound has healed, if we are able to see the foreign body its position will suggest the course to be pursued, as the magnet should always be brought in contact with, or as near as possible to the chip of iron.

The incision through the sclera, choroid and retina should be made from six to eight mm. from the sclero-corneal junction, on a meridional line, and from five to six mm. long. Boldly insert the magnet and complete the circuit, as the effect is strongest at the inception of the current. After allowing it to remain a few seconds, slowly withdraw the instrument, and, if successful, the fragment of iron will be seen on its point. It may be necessary to make several excursions into the vitreous, and with tubes of different shapes, before producing the result.

It is astonishing to what extent the vitreous can be stirred up by the magnet, if the rules of antiseptic surgery are carefully complied with, as the report of the following case will illustrate:

H. M., aged 44 years, was referred to me by Dr. Hitchcock, on Oct. 13, 1892, with the following history: While at work driving rivets on Oct. 11, in the Brennan boiler shops, Detroit, a piece of the hammer he was using broke off and struck his right eye, wounding that organ. He was immediately taken to the office of an oculist, who, after carefully examining the injured eye, advised him to have it at once enucleated, in order to save the other eye from an attack of sympathetic ophthalmia. It was forty-eight hours after the accident before I first saw the injured eye, which appeared to have suffered a penetrating wound of the cornea in close proximity to the temporal side of the sclero-corneal junction, on a line with, and a little higher than the center of the pupil. The laceration was from five to seven mm. long, and had not completely closed. There was a rent in the iris opposite the corneal wound. The media were obscured. The patient had no pain in the eye and has never had any since the accident. I gave the opinion that a foreign body had penetrated the eye and probably was in the vitreous, or embedded in the background of the eye; and strongly advised him to consent to my using the electro-magnet. On his acceding, I operated upon him that night, at 11 p.m., at Harper Hospital, in the presence of Drs. Hitchcock and Hickey. Having first subjected the eye, eye-lid, etc., to a bath of a solution of 1-5000 of the bichlorid of mercury, I introduced the straight tip of the magnet through the wound in the cornea and iris, in the track made by the chip of steel, which it easily followed into the vitreous.

The tip was allowed to remain in the vitreous several seconds, and was then carefully withdrawn; but it did not succeed in bringing forth a chip of steel. The straight tip was now exchanged for a curved one, and made to enter the vitreous by the same route; and after slowly and delicately searching the vitreous in all directions, was withdrawn from the eye; but without the desired result. It was introduced for the third time, and was again unsuccessful; when, feeling that the vitreous had already been stirred as much as I dared, I decided on not attempting another trial. The eye was dressed and bandaged, and the man entered as a ward patient, and was turned over to the attending oculists of the Hospital. He remained in the Hospital for ten days, and shortly afterwards returned to work.

I examined him only a few days ago, on April 12, and was surprised to find he had absolutely normal vision with the wounded eye. The lens had miraculously escaped injury; there was but a slight adhesion of the iris to the cornea; and the rent in the iris had a background of clear media. In the fundus, on a straight line back of the wound in the iris, fortunately a few mm. to the outer side of the fovea centralis, is a deep fissure involving the retina, choroid and sclera, and in the central part of this, which shows as a white patch, a pointed bluish-gray object projects anteriorly into the vitreous. It seems firmly embedded in the sclera; extending three mm. into the vitreous—measured with the ophthalmoscope; and can not be made to stir. For various reasons in

connection with the facts given, and including the shape and color of the object, I am of the opinion it is a sliver of metal.

I have acquainted the patient with the existing condition of his eye, advising him to consult an oculist should the sight become impaired, or pain or redness manifest itself, or should there occur other indications of a foreign body exciting a disturbance; when the magnet can be again called into use; and, if unsuccessful, the eye be enucleated, in order to save the sight of its fellow. Considering that almost every structure of the eye was severely wounded, and the heroic measures exerted for its relief, it is remarkable that the eye retained the power of sight—normal vision at that.

A distinctive instance of the great value of the ophthalmoscope as a diagnostic aid, and of the successful use of the magnet in extracting from the eye a chip of steel which had remained in the vitreous nearly eight months, is given in the following case:

On June 20, 1893, W. P., of Detroit, aged 39 years, while driving a cast steel hammer through an inch board, by striking the former with a wrought steel hammer, had a small piece of the steel split off and strike his right eye. He was satisfied that the chip had not penetrated the eye, as all he could notice was a slight abrasion on the upper and outer part of the sclera. As there was no redness or pain, he did not consult a surgeon until a month later when, on account of a blurring of the vision he visited an oculist, who examined his eyes, and finding an error of refraction, prescribed glasses. This seemed to assist his vision; although he was not conscious of any improvement in the case of his injured eye, the sight of which was very much impaired, but to what extent he can not now state. This condition continued without any material discomfort until about Jan. 1, 1894, when the injured eye began to pain him. For this he treated himself, and continued at his daily labor until January 16, when the pain became so severe he was forced to stay at home. On this he consulted another oculist who referred him to me.

I saw the case for the first time on February 7. I found there was no scar on the eye-ball. Vision equaled perception of light only with the right eye, while the left eye had normal vision. From the history he gave me I suspected a foreign body in the eye was the cause of all his trouble; and my suspicions were confirmed by an ophthalmoscopic examination which revealed an intrusive substance in the vitreous lying on the floor of the fundus.

It was with difficulty that I could make him believe that the chip of steel was in the interior of his eye, and had been there for nearly eight months. He entered St. Mary's Hospital and consented to my attempting the removal of the chip with the electro-magnet; giving me permission to enucleate the eye if the magnet failed to extract the bit of steel. In the Hospital amphitheater, before a number of physicians and students of the Detroit College of Medicine, I made with a Baer's cataract knife an incision about eight mm. long, through the sclera, retina and choroid into the vitreous, commencing about five mm. from the sclero-corneal junction, parallel to, and on a line with the insertion of the inferior rectus muscle, so as to make the opening as near as possible to the foreign body. The large curved tip of Hirschberg's magnet, through which passed a strong current from a McIntosh storage battery, was brought into the mouth of the wound, but failed to attract the alien particle. I then plunged the tip into the vitreous, and turned its point on to the floor of the fundus; and on withdrawing the magnet had the extreme pleasure of seeing a chip of steel adhering to its point, confirming my diagnosis. Not a drop of vitreous presented itself in the wound. A stitch was taken, uniting the conjunctiva over the wound, and the eye was thor-

oughly bathed in a 1-5000 solution of the bichlorid of mercury and bandaged. The chip of steel is triangular in shape and weighs a quarter of a grain. The patient, complained of great pain in the eye on the night following the operation. This, however, gradually passed off; and he awoke the next morning free of all distress, and he has not had the slightest discomfort ever since. He left the Hospital in seven days, and was able to return to work in three weeks.

The eye is slowly clearing from the brown (oxidation) stain of the iron; but it is probable it will take a considerable time to fully recover from this. Though the vision of the injured optic is not improved to any appreciable extent as yet, as the ball retains its shape and almost normal appearance, it is far better than an artificial eye; and the patient is enthusiastic over his recovery, fully realizing that the removal of the piece of steel has saved his only useful eye from probable blindness through sympathetic ophthalmia.

The prognosis of magnet operations is in general favorable. Dr. Heinrich Hildebrand, of Hagen, Germany, has collected 328 cases of magnet operations, including 66 of his own. Eighty of the operations concerned the anterior half of the bulbus, the rest were in the vitreous. Of the operations in the anterior half, 67 turned out favorably. Of the 248 "vitreous" operations, 74 failed to extract the foreign body. In the remaining 174 cases, 23 suffered phthisis bulbi; 26 had to be enucleated, later on; 62, or 36 per cent. of the cases, recovered with normal vision, or a part thereof; while 91 cases retained the form of the eye-ball, without vision. These results should prove the powerful aid afforded by the electro-magnet in rescuing the eyes of the victims of flying particles of iron or steel.

When there is failure to extract a foreign body from the interior of the eye, a most important and sometimes perplexing problem presents itself; namely, whether enucleation of the injured member should be performed, for fear of sympathetic ophthalmia attacking the non-injured eye; or whether the eye-ball should be allowed to remain, trusting that the foreign element is in a position to excite no disturbance.

Where the ciliary region, "the ring of danger," has not been wounded, and if the foreign body is a chip of iron or steel, and after a most careful search the magnet fails to bring forth the chip, I am not in favor of immediate enucleation; but prefer keeping the patient under the closest observation for some days, when, by the extent of the inflammatory reaction, the best way of dealing with the case can be determined.

It is not uncommon, it may be repeated, for a particle of iron to embed itself in the walls of the eye, and remain there without interfering with useful vision, or exciting any inflammation; as the former case I have reported, added to numerous others, will show.

No set rules can be laid down as to the best methods of dealing with injuries to the eye-ball; and as Noyes so aptly remarks: "One of the greatest triumphs of the oculist is when he discriminates correctly the dangers of an injured eye, and by skillful treatment and wise forbearance preserves to the patient his precious possession of sight or eye-ball."

It is only proper that I should acknowledge my

indebtedness for some of the opinions I have here presented, to the distinguished oculist, Prof. Hirschberg, of Berlin, under whom I had the honor of prosecuting my studies while in Germany. One can not easily exaggerate the inspiration of his example. His superb technical abilities, including his patient carefulness, and, above all, his unwearied insistence, by precept and practice, of the observance of the requirements pertaining to antiseptic surgery, leave an impression upon those who come into contact with him not soon if ever obliterated. I dwell upon this latter, as too many are apt to belittle or disregard the preparatory precautions which so largely contribute to the success of an operation. Hirschberg is immovable in his adherence to even the smallest of these safeguards; which in one so eminent in his profession may well be considered strong evidence of the wisdom of their employment.

A CAUSE OF FAILURE IN THE SURGICAL TREATMENT OF INTERNAL STRABISMUS.

Read by title before the Pennsylvania State Medical Society, May, 1894.

BY HOWARD F. HANSELL, M.D.
PHILADELPHIA, PA.

The full measure of success in the treatment of functional deviations of the visual axes is attained only with the restoration or establishment of binocular fixation for all distances. This is the ideal result. A partial, but subjectively more important, success is the cure of the deformity, since patients with functional internal squint seldom complain of defective visual acuteness, diplopia or asthenopia; but they ask for relief for appearance's sake. All operators who have followed their cases over a period of several months or years must confess dissatisfaction with the usual routine methods of examination and surgical practice, and admit their frequent failure to restore equilibrium and coordination of the ocular muscles, or even wholly to remove the disfigurement. This is due, in my opinion, not to faulty technique, but to an imperfect conception of the physiologic relation of the accommodation to the straight and oblique muscles.

It seems to me, notwithstanding the able articles on the etiology and treatment of squint by Perinand,¹ Hansen Grut,² Schnellen³ and others, but little advance has been made in the practical management of hypermetropic squint since 1864, when Donders published his well-known explanatory theory. He speaks, in his classical treatise, of four causes, any one of which may cooperate with hypermetropia in developing strabismus: 1, congenital difference in the accuracy of vision, or the refractive condition of the two eyes; 2, spots on the cornea; 3, peculiar structure or innervation of the muscles or easy mobility of the eyes inward; 4, large angle alpha making apparent divergence for far, and too great convergence for near. But he does not allude to a fifth complication, purely physiologic and an extension of his own line of thought which perhaps more often than those enumerated, militates against a scientifically successful result of operation.

Functional internal squint, which excludes strabismus arising from changes in the transparency of the cornea and lens through disease, retinal exudations

and choroidal atrophies in the macular region, paralysis through interruption of the nerve force or nuclear disease, muscular inaction or over action from traumatism, deviations from cicatrices or other organic cause, is dependent in 75 per cent. of cases on hypermetropia.

The correctness of Donders' theory is uniformly acknowledged. You will pardon a brief statement of it. The hypermetrope must accommodate to secure the best acuity of vision in the distance. His relative accommodation may or may not be disturbed. If the former, he must simultaneously converge. But convergence for infinity means diplopia. Therefore the cornea of *one* eye is rotated inward. Fixation with one eye, constant squint, or with either eye indifferently, concomitant or alternating squint, is determined by a difference in the refraction, by amblyopia or by habit. The dependence of convergence on accommodation is based upon the anatomical fact that the ciliary and the interni muscles are under the control of branches of the same pair of nerves, and when the bounds of relative accommodation and convergence are overstepped, stimulation of the ciliary induces a consistent and unavoidable over-contraction of the interni.

If this theory explained all cases we meet in practice, the treatment indicated would be direct and successful, when instituted before the muscular tissue undergoes organic contraction. There is, however, a large proportion of cases, properly classified in direct opposition to Donders, as complicated, when one eye is invariably used in fixation for all distances and the total excessive convergence is borne by the second eye. Donders says they are "simple," suggests correction of the refraction and tenotomy, and intimates a successful result. These so-called simple cases are, in fact, complicated by two anomalies; one of vision and one of muscular action. The squinting eye is amblyopic, congenital or acquired from disuse, and is not only turned inward but rotated inward and upward. The oblique deviation has been persistently ignored. In some text-books it is not mentioned; in none is it described at length or explained. This had been otherwise, were we accustomed to investigate the kind and degree of turning by the only scientific means, namely, the study of the relation of the false and true image, since the relatively slight upward turning is overshadowed by the greater deformity of the convergence.

In concomitant squint, where either eye is used indifferently in fixation, there is no essential difference in the refraction or in vision. If amblyopia is the result of disuse, it can not develop. In constant squint, on the other hand, the deflected eye is always amblyopic and usually has the greater optical defect.

The etiology of the upward deviation is precisely that of the convergence. The third nerve supplies other external muscles besides the internal, and unless there is a peculiar relationship or connection, undemonstrated by the microscope, between the nuclei of the ciliary and interni muscles which does not obtain with the others, we would certainly and logically expect a response to the stimulus given by the accommodation to include the superior and inferior rectus and the inferior oblique, and not be limited to the internus and the iris. The rotation of the cornea in consequence of their combined action must be inward and upward—inward because the antagonist of the internus is not involved, and upward be-

¹ Ann. d' Ocul., Vol. cvl.

² Trans. Oph. Soc., Jan., 1891.

³ Arch. für Opkthal., Bd. 36, Abt. III.

cause the inferior oblique and superior rectus are stronger in their associated action of turning the cornea upward than the inferior rectus in opposing them. Therefore, if hypermetropia is the causative factor in the production of abnormal convergence, and its influence extend to the elevators and depressors of the cornea, it must follow that in every case of hypermetropic internal squint the deviation is oblique, and a purely lateral turning is theoretically impossible. Thus we observe an hitherto unstudied condition in concomitant squint, the existence of which can be readily proven. During fixation with the right, for instance, the left eye turns in and up—the right image will be the true, and the left, which is the false image, will be lower. During fixation with the left, the right eye turns in and up—the left image will be the true and the right, the false image, will be lower; or, while fixation is accomplished by one eye, which must be accommodated to give clear distant vision, but can not converge, the visual axis of the second eye crosses that of the first on a higher plane, and as accommodation and fixation are transferred from one eye to the other, the inward and upward squint is also transferred.

The same principle holds in its application to constant squint where one eye always fixes, and the other always deviates. Here there is no transference of accommodation or deviation, but the result of excessive accommodation in the better eye is manifested in the inward and upward deviation (eso-hypermetropia) of the worse eye and is necessitated by the supra-normal response of the branches of the third nerve distributed to the muscles of that eye.

I have omitted a consideration of the action of the levator palpebræ, which, belonging to the group of muscles supplied by the motor oculi, should also receive additional stimulus from hypermetropic excitation of its nucleus. Its function, however, differs from that of the other members of this group of muscles, and, while its over action in hypermetropia would be important as showing the physiologic relation of all the nuclei, it is independent of, and not kindred to, rotation of the ball. A slight increase in the vertical axis of the commissure in the squinting eye over that of the fixing eye might be difficult to determine, since the halves of the face are seldom symmetrical. The application of this extension of Donders' theory of hypermetropic squint to the treatment is obvious. It is essential that a full correction of the error of refraction shall be constantly worn, from the moment the diagnosis can be made, or the patient is old enough to wear glasses. In lieu of glasses the accommodation can be paralyzed by atropin.

The surgical treatment consists of: 1, in alternating squint, a division of both internal muscles; 2, in constant squint, a division of both internal muscles, and the superior rectus of the deviating and perhaps the inferior rectus of the fixing eye.

The degree to which the tenotomies should be carried must be governed by the distance separating the false and true image of a small light at six m. Hence it should be done in all cases, where a restoration of binocular fixation is possible, under cocain anesthesia.

Failure to secure good results from operation will often be encountered in cases of constant squint, because division of the interni will not correct the hypertropia, and it is essential to the permanency of even a cosmetic effect that the upward deviation

shall be recognized and considered of equal importance to the horizontal. In concomitant squint, the hypertropia is a transient and alternating condition, transferable with the esotropia, and should *never* be surgically treated. By equalizing the convergence by tenotomies, binocular fixation is secured without interfering with the horizontal plane on which the two eyes will act together. This plane may be higher than that of the emmetrope, or after a period of normal accommodation, obtained by wearing full correction for hypermetropia, the elevators of the cornea may be properly and equally antagonized by the depressors and the horizontal plane of binocular fixation be lowered to correspond with that in emmetropia. In either case the visual axes are on the same level.

I earnestly urge, first, an examination and close analysis of the degree and kind of turning of the cornea by a study of the relative positions of the false and true image of a small gas jet or candle flame at six m. and shorter distances; second, a recognition of the hypertropia which will be invariably found to complicate esotropia, of its transference with the esotropia in concomitant or alternating strabismus; third, of the permanent upward deviation of the inward-turned eye in constant squint; and, fourth, emphasize the deductions taught by these conditions, namely, that the hypertropia of the former disappears under correction of the error of refraction and tenotomy of the interni, and in the latter, vertical equilibrium can be obtained only by operation on the vertical muscles.

SOME REMARKS ON TOTAL EXTIRPATION OF THE FIBROID UTERUS: ILLUSTRATIVE CASES.

A paper read before the Ohio State Medical Society, Zanesville, May 16, 17, 18, 1894.

BY RUFUS B. HALL, M.D.
CINCINNATI, OHIO.

PROFESSOR OF CLINICAL GYNECOLOGY, MIAMI MEDICAL COLLEGE; GYNECOLOGIST PRESBYTERIAN HOSPITAL.

The subject of fibroid tumor of the uterus is too broad to be considered in all its aspects, in the time allotted, before this Society. I have therefore thought it advisable to speak of but two phases of the subject: 1, what cases require operation; 2, methods of operating.

Clinical experience demonstrates that only a small percentage of those suffering from fibroids require operative interference for relief. This is so well known that the profession at large have come to regard them as purely innocent growths. This is true in the majority of cases. My experience, based upon more than two hundred carefully recorded cases, justifies me in saying that the majority of women from thirty-six to forty-five years of age suffering from fibroid tumors, do not require operative interference; but this fact increases our responsibility in determining early the cases really requiring operation.

A great many women who are the subjects of fibroid tumor suffer no more inconvenience than a slight pain preceding and during the menstrual period, which is not excessive or unduly prolonged. They suffer but little, if any, from pressure symptoms or peritonitis, and the tumor only annoys them because they are conscious of its presence by manual manipulation or from information given them by their phy-

sician. As long as the patient remains comfortable and her general health is not interfered with by pressure or loss of blood, she certainly ought not to be subjected to an operation.

The chief symptoms and secondary diseases of cases requiring operative interference, are hemorrhage, pain, cystitis, peritonitis and pressure causing temporary intestinal obstruction. These cases when they do not yield readily to internal medication combined with thorough curetting, the patient being put under good hygienic surroundings, are to be looked upon with suspicion and the future progress of the case watched with unusual care and interest. Experience leads me to believe it is out of this latter number, where the symptoms can not be easily controlled, that almost all of the operative cases come. I do not mean by this statement that all of these cases should be at once subjected to the radical operation of hysterectomy, but I wish to emphasize the opinion that these cases should be carefully watched. It is not unusual to have a case referred for operation where there has been severe and frequent hemorrhage with metrorrhagia lasting from ten to fifteen days each month for a number of years. To say that these patients are in the most unpromising condition for such a radical operation is to repeat what you all know. They are exsanguinated to an extreme degree.

Three cases operated upon by me within the past year, although still able to walk had lost such large quantities of blood that the act of rising to the feet caused severe vertigo. They suffered but little pain at any time, but had been confirmed invalids for years. They had had all kinds of internal medication, combined with electricity, before they were referred to me, with the result of only lessening the hemorrhage, not controlling it. These cases illustrate in a forcible manner the point I wish to emphasize; that is, if hemorrhage and metrorrhagia can not be controlled within a few months by careful medication, that case should be referred for operation and not be permitted to become so enfeebled as to make the result of the operation problematical. In other words, if once a patient becomes a bleeder she nearly always continues to be a bleeder, and there is no permanent relief except by operation.

There is another class of cases in which the most prominent symptom is not hemorrhage, but pain from pressure of the tumor. A tumor the size of a cocoon, which has become adherent in the pelvis from inflammatory exudation, may cause intense suffering and a great number of reflex symptoms which demand relief. In support of this I could cite many instances of which the following is a fair illustration:

Miss M., aged 40, referred by Dr. Rhu, of Marion, Ohio, was known to have had a fibroid tumor for more than three years. For one year before my visit she observed that she was growing more and more incapacitated for walking. When she attempted to walk she suffered from a sense of fullness in the pelvis and pain in the legs and head. Much of the time she was practically disabled, so far as locomotion was concerned. She could not walk across the street without causing pain in the legs which was at once reflected to the head, so that she suffered greater pain in the head than in any other part of the body.

I saw the case in consultation with her physician, March 12, 1893, at which time she was just recovering from a sharp attack of peritonitis. On examination, I found the tumor occupying the entire space in the pelvis, with a large nodule above and to the left side, wedged down, firmly fixed by adhesions and causing great pressure. It was evident the

patient could only be relieved by the removal of the tumor. As her life was in danger from recurring attacks of peritonitis, I advised immediate removal. Total extirpation was made at my private hospital, March 16, 1893. The entire lower part of the tumor was adherent. After removal, the tumor somewhat resembled in shape two large cocoanuts joined together. The patient made a prompt and uninterrupted recovery and is now enjoying excellent health. By examination of the tumor, we found a good explanation of the cause of the pain complained of when the patient attempted to walk. The tumor filled the pelvis, where it had become firmly adherent to its walls, the resulting pressure on the nerves of the sacral plexus causing the pain in the legs and inability to walk. The pain in the head was a reflex from the same cause. As the tumor continued to enlarge, it could do so in only one direction, upwards. The weight from above when the patient attempted to walk was an additional source of pressure on the nerves, which was somewhat relieved when the patient lay down. It is hardly necessary to add that this patient had been under constant medical treatment, including electricity, for years before the operation.

That we may have cystitis from the pressure of a fibroid tumor alone, is well illustrated by the following case:

Mrs. K., Dayton, Ky., age 36, married eight years; no children; no miscarriages; referred by Dr. Richards. This patient had suffered several years from pelvic pain, backache, pain in the limbs and metrorrhagia. She did not consult a physician until about a year ago when she was compelled to do so for relief from an irritable bladder. She was not conscious at that time that she had a fibroid tumor, but her physician was not long in determining the cause of the bladder difficulty, which was pressure on the bladder from a fibroid tumor filling up the true pelvis. No medication relieved this tormenting trouble, which gradually grew worse until she developed cystitis of an aggravated form. Her sufferings were very great. When she was referred to me for consultation, March 2, she had not been able to retain her urine for longer than one hour at a time, for more than two months. The tumor was fixed in the pelvis and could not be pushed upwards. Total extirpation was advised and the patient readily consented. It was done March 6. The patient made an easy and prompt recovery; her bladder difficulty improved from day of operation and at the present time she holds her urine for five hours and suffers but little inconvenience. I have no hesitation in saying that in due time she will be perfectly relieved.

Peritonitis is to be dreaded even more than hemorrhage in these cases. My experience convinces me that in almost every case we have the two conditions present. We have periodical hemorrhages extending over long months, or even years, with more or less severe pain located in one or the other ovarian regions, or in both, gradually increasing from month to month, until finally the patient is attacked with acute general peritonitis from which she may or may not recover. This inflammation will recur on the slightest provocation. These cases should be operated upon at the first attack, and not be permitted to go on and have half a dozen or more recurrences, each one jeopardizing life. The cause of peritonitis in these cases, in almost every instance, is a pyosalpinx, a suppurating ovary or both, complicating the fibroid, and it is obvious to every one that the only rational treatment is an early operation. This should be insisted upon in every case at the first attack of peritonitis. The following case illustrates this condition:

Mrs. N., age 52; married thirty years; no children; referred by Dr. DeWitt. The tumor extended three inches above the umbilicus. The patient had been conscious of the existence of the tumor twelve years, but had suffered but little inconvenience until about three years before the operation, when she commenced to have irregular hemorrhages which gradually grew worse, but she would not consent to an operation. For about a year she had suffered considerable pain in both ovarian regions and the hemorrhage had been markedly increased. The patient lost much

flesh, was anemic and very weak. I saw her on May 20, 1893, when she was just recovering from a sharp attack of peritonitis of some fifteen days' duration. Total extirpation was made May 23, 1893. Extensive intestinal adhesions were found; a pyosalpinx and large suppurating ovary holding eight ounces of pus, which was imprisoned below the tumor in the pelvis, were removed with the uterus. The patient made a prompt recovery and is to-day enjoying perfect health.

That intestinal obstruction should be one of the complications which might be anticipated in these cases is plainly evident. A small tumor fixed in the pelvis causes intestinal obstruction by narrowing the lumen of the rectum. This symptom can be overcome in the majority of cases after a few days' careful medication, yet the temporary obstruction is almost always accompanied by an acute attack of peritonitis, thereby endangering the life of the patient, as the following case will show:

I was called in consultation with Dr. Van Meter on May 7, 1894, to see a patient, a strong, healthy-looking German woman 38 years of age, who has been known to have a fibroid tumor for two years. One year ago she had an attack of peritonitis with complete intestinal obstruction for five days; for twelve hours the patient had stercoraceous vomiting. The tumor was so firmly packed in the pelvis, compressing the rectum to such an extent that the finger could not be pushed by the tumor. The intestinal obstruction was finally overcome, only to have it occur again May 1 of the present year. Obstruction was complete for four days, and was accompanied by acute general peritonitis from which the patient is now slowly convalescing. An operation was advised for removal of the tumor but not assented to. This patient has obstruction from pressure of the tumor in the pelvis, against the rectum; without operation she will die from this cause at no distant day.

Just as the question of extra-peritoneal or intra-peritoneal treatment of the pedicle in hysterectomy was so hotly contested a few years ago, so now is total extirpation and the extra-peritoneal method being discussed.

The extra-peritoneal fixation of the stump had the advantages over other methods, used at that time, of controlling hemorrhage and yielding the best results. It therefore became the method that was almost universally adopted. The objections to this method are many and serious. If we use the extra-peritoneal method and clamp, we not infrequently see the pedicle slough and become a menace to the life of the patient for days afterwards. Not a few die from septic infection and peritonitis from this cause. If the patient makes a primary recovery, she is not in all cases restored to health. Quite a number of these patients suffer great pain afterward, owing to the dragging of the pedicle on the tender abdominal scar, and pressure upon the distorted pelvic organs, interfering with their functions. Not infrequently hernia follows this operation, developing at the point of the fixation of the pedicle. Last and by no means least, the prolonged and painful convalescence which necessarily follows this method is a very serious objection to it.

The new methods which have entered the field and are contesting for supremacy in the hands of leading operators to-day are, total extirpation, and Baer's method. Baer's method is extirpation of the tumor and body of the uterus, ligating the uterine arteries, leaving the cervix and closing the peritoneum over it. Both of these methods have their advocates, but as yet total extirpation has yielded the best results and is the method which I prefer above all others. While I am aware of the fact that I have not had as much experience in this line of work as some opera-

tors, yet I have removed the uterus, for all purposes, sixty times, and so feel justified in expressing my opinion upon the subject.

The difficulties attending total extirpation are not so great as one who has never attempted it would suppose. They are easily overcome by one accustomed to performing difficult and complicated pelvic operations. With the patient in Trendelenberg's posture, the time required to perform the operation is no longer than that required in making many of the difficult abdominal and pelvic operations now being performed daily. After ligating off the ovaries and dividing the broad ligaments, the peritoneum is divided across the front of the tumor just above the top of the bladder and across the back of the tumor somewhat lower down. The peritoneum is then stripped down in front of the bladder and separated from the tumor down to the vagina. After stripping the peritoneum from the back of the tumor, the uterine arteries and their branches are easily secured. The ligatures are placed between the two flaps of the peritoneum but do not include this membrane in their grasp. The number of ligatures does not usually exceed two or three on either side. One end of each should be left about six inches long and, after removal of the cervix, carried out through the vagina to be cast off through that passage. The vagina is lightly packed with gauze and the peritoneal edges which were stripped from the tumor are turned in towards the vagina and neatly coapted by a running stitch of catgut. The wound in the vagina is treated as after an ordinary vaginal hysterectomy.

This method has stood the test of experience and is gaining in favor with the best operators of the present time. Theoretically there is little to be desired in technique, as it is very near perfection. It promises as good results in patients with thick abdominal walls as in those with thin abdominal walls. This can not be said of the extra-peritoneal method.

By total extirpation there is not as much danger of hemorrhage as there is in ovariectomy, from the fact that in the latter operation the pedicle is transfixed and ligated in mass. Not infrequently the pedicle is thick and short with great tension upon it, favoring slipping of the ligature and consequent hemorrhage. In total extirpation the broad ligament is divided from the uterus and ligated in sections which are not put upon the stretch, so there is no danger of the ligature slipping off. The ligatures do not include any uterine tissue, therefore the tissue within the grasp is not susceptible to any undue shrinkage and resulting hemorrhage. There is no raw surface left in the peritoneal cavity to form attachments to intestine and omentum. There is no sloughing of the pedicle. There is no distortion of the pelvic organs from the stump being fixed to the abdominal wall, pressing upon the bladder, or interfering with the bowels. The risk from hernia at the point of fixation of the pedicle is entirely obviated. There is a comparatively painless convalescence which is at least two weeks shorter than that of the extra-peritoneal method. And here I wish to reiterate what I said in my first report on this subject, read before the Academy of Medicine in December, 1892. That I was convinced that this method had come to stay, and that the clamp in abdominal hysterectomy would as certainly be a thing of the past as it is now a thing of the past in ovariectomy.

In conclusion, I wish to say that with the present

low mortality following total extirpation of the fibroid uterus, we should not hesitate to advise all patients who are subjects of fibroid tumor to submit to the operation at once, if their life is endangered or health destroyed, either from the tumor or complications arising from it.

WOUND OF LEFT SUBCLAVIAN ARTERY.

Read before the Southeastern Kentucky Medical Society, at Stanford, Ky., April, 1894.

BY J. N. BAUGHMAN, M.D.

FLAT LICK, KY.

Member Knox County, Ky., Medical Society; Southeastern Kentucky Medical Society; Central Kentucky Medical Society; Kentucky State Medical Society; and American Medical Association.

On the afternoon of Nov. 7, 1893, Charles Haywood, aged 19 years, was stabbed in the left side of the neck about one and one-half inches above the clavicle and about two inches from sternal end of clavicle. The knife, which was an ordinary pocket knife about three inches in length of blade, going downward, backward and inward, wounding the subclavian artery in its first division; as to the nature of the wound of the artery, we were unable to tell, but are of the opinion that the knife punctured the vessel. Dr. James Steele and myself saw the case in about two minutes after the wound was received. The red arterial blood was spurting out of the wound in a stream half as large as one's finger and to the distance of about one foot above the boy's head. He was reeling from the shock and the sudden loss of so much blood, and was in what I thought a dying condition. We caught the boy, and by direct pressure, and from his fainting, stopped the blood. Dr. Steele continued the pressure while I went for styptics to my drug store, which was right at hand. The wound was packed with absorbent cotton saturated with Monsel's solution until we could get instruments, etc., to attempt to ligate the vessel, and while we were attempting to do so, we prevented hemorrhage by pressure against the vertebral column. We enlarged the wound but after repeated efforts were unable to reach the bleeding vessel, it being so deeply seated. We saturated absorbent cotton with Monsel's solution and packed it over (*not in*) the wound and held it until a firm clot was formed and the entire mass adhered firmly to the boy's neck and effectually stopped the bleeding, but it made a very ugly and bunglesome mass of blood and cotton. The patient was now resting very easily, and it being dark we decided not to disturb him until morning, when we would be better prepared to again try to secure the vessel.

Dr. B. F. Herndon saw the case with us next morning, November 8, and we decided that as we had the hemorrhage stopped it would not be wise for us to interfere with it, by again trying to secure the vessel and also having the fact staring us in the face that in all probability we would again fail, and even if we did succeed in tying the vessel our patient would be almost sure to die during the operation or soon after; lastly, the friends were unwilling for us to do so, unless we could give more hopes of success.

We had to relieve the bladder with the catheter for several days. We applied Listerin to the mass on the wound every day and by so doing were enabled to keep down all offensive odors, and had the wound entirely cut off from the atmosphere. The patient had scarcely any fever and the circulation was kept

regular with digitalis and aconite. The pupil of left eye was widely dilated and remained so for about two months, when it became normal, and has continued so. The reason of this is supposed to have been on account of the wound being so near the origin of the vessel that it interfered with the circulation in the left carotid artery. A slight abscess also formed in the right ear and discharged for some two weeks a non-offensive pus, but then ceased to give any further trouble.

The second day after the wound was received, we washed the patient thoroughly, except the wound, which was not interfered with until November 19, when the coagulum, cotton, etc., was thoroughly softened with warm carbolized water, and removed, when the wound seemed to be in the very best condition. The entire wound was filled with healthy granulations and we thought our patient would soon be well. The circulation in the left arm was much improved, having been reduced to the minimum when the injury was first received, but the left arm was almost useless and has remained so ever since and is much smaller than its fellow.

When we dressed the wound we saturated absorbent cotton with Monsel's solution and laid it over the sore, Dr. Gross saying it is one of our best antiseptics, and this being the case we would thereby get a double effect from its use. The patient seemed to be doing splendidly until November 24, when we again dressed the wound which was suppurating slightly and not of the most healthy nature. There was a very slight depression in the lower angle of the wound, which was gently dressed with carbolized water and then a linen cloth covered with vaselin was placed over it. The patient was left lying upon his back, in which position he had been from the beginning, and with his head slightly rotated toward the right side. The next day, November 25, the patient became uneasy and had forebodings that he was not going to recover. He also had some fever and his pulse was a little fast. We cheered him up as best we could and left him. Both Dr. Steele and myself lived near where he was.

On Sunday morning, November 26, about 4 o'clock, we were both aroused with the information that the boy was bleeding. Dr. Steele, being endowed with the happy faculty of going into his clothing head foremost, was upon the scene in about three minutes and found the boy had almost bled to death, and he ran to my residence and store for Monsel's solution, which with us in this particular case was a cure all. When we returned the boy had fainted, the hemorrhage had ceased and he was not dead, but was so near the brink we thought we would soon be relieved of our charge.

Dr. Erichson says: "After the first secondary hemorrhage the surgeon may, and after the second he must use heroic measures to stop it." We were inclined to cut down upon the artery and tie it at all hazards, even in the face of the record that there had never been a successful case of this kind, but the friends of the patient objected. Our patient soon rallied and was doing as well as could be expected until December 8, when we were again startled by the cry: "The boy is bleeding!" Luckily for the patient and also for ourselves this was soon after daylight, and Dr. Steele and myself were both up and were enabled to be at the patient's bedside in less than three minutes from the time the hemorrhage began. We

packed the wound with absorbent cotton saturated with Monsel's solution and this, coupled with the boy's fainting, stopped the hemorrhage before damage enough was done to produce death.

At each bleeding he had lost nearly a half gallon of blood and was now in a most deplorable condition; it seemed as if there was no possible chance for his recovery. The friends objected to our again trying to ligate the artery, for while we told them there was no other remedy, we also informed them of the fact that no one had ever recovered from an operation of this kind. In a few days after each hemorrhage, our patient would rally from the shock and loss of blood, and with the exception of constipation which had to be relieved by injections, would be doing nicely for from eleven to fourteen days when he would again have a hemorrhage which would only be controlled by the timely arrival of his medical attendants and from the syncope which resulted in every hemorrhage but one; this time the blood issued in a small stream, and he did not lose over one and one-half pints. There were in all, six hemorrhages, and the patient lost some two or three gallons of blood, but would recuperate from each one so he would live through the next.

After the last hemorrhage he was in a truly deplorable condition, suffering fearful agony and could only be kept easy by giving enormous doses of morphia. There was a good deal of nausea. The last hemorrhage was about the fifteenth of January, 1894, and the patient's neck is now (April 19) and has been for two months entirely healed. It is impossible to know the condition of the artery, but fears are entertained that an aneurism may develop at any time. The patient is now cheerful and able to be sitting up, but from the great anemia he is very weak, and it will be many months before he is well, if such an event should ever occur. Within the last two months he has suffered a great deal from the passage of renal calculi, but now seems to be improving, though he still has some pus in his urine at times. However, he does not suffer from the attacks of renal colic nearly so often as he did a few weeks ago. He has suffered a great deal from general neuralgic pains, and has had one or two swellings of left knee and ankle, but this would only last for two or three days.

One fortunate circumstance is that the patient has never sneezed or coughed since he was wounded. This was one thing we feared, for had it happened it would almost certainly have precipitated another hemorrhage.

We only dressed the wound when we were absolutely forced to do so, but by having the air excluded by packing over it absorbent cotton and Monsel's solution we were enabled to keep it in an aseptic condition, and we applied Listerin over and around the dressing every night and morning.

ADDENDA.—At this date, May 23, the wound is firmly healed and no *bruit* can be heard, which shows the artery to be well healed, with no indication of any aneurism, but the patient is still in a very feeble condition, having to be helped up and down. The left arm remains useless but the circulation in it is good. The patient still continues to pass renal calculi and no treatment seems to abate it in the least. It is evident to my mind the boy will always be an invalid which is due to the great amount of blood lost. As far as the wounded artery is concerned it has successfully healed, which is something won-

derful, and so far as I have learned has never before occurred in so large a vessel. A wound at this point has never recovered save in one case, that of Dr. Dunlap, of Danville, Ky., when he ligated the first part of the left subclavian artery in a negro boy at a Philadelphia hospital. In his case, he tells me, the left arm was useless the same as the above, and the pupil of the left eye was dilated for some time but finally became normal.

SOME OBSERVATIONS ON THE DISEASES OF THE ALIMENTARY CANAL AND THEIR COMPLICATIONS.

Read before the Missouri State Medical Society in convention at Lebanon, Mo., May 16, 1894.

BY PAUL PAQUIN, M.D.

MEMBER MISSOURI STATE MEDICAL ASSOCIATION; SUPERINTENDENT OF THE GASCONADE SANITARIUM; MEMBER ST. LOUIS MEDICAL SOCIETY; PRESIDENT LACLEDE COUNTY MEDICAL SOCIETY.

The diseases of the alimentary canal may be divided into two general classes: The primary and the symptomatic; the primary, in its turn, may be subdivided into specific and non-specific affections. The symptomatic include a variety of morbid conditions too numerous to enumerate. It is my purpose in this paper to make a few general remarks on the morbid conditions in general which affect the alimentary canal, and the complications which are frequently noticed in connection with them.

The primary diseases of the digestive apparatus under the two subdivisions just mentioned include everything, from such serious specific maladies as cancer, tuberculosis, typhoid fever, cholera, etc., to those often confused conditions considered more simple, as indigestion, dyspepsia, etc. I do not wish to be understood, however, in making this classification of the primary diseases of the alimentary canal, that all the diseases usually listed under the title of non-specific, are such in fact; if all diseases due to microbes are specific, there are many more affections of the bowels that deserve this title, than is usually granted. But in the present state of the medical mind, we are justified in terming non-specific a variety of indefinite or definite, microbic affections, causing more or less serious disturbances, but not usually affecting the substance of any organ to a marked degree.

Of the symptomatic or secondary diseases of the alimentary canal, much could be written. A great number of nervous diseases, for instance, produce or favor the development of morbid conditions in the digestive tract. It is so with a number of affections of certain organs of other apparatus; diseases of the lungs, throat, nasal cavities, the liver, kidneys, for instance.

On the other hand, there are certain forms of diseases of the digestive apparatus which result in complications in other organs or sets of organs, principally in the nervous system, the kidneys and the apparatus of circulation.

Until very recently, the diagnosis and treatment of the majority of the diseases of the alimentary canal was more or less empirical. Conclusions were reached from external symptomatic evidence and from the history given by the patient, and treatment was usually based exclusively on such slim grounds. Indeed, this course is prevalent now, very extensively. It is no wonder, therefore, that so many of the diseases of the alimentary canal which at first

seem slight become rebellious and chronic and sometimes never yield to treatment. The digestive apparatus being, as it were, the soul of the machine, *i. e.*, the furnace manufacturing the material for the energy of the economy, is the set of organs that should be most properly and faithfully cared for. As a matter of fact, there are no parts in the human body so greatly abused by the individual, the cook and the polypharmacist of the medical fraternity.

Bouchard, Dujardin-Beaumetz, Matthieu in France; Ewald in Germany; Jaksch, of the University of Prague, and Cagney, of London, have by their extensive researches and experiments established grounds for clinical diagnosis of those maladies, which are of the utmost value for those who devote serious attention to the diseases of the alimentary canal. In the first place, they have given us some reliable means of chemic, microscopic and bacteriologic analyses of the contents of any portion of the alimentary canal, and of those products of the urinary secretions which result from disturbances of this apparatus. They have also established rational grounds for the prescription of rational dietetics, formulated with special reference to any given disease in an individual. Finally, they have given us successful means of treatment which were never before used and which we find, even now, difficulty in bringing to the favorable notice of the medical profession of our country, particularly in the West. Indeed, it has been my misfortune to have heard reputable physicians scoff at the idea of trying to diagnose obscure maladies of the alimentary canal by clinical analysis, and treat them by the new methods of the French, German and English, and the Eastern Americans. I have heard some deery even the use of the stomach tube, which is more harmless than the catheter, and ridicule the idea of the utility of intra-intestinal and intrastomachal electricity. The very same men would affect to believe that intestinal disinfection is, likewise, a theory that can never be applied usefully in practice. There can be but two excuses for such views to-day: Either ignorance of the advanced methods of diagnosis and treatment of the diseases of the intestinal apparatus, or indolence when it is found necessary to go through a long, tedious process of exact analysis and protracted treatment. It is much more convenient, in fact, to write a prescription on an assumption acquired from a cursory examination than to take some days in making the examination, and some weeks or months in irrigation and disinfection, or other treatment of the digestive organs.

The first indication in a given malady is to find its origin and its cause. The next, whether it is complicated or not. These precepts apply emphatically to the digestive maladies. To arrive at these facts one must go systematically through the methods of examination. In the majority of cases, first, the buccal cavity should be examined with reference to the microorganisms and other morbid evidences that may be found there, such as coated and furred tongue, foul breath, etc. It should be noticed also whether there exists any nasal catarrh, with secretions running down into the stomach. Then, if it presents any evidence of morbid phenomena (and sometimes when it does not, positively) the stomach itself, should be examined: 1, as to its dimensions and physical conditions, to establish whether or not it is dilated or hypertrophied, and whether pathologic

lesions or a growth exists; 2, as to the reaction of the stomach contents, and their nature from a bacteriologic standpoint; 3, as to the capacity of the stomach secretions to digest albumen and the effect of the digestive juices on starch and other substances (sometimes it is even necessary to establish the absorption, capacity and the motility of the stomach itself;) 4, as to the existence or non-existence of stenoses or strictures of the cardiac or pylorus orifices. If there are indications we should then examine especially with reference to cancer and ulcers.

In another class of morbid conditions we are first led to examine the stomach to establish whether or not its coats are inflamed, whether the contents contain living microorganisms, and whether there exists catarrh of the stomach. In still another class of diseases we find ourselves in the presence of indications of certain neurotic conditions, as hysterical gastralgia; genuine gastralgia, as a result of the diseases of the central nervous system; neurasthenic gastralgia of the irritating and depressing varieties; hyper-acidity of the gastric juice; nervous vomiting; cramps of the stomach; paresis of the cardiac orifice; nervous anacidity of the gastric juice, which necessitates most of the tedious inquiries just mentioned for a safe diagnosis. Finally, having satisfied ourselves as to the origin and nature of the disease by these investigations, it may be found necessary (and sometimes before the investigation we have to take into account) the relation of the diseases of the stomach to those of other organs. It is here that we have to deal with symptomatic intestinal disturbances and complications. We find them appearing in tuberculosis, in valvular diseases of the heart, in diseases of the kidneys, the liver and the central nervous system, diabetes, rheumatic diathesis, etc.

The examination of the intestines is made on the same general line indicated for the stomach. We first proceed to the physical examination and then to analyses as accurate as possible, including the chemistry, bacteriology and microscopy of such intestinal contents as may be deemed wise to investigate. Our investigations should be made with a view of determining: 1, the physical conditions; 2, whether or not microorganisms play any part in the production of the morbid phenomena presented, what organic lesions, if any, may be revealed in the dejecta. We should establish the form of the intestinal irritation, the nature, if deemed necessary, of the microbes found in the bowels, the kinds of food that fail of digestion, the chemical products of intestinal putrefaction and other kinds of fermentation, the evidences of auto-intoxication that may be presented, the nature of the mucus, if any, expelled, etc. Nor should we stop our analysis here; we should test the urine thoroughly, not only to exhibit its density and reaction or to establish the presence or absence of albumen or sugar, but also with a view of discovering whether any of the intestinal products, due to diseases of or fermentation in the intestines, are excreted with the urine. Having thus carefully gone through the processes necessary to make a safe diagnosis of any given morbid condition of the alimentary canal, we have most important data on which to base treatment.

Generally speaking, most of the diseases of digestion are more or less complicated, or aggravated, at least, by the action of microorganisms; therefore, in

the majority of cases, it will be found of the greatest utility to irrigate the stomach and the colon, and then disinfect the small intestines by the use of such antiseptics as will reach them without losing their power and with the least irritation, and begin at that point to arrest the growth of ferments. This general treatment is applicable, usually, not only in all diseases in which there is so-called dyspepsia, with the exception of cases of cancers and ulcers—in which modifications are necessary—but is applicable also in typhoid fever, in Asiatic cholera, cholera morbus, and in innumerable other morbid conditions of the digestive tract that every physician needs to understand well, and that may occur independently or in connection with some other affections. The stomach tube, for the pure or medicated lavage and disinfection of the stomach plays a most important part. By its use, gallons of water can be used each day or each sitting. The following medicinal agents may be used with advantage in the disinfection of this organ:

ROSENHEIM'S SOLUTION FOR LAVAGE OF THE STOMACH.

Borax	2 drachms.
Creolin	4 grains.
Salicylic acid	15 "
Thymol	4 "

Use with a syphon tube after clear water lavage, once a day for disinfection.

COMPOUND CINNAMON AND CITRIC ACID LAVAGE.

Pasteurine, (composed according to published formula and analysis, of cinnamon, citric acid, gaultheria, witch hazel)	2 ounces.
Water	1 quart.

Use with syphon tube as preceding prescription. Either of these formulas may be used in lavage of the colon.

For the small intestines and for continual disinfection, calomel may first be used in doses varying from $\frac{1}{2}$ to 3 or 5 grains, preceded and followed by an alkalin laxative and then by the long use of acid antiseptics, as Pasteurine, or the use of other products arresting aerobic and anaerobic germs, as naphthol, benzo-naphthol, which spend their force particularly in the small intestines. The stomach and lower bowels can be irrigated with water, medicated or not, with the agents just mentioned, using for the purpose a colon tube four or five feet long. I need not say that the intestinal elimination as well as kidney elimination, should be rendered and continued as perfect as possible. The free use of pure water, hot or cold, is for this purpose, very beneficial. The elimination may be assisted otherwise by medicinal agents as may be deemed best under the circumstances.

There are a number of conditions of the stomach and bowels that can be materially improved and sometimes cured by the proper use of electricity. It is, to-day, practicable to introduce an electrode into the stomach. Having filled it partly with water an electrode is introduced into the stomach, and the other one is applied externally wherever wanted. Galvanism and faradization may thus be produced with perfect safety. The same process of electric treatment, involving the whole length of the canal from the stomach to the rectum, may be used with one pole in the stomach and the other in the lower bowels, thus passing a current longitudinally through the tract. In various forms of atony of the digestive tube, this kind of treatment was found particularly useful.

All these new methods, however, would avail little for permanent cure were it not for the proper use of

dietetics, during and sometimes after the treatment. It is here that the knowledge of the physician in the composition and the physiologic digestion of food is taxed to its utmost capacity; for one can not always prescribe a diet with the assurance of getting favorable results, without being well versed in these branches. Furthermore, it is absolutely necessary in many cases to be acquainted with the physiologic, chemie and bacteriologic condition of the alimentary canal to understand what phenomena must take place when foods of a given kind shall reach it. The haphazard diet that we usually find prescribed in many cases is often fraught with danger or, at least, very commonly produces disturbances more serious than existed before treatment. Very few in general practice would agree, for instance, in giving to the stomach complete rest from any kind of food for as long as six, seven or ten days in the case of catarrh of that organ, feeding the patient during all that time with pre-digested food by colon enemata, and yet this is precisely what is done occasionally in aggravated forms of this disease, and with the very best success.

The greatest difficulty that we find in the way of treating diseases of the alimentary canal by improved methods is that so many object to the use of the stomach tube, fearing its introduction into the organ, because it produces nausea and sometimes a sense of choking; and physicians who will not use this method have encouraged this repulsion and thereby robbed many a patient of this one means of salvation, until no remedy could be successful. On the other hand, I have met practitioners who had used the tube for awhile and stopped it for no other reason than that one or two patients never came back, and the doctors lost that much revenue.

I submit, that since the evidences are eminently in favor of most of the modern improvements and methods of diagnosis and treatment of the diseases of the digestive apparatus I have mentioned, it behooves every physician to give them careful attention. True, it requires time and apparatus, but in the matter of reaping satisfactory results it will pay, although it may not yield much financially.

THE RISE AND FALL OF THE LICENSED PHYSICIAN IN MASSACHUSETTS.

1781-1860.

The President's Address at the Ninth Annual Meeting of the Association of American Physicians held in Washington, May 29, 1894.

BY REGINALD H. FITZ, M.D.

BOSTON.

In calling to order the ninth annual meeting of our Association I desire to express the highest appreciation for the honor you have bestowed upon me in appointing me to preside over your proceedings. To conduct the affairs of so aristocratic a democracy has been made a task so easy that the gift of persuasion, or the knowledge of parliamentary law become wholly unnecessary qualifications. The one obligation which has weighed somewhat heavily is the thought of the opening address which is to prepare the way for such communications as you are to make for the advancement of scientific and practical medicine—all the more as my own attention has been particularly directed for the past few months toward a class of practitioners who have no idea of scientific medicine, and whose only thought of the practice of medicine is how much money can be made out of it.

It may not be uninteresting to learn what men like yourselves, many years ago, did in order to discourage such persons—what they planned, what they accomplished, and why they failed. I will, therefore, ask your attention to the rise and fall of licensed physicians in Massachusetts, 1781–1860.

In the "Records of the Governor and Company of the Massachusetts Bay in New England" (1854, III, 153), is to be found the first legislation concerning the regulation of medical practice in Massachusetts. On May 3, 1649, the General Court, held at Boston, voted as follows:

"Forasmuch as the laws of God (Exod: 20. 13) allows no man to touch the life or limme of any pson except in a judicyall way, bee it hereby ordered and decreed, that no pson or psons whatsoeuer that are employed about the bodies of men, woemen, and children for preservation of life or health, as phisitians, chirurgians, midwives, or others, shall presume to exercise or putt forth any act contrary to the knowne rules of arte, nor exercise any force, violence, or cruelty vpon or towards the bodies of any, whether young or old,—no, not in the most difficult and desperate cases—wth out the advice and consent of such as are skilfull in the same arte, if such may be had, or at least of the wisest and gravest then present, and consent of the patient or patients, (if they be mentis compotes,) much lesse contrary to such advice and consent, vpon such punishment as the nature of the fact may deserve; w^{ch} lawe is not intended to discourage any from a lawful vse of their skill, but rather to encourage and direct them in the right vse thereof, and to inhibit and restrayne the presumptuous arrogance of such as through pfreidence of their oune skill, or any other sinister respects, dare be bould to attempt to exercise any violence vpon or towards the bodies of young or old, to the prejudice or hazard of the life or limme of men, woemen, or children."

Until the years immediately preceding the War of the Revolution there was no more stringent regulation of medical practice than this. But in 1760 the City of New York had found it necessary to regulate the practice of medicine within its limits on account of the abundance of quacks preying upon the community. Five years later the Medical School of the University of Pennsylvania was established, and in the following year the New Jersey Medical Society was founded. In still another year the Medical School of Columbia College began its career; and in 1771 the colony of New Jersey passed its act regulating the practice of medicine, to be followed in 1774 by the abortive attempt in Connecticut.

The years thus ripe in revolutionary ideas and acts produced their fruit in Massachusetts.

Although there were excellent physicians in the larger cities and towns of the Commonwealth, and several of them possessed medical degrees received in Europe, they were few and far between. Most practitioners had served merely a sort of apprenticeship to their seniors. There was no medical school in the State, and but two in the country, and these almost as remote as the leading schools of Europe at the present day. Any one undertook the study of medicine in such manner as he saw fit, and entered his practice with as little preparation as he chose. A considerable number of wholly unqualified practitioners thus were to be found, a source of danger to the community, a disgrace to the name of physician, and a cause of jealousy, contention and distrust among the members of the profession.¹

The example set by New Jersey and New York was one which demanded a speedy following, and thirty-one of the leading physicians of Massachusetts, sixteen being from towns outside of Boston, became incorporated as the Massachusetts Medical Society,

"that a just discrimination should be made between such as are duly educated, and properly qualified for the duties of their profession, and those who may ignorantly and wickedly administer medicine whereby the health and lives of many valuable individuals may be endangered, or perhaps lost to the community."

That this purpose might be carried out, the President and Fellows of the Society or their appointees from its members were given "full power and authority to examine all candidates for the practice of physic and surgery, who shall offer themselves for examination, respecting their skill in their profession, and if upon such examination, the said candidates shall be found skilled in their profession, and fitted for the practice of it, they shall receive the approbation of the Society in letters testimonial of such examination," etc. They were obliged, under penalty to hold this examination, although candidates were not obliged to present themselves for approval.

The State thus did not prevent the practice of medicine by any one, but it implied that the letters testimonial of the Society discriminated between the duly educated and properly qualified, and the ignorant and wicked. By the limitation of the maximum membership to seventy, admission to the Fellowship became a proof of distinction which the better educated and higher minded physicians were proud to attain. This number, furthermore, gave evidence of the comparatively few physicians in the State at that time, who were considered worthy of this high distinction. Indeed, it repeatedly happened in the early life of the Society that it was impossible to secure the attendance of a sufficient number of Fellows to form a quorum to transact business.

Two years after the incorporation of the Medical Society the Medical School of Harvard College was established; and it was feared that the power of Harvard College to examine medical students and grant degrees in medicine might interfere with the authority of the Society to examine candidates for practice and issue letters testimonial. According to the memorial of Dr. John Warren in 1811, this "would have produced the most unhappy effects, but for the repeal of an exceptionable article in that establishment, and the accommodating conduct of those who, at that time, were the guardians of science and the patrons of the healing art."²

But doubts arose with reference to the duties and powers of the Society concerning the examination of candidates and its authority to demand and receive compensation for its services, and an act in addition to the act of incorporation was passed in 1789. It was therein made the duty of the Society, "in order more effectually to answer the designs of their institution, from time to time to describe and point out such a medical instruction or education as they shall judge requisite for candidates for the practice of physic and surgery, previous to their examination before them. . . and they shall cause the same to be published in three newspapers in three different counties within this Commonwealth."

The Society continued to fail in its object to create a proper standard of medical qualifications. The population of the State rapidly increased, and the number of practitioners likewise. There was no sufficient inducement to lead physicians to apply for

¹ Proceedings of the Massachusetts Medical Society, 1891, 19.

² Dr. S. A. Green's Centennial Address, Med. Comm. Massachusetts Medical Society, 1875–81, x11, 639, 654.

the approval of the Society; and in the first twenty years of its existence only some twenty candidates had received the testimonials in approval of their professional skill.³ In the same period Harvard had conferred its medical degree upon thirty candidates.

Early in the present century Dr. John D. Treadwell, a young, learned, devoted and public-spirited physician of Salem, impressed with the inability of the Society to accomplish its aims, endeavored to improve its usefulness. An extensive correspondence was instituted among the members and with the assistance of Mr. Sewell, afterward Chief Justice of the State, a bill was drafted which, somewhat modified, was enacted in 1803.

The Massachusetts Medical Society, as it now exists, was then instituted; and its plan of organization became a model for other State societies. It was no longer a close corporation with a limited membership, but it was possible for every physician in the State to become a Fellow. It was only necessary that he should have been a student in medicine agreeably to the regulations of the Society, and pass a satisfactory examination before the censors, after which he received a license to become a practitioner of medicine or surgery; "and after three years of approved practice in medicine and surgery, and being of good moral character, and not otherwise," he became a member of the corporation by subscribing to the by-laws.

The medical graduates of Harvard University were made licentiates without passing an examination, since the right to confer degrees had been granted Harvard College long before the Massachusetts Medical Society was incorporated. "The only means of avoiding collision with that ancient and respectable institution was by the compromise which was adopted."⁴

A duly licensed physician in Massachusetts in 1804 was required to give satisfactory evidence of the following qualifications before being admitted to examination for the license: Some acquaintance with Latin and Greek, and with the principles of geometry and natural philosophy; three full years of study under the direction of some respectable physician or physicians whose practice he must have attended. During this time he must have read the most approved authors in anatomy, physiology, chemistry, materia medica, surgery, and the theory and practice of physic. He was examined in physiology, pathology, therapeutics and surgery.

There was still no obligation on the part of any practitioner to present himself for license; and the only privilege enjoyed by the licensed physician, apart from the right to attend the meetings of the Society and the use of its libraries, was exemption from service in the militia.

Notwithstanding the Act of 1803 made it possible for every properly qualified physician to become licensed and a member of the Society, it proved necessary to take further steps to bring them within the fold, and in 1806 a by-law was passed in the following terms:

"To promote the laudable design of the Legislature, in forming and incorporating this Society, to prevent as far as may be all unqualified persons from practising medicine or surgery, and in order to discourage empiricism and quackery: it shall be deemed disreputable and shall be unlawful, for any Fellow of this Society, in the capacity of physi-

cian or surgeon to advise or consult with any person who having been a Fellow of the Society, shall be expelled therefrom, or with any person whatever, who shall thereafter commence the practice of medicine or surgery within this Commonwealth, until he shall have been duly examined and approved by the censors of the Society or by those of some district society," etc.

The object of this by-law was to guard the public against ignorant, designing and unscrupulous pretenders. The Society had provided the means by which physicians could give evidence of having followed a suitable course of study, and it was its duty to inform the public that if it employed unlicensed practitioners it must suffer the consequences.

Notwithstanding these attempts at compelling practitioners to become educated physicians, the standard was evidently too high for all to attain. Many could not comply with the requirements; others did not find a sufficient inducement in the honors and privileges bestowed by the Society. The Thomsonians, then beginning their career, required no education and no license. There was no law to prevent their entering practice; and Chief Justice Parsons⁵ had then made his famous decision in the case of the Commonwealth v. Thomson, "that if the prisoner acted with an honest intention and expectation of curing the deceased by this treatment, although death, unexpected by him, was the consequence, he was not guilty of manslaughter. . . . There is no law which prohibits any man from prescribing for a sick person with his consent if he honestly intends to cure him by his prescription; and it is not felony, if through his ignorance of the quality of the medicine prescribed or of the nature of the disease or of both, the patient, contrary to his expectation, should die."

The Chief Justice evidently felt that there was likely to be need of some legislation which should prevent the occurrence of such cases, for he closes his decision by saying: "It is to be exceedingly lamented that people are so easily persuaded to put confidence in these itinerant quacks, and to trust their lives to strangers without knowledge or experience. If this astonishing infatuation should continue, and men are found to yield to the impudent pretensions of ignorant empiricism, there seems to be no adequate remedy by a criminal prosecution, without the interference of the Legislature, if the quack, however weak and presumptuous, should prescribe with honest intentions and expectations of relieving his patients."

In 1811 an unsuccessful attempt was made to incorporate a rival society with the same privileges as those enjoyed by the Massachusetts Medical Society, under the title of the Massachusetts College of Physicians. The announced reason was that two societies were better than one; the real object was thought to be the establishment of a new medical school.

The Massachusetts Medical Society strongly opposed the scheme, on the ground that it was unnecessary and would lead to the rejected candidates of the one society being accepted by the other, whatever might be their qualification, thus producing disagreements and animosities injurious to the profession and to the public.⁷

It is possible that in consequence of the recommendation of Chief Justice Parsons, certainly with the view of discouraging quackery which was rapidly increasing under the influence of Thomson, the Legislature in 1818 passed its first "Act regulating

³ Dr. James Jackson's speech at the Annual Dinner, 1856.

⁵ Massachusetts Reports, 1809, vi, 184.

⁶ Op. cit. p. 142.

⁷ Dr. S. A. Green. loc. cit., p. 651.

the Practice of Physick and Surgery," which was supplemented in 1819 by "an Act in addition to an Act entitled 'an Act regulating the practice of Physick and Surgery.'"

According to the first of these Acts, no person entering the practice of physic and surgery within the State could recover by law any debt or fees for his professional services unless he had received a medical degree from some college or university, or had been duly licensed by some medical society or college of physicians, or by three Fellows of the Massachusetts Medical Society, designated in each county by its councilors, with power to examine candidates and grant licenses. Copies of these licenses were to be deposited with the clerk of the town, district or plantation in which the licentiate resided.

In the Act of 1819, that the physician might recover his debts by law, it was necessary that he should be a licentiate of the Society or a medical graduate of Harvard. If the candidate for the license was educated out of the State, the censors might waive a new examination if they were satisfied that he had received an education agreeably to the regulations provided by the Society.

It is stated⁸ that this difficult trust was accepted with reluctance,⁹ that the law was not sought for by the Society, and that it was doubtful whether its action was not rather injurious than beneficial. Of this law Chief Justice Shaw said:¹⁰

"It appears to us that the leading and sole purpose of this Act was to guard the public against ignorance, negligence and carelessness in the members of one of the most useful professions, and that the means were intended to be adapted to that object. If the power of licensing were given to the Medical Society exclusively, there would be much more plausible ground, at least, to maintain that the power was conferred on a body who would have a temptation to abuse it, so as to promote their private interests; but where the power is conferred equally on the University charged with the great interests both of general and professional education, and which can not be perceived to have any such interest, that ground of argument seems to be wholly removed, and it seems difficult to perceive how a power which it is important to the community should be placed somewhere could be placed more safely. The courts are all of the opinion that the law in question is not repugnant to the Article of the Bill of Rights, above cited, and that its validity can not be impeached on the ground that it is a violation of any principle of the constitution."

The licensing of physicians by the Society doubtless aided in restraining a certain number of practitioners from adopting some of the methods of the charlatan; but it did not interfere with the encouragement of the latter by the community. I am indebted to Dr. John Homans for the opportunity of quoting from a letter of Dr. George C. Shattuck to Dr. Homans, written July 26, 1828. It gives evidence of the fondness for quackery in Boston at that time:

"The city has 60,000 (inhabitants?) and seventy-one regularly bred physicians. About one-half, from either youth or age, have not much to do. The irregular physicians are numerous, at the head of which, in popular influence, we may place Thomson, who has formed his botanical society, who have individually learned his system of practice by hot drops and sweating, etc. The disciples of this system, perhaps may embrace one-sixth of the population of Boston. The patent medicines are employed in about, I believe, another sixth of the cases."

In 1831 the Society had reached such a degree of success in carrying out the objects of its incorporation that it included in its ranks "nearly every edu-

cated practitioner of medicine or surgery in the State."

The line of distinction was so strongly drawn between its members and irregular practitioners "that the profession is no longer made responsible in the minds of men for the consequences of their ignorance and malpractice, nor its harmony disturbed by their misconduct; and they are much less successful than formerly in diverting the confidence of the community from regular physicians to themselves."¹¹

At this time, however, there were certain discordant elements within the Society which threatened its prosperity and usefulness. Some of the younger physicians were dissatisfied with the clause in the Act of 1803, which demanded a period of three years of probation in practice before admission to full membership in the Society. The Legislature was therefore requested to repeal this clause, which it did by a special act in 1831, and approved candidates became at once Fellows of the Society.

A more serious disturbance, which menaced the harmony and influence of the Society at this time, was the appeal to the Legislature from the physicians of Berkshire County, in the western part of the State. They desired to be incorporated as an independent body, nominally on account of their distance from the headquarters of the Society, their limited privileges, and their dissatisfaction with the requirements of the censors. It was supposed that this action was largely planned in the interests of the Berkshire Medical Institution, a medical school incorporated in 1823, but without the authority to confer the degree of Doctor of Medicine.¹² It was situated in Pittsfield, and was practically a department of Williams College (not far distant), which had the power to confer degrees, but no medical faculty or medical school. Williams College sanctioned the degree of the candidates educated at the Berkshire Medical Institution. The conditions of this alliance proved important in the courts¹⁴ when the honorary degree of M.D. from Williams College was offered in evidence as a legal qualification. It was decided it was invalid, since the defendant must have both the education and the degree to be a legally qualified practitioner.

In the year following the incorporation of the Berkshire Institution it had petitioned the Legislature to be granted the same privileges as belonged to the medical graduates of Harvard University, the most important of which was that of being acknowledged and received by the Massachusetts Medical Society without examination as regular practitioners of medicine and surgery.

At that time this petition was successfully opposed, on the ground that the Berkshire Institution had no independent board of overseers like Harvard College, and therefore was not under the same restrictions and oversight. The petition to form an independent society was also successfully opposed; but in 1837, with the approval of the Society, an Act was passed, according to which graduates of the Berkshire Medical Institution were "entitled to all the rights, privileges and immunities granted to the medical graduates of Harvard College."

The rights and privileges of the licentiates of the Massachusetts Medical Society had been somewhat extended by the Anatomical Law of 1834, according

to which "the dead bodies of such persons as it may be required to bury at the public expense might be surrendered to any regular physician duly licensed according to the laws of this Commonwealth."

The State had thus definitely committed itself to the regulation of the practice of medicine by the Acts of 1818 and 1819, and had placed the duty of licensing practitioners in the hands of the Massachusetts Medical Society. It conferred but few privileges on the licensed, namely, exemption from militia service and jury duty, the right to obtain and dissect the unclaimed bodies of those to be buried at the public expense, and to collect fees by law.

But unlicensed physicians could take their pay in advance, and were not desirous of the privilege of consulting with the members of the Society. The Thomsonian movement was rapidly spreading throughout the country, appealing to the people by its simplicity and economy, its dogmatic assertions and reports of wonderful cures, its advocacy of vegetable remedies, and its cry of persecution.

The efforts of the Society to include within its ranks all educated practitioners, led in 1836 to the recognition of dentists as practitioners of medicine, since dental surgery was being studied and pursued scientifically by gentlemen of regular medical education.¹⁵

In the following year a further attempt was made in this direction, by requiring that every licentiate or medical graduate of Harvard or Berkshire entitled to admission to the Society must enter within a year after being so entitled, or be deemed an irregular practitioner. This term was applied to all practitioners in the State who were not Fellows or Licentiates of the Society, or doctors in medicine of Harvard or Berkshire. The above regulation was repealed three years later, since it took away "the freedom originally intended to be allowed to all regular physicians to join the Society or not, as they pleased," and stigmatized "as irregular practitioners gentlemen who have been recognized as competent physicians merely for the exercise of this freedom."¹⁶

In 1836, the statutes of the Commonwealth were revised, and the report of the commissioners (1835, Part I, 125), includes all the legislation previously enacted, placing the control of the licensing of physicians in the power of the Society.

But the Legislature did not accept the first section, which read as follows:

"No person who has commenced the practice of physic or surgery, since the year one thousand eight hundred and eighteen, or who shall hereafter commence the practice thereof, shall be entitled to maintain any action for the recovery of any debt or fee accruing for his professional services, unless he shall, previously to rendering these services, have been licensed by the officers of the Massachusetts Medical Society, as hereafter provided, or shall have been graduated a doctor in medicine in Harvard University, or in the Berkshire Medical Institution, by the authority of Williams College."

It also negated a clause making the neglect to record a license a like disqualification to its non-possession.

The Legislature approved this part of the report of the committee with the above exceptions, and it became chapter 22 of the revised statutes, entitled, "Regulations Concerning the Practice of Physic and Surgery."

According to Dr. J. Mason Warren,¹⁷ the first sec-

tion was omitted in accordance with the wishes of the greater part of the (State Medical) Society . . . as being in its action adverse to their interests. It served merely to excite sympathy, especially for the Thomsonians, and could not prevent them from receiving fees for services rendered.

The Society continued in its work of licensing physicians without apparent disturbance until 1848. At this time its effect in controlling the conditions of medical practice in the State is thus expressed by Dr. A. L. Peirson, of Salem, in behalf of a committee of which he was chairman:¹⁸

"We have steadily elevated our profession, by improving medical education, encouraging the harmony and honorable intercourse of its members, and have protected from the mischief of quackery, by discouraging every show of it among regular practitioners. This simple and efficient plan of the Society has accomplished all that was ever intended by its organization in 1803. . . . It is to be regretted that, from natural causes, in no way to be attributed to the form of organization, the concentrated action of the Society has not been equally felt in all parts of this extended Commonwealth."

According to Dr. Z. B. Adams,¹⁹ there were at this time 1,237 medical practitioners in Massachusetts, most of whom belonged to the Massachusetts Medical Society.

On the contrary, Dr. J. V. C. Smith presented the minority report of the same committee, in which he states:²⁰

"The Society was once eminently useful in protecting the community from the encroachment of ignorant pretenders, . . . and it must be obvious to all that circumstances have greatly changed, our legislative tables have been completely turned, and will probably ever remain so. A license, or medical degree, is no longer requisite for the practice of medicine in Massachusetts, and no laws of the State, or of the Massachusetts Medical Society, are of any avail in guarding the entrance into the profession, or regulating the conduct of its members. . . . Less than one-half of the regular practitioners of medicine now nominally constitute the Society. In Berkshire, there are one hundred; less than twenty belong to the Society. In Hampden, one hundred and thirty (about); and of this number only about twenty or twenty-five are members of the State Society. In some other counties there is doubtless a majority, while in others not one-half of the regular physicians are members. The number of Fellows of the Massachusetts Medical Society is not far from seven hundred, which is not probably one-half of the physicians in the State."

These reports were called forth by a resolution presented by Dr. Childs, of Pittsfield, involving a change in the organization of the Society for the purpose of advancing medical science, promoting harmony and good feeling in the profession, thereby contributing to the best interests of society.

Although the councilors largely favored the views expressed in the majority report, the existence of a considerable degree of dissatisfaction and the necessity of remedying it was apparent in the appointment of a committee to consider the question of altering the by-laws. This committee consisted of Drs. John Ware, A. L. Peirson, W. Lewis, J. Jeffries, J. V. C. Smith, H. H. Childs and John C. Dalton. The report of this committee is especially valuable from the character of the latter, and the recognition of the necessity of the Society to increase and consolidate its strength.

They found²¹ that many members had often expressed the opinion that the Society as constituted

did not accomplish all the purposes of which it was capable—and failed to secure the favor of the profession in remote parts of the State. Consequently only a limited number of physicians found it for their interest to become members. They were called upon to obey laws they had no voice in making and to contribute to the expenses of an organization in which they found it difficult to take part: The Society is but little known to those among whom they are thrown, thus has but little influence over them, and is not necessary to their reputable standing among physicians nor to their success with the community that they should be connected with it.

The committee reported various amendments to the by-laws involving favorable action of the Legislature which took place in 1850. By-law V permitted any reputable practitioner of medicine or surgery who had been in practice not less than fifteen years, to be admitted a Fellow, previously to 1852, by the district society where he resides by a vote of two-thirds of the members present at any stated meeting.

The Society was thus endeavoring to increase its influence in the one direction by licensing as many educated and intelligent physicians as possible, and even without examination in certain instances.

This liberality, however, was to be controlled by what many now see to have been an unwise policy, namely, the treatment of the homeopaths.

In 1846²² an applicant for membership stated that he had great confidence in the efficacy of medicine "especially when prepared and prescribed agreeably to the directions of Hahnemann." The councilors referred the application to the censors, with full powers to settle the matter, and they admitted the applicant to membership.

In the meantime the influence of homeopathy was increasing, and in 1850²³ it was moved "that all homeopathic practitioners are, or should be, denominated irregular practitioners, and, according to the By-Laws of this Society, made and provided, ought to be expelled from membership." This resolve was tabled on motion of Dr. Bigelow.

At the next meeting Drs. Hayward, O. W. Holmes and J. B. S. Jackson were appointed a committee "to devise some course of action, to be pursued by the Society, in regard to all homeopaths." This committee reported as follows:²⁴

"1, *Resolved*, That any Fellow of this Society who makes application to resign his Fellowship in consequence of having adopted the principles and practice of homeopathy may be permitted to do so on paying his arrearages; but he shall not be entitled to any of the privileges of Fellowship, nor shall his name be retained in the list of Fellows.

"2, *Resolved*, That a diploma from a homeopathic institution shall not be received as any evidence of a medical education; nor shall the Censors of the Society regard the attendance on the lectures of such institutions, nor the time passed at them, as qualifications which shall entitle candidates to an examination for a license from this Society."

This report was adopted. Three years later the question of homeopathy was again brought before the Society at the annual meeting.²⁵ The Essex North District Society there presented the following resolution:

"Forasmuch as there is no common ground of support or sympathy between homeopathy and allopathy;

"*Resolved*, That if the homeopaths are allowed to retain

their regular standing in the Massachusetts Medical Society, and claim fellowship and counsel with allopaths, we, as consistent and conscientious individuals, request to be honorably discharged from our allegiance and connection with the parent society."

Dr. Spofford presented the following resolution:

"That, while we recognize the right of regular physicians to use medicine in any quantity or doses which they may consider useful to their patients, we consider all use of the name of homeopathy in public papers, on signs or otherwise, as quackish or disreputable, and that all persons who make pretensions to homeopathic practice ought to be excluded from the Society."

These resolutions, together with the whole subject, were referred to the councilors, who appointed the following committee to report upon them: Drs. Bigelow, Metcalf, M. Wyman, Spofford and Alden. Dr. Jacob Bigelow reported in February, 1854, and his report was laid on the table.

In the next year,²⁶ the censors of the Suffolk District Society rejected a candidate for admission who avowed himself practicing upon the principles styled homeopathy, on the ground that he was not "fitted for the practice of medicine." It was voted (Feb. 7, 1855), on motion of Dr. Bowditch, "that the Councilors approve of the course adopted by the Censors of the Massachusetts Medical Society for Suffolk District."

In the following June this district society called the attention of the general society to defects in the by-laws concerning the expulsion of members, with reference to a remedy; and this question, together with that concerning the admission of members, was referred to a committee for a report. A few days later the latter reported. Their report was referred to the councilors for adoption. They, in turn, referred the report to a committee, which altered the recommendations; these were adopted by the councilors in February, 1856, and by the Society on May 29, 1856.

These alterations made it possible to expel a member for any breach of the by-laws, for which censure, expulsion or deprivation of privilege was a penalty, and for any conduct unbecoming and unworthy an honorable physician and member of the Society, in addition to causes hitherto deemed sufficient. A carefully arranged method of conducting trials for offenses was also provided. The report of the committee of the councilors recommending these alterations stated that they had no definite measures to offer with regard to homeopathy, and submitted the subject to the judgment of the councilors. This part of the report was laid on the table without debate.²⁷

June 3, 1856, four days after the adoption of the amended report by the Society, the Homeopathic Medical Society was incorporated by the Legislature. It was authorized to examine all candidates for membership, and, if qualified, give them the approbation of the Society. Its members were declared exempt from militia service.

In the following year, the motion that all candidates for the Fellowship be examined by the censors was referred to a committee, reported upon favorably, and the Legislature passed a special act March 5, 1859, making this method the law.

At this time the revision of the statutes was again under consideration, and the commissioners had made their report to the Legislature, in which the existing laws concerning the regulation of the practice of

²² Loc. cit., 1846, p. 108.

²³ Proceedings Massachusetts Medical Society, 1850, 32.

²⁴ Loc. cit., 1850, 51.

²⁵ Loc. cit., 1853, 102.

²⁶ Loc. cit., 1855, 7.

²⁷ Loc. cit., 1856, 35.

medicine were included. This report was referred to a joint committee, which was subdivided into special committees. The general committee referred the chapter concerning the regulation of medical practice to one of these special committees on May 16, 1859. It instructed this committee, "by special order, to inquire into the expediency of omitting all that part of the chapter relating to the Massachusetts Medical Society and to the regulation of the practice of medicine; and on May 21 they reported to the general committee, amendments striking out every section, and every line, and every word in that chapter which gave the Massachusetts Medical Society any power to examine or license physicians or surgeons, or to prescribe a course of study and qualifications for physicians or surgeons."²⁸

Four days later, the councilors appointed a committee, consisting of Drs. J. Bigelow, A. A. Gould, J. Jeffries, G. C. Shattuck, H. J. Bigelow, H. H. Childs and J. G. Metcalf, and "instructed them to look after the interests of the Society in the Legislature," and they were "authorized to take such measures to protect their interests as they may deem expedient."²⁹

But, in the words of Mr. Benton, "the general committee adopted these proposed amendments, with the addition of a change of title of the Act from 'Regulations concerning the Practice of Physic and Surgery' to 'of the Promotion of Anatomical Science,' and that chapter now stands, with the same title as Chapter 81 of the public statutes. All the amendments were adopted by the Legislature, and were enacted Dec. 28, 1859. . . . The Legislature then deliberately took out of the law of the Commonwealth every provision for the regulation of the practice of medicine or surgery, or for the examination or qualification of physicians or surgeons."

The committee of the Society appointed to look after its interests in the Legislature recommended, Oct. 5, 1859, that "no person shall hereafter be admitted a member of the Society who professes to cure diseases by spiritualism, homeopathy or Thomsonianism," which was adopted. As evidence of the state of feeling at the time, it may be said that at the meeting at which this resolution was approved, it was voted that the Society disclaim all responsibility for the sentiments contained in the annual address of the day previous. This had been delivered by Oliver Wendell Holmes, and was entitled, "Currents and Counter-Currents of Medical Science."

Thus we see that the Massachusetts Medical Society was organized in 1781 with the express purpose of making a just discrimination between duly educated and properly qualified practitioners and those who ignorantly and wickedly administer medicine. For many years its Fellows acted most judiciously in endeavoring to include within their number every educated and moral practitioner in the State. They accomplished this largely by the force of example, association and united encouragement. The State made them the sole source of licenses to practice. The progress of Thomsonianism left their responsibilities essentially intact. The advent of homeopathy found them weak where they should have been strong, short-sighted where they should have been far-seeing. The leaders were obliged to follow, and

the reproof of the censors prevailed against the wisdom of the councilors.

Homeopathic diplomas and homeopathic certificates are now accepted by the Society. Homeopathic physicians have been found fitted to practice by the great public, which decides this question for all. Ten years of increasing intolerance destroyed seventy years of enthusiastic effort, devoted labor, tactful management and wise council in the public interest. The State revoked the control of medical practice, and the people have been the sufferers. The history of Massachusetts in this respect is the history of the country. She was one of the last of the States to lay down the control, and she will be one of the last to resume it.

Thanking you for the patience with which you have listened to an historical narrative which offers but little in the way of moral or example to our own Association, we will proceed to the business of the day.

SOCIETY PROCEEDINGS.

Ohio State Medical Society.

The Forty-ninth Annual Meeting of the Ohio State Medical Society, held at Zanesville, Ohio, May 16, 17 and 18, 1894.

FIRST DAY.

Prayer was offered by the Rev. Charles E. Barnes.

The Address of Welcome was delivered by Dr. E. C. Brush, Chairman of the Committee on Arrangements. The Society was welcomed to Zanesville after a pilgrimage of thirty-nine years.

At the previous meeting held in Zanesville, 1855, Dr. G. S. B. Hempstead, of Portsmouth, presided, and Drs. W. W. Dawson, of Cincinnati, and Charles C. Hildreth, Zanesville, were the Secretaries. Reference was made to Dr. Alfred Ball, of Zanesville, who was the first physician to offer his services to the Governor of Ohio, in 1862, and Dr. Howard Culbertson, who in 1861, was by this Society awarded the prize for the best essay on the use of anesthetics in obstetrics, and also author of the prize essay on excision of the larger joints, presented to the AMERICAN MEDICAL ASSOCIATION in 1876.

The Report of the Committee on Arrangements was then submitted by the Secretary of the Committee, Dr. J. C. Crossland.

Telegrams conveying the congratulations of the Illinois State Medical Society and the Iowa State Medical Society, were received, and the Secretary instructed to return to these bodies, and also to send to the Missouri State Medical Society, the fraternal greetings of the Ohio State Medical Society. These Societies were in session at the same time.

The annual report of the Treasurer and Librarian was read, showing a membership of 665 members, and the Society free from debt. It was accepted.

The report of the Secretary was read and received.

A revised Constitution was submitted by the Special Committee on revision of the Constitution, and was adopted.

The following Committee on Nominations was appointed by the President: Drs. Dudley P. Allen, Geo. A. Collamore, W. J. Conklin, Thad. A. Reamy, and W. J. Scott.

DR. D. S. KELLICOTT, Professor Zoölogy and Entomology, Ohio State University, read the first paper entitled,

THE STATE UNIVERSITY AND MEDICAL EDUCATION.

The author spoke first of the propositions or fundamental principles in accordance with which the University authorities have arranged the course designed especially to prepare students for the successful study of medicine, and then of the course itself.

²⁸ Argument of J. H. Benton, Jr., before the Committee on Public Health, 1886.

²⁹ Proceedings Massachusetts Medical Society, 1859, 112.

1. Thorough training is needed for real success in any profession or vocation. This means that the making of a modern master blacksmith requires one to pass the grammar and high schools and four years of as exacting college work as in any course in any college. It has been said, by General Walker, that: "A good technical course produces better educated men in all that term implies than the ordinary college course."

2. The training which is to fit men to practice medicine should be especially thorough and many-sided. It is not only to prepare men to earn a living, but men who, by virtue of their training and opportunities are to be leaders in their respective communities; men who are to have, and may safely have, in charge the lives and health of the people.

3. Therefore, the least that a State university should be permitted to do by way of direct preparation for this great responsibility is a sound preliminary discipline that has reference to the needs, methods and scope of the more strictly university studies of the professional school. This may be accomplished through the regular courses, where pretty free electives are permitted, or by the briefer special course with strict requirements, designed to bring the student out at a definite place, with special fitness and qualities.

4. Medicine has rapidly advanced in recent years as all biological, or more generally, all physical sciences have done. It is less empirical and therefore less independent than ever before; for, as Prof. Huxley puts it: "It is a peculiarity of the physical sciences that they are as independent as they are imperfect; it is only as they advance that the bonds which really unite them all become apparent." The naturalist or biologist has certainly done much to discover and fashion the foundation stones of medicine.

5. It seems, therefore, to follow naturally that the healing art should be treated, from an educational standpoint at least, as a branch of biology, and that the understanding and interest in biology, its methods and its scope, should be broadened and deepened by proper instruction at the proper time, *i. e.*, in the academic course.

6. It appears from a recently issued report from the United States Commissioner of Education, that the relative number of medical students who have acquired academic or scientific degrees is less than formerly. In other words, a larger number, relatively, enter upon medical training direct from the high school, or from the ranks of school teachers or from those who have failed to get on in some other vocation. In the same report it is shown that a majority of medical faculties agree that their students are as well or better prepared now than in former years, so, after all, it may be that the state of the case is no worse, but this is not enough. The difference between "well" and "pretty well" is very great. The student's preparation for university studies ought to be "well." It ought to be *very* "well," for until students have special elementary training for the medical course, too much time in that course must necessarily be spent unprofitably on mere elements that should have been well in hand at entrance.

7. The time at present required to earn an academic degree in the American college is regarded by many educators as too long, at least, as compared to the time required in the professional schools. President Hall would "degrade the A.B. degree at least a year in the best colleges;" "Harvard tends toward a three years' course;" while "Columbia allows a coördination of college and professional studies;" so it is a grave question whether it is not better, in the long run, to put more time on the professional training and less on the academic, especially so if the student enters upon his work late in life. To meet this question fairly the State university has instituted a three years' course, the studies of which have especial reference to those that are to follow in the medical college. Moreover, for those who prefer the four years' course in either science or letters, with the degree at the end, pretty free electives are allowed in the fundamentals of a medical course.

8. The Doctor of Medicine has magnificent opportunities for investigation in a range of questions of the highest importance. The annals of science attest their ability. No other profession, speaking generally, in this country, has equal incentives and opportunities; hence the scientific training from the first should be, as far as possible, in the laboratory and with the scalpel. The younger the brain and nerves and muscles when they begin to direct instruments of precision, the greater the skill and conscientiousness in the pursuit of truth in after life; the greater will be the ambition and the broader the foundation therefore to leave one's profession better than he found it.

To enter the course preparatory to the study of medicine at the State university, a student must be 17 years of age and have completed the equivalent of the average high school course in English; it is practically what is now required to enter the engineering and agricultural courses. No language other than English is required.

The course requires three years with an average of seven-teen hours per week through the academic year, or about eighteen hundred hours. The time is divided among the several groups of subjects as follows: Foreign language, 432 hours; English, 124; physical science, 318; biological sciences, 656, and the balance upon several subjects designed to make a man a good and strong citizen. In addition, military drill is required one hour per day for the first two years. The completion of this course does not make a finished scholar, but it is claimed that the student concentrates his energy; he has a definite purpose, and there is no subject in the course not germane to his future studies or his future possibilities as a citizen and practitioner. The student who does conscientiously the work of this course is as well or even better prepared to follow and profit by the instructions of specialists than are those who have received a college degree. All the sciences, physical and biological, are taught by the laboratory method. There are two years in physiology and the same in anatomy. One year of three hours a week with text-book, lectures and demonstrations, and one of five hours in the laboratory.

DISCUSSION.

DR. DUDLEY P. ALLEN, Cleveland.—The relative difference between classical training and technical training is discussed in the paper at some length. One difficulty in the United States is that the students do not pass from the preparatory schools into the colleges until 18 or 20 years of age. If they take three or four years special study, they are 26 or 27 years old. If they go through hospitals, that adds another year and a half or two years. If they go to Europe, they come back ready to start at about 30. Men in the United States, beginning the practice after thorough preparation, are considerably more advanced than in Germany or France. A man should be able to begin the work earlier than at present. I presume one difficulty is that a great many colleges are not willing to give a degree to a man who has not studied for years. A good deal can be done in this. Chemistry, materia medica, botany, physics, and also the facts of electricity can be taught in the college or university as well as in the medical college. A four years' college course and four years' medical course could thus be completed in seven years, instead of eight as at the present time.

DR. H. J. HERRICK, Cleveland.—The old idea is that medicine is a learned profession, with theology and law, and it is right it should be so considered. A man hardly knows, before a classical training, what he wants to pursue. Besides books you want manual training. The term should be extended preparatory to studying medicine and perhaps in medicine.

DR. W. J. SCOTT.—The manual training schools are of very great value in training young men how to do and how to think. A boy who is a natural mechanic will make a better surgeon when he studies medicine. This does not argue against a person having a classical education should they desire. With electives in the place of the old regular course in college, the student is sooner prepared to begin the work of life.

The author, in closing the discussion, urged all young men to begin study at an early age, and if they can take a classical course by all means do so, especially where there are electives, as there are now in all leading universities.

THE PREVENTION OF TUBERCULOSIS,

was read by DR. C. O. PROBST, Secretary of the Ohio State Board of Health.

If tuberculosis is a preventable disease surely, considering its prevalence and great fatality no subject of more importance can occupy our attention. Dr. Billings estimates that 125,000 people died of phthisis pulmonalis in the United States in the year 1890. Hirsch says that one-seventh of all deaths among civilized races occur from tuberculosis. The vital statistics of Ohio show the total number of deaths reported from phthisis—laryngeal and pulmonary—during the ten years 1884 to 1893 inclusive, to be 36,455, equal to over 12 per cent. of the deaths reported from all causes. The number reported from tubercular diseases including tubercular peritonitis, tubercular meningitis, hydrocephalous and scrofula, was 42,563, equal to over 14 per cent., or about one-seventh of the deaths from all causes. There were 16,521 deaths from phthisis in males, equal to 10.4 per cent. of the deaths from

all causes in males, and 18,800 deaths from all forms of tuberculosis, or 11.8 per cent. In females there were 19,934 deaths from phthisis, or 13.9 per cent., and 23,762 deaths from tuberculosis in all forms equal to 16.4 per cent. of the deaths from all causes in females. It is usually found that the mortality is greater in males.

In the prevention of tuberculosis we should work in two directions: 1, to prevent the broadcast sowing of the bacillus tuberculosis; and 2, to fortify the soil against its growth.

Let us consider the latter, the predisposing cause, first. How may we control heredity? Whether legislation to prevent the marriage of consumptives, or the children of consumptive parents would be wise or unwise we need not expect any movement in this direction with the present public feeling in the matter. The children of tuberculous parents, however, should be specially guarded against prolonged or close exposure to the exciting cause as in nursing a phthisical person without proper care of the sputa; while by strict and continued attention to all the conditions that favor physical, especially chest development, and the maintenance of a high standard of health their resistance to the tubercle bacilli should be increased. The duty of imparting such instructions belongs to the family physician.

Certain occupations, in which workmen are necessarily and continuously exposed to the inhalations of dusts, especially dusts with sharp cutting points, are attended with a comparatively high mortality from phthisis including phthisis pulmonalis. Against 100 deaths from phthisis in all males between 25 and 65 years, there are 1,576 deaths from this cause in the ten dust-inhaling trades. This greatly increased death rate is doubtless attributable to pulmonary injuries, which favor either the entrance or growth of the bacillus or possibly both; and it is to be noted that while these workers in dust present an unusually high comparative death rate from phthisis, they are still more frequently the victims of other forms of pulmonary disease. Other occupations show a preponderance of death from this disease. This is specially noticeable in occupations carried on in close, badly ventilated rooms, where little physical exercise is required and where constrained position is unfavorable to chest development as among tailors shoemakers, printers and the like. The cause is probably to be found in the constant breathing of pent-up vitiated air, which acts both to concentrate the bacilli cast about the work-shop by those already affected, and to produce a pulmonary condition favorable for their growth. A high death rate is almost invariably found among those constantly exposed to pre-breathed air, as in prisons, barracks, nunneries, etc. An opportunity is here presented for the State to very materially lessen the loss of life from phthisis, and at the same time from other causes. Laws should be enacted compelling owners and operators of shops and factories to provide appliances for the removal of all machine dust. Workmen exposed to dust arising from hand operations, which can not be so removed, should be urged or required, if possible, to wear respirators. Greater attention should be given to the ventilation of such places, and minimum requirements as to air space per capita and renewal of air should be provided for by the State and enforced by its agents. The State should also undertake to secure proper ventilation of school houses, for it can not be doubted that the constant breathing of impure air in schoolrooms lays the foundation for much of the disease, of tuberculous as well as other character, occurring later in life. Municipal authorities should provide for the ventilation of cities by the judicious location of public parks, and by regulating the width of the streets and height of buildings; the proper cleaning and sweeping of streets is also a factor in lessening the spread of tuberculosis and other air borne diseases.

Of the other predisposing causes of tuberculosis, damp soil and damp dwellings may be mentioned. Sewerage becomes a factor in reducing the mortality from phthisis, and municipal authorities might also require the proper drainage of the soil upon which dwellings are to be located.

We turn next to the exciting cause, the tubercle bacillus. This may usually be found in all tuberculous discharges, but is chiefly disseminated by dried sputa of persons suffering from phthisis pulmonalis. If every person suffering from this disease could be induced to expectorate into a receptacle containing a disinfectant solution, or into cloths which are at once burned, the ravages of tuberculosis would undoubtedly be very greatly lessened. Not until the masses are made to realize that consumption may be communicated from person to person, may we hope for general observance of such measures. The public press should be enlisted in this educational crusade; and the State Board of Health, by

properly prepared circulars, should widely disseminate among the people plain instructions for the prevention of consumption. In theaters, halls and other places of public assemblage, and in railway cars and steamers, it would be possible to require that cuspidors containing a disinfectant should be provided. There is always great probability that a room occupied by a consumptive has become infected, and such a room, when vacated, and the clothing and bedding of the patient, should be disinfected. Unless the relatives or friends are both willing and intelligent, this should be done under the direction of the health authorities, and wherever this seems necessary, the attending physician should report the fact to the board of health. Should tuberculosis be made a notifiable disease? In my judgment it would be unadvisable to attempt to enforce such a rule in Ohio until public opinion has declared in favor of it. The establishment of hospitals for consumptives is to be recommended.

One important channel of infection remains to be considered, viz., the ingestion of tuberculous meat and milk. The prevalence of intestinal tuberculosis in children is believed to be due largely to the ingestion of raw milk from tubercular cows. The bacillus is not destroyed by the gastric juice. As we can hardly expect to stop the eating of rare meat or the drinking of unboiled milk, steps should be taken to eradicate the disease among food-producing animals.

The facts and arguments presented seem to justify the following conclusions:

1. Tuberculosis is invariably due to the action of the bacillus tuberculosis.
2. The healthy human body, under ordinary circumstances, is immune to the disease.
3. Among the predisposing causes productive of tuberculosis are: *a*, heredity; *b*, certain occupations; *c*, breathing impure, especially pre-breathed air; and *d*, dampness of soil and dwellings.
4. The knowledge that tuberculosis is a communicable disease, and instructions for its prevention, should be widely disseminated among the people.
5. State and local authorities should combat in every possible way the predisposing causes of the disease, leaving mainly to attending physicians the proper treatment of patients to prevent infection.

INFECTION IN TUBERCULOSIS—FOOD PRODUCTS.

This paper was read by DR. H. H. SPIERS, Ravenna. No factor is more conducive to the well being of a people than diet of food product. England and India may be cited in illustration. Exchange the food products of these two countries for five generations, and think you their relative strength would remain the same? As with the nation so with the individual, though less marked. Bone, brain and muscle are built on food ample in quality, quantity and variety.

At times a staple production fails or is defective or diseased, through climatic or other causes, and a people dependent on one production must then face starvation or become enervated through diet. As examples may be mentioned the famine in Ireland through failure of the potato crop, local outbreaks of ergotism, etc. Again a product may be defective in that it is improperly cared for. Over-ripe fruits, partially decayed vegetables, or meats improperly kept must cause sickness to the consumer. In regard to a food product there is only one royal way: *To select only the best.*

There is only one food product with which we are all familiar that is an ideal perfect food: Pure milk. No article has been more used and abused, and it stands to-day eulogized and condemned. Its purity is affected by intrinsic or extrinsic causes. In other words, milk may be changed during secretion or after it is withdrawn. Of the various changes that take place after milking we will not speak, but simply state that they may all be prevented for a longer or shorter period by a proper sterilization.

Of the changes that take place at or during secretion we wish to speak more particularly:

1. It is asserted by high medical authority that tuberculous animals secrete milk containing bacilli, but so far as known to the author no one argues the presence of the bacilli in milk. Seeing is believing.
2. Sterilization of infected food products does not restore a perfect food. No sterilization will change a diseased grain or partially decayed vegetable into perfect food. Were five tons of moldy hay sterilized after the most approved German method, is there a physician who would pay a full market price for the hay? The hay is an imperfect food before a mold fungus starts, and killing the mold fungi does not restore

perfect bay. Milk secreted by a tuberculous animal is a diseased product before the bacilli are found and killing the bacilli by sterilization does not restore a perfect milk. Milk is a secretion; an elaboration of materials from the blood. If the blood be pure the milk is pure, and *vice versa*. The milk of a syphilitic is poor in quality, and should be nursed only in exceptional cases. What shall we say of the milk of an animal suffering from a constitutional disease? Herein, it seems to the writer, lies a secret of the 50 per cent. of mortality under 5 years of age. Poor as are all artificial infant foods, in that they do not contain the elements of nutrition—they are superior to commercial condensed milk, gathered as it is from unknown sources, in that they do not contain elements of disease. If pure milk be the only perfect food, if the infant human race must live on milk, then the way to obtain pure milk is the desideratum of the century. We must have healthy animals, and these can be best obtained by procuring healthy progeny by selection. The animals must conform to hygiene. The man who sells rotten bananas and robs you of your child is no more guilty than the man who improperly cares for the cows that furnish the infant's food. They should alike be held amenable to law. Every precaution should be taken to keep milk pure, and herein lies a field for sterilization.

As to infection in tuberculosis. Imperfect food product lowers the vital resistance, and lowered vital resistance in a tissue means weakness in that tissue. It is the condition of the system that allows the bacilli to enter.

IS CONSUMPTION CURABLE?

This subject was treated by DR. R. E. CHAMBERS, of Chandlersville. The paper was limited to the discussion of tubercular consumption. Many cases reported as cured, in some instances the report being sustained by post-mortem examination, and doubtless correct, may be chargeable to some accidental cause. A case may be here related which came under the observation of the author:

A young lady was annoyed by a cough which became troublesome. There was hectic fever, excessive expectoration, great emaciation, and other physical signs of consumption. The case was abandoned as hopeless. Finally, during a difficult paroxysm of coughing, she felt something hard in the expectoration, which upon examination proved to be a chicken bone which she had drawn into her lungs years before. The healing process commenced and from that date recovery was manifest. Should the investigator for pulmonary facts examine her lungs, they would reveal cicatrices, similar to those which have been found post-mortem in cases reported as recovered from tuberculosis. Diluted alcohol constantly applied by means of six folds of linen over and across the upper lobes of the lungs seems to have power in checking the progress of the deposition and the softening of tubercle in the lungs, and the number of patients who have recovered from incipient consumption under its use and who after many years are still living and in apparent health, speak in strong terms of its value. I have treated some patients with this, in connection with cod liver oil, but without success.

As to heredity, I may mention in illustration a family under my observation: The mother died of the disease, and the father remarried. The children of the second wife were nursed by the children of the first marriage. One by one the children, whose mother had died of consumption, on attaining their twenty to twenty-fifth year, developed the disease and died. The children of the second marriage did not show a trace of pulmonary trouble, and are living to-day. They all grew up at the same house and with the same surroundings. This would surely speak in favor of heredity; on the other hand, it would indicate that the disease is not contagious. The bacilli, which have been claimed to be the cause, belong to the same class of organized life as our forest trees, simply vegetable scavengers. Some consider this as a result and not a cause, and if this be true, we may well question the plausibility of the culture of this decomposed structure, introduced hypodermically into the muscles of the back, destroying an organism incased in lung structure so long that it has become a part of it. It is now claimed by Koch that this culture will not kill the bacilli; it will only make its home uninhabitable. It is to be seriously doubted whether a cure was ever effected; at least, the author has never seen one cured after the disease was fully established.

DISCUSSION OF "CONSUMPTION."

DR. CHAPMAN, of Toledo, five years ago read a paper on what he called tubercular diathesis, and at that time the author of the first paper took the very same grounds he did.

There is a way to prevent consumption, which we are learning every day. We should try to prevent an heredity that will develop into a condition susceptible to this disease. The time will probably come when medical men will be called into a household to be constant attendants as long as there is a possibility of tuberculosis remaining in the family. The stooping of the shoulders, turning of the arms at the shoulders, and the sluggishness in walking allow the lung to take such a position that air can not readily pass in and there is caused a necrosis, and as this extends the soil is ready and the germ of tuberculosis will lodge there and be developed. I believe the destruction of the bacilli, with attention to the soil, are going to do all that can be done toward prevention, and I believe the history of the future will not show 14 per cent. of deaths from that horrible disease.

DR. H. H. STRAIT, Cleveland, thought the tubercular diathesis is a catarrhal condition; that is, it is not tuberculosis, and that a great majority of those cases recover. It may be termed a pre-tubercular disease. The irritation of the mucous membranes may here be called an apex catarrh. It is certainly well to make a diagnosis before the patient has tubercle bacilli in his sputum. In the dispensary he had seen only one case recover after the bacilli were found in the sputum. There is a catarrh of the lungs that is non-tubercular, but predisposes to tuberculosis.

DR. H. J. HERRICK, Cleveland, regarded consumption as a disease of impaired nutrition, involving primarily the digestive organs. He did not accept apex catarrh. The trouble originates back in the gastro-intestinal canal, and we should look there for the cause of the difficulty and the cure. The tubercle should be regarded as in a measure a deposit, and it is not difficult to show the connection between impaired nutrition and assimilation and this condition of the lung. Creosote as an antiseptic unquestionably does help.

DR. C. E. BEARDSLEY, Ottawa—If a parent is affected with tuberculosis about the thirtieth year, say, his children will have it about the same time. As to whether the bacilli produces the disease or not, it does seem that a condition must exist before the bacilli can be produced; there must be a diathesis. The disease can be cured up to the time that there is a lesion, but afterward it is impossible.

DR. JOHN MURPHY, Cincinnati—While I agree with the author, I must say he is in the minority of the bacteriologists. Koch has not pretended to say whether the bacillus was the cause or the result, and that question to-day is one which is perplexing and troublesome. One thing is certain, and that is these patients are usually materially benefited by a change to a high, dry atmosphere. All people can not enjoy that, and it would be well to have poor people sent at public expense to one of these climates when afflicted with this disease. We often inherit other diseases from as far back as a great-great-grandfather or great-great-grandmother, and why not phthisis?

DR. PROBST—Answers have been received from 1,149 physicians of the State, a little more than one-sixth. As to the immunibility of the disease, there were 509 answers, giving instances of that kind occurring. In answer to the question as to the disease being communicated by the husband and wife, with no heredity in the wife, 82 cases were given; with the husband and wife, when the facts of heredity were not given, 56, making a total of 148. With the wife and husband, heredity in the husband, 68; wife and husband, heredity not stated, 45, where there was no blood relation to account for heredity. These facts indicate the possibility of the communication of tuberculosis without heredity.

"La Grippe in the Differential Diagnosis between Scarlet Fever, Measles and Rotheln," Dr. James L. Tracy, Toledo, was read by title.

DR. AMELIA J. PRIOR, Cincinnati, read a paper on
SCARLATINA.

The author spoke of the disease from an obstetrical standpoint. Some claim that pregnant women are more liable to the disease, and some that they are less liable. In a case in which a young married woman was exposed to it she did not contract the disease; she continued to the end of pregnancy, and the disease was not developed during the puerperal period.

DR. J. S. HALDENAN, Zanesville, discussed the subject of
DIPHTHERIA.

The disease starts from, and fixes itself at the point of inoculation, and extends from that location through the whole system. This idea of transmission, however, stands in contra-distinction to the one, that the poison may be taken into the system some other way, either by the lungs,

stomach or intestines without causing any appreciable local destruction of tissue, penetrates the whole organism, and finally advances centripetally to a certain part and then locates itself. Diphtheria may occur sporadically as well as epidemically, and in certain especially favorable localities it may become endemic. It may be considered a miasmatic contagious disease. It may be conveyed through the air alone or by solid matters, to which it may have become attached. The virulence of the contagion depends very much upon the susceptibility of the individual exposed. Children seem to be particularly impressed by it, especially those under 12 years old; those most likely to be seized and to succumb are from 2 to 5 years old, while under five months they seem exempt and impenetrable to its ravages. The sexes are about equally susceptible. Its period of incubation is variously estimated, and depends upon the amount of infectious material, the force of resistance, and on the structure and texture of the tissues which permit the entrance and absorption of the diphtheritic matter. It usually appears about the third day after exposure.

The disease may assume different forms and degrees of virulence, as follows: 1, the catarrhal, which is the mildest; 2, the croupous, in which the fibrinous exudations are manifest; 3, the septic, in which the disintegration of the exudations takes place, followed by processes of decomposition, and gives rise to septicemia; 4, the gangrenous, in which the inflammation may so deepen and intensify that the textures and functions of the parts may entirely lose their vitality, and the most offensive sloughings obtain.

The disease may be arrested in any one of these forms by timely, constant, careful and correct medication and treatment. The cure in the first and second is much more easily accomplished than in the third and fourth, and in the fourth it rarely takes place. An early diagnosis is therefore important. The catarrhal variety, perhaps, is recognized with the greatest difficulty from the fact of its apparent insignificant symptoms, when other affections may be mistaken for it.

FIRST DAY—EVENING SESSION.

(A CRITIQUE)—THE DOCTOR.

DR. SAMUEL HART, Marietta, read this able article. There is in the title, "doctor," no guarantee and no trade-mark. It is appropriated by the mountebank, the brazen pretender and the doctor of corns. Medicine has had an evolution along the centuries, but superstition, priestcraft and astrology still remain in some modified form as an opponent of true medicine of the present day. The drug trust is custodian and practically owner of all the favorite formulæ of the doctor which are to him valuable personal property, and represent some of the best efforts and experience of his life. The trust appreciates a popular prescription, for it continues to return for "refilling;" not only for the first patient, but for many friends and relatives who are "exactly like" No. 1. The unlimited "refilling" of unindorsed prescriptions is directly responsible for a deplorable amount of alcoholic and narcotic habit, which is induced insidiously by chronic medicine tipling. The immense power of the nostrum and the semi-proprietary trade is directly in the possession of the druggist. It is the disheartening opponent of all honest and intelligent practice. The legitimate drug and pharmacy business is essential, helpful and convenient, and if it will take safe and wholesome care of the public interests it will be appreciated as a good trust. But the doctor is on the defensive against the antagonism of numerous creeds, the popular demands for new and startling cures and plans, the omnivorous craving for pills and the "Spring Renovator" and the "Safe Kidney Bug."

The universal, kind, but dangerous advice-giving by the laity is to be deprecated. Last, the public press is averse to regular, conservative, non-advertising medicine. The immense nostrum business; the disgraceful advertisements covering acres of illuminated pages, must command a friendly newspaper interest and efficient lobbying power in legislation to prevent a clean and wholesome State regulation of medical practice.

But the case of the doctor is not grave; the prognosis is entirely hopeful, the prescription infallible, and of his own medicine; it is comprised in a single word, *merit*—professional merit.

THE VALUE OF RECENT THERAPEUTIC LITERATURE,

By DR. W. C. CHAPMAN, Toledo. The literature on therapeutics is very deceptive, and at present we are unable to derive the benefit from it which we should obtain. There is a tendency to take up new remedies rather than to consider thoroughly the old reliable ones, and this is to be

deprecated. Many remedies are given, having essentially the same action. We need literature upon which we can rely. It is far better to have one good remedy, thoroughly understood, than any number of unreliable ones. It is better we should use the remedies with which we are familiar, and not experiment upon our patients. We are too prone to give medicine when not needed, and to give more than is necessary. It is our duty to assist nature. Take the cases serratum, and about 73 per cent. will recover if given water alone.

DISCUSSION.

DR. C. E. BEARDSLEY spoke of the influence of medicine, and in illustration mentioned the action of salt solution and atropin upon nerves, as demonstrated by the use of the microscope. If we have potent medicines we can surely find use for them therapeutically. By studying the action of these drugs we are able to produce the effects we desire.

DR. W. J. SCOTT—There is no doubt but medicines have influence when properly used. Sometimes two or three remedies may be used to advantage. This, however, does not argue that we should make unnecessary use of them. The therapeutic literature of to-day undoubtedly contains many new remedies of little or no practical value, and these should not occupy the most valuable part of our literature.

DR. E. G. ALCORN—It will not be twenty-five years until the regular school of medicine will be treating symptoms instead of dosing as they are to-day.

The author in closing the discussion advised more precision. Dosage in sickness is not to be condemned, but it is better to have one good remedy that you thoroughly understand than a million that scatter. We should use the remedies that we know. At present one man will use one thing, another will use another thing, and if you analyze those things there is practically no difference in their action. There is no doubt but bromid is an excellent remedy, and so is bromo- and hydrochloral, but it is doubtful whether even these will do everything they are claimed to do. This is one respect in which our present literature is unreliable.

CERTAIN ENTOZOA OF THE DOG AND THE SHEEP,

by PROF. D. S. KELLCOTT, Columbus. The anatomical laboratories and the clinics of the Veterinary Department of the Ohio State University afford exceptional opportunities to study entozoa of domestic animals. Intelligent prevention on the part of the flockmaster or scientific treatment on the part of the physician depends upon a knowledge of the habits and life histories of the parasites. There are many entozoa that have been long known in one stage, but how acquired by their host, or whether they develop direct or in a second host, are mysteries still. The well-bred and well-fed dog is a noble animal, a useful one, and a faithful friend; but the dog of the other sort is a menace and a nuisance. Just why people in general will meekly allow themselves to be overrun by sparrows, insect plagues and the plague of curs, is inexplicable. Cobbold has given a list of twenty-one species of entozoa infesting the dog, six of which occur in the list infesting man.

The paper records observations on five species affecting the dog and sheep; of these one is a distome, three are tape worms, and the fifth a nematode. The distomum sp. was discovered in the lungs of a dog last March. The three tape worms are *Taenia coenurus*, *T. serrata*, and *T. cucumerina* (elliptical). These are the only species thus far found to infest dogs examined at the University. The *T. coenurus* is by far the most common, occurring in from 15 to 20 per cent. of all old dogs that have come under observation. It is safe to say that it is harbored by one in every five to ten worthless curs roaming our streets and fields, who in consequence scatter millions of eggs upon soil and in streams for the infection of sheep or other herbivorous animals. The life cycle of the second specie, *T. serrata*, begins in the rabbit, when it bears the name, *cysticercus pisiformis*. It is rare with us, but Cobbold states that 5 per cent. of English dogs harbor them. It is plain that rabbit for valuable dogs should be cooked. The *T. cucumerina*, common in Europe, is rare in Central Ohio. The intermediate host is the dog louse, *Trichodectes canis*.

Oesophagostoma columbianum, the nematode, in the immature stages produces the "nodular disease of the intestines." The worm evidently has a wider range than was once supposed, and may be doing damage in our section that is attributed to some other species.

DISCUSSION.

DR. KINSMAN—It has been known for a long time that a common cause of death among horses is an aneurismal dilatation of the mesenteric arteries, and manifestations of these

worms have been found post-mortem in Central Ohio. It is found epidemic in sheep. In Iceland, where the people live in close proximity with the animals, the primary stage occurs in the dog and is transmitted to the owner, and we thus have the hydatid disease.

DR. W. J. SCOTT—It has not been mentioned how these parasites are developed. The eggs of the parasite are very numerous, and pass from the bowels of the dog. In his licking to get himself clean and then drinking out of the bucket, he deposits them there, and then the Iclander drinks out of the same bucket, and these are developed. Some years ago a Dr. Cleveland claimed to cure almost any sort of disease with hot water and raw beef. He fed his subjects on raw beef and it was found that a good many of them had tape worms of a peculiar development. These probably came from the cocci contained in the beef.

The eggs are perfectly smooth, five or six times the diameter of the blood corpuscles, and are scattering in bunches all over the thoracic wall. An interesting question is how they got there.

APPENDICITIS—THIRTY CONSECUTIVE OPERATIONS DURING ONE YEAR, WITH ONE DEATH,

by DR. DUDLEY P. ALLEN, Cleveland. The paper contains an account of cases operated upon from April 26, 1893, to May 3, 1894, being thirty in number. Two of them were operated upon by Dr. Wm. H. Nevison, and twenty-eight by the operator. Eighteen were operated in the chronic and twelve in the acute stage. In addition, seven cases were seen in consultation in which delay was recommended, and one case was in a moribund condition when first seen, and died about an hour later. In another case, seen in consultation, a collection of pus was diagnosed in the right lumbar region, and an operation advised, which was made by Dr. Humiston. The case recovered completely. Another case was that of a boy dying with evidences of obstruction of the bowel, the pelvis half way from the pubes to the umbilicus being filled with pus. An operation was strongly urged, although the patient was already in collapse and died some three or four hours later. At the autopsy it was found that the origin of the collection of pus was an ulcerated appendix. The one case which died was that of a young man, seen in his first attack. Though the attack was somewhat severe, he recovered and was seemingly well, but was seen five or six weeks later in a second attack. This was not very violent, but he was positively advised to have an operation performed after the severity of the symptoms had abated. He was again seen in a third attack and similarly advised, but no operation was permitted until the seventh attack, which was six months after the original one. He was then in a decidedly serious condition; the adhesions were found to be very great, and the operation was one of extreme difficulty, but seemingly successful. On the sixth day swelling of the left parotid gland became apparent, and two days later the parotid was thoroughly opened, before any abscess had formed, there being simply multiple minute points of breaking down tissue. The patient died on the fifteenth day. Two other cases in which delay was recommended came to operation in subsequent attacks, and both recovered. During the year there were seen forty cases of appendicitis, thirty having been operated upon, and all but one have recovered. Besides these, one was dying when seen.

In one a large abscess was found and opened in a patient already in collapse, and it was not until the autopsy that its origin was found to have been in an ulcerated appendix. Three cases in which delay was advised were among those operated later. The remaining four cases are still alive, two of the four having suffered from repeated attacks, while two have been lost sight of.

In the acute cases and in those in which pus has been present, the abdominal cavity was packed with iodoform gauze, and the wound left open. When no pus was found, and when possible, the appendix was amputated, invaginated and closed by two or three rows of catgut, and the abdominal wound closed without drainage. In cases with considerable pus present, and extensive ulcerations, too great effort has not been made to remove the appendix. In some cases the appendix was evidently entirely destroyed by sloughing. In others to have found it, would have necessitated opening widely the peritoneal cavity, in which cases it is not wise to pursue the effort too far.

The following conclusions seem justified:

1. Though many cases of appendicitis may recover without surgical aid, it is by no means an easy matter to distinguish these from those which are more serious, and it is of

vital importance if surgical counsel is to be summoned, that it should be called before the disease is so far advanced as to render the operation hopeless.

2. Operations for appendicitis, though often easy, are at times extremely difficult, requiring the skill necessary for the most critical laparotomy, and it would be better in many cases to trust to nature than a poor operator.

3. Careful examination will disclose the fact that many patients, suffering from what is supposed to be a primary attack of appendicitis, have had previous difficulty in this region, and an examination of the appendices removed will demonstrate positively the existence of long standing inflammation.

4. Operations in the acute stage of primary attack are beset with danger, and it is important they should be undertaken before the patient is in collapse, before peritonitis has become general and before the patient is thoroughly septic.

Operations upon recurrent cases, though sometimes of extreme difficulty, are in most instances, if in the hands of a skilful operator, far less dangerous than the disease itself, and in such cases the question of operation should receive careful consideration.

DISCUSSION.

DR. HERRICK.—The question is whether operations for appendicitis are justifiable in a great many cases, and what class to operate upon. Of about fifty cases, I have only known two which were operated upon, terminating fatally. In constantly and rapidly recurring cases of appendicitis, our duty is to operate, and to select the time between paroxysms for operation. However, for the last eighteen months there seems to have been too much of a craze for operating.

DR. KINSMAN—In these cases, as soon as there is distension of the abdomen, there is complete paralysis of the bowel, and then, according to Richardson, we should not operate. In several cases I have seen the McBurney point was clear enough, but there was no tumor found. A positive symptom of appendicitis, which can be relied upon, seems to be lacking.

DR. DANRIDGE—No doubt we should not prolong too long the search for the appendix. Some cases are masked, and very insidious. A case I operated upon yesterday commenced last Wednesday. The case was seen first on Saturday, and there was a well-defined resistance in the right iliac fossa, with marked pain and a slight fever, ranging from 100½ to 102 degrees. The boy did not feel very sick, nor did he present the appearance of being sick. The fever continued, the local condition did not subside, and an operation was undertaken. The appendix had sloughed, the accretion was free, and the terminal portion was gangrenous. There is no doubt whatever but the patient in this case was much safer with the operation than without it, although the symptoms were very slight. The pathologic conditions found indicated that it had existed some time. The surgeons are not so anxious to operate in these cases as they are sometimes charged. It seems that hernia frequently follows this operation.

Every case should not be operated upon, but frequently the surgeon is called too late to operate successfully. It is extremely difficult to determine when to operate. Dr. Richardson recently said to me: "The more I see of appendicitis, the less I know about it." As to diagnosis, I have never yet made an error, but every time I have operated for appendicitis I have found the condition operated for. Definite rules upon which to base a diagnosis can not be given. The condition, however, will usually be found in young people having pain in the region of the appendix.

DR. C. R. HOLMES, Cincinnati, then requested that his paper be read by title: "Diseases of the Accessory Nasal Cavities and Their Influence in Producing Ocular Inflammation; Modern Surgical Treatment and Report of Cases."

(To be continued.)

A Wide Liberality.—The will of the late Jesse Seligman, of New York City, provides for the bestowal of donations to not less than forty-seven public institutions, or for public benefactions. The gifts vary from one hundred to seven thousand dollars respectively. The personal estate left by Mr. Seligman is worth over one million of dollars, of which about one-tenth part is donated to charitable objects. He has been styled "a most catholic giver."

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, JUNE 9, 1894.

THE LICENSED PHYSICIAN IN MASSACHUSETTS.

In his address at the ninth annual meeting of the Association of American Physicians, held in Washington last week, DR. REGINALD H. FITZ, President of the Association, traced the rise and fall of the licensed physician in Massachusetts from 1781, the date of the incorporation of the Massachusetts Medical Society, to 1860, when the Legislature had deprived the Society of any power to regulate the practice of medicine by the examination and licensing of physicians and surgeons or by the enforcement of a prescribed course of study and qualifications.

With abundant citations from historical authorities, the learned speaker sketched the growth of the Society and its increasing usefulness and influence, which, in 1818-19 led the State to definitely assume the regulation of the practice of medicine and to place the duty of licensing practitioners in the hands of the Society. In 1831 the Society had reached such a degree of success in carrying out its objects that it included in its membership "nearly every educated practitioner of medicine or surgery in the State;" and for the next ten or a dozen years its policy seems to have been extremely conservative, even going to the extent of discouraging the granting of further power and authority by the Legislature on the ground that it would be adverse to the best interests of the Society and would serve merely to excite sympathy for quacks and irregulars, and especially for the "Thomsonians," who were rapidly increasing in numbers throughout the country—the system "appealing to the people by its simplicity and economy, its dogmatic assertions and reports of wonderful cures, its advocacy of vegetable remedies and its cry of persecution."

This conciliatory policy seems to have been extended to the "homeopaths," and in 1846 an applicant,

who stated that he had great confidence in the efficacy of medicine, "especially when prepared and prescribed agreeably to the directions of HAHNEMANN," was admitted to membership. The Society continued its work without apparent disturbance until 1848, when it is recorded in the Proceedings of that year that: "We have steadily elevated our profession, by improving medical education, encouraging the harmony and honorable intercourse of its members, and have protected from the mischief of quackery by discouraging every show of it among regular practitioners. This simple and efficient plan of the Society has accomplished all that was ever intended by its organization."

Two years later the growth of homeopathy had become so great that there was a demand by many members for a change from what they denominated the rule of King Log to that of King Stork, and, although a resolution offered at the annual meeting in 1850, to declare all homeopathic practitioners irregulars and to expel them from membership in the Society, was tabled on motion of DR. BIGELOW, the agitation was still continued, and at the next meeting it was ordered that the diploma of a homeopathic institution should not be accepted as evidence of a medical education, nor as a qualification entitling its owner to "an examination for a license from this Society." Meanwhile, the pressure from the district societies for further aggressive action became more and more pronounced, and, in 1856, at the demand of the Suffolk District Society, the by-laws were so amended as to make expulsion from membership the penalty for offenses hitherto punishable by censure or deprivation of privilege; and a hostile public sentiment was aroused at what was stigmatized as the growing intolerance of the Society. Almost simultaneously with these amendments to the by-laws, the Massachusetts Homeopathic Medical Society was incorporated, and thenceforth the breach between the public and the Society widened year by year.

In 1859 the Massachusetts statutes were undergoing revision, and a committee of the Legislature was instructed "by special order, to inquire into the expediency of omitting all that part of the chapter (of the statutes) relating to the Massachusetts Medical Society and to the regulation of the practice of medicine." The committee reported in favor of such omission, and on Dec. 28, 1859, there ceased to be any regulation of medical practice in the State.

DR. FITZ is evidently not sanguine as to the feasibility of State control of this subject. He closes his address with these words: "Ten years of increasing intolerance destroyed seventy years of enthusiastic effort, devoted labor, tactful management and wise council in the public interest. The State revoked the control of medical practice and the people have been

the sufferers. The history of Massachusetts in this respect is the history of the country. She was one of the last of the States to lay down the control and she will be one of the last to resume it."

As a commentary upon this concluding sentence it should be noted that the Massachusetts Senate has already passed a bill for the control of medical practice in the Commonwealth, substantially the same as that in force in Illinois and many other States. Probably in order to avoid any future charge of "intolerance," section 11 of the bill exempts from its operation "clairvoyants, persons practicing hypnotism, magnetic healing, mind cure, massage methods, Christian science, cosmopathic or any other method of healing," provided they refrain from appending to their names "the letters M.D., or using the title doctor, meaning thereby a doctor of medicine." Surely such a concession should allay opposition, even in Massachusetts.

RIGHT OF RECOVERY FOR UNLICENSED PRACTICE IN EMERGENCY CASES.

The Appellate Court of Indiana considers, in the case of Board of Commissioners of Adams County v. COLE, decided March 13, 1894, the right of a physician to recover for services rendered in a case of emergency without his having the required license to practice medicine. The question arose over a physician located not far from the border line in Ohio, being called to attend a man in Indiana suffering from a broken leg. It was shown that there was a pressing emergency, and an urgent necessity to amputate the leg as soon as it could be done, in order to save the patient's life, so that there was no time to be spent in first securing an Indiana license on the physician's part. The statute of the latter State, however, requires every physician or surgeon desiring to practice his profession there to procure a license therefor, and enacts that no cause of action shall lie in favor of any person for services as a physician, surgeon or obstetrician who had not, prior to the rendition of such services procured the prescribed license. The practice of medicine and surgery consists, the Court holds, in the application of science, skill, and experience to the cure or alleviation of the ailments of the human body; and whether a physician exercises his skill upon one patient, or upon a greater number, he is, in each case, engaged in the practice of his profession. According, then to the letter of the law, strictly and literally interpreted, it says that nothing could be recovered in a case like this. But, it is further declared, courts are not always required to give full force to the exact letter of the law, but are oftentimes permitted—nay, more, required—to relax somewhat the rigor of an exact compliance. And this is one of the cases where the exception is to be made. To hold that the physician's conduct, thus

far, was within the inhibition of the statute, would be the extreme of inhumanity. This does not, of course, justify him, the Court adds, in continuing his attendance upon his patient, day after day, without procuring a license for the practice of his profession there, though it does show that he is entitled to recover something for his services first rendered. Among the instructions given to the jury in this case was one to the effect that if a physician competent and qualified, from another State or county, were called on a professional visit for consultation, or the call was made because of some special skill or ability of the physician in a particular branch of his profession, or there was an existing emergency for the attendance of such physician, in order to save life, and under such circumstances the physician acted without procuring a license, such physician would be entitled to recover for his services thus rendered, notwithstanding he had no license, and the law would aid him in making such collection. This charge the Court holds was erroneous. The right to recover is not to be extended beyond the necessity of the actual emergency. It is better that competent physicians should suffer some inconvenience than that the door should be opened for the incompetent. If a physician may safely practice his profession without a license because some one—wise or unwise—judges him to have special qualifications for the treatment of certain ailments, and "the call is made because of some special skill or ability of the physician in a particular branch of his profession," then there will remain few practitioners in all the land who may not utterly disregard the provisions of the law. All that would be necessary for him to show would be that he was called to visit his patient "because of some special skill or ability" in the treatment of some given infirmity; and this he could always do, for the very reason for his call was that his patient believed him to be possessed of such special skill and ability.

CHRISTIAN SCIENTISTS MUST GET CERTIFICATES.

Judged according to both the law and the Gospel, are the so-called "Christian scientists" in the case of State v. BUSWELL, decided by the Supreme Court of Nebraska April 17, 1894; and the judgment rendered is against them. The defendant named in this case was indicted for practicing medicine, as a Christian scientist, without a certificate from the State Board of Health, as required by the State statutes. Strangely enough, the jury rendered a verdict of "not guilty," to which the State excepted, and on its exceptions took an appeal. The Supreme Court sustains the exceptions, but says that in cases presented as this one was, on the exceptions of the State, no judgment can be rendered, and therefore none is attempted. It consequently is here content to pass upon the questions of law raised, for the future

guidance of trial courts. The Act to establish a State Board of Health; to regulate the practice of medicine, in Nebraska, etc., it holds, is as much directed against any unauthorized person who shall operate on, profess to heal, prescribe for, or otherwise treat any physical or mental ailment of another, as against one who practices "medicine, surgery and obstetrics," as those terms are usually and generally understood. The object of the statute establishing a State Board of Health, etc., is to prevent imposition upon the afflicted by ignorant and unqualified pretenders to healing power; and any person not within the exceptions prescribed in the Act, (as persons rendering gratuitous services in cases of emergency, and commissioned surgeons of the United States Army or Navy, and nurses in their legitimate occupations,) and not having complied with its requirements as to a certificate, who shall, under any pretense, operate on, profess to heal, or prescribe for, or otherwise treat any physical or mental ailment of another, thereby renders himself liable to its penalties. The defendant relied upon the teachings of the Bible for his authority as a Christian scientist. Lest his contention be misunderstood or imperfectly stated, the language contained in the brief filed on his behalf is freely used. This and the summary of the evidence given by him and his witnesses furnish some curious reading, though a reproduction of it would not particularly instruct readers of the JOURNAL. The Court also, as before intimated, goes to the Bible for light on the case. It quotes from the eighth chapter of the Acts of the Apostles where SIMON, the sorcerer, figures in the narrative, and he is condemned for seeking to purchase the gift of God with money so as to make gain thereof. The healing of NAAMAN, of leprosy, by compliance with a very simple hydropathic course, and the rebuke of the prophet's servant for taking the reward therefor which his master refused, as well as God's recorded disapproval of BALAAM's partly executed project of profiting by the use of the Divine power with which he was endowed, are cited to show that the exercise of the art of healing for compensation, whether exacted as a fee or expected as a gratuity, can not be classed as an act of worship. Neither is it a performance of a religious duty, as was argued. The conservatism resulting from the study of standard authors might be somewhat depended on to minimize the evils attendant upon unlicensed practitioners' attempts to follow regular and approved methods, although, as against even these, the law should be enforced. Still more stringently, says the Court, should its provisions be rendered effective against pretensions based upon ignorance, on the one hand, and credulity on the other.

MISREPRESENTATIONS BY MEDICAL EXAMINERS.

The Supreme Court of Arkansas re-states, in the case of the Providence Savings Life Assurance Co. v. REUTLINGER, decided March 10, 1894, the law, as determined by many adjudications, with regard to the effect of misrepresentations made by medical examiners, especially of insurance companies. It says that when a medical examiner, authorized by an insurance company to fill up blanks for answers to questions to be propounded to applicants for insurance in a medical examination, or to fill them up is within the apparent scope of his authority, does so by writing false answers, and thereafter procures the signature of the applicant thereto, after he had given correct answers to the questions, and the Company afterwards receives the premiums, and issues a policy, the Company will, upon the death of the insured, be estopped from insisting on the falsity of the answers, although warranted to be true.

This rule is, however, subject to the obvious limitation that if the applicant, knowing the presence of the untrue answer by having read it or otherwise, afterward certifies to its truth, the insurer may set up the untruth. And if, after the delivery of the policy, he discovers that a fraud has been perpetrated on him and the company by means of the false answers, it would be his duty to make the fact known to the company. He could not hold the policy without approving the action of the agent, and thus becoming a participant in the fraud committed. The consequences of that approval can not after his death be avoided.

It is also held, in this case, that where questions propounded to an applicant for insurance upon his life as to his physical condition are in such terms as include the most trivial ailments or injuries, they will be interpreted as referring only to such illness or injuries as affect the risk to be assumed, unless they are in words which exclude such interpretation. The presumption is that trivial ailments or injuries are not within the contemplation of the parties, and that the questions, in the absence of words directing attention to them, are not asked with the view or purpose of ascertaining the existence of the same. The answers of the applicant are interpreted in the same manner as the questions eliciting them; that is to say, as responsive to the questions in the sense in which they are asked.

INTOXICATION OF PHYSICIAN MAY BE SHOWN.

In an action brought to recover damages for the malpractice of a physician or surgeon, the Appellate Court of Indiana holds, in the case of MERRILL v. PEPPERDINE, decided March 30, 1894, the plaintiff may show, by himself and other witnesses, the condition of the physician or surgeon, as to being intoxicated, and as to his appearance, at the time the services were being performed.

CORRESPONDENCE.

Editorial Correspondence.

DENVER, COL., May 30, 1894.

The ASSOCIATION Train arrived at Colorado Springs at 9 A.M., where we had an excellent breakfast at the "Antlers." A trip to Pike's Peak, which had been contemplated, was postponed on account of the rain which fell in torrents, loosening boulders, which rolled down the mountain and smashed everything in their path so that ascent was impossible; but notwithstanding the rain most of the party went to visit the Garden of the Gods. This singular spot is a large circular area of about 80 acres surrounded by rocks rising from 300 to 500 feet perpendicularly, the crests of which seemed to assume fanciful shapes, and which when viewed in profile might by some stretch of the imagination be said to resemble the animals and faces as announced by our coachman. We rejoined the train fully repaid for our toilsome trip, but more than one of the party expressed the wish that Jupiter Pluvius were not in the ascendancy. At Colorado Springs we again met Dr. Maclean's party and congratulations were exchanged at the "Antlers." Dr. Solly, of Colorado Springs, showed our party many attentions. We then left for Denver where we arrived at 5 P.M. amidst a down-pour of rain. We were met at the depot by a delegation of Denver physicians among whom were, Dr. Chas. Dennison, Capt. Le Garde, U.S. Army, Clayton Parkhill, Dr. Hopkins, J. A. Rogers, W. J. Rothwell, E. J. Rothwell, W. S. Bagot, J. N. Hall, W. A. Jayne. Many of our party went to Brown's Hotel for dinner, some were entertained by Dr. Chas. Dennison, others at the various clubs. At the Denver club dinner we noticed the following present:

Capt. LeGarde, Denver; Drs. Graham, Chicago; Mulheron, Detroit; Graham, of Denver; Montgomery, of Philadelphia; Donald Maclean, Detroit; Rogers, Denver; Laphorn Smith, Montreal; E. F. Ingals, Chicago; E. J. Senn, Chicago; Jayne, Detroit; Talbot, Chicago; Frank Woodbury, Philadelphia; Imry, Detroit; Stearns, Indiana; Rano, Connecticut.

Dr. Maclean's party were also in Denver at the same time, and joined our party in the festivities of the evening.

We left Denver at 2:30 A.M.; Dr. Dennison and Dr. Graham of Denver joined our train here.

COLORADO SPRINGS, May 31.

We arrived here for an early breakfast at the "Antlers," and found that the rain had caused landslides at the Manitou tunnel, and a washout near "Divide," so that our train must remain at this point twenty-four hours at least. If the rain continues, the probability is that we will be obliged to remain thirty-six hours longer. The only other road is in an even worse condition by reason of the loss of bridges, so we can not get away and must make the best of it. The party are taking the matter philosophically, but want to see the Peak, which is hidden in the clouds, and the pouring rain does not show at this hour any signs of abatement.

The following is a list of those joining the train at Burrton, Kan.:

C. S. Bond and wife, Richmond, Ind.; Miss Lizzie Hill, Richmond, Ind.; E. Griswold and wife, Sharon, Pa.; J. E. Woodbridge and wife, Youngstown, Ohio; A. C. Brant and sister, Canton, Ohio; A. B. Walker, Canton, Ohio; G. H. Price, Nashville, Tenn.; A. D. Price, Harrisburg, Ky.; Ambrose Morrison, Nashville, Tenn.; G. D. Butler and wife, Pulaski, Tenn.; H. C. Davis, Harrisburg; G. E. Davis, Salvisa, Ky.; C. T. Benner, Tiffin, Ohio; Percy Warner and wife, Nashville, Tenn.; J. A. Nicholls and wife, Pulaski, Tenn.; C. A. Abernathy, Pulaski, Tenn.; Julia Flournoy, Pulaski, Tenn.; A. R. Baker, Cleveland, Ohio; J. T. Reddick, Paducah, Tenn.; A. G. Willey, Spencer, Ohio; Edwin Walker and wife, Evansville, Ind.; A. D. Hahn and wife, Richmond, Ind.; D. C. Willson and wife and daughter, Ironton, Ohio; O. B. Dunn, Ironton; S. C. Martin and wife, Anna, Ill.; S. J. Young and wife, Terre Haute, Ind.; C. Hicks and daughter, Coburn's, Ind.; S. H. Pearce and wife, Mt. Vernon, Ind.; Miss Alice G. Howard, Mt. Vernon, Ind.; Miss Anna Schrader, Mt. Vernon, Ind.; X. C. Scott and wife, X. C. Scott, Jr., Cleveland, Ohio; J. T. Hibberd and wife, Richmond, Ind.; Miss L. M. Hibberd, Richmond, Ind.; Miss E. M. Comstock, Richmond, Ind.; J. E. King and wife, Centerville, Ind.; J. A. Foote, Terre Haute, Ind.; C. T. Brown and wife, Pendleton, Ind.; J. W. Cook, Pendleton, Ind.

Registration in South Carolina.

AIKEN, S. C., June 4, 1894.

To the Editor:—The Legislature of the State of South Carolina, in session December, 1893, passed a medical law which went into effect Jan. 4, 1894. The tenor of it is:

That any one who has not registered in this State to practice medicine and surgery before Jan. 4, 1894, will have to appear before the Board for examination, after they have presented their diploma to the Board. The Board meets the fourth Tuesday in April of each year, and whenever they deem necessary to have an extra meeting. This year we meet again Tuesday, October 9, and all examinations before the Board are written, two hours being allowed upon each branch. Any one who is practicing in this State after the October meeting will be prosecuted. The fine is \$300, and imprisonment for six months.

Any one desiring further information can get it by applying to the undersigned.

C. F. MCGAHAN, M.D.

SOCIETY NEWS.

Chemung County Medical Society.—The annual meeting of the Chemung County (N. Y.) Medical Society was held May 23. The following officers were elected: President, W. E. Colgrove; Vice-President, Jonas Jacobs; Secretary, N. H. Noble; Treasurer, C. T. Squire.

Officers Chicago Medico-Legal Society.—The annual meeting of the Medico-Legal Society was held at the Grand Pacific June 2. The following officers were elected for the ensuing year: President, Dr. James Burry; First Vice-President, Dr. C. D. Wescott; Second Vice-President, Dr. Sanger Brown; Secretary, Dr. Archibald Church; Treasurer, Dr. Joseph Matteson.

Indiana State Medical Society.—At the recent meeting of the Indiana State Medical Society, May 17 and 18, at Indianapolis, the following officers were elected for the ensuing year: President, E. S. Elder, Indianapolis; Vice-President, C. S. Bond, Richmond; Secretary, F. C. Woodburn, Indianapolis; Assistant Secretary, K. K. Wheelock, Fort Wayne; Treasurer, J. O. Stillson, Indianapolis.

F. C. WOODBURN,

Secretary Ind. State Medical Society.

American Physicians and Surgeons.—The Triennial Congress of American Physicians and Surgeons closed its third meeting in Washington, D. C., June 1. The meeting was opened on Tuesday afternoon, May 29, with an address by Dr. Landon Carter Gray and the program embraced papers on "Morphology as a Factor in the Study of Disease;" "Sewer Gas;" "Distribution and Control of Leprosy in the United States;" "Nephritis in its Surgical Aspects;" "The Influence of Animal Experimentation on Medical Science" (by Dr. Alfred L. Loomis, President of the Congress); "The Surgery of the Accessories of the Nose;" "The Influence of Infectious Processes on the Nervous System." Delegates were present from the American Surgical Association, American Climatological Association, Association of American Physicians, American Association of Genito-Urinary Surgeons, American Orthopedic Association, American Physiological Society, Association of American Anatomists, American Pediatric Society, American Ophthalmological Society, American Otolological Society, American Neurological Association, American Gynecological Society, American Dermatological Association, and the American Laryngological Association.

Washington State Medical Society.—The fifth annual meeting of the Washington State Medical Society was held at Spo-

kaue, Washington, May 3 and 4. The attendance was rather small, especially of the members from the western part of the State. The papers presented, were, however, of a higher order than those of any previous meeting.

The following was the program carried out: Opening prayer, by Bishop L. H. Wells, of the Episcopal Church; Address of Welcome, by Mayor E. L. Powell; Report of Chairman of Committee of Arrangements, by Dr. N. Fred Essig, of Spokane; President's Address, by J. W. Waughop, of Fort Steilacoom; annual reports of Secretary, Treasurer, and Publication Committee; report of Committee on Credentials, by G. A. Weed, of Seattle; report of Committee on Necrology, by N. J. Redpath, of Fort Steilacoom; reports of Special Committees; reports of Standing Committees.

The following papers were presented: The Drunkard and His Cures, by W. W. Potter, of Spokane; Auto-Infection, by J. W. Hickman, of Tacoma; Cerebral Palsy of Childhood following Diphtheria, by C. W. Sharples, of Seattle; Cholecystotomy, with Reports of Three Cases, by J. B. Eagleson, of Seattle; Complications and Accidents in Abdominal Surgery, with Reports of Cases, by J. J. McKone, of Tacoma; Surgical Cases of Interest Occurring in Seattle, by C. W. Sharples of Seattle; Surgical Infections, by Edward Bowes, of Spokane; Physiology in the Public Schools, by G. S. Armstrong, of Olympia; Mental Development, by J. M. Semple, of Medical Lake; Concealed Insanity, by W. H. Anderson, of Medical Lake; Some Cases of Optic Nerve Trouble, by R. L. Thomson, of Spokane; Ruptured Perineum, by C. G. Brown, of Spokane; Dry Dressings to Promote Primary Union, by G. T. Doolittle, Spokane; Treatment of Urethritis, by D. G. Russel, of Spokane; Salpingitis, by T. L. Catterson, of Spokane; Cause and Prevention of Peritonitis in Women, by C. P. Thomas, of Everett; Hydatid Cyst of Liver, by J. T. Coleman, of Tacoma; Cleanliness in Surgery, by D. Mason, of Spokane; Trachelorrhaphy Forceps, by J. M. Crump, of South Prairie; Treatment of Foreign Bodies in the Brain, by H. B. Luhn, of Spokane.

The following officers were elected for the coming year: President, Dr. D. Mason, of Spokane; First Vice-President, Dr. J. W. Hickman, of Tacoma; Second Vice-President, Dr. H. R. Keylor, of Walla Walla; Secretary, Dr. R. L. Thomson, of Spokane; Treasurer, Dr. J. B. Eagleson, of Seattle.

Seattle was chosen as the next place of meeting.

PUBLIC HEALTH.

House-to-House Inspection.—The house-to-house inspection, which accomplished so much good last summer in improving the public health of Philadelphia, has been ordered repeated this summer by the authorities of that city. A similar work is being prosecuted, under the auspices of the State Board of Health, in several hundred cities and towns of Illinois, as one of the important features of a sanitary survey of the State.

Another Epileptic Colony.—At the recent meeting of the Illinois State Medical Society a resolution was introduced and adopted, indorsing a proposition for an epileptic colony for the State on the Bielefeld plan. The resolution was referred to the Committee on Legislative Action, with instructions to bring the matter before the next General Assembly and to use all proper means to have such a colony established.

School Vaccination Law Upheld.—In the proceedings growing out of the suit to prevent the New Britain (Conn.) school board from enforcing its school vaccination order, the Superior Court at Hartford has decided that the law giving the school board authority to order all school children to be vaccinated and to exclude from the schools all not vaccinated is constitutional and that orders based thereon must be obeyed.

Vaccination Order Rescinded.—Owing to a conflict of authority between the City Board of Health and the Board of Educa-

tion in the City of Philadelphia, the Board has withdrawn its order excluding non-vaccinated children from the public schools. The reason given is that as no epidemic threatens at present the Board was "not willing to resort to extreme measures." One way to prevent epidemic smallpox is to compel the vaccinal protection of every scholar and to rigidly exclude every child not so protected at all times and under all circumstances.

Floods and the Public Health.—Dr. Benjamin Lee, Secretary of the Pennsylvania State Board of Health, has instructed the medical inspectors of the Board to exercise increased vigilance in the districts of the State affected by the recent floods, "as such conditions will be left as will, undoubtedly, prove extremely prejudicial to the public health." Inspectors are advised, however, to make no promises of material aid, either in the shape of money or of disinfectants, "as the appropriation for the State Board of Health does not contemplate such use of its very limited funds."

Health of New York City.—Reports of the Bureau of Vital Statistics continue to show an excellent state of the public health in New York City. The annual death rate for the four weeks ended May 26 was a fraction less than 21 per thousand, as against 25.48 per thousand for the corresponding period of 1893. The mortality from pneumonia, although diminishing, is still greater than that from consumption. Diphtheria continues to be the most fatal of the zymotic diseases; a considerable number of new cases of smallpox are still reported every week; there is but little typhoid fever in the city.

Michigan Conference of Health Officers.—The second annual conference of Health Officers in Michigan will be held at Ann Arbor, June 14 and 15. The first day's session will be devoted to the subject of tuberculosis. There will be papers on the "Spread of Tuberculosis," by Prof. F. G. Novy, M.D., of the State University, and on the "Restriction and Prevention of Tuberculosis," by Dr. Henry B. Baker, Secretary of the State Board of Health, with demonstrations of the tubercle bacilli, methods of staining, growing and inoculating with the bacilli and postmortems of animals that have been inoculated with the bacilli. Other subjects to be presented and discussed are the "Causation, Restriction and Prevention of Typhoid Fever," the "Relations of Vaccinia, Variola and Varioloid," and a demonstration of the methods employed in the State Laboratory of Hygiene for the examination of drinking water will be given.

Cemeteries from the Sanitary View-Point.—Investigations of the Paris cemeteries strengthen the arguments against intramural interments and in favor of cremation for the disposal of the dead in the interests of the quick. Although M. Rochard asserts that the belief that bad smells emanate from cemeteries is unfounded and that there is an absence of noxious gases in well-kept cemeteries, there are other evils more insidious and more dangerous. Water filtered through the soil of cemeteries becomes polluted, and wells more than 100 meters from the graveyards of Mont Parnasse and Père Lachaise were found to be contaminated from this source. With regard to the theory of germs being stored up in graveyards and later spread about, resulting in epidemics, M. Rochard believes that it is not impossible that when graves are dug microbes rise to the surface and mix with the surrounding atmosphere; but no fact has yet been demonstrated that this possibility has been recognized. It might be added that the well-known longevity of grave-diggers and their general immunity from the zymotic diseases is a disproof of the theory.

Immunization Against Cholera.—Additional proof of the etiological significance of the cholera vibrio and of the feasibility of immunization against Asiatic cholera is furnished in

the experimental work of the pathologist, Sabolotny. He finds that a species of rodent (*Spermophilus guttata*), common in South Russia, is highly sensitive to the cholera bacillus. This animal is readily infected by the cholera culture whether introduced subcutaneously, intraperitoneally, or by the mouth, and whether with or without Koch's preliminary treatment by soda and opium, although this treatment makes infection more certain. It may also be rendered immune by the previous administration of attenuated cholera cultures by the mouth; it then survives the otherwise fatal dose of cholera even when given in conjunction with soda. No doubt, among the numerous species of the *Spermophilinae* which abound in this country—the ground squirrels, prairie dogs, gophers, etc.—there may be found one or more as useful as the *S. guttata* for the repetition of these experiments by American bacteriologists.

The Epidemics.—Cholera is reported to be general in Canton, and a serious epidemic of a disease from which over 7,000 deaths have occurred since the middle of April, is prevailing in Hong Kong. The disease is said to be similar to the plague which decimated the province of Hochow in 1883-4; but it is thought not unlikely to be the same disease so prevalent in Canton. Cable dispatches report cholera "raging" in the districts of Plock, Radom and Petrokoff in Russian Poland. As a precaution against the importation of the disease into Prussia, an order has been issued to compel all Russians entering Prussian territory to pass through Illowo on the frontier, where the strictest sanitary regulations are enforced.

Between Jan. 1, 1894, and May 31, ult., there were 1,739 cases of smallpox in Chicago, with 501 deaths—a mortality of 28.8 per cent. The monthly increase in the number of cases was as follows: January, 128 cases; February, 233; March, 305; April, 544; May, 529. During the first sixteen days of May there were 398 cases—a daily average of 24.8 new cases; during the remaining fifteen days of the month there were 131 cases—a daily average of 8.7 new cases. The epidemic may be said to be at an end for the season, although four or five new cases are still reported daily.

The Infectious Diseases.—With the object of securing a more accurate nomenclature for the infectious and contagious diseases, Dr. W. H. Thomas, at a recent meeting of the New York Academy of Medicine, offered the following classification:

1. Infectious diseases are due to the presence of their respective living microorganisms in the body.

2. Infectious diseases are divisible into three classes: *a*, communicable; *b*, non-communicable; *c*, septic.

3. The communicable diseases are those whose origin is from an animal body—examples of which are smallpox, Asiatic cholera and tuberculosis.

4. The non-communicable infectious diseases are those whose origin is not from an animal body, but from a place or thing—examples of which are ague, yellow fever and miasmatic diseases in general.

5. The communicable diseases are divisible into two classes according to the ordinary modes of their communication: *a*, into the contagious; *b*, into the non-contagious communicable diseases. The contagious communicable diseases are those in which simple proximity to the sick is sufficient to communicate the infection—examples of which are scarlet fever, measles, smallpox, diphtheria, mumps, etc. Isolation of the sick in these cases is, therefore, needful to prevent infection. The non-contagious communicable diseases are those in which the communication is not by simple proximity to the sick, but through intermediate means of communication. Isolation of those sick with them, therefore, is neither needful nor effective in comparison with measures directed against intermediate means of infection—examples are typhoid fever, Asiatic cholera and tuberculosis.

6. The septic infectious diseases are those in which infection is introduced through a wound or abrasion—examples are erysipelas, hydrophobia, tetanus, etc.

This is a fairly commendable attempt at securing greater accuracy in classification, but it can hardly be called perfect. Dr. Thomas, for example, would scarcely, on reflection, classify all forms of erysipelas as "septic," caused by the "introduction of the infection through a wound or abrasion." This takes account only of surgical or traumatic erysipelas, and entirely omits from classification that form of the disease of greatest interest to the epidemiologist, to-wit, the idiopathic or medical form—the form which more frequently than the traumatic tends to become epidemic through faulty hygienic conditions and surroundings. This form clearly belongs in "class *a*, communicable;" and for purposes of sanitary administration, in the "contagious" subdivision of this class.

MISCELLANY.

Resignation of Dr. Edwards.—Dr. Joseph F. Edwards has resigned his membership in the Pennsylvania State Board of Health.

Practice in Switzerland.—In theory at least, the prohibition of the practice of medicine in Switzerland without the government license, is so strict that a physician without such license is forbidden to prescribe for his own wife during a temporary sojourn in that country.

An Abiotic Region.—Analyses of the air, water and soil of the Spitzbergen group of islands in the Arctic region show an extraordinary poverty of bacterial life. While the air of the streets of Paris contains an average of 51,000 bacteria to the cubic meter that of the Arctic Sea contains only 3 to the meter; and the water of Spitzbergen is not only devoid of any pathogenic microorganisms, but is also entirely free from any kind of bacilli.

The Deadly Decimal Point.—Our esteemed contemporary, the *British Medical Journal*, is another victim of the proofreader's hostility to the decimal point, although we are the actual sufferer. In a recent issue of our British namesake, there appears the following: "There is (says the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION) an average increment of nearly 6,000 new home-made medical practitioners every year, and, while the population of the United States increased 248 per cent. during the decade 1881-90, the number of newly-graduated doctors increased over 50 per cent. in the same period." The insertion of a point before the figure 8 in the percentage of increase of population will relieve us of the charge of indulging in "Yankee bounce" as to our growth, at the same time that it will make clear the lesson of the figures, *i.e.*, that our increase in the number of newly-made doctors is more than twice as great as the increase in population—over 5 per cent. per annum for the former and less than 2.5 per cent. per annum for the latter.

Circumcision Specialists.—In England, where the custom of announcing births in the public prints obtains much more largely than in this country, the proud parents are promptly deluged with samples and circulars of every article pertaining to infant life—from soaps to sucking-bottles, from puff powders to perambulators, from infant foods to physics. The latest development in this line of infant industries is the "circumcision specialist," whose services are straightway offered to the male infant even before he has voided his meconium. The *British Medical Journal* has received the circular of one of these preputial operators, who urges the importance of the youngster being circumcised without delay and offers to do the business in half a minute in an ordinary case and within a minute even in the most difficult. Among the moral and physical reasons for its performance

ADDRESS.

THE NERVOUS SYSTEM IN DISEASE AND THE PRACTICE OF MEDICINE FROM A NEUROLOGIC STANDPOINT.

MEDICAL PROGRESS—PROGNOSTICATIONS OF THE FUTURE
OF MEDICINE.

Address in Medicine, read before the AMERICAN MEDICAL ASSOCIATION,
at San Francisco, June 6, 1894.

BY C. H. HUGHES, M.D.
ST. LOUIS.

In this age of preëminent progress in every department of human research and endeavor, I congratulate you on the onward march Medicine has made and is yet making towards its glorious goal—the mitigation of human misery and the mastery of disease, and especially do I congratulate you on the part American Medicine has taken in the scientific triumphs of the closing century over the encompassing elements and environments adverse to man's health and strength and consequent happiness and efficiency in the affairs of life. If we look back over the passing century for only a few decades, at her contributions to the welfare of man, we find that she has given more than her full quota to the common fund of human happiness. She has made physical and psychical tranquillity and power, happiness and length of days, possible to man under the strain and pressure of modern progress. She has searched out and is searching out the causes which are inimical to, or promotive of, man's strength in the battle of life. She teaches him how to evade the one and to utilize the other in power of mind and body.

As our father Hippocrates drove the devotees of superstition from the temple of Hygeia, and taught the people that offended gods could neither bring, nor propitiated gods dispel disease, and was an example of medical hygiene in his own longevity, far beyond that of any man of his time, and as that later medical devotee of Æsculapius, Andreas Vesalius defied the popular prejudice and ecclesiastical power of his day at the risk of his own life, to make his first human dissection (and whose unfortunate untimely death the world has never ceased to deplore), so we, his professional descendants, continue to this day breaking down and ignoring the barriers of ignorance, of prejudice and superstition that have stood or now stand in the way of man's happiness and prosperity, unlocking the secrets of nature's *arcantum*, and setting the captive mind and organism free from the enthrallment of disease and the gloom of untimely death.

Substitutive inoculations, beginning with the triumph of vaccinia, for establishing tolerance and immunity from other violent diseases, are spreading the rescuing power and glory of our noble profession, and the names of Jenner and Pasteur are now immor-

tal. And the "great white plague," consumption, with its 165,000 annual victims in this country alone will soon be a thing of the past, through wisely applied antiseptics.

Electroscopic explorations now penetrate the dark and otherwise hidden places of the human body, making it a glow of light to the diagnostician, while other diagnostic means, electric, physical, chemical, dynamometric, æsthesiometric, thermometric, ophthalmoscopic, laryngo-pharyngoscopic, otoscopic, microscopic, spectroscopic, oncographic, sphygmographic, auditory, percussional and tactile diagnosis and urinalysis, come to the aid of the modern physician in searching out disease. What would our painstaking fathers in the profession have given to have seen this day of accurate methods of determining the existence and place and boundaries and prognosis of morbid conditions. By these means, no viscus and no system of the body escapes the searchlight of modern medical diagnosis.

With these aids at our command, but little, if any, of the human anatomy in health or disease is absolutely beyond the reach of our science, and scarce any part beyond some relief from the multiple resources of medical art. That *noli me tangere* of our ancestors, the abdominal cavity, is no longer a *terra incognita* to the resources of surgery, thanks to Wm. Lister, of London; McDowell, of Kentucky; Battey, of Georgia; and Murphy and Senn, of Chicago; Lane, Gross, Agnew, Frank Hamilton and John T. Hodgen. The once hidden recesses of the brain also are now with impunity penetrated to where our ancestors dared not go, saving lives and minds formerly doomed to destruction, thanks to Fritsch and Hitzig, of Germany, Ferrier and Horsley, of England and Bartholow, of America, the latter having been the first physician in the world to explore and prove the truth of cerebral localization by demonstrations on the living human brain.

"The time has been that when the brains were out the man would die." But we have changed all that. With judicious neuroiatic council, profound anatomical knowledge, and skilful surgery, science now penetrates to the very dwelling place of thought and volitional motor impulses in the cerebral cortex, enabling perishing victims to be saved by the helping hand of modern neurology and cerebral surgery.

Thus does medical science move majestically onward in her benefactions, and man, her beneficiary, moves forward to his higher destiny, under her benevolent ministrations.

I could not in the time allotted to this address give even an outline of general medical progress in our day, and I presume it is more appropriate and really expected that I should make an address more in the line of my special observation. Accordingly, since general practice is advanced by light from every quarter, I ask your attention to points in the prac-

tice of medicine from the standpoint of a neurologist.

LA GRIPPE, A TOXIC NEUROSIS.

I begin with that discomfoting, distressing, disastrous and often fatal malady, la grippe. A disease with which all of us have become painfully familiar; a malady whose insidious destructiveness has not been properly appreciated by either the public or the profession; a disease which has been laughed at and sneezed at by doctor and patient, even while death was stealthily approaching to claim the unapprehensive victim; a disease whose nervous sequences, where death has not intercepted them, have been astonishingly various and grave. I discuss chiefly the neuropathic aspects and sequelæ of this disease. It is, in my judgment, a toxic neurosis, in its early stage a nervous fever, its later symptoms depending on the centers specially touched by its toxine.

Notwithstanding the warnings and apprehensions early aroused in the minds of a few clinicians of keen observation, the gravity of the grippe, especially in its toxic neuropathic sequence is only just beginning to be generally recognized, though many months have elapsed since Julius Althaus, Symes Thompson and W. R. Gowers, of London; Chas. K. Mills, of Philadelphia; myself and other writers, first called attention, since the appearance of the late epidemics, to this now clearly demonstrable fact. And long before these, in former epidemics, Theophilus Thompson, (the father of Symes) and Graves, Blakiston and Peacock had noted the prominence of the nervous symptoms, especially evidences of vagus implications. Its possible fatality in certain familiar forms is now, after a larger clinical experience, much more generally apprehended and dreaded by the profession, especially since the publication of the post-mortem findings of Kusskow, of St. Petersburg in forty cases, and the fatal results in isolated instances reported in the journals from different sections of the country where epidemic influenza has prevailed.

Kusskow's post-mortems showed hemorrhagic and pyemic or septico-pyemic results as the two forms, with purulent and gangrenous inflammation of lung tissues and frequent metastasis to other organs. Hemorrhages and hematomas in the muscular tissue, parenchymatous bleedings and bleedings by diapedesis, pachymeningitis hemorrhagica interna, in one case. In 50 per cent. of the cases, hyperemia of the pia, also meningeal infiltration and suppurative meningitis and hemorrhage into the lateral ventricle, and very frequently lobar pneumonia. The heart muscle was soft, friable and anemic.

Peritonitis was never discovered. The kidneys were found to be usually affected, the spleen contracted, the intestinal canal was unchanged. Calcification was found in the muscle cells similar to those found in typhoid lesions of the bowels, venous thrombosis more often than arterial, besides the often described pharyngo-laryngeal infiltration. As the hemorrhages were invariably unilateral, the author concludes that the lesion involves the sympathetic centers.

But these fatal endings are but little more serious than some of the results of the invasion of this disease into the region of the cerebrum, middle ear, meningeal and brain inflammation and softening, and the issue of insanity.

I have known of several cases of insanity, profound melancholia, abscess of the brain, general neuritis,

facial and sciatic neuralgia and fatal paralysis (one hemiplegic), but most of the vagus in this disease and its more chronic sequelæ are largely neural. The heart failure mentioned by Wilks, and seen perhaps by most of us to end life in influenza, is also due to involvement of the vagus center in the medulla, as in so-called grippe pneumonia, which accounts for the rapid fatality of lung implication in grippe, and this heart failure also causes emboli and their consequences. This vagus center involvement accounts for "the great and alarming prostration and cardiac weakness out of all proportion to the intensity of the fever" noted by the authorities. And those other "striking features" likewise referred to; "delirium," the great nervous manifestations, headache, pain in the back and limbs and unbearable aching and soreness like the dengue fever misery, point also to the nervous system. This, with the meningitis with which the pneumonia is associated, the neuritis and the mental disorders, disinclination to mental effort, melancholia and insanity which follow, as well as the numerous paralyses resulting, some of which, as already noted, terminate life, point plainly to the part the nervous system plays in revealing the presence of this peculiar and rapidly traveling poison of the air, which could spread from St. Petersburg to St. Louis in the short space of a few months.¹

The profound depression and the feeble intermittent pulse reveal to the neurologist the pathetic power of this poison in its attack upon the vital nervous centers, and the bronchitis and the pneumonia, the swelled pharyngo-laryngeal mucous membranes, the middle ear and Eustachian catarrh, coryza, intestinal catarrh and the nephritis, even, are no antagonizing exceptions, nor does the occasional finding of pneumococci invalidate this neuropathic view. They are seldom found in the grippe and more often elsewhere.

The grippe pneumonia, which is one of its most characteristic and fatal symptoms, is such as might come from section of the vagi, and a study of the origin and many distributions and functions of these nerves, pulmonary, cardiac, etc., gives us lucid explanation of the phenomena of the disease not otherwise so readily understood.²

¹ It is a mistake, therefore, and in the light of lately recorded experience and in that of my own limited observation, to say that "in the delicate and aged alone do we see fatal results," and it is a further mistake to attribute such results, when they do occur, "only to the intensity of the fever," as one of our most brilliant and gifted authors (Wm. Osler, "Practice of Medicine," 1892) has done. His sagacious clinical acumen compels him, however, to add "profound depression."

² The vagus largely governs the lungs, the heart and the circulation in this disease, and toxic irritation and depression of the medulla and pons explain most of the symptoms of la grippe. Section of both vagi above the origin of the superior laryngeal nerve is followed by loss of power in the muscles of the larynx, as well as of sensibility in larynx, trachea, bronchi and lungs. The reflex act of coughing is abolished, the glottis does not close, food and foreign bodies, saliva and irrepirable gases get into the respiratory passages and cause inflammation. This was shown as far back as 1740 by Valsalva and Morgagni; also by Langlois in 1812. This has been confirmed so often since that no one now disputes it. The vessels of the lungs become surcharged with blood, owing to the labored and difficult respiration and the long distension of the lungs between inspiration and expiration; serous exudation and pulmonary edema follow, blood exudes and pus forms in the air vesicles and a probable paralysis of the pulmonary vasomotor nervous system takes place to add to the pulmonary engorgement through the capillary system of the lungs. The pneumonia which takes place immediately after section of the vagi was found by Michaelson, according to Landouls and Sterling, to be in the lower and middle lobes; the pneumonia following section of the recurrent nerves is shown more slowly in catarrhal inflammation of the upper lobes especially. Rabbits die with symptoms of pneumonia from section of the vagus. They may live for several days, if the recurrents only are cut. Dogs live longer. If the ninth, tenth and twelfth nerves are torn out from one side in a rabbit, death also takes place from pneumonia, according to Grünhagen.

In birds the upper larynx remains closed firmly and death does not take place for eight or ten days, and then with symptoms of inanition and fatty degeneration of the heart. The heart shows cloudy swelling and wax-like degeneration. Frogs die of asphyxia under the same circumstances. Some fibers of the vagus seem to exert a trophic influence over the lungs and heart.

Unilateral section of the vagus in rabbits is followed within forty-eight hours by the appearance of yellowish-white spots in the myocard-

It would be interesting, but too tedious at this time, to further follow this wandering and widely connected nerve, and note its relation and that of its near neighbor nerves, which originate in the fourth ventricle.

All that we have thus far said has just warrant in the recorded and accepted facts of neural physiology, and the careful clinician will not fail to note their significance, and much more by study of the physiology of the other nerves whose nuclei originate in the fourth ventricle, and this nerve center when touched with its peculiar toxine, in its bearing on the symptomatology of la grippe.³

Influenza greatly weakens the *vis medicatrix* of the nervous centers, permits latent tendencies and slumbering diseases to spring into active force and leaves the patient, after the active febrile stage has passed and after what is erroneously regarded as the stage of convalescence, in a state of profound neurasthenia or toxic neuratrophia, from which spring many ills. It will develop into mischievous activity a latent rheumatic gout, neuralgia, malaria or syphilis. We may expect to combat every morbid tendency the patient is prone to, before we have entirely cured him of this malady. These latent morbid aptitudes so brought into renewed activity seriously complicate la grippe and embarrass prognosis. These should be appropriately combated, to leave nature as unembarrassed as may be possible, to contend with the devastating foe. And because of the gravity of the nerve prostration and of the nervous sequelæ, the patient should be put to bed and kept there till the fever storm is over, and in the house much longer in order to conserve the fighting energy of the assaulted nerve centers.

This injunction should be as imperative in many cases of grippe as it should be in cholera, for influenza is a far graver malady in its immediate and especially remote effects on the nervous system, than it at first sight appears.

ium, especially near the inter-ventricular septum; on the papillary muscles and along the furrows of the coronary arteries. The muscular fibers exhibit retrogressive changes whereby their striæ disappear; they become swollen and filled with albuminous granules. After eight or ten days the interstitial tissue of these foel becomes infiltrated with small round, granular cells, especially near the blood vessels. At a later stage the interstitial connective tissue increases in amount and the muscle atrophies. No effect is produced by section of the depressor or sympathetic fibers, and Fantino thus concludes that some of the fibers of the vagus exert a trophic influence on the myocardium. The same fact is not so nearly demonstrable in regard to the lungs, but it is equally inferable.

The pulmonary branches of the vagus supply motor and sensory (cough exciting) branches to the whole bronchial system of the lungs (the pulmonary vessels being supplied with vasomotor nerves) from the sympathetic system.

They send afferent fibers to diminish, under stimulation, the activity of vasomotor centers, and thus cause a fall of the blood pressure during forced expiration, and similar fibers to act on the inhibitory centers of the heart, and thus accelerate the heart's contractions. Simultaneous stimulation of these two sets of fibers alters the pulmonary rhythm.

The vagi also contain afferent fibers which go from the pulmonary parenchyma to the medulla, which are continually in action, stimulating the respiratory center. Consequently, section of the vagi deepens the respirations and diminishes their frequency. Stimulation of the central end of the vagus also accelerates the respirations. Labored and difficult respiration may occur either when these fibers, which excite the respiratory center reflexly, are cut off, or acting centripetally to afferent impulses proceeding upward in the vagus. Conditions determining pneumonia may therefore exist in the nervous mechanism of the lungs and in its points of origin in the cord and superimposed medulla oblongata. If the trunk of one vagus or its center is paralyzed respirations are labored, deep and slow, such as follow section of both. Stimulation of the cardiac branches of the vagus may cause temporary suspension of the cardiac contractions, a feeling of great depression and of impending dissolution, such as we see sometimes in grippe, and as we see in dyspeptic asthma and the abdominal frog tapping experiment of Goltz.

³ The therapeutic lesson of the neuropathic implications of influenza is rest and reconstruction (pending the search after its causative bacteria and their proper bactericide), rest and reconstruction, that phagocytosis may be promoted in the blood, chloral as the best antiseptic, hypnotic and calmative, for even the delirious stage. In the later, ammonium bromidum added. For the pain, the coal-tar derivative analgesics, and sweat-producing opiate combinations, the elimination of all disturbers and depressors of nerve centers entering through the blood, like the rheumatic and malarial or venereal poison.

DYSPEPSIA AS A BRAIN DISEASE.

What is true of the neural relations of grippe is largely true of those of dyspepsia, a disease which, as Amariah Brigham, an American physician, was the first to show, about 1840, usually has its origin in the brain, as I have elsewhere attempted more elaborately than I shall do at this time, to establish.

I shall only ask you hear to consider it as a possible brain affection from what we know of its causes, those in whom it usually exists and the conditions of mind, occupation and environment of those in whom we find it most often manifest.

Dyspepsia belongs to the brain working, brain worrying and nerve tone exhausting class, to those who bother their brains and eat little or not over much, rather than to those who gormandize; to those who burn the midnight oil in study, do not sleep from fret and worry and from carking care, rather than to the *bon vivant* high liver, and he who tarries long at the wine. It belongs to the men of affairs and women of care, to the infelicitous and the disappointed in hope and ambition, those whose cerebro-spinal systems are inordinately strained and inadequately repaired in life's battle, so that their lower corporeal functions suffer from defective innervation of the viscera concerned in the maintenance of organic life, and whose cerebro-spinal systems consequently reciprocally suffer from defective appropriating power and inadequate nutrition, but starvation alone seldom develops dyspepsia.

It is through the neural connections of the brain and stomach that the acknowledged *apepsia nervosa* of neurology is a clinical fact. It is thus also that the relationship of nausea to migraine as the concomitant of the latter, but so long considered the cause, is explained, and conversely, that we understand *vertigo e stomacho laeso*, as first described and explained by the great master in medicine, Trousseau.

The brain influences the stomach and the stomach influences the brain, but the power of the former over the latter is far greater than the latter over the former in chronic conditions.⁴

To concede this influence of the nervous system over the digestive processes, we need not ignore any fact of chemico-biologic research, nor shut out any of the light thrown on the subject by the distinguished American investigator, Beaumont, and those who have followed him in elucidating the functions of the stomach. On the contrary, Beaumont's investigations proved the power of mental state over the digestive processes of Alexis St. Martin.

The liver, the kidneys, the bladder and the bowels are similarly influenced by emotion, and the lymphatic system is likewise under nervous control like the arterioles, by the vasomotors.

A center in the medulla also influences through the chorda tympani nerve and probably the sympa-

⁴ Great brain and nerve strain, as in insanity, brittles the bones; grief and fright blanch the hair and face; fear paralyzes the heart, depresses temperature, causes excessive and clammy perspiration; anxiety arrests secretions and shrivels the skin; remorse wastes away the body; anger flushes the face, and so fills the brain with blood that its vessels burst and the victim falls with apoplexy; shame flushes the cheek, slows the heart and respirations; sorrow shows itself in tears; love and good fortune brighten the countenance and quicken the step and pulse, and lift up the form, while adversity and remorse sadden the face, slow the pulse, bend the form and depress the bodily movements. These things and many needless to mention, show us the potency of mental influence, through its proper neural channels, on the movements of the organism. We can not deny them in regard to the stomach. On the contrary, as we see the systole of the heart arrested by emotion, so we see digestion stayed by disagreeable and depressing thought. Mental force, through psycho-neural media, pervades the body and the stomach is not exempt from its invigorating or depressing influence over its physiologic functions.

thetic, the salivary secretion. A center there also influences the action of the kidneys. The chorda tympani contains secretory and vaso-dilator fibers, the sympathetic, vaso-secretory and vaso-dilator. Salivary secretion is induced reflexly by mastication and the irritation of the presence of food in the mouth and stomach and by the vivid remembrance of certain foods whose eating has made an agreeable impression, and by emotion.

We swallow, we digest, we sob and vomit by means of vagus fibers, and its fibers go to the celiac plexus, the spleen, the liver, the kidneys and the small intestine. Esophagismus, gastrodydia, or cardialgia, tachycardia, palpitation and angina pectoris and spleen, intestinal liver and kidneys, are influenced by this wonderful nerve, as well as asthma and exophthalmic goitre and many affections of larynx and lower air passages; notwithstanding the complete pathology of this wonderful nerve and of many of the interesting diseases connected with it may be said to be yet somewhat obscure.

The vagus and the vasomotors influence or govern circulation, respiration and digestion.⁵

The dominion of the nervous system over the spleen is also evident. This fact is one of the concessions of the physiology of our day. Stimulation of the medulla leads to contraction of this organ. Not only its arteries but the organ as a whole is maintained in a state of tonic contraction to a certain extent through the agency of the nervous system.⁶

HYSTERIA.

No better or more familiar illustration of the possible potential relation of the nervous system to disease need be mentioned before a body of practical clinicians that that of hysteria and its neural peculiarities and associated functional disturbance of organs (that mimic of all diseases with its protean features in so many instances), its atrophies, paralyses, contractures, alternating anesthetics, hyperesthesias, paresthesias and aphasias, aphonias, dysphagias, stigmata, emeses, suppressions, excesses and and perversions of excretions, nutritional, sensory, motor, psychical, visual, tactile, auditory and emotional derangements.

Hysteria illustrates in an especially forcible manner from the standpoint of clinical observation how suddenly and how extensively nearly all the organs of the body may be profoundly disordered in function by morbid impression through the nervous system and these pathologic impressions often repeated and prolonged do sometimes develop actual and enduring organic diseases.

There is a suggestive practical lesson in this "neuromimesis" or mimic neurosis, as to the relation of the nervous system to diseases in general. As the

⁵ This is just such an observation as should come more frequently from general practitioners. The vasomotor nervous system is omnipresent in its organism. It follows the vascular system to the innermost recesses of the body, and the number of its morbid functional possibilities is beyond computation. Some of the vasomotor ataxias, quite familiar to practicing neurologists who have opportunity for general medical observation, have been noticed and given a clinical grouping under the tenor "Vaso-Motor Ataxia," by S. Solis-Cohen. Vide "Vaso-Motor Ataxia," by S. Solis-Cohen, American Journal of the Medical Sciences.

⁶ Physiologists now maintain that its metabolism is controlled directly by the nervous system and they are far nearer than formerly to an understanding of its function, just as the same system is concerned in the billous and glycolytic functions of the liver as we see demonstrated in the fourth ventricle puncture proof of artificial glycosuria, and excision of the pancreas has resulted in glycosuria influencing the nervous system as profoundly as thyroidectomy. The spleen may be diminished in size either generally by the stimulation of one of the afferent nerves, and, locally, by direct application of the electrodes to the surface of the organ. And Paul Gibier has produced glycosuria by psychical excitation of animals. (Vide, Trans, N. Y., Acad. Med., 1893.)

study of this disease led Goodell to discern and portray the nerve counterfeits of uterine disease and to say: "The crying error of the day is the mistaking of nerve disease for womb disease;" so I say of disease in general, the crying error of the day is the ignoring of neuropathic implications, concomitants and sequences of organic, visceral and general diseases, and the mistaking of nervous for other diseases.

As any organ of the body may fail functionally and be perverted in the performance of its functions, so may we have organic derangements from frequent repetitions of functional disorder, if the trophic and vasomotor nerve centers share in the functional disturbance.

THE TROPHO-NEUROSES.

Here we enter the clinical domain of the tropho- and vasomotor neuroses whose name is legion, from symmetrical gangrene and local asphyxias of Raynaud's disease, to the ecchymoses, etc., pigment hypertrophies, cornifications, naevi, pigment atrophies, (lepra, vitiligo, etc.), arthritic atrophies, climacteric and menstrual cutaneous swellings, etc., urticaria, angioneurotic edema, the night palsy of Ormerod, secretion anomalies like seborrhea, hyperidrosis, amidrosis and the occasional vasomotor disturbances of the fevers, as in typhoid and of dropsy and anasarca.⁶

About all the changes which come under our eye in the skin and muscles, are due to impressions made through the trophic and vasomotor nerves, influencing the circulation and growth, among which we may instance scleroderma, myxœdema or cachexia pachydermique and the myopathies, pseudo-hypertrophy and progressive muscular atrophy.

PHYSIOLOGIC RHYTHM, ETC.

The nervous system regulates the law of rhythm in the animal economy in both its physiologic movements and pathologic perversions of movement, and this fact affords us, from a neurologic standpoint, important hints for the management of our patients and therapeutic suggestions, hints often overlooked in practice.⁷

The nervous system is almost an omnipresent system of the human organism. The more we learn of it the more do we wonder at man's wondrous mechanism. The more we see of its relations to organism the more we discern of its omnipotence and of its subserviency in the workings of the human economy. It excites, it controls, it reveals and is revealed and influenced by disease. The sensory nerve trunks and branches can be traced as clearly by neuralgia (sciatic, intercostal, trifacial, etc.), and by neuritis, as by the anatomist's scalpel; and the various paralyses reveal the channels of motor conduction and centers of origin of motor impulse, thus affording us means of diagnosis beyond the reach of our unaided vision. Thus cerebral localization has been confirmed

⁶ The term, trophic disorder of muscles and organs, is at present much more restricted than it manifestly will be when physiology shall have more accurately numbered and located the trophic centers, whose influence over the tone and quality of the tissues and organs is now no longer a question. Certain nerve centers and nerve fibers do undoubtedly influence the growth and repair and atrophy or decay of the tissues, and Romberg, in this discovery, has rendered medical science in its practical aspects a priceless service.

⁷ It suggests, for instance, that we should interrogate our patients as to the normal rhythmic time for eating, defecating and sleeping, in the administration of food, of laxatives and hypnotics, and suggests also the best part of the day for necessary disturbance of our patient with medical ministrations, ablutions, driving, exercising, etc. All habit, physiologic or pathologic, is bound up in the law of rhythm and a nervous system is essential to this phenomena.

as a fact of neuro-physiology, as well as by electrovivisection.

In the interrogation of morbid symptomatology; convulsive disturbances, tremors, subsultus, paralysis, circulatory changes, the periodicity of intermittency and remittency, temperature changes, delirium and other phenomena of the fevers, the collapse, spasm and ricewater discharges of cholera, and even of the remote causation of cancer and of many of the dermatoses, we can not help but see how intimately associated the nervous system is with the movements of the organism under the influence of disease. These phenomena may, truly, in a manner be called nervous. Certain it is that the nervous system in disease plays no insignificant part, often the most important; and to timely tranquillize and reconstruct it against the assault of the causes of disease in the organism is no small part, if not the chief part of the physician's work, for, though the blood carry germs of deadly disease to vital nerve centers, to conserve these centers by suitable therapeutic reinforcement against their destructive work, means victory over impending dissolution.

The *vis medicatrix nature* resides in these nerve centers and in their power to maintain, under stress of invading disease, the normal metabolism in the various organs, and as I believe, though this is not yet susceptible of scientific proof, of the furnishing and multiplying of the phagocytic hosts of conservative destruction in the healthy blood. If the blood is the life, the nervous system is likewise the life of the organism. In this dual government of the economy in health and disease, both

"Are parts of one great whole,
Whose life the blood is,
And the nerves the soul,"

if this liberty of paraphrase before employed by me may be here again permitted. If we realize this fact in our clinical conclusions and efforts at treatment, we make better practitioners at the bedside than if we seek to explain the phenomena of disease by a single factor like modern humoralism or solidism, or visceralism, or the germ theory, absolute and unconditional. It requires something more than a morbid germ to develop disease. The other factor is an assaulted, yielding and morbidly responding organism, and back of that are the disturbed or resisting mechanisms of neural control, central or peripheral, which resist, cast out or succumb to disease.⁸

THE IMPORTANCE OF EARLY RECOGNIZING NEURASTHENIA.

A great advance was made in clinical medicine when neurasthenia, or as I have called it, general functional neurasthenia, was first recognized and differentiated from secondary exhaustion of the general nervous system, from the auto-toxicity of retained excretions and profound physiologic brain and nerve and muscle tire. This condition described by Van Deusen, an American physician, in 1877, followed by

⁸ Certain phenomena of reflex, in clinical and surgical therapy too, are better appreciated by him who thoroughly considers the nervous system in his practice. Such an one usually recognizes two factors in the peripheral causation and the morbidly responding center, which he trays in an extraordinary manner the exaltation of the irritation, peripheral or central.

Benjamin Rush notes the fact that Leo X. died of joy upon hearing that a great calamity had befallen the French nation; the door-keeper of Congress died from the same cause, including cerebral apoplexy, upon learning of the capture of Lord Cornwallis and his army during the Revolutionary war; and the great Harvey, who discovered the circulation, died in a fit of anger. It is because impressions upon the nervous system have the power to kill that they may also engender and cure disease. This malevolent potency makes psychotherapy a benevolent possibility in practice, and no wise physician ignores it.

Beard, another American physician, in 1878, is one in which the nervous system appears to suffer in its nutrition, normal stability and power, involving the viscera and nervous system only in a functional and secondary manner.

Neurasthenia or general functional neurasthenia, shows itself chiefly in the brain and is psychically characterized by timidity of conduct, nervous irritability and morbid fears, bordering on, but not becoming delusions, and physically by functional atonicity of the viscera, especially of stomach, heart, bowels, and motor and psychical areas of the brain. It is the cause and source of apepsia nervosa and of cerebro-spinal irritation, and differs from hysteria, with which it is sometimes mistakenly confounded, in being continuous and not paroxysmal, and in being far more common in men than in women.

It is a conservative neurosis like migraine, saving its victims from profounder breakdown, because the individual will endure but so much and can not stand a longer strain without a period of rest and repair, whereas if he could endure more, the issue would be apoplexy, paralysis or other organic trouble. Before its recognition, it was thought necessary that some organ or system (the sanguineous, hepatic, etc.) should be profoundly affected to justify a conclusion of disease, and great injustice was done its victims under designation of hypochondriasis, hysteria, simple nervousness, etc., not requiring medication. Neurasthenia is a nineteenth century evolution in clinical medicine.⁹

THE RELATIONS OF NEURAL OVER-STRAIN TO THE DEVELOPMENT OF CANCER AND CONSUMPTION.

The developmental relations of cancer to neural over-strain, worry and decadence of the brain and allied nervous system have lately received renewed consideration, since the writer first called attention to this singular fact in the cases of General Grant, Napoleon Bonaparte, Thomas H. Benton and others. I believe, as I many years ago stated, that a breakdown in the central nervous system by which its trophic and resisting power are greatly lessened, makes possible and precedes all cases of cancer. But for this, cancer germs, if such exist, would be innocuous. The same fact is in a manner true in regard to the receptivity of phthisis and other diseases of bacillic or bacteric origin. Seeds, to germinate, must have receptive soil, and in relation to cancer, as Sims Woodhead, who believes in its parasitic causation, declares, the germs require a lowered condition of the vitality of the epithelial elements in which they make their habitat, as conditions of their growth and development. Finding a soil, they multiply, secrete their toxins, and by their irritant action on the parts which they invade, resemble certain well-known pathogenic microbes, especially Koch's bacillus, in the degenerative processes and products which they entail.¹⁰

⁹ Dr. Geo. M. Beard forced the general recognition of this functional morbid state of the nervous system by the profession, though some physicians of eminence yet dispute it.

¹⁰ But the question of the parasitic origin of this disease was left *sub judice* at the last International Congress at Rome, at the close of the most interesting and learned discussion ever held upon the subject, Pio-Poa, the referee's, advocacy of the parasitism of cancer being ably contested by Cuzin, Dupuy and Cornil. Pio-Poa, supported by Morpurgo, of Turin, maintaining that these parasites are encapsuled protoplasmic bodies within or without the nucleus of the cancer cell, similar to the descriptions of Clarke, Soudakeritch, Walker and others, resembling the spores of protozoa or malaria hematozoa, and are common to all cancers of glandular degeneration.

The peripheral neoplasms contain small parasites, the deeper, large sporocysts. Mitosis or karyokinesis is absent or scarcely perceptible where the parasites are absent or few. Dr. Shattuck (editor of the *Boston*

NEURODERMATOLOGIC ADVANCE.

Mr. Malcolm Morris, in his presidential address before the Harveian Society of London, reviewing the progress recently made in dermatology, after noting the fact that we now recognize the precise microbic agents which produce lupus, scrofuloderma, impetigo, leprosy and glanders, and speaking of the "new light" which experimental pathology has thrown on the nature of disease processes and the factors concerned in their production in the skin as in other organs, says: "Almost the only distinct evidence of progress apart from local treatment to which I can point, is the fuller recognition which has been arrived at of the influence of the nervous system in the production of skin affections. . . . The knowledge of the intimate pathologic connection between the nervous system and the skin gives the key to the successful treatment of many cases which defy all local measures."—(*British Medical Journal*, Jan 27, 1894.)

The same light has recently dawned on gynecology and every department of medical practice. We are approaching an era when the whole patient is to be treated, no more only a part or organ solely, and neurology will have a paramount place in general clinical medicine, notwithstanding the recognized and merited advances of bacteriology in pathogenesis.

CERTAIN HEART AFFECTIONS PROCEED FROM THE BRAIN.

What is true of the influence of the nervous system over the stomach in dyspepsia, and the lungs in the pneumonia of influenza, is also true of its influence in the production of certain diseases of the heart. They come from states of the brain, and here again has medicine in its work for the world's welfare, through physiologic research, faced the prejudices of a frowning world against the so-called cruelties of vivisection.

Though the heart of a frog removed from the body will pulsate for hours, if fed with blood or blood serum, and will continue to beat even when divided into sections except at its apex, and even this will beat if tied to the end of a tube and fed under pres-

Medical and Surgical Journal, the first journal to report these facts from the Eleventh International Congress) in commenting on this latter fact, says: "This shows that they (the parasites) live, but in tissues whose vitality is low."

In this memorable discussion the following facts were opposed by Prof. Cornil and others to the statements of Pio-Foa and his adherents: Cancer exists in many modified cell-formations and has many nuclei resembling parasites. He asserts that Pio-Foa's parasites are metamorphosed nuclei resulting from morbid karyokinesis; that "there are found also in cancer, degenerated cells whose protoplasm stains red, and which contain in place of nuclei granules, filaments or masses of nuclein, representing the different forms of indirect division, without the occurrence of achromatic filaments or of clear space around the divided nuclei. These are cell degenerations arrested in one of the phases of indirect division of the nuclei. Cornil remarked that even migrating leucocytes interposed between cancer cells had been mistaken for parasites, especially when they had retrograded and had broken up into fragments of nuclei."—(*Boston Medical and Surgical Journal*.)

And a yet stronger criticism of the parasitic origin of cancer is the failure of inoculation experiments to generally produce cancerous reaction, as Dr. Shattuck observes.

But even successful inoculations only bring us back to that other well-attested fact, the necessity of an adaptable soil and the absence of organic resistance, which we have placed in the neural regulation and normal inhibition of vital cerebro-spinal centers.

So that while conceding spontaneous muscle cell pressure and protoplasmic contractility, we know that in certain cases cardiac contractility is modified by medulla and vagus stimulation, to the degree of arrest, slowing, enfeeblement or intermittency.

When the vagus influence is altogether inhibited, the heart's action is increased in force and frequency, while section of both vagi leads to histologic alteration and fatty degeneration. The sea turtle's heart has been suspended through vagus stimulation for six hours, causing its death.

The heart dilates with or without blood during vagus arrests from vagus section, drug impression or electric excitation.

The heart may be reflexly inhibited by gastric and abdominal reflex irritation, flatulent dyspepsia, the Klopersucht of Goltz, etc.

If one or both vagi are intact, stimulation of the medulla arrests the heart.

The conclusion of a cardio-inhibitory and accelerator center in the medulla, which influences the heart through the vagus, is the obvious teaching of physiology.

sure, its conditions of nutrition in vertebrates are determined directly by the nervous supply of the organs and indirectly by the blood (Mills), and the influence of the cardiac nerves becomes more pronounced as we ascend the animal scale, and in the heart of a frog there are ganglion cells, in the sinus venosus, in the auricles and ventricles (ganglia of Ludwig, Remak and Bidder). They are also in the warm-blooded animals, dogs, sheep, etc."

When the heart is severed from the central nervous system by section of the vagi nerves, or destruction of the vagus center takes place by traumatism or disease, profound changes in the heart's structure ensue; this points to central trophic influence through the vagi and to the often central nervous origin of heart disease. The regularity of the heart's rhythm from and strengthening of its beat through vagus stimulation and central stimulation, as by certain volatile and internal stimulants, is suggestive.

We are now able to understand how many disorders of the heart are coincident in their inception with occasions of fright and worry and anguish, sudden accesses of extreme ire, disappointment, prolonged enforced vigilance and other brain strains. These, as Mills tersely says, point to influences of a central origin as greatly affecting the life processes of this organ.

Czermack, pressing a bony tumor in his neck against the vagus nerve, and Hermann and Col. Townsend repeatedly suspending the heart's beats at will (the latter once too often, for he died from his final experiment), also prove the central and vagus nerve influence over the heart. Nervous influences certainly play no small part in the causation and modification of the heart, and with Mills we would "extend such a view to all parts of the body," especially in man. The source of the heart's diseases is often in the brain and other parts of the nervous system, and so is the source of many other diseases for which only the organ displaying the functional disorder and the blood which nourishes it are treated, whereas we should more often treat the whole man, nervous system and all, but the nervous system especially, if we would be most successful.

Now, therefore, in a newer, broader, truer sense than ever before, do we recognize the monism of man. Not in the sense of the philosophical schools, but in a psycho-neuro-physical sense in our survey of his physiopathology. In estimating the causes, concomitants and sequences of his diseases, we consider the whole man in his psycho-neuro-physical relations. As the "medulla oblongata is functionally the ruler of vegetative life," so it governs and influences many diseases, as the psychical and psychic centers of the cortex influence it and the centers below it, as the recto genito-urinary centers of the cord, etc.

As we recognize psychic influence over our physiologic life, over physical and mental habits, so must we come to acknowledge it more generally in our dealings with disease. The physiologic law that habit in the psychical life develops a tendency to recurrence, is also exemplified in the disposition of certain diseases to recur and the inter-relation between muscular and mental tonus suggest the importance of maintaining the psychical tonus in the treatment of all diseases, and the successful therapeutics of hypnotism proves it in many.

As it is difficult to believe in force existing not in

contact with matter and without matter existing on which force can display itself, so it is difficult to conceive of the existence of disease in the human body without an influencing or influenced, *i. e.*, disturbed, nervous force.

Henry Maudsley has likened the physiologic life of the cerebro-spinal centers to the mutual inter-related and subordinated movements of the companies, battalions and brigades of an army under command of the higher ganglion cells of the headquarters in the brain, and mental disease to mutiny and rebellion. Huxley has likened the body to "a machine of the nature of an army, not that of a watch or of a hydraulic apparatus. Of this army each cell is a soldier, an organ, a brigade, the central nervous system headquarters and field telegraph, the alimentary and circulatory system the commissariat. Losses are made good by recruits born in the camp, and the life of the individual is a campaign conducted successfully for a number of years, but with certain defeat in the end." Each tissue under the trophic influence of neural communication with its appropriate nervous headquarters conducts its own repairs, *i. e.*, replenishes its own forces. When proper physiologic conditions, including neural connections, are maintained, each tissue in the animal economy correlates its own proper life force. Destroy a trophic center and the part it innervates atrophies; sever a motor nerve and the muscle it supplies is paralyzed; cut a sentient nerve and no power of our art will restore sensibility over that channel that does not reunite or reproduce the nerve. Our aim in the practice of medicine, then, should be to save the nervous system, to conserve neural integrity and force in relation to all parts of the organism suffering under the depressing influences and destroying tendencies of disease.

This should be our aim always, whether we are enabled to make a satisfactory local diagnosis or not, for if we succeed in saving the nervous system absolutely, we save the man, for it is only after disease makes its final resistless inroads here that our patient dies.

HEMOPHILIA AND THE VASOMOTOR SYSTEM.

The neuropathic source of hemophilia in the vasomotor system is more probable than any asserted dyscrasia of the blood, and cholera is so largely a condition of nervous prostration in its symptomatic expression, that if we treat it on this theory, keeping the patient absolutely recumbent and give him copious hot water drinks and enemata, we are more apt to save our patients by this than by any other one plan. Of course, the comma bacilli should be searched out at the same time, with our hot drinks and colon clysters, and destroyed so far as may be practicable, but it is the damage done to the nerve centers that we wish to guard against in this disease till the collapse stage passes, the bacilli are destroyed and reaction comes on. Cold colon douches are likewise of some benefit. I think the water does the work and not the soap in Elmer Lee's plan of treatment, which I uphold on the physiologic principle that the abdominal ganglionic centers and by eccentric impression the spinal nervous system is favorably impressed by his method, while such bacilli as the water can reach are washed out of the intestinal tract, but these are not the most of them.

To divest ourselves of undue skepticism in regard

to the influence of the nervous system in the development of what we are accustomed to call disease, but which is often the sensible pathologic product of a morbid process, we should recur often to the physiologic possibilities of the mechanisms of neural control over the arteriole system and of sensation and motion.¹²

BODY TEMPERATURE AND FEVER DEPENDENT ON THE CONDITIONS OF THE NERVOUS SYSTEM.

That remarkable phenomenon, the uniformity of the temperature of the human body at all latitudes and in all seasons, is due to the regulating adjustment of the circulation, perspiration, etc., to environment through the nervous system, and when temperature is disturbed it is due to irritation, mechanical, chemical or toxic, of the nervous system as in traumatic violence, microbic, septic or drug disturbances.

It must by this time be apparent from what we have already said that the intimate physiologic relations between the nervous and the vascular and glandular systems justify these pathologic inferences and confirm the clinical facts.

"The nervous system has so close an alliance with the functional activity of the secretory and excretory glands of the body that emotional disturbances, according to their character, act as depressants or excitants of the functional life of these organs. Some of the more common of these effects are every-day familiar facts, as when the flow of tears is excited by grief, or the secretion of saliva and gastric juice by the smell of food." And it is believed that, "in the same manner as the superficial glands are easily influenced, so, in all probability, are the blood-making or ductless glands¹³ regulated and controlled by the organic nervous system.

THE NERVOUS SYSTEM AND THE LIVER.

The influence of the nervous system over the liver was believed in by the ancients who, mistaking coincidence for sequence, attributed melancholia to atrabilis. Murchison asserts a well-observed fact that the secretion of bile is interfered with by prolonged mental anxiety, worry and incessant mental exertion, and that sanguification and blood changes in which the liver takes part often result from mental causes.

I think we need no longer doubt this or indeed any possibility to neural influence when we see pernicious anemia follow degenerations of the spinal cord, and

¹² See Brown-Séguard, for instance, producing hemorrhage into the auricles of guinea pigs by section and irritation of the restiform bodies in the medulla and flushing the neck and face by section of the cervical sympathetic! In this we have the explanation of hematoma auris and cerebral hyperemic states.

It is through the nervous system that we may understand how the hair turns in melancholia and may thicken in chronic mania or dementia of the less distressed and more stupid and inactive forms, how its color may turn from dark to white and back again to dark, with the access and recoveries of recurrent insanity how it may gloss and dry, erect or flatten, be lost and regained under mental states, and how the teeth may decay, the bones and nails grow brittle and the skin harsh from the same cause and how from neuritis, the nails transform and the limbs waste as well as fall in sensibility and mobility, besides the eczematous, pigmentary and horny changes of the skin from nerve injuries.

¹³ Dr. A. D. Rockwell, in a paper in the New York Medical Journal, Dec. 10, 1892, maintaining the nervous origin of jaundice, said: "He had had occasion to see and treat a considerable number of cases of jaundice dependent upon a great variety of causes, and he had been impressed with the frequent occurrence of cases due to deranged innervation, interfering with the normal metamorphosis of bile. Acute atrophy, in which the secreting cells were rapidly disintegrated and the functions of the organ arrested, appeared to him in many instances to have a purely nervous origin; and very often the first symptoms of the disease occurred immediately after a severe fright or an outburst of passion in a person previously healthy. An impression made upon the brain appeared to be reflected to the liver and to derange its nutrition. Even cancer of the liver appeared sometimes to result from the functional derangement induced in the first instance by mental trouble. So this condition appears to us."

progressive muscular atrophy and anemia follow cerebro-spinal concussions.

If the mind has such potency how careful should physicians be of their demeanor or speech before patients. How guarded as to prognosis. And the surgeon, how careful should he be as to the undue and inopportune display of his operative armamentaria. With these facts in view the propriety of large medical and surgical wards where the sufferings and death of one patient may be readily known to the others in the ward is questionable. Other obvious considerations needless to mention here are suggested in this connection.

These neural connections, direct and indirect, between centers of the brain and the circulation, the viscera and the secretions reveal the physiologic basis of all forms of psychotherapy, of faith cures, mind cures and modern miracles, of the principles of which those who perform them are usually ignorant; also, of hypnotism and its therapeutic results.¹⁴

LEUKEMIA AS A NEURATROPHIC BLOOD DISEASE.

Leukemia is another and most remarkable condition which may result from profound nervous exhaustion or shock or from malarial neuratrophia, and shows how the blood may change through nerve influence as cretinism and pachydermic cachexias show the relationship of thyroid and nervous degeneration and as thyroid extirpation also proves.

THE RATTLESNAKE POISON FIRST A DEADLY NERVOUS SHOCK.

If the remarkable blood cell changes of this disease may originate in morbid neural impression, it would seem unnecessary to go further for proofs. But the poison of the rattlesnake and other toxic substances may kill through immediately fatal shock without detectable lesion, though grave structural changes follow, especially in the destruction of the blood's fibrin and later putrefaction, in the case of crotalus poisoning, if the patient survive any considerable length of time.¹⁵

The nervous system is the supreme ruler in the organism. When disease enters it is weakened; when death takes place, it is dethroned. The germs of malaria, tubercle, cholera, typhoid, tetanus, etc., or the living virus of any fever, make no fatal inroads until they break down and destroy centers of neural control and resistance.

Whatever view we may take of bacilli, bacteria or cocci which our glass may reveal to us in the damaged organism, whether we regard them as carrion about a carcass, rats forsaking a sinking ship, thieving, destroying, or scavenger parasites, one thing is certain, viz., disease becomes manifest only after the mechanisms of neural sensation, emotion, ideation or control reveal it, for as I have elsewhere said, the

¹⁴The wise physician combines chemistry and a scientific *materia medica* with honest and hopeful mental impression, establishing in the patient where he can and is justifiable by the clinical facts without deception, a bnoyaut psychotherapensis in the patient himself. The lengthened visage, the hopeless foreboding, the dismal and solemn aspect and funereal demeanor on the part of the physician are not only out of place and unjust to the patient, but are bad therapeutics.

¹⁵How speedily the symptoms of this poison follow, if death be not instantaneous; the cry of terror, the giddiness, the syncope, the vomiting, the prostration, the rapid, irregular, imperceptible pulse, the sunken eye, the swollen face and body, the jaundiced, cold, clammy, vesicled skin, the delirium, sleeplessness, torpor, coma, involuntary intestinal and vesical discharges, tremors, convulsion and death? First the nervous shock and then the blood disorganization and organic dissolution.

Drysdale examined the cases immediately fatal with the best of lenses and found no lesion. The nervous system was directly stricken, and life, of which the cerebro-spinal and ganglionic systems in man are the representatives, ceased. The physiologic barrier wall in the nervous system is broken and disease invades.

nervous system is the central executive and universal sentinel system of the organism. It governs and legislates for the physiologic body, exercising, moving, restraining, regulating or inhibitory power over organic processes in health and in disease. It has its subordinate tributary and sustaining forces in the glandular, vascular, osseous and other systems. It commands, governs and regulates them and they influence it, as the citizens and subordinate officials of the State may influence, and even govern the chief executive or the king.

Raynaud's disease, with its local asphyxia and symmetrical gangrene of the extremities, though its cause may be uric acid, as Haig ("Uric Acid in Causation of Disease," 2nd edition, page 201) maintains, is manifest to us, as Raynaud believed, through spasmodic contraction of the capillaries, as the gangrene of ergotism is.

Haig contends that the uricacidemia of gout and rheumatism "contracts the arterioles and produces high arterial tension," and that glycosuria is alternative of, and contemporaneous with gout, Ord maintaining that the congestion of the liver is due to high arterial tension, while Pavy, according to Haig, credits diabetes "to a vasomotor paralysis of the chylopoetic circulation, which allows arterial blood to be supplied to the liver in place of venous." (*British Medical Journal*, 1883, pages 863 to 866.)

Haig concedes that the hepatic congestion dependent on the state of the vasomotors develops the saccharine diabetes, thinks the uric acid causes that, but attempts no explanation except a dietary one, of the uric acid in the blood.

If I had the time to write a book on this occasion, I think I could show the nervous system to be primarily at fault in the uric acid diathesis and that migraine, epilepsy, morbus brightii, diabetes and melancholia, which attend upon the chronically gouty and rheumatic and alternate with these states, are varying neuropathic states with uricacidemia, albuminuria and sacchemia as their sequences. But this would be profitless. The practical clinical and therapeutic lesson is to correct both the abnormal blood and the faulty nervous states.

The contracted arterioles which raise the tension in the arterial system and diminish the circulation through the organs and tissues of the body need remedying, as well as the uricacidemia, the "hetero-albuminemia, albuminuria, etc.," and the deficient circulation and the deficient metabolism of organs and the disordered assimilation, as well as diet; for some persons may eat any kind of food and have neither gout nor rheumatism, nor diabetes, nor Bright's disease, so long as the governing nervous system maintains the physiologic equilibrium and sustains and secures it against pathogenic forces from without and within.

A change in the weather or a certain exposure sends one man to bed with rheumatism, another with pneumonia and a third comes down with remittent or intermittent fever or phthisis. We say uric acid in the first case, pneumococci in the second, malaria in the third and tubercle bacilli in the fourth.

But why do these morbid forces now more than any other time come so opportunely and seize upon their prey?

We say it is because the vitality is lowered and the organic resistance is lessened. What is that vitality, that organic resistance which permits one man to

brave an atmospheric or climatic environment with impunity from disease, in which another falls a certain victim? What is it that permits one man to eat everything without being made dyspeptic, while another can swallow scarcely anything without suffering the gastric distress of indigestion? We say one has a weak stomach, but if we take into account the whole man, we find it is the brain of the dyspeptic rather than his organs of digestion, that has been always punished by its owner's imprudent and reckless habits, though the stomach too may have been abused. We get a similar answer in regard to the remote causation of determining factors of disease of many other organs. We have invented, for evasive answer, certain elucidating terms, as idiosyncrasy, diathesis, morbid proclivity, inherent organic tendencies, etc., and we make many special explanations, like the little fibs the school-boy tells to extenuate a folly, each leading to some other and bigger fib, until he finally realizes that honesty is the best policy and then owns up.

My answer has already been intimated. I can not on this occasion weary you with further detail in elucidation.

I say only in conclusion, to forestall certain criticism, that, though the primal potency of the nervous system resides in the sarcode, much of its potentiality in the highest and most complex animal life, seems to have passed in process of evolution from protoplasm to nerve centers and the most there is of man is his nervous system. In this system resides, in highly evolved form, spontaneous and reflex motion, sensation and the governing influences of assimilation and reproduction. What should we not expect of such an organism impressing and impressed by disease.

This brief survey of a broad subject brings us across the century, twenty years before the one now soon to close had begun, to the immortal dictum of Cullen, the truth of which the progress of medico-scientific research in clinical medicine now confirms: "*Quantam ego quidem video motus morborum fere omnes a motibus in systemate nervorum ita pendent, ut morbi fere omnes quodammodo Nervosi dici queant.*"

And now in the sunlight of advancing science and of the approaching twentieth century, I proclaim that neuriatry and the practice of general medicine are practically one.

The practice of medicine is rapidly becoming one of neurologic methods, of neuriatry and psychiatry, and the best neurologist, all other attainments being equal, must of necessity make the best general practitioner. What Lord Chesterfield said of a Christian gentleman, I would paraphrase and say of the neurologist, He is the highest style of physician; and of medicine as a whole, with Hippocrates, It is of all arts the most noble.

Thus much, and yet not a moiety in regard to the relation of the nervous system to disease and practice! Thus much of neurologic progress relative to general medicine. Obviously we can not now enter into the marvelous advances and wondrous resources of modern medicine. In the pages of a thousand volumes and the works of a thousand modern hospitals her glorious record is partly made for the welfare of man, as the nineteenth century recedes into history. But there she stands in her grace and grandeur, the peer of all professions! Ever faithfully by the side of man from the cradle to the grave, in the hour of

his saddest need, mindless of home or creed, she bends with pitying substantial aid over his suffering and prostrate form and lends strength to his weakness.

Handmaiden of sweet charity and exemplar of the golden rule, she unshackled the lunatic and brought him from his dark and dreary dungeon into light and liberty, while theology was yet calling him demon or devil-possessed, and she now extends her helping hand to the inebriate, while the world yet condemns him and largely withholds its sympathy. She has likewise extended her protecting charity to the epileptic, the hysteric, the victim of chorea or St. Vitus' dance and the so-called creatures of obsession.

She has influenced courts to modify the former harshness of their ruling towards certain classes, and caused them to recognize disease and degeneracy of brain in extenuation of crime, thus tempering justice with mercy towards the organically weak and maimed in brain and mind. Judicial theories of what should constitute insanity and allied conditions exempting from responsibility to law, have given way to clinical fact ascertained through psychologic expert testimony, and the "knowledge of right and wrong" test of mental aberration has, in consequence, ceased to be the sole criterion of responsibility in questions of insanity before the law.

THE TREATMENT OF INEBRIETY.

America was the first country, the great Rush was the first physician to recommend the "establishment of a hospital in every city and town in the United States for the exclusive reception of hard drinkers," and to regard the drink habit as a disease and advise the blending of medication with religious and moral suasion. And how many regular hospitals, assisted by our State laws, are saving the inebriate from that destruction from which neither his own will, nor moral suasion nor any other influence could rescue him. Yet no monument at the nation's capital bears testimony of the people's gratitude to this great physician and signer of the Declaration, and surgeon of the Revolutionary Army. I can not help this digression when I reflect upon this nation's long neglected debt of gratitude. I repeat the plea I made last year: Benjamin Rush's name is immortal, whether his memory is preserved in monumental bronze or not, but the Government owes his memory, his country and the world, this debt; and every consideration of delicacy, and of decency and of justice to its meritorious dead, and of patriotism, demands its honorable discharge. I have elsewhere discussed this subject *in extenso*. *Vide*, "Treatment of Inebriety," etc., in Bibliography.

This is the fruit of our friendship for the unfortunate lunatic, and in American courts the product of ripened seed planted in the field of forensic psychiatry by that eminent and immortal American medicolegal jurist, Dr. Isaac Ray, of Philadelphia, whose great work, the "Jurisprudence of Insanity," was the beginning of a memorable era in medico-legal progress, and gave American psychiatry a distinguished standing before the courts of the country and of the world. In this classical American work, the disease of brain and change of character criterion received their clearest elucidation after Andrew Combe, and since the decease of this great American alienist, that other and congenital form of mental disease, paranoia, has received clear elucidation and distinc-

tive differentiation through the contributions of Kiernan, Spitzka, McLain Hamilton, Mann, and other American writers following the treatises of Erb and others abroad.

The hospitals for the insane which made the names of Pinol, the Tukes, the Chiarugis and later alienists immortal, among them our own Kirkbride and Tyler, have been followed by homes and schools and hospitals for the feeble-minded, in connection with which Edouard Seguin, of America, has an undying place in the philanthropic heart of the world, along with that of Froebel and Howe, in Germany, from whom Seguin got the inspirational inceptive idea and patience of training and improving the mental evolution of these unfortunate defectives, and American surgery, thanks to Dr. Wm. Fuller, of Grand Rapids, Mich., who first suggested (in the face of the old world's sneers) a possible operative remedy for the relief of certain of these defectives, the feasibility and value of which has lately been acknowledged abroad and demonstrated at home. Linear craniotomy has proven its right to a trial. It will not relieve microcephalic or porencephalic idiocy, but in other forms of arrested brain development through premature contraction of the cranial vault, this procedure has made it possible for the brain to develop, the speechless to speak and the convulsive to cease their spasm, just as other forms of craniotomy have done for pressure, aphasia and epilepsy.¹⁶ This devoutly-to-be-wished consummation will be hastened through general use for cerebro-pathic investigation and description of the marvelous piece of neurologic mechanism which I now show you as the ingenious handiwork of an American anatomist, not yet so widely known to fame as he deserves to be, Dr. J. P. Fuller, of Grand Rapids, Mich. In this unique contrivance the brain has been represented in thirty-seven transverse sections, hinged together in natural form and shape, with the superimposed superficial psychomotor centers. The downward paths of conduction to the cord, and the entire brain in its median and spherical and interior aspects are separately and relatively shown.¹⁷

The saving triumphs of brain surgery in other directions of prudent neurology are now simply marvelous, but more marvelous far than this wondrous work of salvage will be the saving of the brain and nervous system from the necessity of surgery, the

¹⁶ Dr. J. F. Blinney, of my own State, has this year reported in the *Annals of Surgery*, for April, one such successful operation, and Paschall reported in the *International Medical Magazine* another last year; both being followed by marked mental improvements. Each of these gentlemen likewise report other cases without satisfactory results. Frank, of Chicago, has paved the way, I think, to the ultimate success of cerebral ventricular puncture.

¹⁷ Dr. Fuller says in his preface to the great demonstrative work of his: When a medical student, the author of this work experienced great difficulty in understanding the anatomy of the brain from plates and descriptions in books, and recognizing the fact that, compared with the number of students, the opportunity of studying the anatomy from the natural brain is sure, he has carefully prepared a series of casts from actual dissections and casts, which he hopes will materially aid the teacher, and render the task of the student much easier.

The dissections presented in this specimen are made from photographs taken of sections of a carefully prepared brain, cut one-sixteenth of an inch apart and perpendicular to a line drawn from the external process to the occiput.

Familiarity with these plates and their situation in the brain will enable the necroscopist to recognize, at a glance, any section that he has made of the natural brain, and to select the proper plate from a book of similar plates which accompanies the preparation, upon which to describe any lesion found, and which he can attach to his report of a post-mortem examination, so that others also familiar with the position of the plates comprising this series will be able to locate the lesion described.

In this way a more ready understanding will be effected between neurologists, and it is hoped that, by this means, together with the careful observations of symptoms, the functions of many parts of the nervous system now obscure, may be more clearly understood.

This preparation is also invaluable to those interested in the surgery of the brain, showing as it does, the relation of the external markings, with deeper structure beneath.

mark at which general medicine and neurologic medicine are now aiming, and a goal much nearer reached now, than in the past.

Should men contest the claim of medicine to being the greatest of the world's benefactions, we reply: The germ theory of disease causation alone, with its applied antagonisms, hygiene, antiseptics, perfect cleanliness and resistive and tolerant inoculations, has done, is doing and is yet destined to do, more for the physical welfare and salvation of mankind, than all other causes of man's comfort, conceived in the mind and heart of man.

But for our applied teachings of hygiene, the world having its population in the last one hundred years nearly trebled, and civilized life having become so complex and degenerating in populous centers, the race would now be on the road to extinction.

The world is beginning to clean up, and mankind to recognize the necessity of cleanliness. We are promoting this antiseptics on our part in giving to man the purified air of heaven and the waters of the earth freed from pollution; the air and water and the spirit in man to conceive and apply measures for their purification, together with the uncontaminated and uncontaminable sunlight, are the direct gifts of God. We have taught mankind the value of cleanliness, the life-saving and prolonging value of physical and moral purity, and putting our precepts in practice, when permitted, we put back pestilence and turn death and decadence from individuals and peoples. We are not gods of the air, but we walk the earth as watchful pitying gods in the service of man, saving him from pestilences that walk in darkness, and of which he knows nothing save in their destructiveness, until medicine enlightens him and overthrows the destroyer of his health and strength and attendant happiness. But for the interposing monitions of medicine, man would not to-day be awakened to the danger of making a beverage of the attenuated liquid pollutions of the soil and falling ill all unconsciously with typhoid and other maladies, as in the days of the not far distant past; reverently submitting to the mysterious ways of the all-wise Providence, as did his remoter ancestors, attributing all affliction to the wrath of offended deities. So little a thing as the timely boiling and filtration of all drinking water will confer a boon on mankind, in warding off disease, which can not be computed. The application of the discovery of Jenner is as nothing in comparison—not even the great disease-averting and life-saving discoveries of Pasteur could be so potent.

As "the sun smiles on the earth, and the exuberant earth returns that smile in flowers," so do the silent ministrations of our noble profession fall upon a recipient world, which blossoms in healthful response. Our ministrations of medical charity, like those of mercy, drop

"Like the gentle rain
Upon the place beneath
Blessing him that gives
And him that takes."

Noble followers of a glorious vocation, grand and beautiful profession! Sublimest and best of the callings of men, save that alone of the Great Physician of Galilee, whose example encourages us and whose voice approves.

Besides the ten thousand hygienic resources for warding off disease and promoting the world's comfort, which it unconsciously and without thanks to our beneficent profession daily employs, medicine

now mitigates and annuls pain through analgesics and anesthetics (local and general) and contributes to human comfort under the most painful circumstances to a degree far beyond that of any other physical benefaction to mankind, Medicine has minimized and trained the lightning so that it ministers to the relief of human misery and the cure of disease. She has made of it a search-light for the human body, an assuager of pain, a producer of sleep and a destroyer of destruction.

The boon of hypnosis and narcosis under the many methods for its induction known to our art, saving the insomniac from the precipice of mental over-throw or neural failure in the lower centers of the cerebro-spinal axis or peripheral nervous system; the power of antiseptics, and through it the wonderful procedures and possibilities of modern surgery, and this *fin de siècle* hygiene; the many and marvelous therapeutic and hygienic advances in promoting the phagocytosis of the toxic bacteria; the destruction of the ptomaines, and in other directions of relief and cure; the discoveries of pathology, histology, medical chemistry, biology, neurology, psychology, psychiatry; and the contributions of surgery, gynecology, ophthalmology, otology, laryngology, proctology and the other specialties of study and work, have made the latter decades of the present century the most memorable in resourceful discovery in the history of medicine or in the history of mankind.

Intravenous injections of immune animal blood serum, promise much for the cure of phthisis and other chronic contagious diseases, and there appears good therapeutic promise for the coming years in mycdermic medication.

These grand achievements give us hope and promise of even grander contributions to the weal of mankind before the close of this final decennium of nineteen hundred.

Medicine has made the Pontine Marshes of ancient Rome, the jungles of darkest Africa, comparatively safe to the traveler, and the valleys of the Nile and Mississippi are no longer menaces to health. Quinin, eucalyptus, picrate of ammonia and tasteless Fowler's solution, have augmented human happiness and spread the commerce of civilized nations beyond computation. The world applauds its Livingstons and Stanleys, yet omits its meed of praise to those who have made their discoveries and the fruition of them a possibility.

Thus we see medicine ever advances towards its final goal, the health and consequent happiness of mankind. Thus we see, though with contracted view only, from this cursory survey, how much the past few years have done in the direction of medical advance. Thus we see that this great profession, the uplifter, the friend and benefactor of mankind, though the jest betimes of the world's great wits, continues its too-little appreciated benefactions. Its votaries, forsaking or ignoring common routes to glory for paths of duty, have gone on ameliorating human misery and conserving and saving limb and health and life, and through health, the welfare of the State; deserving, but not receiving, the conqueror's word of praise, marking the march of medicine with blessings on mankind, and entitled to the world's gratitude far beyond what the world has ever recognized. In the fierce contentions of mind with mind and strain of modern business and professional

life, and in man's contests with nature and battle with the elements, medicine preserves and fortifies man's organism for the fierce fray, that he may fight on and conquer success, prosperity and happiness for himself, for his family and for the commonwealth.

When will a gratefully appreciative nation erect suitable monuments to our workers, our warriors, our martyrs in the glorious cause of human happiness and human progress? for without health man is nothing. In the struggle for the survival of the fittest he falls in the fight for existence, and becomes the victim rather than the vanquisher of his environment, and nations do likewise.

The world owes medicine much. When will it ever repay even half the debt? It will be when "isms" and "pathies" in practice are dead; when the now vanishing days of sectarian theories shall have passed away forever; when a unified profession practicing in the faith and teachings of true science shall have its legitimate combined influence over all the people. It will be when students are taught a sufficient length of time (five years or more) in our medical colleges, to enable them to master the principles of medical science and the precepts of medical practice, and to practically appreciate the ethics of their profession. It will pay back the debt in tributes of honor and glory and adulation, and in monuments of marble and bronze, when human progress shall have reached that high stage of evolution when there will be more renown for him who saves life in the name of charity than for him who takes it in the name of national glory; more glory for him who builds up, than for him who tears down the fabric of human happiness. In that on-coming day of human enlightenment the true physician will be esteemed above the warrior. Nations will give him merited places of honor in ministry, in cabinet and council, and on tented and battalioned fields. Then it must needs come that the physician will assert and secure his peerage among the people. History will then give medicine an illumed and illustrious niche in her temples of enduring fame, and the glorious deeds of her worthy sons will be justly immortalized in poet's song. America will then render long-neglected memorial justice to her great medical benefactors. Bronze and marble forms of her great dead doctors, who have dared and done more than warrior or statesman for the public weal, will adorn her public parks and grace her public halls. The enlightened citizen standing beneath the dome of the nation's capitol, as he looks upon the immortal names there inscribed, will see those of America's great physicians written alongside of her other philanthropists, her jurists and her presidents. American philanthropists will read their names there inscribed "in letters of gold and in pictures of silver," and revere their memories as the patriot now reveres the memories of Washington, of Jefferson, of Franklin and of Patrick Henry. The names and remembrance of Benjamin Rush, of Ephraim McDowell, of Marion-Sims, of Beaumont, of Crawford and Jackson, of Bowditch, Agnew, Gross, Wells, Long, Paul Eve, Gaston, Marcy, Weir, Mitchell, Valentine Mott, and their good work for the weal of the world will be as immortal as those of our Clays, our Websters and our Bentons. Every patriot will revere them, because they have contributed to conserve the health of the public, realizing that in the good health of a people is their happiness, their physical, political, mental and moral power, and to be without

this power is to be as pigmies among the nations, puny in prowess and pitiable in all that makes man or nation great and good.

VACCINATION.

Read before the New York State Medical Association, Fifth District Branch.

BY HENRY H. MORTON, M.D.

Dermatologist to Kings County Hospital and Long Island College Hospital Dispensary; Assistant to Chair of Genito-Urinary Diseases, Long Island College Hospital; Attending Physician to Consumptives' Home; Expert on Contagious Diseases, Brooklyn Board of Health.

It would almost seem to be a work of supererogation at the present day, with the accumulated experience of the past hundred years, to speak of the protection which vaccination has afforded the human race against smallpox.

There are a few people in the community, however, who object to availing themselves of its advantages; the ignorant and uneducated who are willing to suffer the dangers to themselves of sickness and death from smallpox and the certainty of spreading the disease to an indefinite number of others, in order to avoid the slight inconvenience, for a few days, occasioned by the possibility of a sore arm; and the limited number of persons, with some degree of education who, for the sake of a little cheap notoriety, or because of an inborn mental twist, a sort of internal strabismus, which keeps them from looking fairly and straight upon any subject which is presented before them, oppose vaccination upon the premises of falsified statistics, misquotations and untrue statements, backed up and rounded out by a choice flow of denunciation and general abuse.

We can form but a faint idea of the destructiveness of smallpox before the year 1800 when vaccination began to be employed, by referring to history.

Macaulay says: "Smallpox was always present, filling the church yards with corpses, leaving on those whose lives it spared the hideous traces of its power, for two-thirds of the pauper blind in England were made so by this cause."

Another historian states that it was the exception to see a face in England that was not pitted and scarred by smallpox.

In Iceland it is said to have destroyed 18,000 persons out of a population of about 50,000 during the eighteenth epidemic which occurred in 1797.

In Greenland, in 1734, when the first epidemic occurred, two-thirds of the inhabitants died.

In Germany, before the time of vaccination, 66 deaths in every 1,000 were the result of smallpox.

It was no respecter of position in life, or high station, and a long list of royal personages is to be found who died from it.

The same condition of affairs is to be found to-day in some semi-civilized countries where vaccination is not practiced. A missionary, writing from Turkey in Asia, states that one scarcely finds two persons out of a hundred who remain free from smallpox.

It has been claimed by its opponents that the diminution in the number of cases of smallpox since the introduction of vaccination has been due to the improvement in sanitary conditions.

Our experience shows that persons in the better walks of life are just as liable to be attacked when exposed to the disease, unless protected by vaccination, as the poor who live in filthy and crowded tenement houses. It is true that smallpox spreads more rapidly among tenement houses than among private dwellings, because of the neglect of precautions of vaccination, the close contact and communication of the inhabitants, the want of ventilation of the rooms allowing the poison to become concentrated, and the fact that medical attendance is often not sought for until days after the disease has made its appearance.

An objection to using human virus, and one which is well founded, is that syphilis may be conveyed through it. The contents of the vaccine vesicle do not contain the syphilitic poison and are harmless, but as the poison is in the blood of a syphilitic individual it is very difficult to avoid conveying some blood corpuscles when vaccinating from a crust and so producing syphilis. This danger does not exist with animal virus.

It has been claimed that vaccination may be the medium of infecting persons with tuberculosis, but although not definitely proven it is highly probable that tubercle bacilli do not exist in the vaccine lymph. In order to take all precautions to avoid the possibility of danger from this source, the managers of the vaccine farms have calves carefully inspected by competent veterinarians, to make certain that they are free from tuberculosis before inoculating them with vaccinia. The calves are subsequently killed and then examined, and if any evidences of tuberculosis are found the lymph is destroyed.

To avoid the danger of inoculation with septic germs, attention to cleanliness should be observed in the operation. The ivory point upon which the dried vaccine lymph is sent out, or a clean cambric needle which can be thrown away after each vaccination is better than a scalpel or scarifier which has to be cleaned. No dressing should be applied while the vesicle is present, as it tends to soften it and bring about a premature discharge of the contents.

The English vaccination law requires every child to be vaccinated before reaching the age of three months, and experience shows that infants under this age have less trouble from fever or sore arms than older ones.

Let us glance for a moment at some of the results of the protective power of vaccination.

In 1799 and 1801 about seventy-five hundred persons were vaccinated at the smallpox hospital in London and in order to test the value of Dr. Jenner's discovery about half of these were subsequently inoculated with smallpox matter, and in none of them did smallpox produce any effect. Such an experiment would not be justified to-day, but at that time inoculation with smallpox matter was in vogue as an everyday practice, as it was found that the cases of smallpox so induced were milder than those acquired in the ordinary way by contact.

In referring to tabulated statistics, we find that in Copenhagen the fatality from smallpox is but one-eleventh part of what it was before vaccination was introduced; in Sweden about one-thirteenth; in Berlin and parts of Austria one-twentieth; in Westphalia one twenty-fifth.

The German army, where vaccination and re-vaccination are compulsory, and which numbered a million men during the war with France in 1870, lost

only 286 men with smallpox, while the French army lost several thousand by that disease.

In Dr. Welch's statistical report of 5,000 cases of smallpox treated in Philadelphia, the death rate among the unvaccinated was 58 per cent. and among the vaccinated only 16 per cent. In 1884 to 1892, out of 1,201 persons employed on the hospital ships for smallpox, of Great Britain, only six or $\frac{1}{2}$ per cent. contracted smallpox and all of those attacked recovered.

But dry statistics do not appeal to one as strongly as personal experience. Time and again, during the recent epidemic, I have seen the unvaccinated members of a family taken sick and those recently vaccinated escape. I recall the case of an Italian family, living in Hudson Avenue, which I lately saw, consisting of father, mother and four children, who had a relative with a child 3 years old staying with them. This child was attacked with smallpox, was not attended by any physician and recovered after a three-weeks' illness. The other members of the family had been vaccinated recently and all escaped, although exposed during the entire time. A colored woman living on the opposite side of the hall who had not been vaccinated since childhood contracted the disease.

In another instance a person living in Fiftieth Street was attacked with the smallpox in January, was removed to the hospital and the premises were fumigated. Vaccinations were made in that and the adjoining houses at the same time; a few days later a child was born in the next house, who after fourteen days was attacked with smallpox and died. The party wall between the houses was shown to be pervious by the sulphur fumes produced by fumigation coming through into the next house where the child was subsequently born. The poison had no doubt passed through in the same way, being kept active in the walls by the warmth derived from the stoves. All the other persons in the house had been vaccinated and no one else took the disease.

Again I have frequently seen instances of persons who had been exposed to the smallpox and were promptly vaccinated, with the effect of entirely preventing smallpox from developing, or modifying it so much that it was but a mild affection.

It is a question of the utmost importance as to how long the protective power of a vaccination lasts. Many of the laity consider that they are protected through a lifetime by one vaccination in infancy. This is a fatal mistake and most of the cases of smallpox which I have seen in adults had one or more vaccination scars on their arms.

Vaccination is an absolute protection against smallpox for a certain length of time, but as years go by the protective power disappears, and if the individual acquires smallpox it may be the unmodified form resulting in death, or if less time has elapsed since the last vaccination, the case may be one of varioloid.

The term of immunity will vary with the individual, some cases being protected until puberty by a vaccination done in infancy and others having a vaccination take every few years. It may be laid down as a safe rule that a person should be vaccinated whenever exposed to smallpox or at least once in five years, as a precaution, and that the vaccination must take in order to be a protection.

An illustrative case occurred in my experience a

few weeks ago. A man of 35 years of age, in comfortable circumstances had been vaccinated several times, the last four years ago but unsuccessfully. He was exposed to smallpox and developed the disease, having it in a very mild form, about a dozen pustules in all on the body. The protective effect of his former vaccinations had not entirely disappeared at the time he was vaccinated last, but was sufficient to prevent the vaccination from taking. Four years later, however, the effect had still further diminished thus allowing him to acquire smallpox, although in a very mild form.

Dr. Welch's statistics show that of the children who were admitted to the smallpox hospital in Philadelphia under one year of age, seventy-eight were unvaccinated and fifty-seven died; two had been vaccinated and had exceedingly mild cases.

From the ages of 1 to 7 years:
 404 were unvaccinated and 208 died . . . 51 per cent.
 35 were vaccinated in infancy and 2 died, 5 per cent.

From the ages of 7 to 14:
 222 were unvaccinated, 71 died 31 per cent.
 137 were vaccinated in infancy, 13 died . . . 9 per cent.

From 14 years and upward:
 1,038 were unvaccinated, 681 died 65 per cent.
 2,967 were vaccinated in infancy, 495 died, 16 per cent.

The deductions to be drawn from these tables are that the liability to acquire smallpox and to die from it increases as years elapse after the vaccination.

In the recent epidemic of smallpox which occurred in Leicester, England, there were 281 cases. Of these, 126 were unvaccinated and 13 died; while 155 had been vaccinated in infancy but not re-vaccinated—of these none died. The chairman of the Sanitary Committee makes the striking statement that no case of a vaccinated child under 10 years of age had been treated for smallpox.

The committee appointed by the Epidemiological Society to examine the statistics in regard to nurses in attendance on cases of smallpox, reported that out of 1,500 such attendances, 43 contracted smallpox and not one of these 43 had been re-vaccinated.

Dr. Collie says during the epidemic of 1871, 110 persons were engaged in the Homerton Fever Hospital, in attendance on the smallpox sick—all these with two exceptions were re-vaccinated and all but these two escaped smallpox.

The experience of 1876-77 was of the same kind, all re-vaccinated attendants having escaped, while the only one who had not been re-vaccinated took the disease and died of it.

So in the epidemic of 1881, of 90 nurses and other attendants of the Atlas Hospital ship for smallpox, the only person attacked was a housemaid who had not been re-vaccinated.

Dr. Edwards states that of 734 nurses in the Metropolitan Board Hospitals, 79 had had smallpox previous to their entrance and they escaped. Six hundred and forty-five were re-vaccinated on entrance and not one took smallpox; ten escaped re-vaccination and the whole ten took smallpox.

Dr. Welch states that in a service of twenty-three years in the Philadelphia smallpox hospital, not one person employed in the hospital who was properly re-vaccinated before entering on duty has taken smallpox.

A careful study of the literature of vaccination, combined with a personal experience of its protective power, demonstrates conclusively the correctness of

Dr. Jenner's statement, namely, that if every person were vaccinated and re-vaccinated as their acquired immunity disappeared, smallpox would be stamped from the face of the earth.

In case of an epidemic existing or threatened, any one is liable to contract the disease and infect an indefinite number of others with smallpox, so that due regard to the rights of the community as a body, would necessitate the vaccination or re-vaccination of every person who may become a menace to the public health and safety, irrespective of his wishes in the matter.

PREVENTION OF PERTUSSIS.

Read before the Ohio State Medical Society at Zanesville, May, 1894.

BY GEO. M. CLOUSE, M.D.

PROFESSOR OF DISEASES OF CHILDREN IN OHIO MEDICAL UNIVERSITY OF COLUMBUS, OHIO.

As far back as I have been able to compare diseases, I have wondered why whooping cough was allowed to be considered by the laity as it is now, when the profession knows so much about it. There are many parents who, for want of the proper advice, have said that they want their children to have this or that disease, believing "it will not go so hard with them if they have it while young." They are not taught that adulthood is a fair immunity from childish, infectious diseases, and that it is no more necessary for children to have chickenpox, mumps, measles, whooping cough, etc., than it is for them to have smallpox, diphtheria, pneumonia or any other disease.

Again, they are not impressed with the fact that whooping cough is one of the most contagious diseases, and one among the most fatal diseases to which children are heir. Too often do we meet pertussis on the streets, in the car, in the boat, in the pew, in the schools, and its victims in the hearse.

In the *Rules and Regulations of the Ohio State Board of Health* adopted June 30, 1893, we find Rule 1 says: "No person suffering with diphtheria, scarlet fever, smallpox, measles, whooping cough, or other dangerous communicable disease, shall be admitted into any public, parochial, or private school or college or Sunday-school, or shall enter any assemblage or railway car, street car, vessel or steamer or other public conveyance." Is this rule obeyed or enforced or even attempted to be, in cases of whooping cough or measles? No; at least in many cases it is not.

Rule 4, says: "It shall be the duty of every physician called to attend a person sick or suspected to be sick with cholera, yellow fever, smallpox, diphtheria, scarlet fever, measles, whooping cough, typhoid fever, typhus fever, within twelve hours thereafter, to report the name and residence of such person, to the Board of Health . . ." Are these requirements met in cases of measles, whooping cough, typhoid and typhus fevers, which four diseases aggregated 1,725 deaths in Ohio in the year of 1892, 15 more than the first five (cholera, yellow fever, smallpox, diphtheria and scarlet fever)? No; not assuming that whooping cough, measles, etc., are as destruc-

tive as cholera, yellow fever and smallpox, but that while we are intently gazing through the field-glass of quarantine at yonder cannonade of yellow fever and smallpox, the musketry of whooping cough and measles pour in with epidemic volleys in close range, year after year, until the death rate is greater than we suspect.

Rule 5, says: "It shall be the duty of the Board of Health . . . when a case of smallpox, yellow fever, typhus fever, diphtheria, scarlet fever, or measles is reported within its jurisdiction, to at once place . . . in a conspicuous position on the house wherein any of the aforesaid diseases occur, a quarantine card or flag . . . and to prohibit entrance to, or exit from such house . . ." Here, whooping cough, the most highly contagious disease known, except scarlet fever, is not mentioned for placarding. Neither is measles or typhus fever placarded, which the rule requires.

Rule 10, says: "No public or church funeral shall be held in connection with the burial of a person who has died of cholera, smallpox, yellow fever, typhus fever, diphtheria, scarlet fever, measles, or whooping cough, and the body of such person shall not be taken into any church, chapel or other public place." Yet how inexcusably is this good rule disobeyed in the deaths from whooping cough and measles.

The State Board of Health with its local boards has saved untold hundreds of lives; and we advocate the belief that it can save at least a few more lives by acting upon the disease of pertussis more earnestly.

Whooping cough is a malady almost entirely limited to infancy and childhood, and but few escape it because of its great activity of contagium; of the carelessness on the part of the profession; and of the ignorance on the part of the laity. The following information has been gleaned from the *Vital and Nosological Statistics* of Ohio from the year 1889 to 1892 inclusive:

"During these four years, pertussis has caused a little less than 1 per cent. of all deaths; and has caused 26 per cent. of all deaths under 10 years old. And during these four years it has caused 1,197 deaths, while scarlet fever has caused *only* 397 more deaths at the same time. Owing to the unreliable sources of collecting vital statistics by the assessors, the Secretary of our State Board of Health says that at least 40 to 50 per cent. of the deaths of Ohio are not returned. This is perhaps more true in regard to whooping cough than scarlet fever, because of the universal belief in the insignificance of the former. Dolan says whooping cough ranks third in fatal diseases of infancy in England; and causes one-fourth of the annual deaths of children in London. In Ohio the death rate is still higher from the same cause.

Griffith says 120,000 died from this disease in England and Wales in nine years; and 85,000 in Russia in five years—an average of 17,000 deaths per year. Winters says it is thought that whooping cough with its complications and sequelæ is more fatal than either diphtheria or scarlet fever. Starr says that next to scarlatina, whooping cough has the highest mortality of all diseases among children.

Whooping cough *per se* is not dangerous but the high mortality is due, as Dr. Winters has said, to the complications and sequelæ which are said by Goodhart to occur probably in one-third or one-fourth of

all cases. There are three general reasons why these complications or sequelæ come on: 1, the younger the infant or child, the more prone, except under three months; and greater are the deaths; 2, children insufficiently clothed and nourished; and children whose vitality is reduced by constitutional disease, or by anti-hygiene; 3, a susceptibility to be seized at the same time with measles, each rendering the other more hazardous.

These complications and sequelæ are: Broncho-pneumonia, bronchitis, lobar pneumonia, atelectasis, pleuritis, emphysema, pneumothorax, tuberculosis, nephritis, heartstrain, pericarditis, dropsy, edemia of glottis, membranous croup, aphasia, paralysis, hemiplegia, epilepsy, eclampsia, meningitis, cerebral hemorrhage, hemioptysis, epistaxis, aneurism, sub-conjunctival hemorrhage, conjunctival ecchymosis, emesis, anorexia, enteritis, hernia, rectal prolapsus, blindness, deaf-mutism, lingual ulceration, goitre, eruptive fevers, sclerosis and marasmus; only about forty in all. Fortunately, many of these complications and sequelæ are uncommon or perhaps rare, and some too often accidental; but unfortunately, the most serious are the most common, *i.e.*, broncho-pneumonia. It would be no extravagance to presume that the mortality from pertussis would be still higher if the death reports were more completely and properly reported and classified. It is a peculiar fact that when a secondary affection attacks, the primary disease abates or is lost sight of entirely for a greater or less time. Therefore, a child in several years hence may die from phthisis, heartstrain, etc., whose origin was whooping cough, which was not so reported and recorded, and the real cause of death is, consequently, unknown. Allow me to say here that we, as physicians, do ask for more complete vital statistics in Ohio.

The prevention of pertussis is the avoidance of the cause; and the cause is an active contagium epidemically inclined. If this be true then it is a preventable disease; and if it is a preventable disease, connected with the knowledge of the high mortality and low record, we should censure ourselves for such a condition laid at the door of the medical profession. It seems to me horrifying to let a single life go out that might have been saved by our present knowledge of medical science and art. Any movement that would reduce the mortality to any per centum would be commendable in proportion to the reduction produced.

Whooping cough and measles seem to be considered of no great importance, even by the boards of health, from the fact that no precautions are enforced. Diphtheria, the most dreaded of all diseases of children, caused 383 deaths *less* than did measles and whooping cough; and these two diseases caused 69 per cent. of as many deaths as diphtheria and scarlet fever together. It is the consensus of a few authors and secretaries of State boards of health, with whom I have been communicating on this subject, that quarantining against whooping cough would be beneficial, but from the suffering it would produce they would not like to see a system of house quarantine. Considering the longevity of the attack and the sordid or poor classes which are most likely to suffer from its ravages, quarantining would now be not impossible but impracticable. But we must not compare health and life with trouble or expense, for there is no comparison. What are we to do? 1,

remove to an infectious disease hospital; 2, isolate; 3, teach.

1. A hospital for infectious diseases only, and maintained by the corporation would be the ideal method of prevention of pertussis, but alas! 'tis only a dream; 2, isolation would be more tangible, but would be unsatisfactorily enforced for several reasons. Serious objections were proposed against quarantining smallpox at first, but no one questions that wisdom now. To card the house for whooping cough (and measles) the same as we do for diphtheria and scarlet fever, would be doing little enough towards quarantining. It is uniquely strange that children who have whooping cough or measles, the two most highly contagious diseases, (with very few exceptions), which kill nearly three-fourths as many as the two most dreaded maladies common to children, are permitted to go at liberty on the streets and elsewhere. It is a shame for intelligent Ohio!

About the only objection to house-carding for whooping cough, are the difficulties of making an early differential diagnosis; also, the irregularity of the course of the disease; also, the contagiousness of pertussis patients which is as long as the patient coughs, but not the same degree as in the paroxysmal stage. Because we can not prevent all the children from this contagium is no reason why we should not attempt to prevent as many as we can. We will then be doing more than we are now doing, and in time will receive our merited reward.

3. Teaching the laity the destruction secondarily caused from whooping cough is our duty much neglected. We should be the people's protectors and be active against everything that would jeopardize their health or life. To have them call our attention to any point of danger or benefit of health, is a served notice of our slothfulness. And this notice has been served on me not a few times during the epidemic of whooping cough just now abated. The laity can be taught to obey restrictions on one disease as well as another; and whooping cough will be no more difficult to restrict than tuberculosis which we hope will soon be under some kind of restrictions. There are people who send their children to school in any condition, for almost the sole purpose of getting rid of them for that time, caring nothing for the danger of their carrying the infection to others. Such parents or guardians should be fined or in some other way punished by the health officer. Again, there are children who for fear of being kept away from school will use deceit in the early part of the disease, thereby exposing others. It would then be necessary for each school teacher to be qualified to act on the prodromic and early diagnostic symptoms of contagious diseases, and prohibit entrance to the school yard until the receipt of a physician's certificate or a personal visit by the teacher at the home.

GASTRO-HYSTERORRHAPHY WITHOUT OPENING THE ABDOMINAL CAVITY.

BY FRITZ BAUM, M.D.
KANSAS CITY, KAN.

Our negative results in treatment of prolapsus uteri and retro-misplacements by pessaries and supporters have proven conclusively that we can never gain our point in supporting the prolapsed uterus from below, and that we must find some means to uplift same from above, and in this way substitute the office of the re-

laxed round and broad ligaments. For this purpose we have constructed the following instrument, consisting of a hollow tube like a big uterine sound; within this there is a piston-like rod with a handle at the outside and two needles threaded to one thread at the end inside. Now our idea is the following one: Place the patient in Trendelenburg's position, insert this instrument called uterine ventro-fixator into the uterus and after correcting misplacement of same, bring the fundus as high up as possible in direct contact with abdominal wall; then push the rod up until the needles protrude through the skin, unthread needles and draw the piston back, thus removing the needles and withdraw the instrument.

Pull the thread up as high and tight as feasible, then tie a strong knot after having made a little incision through the skin of the abdominal wall to embed the stitch, in this way fixing the uterus to the abdominal wall. The place is then dusted with iodoform and sealed with collodium.

As far as we can see, the first question, which would arise would be the following one: Is there danger of sepsis? We say not, if properly managed.

The vagina should be first well cleansed and packed with antiseptic gauze until rendered aseptic. Then on the day of the operation the uterus should be curetted and washed out with a strong antiseptic solution and then after perfect boiling of the instru-

ment, needles and thread, we think this danger would be eliminated.

The next question would be, shall we get adhesions by holding the uterus in contact with the abdominal wall in this way? We think we should, because by pulling the uterus up against the abdominal wall, these stitch holes must naturally give a little, perhaps they will even tear some; this will set up some local inflammatory action which will result in adhesions, which "report of cases" will prove, if the uterus is brought in firm contact with the abdominal wall. We may either leave this stitch in there permanently or may remove it after two to three weeks.

The only contra-indication for this operation, as far as we can see, would be adhesions of the intestines to the fundus uteri or portions of the abdominal wall, or firm adhesions of ovaries and tubes to the back, or presence of pus about the uterus and appendages. The interference with a large bladder can be easily avoided by keeping a sound in it during the operation.

Whoever has operated or seen the operation, will be convinced that the danger of wounding the intestines is almost eliminated because the uterus can be so plainly felt through the abdominal wall and manipulated in such a manner that all intervening tissues can positively be excluded.

Case 1.—Miss M. D., age 19. Retroversion with strong adhesions, after severe fall four years ago; since that time frequent painful urination, backache and difficult menstruation. I made the first operation at Bethany Hospital, Kansas City, Kan., April 21, under assistance of Drs. J. D. Griffith and S. I. Harrison, and R. A. Roberts, of Kansas City. Uninterrupted recovery; highest temperature recorded was 99.4. Patient had no pain nor inconvenience whatever and was discharged after three weeks' stay, (two weeks in bed) in the Hospital, with her uterus firmly adherent to abdominal wall hardly within the reach of the finger in vagina.

Case 2.—Mrs. F. O., age 37. Three children, youngest 5 years old; after last confinement, prolapsus uteri with pertaining complaints; operated April 22; highest temperature 99.7; very little pain; remained in bed thirteen days; discharged after three weeks; uterus in proper place. Uterine supporter was fitted to be worn about one or two months.

Case 3.—Mrs. R. T., age 26. After tedious labor case and forceps delivery, patient complained of backache, headache, and frequent painful urination. Examination showed retroflexio uteri. Operation April 24; temperature remained normal; slight pains over region of stitch. Contrary to my custom I did not embed the stitch in abdominal tissue but severed it the seventh day, in order to test adhesions which proved strong enough to make the uterus adhere to the abdominal wall. Uterine supporter was fitted and patient was discharged seventeen days after operation completely cured.

Case 4.—Mrs. A. K., age 43. Prolapsus uteri of nine years' standing. Operated April 25; clipped stitch May 2; found uterus strongly adherent and fitted uterine supporter. Discharged May 19 completely relieved.

Case 5.—Miss F. L., age 18 years. Kicked by horse in the abdomen about one year ago; since that time dysmenorrhea, headache, backache, fatigue feeling, etc. Diagnosis, retroflexio uteri. Operated April 26. No elevation of temperature; had a circumscribed peritonitis around the stitch as large two silver dollars. Made uninterrupted recovery and was discharged two weeks after the operation.

Case 6.—Mrs. A. B., age 25. Gave birth to twins, forceps delivery, two years ago. Diagnosis, retroflexio uteri. Was unable to do her own housework because of backache, headache, and constant desire to urinate. Operated April 29; highest temperature 99; very little pain. Did not embed stitch but cut it twelve days after operation; uterus remained in place. Uterine supporter fitted and patient was discharged twenty days after operation completely relieved.

Case 7.—Mrs. L. M., age 36. After fall from a wagon two years ago had adhesive retroversio uteri; difficult menstruation with constant backache and headache. Operated May

1; no rise of temperature; was discharged relieved, within two weeks after operation.

Case 8.—Mrs. J. K., age 26. Had three children. According to her own report had miscarriage two years ago; after that puerperal fever. Examination shows retroverted uterus almost immovable. Operation May 4; greatest difficulty in destroying adhesions. Rise of temperature second day to 102.2; third 101; the following day 100.3, but found in changing the vaginal tampon that uterus had dropped back as I expected.

There were three more cases operated upon which gave complete satisfaction though they are still under treatment, therefore reports later.

THE SURGICAL TREATMENT OF GRANULAR CONJUNCTIVITIS.

BY J. A. BACH, M.D.

PROFESSOR OF DISEASES OF THE EYE AND EAR, WISCONSIN COLLEGE OF PHYSICIANS AND SURGEONS, MILWAUKEE, WIS.

The important feature in all forms of treatment of granulations of the eye-lids, whether surgical or otherwise, is to remove pathologic elements and prevent further invasion of the same with their destructive consequences, with the least possible harm to the conjunctiva and lids. Without proper treatment we know that granulations will in many cases ruin eyes, and in others cause serious lesions, either by inducing ulcerative processes or, in the more favorable cases, by producing cicatricial contractions and deformities of the lids. In fact, a large percentage of cases as they come for treatment, have already suffered in some way or other in the mobility or form of the eye-lids. These complications by the additional irritation they induce, further aggravate the unpleasant symptoms and not infrequently produce spasmodic contractions of the muscles of the lids, forming a serious obstacle to the successful treatment of the case. Therefore, often one of the first considerations in the surgical treatment is to remove such complications by the proper operation. A canthotomy in cases where this is indicated, through the powerful contractions of the orbicularis muscles, will give us the most valuable aid as a preliminary step to further treatment.

Other abnormal conditions as to mobility or shape of the eye-lids can frequently be corrected with great advantage before proceeding far in the treatment proper of the case before us.

The surgical treatment to be of any advantage in the cure of granulated eye-lids must be of a conservative nature and must seek, as far as possible, to protect rather than destroy invaded elements of the conjunctiva and deeper tissues. We must therefore place as foremost of all surgical measures, the expression rather than excision of the pathologic elements in all cases where this can be done. By this means we may not succeed completely in removing all the granulations, but we will succeed in suitable cases if the operation is thoroughly done, as it ought to be, to remove most of them and at the same time so stimulate absorption and physiologic tissue changes as to lead to a rapid cure of the condition, whether supplemented by further local applications or not. It is not to be forgotten that the ordinary remedies are applied, not with the idea of directly destroying the granulations but for the purpose of inducing that state of local hyperemia which most favors absorption, so that if we can directly, by expression remove these deposits, we gain valuable

time besides producing the same results physiologically, that topical applications produce.

Expression of granulations can be used in all cases, but is more especially adapted to the first stages of the disease, before the deeper tissues are much involved. Where severe inflammatory symptoms usher in the disease, it is well to allay such inflammations before applying surgical measures of any kind.

A number of instruments have been devised for the purpose of expression, the most suitable of which are Knapp's roller forceps and Noyes' forceps. Another instrument that can be used with great advantage is the ordinary Desmearre's entropion lid forceps, and which in many cases I prefer to other means. However, it is not the particular instrument that one may use in this performance; it is the completeness with which the operation is done that goes to cure our case. Frequently, expression can be successfully done by the use of the finger nails. Friction, as applied by means of a brush or similar means sufficiently strong to tear the superficial capillaries and soft friable granular masses, but without destroying the normal tissue fibers has been extensively used in some quarters with great satisfaction. Grattage or scratching by means of a stiff brush or by a small metal rake, is a similar means but rather more severe, and ought to be used with care and discrimination. In the first stages of the disease it might do considerable harm by tearing and lacerating the conjunctiva and therefore it is applicable only where we have exuberant and fleshy granulations covering the whole lids; where the conjunctiva is so completely infiltrated and covered as not to be recognizable. Expression in such cases is frequently not sufficient, as we have here to deal largely with hyperplasia of tissue elements. The results obtained by friction or grattage as indicated, will by tearing the superficial capillaries, as well as the softer pathologic elements, cause local depletion and greatly improve circulation and absorption. It is surprising how quickly these thick fleshy lids can be reduced in a few days by this means, where it would take months by means of the ordinary topical stimulation. The good results of this procedure can be augmented by the additional use of antiseptics and astringents. In the more advanced stages of the disease, where deep deposits have taken place especially at and in the fold of transmission, the venous circulation often becomes very sluggish owing to mechanical obstruction. Absorption under such circumstances is deficient and practically at a standstill. Neither expression nor grattage is fully capable of removing this condition of affairs. Thorough massage has produced good results, although this is not always sufficient. Through the thickening and stretching produced, the conjunctiva becomes redundant and the careful excision of the fold of transmission has been practiced in such cases with decidedly satisfactory results.

A two-fold indication is met in this way:

In the first place we remove a large amount of infiltrated, and objectionable tissue, and in the second place we destroy the over dilated and inactive blood vessels and improve the local circulation and nutrition.

It has been held that by means of excision of the fold, disagreeable contractions are liable to occur. This, however, is not the case if the excision is done in the proper cases and properly executed. It is de-

sirable to excise as little as possible of the conjunctiva, and as this membrane is quite redundant in these cases no harm can come from this. The main object is to excise the subconjunctival tissue deep in the fold.

Galezowski is an ardent advocate of excision of the fold of transmission, and does this as a routine practice in all advanced cases. In his experience he has had no unpleasant results following the operation. Special instruments have been devised for the purpose of excision, among which may be mentioned Galezowski's forceps.

Cauterization by the actual cautery has been practiced to a limited extent and, in my opinion, can not be considered a rational measure. It certainly offers no advantages over excision or grattage, besides being much more liable to leave hard and irregular cicatrices. The principle of electrolysis which has been practiced by different men with good results, would seem more conservative and therefore more applicable. I have had no experience with this method, nor do I believe that it can be made to answer the purpose as well as other means at our command. The operation of scarification of flabby granulations is in my opinion objectionable, as by its use we will necessarily sever and greatly injure the conjunctival covering without offering any advantage which can not better be achieved by grattage. The use of massage, although not strictly a surgical measure is one of great advantage in conjunction with the various other procedures. In cases where the disease has run its course and has left behind large atrophic areas of the conjunctiva, or where this has occurred through severe caustic or surgical treatment, transplantation of conjunctiva of the rabbit to cover these defects, might suggest itself. By thoroughly removing the overlying tissues, it would seem simple enough to transplant healthy conjunctiva and give the globe a more acceptable protection.

INTRALIGAMENTOUS AND RETROPERITONEAL TUMORS OF THE UTERUS AND ITS ADNEXÆ.

Abstract of a paper read at the meeting of the American Gynecological Association, at Washington, D. C., May 29, 1894.

BY WILLIAM H. WATHEN, M.D.

LOUISVILLE, KY.

While paroöphoron cysts and retroperitoneal myomata of the uterus and its muscular processes have nothing in common in their etiology, I would include both kind of tumors, because the technique of the operation for their successful removal is practically identical. With few exceptions, cysts that unfold the layers of the broad ligament and burrow deep into the pelvis and retroperitoneal connective tissue, often developing nearly continuity in relation to other structures, probably arise from remnants of the mesonephros in the paroöphoron. Either the cystic or solid tumor may separate the peritoneum anteriorly and lie in front of it attached to the bladder, fascia and muscles of the abdominal wall, the separation sometimes being so extensive that it may be possible to reach the tumor and enucleate it through a median incision between the pubes and umbilicus without wounding the peritoneum. The separation, however, is usually from the posterior pelvic and abdominal walls; the tumor having passed beneath Douglas' sac unfolds the mesorectum, meso-

colon or mesentery of the small intestine; or, passing under the appendix, the cecum or the ascending colon, lies between them and the abdominal walls. The blood vessels that cause the most hemorrhage in enucleation are confined mainly to the capsule, and these vessels are sometimes huge sinuses, and especially is this true when the tumor has unfolded the mesentery of the rectum, the colon or the intestine.

No one should attempt the removal of intraligamentous or retroperitoneal tumors who is not familiar with the normal relations of every one of the pelvic and abdominal viscera and the relations that these tumors may sustain to surrounding tissues, otherwise he is at sea without a compass, and the immediate and subsequent results of his work will be bad. He should know that these tumors are mainly supplied with blood from the ovarian and uterine arteries, and that successful enucleation depends largely upon a correct ligation of these vessels.

The dangers of the operation which should be anticipated are:

1. Hemorrhage from separated adhesions, from the capsule of the tumor, from the denuded surface of a myoma, from injury to the spermatic and uterine arteries, the iliac arteries and veins, and inferior vena cava.

2. Wounding the ureters, the bladder and the intestines.

The causes of death are hemorrhage, shock and sepsis.

The results of the operation depend mainly upon controlling hemorrhage and successful enucleation. To prevent injury to a ureter that may be in front of the tumor it is best to incise the capsule and introduce ligatures *parallel* to the abdominal wound; in incising the capsule avoid large vessels. Hemorrhage will be greatly lessened by careful enucleation close to the cyst wall or the substance of the myoma, thus pushing the vessels in the capsule and in the connective tissue away from the tumor without wounding them. If the spermatic arteries have previously been ligated near the uterus and near the pelvic walls, the enucleation may sometimes be completed without wounding a vessel large enough to cause troublesome hemorrhage—in fact, it may be possible in some cases, by enucleating close to the tumor and the uterus, to perform total hysterectomy without ligating the uterine arteries, they being pushed aside and left in the pelvis uninjured. Great care must be observed in separating the tumor from the bladder and the intestines, otherwise these organs may be wounded or the coats so injured that sloughing may result, and when the enucleation has reached the pre-vertebral space careful dissections must be made, always hugging the tumor, avoiding the ureters or deep-seated vessels.

As gum tubing can not be used in many of these cases, hemorrhage may be controlled by forceps, separate ligation, ligation *en masse*, or a continuous suture; and hemorrhage from the substance of a soft cavernous myoma may be controlled by firm gauze pressure, or ligation *en masse*, the ligature being introduced deep under the bleeding vessels with a long curved needle. Forceps should be so shaped as to be readily applied to any part of the separated capsule, and the surface of the blades should be comparatively smooth and the edges so rounded as not to cause hemorrhage by cutting through the thin and fragile walls of the vessels. I

here present two forceps of my own device that well illustrate this point. Adhesions should be separated, if possible, between forceps or ligatures. The cyst should be tapped before enucleation is begun, and when this is done the caliber of the vessels in the capsule contracts.

If hysterectomy is necessary, total extirpation is preferable, for we can not get sero-serous union over the uterine stump, and unless this can be done the cervix ought to be removed. If possible it is best to ligate the uterine arteries outside of the ureter before they give off branches that supply the upper part of the vagina and cervix, otherwise ligate them close to the cervix to prevent injury to the ureters. The patient should be in the Trendelenburg position, so that the different structures and their relations may be seen as we proceed. There is no fixed opinion or uniform practice in the treatment of the sac cavity. It is drained through the vagina; through the abdominal walls, with or without suturing the capsule to the abdominal wall; or it is not drained at all. If hemostasis has been nearly perfect and the operation aseptic, drainage is not necessary, and then in total extirpation the vaginal vault should be closed by interrupted sutures.

MEDICAL EXPERTS.

BY WILLIAM S. FORREST, ESQ.

OF THE CHICAGO BAR, CHICAGO.

[Response to a toast at the annual banquet of the Alumni of Rush Medical College, May, 1894.]

Justice can not be administered in our civil or criminal courts without the aid of medical science. In the detection of crime, in the demonstration of innocence, in determining the probable cause, nature and extent of personal injuries, in shedding light upon the validity of wills, in ascertaining the existence and degree of mental impairment, the courts are compelled to lean upon the special research, observation and experience of the physician.

Originally, in England the medical expert aided the court by reporting to him his conclusions somewhat as is now done by a Master in Chancery. In those days he was selected by the judge and not examined by counsel. That system failed, and in its place arose the present system, which requires the expert to respond to a subpoena, if his reasonable charges are tendered him, and to submit, under oath, to examination and cross-examination. There is nothing, however, in the law or practice to-day that prevents a trial judge, of his own motion, from selecting and compelling any physician to give expert testimony as to the matters in issue in any case, when his testimony is relevant, if the court tenders him his reasonable fees. A fund to be provided by the county board in any county is all that is required to invest the courts of that county with full power to introduce in every case the testimony of that physician, whom the presiding judge may deem the most competent, within his jurisdiction, to elucidate the controverted medical question.

Of late there have been frequent complaints of medical expert testimony. Most of these complaints, in the judgment of lawyers, are based on prejudice and the want of full and accurate information. Sometimes they are prompted by the bias and the enthusiasm that flow from the zeal of partisanship.

American journalists have ceased to be impartial

reporters and reviewers of legal proceedings. They are advocates in a forum in which no effective reply can be made by persons who are not editors or proprietors of newspapers, and where usually the contentions of one party are maintained by argument, evidence, rumor and suspicion, while the contentions of his opponent are assailed by the truth, in so far as the truth is serviceable, but when it fails to hit the mark by appeal to prejudice, by insinuation, by caricature, and even by the coinage of the imagination. Their tone indicates that they know the whole truth. The greater number of their readers, especially those whose literature is exclusively the newspaper and the magazine, assume their expressed degree of certainty as to the actual truth and, when "gravelled for lack of matter" in ordinary conversation, earnestly state and warmly discuss their opinions concerning the last or the approaching trial of a great case. This agitation in the press and discussion in society lead nearly the whole body of the people to prejudge the controverted points in all celebrated causes, civil and criminal, and to cling with pertinacity to their prejudgments, regardless of the evidence, until the final order is entered and the actors in the legal drama pass from the stage. Hence arises a long train of mischiefs, not only to the medical witnesses, but also to all persons in any way connected with modern jurisprudence.

Some of these complaints, I have said are groundless; others, however, and those not commonly noticed, are fully warranted by the experience of men acquainted with litigation.

Although medical expertism is not what it ought to be, it is by no means what it is represented to be. Yet, it must be conceded that it has fallen from its former estate in popular opinion. The prevailing notion as to its character is due, in my judgment, to impertinent and improper cross-examination, to improper rulings by the trial judges as to the competency of certain questions and as to the scope of the cross-examination, and to the imperfect, if not incorrect, reports of medical testimony in the daily newspapers, as well as to the shortcomings of the experts themselves.

Within the past year, a physician who was called to answer a hypothetical question as to the nature and effect of certain wounds, was cross-examined for several hours on psychology, neurology, chemistry, anatomy, physiology and histology. Objection to the latitude of the cross-examination was promptly overruled. If such an examination is permissible, then any industrious lawyer who has been instructed by a learned coach, can make the average medical expert in any case appear ridiculous. If such a method of interrogation is admissible, then no medical expert can pass creditably through the ordeal of cross-examination in any trial unless he is prepared to answer questions, not only on the subject on which he offers himself as an expert and what is fairly involved in it, but also on the whole science of medicine with all its ramifications.

Willingly admitting that the bar, the judiciary and journalism are in this way partly responsible for the want of public confidence in medical expert testimony, still I claim that its chief cause will be found in such intellectual deficiencies of the average medical expert as are disclosed by the legitimate cross-examination daily conducted in our courts. These intellectual deficiencies are: 1, unfamiliarity with

the minutiae of the particular subject on which he is called to give testimony; 2, his lack of reasoning power; 3, his apparent incapacity to test the opinions, which he seeks to maintain, by the cardinal rule of all scientific investigation, namely, that no theory is proved, unless it is consistent with all the genuine facts and excludes, to the degree of certainty required, all other theories.

The daily practice of the physician, which requires him to do the best he can in view of the symptoms disclosed, results in habits of mind which, if not corrected by earnest endeavor, unfit him for scientific investigation and scientific statement, and, therefore render him incapable of presenting his opinions in a logical form and of maintaining them in a contest with a thoroughly equipped lawyer, who has a clear advantage, because he is the questioner, and is fresh from a special study of the subject.

In the sick chamber, not to appear to know and to act accordingly, is failure. In a court of law, not to give an opinion unless you are certain that it is sustained by the facts presented and the teachings of medical science, is success.

Assuming, then, that the cause of the prevailing opinion of medical expertism has been correctly stated, what is the remedy?

A board of medical experts to be appointed by the judges of our courts of record is often proposed.

In the nature of things this scheme can be a remedy for so much of the complaint only as is caused by the partiality towards the defense of the experts retained by it. If such partiality be the cause or the chief cause of the complaint, then the remedy suggested is appropriate; and whenever the defendant is poor and without influence will be decidedly effective.

On the other hand, if our analysis is correct, that remedy will be merely sweetened water given to cure a deep-seated difficulty.

If it were possible to organize and maintain a board or college of experts, whose knowledge and skill embrace and completely cover in all its parts the whole field of medicine and its accompanying sciences, and who are endowed with that form of moral courage which inspires a man to tell the truth in absolute disregard of public opinion, when it is his duty to do so, I do not know of any measure within the range of possible legislation, that would be of more enduring benefit to the administration of criminal justice, considered from the point of view of the defense as well as the prosecution.

I insist, however, that there is not resident in Illinois any responsible public authority that is competent to select such a board, and that, if there were such an authority, politics would prevent the election of the most competent physicians.

Besides, the science of medicine to-day is too varied to be represented by any number of physicians possible to be gotten together in any board that can be created and supported at the public expense.

It may be replied that we ought not to expect perfection. True. Do not forget, however, that under the powers with which the judiciary is now invested, if your county board will appropriate the requisite funds, any trial judge may compel any physician to testify, upon whom a subpoena can be served within the jurisdiction of the court. For all practical purposes, therefore, more efficient service can be had in

the present state of the law than would be rendered by the proposed board of medical experts, provided the judges exercise their powers and the county board makes a sufficient appropriation. We have, in effect, now a board of medical experts which consists of the entire medical profession of Cook County. Why limit it by creating a legal board?

Furthermore, such a board, if created in Cook County, would furnish testimony that would be more imperfect in the respects in which medical expertism is now imperfect than the system which at present obtains.

Gentlemen who favor the creation of such a board admit that our governors and State boards of health are not competent to select it, but they claim that our judges are.

I can not agree with them, yet I yield to no man in my respect for the ability, impartiality and uprightness of our local judiciary.

No set of men are competent to select a board of medical experts with the proper qualifications, unless they are acquainted with the leading physicians, able justly to estimate their proficiencies, sufficiently prescient of the future to know the medical questions that will arise during the term of office of the members, and strong enough to resist and overcome the pressure of politicians and the insistence of personal friendship.

In urging that our judges are incompetent to perform the duties under consideration, I merely insist that they are human and have the usual limitations of good lawyers, who have assiduously devoted themselves to the practice of their profession, and are now dependent for their official existence upon votes cast in political conventions. They, like the rest of mankind, ought not to be led into great temptations.

Suppose our judges were empowered to organize such a board, in what proportion would they divide them among the different schools of medicine? Who would finally be appointed? Physicians named by politicians. How do we know? By experience. Our judges now name the South Park commissioners and justices of the peace. Do you know of a South Park commissioner or a justice of the peace who does not owe his position to politics? Did not our circuit judges lately divide into two sets respecting the appointment of one of those commissioners, and did not one set refuse to meet and confer with the other, until the seceding set had their way as to the politics of the new appointee?

If our judges were empowered to appoint a board of medical experts, is it not morally certain that no physician would be considered whose application was not supported by political influence? Would not the applicants be so numerous that combinations would be formed among them and their friends? Would not the different nationalities also put in their claims for recognition? And would they not obtain it?

All the past records of the human race teach that the appointing power tends to weaken and corrupt its possessors. Let us not, therefore, attempt to elevate modern expertism by increasing the patronage of our judges. Rather, let us elevate the judiciary by relieving it of the appointing power with which it is now burdened.

Remember, too, that each one of our trial judges constitutes a tribunal that is finally to pass upon the sufficiency as well as the credibility of the expert evidence. The tribunal that is to determine these two

questions is not the one that should be permitted to select the witnesses. Every one has an inclination to credit the witness whom he selects.

In Germany there is an official board of experts, but its members are not named by the judges.

Another objection to a board of experts to be appointed by any public authority is, that it would be compelled to decide questions submitted to it in accordance with public clamor, and its members would be more or less controlled by the politicians who secured their appointment.

The common supposition is that persons who hold quasi-judicial positions, elective or appointive, perform their duties in a fearless and impartial manner. This ancient notion ought to be classed with the old superstitions with which the ignorant are silenced, if not convinced and controlled. Our prosecuting officers are intended by the law to be impartial; but what prosecuting officer in this county ever hesitated to avail himself of public opinion in order to obtain a conviction? In so doing have they been always right? Your supreme court has frequently found that they were radically wrong.

Five physicians of this city, distinguished for their learning and integrity, of large experience in treating the insane, and acknowledged to be in the first rank of their profession, within the past year were retained by the prosecution to examine a man indicted for murder whose defense was insanity. They made the examination and, they say, were compelled by the evidence to conclude that he was insane. They so reported to the prosecuting officer, were not called as experts on behalf of the prosecution, and afterwards went upon the witness stand in obedience to a subpoena by the defense and testified that the accused was insane. Had they concluded that he was sane and so testified, they would have been well paid out of the county treasury. As witnesses for the defense they waived compensation, on account of the poverty of the accused, and gave their testimony as experts without fee and without the expectation of any reward, except that which ought to follow the discharge of public duty.

This beautiful act of humanity, this splendid manifestation of manhood has been stigmatized by the press as "treason to the State." And these five physicians are regarded in certain quarters, because of this charge, not as men who served the public well but as physicians who betrayed their trust and basely served a cowardly assassin.

Scientia et humanitas is the motto of your graduating class. Young gentlemen, the story of your generation, when told, will contain no better exemplification of your motto than the conduct of these five physicians.

Suppose these five physicians at the time they gave their testimony constituted the board of medical experts for Cook County and that their term of office expired a few days afterward. Could they have been re-appointed? What pitiless attacks would have been made upon them, and what revenge would be threatened against the judges who should vote for their re-appointment?

Some of the members, not fitted by the kindly offices of their profession to endure a storm of detraction, would seek refuge in withdrawal, or if their term had not expired, in resignation.

Other members would not wish to be re-appointed, because of their distaste for the fierce conflicts inci-

dent to all forms of public life. In their places would appear five medical politicians who would enter upon the duties of their high office with the unexpressed feeling that, in order to avoid the abuse heaped upon their predecessors, it would be necessary for them to formulate their opinions in the next criminal case in accordance with the edicts registered in the columns of the newspapers and echoed by the cries of the populace. Thereafter the tendency would be from silence to evasion, thence to trimming, then acquiescence, and finally abject willingness to let the crowd have its way.

It has ever been so. Now and then the course of events makes necessary the sacrifice of some human being in the courts of law. Jurors and judges have seldom been able to render true verdicts and just judgments on the first trial of those cases that stir deeply the passions of the people. Humane legislators have provided courts of appeal, partly in order that there may be a tribunal with revisory power, distant from the passions and influences to which the trial courts are always subject.

Athens, at the height of her greatness, condemned Socrates as a criminal and put to his lips the cup of hemlock. Even Socrates, the good and wise and pure, was judicially murdered by a jury of his fellow citizens, every one of whom knew him personally. How the jurors were applauded for their verdict as they filed into ecclesia at the first meeting of the citizens convened thereafter. Public opinion had demanded the removal of Socrates and the Athenians honored the men who removed him.

Jesus of Nazareth was put to death in obedience to the shouts of the populace: "Away with him!"

In staid and justice-loving England, Titus Oates and his fellow witnesses supplied the perjured evidence which dragged innocent men to the scaffold, in compliance with the excitement and rage of London Town.

Down in old Salem among the pious and sober-minded Puritans, good mothers confessed in open court that they were witches, and the juries and judges believed their confessions and hanged them. Public opinion had so decreed.

Heads dropped from the guillotine in France, sent thither by tribunals that quailed before the wild mob and the master politicians of the age.

These instances of the sacrifice of human life to public prejudice and popular clamor are taken from the histories of the great nations of the earth, the nations that have given modern civilization its philosophy, its religion, its humanity, its sweetness and light.

Varied were the issues and unlike the accused in these trials. Very different also were the laws, the manners and characters of the people in whose courts the judgments were rendered. But in one essential and supreme aspect they were all exactly alike—in all of them the verdict was determined and dictated by popular fury.

History repeats itself, also, in criminal jurisprudence. What happened then, happens now. The difference is that you and I are too near to the trials that have taken place in our generation to view and discuss them in the manner in which they will be viewed and discussed by posterity.

When there is proposed a measure which may affect the fortunes, the liberties and the lives of great numbers of the citizens, it behooves us to deal with

the evil we seek to correct in the light of the experience of mankind. Any change in order to be effective must be made with reference to the directing and dominating forces of the times.

Our age is ruled by newspapers as the feudal age was ruled by the great barons. As our courts and juries are influenced and in great trials intimidated by public clamor, so will any board of experts created by any popular authority, be controlled in the end by the same clamor. Relief may be obtained in the courts of appeal from the errors committed by judges and juries; but there is not any tribunal on earth that can right the wrong done by a board of medical experts, who should yield to the madness of the hour and testify, against their judgments, to that which will tend to convict a man on trial for life or liberty.

Within the past ten years a physician, then connected with the county physician's office, testified in a murder trial, on his direct examination to the theory of the prosecution, and on the cross-examination fully and unequivocally to the theory of the defense. I inquired of him after the trial the cause of this great discrepancy. He replied that his real opinion was stated in his answers on the cross-examination; that before the beginning of the trial he had informed the State's attorney of his opinion, and that that attorney had threatened to ruin him if he gave it in evidence. He then reminded me of the savage attacks on him in the columns of the newspapers that followed his departure from the witness stand, as proof that the State's attorney had attempted to execute his threat.

An effective remedy for the evils of medical expertism in Illinois will not be found in any change or modification of the system by which experts are selected. I care not what the system is, if there be in the community any objectionable experts, of push and energy, these experts will become a part of that system. Force and persistence win in the scramble for office, in spite of all safeguards. What is needed is not a change in the system of selecting experts, but greater ability, skill and knowledge on the part of the average medical expert, and the average medical expert is the average physician.

The only adequate remedy for the evils of medical expertism, in so far as a remedy is required, must come from the cooperation of the legislature, the judiciary, the bar, the medical profession and the editors of our great daily newspapers.

First, then, I suggest that the Legislature enact that a medical expert witness is one who has actual knowledge of the subject on which he is called to testify, derived from clinical experience. No physician, for example, should be accounted a medical expert in cases where insanity is the issue, unless he has actually treated the insane. Under the law at present any physician can qualify as an expert in any civil or criminal case, if he is in practice and acquainted in a general way with the literature of the subject involved in the issue.

The judges should restrict the hypothetical questions to the facts in evidence, except in so far as such questions are permitted in order to test the competency of the expert. The cross-examination should be confined to what is germane to the phase of medical science involved in the case on trial. When such a law is enacted and the judges enforce it and the rules of evidence, as they now exist, the lawyers will

be constrained to do their duty on the trial, and thus they will contribute their part to the restoration of public confidence in medical testimony.

The medical colleges may raise the standard of medical expertism by devoting more time to medical jurisprudence, and by increasing the requirements for admission and graduation.

Rush Medical College has done its duty. Recently it increased the requirements for admission, lengthened the course of study to four years, and extended each year's work one-third.

As to the lack of the power of logical statement and of the capacity to reason in accordance with the method of science which, I have urged, characterizes the medical expert, nothing will supply this except that which advances any man in any profession, whether he be self-made or college-made; application and severe self-discipline.

Finally, our genial and learned editors may render great assistance by not permitting the publication of reports of medical testimony that are so incomplete as to amount (unintentionally, of course) to the suppression of the truth and the suggestion of what is false.

It is not sufficient to administer the laws in a just and even-handed manner. It is indispensable that the people should *believe* that they are so administered.

Such concurrence of effort will enable us to leave the jurisprudence of Illinois in a better condition than we found it, and restore medical expertism to the confidence of the people. Nay, more, it will place the medical expert in a position in our courts closely akin to the sacred relation which the family physician now bears to the American home.

SOCIETY PROCEEDINGS.

Ohio State Medical Society.

The Forty-ninth Annual Meeting of the Ohio State Medical Society, held in Zanesville, Ohio, May 16, 17 and 18, 1894.

(Continued from page 888).

RACHITOMY FOR INJURIES OF THE SPINE.

by DR. J. C. OLIVER, Cincinnati. The basis of the paper was a case upon which the author had operated fourteen months after the injury. The patient was a young farmer, age 34 years, who was injured by falling from a tree. Complete paraplegia resulted *immediately*. Within two days a bed-sore developed over the sacrum, which persisted for eight months. The bladder and rectum were involved. At the time of examination, fourteen months after the injury, there was absolute paraplegia, motor and sensory, and a constant dribbling of urine and rectal apathy. There was a projection over the eighth and ninth dorsal vertebra. The reflexes were all exaggerated. The legs were not atrophied or contracted. His general condition was excellent. It was decided to thoroughly explore the spinal canal and ascertain the condition of the cord, but no hope of benefit was held out to the patient. The operation was performed Sept. 28, 1893. It was found that the eighth and ninth dorsal vertebrae had been fractured, and the seventh had been twisted to the right, so that a portion of the cord about one-half inch wide had been caught by the bones and was completely disorganized. Aside from a transient improvement in the patient's ability to retain his urine, no benefit occurred.

The question as to operable and inoperable cases was then discussed, and the most favorable time for operating considered. The importance of these fractures and injuries depend entirely upon the amount of injury done to the nervous structures contained within the spinal canal. This class of cases may be compared with fractures of the skull, and such a comparison is legitimate. Hence, operations to accomplish any good results must be undertaken early,

before injury to the cord becomes permanent. In injuries from direct violence immediate operation should be advocated. In injuries from indirect violence, operation will very rarely accomplish anything.

SECTION ON PRACTICE OF MEDICINE.

SECOND DAY—MORNING SESSION.

The meeting was called to order at 9:00 A.M. by the Vice-President, Dr. S. L. McCurdy, of Dennison.

The first paper was read by DR. D. N. KINSMAN, Columbus. STUDIES IN IMMUNITY AND TREATMENT OF A SPECIFIC FEVER, *i. e.*, HOG CHOLERA.

It was a report of special work done on hog cholera, to determine whether or not it could be treated by serum or antitoxines successfully. Cultures in bouillon or blood serum, were sterilized by heat, so as to kill the microbes and leave the toxins free in the fluid. Experiments were made both with the attenuated cultures of the microbe and by the use of the toxins. Before the third or fourth day of the disease the use of the latter secured immunity, the hog being able to withstand an injection of the pure cultures which would kill the unprotected animal.

Discussed by Drs. W. J. Scott, Fackler, Hutchinson, Conn, Beardsley, Lindsley, Spiers, Graham and the author. Dr. Beardsley had used pulverized charcoal and the arsenite of copper with the effect that the disease stopped at once, and the hogs ceased dying. They were given all they wanted of it.

IS THERE A BETTER REMEDY IN CHOLERA?

DR. E. B. FULLERTON, of Columbus. The author recommended the use of sulphate of quinin, and endeavored to show the following:

1. That, as the epidemic of 1892, in Western Europe, has shown the old rate of mortality of about 52 per cent., it may be considered as settled that *all modern remedies for the disease have failed*.

2. That, reasoning by the deductive method, the remedy recommended by the author should be chosen before all others, because it alone may be given in sufficient amounts to effect promptly inhibition, followed by almost coincident disinfection of the intestinal tract.

3. That, although Prof. Koch was the first to establish the degree of the inhibitory powers of quinin sulphate, he did not recommend its use in cholera because he knew it had failed to cure the disease.

4. That the reason it failed to cure the disease is found in the fact that the germ of the disease has its habitat in the human body only in the intestinal tract, and furthermore that quinin sulphate, when given hypodermatically or intravenously, escapes by the kidneys without reaching the germ.

5. That, reasoning by the inductive method, wherever given by the mouth in sufficient doses, in every epidemic from and including that of 1831, to, and including that of 1873, it has accomplished all that may reasonably be expected of any remedy, reducing the mortality in advanced stages of the disease to 14.25 per cent. in Asiatic cholera, exclusive alike of choleraic diarrhea and of collapsed cases, to a bagatelle of 2.5 per cent.

6. That, if the ability to show that a remedy *should* be most effectual in the cure of a disease, and furthermore, that wherever rightly given it always *has been* so effectual, does not constitute an important addition to therapeutic knowledge, there would seem to be no reasoning in therapeutics, or "help in us."

DISCUSSION.

DR. BLEILE thought the author's logic unexceptional and the treatment rational.

DR. GORDON, Georgetown, in 1855 read a paper on cholera, treatment with quinin sulphate and mercury in solution, by the mouth, and has continued this treatment ever since.

DR. FULLERTON—Quinin is the only remedy that stands the practical test.

DR. ROBERT PETER, Canal Dover, read a paper on THE RATIONALE OF SYSTEMATIC ELIMINATION IN THE TREATMENT OF TYPHOID FEVER.

The most promising eliminative treatment is ideal prophylaxis. To stamp out their causes is the best preventive of diseases. The technique of systematic eliminative treatment of typhoid fever may vary. The most direct methods are: Expulsion of the poison, by purgation alone; conjointly by purgation and irrigation of the bowel; by irrigation of the bowel alone; or, by conjoint purgation, irrigation and baths. Any purgative may be prescribed. A good selec-

tion is podophyllin, which has the advantage of directly increasing the secretion of bile. One-eighth to one-fourth of a grain every six hours may be given, and this will usually insure from four to six stools every twenty-four hours of its use. A more vigorous effect may be secured by the use of the compound podophyllin pill. If the stools are already too frequent, calomel may be given in broken doses, one-eighth to one-fourth of a grain every half hour. This will allay irritation and remove the gases and other toxic intestinal contents, which are causing these frequent irritative but not eliminative stools. Purgation by irrigation of the bowel has only an indirect effect upon the ileum. If a tonic is suggested, quinin may be given in 2 grain doses every three hours, nux vomica in one-quarter grain doses every three hours, and if there is loss of strength there may be administered every four hours the comp. syrup of hypophosphites and strychnin, one twenty-fourth of a grain of the latter to one dram of the former. Abortion of the disease is possible when the treatment is undertaken not later than the fifth day. Purgation does not increase, but actually diminishes the danger of perforation. In the late stages of the disease, irrigations alone are the best form of eliminative treatment. The treatment must be pushed until the disease is eliminated, and it will abort typhoid fever by the ninth or twelfth day, if early begun and effectually carried out. The patient should be allowed to eat anything he may desire. Eliminate the poison and nutrients will be borne well.

DR. JOHN E. WOODBRIDGE, Youngstown, then read a paper on

TYPHOID FEVER.

This was a supplementary report of two cases, and a presentation of charts. The patients were the son and wife of Mr. W. W., and are of special interest because there were cases of typhoid fever with well-marked symptoms on either side of his residence, and because he had previously lost a son and daughter from typhoid fever. Both cases presented absolutely pathognomonic symptoms of typhoid fever. In one case there was nose bleed and delirium, and in both intense headache, tympanites, gurgling in the right iliac fossa, rose spots and bronchial catarrh. Both cases recovered in less than two weeks as a result of the treatment, which consisted of a No. v capsule of the following:

R. Hydrarg. chlor. mitis	ʒi.
Guaiaicol carb	ʒvi.
Thymol	ʒv.
Menthol	ʒj.
Sugar	ʒii.
Eucalyptus, as much as possible	

The dose was repeated every half hour the first day, every fifteen minutes the second day, every hour the third day, followed by eucalyptol m. x., guaiacol m. i., every three hours, in the first case one day and in the second case two days; followed by a No. v capsule of the first mixture, every fifteen minutes in one case and every hour in the other case, for one day, when the eucalyptol and guaiacol mixture was used until the temperature was normal. Mrs. W.'s bowels not having moved since her illness, she was given a little magnesia, and since she had not slept for four or five nights, her husband gave her a gtt. xx dose of the tincture of opium. Both were given a little ipecac.

Thus the author claimed to be able to cure every case of typhoid fever. The disease is aborted in every instance. Were this country threatened with the invasion of a foreign enemy capable of destroying the lives of 50,000 of her people and prostrating a half million more, as does typhoid fever every year; and were a military man to present evidence of his ability to defeat that foe, such as has been given of the author's ability to save the country the tremendous suffering and loss of life and time caused by typhoid fever, the entire resources of the nation would be placed at his disposal. He said: "I ask you, does not the country owe me one typhoid hospital in which to alleviate a little more suffering and save a few more lives than is possible in private practice? If the profession and the people can be made to recognize this disease by its earliest symptoms, and send its victims to me as soon as it makes its appearance, I make you a solemn promise to return every one of them without a death in much less than one-half the time, and with little or no impairment of the constitution."

DR. COLLAMORE—These papers are very interesting, in that they offer a decided treatment of typhoid fever. A good working theory is the one commonly accepted, that typhoid fever is due to the presence of the typhoid bacillus in the intestinal canal, and the typhoid condition is induced by

the action of the toxines produced by this bacillus. Two theories have been offered. The first essayist would drive it out of the system by repeatedly sweeping out the intestinal canal. Theoretically that is good treatment. The other theory is the destruction of the germ or toxine, and the initiative treatment by full doses of calomel recognizes both theories. They work together harmoniously, and they are combined in the treatment given by Dr. Woodbridge. His theory is good because it offers a positive treatment for typhoid fever, and one which is followed by excellent results, as his statistics show. There is only one criticism, and that is the recipe given resembles the so-called "shot-gun" prescriptions. It would be interesting to know whether the entire combination is necessary.

DR. MURPHY, Cincinnati—When any physician claims that he never lost any case of disease by a certain method of treatment, his statement is open to challenge. The fever curve is not always characteristic, and many times the symptoms are misleading. It is a question whether the author of the last paper has not been mistaken in diagnosis. The efforts to eliminate the poison, suggested by the author of the first paper, would not be effectual, because the bacillus can not be gotten out in that way. The best treatment is almost nothing.

DR. J. E. CONE, Youngstown—I am also from Youngstown. We have had several fights over this, and we are still watching his cases.

DR. HERRICK, Cleveland—In all diseases there is a disturbance of normal nutrition. The conditions of nutrition are disturbed from without or from within. In typhoid fever the Peyer's glands of the intestines, in the ileo-cecal valve region are diseased. The infection is conveyed either through the veins to the portal vessel and the liver and lung, or by the lymphatics it is poured into the left subclavian vein. There is no other avenue of approach to the system. In the treatment, rest is of most value. The patient should avoid all solid food, even milk. Warm applications over the abdomen have a grateful effect.

DR. BEARDSLEY, Ottawa—Cases of typhoid fever can be positively diagnosed only upon post-mortem. Flushing the bowel with calomel or podophyllin is of great value in the treatment. Some of the salts are probably to be preferred. The Doctor's "shot-gun" treatment is not to be recommended. Small doses of something of an antiseptic character may be administered, and perhaps some stimulants. Milk should not be given, and the patients should be kept quiet. The sulpho-carbolate of zinc is of value to flush out the intestinal canal, and should be pushed until its effect is apparent.

DR. SINNETT, Granville, reported two cases, nurses, successfully treated with not more than twenty doses of medicine in six weeks, and also eighteen cases occurring in the infirmary which recovered under similar treatment. Alcohol and nitric acid combined is a valuable remedy. We should always endeavor to give rest. Dover's powders may be administered. A prohibition of milk is not necessary.

DR. ROBERT PETER—By removing the contents of the bowel we give rest. If we have an armful of wood, the arm is distended and the muscles become tired; we secure rest by relieving the arm of the burden. So in typhoid fever, the bowels are distended and the tissues on the stretch, and they can only be rested by getting rid of the contents.

DR. WOODBRIDGE—The remarks of Dr. Murphy, eloquent and learned as they are, are not at all unique, but are such as we have heard many times before. They simply repeat the old, old story, that typhoid fever can not be treated. If we have in a vessel the bacilli which cause a disease, and know how to introduce something into the vessel that will destroy them, we can with certainty destroy them in every vessel. Having proven that it can be destroyed in one case, it follows that it can be cured in every case. If you institute early treatment for typhoid fever in every case, you will treat every disease that can possibly be mistaken for it in the best possible manner, and will save every case of typhoid fever.

SECTION ON SURGERY.

SECOND DAY—MORNING SESSION.

The Section was called to order at 8:45 A.M., Dr. Dandridge in the chair. The invitation of the Cleveland Medical Society, inviting the Society to hear a lecture to be delivered by Dr. Wm. Pepper before the Cleveland Medical Society, June 22, was received.

"Unjust Malpractice Suits; Causes and Prevention," by DR. WILLIAM ESTEP, Loydsville, was read by title.

DR. W. D. HAMILTON, of Columbus, then read a paper, "A Case of Cirroid Aneurism;" and DR. J. C. CROSSLAND, Zanesville, presented a case of aneurism by anastomosis. DR. W. J. CONKLIN, Dayton, read a paper on "Splenectomy," with the report of a successful case.

DR. DONALD MACLEAN, Detroit, read a paper on

THE TREATMENT OF FRACTURES IN THE LIGHT OF ADVANCED HISTOLOGY AND PATHOLOGY.

No material benefit can be secured in cases of fracture of the thigh by the so-called methods of extension and counter-extension. So far as that part of the treatment is concerned, our efforts are futile. No method has ever been invented which would extend or counter-extend to any extent. If a patient is put under extension and counter-extension by any method, in a case of fracture of the thigh, you will in a great number of cases, within a day or two, find the weight on the floor and the patient propped up with pillows. For one reason or another, extension and counter-extension is not carried out in the treatment of fracture of the thigh. In fractures of the humerus, bones of the leg and ribs, extension and counter-extension are not employed, and why should it be more necessary in cases of fracture of the femur than of other bones? But if the surgeons are deprived of extension and counter-extension in the treatment of these fractures they should be given something better instead. Keeping the mode of formation of new bone in view the physician should watch it closely and keep the parts in position by means of sandbags, and often manipulate it to see how things are progressing, moving the sandbags one way and another without subjecting the patient to any pain. Union will thus be secured in good position. We should not leave fractures of the thigh to take care of themselves.

DR. ALLEN opened the discussion, speaking of fractures of the neck of the femur. Here the injury is often slight, most common in persons beyond middle life. The shortening may not be beyond a quarter of an inch, and if there is previously a difference in the length of the legs, and the injured leg was the longer, they may then be the same when injured. Under normal conditions a line from the anterior spinous process of the ilium down to the sacrum will go over the tip of the femur, and this point is of greatest value in diagnosis.

DR. LEONARD FREEMAN, Cincinnati—In fractures of the femur, with shortening which can not be overcome, in which the fragments can not be put in place, it would be perfectly proper to cut down on the femur and adjust them with the fingers. In Colles' fracture, the periosteum passes from the fragment above to the fragment below, binding the two fragments together so that the lower one will not slide on the upper and the fragment can not be easily replaced. This may be overcome by over-extending the end in the direction the injury took place, thus making everything loose. With the thumb the fragment may be easily replaced. It is best not to apply any dressing at all to such a fracture. If a bandage is used it should not be tight.

DR. STAMM, Fremont—If the patient is able to elevate the leg you may exclude fracture. There is often absolutely no evidence of fracture to be found, and yet there is afterward found to be fracture. As to the treatment we should pay more attention to massage.

DR. HERRICK—In proportion to the condition of development of the animal and the age of the individual is the reparative power facilitated or impaired. The proper time for adjustment is during the collapse from the injury causing the fracture. That having past, the patient should go over the period of excitement and inflammation.

DR. THAD. A. REAM, Cincinnati—A Zanesville patient about 10 or 12 years of age came under my care when I was practicing general surgery. He had fallen out of bed, causing a fracture, and he has recovered, without shortening of the limb, by the application of a plaster-of-paris cast. In another case, fragments from both bones of the leg were removed at two separate operations, and they afterwards grew in.

DR. LARIMORE, Mt. Vernon, stated that he was going to stick to the orthodox treatment of fractures of the femur for fear of the results of a malpractice suit which might follow, and which he felt he could not afford. A good many physicians have their world's goods in their wife's name, which is a good plan.

DR. FORBES, Toledo—To let go these safeguards will certainly expose the physician to criticism and malpractice suits and it can do no harm to follow in the footsteps of those who have gone before. In this connection, it is best to apply extension from which no evil can result and which may save shortening.

DR. MACLEAN in closing, said: In order for any science to advance, it is necessary to seek to improve upon the ways of our forefathers, and we should not, therefore, be satisfied to follow in their footsteps. The author will be satisfied if the paper presented to-day will set going a new train of thought in regard to the subject of fractures.

DR. HUNTER ROBB, Baltimore, Md., read a very interesting paper on "Practical Application of the Principles of Sterilization." Discussed by Drs. Oliver, C. A. L. Reed and Kelly.

On motion of Dr. Reed, the thanks of the Society were tendered Dr. Robb and Dr. Maclean.

DR. M. STAMM, Fremont, read a paper on "Gastrostomy; A New Method," and presented a specimen in illustration.

THE RADICAL CURE OF HERNIA.

This paper was read by DR. F. C. LARIMORE, of Mt. Vernon. Report of five cases, supplementary to cases reported to the Society in 1891 and 1892, making a total of ten cases. The five previous cases are recorded in the Transactions of the Society for 1891, p. 94, and 1892, p. 297.

The suture employed in each case was kangaroo tendon, and the dressing, iodoform collodion and a compress of cotton.

The author also gave an interesting table of operations for non-strangulated hernia, performed in Europe and America. The following conclusions were reached:

1. The operation for the radical cure of hernia is a safe operation. Mortality, .86 per cent.
2. The operation results in a permanent cure, relapses occurring in but 7.5 per cent. of the cases.
3. The operation should be made with the strictest aseptic technique.
4. Make a free incision over and with the long axis of the tumor, from without inward.
5. Open the sac and examine the contents deliberately and carefully, generally resecting the omentum.
6. Dissect up the sac, ligate its neck high up with a chain suture, and resect it below the suture.
7. Restore the obliquity of the inguinal canal by two rows of deep, continuous double sutures.
8. Close the integument with a buried suture.
9. For all sutures use kangaroo tendon, and do not draw so tight as to constrict the tissues.
10. Final dressing: Iodoform collodion.
11. Keep patient in bed from three to seven days.
12. Do not put on a truss.

DR. LAWRENCE, Columbus, considered "radical" in itself a reflection on surgery.

DR. C. N. SMITH—A solitary case, except in childhood, rarely occurs except in the corpulent, those weighing from 270 to 280 pounds. He also mentioned a case of strangulation in which there was found nine ounces of sloughing omentum.

DR. MEANS complimented the paper, and thought no doubt almost all ordinary cases may be radically cured.

The Committees on Publication, Legislation and Ethics were then announced.

GENERAL SESSION—EXECUTIVE.

SECOND DAY—AFTERNOON SESSION.

The first item of business was the reports of committees. The Committee on Admissions reported through Dr. Chapman, and on motion the report was adopted. The reports of the Committees on Finance and Publication were also heard and adopted.

The following were then appointed delegates to the AMERICAN MEDICAL ASSOCIATION: Dr. Loving, Columbus; Dr. Taylor, Cincinnati; Dr. X. C. Scott, Cleveland; Dr. Larimore, Mt. Vernon; Dr. Bricker, Shelby; Dr. Fowler, Delaware; Dr. M. Stamm, Fremont; Drs. R. C. S. Reed, Holston, Woodbridge and Alcorn.

DR. CULBERTSON moved that a Committee on State Legislation be appointed, consisting of a chairman, and one member from each county society. An amendment was added, by Dr. Scott, Cleveland, that a member be appointed from a district society in those counties not having a county society. Accepted and unanimously adopted.

DR. HUNTER ROBB and Dr. Maclean were elected honorary members of the Society.

THE PRESIDENT'S Address was then delivered. He said that if the Society is to play its rôle as an active compact organization, it must be composed of a well-defined permanent membership, which continues from year to year. One of the definite purposes of the Society is the promotion of all

measures adapted to the relief of the suffering, the improvement of the health, and the protection of the lives of the community, and in furtherance of this object, this purpose can most certainly be accomplished by drawing in close sympathy with those bodies created by the State for the preservation of the health and lives of its citizens. No more important communication could be made to the Society at this time than a brief bulletin, stating the present condition of diseases throughout the State, their tendency to spread or evidence of their decline. The time is past when the few years spent in the medical school could possibly furnish all that is necessary in a medical education. We must look to the schools and universities, with their laboratories and instructions in chemistry and physics and biology for a large part of the essential training necessary for the more special study of medicine.

DR. C. A. L. REED, Cincinnati, read a paper on

THE TREATMENT OF UTERINE FIBROIDS AS INDICATED BY THEIR NATURAL HISTORY.

The diagnosis of uterine tumors must be made in recognition of their natural history, and the following conclusions were reached:

1. The natural history of uterine myomata indicates that *a*, multinodular myomata which are yet small and apparently indolent and which do not cause embarrassing hemorrhage, may be safely left to observation before relegating them for operation; and *b*, that single soft myomata and diffuse hyperplasias of the uterus are essentially progressive growths and should be operated upon as soon as diagnosed.
2. That in operating upon multiple myomata of small size we should have recourse to *a*, extirpation of the appendages; and *b*, that ligation of the uterine arteries should be practiced only when the patient will consent to it and will not consent to abdominal incision.
3. In all cases of large multiple myomata showing a tendency to growth, complete extirpation should be practiced.
4. In all cases of simple myoma or of diffuse progressive hyperplasia (the "soft fibroid" of many authors), complete removal should be practiced as soon as the diagnosis is established.

DR. REAMY, Cincinnati, referred to the last point in Dr. Reed's paper. It indicates that not only should the clinician estimate the size of the growth, the age of the subject and the physical condition of the patient, but he should inquire whether the growth is a multiple or a single tumor; whether it is smooth or nodular. A single tumor will not be arrested by removal of the appendages with anything like the certainty a multiple tumor will be. If several combined, or two or three or more with a size each equal to the single tumor, the multiple one will be arrested in growth by removal of the appendages more certainly than the single tumor. However, the single tumors sometimes cease to grow, either spontaneously or under treatment, and these cases do not invariably demand surgical interference, and the question arises whether the reasonable certainty of growth in this class of tumors justifies us in taking advantage of the difference in ease with which the operation may be done, and the difference in danger of the operation. It is well enough to keep the case under observation, determine whether it continues to grow, and subject it to the same treatment as in multiple neoplasm. If a tumor of this character does not produce bad symptoms we are not always justified in subjecting the patient to operative interference. The mortality in the hands of experts is such that the question of prime importance is no longer whether the patient will survive the operation but the principal question is, What will be the influence of the removal of the appendages upon the woman's psychologic as well as social condition. The glory of surgery will be when we are able to not only make the diagnosis and classify the cases, but when we will be able to arrest the growth of the tumor in these cases without removing the uterus. Experience in the dead room shows that one out of five of women 35 years of age have a fibroid tumor of the uterus, and this shows that in an enormous number of these cases arrest of the growth does take place without the aid of either the physician or surgeon. The administration of ergot will increase the tendency to arrest the growth of these tumors, and it is our duty to try to arrest them while they are young. For this purpose electricity also is valuable. Some methods are best in some cases, and other methods are better adapted to other cases.

SOME REMARKS ON THE TOTAL EXTIRPATION OF THE FIBROID UTERUS, WITH ILLUSTRATIVE SPECIMENS, was read by DR. RUFUS B. HALL, Cincinnati. Only a small

percentage of those suffering from fibroids require operative interference for relief. This fact, however, only increases our responsibility in determining early the cases really requiring operation. The chief symptoms and secondary diseases of cases requiring operative interference are hemorrhage, pain, cystitis, peritonitis, and pressure causing temporary intestinal obstruction. With the present low mortality following total extirpation of the fibroid uterus, we should not hesitate to advise all patients who are subjects of fibroid tumor, if their life is endangered or health destroyed, either from the tumor or complications arising from it, to submit to the operation at once.

DR. C. N. SMITH, Toledo, read a paper entitled, "Total Extirpation of a Pregnant Myomatous Uterus, with Specimen."

GENERAL SESSION.

THIRD DAY—MORNING SESSION.

The meeting was called to order at 8:45 A.M., Dr. Danbridge presiding. The following papers were read by title and referred to the Committee on Publication: "Nephrectomy for Tuberculosis," DR. R. HARVEY REED. "Multiple Neuritis," by DR. JOS. RANSOFF.

DR. A. E. BELL, Zanesville, then read an interesting paper on "Pneumonia."

THE PHENOMENA OF FERTILIZATION AND THEIR BEARING ON HEREDITY.

This was presented by DR. J. PLAYFAIR McMURRICH, Professor of Biology, in the University of Cincinnati. The author showed that our knowledge of the laws of heredity depends upon our understanding of the phenomena of fertilization of the ovum, since through the primary cell all heredity is transmitted. The paper showed great research along biologic lines.

On motion, the thanks of the Society were extended to Drs. McMurrich and Kellicott.

THE IMPORTANCE OF DETERMINING REFLEX IRRITATION IN THE TREATMENT OF CERTAIN CATARRHAL DISEASES,

was given by DR. JOHN P. SAWYER, Cleveland. The sympathetic relations existing between the various mucous membranes of the body are so intimate that disordered conditions in the one induces disturbance in its fellows, and that relief of the first is usually followed by relief in the second. This relation exists because of the connection between mucous membranes and the control of their functions exercised by the nervous system. The liver and pancreas, as well as the kidney, are to be considered as extensions of mucous structure. The well-known digestive and urinary disorders of menstruation, and of endometritis or ovaritis, call to mind the effectiveness of reflex irritants from the genital organs. The relief of headaches, vertigo and digestive disturbance by proper treatment of faulty accommodation of the eye may also be mentioned. In a large number of cases within the past two years, careful examination revealed peripheral sources of irritation, after the relief of which marked improvement was observed in the course of nephritis, diabetes, hepatitis and pulmonary catarrh. The author reported three cases in illustration. Discussed by Drs. Sabin and Gray.

"Diseases of the Cornea in Childhood," by DR. C. W. TANGEMAN, Cincinnati, and "Syphilitic Spinal Paralysis," DR. C. J. ALDRICH, Cleveland, were read by title and referred to the Committee on Publication.

DR. WILLIS W. HALL, Springfield, Ohio, then read a paper on

SUBCUTANEOUS OSTEOTOMY, WITH REPORT OF CASES—A NEW OSTEOTOME.

The author referred to the correction of genu valgum and genu varum by subcutaneous osteotomy. In the cases reported four sections were made above the knee and two below. In all the cases there was immediate union of the soft parts and rapid and firm union of the bone. No pus appeared in any of them, and in none was the temperature above 99 degrees. The instrument used is an osteotome, a little shorter than those generally used, and therefore under better control of the operator. The mallet for driving the osteotome is of lignum vitae, with hard wood handle, and weighs twelve ounces.

DR. J. E. CONE, Youngstown, presented a paper on "Multiple Gangrene."

PRACTICAL POINTS IN ETHER ANESTHESIA,

by DR. W. D. PORTER, Cincinnati. The first subject discussed was the Trendelenberg position, with reference to its effects on anesthesia. It was stated that the table is often

made so that the shoulders of the patient are crowded into the angle formed by the inclined and horizontal portions, thus flexing the head on the chest and interfering with respiration. The thighs, body and head ought to lie on a single inclined plane. The body should be secured from slipping down the incline by fastening the legs or feet. The plan of allowing the shoulders to rest against hooks is to be condemned, as they interfere with the free action of the chest muscles. In producing anesthesia the ether should be given very gradually until consciousness is about lost. Up to this point the open method should be used. Then the ether should be pushed to full anesthesia, the whole process requiring on the average five or six minutes. The Clover inhaler is advocated. The author employs the bag only during the last two or three minutes required to produce anesthesia, and then he discards the bag altogether and maintains anesthesia by the open method. The main indication in maintaining anesthesia is to select the proper depth for the narcosis, and to shorten as much as possible the necessary vacillations above and below this plane. For this purpose the Clover inhaler is valuable, as it gives the anesthetizer accurate control over the amount of ether inhaled, and enables him to make prompt changes in the quantity. Attention was called to dangerous relaxation and respiratory failure, sometimes following excessive muscular rigidity occurring in the first stage of narcosis. The author has observed it in three cases, and thinks it is due to reaction from the excessive strain on the muscle fibers. In conclusion, he advocates, at length, the importance of having a hot room in which to administer the anesthetic. It lessens the danger from shock, the danger to the lungs and the danger to the kidneys. The temperature should be 80 to 90 degrees F., depending on condition of patient and the nature of the operation.

DR. LEONARD FREEMAN, Cincinnati, read a paper on "Trephining, with Report of Cases," and a paper on "Tonsillitis" was presented by DR. H. J. NOYES, McConnellsville.

The following officers were elected for the ensuing year: President, D. N. Kinsman, Columbus; First Vice-President, C. O. Probst, Columbus; Second Vice-President, M. Stamm, Fremont; Third Vice-President, J. C. Buckner, Cincinnati; Fourth Vice-President, Robert Peter, Canal Dover; Secretary, Thomas Hubbard, Toledo; Assistant Secretary, Chas. Graefe, Sandusky; Treasurer, Jas. A. Duncan, Toledo.

Committee on Finance, term 1892, F. C. Gray, Dayton (unexpired term of Dr. Pomeroy, deceased); term 1894, N. P. Dandridge, Cincinnati.

Committee on Ethics, F. C. Larimore, Mt. Vernon. Committee on Publication, Jno. P. Sawyer, Cleveland. Committee on Legislation, Wm. D. Hamilton, Columbus. Committee on Admissions, W. C. Chapman, Toledo.

The Society then adjourned to meet at Columbus the third Wednesday in May, 1895.

SELECTIONS.

Ethnology of the Natives of North Greenland.—Dr. Frederick A. Cook, ethnologist of the first Peary expedition, has given to the *New York Herald* some interesting facts noted by him while in the Arctic country. His observations relate to the Esquimaux living and prospering—in a small way—in latitude 77° 35' north. The winter camp of the expedition was pitched, in that latitude, on the southerly shore of MacCormack's Bay. Dr. Cook was constantly on the alert to study the natives who presented themselves at the camp. He states the following leading particulars:

"All the natives whose curiosity led them there to see a white man for the first time were disrobed, examined and photographed both in full costume and nude. Eighty of this tribe of 243 were thus minutely examined and photographed, showing front, side and rear views, bringing out accurately in the nude pictures many of the anatomical peculiarities. These photographs have been turned over to the Academy of Natural Sciences of Philadelphia and the Smithsonian Institute at Washington, where men of science can study them.

"The camera is certainly one of the most important adjuncts to an explorer's outfit. Not only does it render faithfully what the traveler sees and learns, but it prevents that perversion and distortion of facts to which, unfortunately, many observers are prone. Each individual observer

sees differently, all seemingly in the direction of exaggeration; therefore, ethnographical observation should be reduced to a single standard of comparison—that of photographs and figures. Hence I have reduced my physical observations as far as possible to figures and pictures.

"The Esquimaux are short in stature. Men average 5 feet, 1½ inches, and weigh 135 pounds, and women are 4 feet 8 inches and average 118 pounds. They are of an olive color, but to get the true shade of Esquimaux skin a prolonged bath is necessary, and this, from birth to death, is foreign to the Esquimaux. Upon the question of washing or bathing, their customs are fixed both by tradition and habit, hence it requires a great deal of persuasion to have an Esquimaux maiden indulge in what she considers a useless task. The color of an Esquimaux's skin depends much upon her age.

"In the isolation of that long and seemingly endless night—the Arctic winter—human adaptability is such that one early learns to admire these greasy faced, dark-eyed maidens, dressed in skins, about as well as our blue-eyed daisies in silks and satins while at home. Our practice of baths was to them ridiculous, and they never failed to call our attention to the fact that the day after a bath washing was again as necessary as the day previous. In this way they criticised many of our actions, much to their amusement. Our manner of dress, our table etiquette, our food and drink were sources of endless amusement to them. They are a people with broad skulls, nearly circular, retreating foreheads, and slightly protruding chins; black, coarse hair, very prominent molar bones, a small nose, composed largely of fat; eyes invariably brown, with small pupils, and well adapted to seeing objects at great distances, but the eye is horizontally set, or nearly so, and not obliquely as those of the Chinese. Their faces are often nearly square and flat, so that if a pencil be laid from cheek to cheek over the bridge of the nose it would not touch it. This great development of the muscles of the cheeks is due to their method of tanning skins by a process of chewing, and by eating raw and frozen meat, which is not always tender. Men do not develop beards or mustaches until they arrive at the mature age of 40 or 45 years, and they inferred from this that since I had a heavy beard I must be a very old man, because their oldest men had but a few straggling hairs on their chins and lips.

"The women are absolutely hairless, except their heads, and many of the old women are bald. The skin of the Esquimaux varies in color from that of a slightly jaundiced hue to a bronze or olive color. It is much less porous and less active than that of other races. The Esquimaux is favored with a superabundance of blood. So full blooded is he that a small cut would bleed for hours, while among us in the low temperatures our blood retreated from the skin and when cut we would hardly bleed at all. The slightest excitement of unusual character would cause profuse bleeding from mucous membranes of the natives. The Esquimaux, like most Arctic animals, have beneath their skin a blanket of fat or blubber, which encases the body and protects it against extremes of temperature. The abundance of blood and blanket of fat are very important elements in the construction of the Esquimaux body. It will seem from this that nature has fortified these people against the rigors of the rough Arctic climate. Owing to their wandering existence and extensive exercise their muscular system is thoroughly developed, and the picture of Ikwa carrying a stone nearly as large as himself will show the muscular power of these people.

"I could hardly say that their nerves were well developed or their sensation very acute. Their clothing is so made that when an Esquimaux stands perfectly straight a part of his bare abdomen is exposed to the blasting winds and drifting snow, and when he stoops a band of bare skin between the trousers and coat, directly over the kidneys is exposed, and this often in a temperature of 80 degrees below the freezing point. No evil that I could discover resulted from these exposures. We adopted the Esquimaux style of dress, but so modified the coats and trousers that our stomachs and dorsal regions were well protected.

"The appendages of the Esquimaux are all small. Hands, feet, nose and ears are exceptionally small. It would seem that nature had provided them with these to lessen their chances of freezing.

"One can not fail to notice the prominent abdomens of both men and women. This is due to their gluttonous eating, and since they live on an absolute animal diet, much more surface is necessary for intestinal absorption, and although I was not afforded the opportunity of measuring

their intestinal length and capacity, I believe they have several feet more intestines than we have. Certainly they have the ability to put away about as much meat at one meal as an ordinary Caucasian would eat in a month."

The Methods of the Mannal Training School in Medical Education.¹

—There can be mentioned scarcely a system of education so imperfect and so unphilosophical as that which prevails in the medical colleges of this country. The American physicians who have become skilful practitioners and distinguished teachers or writers, have become so in spite of the system under which they were taught in college.

Although there is improvement in our schools, there still exists too great disproportion in the efforts of teachers to tell and show students, as compared with those which require them to do for themselves.

The absurdity of this system becomes the more apparent, if possible, by a comparison with the methods by which mechanics learn their trades. Young men in our machine shops do not spend nearly all their time listening to lectures on machinery and looking at workmen using tools in its construction. What apprentice could ever learn in this way to make a shoe, an engine, or sewing machine?

The apprentice commences from the first with his tools to perform the work to which he expects to devote his life. The art of medicine can only be well learned by acquiring skilful use of the necessary instruments and remedies.

The admirable address of Professor Vaughan at the last meeting of this Association leaves little to be said regarding certain departments of medical instruction. I wish at this time to discuss some of the principles to which Professor Vaughan made brief mention at the close of his address.

Assuming that the student in laboratory work acquires practical knowledge of the microscope sufficient for his progress in its use without a teacher, I wish first to direct attention to the importance of due instruction in the use of the ordinary instruments employed in studying diagnosis. These are chiefly the stethoscope, the hammer and pleximeter, the laryngoscope, rhinoscope, the ophthalmoscope, otoscope, the probe, the exploring needle, the catheter, and speculum.

It is a lamentable fact, whatever may be stated in the annual announcements of our colleges, that instruction in the manipulation of these instruments, even those used in auscultation and percussion, is wholly inadequate for the needs of the student.

Let me explain my meaning by referring to a method of teaching the use of three important instruments, two of which present considerable difficulty to nearly all students.

Models of the head in papier-maché may contain most admirable representations of the normal and of the abnormal tissues of the throat, nostrils and ears. In the orbits may be placed ordinary transparent models of the eye (schematic eye) such as are constructed for teaching the use of the ophthalmoscope. These eyes are remarkably like the human eye and illustrate accurately many of the intra-ocular diseases and also the errors of refraction. By the aid of these models the use of the laryngoscope, ophthalmoscope and otoscope may be perfectly acquired. After due practice the beginner can easily and intelligently examine eyes, ears and throats of patients. The principles of this method may be applied in teaching the use of the other instruments of diagnosis I have mentioned, the human body—either dead or living—being employed in certain cases instead of models.

The instruments which are employed in treatment are chiefly the knife, scissors, forceps, needle and thread, curette, drill, saw, chisel, sound, catheter, bandages, splints and braces, and obstetrical instruments.

Is it not true that the average student, even in our best schools, does not receive adequate training in the manipulation of these ordinary instruments? I emphasize the word adequate. To furnish such training is simply to introduce in their extent and perfection the methods of our best manual training schools.

In obstetrics we find a sad deficiency in practical instruction. The "alcohol baby" and the "rubber mother," the recent fetus and the eviscerated female cadaver afford excellent means for training the beginner in certain procedures. They should, however, simply prepare the way for bedside instruction.

It is far from my intention to attempt to persuade this

assembly of teachers that undergraduates can become experts in the manipulations which are practiced in medicine, surgery and obstetrics. I do, however, insist, upon the proposition that every young physician should be as well prepared for his future work as a young "journeyman" for his trade.

We may now consider certain difficulties which arise in attempting to introduce honestly and faithfully these methods into our schools. First, the expense. The laboratory instruction as arranged by Professor Vaughan, and the practical work which I have suggested, in a school of 600 students, implies an aggregate of buildings which can be provided only at an enormous expense. The cost of material, including apparatus, human cadavers and the bodies of animals would also be very large. No small sum would be required for salaries of increased numbers of efficient professors, instructors, demonstrators and assistants of various grades.

A lying-in hospital which could provide the adequate bedside experience, which every student should receive, would still further increase the expense beyond the means of nearly every school in the country. This difficulty, in the present state of medical education is absolutely insurmountable, for no school can provide instruction on the broad plan I have sketched, with the means derived solely from the fees of students. State aid, private munificence and increase of fees will render feasible the plans I propose.

The next difficulty to which I will allude is that of so dividing the student's time that he may perform all this variety of practical work and yet neglect neither lectures, recitations, clinics, nor the study of his books. There are several ways in which this difficulty may be diminished. A more careful, yet reasonable, preliminary examination in English literature, physics, mathematics and the rudiments of Latin will indirectly accomplish much to economize the student's time. The mental discipline in gaining this knowledge, and the knowledge itself, furnish the student with valuable mental time and labor-saving instruments. An obvious and simple means of diminishing this difficulty is to demand attendance during at least four terms of nine months each. Valuable time may be saved for the student by reducing the number of typical didactic lectures to such a minimum as may be consistent with the best interests of the student.

Since no student, however industrious he may be, can acquire more than a knowledge of the fundamental facts and principles of his science, the greatest care should be observed by his teachers that he spends little time on those matters which he can well pursue independently after he has been graduated. Turn for example to the subject of *materia medica* and therapeutics. A good text-book in which forty or fifty remedies only are carefully discussed may contain all the average student really needs. He can investigate at his leisure and understandingly all other articles of the *Pharmacopœia*, after he has entered upon practice.

There is one more difficulty, which will not be overcome without great effort on the part of our schools and of the State. The mass of students in this country are seeking primarily, not a good medical education, but diplomas, that they may at the least expense of time and money commence practice and earn a living. Our medical schools have been compelled from want of means to supply simply what students demand—diplomas with very inadequate teaching.

This is analogous to the condition which prevails in our trades. Few boys are willing to learn well a trade. They are content to acquire facility in performing a very small part of what is expected of a thorough workman—so impatient are they to earn wages.

In our medical schools the state of affairs will at once improve if the license to practice shall depend upon an examination before a State board, which shall perform its duties strictly yet judiciously.

In conclusion I may say that it is the task of our schools to devise a curriculum, which in due proportion—whatever that may be—will employ laboratory methods in teaching the art as well as the science of medicine. By the science of medicine I mean that which may be taught by laboratory work in anatomy, physiology, chemistry, bacteriology and pathology. By the art of medicine I mean that which may be taught by adequate laboratory methods regarding every procedure and the manipulation of every instrument which is employed in medicine, surgery and obstetrics.

In connection with this work will be clinics, recitations, didactic lectures and exercises in handling and measuring medicines and in writing prescriptions.

F. J. REBMAN, LONDON AGENT, 11 Adam Street, STRAND, LONDON.
W. H. LOWDERMILK & CO., WASHINGTON, AGENTS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, JUNE 16, 1894.

HOSPITAL SPREAD OF SMALLPOX.

Popular dread of the "pest-house" and the bitter opposition of the average neighborhood to its proximity are among some of the difficulties with which the sanitary executive has to deal during the prevalence of smallpox. During the recent epidemic outbreak of the disease in this country, numerous instances occurred where violence was resorted to in order to prevent the removal of patients to hospital; successful resistance was opposed to the establishment of such hospitals on given sites; and the axe and the torch in the hands of mobs were used for the destruction of those already in existence.

That hospital treatment of smallpox is wholly defensible—not only because of the measure of protection it secures to the public by the better isolation of cases, but because of the greater chance of recovery of the patient himself—has been abundantly proven. The late DR. RAUCH, who thoroughly improved his exceptional opportunities for the practical study of smallpox epidemics, has shown in his history of the pandemic of 1881–83, that the mortality ratio of hospital patients was notably less than that of those treated at home. In one large city cited, among 6,976 cases reported there were 2,518 deaths—a mortality rate of 36.09 per cent.; of this total number, 4,533 cases were treated at home, with 1,874 deaths—a mortality rate of 41.12 per cent.; 2,055 cases were treated in hospital, with 598 deaths—a mortality rate of 29.09 per cent. These figures, and they are sufficiently large to warrant a generalization, show that the smallpox patient has an appreciably better chance of recovery in hospital than at home.

There is thus seen to be no good reason for opposition to removal to hospital, but the contrary.

Recent experience, however, tends to show that the popular antipathy to the propinquity of a "pest-house" may be justifiable. There seems to be a gen-

eral belief that the contagion of smallpox is not carried aerially beyond 200 feet, but is destroyed by dilution and oxydation within that distance. This belief is purely empiric; there are no scientific data for its foundation; and what is known of the diffusibility and persistence of the smallpox contagium makes it not unlikely that it may be conveyed aerially to much greater distances, as are other emanations of the human body which are recognized at such distances by the keen-scented lower animals.

A recent report on the smallpox epidemic of 1892–3 in the notorious anti-vaccination town of Leicester, Eng., strongly bears out this latter view. The smallpox hospital of the town is situated in a district locally known as Newfoundpool, having a population of about 3,000 persons living in 600 houses. A distance of 620 feet separates the hospital from the nearest house and the farthest group of houses in the district is 1,750 feet from the hospital. DR. PRIESTLEY, the Medical Officer of Health for the town, has traced the origin of cases with exceptional thoroughness and success, and he finds that almost one-fourth (24.4 per cent.) of the total number of cases during the epidemic were "possibly due to hospital influence," and that nearly one-fifth (18.7 per cent.) were "almost unquestionably due to the direct agency of the hospital."

In order that there may be no question as to the meaning of the phrases, "hospital influence" and "direct agency of the hospital," and to show that DR. PRIESTLEY is distinctly dealing with the aerial spread of smallpox from a "pest-house," it should be noted that he shows that, in February, when there was an average of fifty-four cases in the hospital and the wind was blowing away from Newfoundpool, there was no special spread of smallpox in the district as compared with the rest of the town; while in June, with a less number in hospital (an average of only thirty-four), but with the prevailing winds blowing directly over the district, "there was a great proportionate spread in the locality."

Especial care seems to have been taken to ascertain if conditions other than that of hospital aerial agency could be made responsible for the disproportionate incidence of smallpox in the special hospital district; but without success. No dissemination from personal contact could be traced; the sanitary conditions of the Newfoundpool houses in which smallpox occurred were personally investigated by DR. PRIESTLEY and found, "with very few exceptions," to be good; even the possible agency of flies and rodents was considered. All the evidence, both of a positive and of a negative character, makes for the conclusion that smallpox contagion was carried from the smallpox hospital through the air a distance of 625 feet to the nearest group of houses; and, in a circle of 2,000 feet around the hospital, caused

smallpox in the enormous proportion of 15 cases in this locality to every single case that occurred in the rest of the town.

Obviously, there is a very important lesson for health authorities in these facts and figures. It becomes a serious question whether, in the light of this Leicester experience, the courts would sustain the establishment of the usual hospital for contagious diseases within 2,000 feet, at least, of human habitations. Fortunately, it is not necessary—and it has not, for many years, been justifiable—to adhere to the usual construction of the contagious-disease hospital. This essential adjunct to the “plant” of the urban health department may be so built as to deprive it of any menace or offense to its immediate neighborhood. The method of ventilation by aspiration through a furnace or sheet of flame effectually destroys all possibility of the escape of disease germs or contagion into the surrounding atmosphere. The construction of a hospital for contagious diseases on any other plan should not be countenanced.

WATER SUPPLIES OF LARGE CITIES.

“Cholera is a sensational disease,” observes MR. ALBERT SHAW in his paper on “Hamburg’s New Sanitary Impulse,” in the current number of the *Atlantic Monthly*. Like that other typical filth-produced disease, typhoid or enteric fever, a single epidemic outbreak of it may result in greater sanitary gains than the constant ravages of more distinctive but more insidious and commonplace maladies, familiarity with which breeds municipal tolerance, if not contempt.

The filtration of the entire water supply of Hamburg from the River Elbe had been under discussion and had been recommended for nearly twenty years; but, in the absence of any pressing emergency, it was not until 1890 that it was actually determined upon, and plans adopted and estimates made by which it seemed feasible to have the filtration plant ready for use during the present year. Cholera made its appearance in 1892, and its epidemic spread was so clearly due to the contaminated water supply that prodigious effort was put forth and the plant was in operation nearly a year earlier than the most sanguine had ventured to anticipate. By these filters the water of the Elbe, which was found to contain the cholera vibrio constantly during the summer and autumn of 1893—after the plant was put in operation—and which regularly contains from 30,000 to 100,000 bacteria to the cubic centimeter at flood tide and from 400 to 1,200 in the river beyond the tidal influence, is now so purified as to contain only from four to ten to the cubic centimeter, and frequently no bacteria whatever are found in the water as it leaves the filters.

As all the world knows, Hamburg had no recurrence of Asiatic cholera in the summer and autumn

of 1893; but as all the world does not know, the River Elbe, the source of Hamburg’s water supply, was as badly polluted with cholera poison in 1893 as it was in 1892.

Naples had a similar experience with similar results from the cholera epidemic of 1885; Chicago from her typhoid epidemic of 1890-92; and London, Paris, New York and other large cities have been driven, from time to time, by some unusual incidence of a “sensational disease,” to seek the improvement of their water supplies even at enormous outlay. In England the great cities of Liverpool and Manchester are now engaged in this work. The former, by one of the greatest engineering undertakings of modern times is impounding a river 68 miles from the city in an artificial lake with a storage capacity of 1,500,000,000 gallons; while Manchester is increasing its present daily supply of 10,000,000 gallons from Thirlmere to 50,000,000 gallons, by an engineering invasion of that loveliest spot in all the Lakeland—the beloved of Wordsworth and Coleridge. So, too, in France, where the municipality of Paris is debating a plan for supplying the city with water from Lake Neufchatel through an aqueduct 300 miles long at an expense of \$60,000,000, and involving a tunnel through the Jura Mountains.

These latter plans all look to supplies from unpolluted and unpollutable sources. The Hamburg experiment is that of taking a sewage-contaminated river supply and making it potable; and hence is of more direct interest to this country, where, in the valleys of the Ohio, the Mississippi and the Missouri, so many of the cities must depend upon the rivers for their supply. Already the pollution from inhabitation is a serious evil and it is one which will increase with increasing density of population. The success of the Hamburg filtration system points out the remedy.

Not that the system is new; its value had already been satisfactorily demonstrated at the sister city of Altona, in London, Paris, Berlin and elsewhere. But the Hamburg demonstration is the largest and most successful that has yet been made and the daily tests, prosecuted with rigid scientific accuracy, prove that a badly polluted river may be made to furnish a wholly satisfactory water supply for a large city.

CONSTITUTIONAL POWER OF CITIES TO PUNISH ADULTERATION OF MILK.

A city council may protect health, under its police power and statutes delegating authority to it, the Supreme Court of Louisiana holds, in *State v. Stone*, by prohibiting the adulteration of milk, and may adopt ordinances to that end. Such ordinances are not open to the objection that they transcend the limits of municipal authority; the purpose being the protection of public health. To secure such a

purpose, persons and property are subjected to many restraints and burdens. Those who directly feel the restraints and burdens are presumed to be rewarded by the common benefit secured. Ordinances prohibiting the adulteration of milk are designed to insure the purity of an article of food upon which many families are dependent. It is of universal consumption. So police regulations upon the subject are designed to prevent fraud and protect health. The standard adopted to test the purity of the milk can not operate to the exclusion of all other evidence upon the subject. Upon proof of the unreasonableness of the standard, that part of an ordinance relating to standard of purity of milk will be illegal, and amenable to the charge of unreasonableness.

REMOVAL OF LODGE PHYSICIANS.

Brendon v. Worley, decided by the General Term of the New York Court of Common Pleas May 7, 1894, was an action brought by a physician to recover for services rendered, as such, to a lodge. He was elected its physician, pursuant to a provision of the by-laws of the lodge that a legally qualified physician should be elected and remain in office during the pleasure of the lodge. The compensation was payable quarterly. No provision was made for the removal of the physician of the lodge at a special meeting, or one called for that purpose, nor was there anything inconsistent with the right of the lodge to discontinue its employment of the physician at a regular or stated meeting. Nor was any ambiguity apparent from the by-law for the election. Under these circumstances, the Court holds that, with the adoption of a resolution, at a regular meeting, for the physician's dismissal, and notice thereof to him, his employment must be deemed to have come to an end, and that he could not collect compensation beyond that time.

RIGHTS PENDING APPEAL FROM JUDGMENT REVOKING LICENSE.

The Supreme Court of Montana holds, in the case of *Board of Medical Examiners v. Kellogg*, decided March 19, 1894, that the staying, pending an appeal of the operation of a judgment revoking a physician's license is a matter of discretion in the trial court. Consequently, where such Court refuses to grant the stay, and there is nothing showing that its discretion has been abused, its action in the matter will be treated as final. Whether such an order staying proceedings on the judgment, as was sought in this case, for the purpose of permitting the former licensee to continue the practice of medicine, notwithstanding the revocation of his license, until review and final determination of the appeal to the Supreme Court would, if granted, stay the operation of the statute against one practicing medicine without license, and shield him from the prosecution and

penalty therefor, especially if the judgment revoking his license be affirmed, the Supreme Court says, is a question of grave importance, which would arise in the event of such a prosecution, but which it does not feel at liberty to determine in this collateral presentation.

PRIVILEGE DOES NOT EXTEND TO CRIMINAL CASES.

The rule as to privileged communications between patient and physician, the Supreme Court of California holds, in the case of *People v. Lane*, decided March 3, 1894, does not apply in criminal cases. The chapter on "Witnesses" in the California Code of Civil Procedure, limits the rule to civil actions, and the Penal Code, which expressly preserves the rule as to husband and wife in the chapter determining "who may be witnesses in criminal actions," makes no mention of physician and patient. At common law the rule as to physicians was not observed in either civil or criminal cases. The statutory privilege was not conferred to shield a person charged with the murder of another, and it certainly was not intended to be used as a weapon against one charged with crime.

CORRESPONDENCE.

Editorial Correspondence.

SAN FRANCISCO, CAL., June 4, 1894.

We left Denver at 2:30 A.M., May 31, and arrived at Colorado Springs at 5 A.M. It still rained, and the Pike's Peak railway having been washed out by the mountain floods, there was nothing to do but to see what we could of Colorado Springs. Mr. Buckman, of the Chamber of Commerce, informed us that the El Paso Club was open to the pilgrims and many availed themselves of the privilege.

Dr. Anderson invited a party to luncheon in the afternoon, and Dr. Solly invited a party to dinner. It rained too hard to go out and there was music and dancing at the "Antlers." There was no prospect of getting away by the Colorado Midland and the railway company finally concluded to send us to California by way of the Atchison, Topeka & Santa Fé, Mojave route, and we remained that night in Colorado Springs. Various members of the party were entertained at luncheon, by Dr. Moore, and Dr. Hunter took as many as possible out driving, the clouds having stopped dripping for the nonce. The mist lifted from the brow of the noble peak and the pilgrims had a good view of the monarch of the Rocky Mountains. We left Colorado Springs at 4:35 P.M. for California by the Southern route.

A word about Colorado Springs may not be out of place. There are no springs there; the springs are at Colorado City and Manitou—the former three and the latter six miles distant. The place seems largely dependent for support on the crop of valetudinarians who come to be harvested there. Our party were quite unable to judge of the merits of Colorado Springs as a resort for consumptives, on account of the almost incessant rain during the time of our visit. The physicians are clever, and the people hospitable and sociable.

Shortly after leaving the Springs we arrived at Pueblo, Col., which place was largely under water, owing to an inundation by the Arkansas River. The railway tracks and the lower part of the city were badly damaged. After much

difficulty our train was sent over the Denver & Rio Grande Railway to Trinidad, where we arrived about 5:30—owing to the wretched condition of the road on account of rains we only averaged about seven miles an hour on this part of the journey. We were at Trinidad furnished an extra engine and our train made about fifty miles an hour up to Raton, N. M., where we had an excellent breakfast. Here we had a fine view of the "Spanish Peaks," lifting their snow-capped tops grandly in the air. We dined at Larny, the Santa Fé junction, and took supper at Albuquerque, N. M. At the latter place the travelers visited the old town, peered curiously into the adobe houses built upon the narrow, crooked streets, saw the old Mission, now nearly three hundred years old. We then took a new train crew and pounded along on our way across the plains and up the mountains to Flagstaff.

I omitted to mention that Dr. X. C. Scott and Dr. J. E. Woodbridge and party rejoined us at Pueblo. They had anticipated a trip through the mountains on the Denver and Rio Grande Railway to join us at Buena Vista, Col., while we visited Denver, but their trip was cut off by the floods. They were finally taken in farm wagons about twenty-five miles, in the midst of a pouring rain, to Pueblo, where as already stated they found their way back to the ASSOCIATION train. Dr. Maclean's party that had intended to go with us via the Midland Railway, left Colorado Springs for Denver the same night. I inclose a list of them:

LIST OF DR. MACLEAN'S PARTY.

Donald Maclean, A. N. Collins, R. W. Gilman, A. W. Imrie, D. LaFerte, F. W. Mann, J. J. Mulheron, F. W. Robbins, F. B. Tibbals, W. G. Hasty, Detroit, Mich.; W. E. Burtless, St. Clair, Mich.; H. S. Chapman, F. B. Galbraith, Pontiac; W. T. Dodge, Big Rapids; H. Kremers, Holland; D. McLeay, Prarieville; C. G. Suylandt, Gladwin; H. D. Thomason, Albion; D. E. Fuller, Hastings; G. W. Stoner, Mich.; M. Stamm, Fremont, Ohio; A. L. Smith, Montreal, Canada.

Sunrise on the morning of June 3 found the ASSOCIATION train making only moderate time climbing the mountains near Flagstaff. The snow-capped San Francisco peaks were in sight, the air cool and the day bright, altitude 7,960 feet. We crept down the mountain about a thousand feet or thereabouts and breakfasted at Williams. From there we made a rapid descent to the Colorado River where it forms the California boundary, and the basin only 450 feet altitude. Certain high rocks here called the "Needles," give the station its name. Here we entered the great Mojave Desert, and after dinner at the "Needles" two powerful engines pulled us up to Barstow, Cal.

The ASSOCIATION train left the "Needles" at 7 o'clock P. M. June 3 and proceeded to Mohave, where it was turned over to the Southern Pacific Railroad. We breakfasted at Bakersfield June 4. A committee, consisting of Drs. Chas. Denison, X. C. Scott and the editor, having collected money sufficient for the purpose from the passengers, who very cheerfully responded to their request, a souvenir to consist of a gold watch chain with a suitably inscribed medallion, was presented to Mr. J. M. Connell, the efficient and courteous agent of the Santa Fe line, who had accompanied us during the long journey.

The presentation speech of the editor, as near as I can remember it, was as follows:

"Mr. Connell: I have been deputed by my colleagues of the committee, to present to you, on behalf of the passengers of the ASSOCIATION train, this souvenir as a token of our appreciation of your untiring energy, your uniform courtesy and the care with which you have attended to our wants and endeavored to facilitate our progress.

"We have crossed mountains, traversed floods, and tackled the steaks of Bakersfield, and through it all you have done your best to reassure the timid, to encourage the wearied, and generally to assist us in every way."

Mr. Connell, in replying, seemed visibly affected by the unanimity of sentiment expressed by the passengers, but he

distinctly disclaimed any responsibility for the Bakersfield steaks.

The Southern Pacific people pushed the train on its way with great rapidity, and we arrived in San Francisco about 4 o'clock, where some of the members of the Committee of Arrangements met us at the Oakland ferryboat. We found that Dr. Maclean's party had arrived a few hours before. Others by other roads arrived about the same time or a little later, so that it may be fairly said that the delegates from east of the Rocky Mountains were in San Francisco on the day before the meeting.

JOHN B. HAMILTON.

Letter from Europe.

PRAG, BOHEMIA, May 15, 1894.

To the Editor:—I have delayed writing until I had become fairly settled and sufficiently acquainted with the methods of work here to be able to give you in a few letters to the JOURNAL, as you requested, some idea of the methods of study in a German University and particularly some idea of what is being done in internal medicine. As I came abroad to do some practical work in pathology and clinical diagnosis, I shall not travel about from place to place to see different men, but shall remain at Prag until the end of the summer semester, the latter part of July. My letters may therefore be lacking in the interest that would come from change of scene and personages.

Prag is a wonderful mixture of the old and the new; it is a city of delightful surprises and of strange contrasts. Beautifully located in the valley of the Moldau, it has on the west a hill crowned by the venerable, imposing and historic Hradschin, the former capitol or citadel of the city, more than six hundred years old; on the east a hill, the Weinberg, covered with modern buildings, and with the gilded dome of the new Bohemian Museum shining in striking contrast to the somber gray spires of the old cathedral across the river. Crooked, narrow, mediæval streets bring one with a sudden turn into modern busy thoroughfares.

The mixture of the two races, the Germans or Teutons and the Bohemians (Czechs) or Slavs, does not, perhaps, seem as unnatural to one coming from a cosmopolitan city like Chicago or New York where one hears all languages, as to one coming from a city or town where practically but one language is spoken. But it does seem strange that after many years of commingling, the tendency of the two races to-day is to grow more and more separate. Of the three hundred thousand inhabitants of Prag about forty thousand are Germans. Their intelligence, industry and sobriety have given them more and more power until the Czechs view with alarm, or at least with envious jealousy, the riches, position and prosperity of their Teutonic neighbors. There is much bitter feeling between the two races, and one may find stores where only Czechish is spoken and this sometimes when the proprietors are able to speak the German language but where, unless one speaks Czechish one can not buy.

The University, the oldest in Europe, founded in 1348 by Charles IV., has two departments, a German and a Czechish. In medicine there are two faculties and two bands of students as distinct as two bodies of homeopathic and regular students. The hospital patients are divided, each faculty getting its proportion. This arrangement, now in vogue for eight years, seems to work well. Although the students mingle on the street and in the corridors of the hospitals common to both, there is apparently no clashing. I have naturally seen and heard only the German side and judge perhaps not impartially, that the medical work of the Germans is vastly superior to that of the Czechs.

The hospital buildings of the medical faculty show the

same striking contrast seen in other parts of the old town. Some of the work is done in buildings that must be hundreds of years old. The General Hospital was built in 1790 and enlarged about sixty years ago. It is far inferior in many respects to the more modern hospitals. It is being gradually remodeled, however. Thus I find that while the second medical clinic, that of Jaksch, has at its command several small, dingy old rooms, the first, under Pribram, has a pleasant, well-lighted amphitheater with nicely equipped rooms for the Professor and his assistants, a microscopic room, a bacteriologic room, etc., and wards that will compare well with those in more recently constructed hospitals. The Institutes of Anatomy, Pathologic Anatomy and Chemistry are all modern and leave little to desire in the way of construction and equipment. The Lying-in Hospital is also a large modern building. I shall try to speak later more in detail of these buildings and of the work done in them.

The fact that fine buildings are not necessary in order that good work may be done is well illustrated here. For instance, Jaksch in his not very inviting quarters has taught and studied so that now he is known over Europe, and America as well, as one of the leading authorities in clinical diagnosis. He feels, however, the need of better accommodations. He remarked to me the other day that probably nothing short of an epidemic of cholera where he was sure in his miserable quarters the death rate would be high, would induce the authorities to remodel or rebuild this portion of the hospital.

I was asked several times why I chose Prag in preference to some of the larger schools, such as those of Vienna, Berlin or Munich. The two names that drew me to Prag were those of Chiari and von Jaksch. I have not been disappointed in the men. And with the smaller number of students one comes very close to the professor and does not have to rely entirely upon assistants. These are not by any means the only strong men in the faculty. A faculty including, among others, such men as Huppert in chemistry, Huetpe in bacteriology. Hering in physiology, Rabl in anatomy, Gussenbauer in surgery, Rosthorn in obstetrics, is certainly one to be proud of.

In my next letter I shall try to speak more in detail of the work of some of these men. Very truly yours.

JAMES B. HERRICK.

A Correction.

PHILADELPHIA, June 4, 1894.

To the Editor:—In the discussion before the College of Physicians of the city of Philadelphia, on the registration of tuberculosis, on Jan. 12, 1894, I made the following statement: "Dr. Williams, of the Brompton Hospital, has been quoted as an opponent of the theory of contagion, but he has written a paper in which he shows that a large number of nurses of the Brompton Hospital have contracted tuberculosis. I think that he has traced some fifteen or twenty cases." Dr. Williams has since then called my attention to the fact that I misquoted his article, and a re-reading shows that this is true. In my speech I spoke from memory and entirely extemporaneously. The fifteen or twenty cases which I credited to nurses occurred among persons who had been employed in one capacity or another about the hospital and really only one case occurred in a nurse during her time of service. The time covered by Dr. Williams' investigation is thirty-six years. While I still believe that the conclusion which I meant to draw from Dr. Williams' paper, namely, that the experience of the Brompton Hospital can not be used as an argument against the contagion theory of tuberculosis, is correct, I deeply regret having

misquoted his article in letter and most cheerfully make the correction. Dr. Williams contends that his paper "furnished only one case of consumption contracted during residence among the Brompton nurses, and that a doubtful one, in a period of thirty-six years." Respectfully,

LAWRENCE F. FLICK.

ASSOCIATION NEWS.

American Medical Association.—At the opening of the general session of June 8, Dr. Holton presented the majority report of the committee on the revision of the Code of Ethics.

The minority report was read by Dr. Didama. On motion of Dr. Scott, of Pennsylvania, the minority report was substituted for that of the majority, and on motion of Dr. E. Fletcher Ingals this was laid upon the table.

The Committee on Nominations of the AMERICAN MEDICAL ASSOCIATION presented the following list of officers for the ensuing year, which was adopted without opposition: President, Donald Maclean of Michigan; First Vice-President, Sterling Loring of Ohio; Second Vice-President, William Watson of Iowa; Third Vice-President, W. B. Rogers of Tennessee; Treasurer, H. P. Newman of Illinois; Secretary, W. B. Atkinson of Pennsylvania; Assistant Secretary, G. H. Rohé of Maryland.

Board of Trustees—J. T. Priestly, J. E. Woodbridge, W. Graham, I. C. Patterson, Joseph Eastman.

Judicial Council—D. W. Crowse, R. C. Moore, T. D. Crothers, G. B. Gillespie, W. T. Bishop, H. C. Hughes, J. I. Heilberger.

Annual Address on Medicine—W. E. Quine of Illinois.

Annual Address on Surgery—C. A. Wheaton of Minnesota.

Annual Address on State Medicine—H. D. Holton of Vermont.

Secretary Atkinson announced the election of the various Section Officers, as follows:

Physiology and Dietetics—E. H. Woolsey, of Oakland, Cal., Chairman; C. G. Cloddock, St. Louis, Secretary.

Surgery and Anatomy—J. Ransohoff, Chairman; R. St. Sayre, Secretary.

Practice of Medicine—E. W. Kellogg, Chairman; W. E. Quine, Secretary.

Neurology and Medical Jurisprudence—D. R. Brown, Chairman; W. J. Gavigan, Secretary.

Obstetrics and Diseases of Women—C. N. Martin, Chairman; O. Worder, Secretary.

Ophthalmology—Edward Jackson, Chairman; H. V. Würdemann, Secretary.

State Medicine—Liston Montgomery, Chairman; C. H. Sheppard, Secretary.

Laryngology and Otology—J. F. Fulton, Chairman; T. J. Gallagher, Secretary.

Diseases of Children—E. H. Small, Chairman; G. N. Michel, Secretary.

Materia Médica and Pharmacy—W. Helpsey, Chairman; G. F. Hanson, Secretary.

Dermatology and Syphilography—A. E. Regensburger, Chairman; D. H. Rand, Secretary.

Dental and Oral Surgery—M. H. Fletcher, Chairman; E. S. Talbot, Secretary.

Baltimore was chosen as the next place of meeting, and Dr. Chisholm was elected Chairman of the Committee of Arrangements.

The question of the JOURNAL advertisements was referred to the Judicial Council.

The revision of the Constitution and Code of Ethics was indefinitely postponed.

The reports of Drs. Wingate and Comegys, favoring the establishment of a National Department of Public Health, were indorsed by the ASSOCIATION.

Resolutions were adopted favoring the transfer of the ASSOCIATION Library to the Newberry Library, at Chicago.

The salary of the Treasurer was fixed at \$300.

Resolutions on the death of Dr. John H. Rauch were adopted.

A resolution of thanks was tendered the retiring officers and the people of the Pacific Coast who had made the meeting a success.

PUBLIC HEALTH.

Decrease of Typhoid Fever.—Typhoid fever has decreased in Paris from 2,120 deaths in 1880 to 1,035 in 1886 and 533 in 1893, when the population was 2,350,000. Last year there were 676 deaths from disease in Chicago when the population was estimated at 1,600,000. The disease has, however, diminished remarkably in this latter city since 1891, when there were 1,997 deaths in a population of 1,322,000.

Alexandria's Water Supply.—The water supply of Alexandria is pronounced deplorable and a constant menace to the most important seaport town of Egypt. The defects, as pointed out by Koch in 1883, by Hobrecht subsequently, and now by Dr. Bilter, the Sanitary Inspector of the municipality, lie in the inadequacy of the filter beds; filtration exists only in name; bacteriologically the water is as impure after as before filtration, owing to the rapidity with which it is passed through the beds; each cubic centimeter of the so-called filtered water contains from 2,000 to 5,000 bacteria. The cause of the delay in applying the remedy is the usual one in Egypt—general bankruptcy and maladministration.

Leprosy in North America.—Based upon the statistics of the American Dermatological Association and of others, Dr. James Nevins Hyde reports that there have been 560 cases of leprosy in the United States, distributed as follows: Arkansas, 3; California, 158; Dakota, 2; Florida, 6; Georgia, 1; Idaho, 2; Illinois, 13; Indiana, 2; Iowa, 20; Louisiana, 85; Maryland, 4; Massachusetts, 5; Minnesota, 120; Missouri, 2; Mississippi, 2; New York, 100; New Jersey, 1; Oregon, 3; Pennsylvania, 6; Utah, 3; Wisconsin, 20. Dr. Hyde, while admitting that tuberculosis "exposes the health of our population to a greater danger than leprosy," nevertheless believes that the presence of leprosy in this country offers a constant menace to its inhabitants and "presents a problem in State and sanitary science which the general government alone can solve."

Contagion in Public Conveyances.—The *Boston Medical and Surgical Journal* calls upon the physicians in that city to discourage the use of public hackney vehicles for the conveyance of cases of contagious and infectious diseases to hospital, and cites the police regulation which forbids such procedure. There is a hospital ambulance for these cases, but the *Journal* admits, while urging physicians to its use, that there is no assurance against secondary infection traceable to the same ambulance being used for both scarlet fever and for diphtheria cases, and no assurance that the same pillows, mattresses and blankets are never used without precautions for more than one patient or that the ambulance is disinfected after each trip. However, this is a minor matter as compared with the menace to public health by the conveyance of infected persons in public hack vehicles.

Retrospective Sanitary Legislation.—For nearly eighty years every town in Massachusetts has had its board of health to which the people had a right to look for sanitary protection—a board either elected as such or, in the event of failure to elect, then the selectmen of the town *ex officio*. A correspondent in the *Boston Herald* calls attention to the fact that, by the provisions of Chapter 218 of the Acts of 1894, this provision has been repealed so far as all towns having more than 2,000 inhabitants in each are concerned, and the

voters in such towns may or may not elect boards of health as they see fit. The long-standing provision by which every town, no matter what its size, had its legally authorized board of health is now restricted to places of less than 2,000 population. This correspondent says: "Now it is nothing less than a sanitary axiom that increasing density of population requires the enactment of better sanitary laws for the protection of the people; and, since . . . this increase has been mainly in those towns which have a population of more than 2,000 in each, and not in the small towns, the legislation in this direction ought to be in the line of improvement and not of retrogression. Measures ought to be taken therefore, to remedy this defect before the close of the present session."

The Much-maligned Sewer Gas.—At one of the general sessions of the recent Congress of American Physicians and Surgeons no less than three papers on sewer gas were presented and in two of these the innocuousness of the air of sewers was advocated. It is asserted that exact methods of investigation show that, as ordinarily found, it does not differ conspicuously from the air we are accustomed to breathe; that there is a comparative poverty of bacterial life in sewer gas—that, in fact, more disease germs are found in the air of houses and school-rooms than in the air of sewers; that there is no conclusive demonstration that sewer gas stands in causal relation to the diseases for which it has been held accountable; that the worse the odor of a sewer the less the danger of contracting disease from it—particularly diphtheria, etc., etc. A writer in a recent number of the *Pall Mall Magazine* confesses to a melancholy amusement in reading similar statements in the scientific journals of our "kin beyond the sea." He finds it grimly diverting to now learn, "after the hundreds of sanitary tracts in which the deadliness of sewer gas has been an axiom of faith, after the thousand-and-one deaths from it in the contemporary novel, that it may be welcomed without fear to our hearths and homes;" and opines that "we may yet live to see it manufactured artificially for the improvement of the public health, and conveyed to our overcrowded drawing rooms with all the paraphernalia of pipes and the mendacious meter."

Cholera in Mecca.—Notwithstanding all that we have been told of the sanitary precautions enforced with the Mecca pilgrims, it is announced that Asiatic cholera has again broken out in "the holy city." What this foreshadows the student of cholera literature can best appreciate. Some more radical measures than have yet been resorted to are obviously necessary to secure the world against the propagation and spread of this disease by the Mohammedan devotees. The Moulvie Rafiuddin Ahmad has contributed to the *British Medical Journal* his views on the subject, which are of more than ordinary interest as coming from a Moslem of the Moslems. He holds the British Government responsible for the redress of the following grievances: Overcrowding of pilgrim vessels; neglect of sanitary measures on the part of the authorities on board ship; absence of wholesome food and insufficiency of fresh water supplied to the pilgrim passengers; absence of suitable medical aid (Mohammedan lady patients can only be treated by female doctors, therefore every pilgrim ship must have one male and one female doctor, both understanding at least two Mohammedan languages of the East); absence of suitable lodgings and competent doctors at quarantine stations. He concurs in the opinion of those who have studied the subject, that the Sultan should appoint a commission to inquire into the following: The principal sources of cholera in the Holy Land; the burial of flesh and blood of animals sacrificed during the Hadji; the condition of latrines and drainage in general; the purity and sufficiency of water supplied to the pilgrims; the poverty of the pilgrims; the hardship imposed upon pilgrims by enforced quarantine; causes of sickness

upon pilgrim vessels; the condition of houses occupied by the Hadjees; cases of extortion and official despotism; the best means of protecting the property of the Hadjees; prevention of danger to the life and limb of the Hadjees; how to secure a safe and comfortable journey to the pilgrims. He declares that the pilgrims "ask nothing but the barest necessities of human existence and the most essential rights of citizenship, namely, pure air, pure water, and security of life and property." He is discreetly silent as to the prospect of the British Government attempting to redress the grievances specified; points out that the expenses of the commission to be appointed by the Sultan must be defrayed by those interested in the sanitary improvement of Mecca and in its historic and religious features, since the Porte is in chronic financial straits; and makes an urgent appeal to the Sultan for his consent to the commission on religious and patriotic grounds.

MISCELLANY.

Mexico's Great Sanitary Undertaking.—It is announced by telegraph that on June 4, the civic authorities of the City of Mexico had entered into a contract for the completion of the great drainage works of the Mexico Valley. The estimated cost is \$3,500,000. The work is to be done on or before May 1, 1896.

The N. S. Davis Chair.—Mr. William Deering, a wealthy Chicago manufacturer, has given \$50,000 to the trustees of the Northwestern University, to endow a chair in honor of Dr. N. S. Davis in the medical department of the University—the old Chicago Medical College, of which Dr. Davis was the founder.

American Medical Editors Association.—The Association of American Medical Editors met at San Francisco June 8, and elected officers for the ensuing year as follows: President, John B. Hamilton, of Chicago; Vice-President, G. H. Gould, of Philadelphia; Secretary, H. B. Ellis, of San Francisco. The next meeting will be held at Baltimore during the session of the American Medical Association at that city.

The New York Woman's Medical College Commencement.—The "Blackwell institution" held her twenty-sixth annual celebration, with a graduating class of seventeen somber-robed lasses, on June 1. Mr. Robert Olyphant gave away the diplomas, the Rev. Dr. Bradley gave the address of warning to the graduates, and Dr. J. W. Roosevelt congratulated the Faculty on the exit of the class of 1894.

Sir James Paget.—On May 23, the eminent London surgeon celebrated his golden wedding-day. The General Medical Council of Great Britain, on that day, took the lead in presenting, through its president, a resolution of hearty congratulations to Sir James and Lady Paget respecting their half-century of eventful and happy wedded life. Hundreds of American physicians will join in the sentiment of congratulation and good will.

Localized Casualties.—Noting the statement of the *Medical World* that "we feel compelled to refer again to the poor woman who was shot in the oil regions some time ago," the *Medical Age* asks: "And why not drop a tear for the man who was fatally stabbed in the rotunda, and for him who was kicked on the highway?" whereupon the *California Medical Journal* recalls the case of the woman who was accidentally shot in the waterworks, and that of the man injured upon the long bridge.

Perils of Football.—The London *Lancet* has compiled a partial list of football casualties that occurred in England from October, 1893, to March 20, 1894. Ten deaths are recorded. The different British football games are considered. It concludes that: 1, football is dangerous; 2, contemporary changes have in some respects increased, in some respects

lessened, the dangers; 3, probably no modification in the law (so as to arrest the dangers) would leave the game as good a one as it now is from the athletic point of view. A drastic code is advised, favoring a sweeping and inclusive definition of that growing evil, "professionalism."

Indecency in Photography.—"Medicus," in the *New York Medical Journal*, doubts whether photographic illustrations of anatomical and surgical phenomena exhibited by the human body convey as clear and instructive ideas of the conditions worthy of attention as may be conveyed by outline illustrations and drawings. But he has no doubt whatever, and the profession generally will agree with him, that if photography is to be employed at all in depicting the human body and its organs, decency requires that, even in medical publications, the scope of the photograph should be confined to the parts in which the phenomenon noted occurs; that the rest of the body, being unnecessary to the demonstration, be left out of the field, or be suitably covered up.

Billroth's Successor.—To bend the bow of Ulysses, says the London *Lancet*, is proverbially a difficult undertaking, and to succeed a Billroth in the chair he adorned is an object of ambition to which few indeed legitimately aspire. Still, the duties of that chair have to be discharged, and the Vienna school has just taken the primary steps to fill it. At a meeting of its medical faculty three candidates were nominated for the post: *Primo loco*, Vincenz Czerny, Professor of Surgery in University of Heidelberg; *secundo loco*, Karl Gussenbauer, Professor of Surgical Pathology and Therapeutics in the University of Prague; and *tertio loco*, Johann Mikulicz, Professor of Surgery in the University of Breslau. There is little doubt that the first named surgeon will be appointed.

An "Extempore" Operation.—Just one week after the official announcement of the perfect health of Kaiser Wilhelm II, as detailed in a recent number of the *JOURNAL*, that sensational sovereign submitted to an operation for the removal of an encysted tumor from the imperial cheek. It was gravely explained, soon after, that the incident was entirely fortuitous; Prof. Bergmann having through a misapprehension, appeared at a *fête* to which he had not been invited, the emperor, in order to put him at his ease, suggested that he should operate for the entertainment of the guests, volunteering, at the same time, to furnish the tumor. Later advices would seem to show that, for an extempore performance, there had been ample preparation made; Prof. Bergmann was assisted by Profs. Leuthold and Schlange.

Medical Instruction in China.—The first session of the European Medical School at Tientsin, under the auspices of the Viceroy, Li-Hung-Chang, gives gratifying promise of success in this effort to spread modern ideas of medicine in the Flowery Kingdom. There are in attendance a class of twenty-three Chinese students, selected by examination at Shanghai and Ningpo, all of whom speak English. The lectures are given in accordance with modern methods, except that there are as yet no cadavers available for dissection and anatomy is, therefore, taught by wax models. On the recommendation of the late Sir Andrew Clark, the direction of the school has been put in the hands of Surgeon-Captain Heuston, of the British Army Medical Staff, who has taken out to the school a complete outfit for its laboratories, which will be made equal to the best modern laboratories in every respect. The first cost of the school was about \$24,000, and the income necessary for its maintenance is assured by annual contributions furnished by the native customs authorities of Chefoo and Tientsin.

Tramps and the Smallpox.—The tramp as a factor in the dissemination of the contagious diseases continues to be a subject of solicitude by sanitary authorities, not alone in

this country but abroad. A recent report by Dr. Armstrong the Medical Officer of Health for Newcastle-on-Tyne shows that of sixty-three towns in England, invaded by smallpox in 1892-93, more than one-half, 59 per cent., had the infection primarily from vagrants or tramps. In only nineteen out of the sixty-three towns was it reported positively that the disease was due to some other source, while subsequent infection by tramps occurred nine times in three towns, twelve, fifteen and eighteen times in one town each and no less than twenty-five times in the town of Nottingham. As a result of Dr. Armstrong's inquiries it is considered desirable: 1, that vagrants should be restrained in their powers of carrying infection about the country, especially during epidemics; 2, that they should be made to report their movements; 3, that they should, when considered requisite, be subject to disinfection and detention for such times as the sanitary authority of the district in which they are found may think necessary for the protection of the public health; 4, that in epidemic times all persons frequenting casual wards or common lodging-houses should be medically examined on admission; 5, that sanitary authorities and the police should have power to detain for medical examination any vagrant found in any public place.

Medical Missions at the "May Meetings" in London.—The great Church of England Society for Missions, depends largely upon its medical corps. At the "May Meetings" for 1894, the influence of medicine as a means to the end that is held in view by that Society was enlarged upon as never before. At one of the great gatherings held in Exeter Hall on May 18, the following statements were brought forth by the medical representatives there present:

"Dr. Herbert Lankester presented a report, in which it was stated that the first medical missionary of the Society was William Welton, a Suffolk surgeon, who was ordained forty-five years ago, and went to Foochow. Until 1870, however, they had only two unordained medical missionaries. Now they have twenty-five, besides one who was ordained, and one lady. These all had British qualifications, some being of the highest order. There were also medical men with native qualifications working in Palestine and the Punjab. Until 1891 the Society only granted \$500 for each missionary, who had to collect what more was needed. They now raise \$5,000 among themselves. Rev. F. E. Wigram, who occupied the chair, said that opportunities for evangelizing the people were obtained by medical missions which could be got in no other way. Rev. Dr. Elliott said that he had spent six and a half years at Gaza, a most fanatical Moslem town, where other Christian work was forbidden, and he had been freely allowed to preach Christianity to his patients, whose numbers sometimes reached 180 a day. When he went to Gaza there was not another medical man, with either British or Turkish qualifications, in a population of 28,000. There were only quacks, *who beat girls black and blue for hysteria*, and gave as a panacea for serious fevers the water with which the name of Allah was washed off a dish on which it had been written. Scientific treatment came as a revelation to the people of all classes, and had a wonderful effect in breaking down prejudices. It was a remarkable fact that the Jews in Jerusalem braved the excommunication of their rabbis and went to the Christian doctors of the London Jews' Society, rather than to the hospitals amply equipped and freely opened by European Hebrews such as the Rothschilds."

Professor Czerny Succeeds Billroth: A Great Work Proposed.

—Dr. Vincenz Czerny, of Heidelberg, Billroth's "most distinguished pupil," has been invited to the post of Lecturer on Clinical Surgery in the University. It is stated in the London *Lancet* that Czerny at first refused to take the chair, but afterwards consented on the proviso that the authorities would undertake to remove certain drawbacks, local and architectural, against which Billroth, with all his force and prestige, had long struggled in vain. Changes will be made by the demolition of old buildings and by the erection of a series of new buildings for medical and surgical instruction on the site that was identified with Billroth's career. Czerny's acceptance of the position has hinged upon the ex-

ecution of plans little different from those that were the cherished aim of Billroth's maturer years; one of whose objects was the founding of a suitable museum of pathologic specimens accumulated by himself and his pupils in intestinal surgery and other preferred branches. These changes will in effect, be a kind of monument to Billroth, rendered possible by the fealty of his former associate to his, Billroth's, conception of what Vienna owed to the cause of surgery, if not to the master in his lifetime. The praiseworthy insistence of Czerny, as the *Lancet* remarks editorially, indicates the *esprit du corps* that has been observed again and again in the highest walks of science and the healing art of Germany, having for its recent and most effective parallel the animus disclosed by Pettenkofer on behalf of sanitary science. When he was asked by the civic authorities, says the *Lancet*, what best reward they could furnish him as a return for his sanitary achievements for Munich, Pettenkofer's reply was: "Build a sanitary institute." These great lights of Germany are zealous to make it easier for their successors to reach results than they have found it, even in the greater universities. While Billroth's efforts towards a higher standard of clinical facilities were frustrated in his own lifetime, Czerny will see to it that his master's ideals are in part at least, materialized without delay. Czerny himself will doubtless reap some of the advantage, from the important changes proposed, as well as the University, and science and the faculty of the future.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from June 2, 1894, to June 8, 1894.

First Lieut. EDWARD L. MUNSON, Asst. Surgeon, upon being relieved from duty at Camp Merritt, Mont., by First Lieut. WILLIAM H. WILSON, Asst. Surgeon, will proceed without delay to Ft. Yellowstone, Wyo., and report to the commanding officer, for temporary duty with troops in the National Park during the season.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending June 9, 1894.

Medical Inspector GEORGE A. BAIGHT, detached from U. S. S. "Newark," ordered home and granted three months leave.

Surgeon R. A. MARMION, detached from Smithsonian Institute, and ordered to the U. S. S. "Newark."

Medical Inspector D. MCMURTRIE, ordered to the Smithsonian Institute.

VOL. XXII.

CHICAGO, JUNE 23, 1894.

No. 25.

ADDRESSES.

VACCINATION.

The Address of Section on State Medicine, Illinois State Medical Society, 1894.

BY WM. E. QUINE, M.D.

CHICAGO.

President Illinois State Board of Health; Professor of Practice of Medicine and Clinical Medicine, College of Physicians and Surgeons, of Chicago, and President of the Faculty.

Vaccination was introduced to the attention of the medical profession by Edward Jenner in 1798, as the result of twenty years of investigation.

During the century preceding, according to the estimates of our most authoritative statisticians, smallpox, "the most terrible of all the ministers of death," destroyed in Europe alone 50,000,000 human lives.

Think of it. Five hundred thousand deaths every year from the most loathsome pestilence known to man; thirteen hundred deaths every day; nearly a death every minute for a hundred years!

If it be true, as is believed by enlightened people the world over, that universal vaccination and re-vaccination, efficiently done, can put an end to the desolation and horror of epidemics of smallpox and possibly eradicate the disease altogether, it would appear that the discoverer of vaccination is the greatest benefactor that mankind has known.

Alexander was great. Cæsar was great. Hannibal was great. Napoleon was great. They were all great as destroyers. But what have they done; what have all the warriors and conquerors of earth done in comparison with this one member of the medical profession, in the direction of *adding* to the sum total of human happiness and human life?

Is it too much to say that wide-spread epidemics of smallpox are now entirely unnecessary in civilized lands? Is it too much to say that such epidemics are always the result of negligence, that they are always preventable, and that their occurrence is a crime against civilization for which the medical profession is largely responsible? Take a glimpse of what vaccination has already accomplished and then try to imagine the results of its universal, systematic and thorough employment by physicians whose high-conceptions of duty and most serious efforts relate to the prevention of disease.

During the epidemic in Marseilles in 1804, 8,000 unvaccinated citizens furnished 4,000 cases of smallpox, and 30,000 vaccinated persons furnished only 2,000 cases.

During the same year six negro children were vaccinated and then shipped aboard a vessel bound for one of the Seychelle Islands to perform quarantine service for smallpox. For three months the children were exposed to the contagion in every conceivable way. They slept under the same blankets with the

sick and in contact with their pustules. They were inoculated again and again with the virus taken from those pustules and yet they continued in undisturbed health every minute of the time.

During the Franco-German war of 1870-71, the number of deaths from smallpox in the vaccinated German army was 261, and in the unvaccinated French Army it was 23,469.

In Berlin in the year 1872 the mortality of the disease was 243 per 100,000 population and the year after it was 262. Thereupon vaccination during the first year of life and re-vaccination at the age of 12 years was made compulsory by law,—and with the effect that in the year 1875 the death rate was lowered to 36 per 100,000 inhabitants; the next year it was lowered to 31; the next to 3; and so on through later years with an average annual mortality of one and seven-tenths per 100,000 people. During the year 1890 only fifty-eight cases occurred in the whole German Empire, or one and eighteen-hundredths cases to each million of population.

A village in Leicestershire (England) of 1,300 inhabitants was visited by the pestilence in 1872. All but two of the inhabitants were efficiently vaccinated and escaped the disease; whereas the two unvaccinated persons died of it.

The late Dr. J. H. Rauch, for many years Secretary of our State Board of Health, has shown that in the Illinois epidemic of 1881-83, the mortality rate of the vaccinated was approximately 6 per cent. and of the unvaccinated it was 49 per cent.

Corbally has demonstrated that, in the Sheffield (Eng.) epidemic of 1887-88, vaccinated children were, as compared with the unvaccinated, twenty times less liable to attack from smallpox and twenty-four times less liable to die when attacked. That is to say, the vaccinated children had, as compared with the unvaccinated, four hundred and eighty fold security against death from smallpox.

In the Halifax (Eng.) epidemic of 1892-93, the death rate from smallpox among vaccinated persons was 1.8 per cent. and among the unvaccinated it was nearly 41 per cent. No case occurred in a vaccinated child under 5 years of age and in the Leicestershire epidemic of 1893 no case occurred in a vaccinated child under 10 years of age.

From the records of 5,000 cases treated in the Municipal Hospital of Philadelphia, (W. M. Welch, in the *New York Medical Journal*, March, 1894) it appears that the death rate in that institution in post vaccinal cases,—and all in which there had been an attempt at vaccination are included,—was 16.26 per cent.; and the death rate in the non-vaccinal cases was 58.38 per cent. Seventy-three per cent. of the cases in unvaccinated infants under one year of age ended in death and no fatal case occurred among vaccinated infants of the same age. Between the ages of 1 and 7 years the mortality of post vaccinal

cases was 5.7 per cent., and of non-vaccinal cases it was 51.5 per cent.

In Chicago only seventeen cases of smallpox have occurred in the last fifteen years among the well vaccinated public school children of that city whose average number exceeded two hundred thousand.

The foregoing are a few illustrations of the utility of vaccination. I could easily occupy your time for hours with statistical quotations from standard authors, for thousands of pages of authentic medical literature are teeming with illustrations of a like kind; but longer continuance on this line of exposition would be wearisome and it could serve no other purpose than that of emphasizing what has already been demonstrated. Physicians everywhere have encountered striking examples of similar bearing; and, as individual experiences may make a more intelligible impression on some minds than any aggregation of figures, I make free to include a few of them.

From numerous memoranda furnished by my friend, Dr. A. R. Reynolds, Health Commissioner of Chicago, I select the following at random:

1. A mild case of smallpox ended in recovery. In the family were five vaccinated persons and five unvaccinated. Every one of the vaccinated persons escaped and every one of the unvaccinated contracted the disease.

2. A non-vaccinated child 5 years of age developed the disease. The family included eight other children and the parents. Five were vaccinated and six were not. Of those vaccinated one contracted mild varioloid—the others escaping; and of the non-vaccinated every one developed confluent smallpox.

3. A case of smallpox in Pullman, regarded by the attending physician as one of chickenpox, ended in recovery. About twenty-five persons were exposed, all of whom except three were vaccinated. These three contracted the disorder and two of them died. Of those tardily vaccinated one died of smallpox and three recovered from varioloid. The one who died was the doctor who made the mistake in diagnosis.

If I were addressing an exclusively medical audience I should feel ashamed of appearing to think it necessary to cite proofs of the efficiency of vaccination as a life-saving device, since nothing in the whole domain of human experience is more clearly and strongly established than this. Intelligent physicians everywhere are well aware that liability to smallpox is enormously lessened by vaccination, as is liability to death when smallpox actually appears.

When shall Vaccination be Done?—In view of this fact it would seem that the protective influence of vaccination can not be invoked too early in life. Smallpox is a disease of infancy and childhood. Children are more liable to contract it than mature adults and when they do contract it they are more likely to die; hence there is imperative reason why they should be vaccinated soon after birth. In some countries this is made compulsory by law. Physicians the world over, urge that vaccination be done during the first year of life and when smallpox is prevalent they demand that it be done within the first three months of life. If there be certainty, or even strong probability, of the exposure of the newborn to the contagion, it should be thoroughly vaccinated immediately after its birth.

How Soon after Vaccination does Protection from Smallpox begin and When does it become Perfect?—This

is a very important question for it frequently happens during an epidemic of smallpox that an exposed and susceptible person has the opportunity to watch, in his own life, a race between the protective power of vaccine lymph, tardily inoculated, and the infection of pestilence which had gained entrance to his body. Protection begins about the fourth day after efficient vaccination and is perfect on the eighth or ninth day. On the other hand, the incubative period of smallpox is ten or twelve days,—say ten days. By "incubative period" is meant the time intervening between exposure to contagion and the appearance in the individual of the evidences of the resulting disease. The period is not uniform as the poison or contagion may linger in the clothing for some time after the exposure occurred and its absorption be delayed. It is obviously the part of prudence to regard the minimum period of incubation,—ten days,—as the period likely to obtain in any given case. Accepting this as a fact and remembering that the protective influence of vaccination begins on the fourth day and is perfect on the eighth, it follows that a person may be protected from smallpox even a couple of days after he had been exposed to it by efficient vaccine inoculation. If vaccination be well done within forty-eight hours after exposure, the exposure proves harmless; if it be delayed till seventy-two hours the victim is likely to develop varioloid; and if it be delayed till ninety-six hours it makes little or no impression on the consequences of that exposure.—(Trousseau).

How long does the protective power of thorough vaccination last? The term is different in different individuals. Many can be successfully vaccinated but once in a lifetime, and others can be successfully vaccinated again and again. In the great majority of cases one attack of smallpox confers immunity for the remainder of life; but there are individuals who have the disease again and even die of a second or third attack. The degree of protection against smallpox conferred by vaccination gradually diminishes in most persons, until approximately the original liability to the disease is finally re-established. One could not reasonably expect greater protection from an attack of cow smallpox (*i. e.*, vaccinia or vaccination) than is conferred by a previous attack of human smallpox, and since a person may have a second or a third attack of human smallpox, it is not surprising that he may die of human smallpox after he has been thoroughly inoculated with the cow smallpox and exhibited the characteristic manifestations of that disease. The longer the interval since efficient vaccination the less is the protection conferred by it. We have already learned that it is extremely rare for a well-vaccinated child under 10 years of age to develop smallpox, and that when the disease does appear it is almost invariably of the modified and mild type known as varioloid. However, it is well known and important to keep in mind that any severe sickness, such as typhoid fever, is liable to greatly impair the protective influence of vaccination, even to the extent of destroying it altogether. It is maintained by some of the most authoritative writers of the day that there is not a single case of smallpox, of authentic record, as having occurred within a period of seven years after a typically successful vaccination. This conclusion does not preclude the propriety of universal re-vaccination every time the smallpox becomes obtrusively prevalent.

The problem that confronts us is, not how few vaccinations can be gotten along with, but how to employ the benign measure so as to escape liability to smallpox with infallible certainty. Vaccination and revaccination, efficiently and frequently done, is the only known means of securing absolute immunity; and if the practice of efficient vaccination and revaccination ever becomes universal, then human smallpox will become a thing of tradition and history. Every person should be carefully and thoroughly vaccinated at least three times—during the first year of life; about the time of puberty; and again between the ages of twenty and thirty years. If this be done, and well done, the individual will have good protection for life; but let me repeat that another vaccination is always proper, and on the side of prudence, whenever smallpox becomes extensively prevalent.

Abortive and Worthless Vaccination.—Vaccine lymph is a very perishable substance and rapidly deteriorates on exposure to a warm atmosphere. This is particularly true of the bovine lymph furnished on the bone "points" now in universal use. The lymph or "virus" may be of good quality when purchased, but after it has been carried in the vest pocket a few days it is liable to be worthless. Formerly, propagators and dealers took the pains to protect the "points" from the air by a covering of cotton batting and rubber tissue; but this is rarely, if ever, done now. The absence of reasonable evidences of care in the collection and preservation of the lymph is in pitiful contrast with the magnitude of the interests involved. The only propagators in this country who take any pains at all to protect the "points" from the atmosphere and from unnecessary handling—hence, from liability to contamination—are those of the "National Vaccine Establishment," of the District of Columbia.

However, it is asserted by high authority (Pepper) that, in times of active demand for virus, propagators have been guilty of applying irritants to the sores on the udder of the heifer with a view to increasing the product. The sero-purulent discharge resulting from such applications was used to coat the bone "points" and the latter were then foisted upon the profession as pure bovine virus. And this is not all. I feel certain that dealers sell, at times, points that have been prepared by dipping the pieces of bone in an aqueous mixture of bovine scabs. The granular and dirty appearance of such "points" is plain enough to evoke instant attention and condemnation. In view of these considerations, is it difficult to understand why bovine lymph is unreliable and why, now and then, unpleasant and unnecessary complications attend the use of it? If bovine lymph were collected and preserved with such admirable care as obtained with humanized lymph when every doctor propagated and preserved his own supply, there would be greater uniformity of effect and the reputation of vaccination would be less frequently marred by "accidents." Every "point" of bovine lymph is an experiment. A susceptible person may be inoculated repeatedly without any effect whatever—and particularly without the effect desired. Commissioner Reynolds informs me of a person who had been unsuccessfully vaccinated *thirteen times*. The fourteenth attempt yielded a perfectly typical result. Can you not understand, then, how a person who has been "vaccinated" may readily contract smallpox when exposed to it? It is

easy to comprehend the "insusceptibility" to vaccine lymph which many persons claim. Apparent "insusceptibility," when not due to a previous attack of smallpox or to a previous genuine vaccination, is due, in probably every instance, to worthless virus or to the careless and incompetent use of good virus. Carelessness on the part of the doctor is responsible for much damage to the effectiveness and reputation of vaccination.

The operation is so simple and familiar and so generally successful and free from unpleasant intrusions of any kind, that it is habitually performed in a perfunctory or indifferent manner. In many instances the doctor does not learn whether it has been successful or not. In many instances he certifies that a school child is well protected against smallpox, without having examined the child at all or knowing anything about its vaccinal condition. In some instances a person is practicing as a physician who does not know a normal vaccine sore from a spurious one—a typical scar from an atypical one—success from failure.

In order that vaccination be effective it is essential that it be normal in every respect. When the arm gets to be enormously swollen, and very painful, and the patient very ill in consequence; or when a slough has formed and, separating, leaves a large suppurating ulcer which heals slowly and makes an ugly scar; it is commonly assumed by the uninitiated that the vaccine virus has taken with admirable vigor and that the fortunate individual is exceptionally well protected; whereas, in fact, the vaccination is spurious and may confer no protection whatever. The process of development of the vaccine sore and the scar following, constitute the basis of a rational opinion as to the efficacy of the vaccination. A typical scar may be accepted as a proof of good vaccination. Such a scar may preserve its characteristics throughout life or it may fade away. It is often impossible, after the lapse of years, to tell from the appearance of the scars whether the vaccination had been a success or a failure. Thousands of persons who rejoice in the possession of large and deep scars have no protection at all against smallpox; and if they contract the disease and survive it they are found on exhibition ever after as living proofs of the inutility of vaccination. But some of them do not survive. Nearly half of them die. Are we of the medical profession guiltless in such cases? No, sir! We are guilty of trifling with human life and of bringing into disrepute by reason of our carelessness and lack of appreciation of the magnitude of the issues, one of the most beneficent and harmless of the measures of protection vouchsafed to our race. Every doctor is perfectly satisfied with the completeness of his knowledge of the subject and yet how many would be able to sustain themselves creditably in debate with a well-informed anti-vaccinationist? We are so well satisfied with what we know that many of us never read a page on the subject in all our lives. And yet what is there in medicine or surgery that has the life-saving power of vaccination? Is this an unimportant measure, or is it one of the finest applications of biologic science? Our young graduates have been thoroughly instructed in appendicitis and in intestinal anastomosis but they do not know a typical vaccine sore from an example of pemphigus.

Fortunately, however, the epidemic of appendicitis

is on the decline and our teachers may be able to find time to say a few words about vaccination.

It is not sufficient that a person be vaccinated; he must be thoroughly vaccinated. It appears highly probable from the statistics of Marson, Simon, Trousseau and Welch that one point of vaccine inoculation does not confer as reliable protection upon the individual as do two or more points of inoculation. In view of the unreliability of the bone "points" of bovine virus in common use, the imperative necessity of using two or more of them on each person vaccinated is obvious. In Europe, vaccination is done with much greater thoroughness than is the rule in this country. There they vaccinate. We vaccinate. They take pains to saturate. We do not. When they get through we find three or four scars on each arm. We are through when the patient has two scars. In view of these various facts is it surprising that we have an outbreak of smallpox every few years? The subsidence of an epidemic lulls us into the negligence of fancied security; spurious vaccinations mislead; the immunity conferred by genuine vaccination, dwindles away; children are not vaccinated till they reach the school age and many are not vaccinated then; a case of smallpox is imported and lo! another epidemic appears. How many lessons of this kind are necessary to arouse the medical profession to a proper sense of duty and the community at large to a common sense appreciation of the demands of self-protection? The experience of the world has demonstrated again and again with terrible impressiveness that so long as unvaccinated children are allowed to accumulate, and so long as people continue to neglect renewal of immunity by revaccination, epidemics of smallpox are certain to make their appearance. Such epidemics are a hideous disgrace to civilization. The disease is preventable. It is eradicable. And yet I question if a particle of progress has been made in the direction of eradicating it from our country during the past quarter of a century. We do just as our predecessors did—vaccinate furiously when smallpox becomes, or threatens to become epidemic, and then neglect vaccination till the next epidemic arrives. Carelessness is growing and the results of it are multiplying. "In England and Wales where there is a law requiring vaccination in the first year of life the number of unvaccinated children over one year of age has been steadily increasing of late years."—*British Medical Journal*.

Dangers and Complications.—"It is estimated by competent authority that 22,000,000 people are vaccinated annually."—(Pepper.) The course of a normal vaccination extends over a period of three weeks and every derangement of health within that time is likely to be ascribed to impure lymph. It is obvious that among 22,000,000 people a great deal of sickness is certain to occur every day quite independently of vaccination. But it is not denied that vaccination is responsible for some of it. In view of what has already been said about errors—if that is the right word to use—in the collection and preservation of virus, some admissions at the present time would have, not only the merit of truth, but the charm of logical continuity. My friend, Dr. Gehrman, of Commissioner Reynolds' staff, has examined a great many "points" microscopically and found pus and pus-producing microbes (staphylococci) on nearly every one of them, to say nothing of microbes of other kinds from atmospheric contagion.

Erysipelas.—This is the pest of vaccination and the cause of the only fatalities that have come within the range of my investigation. When it appears within twenty-four or forty-eight hours after the inoculation, and especially if the vaccinal abrasion was made with the bone point, it is almost certain that the erysipelas is due to streptococcus infection of the "point;" but if the appearance of the complication be delayed much longer than twenty-four hours it is probably caused by infection of the abrasion from other sources. The skin, clothing and atmosphere are always contaminated with pyogenic microbes, and various other kinds as well, under ordinary circumstances of city life; but there is no doubt in my mind that erysipelas results much more frequently from the use of carelessly collected and distributed bovine virus than it did in years gone by from the use of *carefully* collected and preserved humanized lymph. But the fatal objection to the use of humanized lymph—its liability to contamination with syphilitic virus—does not apply to the product of the heifer, since the human species enjoys—no, it does not *enjoy*, but it possesses—practical monopoly of the venereal diseases—a gonococcus and a cocco-gonus trust. With the single exception of syphilis, vaccinal complications are more common to-day, I believe, than ever. Inflammation of various kinds and degrees, from a simple erythema to an intense phlegmonous process, gangrene and septic pyemia, occur in rare instances—but they are by no means as rare as they would be if propagators, dealers in and users of bovine virus were alert and actively conscientious in the discharge of duty. A little tenderness and swelling of the axillary glands, rarely advancing to suppuration, now and then mars the course of normal vaccinia, but it is a transitory and unimportant affair. Here and there a physician is heard speaking loosely but positively of the liability to inoculate tubercle bacilli with bovine lymph. So far as I have been able to learn, tubercular infection has never been known to result from vaccination. Conceivably, nay, undoubtedly, a latent tuberculosis of neighboring lymphatics may be aroused into active progression by the process of normal vaccination—or cow smallpox—as it may be by any other process of local irritation or constitutional derangement. The popular prejudice against vaccination, based on the knowledge that constitutional diseases *have* been inoculated with contaminated lymph, has stimulated scientists to attempt to cultivate the lymph—or the essential ingredient of it—on artificial media; but without the slightest show of success. Six cases of tetanus are charged against it—to say nothing about skin eruptions of various kinds. The flippant readiness with which *post hoc, ergo propter hoc*, arguments are used against vaccination by ignorant and prejudiced persons, is well exemplified in the testimony offered during a recent trial in Terre Haute, Ind., where the principal of a public school had been enjoined from enforcing the order of the local Board of Health to exclude unvaccinated children. A venerable and well-preserved anti-vaccinationist, 70 years of age, testified that he had been vaccinated sixty-eight years ago and had been struggling against the evil effects of it ever since. Poor old man! True, he had never died of the smallpox, and never had had the disease at all; but there is no telling how old he would be now, if he had not been vaccinated. Another witness testified that he had been vaccinated on

the arm and six years later a running sore made its appearance on his leg. Yes, sir! On his leg! Spread the knowledge of the contaminating and bestializing effects of vaccination and let organized resistance be strengthened!

Every physician of large experience has seen vaccinal complications of various kinds; but it is extremely rare for death or permanent injury to result from them. A fair idea of the actual danger may be obtained from contemplating the following facts: Since Jan. 1, 1894, Health Commissioner Reynolds, of Chicago, has supervised 320,000 vaccinations, and two deaths have been ascribed to the inoculation of impure lymph—or to a complicating infection of some kind. Dr. O. C. De Wolf, former Health Commissioner of Chicago, reports 250,000 vaccinations without a seriously hurtful consequence of any kind. The late Dr. J. H. Rauch, for many years the efficient and honored Secretary of our State Board of Health, testified before the Royal Vaccination Commission of England that during the smallpox epidemic in Illinois during the years 1882–83, he had conducted and supervised 250,000 vaccinations, and had never seen or known of a more serious complication or sequel than temporary inflammation of the axillary glands and now and then a sluggish, slowly healing ulcer on the arm. I estimate that the family physicians of Chicago have vaccinated as many persons, probably, as have been vaccinated by the assistants of the Health Commissioner. The aggregate number exceeds a million—and there have been two *alleged* deaths. This represents the dangers of vaccination when done in reckless haste and carelessness—or, at least without the slightest pretense of attention to precautionary details. Assuming that such fatalities are unavoidable—but they are not unavoidable; they are the result of criminal carelessness somewhere—and contrast the smallness of the danger with the magnitude of the protection. A recent report of the Local Government Board of England shows that unvaccinated children under 10 years of age are twenty times more liable to take smallpox and twenty times more liable to die when they do take it, than vaccinated children of the same age. It also shows that unvaccinated persons over 10 years of age are five times more liable to take smallpox and twenty times more liable to die when they do take it, than vaccinated persons of the same age; their life prospects during an epidemic of smallpox being rated as ONE TO FIFTY-FIVE.

I have said that fatal complications are avoidable. The fact that only two cases of the kind have occurred in over a million vaccinations is proof enough of that. If further proof were needed it would be found in the official Governmental reports on vaccination in Germany which show that in the year 1890 there were 2,485,485 vaccinations in that Empire without a single fatality.

Accidents are not an argument against vaccination but they are an argument against the careless performance of vaccination. There is not a single instance in the whole history of the human family of a person, previously in good health, being killed or seriously injured by inoculation with pure vaccine lymph. Complications result from the use of contaminated lymph or from the use of scabby or purulent substitutes; and the propagators and dealers are largely responsible for the bad results. It must be admitted in this connection, however, that the bone "points" may be genuine and pure when they leave

the hands of the propagator and that contamination may result from subsequent handling and exposure to the atmosphere. It must also be admitted that infection of the vaccinal wound may result from the unclean skin and clothing of the individual and from exposure to the atmosphere. We have already learned that pus producing germs are well-nigh everywhere—on apparently clean skin, on spotless clothing, and in apparently pure air; and they, not to speak of other germs, are liable to invade a vaccinal wound even when some attempt is made to exclude them, and any attempt to exclude them is not made once in a thousand times.

The means of protection against accident are well understood by every intelligent physician. We must have pure lymph to begin with and it must be protected from atmospheric and contact contamination by being kept hermetically sealed until brought into actual use. The skin of the patient and the hands of the doctor must be clean—in the surgical sense—that is, free from microbes. When the vaccinal abrasion is made and the moistened lymph on the bone point rubbed into it, the abrasion is to be properly covered with an aseptic dressing so as to exclude hurtful germs. These measures will be regarded by the multitude as somewhat fantastic and unnecessary; and by our local political economists—the bar-room politicians—they might be "viewed with alarm." The employment of such measures would make public vaccination five to ten times more expensive than it now is. Assuming that it would take fifteen minutes longer to vaccinate this way, than it does the familiar way; and applying the assumption to the 320,000 vaccinations of the Commissioner of Health, what do we find? Quarter of an hour consumed by each person; 80,000 hours by the 320,000 persons. Ten hours a day's work; 8,000 days—over twenty-five years. Our city vaccinators get \$900 a year; \$22,500. Now, assuming that every bone point had been perfectly pure, and vaccination had been performed aseptically at a total expense of \$22,500; the two lives alleged to have been destroyed by careless methods would have been saved. If propagators supply us with pure lymph, protected from the air and from unnecessary handling, vaccinal complications will become so rare as to be classed among the curiosities of experience.

Anti-Vaccinationists.—Organized resistance to vaccination is much less formidable in our land than it is in England and Wales; and it is interesting to note that much of the opposition discovered in this country comes from people of the lowest grades of intelligence and character who had been compelled to submit to vaccination laws in their native home. "They are agin the government." But their fantastic and disorganizing conceptions of "personal liberty" do not put them beyond the reach of reason; on the contrary, they are readily responsive to a fair presentation of the subject. A few resist vaccination because they prefer not to be inconvenienced by it. They are "not afraid of smallpox," you know. But the genuine anti-vaccinationist is the person of incomprehensible mind who goes by the name of "freak." He is, in some instances, a citizen of education, position, refinement and influence, whose reasoning powers are dominated by a prejudice against vaccination which amounts to positive abhorrence and loathing. He is ready with *post hoc* arguments, false statements and factitious statistics and

is a pestiferous nuisance and an impediment to sanitary progress. He founds "anti-vaccination societies." He gets on school boards for no other purpose than to resist vaccination ordinances. He enjoins sanitary officers and makes us feel like vaccinating him with a pistol. He is at the aggressive end of lawsuits now in various parts of New York, Pennsylvania, Ohio, Indiana, Iowa, Illinois,—doubtless in other States. There are people who profess to regard smallpox epidemics as processes of wholesale purification, beneficent visitations of Providence. Vaccination they denounce as bestializing and as being on the one hand, incapable of any good to the human family, and on the other, as being responsible for multifarious and hideous ills. They do not know that "vaccinia," "cow pox," "cow smallpox," is human smallpox modified and mitigated by transit through one of the cleanest of God's creatures,—whose milk they drink and whose flesh they eat, every day.

Compulsory Vaccination.—It is easy to understand the need of laws, or of adequate provision of some kind, for the protection of communities against the consequences of habitual inattention and of organized opposition to vaccination. Such laws do exist in nearly all the European countries and in Japan, Egypt and Manitoba; but in most countries the laws are not only inherently inadequate but inefficiently administered as well. In England, the birthplace of vaccination, where the law requires infants to be vaccinated during the first year of life and makes no provision whatever for re-vaccination, the number of unvaccinated children under one year of age is steadily increasing from year to year. In Germany the law compels vaccination during the first year of life and again at the age of 12 years; and soldiers, on entering the army, are again vaccinated without reference to their previous vaccinal history. These laws have been in operation since 1875; and when I say that there has not been a death from smallpox in the German army since the year 1874 and that the death rate from this disease for the whole German Empire is only *one and seventeen-hundredths* per each million inhabitants; and when I add that 2,485,485 vaccinations were performed without a single fatality; there is no need of any other argument.

In this country there are no compulsory laws. In many States there is provision for excluding unvaccinated children from the public schools; and in some of them punishment for non-compliance with the law is prescribed. But there is no law which compels vaccination. In our own State, unvaccinated children are denied the privileges of the public schools; but, if school directors happened to be anti-vaccinationists and refuse to enforce the law there, is no provision for compelling them to do it or for punishing them for not doing it. *But the State Board of Health can close the school.* These school laws are vigorously resisted in many quarters and two suits are now pending in Illinois. Such contentions invariably eventuate in the defeat of the enemies of vaccination. In every instance the State Board is willing to relieve local authorities from the responsibility of enforcing the law and of defending litigation growing out of such enforcement. This is not compulsion for it leaves to everybody the liberty of choosing; but it is more effective than the compulsory laws of several European governments.

A similar force, yet short of actual compulsion,

can be brought to bear by State and local sanitary authorities upon employers of labor and in favor of the vaccination of their employes. Railroad corporations promptly supervise the vaccination of their employes when required to do so by competent authority; *for every train can be stopped at the State line for purposes of inspection* on the order of such authority. And when it is remembered that in times of wide-spread pestilence a system of universal inspection and disinfection can be brought to bear upon manufacturers and merchants everywhere, and can even be carried to the extent of destroying their goods in case of refusal to comply with reasonable precautionary demands, it will be readily seen that the absence of compulsory laws is not a matter of much consequence. This kind of coercion is less offensive and hardly less effective than statutory enactment would be; and under some circumstances the employment of force would doubtless be sustained by public opinion if not by the law.

It is a crime to destroy the property of another without reason; but to destroy a building in order to arrest the progress of a fire is consistent with good sense and good citizenship. Similarly when smallpox becomes prevalent, and its prevalence extends so rapidly as to threaten the safety of a city, a State or a continent, there are not many people in the world—certainly not many in the medical profession—who would stop to listen to a dissertation on personal rights before vaccinating a person known to have been exposed to the contagion of the disease. Vaccinate first and listen after.

The duty of the hour is plain. Educate. Educate the medical profession to a proper appreciation of the demands of duty, so that every physician shall feel compelled by the mandates of professional honor to vaccinate and re-vaccinate everybody who looks to him for guidance and protection. Educate medical students so that they shall be able to wield the weapons of protection with maximum skill and effect. Educate health boards so that they shall administer sanitary laws, not paroxysmally nor excitedly, but continuously, steadily and sensibly every day in the year. Educate school teachers by courses of instruction in hygiene at "teachers' institutes." Educate school children by including in their studies the subject of personal hygiene. Educate the community through the press and by public utterance. Educate the conscience of propagators and dealers in vaccine lymph so that they shall furnish a product that is free from extraneous infection. That is the duty which confronts us now—if the glory and the boast of our profession be founded on truth—that its highest aim is the prevention of disease.

AMERICAN MEDICAL EDITORS' ASSOCIATION.

ADDRESS OF THE PRESIDENT, C. H. HUGHES, M.D.
ST. LOUIS, MO.

Fellow Cranks:—As you accepted the term kindly last year in the East, when we were assembled around the board in the "Arlington" at Washington, so I re-apply it here in the West at the Golden Gate in this festal hall of the Palace of the Occident.

Fellow cranks: I congratulate you that the revolution of the wheels of time has brought us to this goodly place, and that the cranks still go with the wheel, for from what we already know of California

and the Californians we have promise of a lively time here in San Francisco. We are going to see all the sights of Chinatown, and Benicia Bay, and the Golden Gate, and the seals of Seal Rock, and the Garden and the Midwinter Fair and last, but not least, the bright eyes and handsome faces of San Francisco's warm-hearted and beautiful wives and daughters whose qualities of head and heart have done so much to make the men of San Francisco what they are—the noblest hearted and most manly men of the Pacific Slope,—as good as any crank in this crowd and that is paying them the highest of compliments, because we are all jolly good fellows and not the sickly kind of kranks (spelled with a k) that some folks take us to be, but cranks spelled with a capital C, that turn the tides in the affairs of men, move the wheels of medical advance and likewise help to make the wheels of commerce revolve by keeping men in condition always to get a move on and to make things lively. Why if it were not for the editorial crank, medical, financial, commercial, professional, manufacturing and mining, the gods of this world would cease to grind their daily grists and their little bells would cease to jingle.

The world's theological, moral, political, scientific, hygienic and therapeutic battles are largely fought by the press. We are the fighters who believe with Darwin in the survival of the fittest, but we differ from him in advocating the *ascent* rather than the *descent* of man. We are the "Benicia boys" and "Corbetts" that have the ring all to ourselves. It is our business to boost business, to elevate and advance the world's medical and sanitary interests and thus to promote its general welfare. In doing so, we elevate ourselves and we feel elevated to-night, not only because of our calling, but also on account of the excellent and highly spiritual company we are in. The influence of an occasion like this is always elevating to medical editors and they take kindly to this kind of elevation. We do not have to sing: "The wine cup, the wine cup bring hither," for it is already here. In fact it is always handy in a company of Californians or an occasion like this. In regard to their hospitality, we may truly express the hope that "the wreaths they have won may never wither," nor "the star of their glory grow dim." These are my sentiments; our sentiments, are they not, gentlemen? So say we all of us.

Gentlemen, I am heartily happy to be with you to-night, because you are all good fellows, brainy fellows, and my specialty in the world's medical work is brains and I may say, confidentially, I have not mingled with so brainy and brilliant an assemblage since over twenty years ago, I surrendered the superintendency of the Missouri State Lunatic Asylum. Gentlemen, I dote on brains. I adore brains. Brains and a full purse move the world. Archimedes would have needed no other lever.

My especial occupation is to treat brains and advise men how to care for them. We live in an age when vigorous brains are really of great value in the affairs of men, notwithstanding the marvelous success of some men in making money would seem to indicate that this article was unnecessary. My friend, Dr. J. T. Searcy, of Tuscaloosa, Ala., seems to regard brains as very essential to success in life, as may be seen from his recent address on the secret of success before the students of Alabama Medical College at Mobile. But he also got the best of his

experience as to the value of brains in a hospital for the insane, and brains are really a very useful article in such institutions. He talks very learnedly and entertainingly about the phylum, the mother's phylum, the father's phylum, the hereditary phylum and their influence on the brain ascendancy and degeneracy of man.

But here is the way he talks, and he is right sensible for an Alabamian, and it is a rule with me that whenever I can get a sensible man to think and talk for me, I prefer to speak by proxy.

He says: "Anything and everything that in any way injures brain structure or injures or impairs its functional activity, just so much impairs the man's ability to succeed and excel and to 'live properly.'"

"There is no question in which we are more interested than in the functional capacity, and the structural integrity of this 'nerve center' within us. Our safety, our survival, as well as the continuance of our phyla after us with abilities to survive, depend upon the questions involved in brain improvement and brain hygiene, more than anything else.

"The brain is the organ that adjusts the man to his environments.

"The individual receives his phylum from his ancestry or, rather, is a prolongation of the ancestral phylum, at a certain level of intellectual competitive ability and endowed with certain inherent habits of observing rules of conduct; he then raises or lowers these levels by the amount and the kinds of practice he performs himself, and his phylum goes past him into its stage of another generation at a higher or lower level, in either or both of these particulars, according as he has done abundant or little high-grade practice. Nature's way of improving abilities is by eliminating the less capable.

"To increase the brain ability of a phylum above the level that naturally belongs to the ancestral line requires great and continued effort. It is not accomplished in a day, nor by fits and starts, but it takes the steady work of a lifetime and of generations. It is hard to improve lineal ability; there is no royal road. On the other hand, it is very easy to lower and let down lineal ability; simply doing nothing, does it in one short generation; and besides anything like disease, injury, defect or failure of the brain does it.

"The 'abnormal man' is very numerous in human society. He is a very troublesome factor in it. He is not adjusted to its highest attainments, consequently he is either an incubus upon its welfare by his intellectual disability to care for himself, or he is a menace to its safety by his inherent habits of not adjusting his conduct according to high moral and ethical rules. What to do with him is a most serious question. The 'abnormal man' is generally a degenerate; he has come down from higher levels and is defective, both intellectually and morally. There are many kinds of "defects" in society. We have some good, easy, good-for-nothing fellows, who are intellectually weak and passively good. Such a man is inherently intellectually, incapable of making or competing for his living, while he possibly passively adjusts his conduct to the rules of society. Those who are simply paupers are of this class. There are real paupers in high life, in wealthy lines, supported by the wealth accumulated for them by others, though they naturally belong to the eliminating ranks. Left to themselves, they rapidly take that

direction—they can not compete—in time they or their phyla disappear.

"Among the abnormal men we also have the inherently vicious and the insane. Nothing is more true than the statement, abnormalities in the large majority of cases belong to degenerating deteriorating phyla; they are such as we find them because their phyla are not maintaining their comparative levels,—they are on the down grade."

You see he thinks about two-thirds of all of the phylums are wasted or become extinct. If he were out here among these denizens of the Golden Gate City he would think differently, because you would show him how to fill them up again.

PSYCHICAL AND PHYSICAL SANITATION AND QUARANTINE.

Dr. Geo. F. Shrady is reported to have said in a recent interview that more important than a bureau for distributing seed is it to have a bureau for killing the seeds of disease. These will be provided when the people heed their health interests as they do their agricultural, and endeavor to stamp out hereditary death and degeneracy as they do to drive out foreign pestilences when they threaten to invade the land. These will be provided when men care as much for their brains as for their bodies, and for both as for their houses or horses.

In my address at Washington last year I recommended the creation of a Sanitary Department, with its chief a member of the Nation's Cabinet, that the people might be saved the final doom of decadence that befell the nations of antiquity, through ignorance and neglect of national sanitation, moral, mental and physical.

We quarantine against the degenerate, the defective, the diseased and the poor in purse from abroad, but do nothing as a State or Nation to quarantine against the commingling and spreading of our own bad blood, which breeds and multiplies defectives of mind, morals and body. We build hospitals, homes and reformatories for these, but not so fast as the insane, the idiotic and the vicious are increased to overcrowd them, by marriages that ought to be interdicted by law.

If municipal governments conformed in their statutes to the light of modern medical knowledge and surgical suggestion on these subjects, the insane, epileptic and most of the nervous hospitals and homes for the idiotic, the insane, the mute, the imbecile and the penal reformatories would soon be unnecessary. These monuments of our enlightened advisory philanthropy would give place to wholesome laws of prevention, commemorative of our admonitory providence. The insane temperament and neuropathic diathesis, breeding their hordes of degenerates would then be in the way of extinction. What right has an insane man, a "crank," an epileptic or an idiot to afflict posterity, blemish and cripple society or burden the State with the perpetuation of his kind, and what right has any man or woman to marry such? What rights have the consumptive or the syphilitic in this direction? Through the advances made in medicine and proclaimed to the people, the world is gradually getting its eyes open to the perils of morbid and vicious heredity, and the entailed aptitudes of individuals to disease are largely in the defective resistance of the nervous system to exciting causes of disease. Bacteria furnishes many of the seeds, but an

unresisting organism gives the soil essential to morbid implantation and growth. If the soil be not recipient, the bacteriologic seeds fall on stony places. When as much public attention is paid to sanitation as is now given to agriculture, arms and education, there will be a Sanitary Department of State, and it will seek out and inform the people from the teachings of our profession how they may be made strong enough to resist disease and build and maintain the greatest and most enduring among the great nations of the earth. Violent and radical remedies and revolutions for small political ills magnified by morbid imagination are the offspring and suggestion of unhealthy minds. Already that great messenger of light, the daily press, is seeking to learn from us how the people, and the nation builded upon the people, may be psychically and physically saved from those destructive influences which tell against health and longevity and against the perpetuity of our institutions. The press and people used to get their information from the quack advertisers, but now they get it in the regular way.

In view of the power of the medical press we should, in my judgment, continue to insist upon advancing the standard of medical education until no school in the United States has a curriculum of less than five years of college study, and until a National Sanitary Bureau exists in all the States and in the District of Columbia; and a sanitary medical officer, perhaps a medical editor, shall sit in the President's Cabinet, the peer of the head of any other department of the Government.

And we should further continue our efforts until the profession of medicine is unified on the broad non-sectarian basis of a liberal scientific and clinical education, and the physician stands before the world the political and social peer of any man, as he now is, when educated and trained in the principles of our ethics and in the full light of clinical and collateral medical science.

The medical press, more than all other agencies, has promoted the advancement of anthropologic science in its physiologic and pathologic aspects, and made it more than ever apparent to the profession and the people that the highest and most "proper study of mankind is man." It has elevated the profession, elevated mankind and exalted appreciation in both, of the art of healing and the science of conserving health. Thus it has promoted and promotes the welfare of the people.

The secular press is indebted to us for more matter of value to the highest interests of mankind than to any single source upon which that wondrous nineteenth century miracle, the newspaper, draws to supply its columns. Many of the most ingenious devices of modern suicide are the perverted resources of medicine obtained from the medical press. The pleas to procure exemption from consequences of crime are distorted and legally misapplied principles of modern medical science, while real extenuations of apparent crime are obtained by lawyers from our pages.

The numberless cure-alls heralded to the public as panaceas for all the ills flesh is heir to, have all been modestly heralded for more limited and restricted use by us.

The ten thousand saving resources of hygiene by which epidemics are stayed and the degeneration of the race is retarded and its active diseases averted or modified in their courses, and the preservative em-

balming processes for the dead, have all first passed through the columns of the medical press, and we have furnished most of the subjects. We have been an everlasting boon to the undertaking and the tombstone business.

The great sanitary problems of the day which promote the comfort and health of the people have all first been solved through our pages.

We have taken the initiatory in all educational reforms in the secular and medical schools, and forced the latter and the profession to higher standards. The *esprit du corps* of the profession has been steadily advanced through our influence.

These are reasons enough for the existence of the medical press, and as individual influence is promoted by unity of effort this is reason enough for our existence as an association.

The medical journal goes to the physician's home and office with the latest advances in the science and art, and keeps the alert practitioner posted in advance of the books. It promotes progress and fraternity and stimulates medical ambition and professional pride. Our journals are all medical mirrors, though only one bears that name.

The medical press has put a premium on brains, energy and research in the medical profession, and made the profession respectable before the people. It puts a damper on mediocrity, show and pretense in the profession, applauds and sustains merit and brings out modest worth so that it receives its true reward. It makes worthy men great, and measures littleness with the shortened tape-line of its own deserts. It gives to all deserving men liberally of well-earned praise, and takes away nothing from the undeserving.

The medical press has aimed high and persevered until it has filled the world with the true glory of American medicine and placed her great medical men where they justly belong, "high on the topmost stone of Fame's triumphal arch."

The medical press has made it a popular thing for the practitioner to read current medical literature, and lay upon the shelf the moldy precedents of the past until to be an advanced and reading physician is to be among the greatest of men.

The medical press has robbed medicine of its sectional prejudices so that the profession now knows no North, no South, no East, no West, and under its influence narrow sectionalism and narrower sectarianism have retreated into the shade under the searchlight of brilliant discovery and advancing science. After our late war the AMERICAN MEDICAL ASSOCIATION was the first public body to be reunited through our benign influence.

The manifest destiny of the medical press is to shed the light everywhere until there shall be but one broad, non-sectarian profession, learning only truth from the teachings of science and applying it to the noble art of healing, of destroying and preventing disease.

The best men of our profession to-day are the men who write for the medical press. The press has made them and they have made the medical press what it is.

The mental caliber of the medical editor has expanded until he is now the peer of the best among his fellows in the profession, and the accepted teachers of the profession have advanced in ability until they are nearly equal to the medical editors, and that is the highest compliment that can be paid them.

The medical press is the telescope that searches out new worlds of observation and thought, the phonograph that registers and reproduces the thoughts and observations of its master minds, and the mimeograph that sets before the world a good type and copy for imitation and emulation by the medical men of the world.

In my last address to you, gentlemen, as I have said, I recommended a Health Department and a physician in the Cabinet, but I have seen no nomination as yet. Neglect of President Cleveland and of Congress in this important matter may be the cause of their luck in pleasing the country. Things will never go right until a doctor and a medical editor get into the Cabinet. A President should always take the right medicine. Congress seems to have taken the wrong medicine or none at all. It needs to get a "move" on.

I now take pleasure in introducing the toastmaster of the evening with a little preliminary note of warning. I have examined his head and I find him all right now. What he may say now you may safely accept, but he is sometimes troubled with night blindness and is not likely to see well after 12 P.M., and he does not mean all he says after that hour. But if you listen to him now, he will bubble with mirth like a bursted champagne bottle, and boil over with love for all the Fellows, and all mankind and the bottle in particular. His name was never "Dennis," but always Love, and I always love to introduce him.

ORIGINAL ARTICLES.

THE NECESSITY OF A MYDRIATIC IN ESTIMATING ERRORS OF REFRACTION.

Read before the St. Louis Medical Society, April 14, 1894.

BY J. ELLIS JENNINGS, M.D.

LATE CLINICAL ASSISTANT ROYAL LONDON OPHTHALMIC HOSPITAL; OPHTHALMIC AND AURAL SURGEON TO THE ST. LOUIS MULLANPHY HOSPITAL.

There seems to be a tendency for the practice of ophthalmology to take a circular course in its search for higher development. We are making steady progress upward, but every now and then we find ourselves treading familiar paths; ground over which we had never expected to travel again.

In the treatment of corneal ulcers we go from curette to cautery and from cautery to curette; from atropin to eserin and then back to atropin until one becomes confused. A learned London oculist gave expression to this uncertainty when he said to me: "First try atropin and if that don't work use eserin."

The history of cataract extraction furnishes us with another illustration of this tendency to move in a circle. Extraction was first practiced by Daviel, of Marseilles, about the middle of the last century. He and his followers were careful not to wound the iris. Then came the brilliant Von Graefe who taught the world to remove a portion of the iris before extracting the lens, and it became the recognized mode. But in recent years there has been a reaction, and now we find the majority of oculists arrayed on the side of simple extraction.

But yet another change confronts us—a movement which is insidiously undermining the very foundation of sound ophthalmologic practice and which threatens to lower the standard of "the most exact of the specialties." A glance at the medical literature

of the day shows a tendency to do away with mydriatics in the estimation of errors of refraction. We are justly proud of the reputation which American ophthalmologists have gained, of being the best refractors in the world. How has this enviable position been attained? By insisting upon the use of a mydriatic and thus estimating the total amount of refractive error. Shall we lightly abandon that which has served us so well in the past? In order to answer this question rationally let us consider for a moment the methods used in estimating errors of refraction and the relative value of each. We have the ophthalmoscope, the ophthalmometer, the shadow test and the trial lenses.

1. *The Ophthalmoscope.*—This splendid instrument has done more than any other one thing to make ophthalmology the beautiful study it is. With it, we can investigate the hidden mysteries of the eye-ball and throw new light on many obscure causes of disease. But the oculist who thinks he can accurately measure cases of hypermetropia, myopia and astigmatism with it, believes in a delusion and a snare. Some time ago it was my privilege to work with one of the most brilliant ophthalmologists of London. He was a man of keen observation and used the ophthalmoscope daily on a great number of patients. He prided himself upon his ability to refract by the direct method and, indeed, often prescribed glasses without further investigation. But subsequent work by me with retinoscope and trial lenses made plain the fact that his estimations were often faulty.

2. *The Ophthalmometer.*—This is an instrument which when perfected is destined to be universally used in estimating astigmatism. But in its present form there are limits to its usefulness and many claim that the results are often unreliable. Be this as it may, certain it is that the ophthalmometer is to be found in the office of most oculists. If questioned as to its utility, each and every man sings its praises and declares that he could not get along without it. This is probably theoretical, for practically the half inch of dust which has accumulated upon its many sides belies the statement and proves it to be more ornamental than useful.

I have mentioned these points, not to detract from the merits of the ophthalmoscope and ophthalmometer—they are grand instruments—but to show a limited value in estimating errors of refraction. We have, then, two methods left for consideration, the "shadow test" and trial lenses; an objective and a subjective mode of procedure.

When used together they enable us to do our work easily, quickly and accurately; provided, however, that a mydriatic is used. Without it the results are very uncertain and unsatisfactory. The "shadow test" is the most reliable objective method we have for estimating the amount of ametropia. The skilled eye can refract, in a few minutes, the most difficult case of astigmatism, and with Thorington's "Axonometer" (*Medical News*, March 3, 1894) find the axis of the cylinder. This method deserves to be more generally used and is especially valuable when we come to deal with children. In these cases the trial lenses alone are apt to prove unsatisfactory. After we have recorded the results of the "shadow test" we go to the trial box with confidence, and select lenses which approximately correct the error. A little addition or subtraction, a slight turn of the cylinder and we have done.

But there are many ophthalmologists who do not use the "shadow test" in their practice, and a few who do not use a mydriatic. St. Louis is an old offender in this respect, and numbers among her oculists a few who still cling to the crude and unscientific method about to be described. It is unscientific because it is based wholly upon the statements of the patient.

I quote from an article in the "Reference Handbook of the Medical Sciences," Vol. III, page 782:

"The accurate correction of the total hypermetropia is the end to be kept constantly in mind in giving convex glasses to a hypermetrope. Nevertheless, it is often better to reach this full correction by successive stages. Thus a hypermetrope may find it impossible to relax his accommodation fully on first using convex glasses, and may therefore reject neutralizing glasses as impairing distant vision and compelling him to read or work at an inconveniently or uncomfortably short distance. On the other hand, he will probably take very great satisfaction in glasses of somewhat longer focus, which fully correct or perhaps somewhat over correct his manifest hypermetropia. After wearing such partially correcting glasses for a few days or weeks, a larger fraction of the total hypermetropia will have been rendered manifest and the glasses may then be changed for others of shorter focus, and these again for others until the full correction is reached."

This "expectant" plan of treatment subjects the patient, not only to repeated visits to the oculist, but to the extra expense of purchasing stronger lenses every few days or weeks. If this method should come into general use, it would be a good investment for each and all of us to become silent partners in the optician business. Why these repeated visits, this extra expense? This leads me to discuss the disadvantages and advantages of a mydriatic.

1. *Disadvantages.* The learned author above quoted says: "To spare the patient from the very considerable inconvenience and possible disqualification for work, attendant upon the production of complete paralysis of accommodation, by the free use of the stronger mydriatics." And I add the following:

2. The patient may object to the use of drops.

3. The possibility of setting up an acute glaucoma.

1. The first objection could have been raised with propriety in the olden days when atropin was the only drug used to paralyze the ciliary muscle. The loss of ten to fifteen days was a great hardship. But at the present time when by using homatropin we have only a loss of five hours' time (Fuchs), this objection is not tenable.

Contrast this loss of five hours with the loss occasioned by six or eight visits to the oculist and the weary hours of waiting in the outer office before the patient receives attention.

2. The patient may object to the use of drops. On this point, Dr. Oliver says ("Norris & Oliver Text-book of Ophthalmology," page 260): "If certainty is felt that ciliary paralysis is necessary before proper lenses can be chosen, the surgeon had better be prepared to lose the patient than to give him imperfect work." Again, "Although this plan may often result in patients seeking advice from others who may rest content with an imperfect correction of some manifest error, yet in all such instances it is far more

than equivalent recompense to know that the steady, quiet reputation of many years of but little error in refractive work, is infinitely better than the flash-like brilliancy of the moment in quickly giving corrections that may or may not be right."

3. The possibility of setting up an acute glaucoma by the use of a mydriatic. This would be a very important objection if clinical facts sustained it. Listen to the experience of Dr. Risley (*Univ. Med. Mag.*, January, 1893): "I have used these drugs with impunity, both in private and public practice, in many thousand of eyes during and after middle life, and I have yet to meet the first instance of an acute glaucoma precipitated by the employment of a mydriatic. But, I have always taken the precaution to avoid their use except with the greatest caution in all cases when there is increased tension of the eye-ball, with diminished range of accommodation not accounted for by other recognized conditions, or with characteristic abnormalities in the field of vision."

Advantages of a mydriatic. The recording for all time of the total error of refraction. Here we deal with no uncertain quantity; we have the key to the situation and can use the information as our experience and judgment may dictate. As Dr. Risley says: "In the endeavor to correct the manifest error of refraction we are dealing with an unknown because an ever changing quantity, which constantly vitiates results, and the work done is unsatisfactory because it does not secure perfect relief."

Another advantage of a mydriatic is the dilated pupil which allows us to examine the interior of the eye-ball at our ease. We are not forced to screw our eye out of shape, as is necessary when we view the fundus through a pin-hole pupil. We examine the peripheral portions of the lens for striæ, the vitreous for fine opacities, and search the outer parts of the fundus for pathologic changes. The impossibility of making the above investigations without the use of a mydriatic, force us to the conclusion that those gentlemen who forego its use, cripple their diagnoses and allow many important points to escape them.

Lastly, by using a mydriatic we have the satisfaction of knowing that our work is well done, and that the foundations of our treatment rest upon the rock.

In conclusion, I wish it understood that I do not advocate the use of a mydriatic in every case. I have endeavored to show that it is an invaluable aid to diagnosis, and that its advantages overshadow its disadvantages, as the mountain the mole hill. Therefore the oculist who refuses to use it will surely either be dashed to pieces upon the rocks of Scylla or be dragged down into the whirlpool of Charybdis.

ASSOCIATION NEWS.

AMERICAN MEDICAL ASSOCIATION.

Proceedings of the Forty-fifth Annual Meeting,
San Francisco, June 5-8, 1894.

First Day—June 5.

The President, Dr. Jas. F. Hibberd, of Indiana, called the Association to order at 10:30 A.M. The second Vice-President, Dr. I. N. Love, of Missouri; the Permanent Secretary, Dr. Wm. B. Atkinson, of Pennsylvania; and the Assistant Secretary, Dr. H. B. Ellis, of California, were present.

Prayer was offered by Rev. Robert Mackenzie, D. D., of the First Presbyterian Church of San Francisco.

In the absence of the Governor of California, and the Mayor of the city, Supervisor J. G. James welcomed the Association to the city.

Dr. G. L. Simmons, on behalf of the profession of the State delivered an Address of Welcome.

Dr. R. H. Plummer, Chairman of the Committee of Arrangements, reported the program of papers and entertainments during the session. In conclusion, he presented a valuable gavel made of redwood, and bound in gold, to the President, and gavels of native woods, from the Oregon State Medical Society for the Chairman of each Section.

Vice-President I. N. Love having taken the chair the President delivered the Annual Address. (See *JOURNAL*, June 9, 1894).

On motion of Dr. W. T. Bishop, of Pennsylvania, a committee of five was appointed to consider the suggestions in the address and report at this meeting. Committee: Drs. W. T. Bishop; L. Beecher Todd, of Kentucky; R. Beverly Cole, of California; F. W. Mann, of Michigan and J. E. Woodbridge, of Ohio.

On motion of Dr. I. N. Quimby, of New Jersey, a committee of five was appointed to prepare a preamble and resolutions in reference to the threatened danger of a reduction in the number of Assistant Surgeons in the Army. Committee: Drs. I. N. Quimby; Jerome Cochran, of Alabama; John B. Hamilton, of Illinois; Edw. E. Montgomery, of Pennsylvania, and J. Milton Duff, of Pennsylvania.

On motion of Dr. Atkinson, the delegates representing the American Pharmaceutical Association were received and invited to seats with the Association.

The Permanent Secretary read the report of the Treasurer.

REPORT OF THE TREASURER.

I have the honor to present the report of my seventeenth year of active service as Treasurer of the American Medical Association. It would have given me great pleasure to be present at this meeting, and to read my report personally, but illness in my family will not allow me to be very far away from home at present.

My absence, under the rules of our By-Laws would naturally create a vacancy in the office of Treasurer, for it is provided therein that every one elected for any office in the Association shall be chosen from those present at the annual meeting; a desirable provision so far as honorary official positions are concerned, but in the case of an office like that of the Treasurer or Secretary it is not expedient or proper, for in case of illness or other unavoidable causes the Association might be deprived of the services of a valuable officer, whom it might be preferable to retain. In my own instance, this rule is immaterial, as it has been long known to my friends that I was desirous of relinquishing my position at each annual meeting for several years past; and only retained it at their urgent solicitation.

The labors of the Treasurership have now become so onerous that the giving of proper personal attention to the duties of this responsible office is a business of its own, requiring much more supervision and direction than mere clerical attention. I would suggest that hereafter the Treasurer should be a salaried officer, receiving annually a compensation commensurate with the amount of labor which must inevitably devolve upon him in the faithful execution of his office. Several items of interest derived from my personal experience occur to me as worthy of mention at this time.

In several of my annual reports I have pointed out the desirability of abolishing the rule which virtually allows a member to remain such, even if he is for two years out of every three years delinquent. This rule was adopted before the publication of the *JOURNAL* and should be entirely eradicated, so that membership and the receipt of the *JOURNAL* may go directly, hand in hand. No list of members can ever be perfectly maintained, with the hundreds of changes annually occurring by death, resignation, delinquency in payment of dues, etc., if in spite of the latter the delinquent member still remains on the membership list, regardless of the fact that he may no longer be a recipient of the *JOURNAL*. The opportunity is now offered for the Association to reduce the three year rule to one year, and it is to be hoped that the necessity of the change will be promptly appreciated by all the members.

On motion of Dr. John B. Roberts, of Pennsylvania, in order that all members might be able to be present at the general sessions, the hour of meeting was changed from 10 A.M. to 12 M. each day.

The Permanent Secretary read the following from the Executive Committee:

WHEREAS, Each of the sections should have three members on the Business Committee of the Association; and

WHEREAS, A considerable number have signified their inability to be present this year,

Resolved, That the officers of the various sections be hereby instructed to appoint from the members in attendance, alternates, to act at this meeting for those who are unable to be present.

On motion, this was adopted.

The Permanent Secretary presented several communications which were referred to the Judicial Council.

On motion of Dr. I. N. Quimby the following was adopted:

WHEREAS, Dr. R. J. Dunglison has been for seventeen years a faithful, energetic Treasurer of this Association, without any compensation; therefore be it

Resolved, That the hearty and unreserved thanks of this Association be cordially extended to him for his efficient and laborious duties in behalf of this Association, and a copy of this resolution be forwarded by the Secretary to Dr. Dunglison.

Dr. E. E. Montgomery offered a resolution that an honorarium of \$300 be given to Dr. Dunglison.

On motion, this was referred to the Board of Trustees.

On motion, the Association adjourned until Wednesday.

WEDNESDAY, JUNE 6.

The President called the Association to order at 12 M.

The Committee of Arrangements announced an invitation from Spreckles Bros. to visit their place. He then offered as member by invitation, E. C. Ingals, Chicago, Ill.

The President asked the ex-Presidents present to take seats upon the platform.

Dr. I. N. Quimby, Chairman of the Committee on Army Medical Department, presented the following report:

Resolved, That the American Medical Association urge upon Congress the advisability of preserving and promoting the efficiency of the Army Medical Department.

Resolved, That any reduction in the present membership of the Army Medical Department would be prejudicial to the interests of the Army and the country.

Resolved, That the Permanent Secretary communicate this action to Congress by telegraph.

On motion, the report was received and the Secretary was instructed to telegraph it to Congress,

Dr. C. H. Hughes, of Missouri, read the Address in Medicine. [See JOURNAL AMERICAN MEDICAL ASSOCIATION, June 16.]

On motion of Dr. H. D. Didama, of New York, the thanks of the Association were tendered Dr. Hughes for his admirable, scholarly and original address.

Dr. H. O. Marcy, of Massachusetts, rose to a question of privilege, and offered the following:

A CIRCULAR LETTER TO THE STATE MEDICAL SOCIETIES.

WHEREAS, This Association has long recognized the advantages to be derived from the more intimate relation between the State Medical Societies and the American Medical Association; it is hereby

Resolved, That we request the various State medical societies to perfect their local organizations, so as to include, as far as possible, in the membership of their district societies every regular practitioner within the State;

That these local societies shall actively cooperate in urging a general attendance upon the annual meetings of the State Societies;

That the date of the same be so fixed that it shall not interfere with the attendance of those members who are delegates and members of the American Medical Association; in order that a general unification of the interests of the medical profession of America be promoted, and the American Medical Association become in a yet higher degree the exponent of the profession.

That we also request the State societies to unite in establishing a uniform standard of professional requirement for admission to the practice of medicine and to aid, as far as possible, in advancing the scientific status of the same by the appointment of State Examining Boards, independent of the teaching faculties of the medical colleges. To this end we further direct that the Permanent Secretary of the American Medical Association enter into correspondence with the secretaries of the several State medical societies and furnish annually a written report of the membership of the State societies and the working effectiveness of their organizations.

On motion of Dr. E. F. Ingals, of Illinois, this resolution was referred to the Committee on Business.

The Secretary read the report of the Librarian, which on motion was referred to the Committee on Business.

To the Officers and Members of the American Medical Association:—Your Librarian begs leave to submit the following report:

At the meeting at Milwaukee last year it was voted by the Association to leave the transfer of our Library to the Newberry Library at Chicago, to the Librarian and the Board of Trustees, the terms to be in accordance with my report of the previous year.

That report recommended that our Library be deposited with the Newberry Library, and that the deposit be made permanent so long as the books were properly cared for. The Trustees of Newberry Library absolutely refused to accept the books unless the deposit be made permanent. This is only just to them as the expense of binding, shelving, etc. will be considerable, and I therefore recommend that the transfer be made in accordance with terms of the appended agreement, the Trustees of the Newberry Library having agreed to all of the terms. Otherwise the Association must immediately arrange for the removal of the books from the Smithsonian Institute at Washington, and for their subsequent care, as I have received notice that the room is very much needed.

AGREEMENT.

It is hereby mutually agreed by the Trustees of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and the Trustees of the Newberry Library, that the American Medical Association shall permanently deposit in the Newberry Library its entire collection of books and pamphlets now in the Smithsonian Institute at Washington, or elsewhere, and in consideration thereof the following arrangements are made and agreed upon, namely:

1. That the said books and pamphlets shall be treated by the Newberry Library in all respects as its own, and as it treats its own books, except that in labeling, stamping, or otherwise marking them they shall, when received, be so marked as to show that they belong to the collection received from the American Medical Association; and the said Association shall never thereafter have any right to remove said collection of books or any part thereof from the custody and control of the Newberry Library.

2. That duplicates or other books may be exchanged or sold at the discretion of the Librarian or Trustees, but that such books received in exchange or purchased with the proceeds of sale shall be marked or stamped as above provided for.

3. That the American Medical Association may hereafter continue to deposit in the Newberry Library all the books, journal, etc., donated or contributed to it from any and all sources; except those given to reviewers for writing the reviews, and such journals as are needed to keep complete files in the office of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. All such books, etc., shall be treated in all respects as hereinbefore provided concerning the collection at present existing.

4. That the Newberry Library will defray the expense of

transporting the aforesaid collection to the Newberry Library.
GEO. W. WEBSTER, M.D., Librarian.

Dr. E. E. Montgomery, of Pennsylvania, read the report of the Trustees.

ANNUAL REPORT OF THE BOARD OF TRUSTEES OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Mr. President: The Board of Trustees in presenting its annual report would felicitate the Association upon its present financial condition. Notwithstanding the past year has been one of unparalleled financial depression—one which has taxed the resources and awakened the anxiety of every monetary institution throughout the country—this organization has weathered the storm and is able to show a larger balance than at the close of the last fiscal year.

The receipts of the Association from all sources have been \$35,788.10, of which have been expended \$27,759.22 leaving a total balance of \$8,038.88.

The Association Treasurer's accounts have been audited, and show his receipts were \$20,728.43, his expenditures were \$14,574.63, making a balance in his hands of \$6,153.78.

Ten thousand dollars of the expenditure was upon account of the JOURNAL.

The receipts of the JOURNAL, including the amount just mentioned, were \$24,969.67, making its net receipts \$14,969.67. Its expenditures were \$22,084.57, leaving a balance in the Board treasury of \$1,885.10.

In presenting this statement the Board congratulates itself and you upon what, in this year of marked monetary depression affecting the medical profession probably more deeply than any other, must be considered as an absolute financial triumph. The Board would do itself an injustice did it not indicate to you how thoroughly this success is due to the earnest efforts, the untiring energy and loyal devotion of the present editor, Dr. John B. Hamilton. Upon resigning as a member of the Board he was last year elected Editor at the first meeting of the Board, and assumed the duties of the position about July 1. At that time, owing in part to the monetary stringency, the future of the JOURNAL looked serious; an average of five letters daily were received discontinuing the JOURNAL. The evident decrease in its circulation, and the financial stringency made it difficult to continue the old, and secure new advertisements. Out of this maelstrom of discouragement, however, we have been able, through the aggressive policy and wise management of its Editor, to place the JOURNAL upon a better footing than ever. As you have noticed, its pages have been increased, news items and matters of professional interest have been added, and the JOURNAL has become one that may well appeal to your professional pride and demand your earnest support. Notwithstanding the success of your Board in carrying the JOURNAL over the financial breakers of the past fiscal year, it has been unable to escape criticism, and at this meeting the Judicial Council has been asked to pass censure upon its members.

During the entire existence of the JOURNAL no question has presented greater difficulty or afforded your Board more embarrassment, than to discriminate as to what may be considered as proper matter for its advertising pages. The policy adopted was, that having entered upon the business of publishing a journal, we would be governed by the same rules followed by those considered reputable, who were engaged in the same business. The *British Medical Journal*, representing an association with similar purposes and aims, was particularly indicated as a standard.

Beyond insertion of the advertisements, the JOURNAL has scrupulously avoided any expression which could be interpreted as an indorsement of the advertisers, believing the owners of the JOURNAL—the profession—were capable of discriminating as to what would serve their interests. At the Detroit meeting the following resolution was adopted:

"Resolved, That the attention of the Trustees of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION be directed to the fact that the Code of Ethics prohibits all commendatory mention or advertisements of secret preparations, and that said Trustees are hereby instructed to respect said prohibition in the future conduct of the official journal of the Association."

The Trustees immediately gave the following direction: "When the Editor is in doubt about the character of an advertisement, he shall refer the same to the Committee on Advertising, and that an advertisement of a proprietary medicine shall be accepted in the discretion of the Committee when the proprietors thereof shall furnish the complete formula."

This course has since been our governing policy. The Board asserts that it has complied with the letter of the law in demanding that a formula of all secret and proprietary remedies should be submitted to its Committee before being advertised in the JOURNAL, but it would direct your attention to the fact that had the apparent intention of those who censure our action been established, we would be obliged to present you to-day a considerable financial deficit. However desirous the Board might be to comply with the wishes of some members of the Association, it could not forget that under the present Constitution of the organization, the members of the Board were the only parties legally responsible for obligations incurred, and they had too much confidence in the sense of justice of this body to believe it would demand they should "make bricks without straw," and discard a source of support utilized by other reputable journals.

No advertisements have been inserted in the JOURNAL which do not find place in such publications as the *British Medical Journal*, *Boston Medical and Surgical Journal*, *New York Medical Record*, *New York Medical Journal* and the *Medical News*.

Owing to the death of Dr. D. C. Patterson and the resignation of the editor, Dr. J. B. Hamilton, as Trustee, there are now five vacancies upon the Board of Trustees. Fill these vacancies with men in whose business integrity you can have confidence, give them your earnest support, and leave them as untrammelled as are the managers of the journal of the British Medical Association, and you can feel assured you will have a journal to which even that publication may take second place.

The United States Postoffice Department has decided that the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is not entitled to be entered at the Chicago Postoffice as second class matter under existing regulations. Unless this difficulty can be met, the postage will be increased about \$100 per week. In order to comply with the postal laws of the United States we would request:

1. That with this meeting and hereafter the \$5.00 paid by delegates and members as annual dues to the Association shall be divided so as to provide that \$1.50 shall be for general Association purposes, and \$3.50 shall constitute the annual subscription to the JOURNAL.

2. That to persons not members of the Association, the subscription of the JOURNAL shall be \$5.00 per annum in advance.

A. GARCELON, President,
E. E. MONTGOMERY,
P. H. MILLARD,
E. FLETCHER INGALS,
L. S. MCMURTRY,
LEARTUS CONNOR.

Dr. X. C. Scott, of Ohio, moved that report be received and adopted.

Dr. Edw. Jackson, of Pennsylvania, moved to amend by substituting, "that the report be received, that thanks be tendered the Trustees for their efforts in behalf of the JOURNAL, that the other suggestions be adopted, but that the Association does not approve the policy of the Trustees with regard to advertisements."

A motion by Dr. J. Cochran, of Alabama, to lay this amendment upon the table was adopted by 86 ayes to 33 nays.

Dr. Josephi, of Oregon, rose to a point of order that this action laid the whole matter on the table.

The President decided him to be out of order.

The motion of Dr. Scott to receive and adopt the report was then adopted.

The subject of the amended Constitution, etc., being next in order, Dr. X. C. Scott moved that it be made the special order on Thursday at 10:30 A.M.

A motion by Dr. Quimby to lay this motion on the table was lost and Dr. Scott's motion was adopted.

The Association then adjourned until Thursday.

THURSDAY, JUNE 7.

The President called the Association to order at 10:30 A.M.

An invitation was presented from the Mississippi Valley Medical Association asking the members to attend the approaching session at Hot Springs, Ark.

The Committee on Nominations presented a partial report,

naming Dr. H. Brown on the Judicial Council to fill the vacancy caused by the death of Dr. J. H. Murphy, of Minnesota. This action was approved.

Dr. H. D. Holton, of Vermont, Chairman of the Committee on Revision of the Constitution, etc., read an amended report from the majority.

AMERICAN MEDICAL ASSOCIATION.

CONSTITUTION AND BY-LAWS.

To Amend the old Constitution by striking out all that follows Section One and substituting the following provisions.

MEMBERS.

Members shall consist of the members of the several State societies and of their constituent local societies which subscribe to the Constitution and By-Laws of this Association, and of commissioned officers of the medical staff of the Army and Navy and of the Marine-Hospital Service of the United States. Members shall be distinguished as delegates and permanent members.

Delegates shall receive their appointment from permanently organized State and local societies in affiliation with this Association, or from one of the Surgeons-General of the United States, or an officer authorized to act for him. Each body entitled to representation may send one delegate for every five of its resident members and one for every additional fraction of more than one-half of that number.

The medical staff of the Army and Navy shall be entitled to four delegates each, and the Marine-Hospital Service shall be entitled to two delegates. Each delegate shall be duly enrolled on presenting his credentials to the Committee of Arrangements, including a receipt from the Treasurer for subscription to the JOURNAL of the Association for the preceding year. He shall hold his appointment for one year until his successor is designated, and shall participate in all the business of the Association. Members who have twice served as delegates shall thereafter be entitled to vote at annual meetings on complying with the other conditions of membership.

PERMANENT MEMBERS.

All members of affiliated societies may become members of this Association on presenting to the Committee of Arrangements at any annual meeting a certificate of endorsement from the officers of their Society and a receipt from the Treasurer for the subscription to the JOURNAL of the Association for the current year; or such persons may become members of the Association by sending to the Treasurer at any time the annual subscription price of the JOURNAL, together with a certificate of endorsement, from their local Society. Members of the Public Service may join the Association on presenting a certificate of endorsement from the Surgeon-General of the corps to which they belong, or an officer authorized to represent him, together with the Treasurer's receipt.

To all complying with the foregoing requirements the Committee of Arrangements shall issue the credentials necessary for participation in the annual meeting. Membership in the Association shall be conditioned on the payment of the annual subscription to the JOURNAL and the continuance of good standing in the local or home organization.

No person shall be permitted to take part in any annual meeting until they have completed the conditions of membership at that meeting, and can exhibit certificates to this effect from the Committee of Arrangements. But suitable persons may be introduced as guests, either at the general session or the Section sessions, and be invited to engage in the scientific and social exercises of the meeting without taking part in the transaction of business.

CONSTITUTION.

Name.—This organization shall be known as The American Medical Association.

Members of Canadian and Mexican medical societies shall be admitted to membership upon the same terms as those in the United States. The regular graduates of such schools and colleges of dentistry as require of their students a standard of general education and a term of professional

study equal to those of the best class of medical colleges in this country, and embrace in their curriculum all the fundamental branches of medicine, differing chiefly by substituting practical and clinical instruction in oral and dental surgery in place of practical and clinical instruction in general medicine and surgery, shall be recognized as members of the regular profession, and shall be eligible to membership upon the same terms as other members.

MEETINGS.

Meetings.—The regular meetings shall be held annually at such time and place as may be advised by the Nominating Committee and ordered by the Association. Special meetings may be called by the President at the request of a majority of the Business Committee.

OFFICERS.

Officers.—The officers of this Association shall be a President, four Vice-Presidents, one Secretary, one Assistant Secretary, a Treasurer and a Librarian. These officers shall hold office during one year or until their successors are elected, and shall enter upon their duties immediately after election.

The President shall preside at the meetings, preserve order and decorum in debate, giving a casting vote when necessary, and perform all the other duties that custom and parliamentary usage may require. At the opening session he shall deliver an address to the general meeting, not to exceed thirty minutes in length.

The Vice-Presidents may be called upon to assist the President in the performance of his duties, and during his absence, or at the request of the President, one of them shall officiate in his place.

The Secretary shall record the minutes of the general sessions and authenticate the proceedings; give due notice of the time and place of the next annual meeting; and prepare the official program; then notify all members of committees of their appointment and the duties assigned to them; hold correspondence with other organized medical societies, both domestic and foreign, and carefully preserve the archives and unpublished transactions of the Association. He shall publish the rules governing the reading and discussion of papers and the order to be observed in the business of the general and sectional meetings; shall receive and announce all papers communicated, and, with the several Section officers determine the order in which the papers shall be read and discussed.

For his personal expenses in attending the annual meetings the Secretary shall draw upon the Treasurer of the Association.

The Assistant Secretary shall aid in recording and authenticating the proceedings of the Association; serve as a member of the Committee of Arrangements, and perform all the duties of the Secretary, temporarily, whenever that office shall be vacant by death, resignation or removal.

The Treasurer shall also be the Treasurer of Board of Trustees and shall have the charge and management of the funds of the Association. He shall give the Board of Trustees bonds for the safe keeping and proper use and disposal of his trust. Through the same Board he shall present his accounts, duly authenticated, at each regular meeting. He shall each month furnish the President of the Board of Trustees with a statement of accounts for the guidance of the Board in its expenditures. For his personal expenses in attending the annual meetings, he shall draw upon the Treasury through the President of the Board of Trustees.

The Librarian shall receive and preserve all property in books, pamphlets, journals and manuscripts presented to or acquired by the Association, record their titles in a book prepared for this purpose, and acknowledge the receipt of the same. He shall deposit these documents in such place and manner as the Association may direct, after advising with the Board of Trustees.

STANDING COMMITTEES.

The Committee of Arrangements shall be composed of at least seven members, of whom the Assistant Secretary shall be one, all residing in the place at which the Association is to hold its next annual meeting. It shall provide suitable accommodations for the meeting; shall verify and report upon the credentials of membership; shall issue credentials of membership to such as fulfill the conditions; shall prepare a list of members present on a separate roll for convenience in calling the ayes and nays, when these are demanded; and shall cause all members to register their names, residences and temporary addresses during the annual meeting, and the name of the Section in which they will sever-

ally vote for Section officers. The necessary expenses of a hall for the general meeting, of rooms for the Sections, programs and cards of membership, shall be met by the Association, but all such printing shall be done by the JOURNAL of the Association. Should the Committee incur other expenses, it must meet them from its own resources.

The chairman of this Committee shall be nominated by the Nominating Committee, and elected by the Association.

The Board of Trustees shall consist of nine members, three of whom shall be elected annually on nomination by the Nominating Committee, and serve for three years. This Board shall manage all matters relating to finance and publication. It must provide for and superintend the publication and distribution of all such proceedings of the Association as may be ordered to be published, in such manner as the Association may direct. In doing this it shall have authority to appoint an editor and such assistants as may be necessary, and to determine their salaries. It shall procure and control such materials as may be necessary for the performing the duties assigned it. To the Board or its representatives must be delivered, during the annual meeting, or as soon thereafter as is possible, by the Secretary of the Association and by the Section Secretaries or Executive Committees, all records of meetings, papers or discussions, and such other documents as were ordered published by the Association.

All money received by the Board of Trustees or its agents, resulting from the discharge of the duties assigned them, must be paid to the Treasurer of the Association, and all orders for disbursements of money, in any way connected with the work of publication, must be endorsed by the President of the Board of Trustees. It shall further be the duty of the Board of Trustees to hold the official bond of the Treasurer for the faithful execution of his office; to annually audit and authenticate his accounts, and present a statement of the same to the Association. This report must specify the character and cost of all publications of the Association during the year; the number of copies still on hand, and the amount of all other property belonging to the Association, under its control, with such suggestions as it may deem necessary. It shall yearly publish a list of members, their addresses in full, year of admission, Constitution and By-Laws and Code of Ethics, and such other information as may be deemed useful, for distribution to the members at each meeting.

In each number of the JOURNAL it shall publish a disclaimer by the Association for any responsibility for opinions expressed in the volume.

To this Board must be referred all propositions for the appropriation of money, to be considered and reported upon before the final action on the same by the Association.

The General Business Committee shall be composed of the several Section Executive Committees, selected as hereafter described. It shall hold daily meetings during the sessions of the Association, and such other meetings as may be deemed necessary for the performance of its duties. All matters of business not provided for by the Committee of Arrangements, the Nominating Committee, the Board of Trustees, the Judicial Council and Special Committees, shall be referred to it without debate, for consideration and report to the Association. In general, this Business Committee shall give especial attention to the interests of the Association as a whole, and through these interests shall seek the development of the Sections; it shall consider all matters of business referred to it by the Association, and report upon them at the earliest possible moment, when the Association may accept or reject said report, as it may deem best.

NOMINATIONS.

During a recess of twenty minutes at the first morning session of the Association the accredited delegates shall meet in groups representing each of the States and Territories, the District of Columbia, the Army, the Navy and the Marine-Hospital Service; each group being authorized to select one delegate who shall serve as a member of the Nominating Committee.

The Nominating Committee shall make and present the nominations for officers of the Association and its Standing Committees, and recommend the time and place of the ensuing meeting. It shall appoint its own officers, and adopt rules for the orderly performance of its duties. Finally, it is expected that it will perform all its duties in the interests of the advancement of scientific medicine.

The Judicial Council shall consist of twenty-one members, not more than two from any one State, whose duty it shall be to take cognizance of and decide all questions of an

ethical or judicial character which may arise in connection with the Association, and the Association will accept such decision as final.

Of the twenty-one members first appointed, the first seven named upon the list shall hold office one year, and the second seven two years. With these exceptions, the term of office of the members of the Judicial Council shall be three years, seven being nominated by the Nominating Committee yearly, elected by the Association. The Council shall organize by and choosing a President and Secretary, and shall keep a permanent record of its proceedings. The decisions of said Council shall be final upon all ethical questions referred to it by the Association, and must be accepted without debate. Such decisions shall be reported to the Association as soon as practicable.

All questions of a personal character, including complaints and protests, and all questions on the ethical standing of medical societies shall be referred at once, when presented to the Association, to the Judicial Council, and without debate.

INCOME AND EXPENSES.

The income of the Association shall be derived from subscriptions to its journal and advertisements therein, from specific publications and voluntary contributions for specific objects.

Its funds may be appropriated for the expenses of halls, for general sessions and Section meetings, and for cards of membership, and such other expenses of the annual meeting as are essential for the conduct of the routine work; for meeting the necessary personal expenses of the Secretary and Treasurer while attending the annual meetings and in conducting the necessary correspondence; for publications; for enabling standing committees to fulfill their respective duties and conduct their correspondence; for the encouragement of scientific investigation by prizes, and for defraying the expenses of scientific investigation under the instruction of the Association, where such investigation has been accompanied with an order upon the Treasurer to supply the funds necessary for carrying it into effect.

AMENDMENT.

No amendment or alteration shall be made in any of these rules except at an annual meeting next subsequent to that at which such amendment or alteration may have been proposed, and then only by the voice of three-fourths of all the members present. Provided, however, that when an amendment is properly under consideration, and an amendment thereto is offered germane to the subject, it shall be in order, and if adopted, shall have the same standing and force as if proposed at the preceding meeting of the Association.

BY-LAWS.

1. *Order of Business.*—The order of business at the annual meetings of the American Medical Association shall be subject to the vote of three-fourths of all the members in attendance. Until thus altered, except when suspended, it shall be as follows:

1. Calling the meeting to order by the President.
2. The report of the Committee of Arrangements on the credentials of members, after the latter have registered their names and addresses; and on such other matters as it desires to present to the Association.
3. The reception of guests of the Association.
4. The annual address of the President.
5. The reception of reports from all special committees.
6. The reading and consideration of reports of standing committees, the Board of Trustees, Business Committee and Judicial Council.
7. New business and instructions to standing committees.
8. The report of the Business Committee and the election of officers of the Association; the selection of next place of meeting.
9. Reports from the Executive Committees of the Sections.
10. Reading of the minutes by the Secretary.
11. Unfinished and miscellaneous business.
12. Adjournment.

MEETINGS.

The Annual Meetings of the American Medical Association shall be held in May if the place be in the South, and in June if the place be in the North. The day of opening of the general sessions shall be the first Tuesday after the first Monday of the month selected. The hour of opening on the first day shall be 10 A.M., and on the following days 4:30 P.M.

SECTIONS.

The several Sections shall hold their first meeting at 1:30

P.M. on the first day, and at 9 A.M. and 1:30 P.M. thereafter daily.

The several Sections are as follows:

1. Practical Medicine.
2. Obstetrics and Diseases of Women.
3. Surgery and Anatomy.
4. State Medicine.
5. Ophthalmology.
6. Diseases of Children.
7. Dental and Oral Surgery.
8. Medical Jurisprudence and Neurology.
9. Dermatology and Syphilis.
10. Laryngology and Otology.
11. Materia Medica. Pharmacy and Chemistry.

Officers of Sections.—The officers of each Section shall consist of a Chairman, Secretary and Executive Committee. The Chairman and Secretary shall be elected annually immediately after the Section is called to order on the afternoon of the second day. During the session of the first day, the Chairman shall appoint a Nominating Committee, consisting, if practicable, of ex-chairmen of the Section, to report at the opening of the afternoon session of the second day. Election shall be by ballot.

The Executive Committee of each Section shall, when first appointed, consist of three members from among those who have been in attendance at the sessions of the Section for at least two years, to serve for one, two and three years respectively; and thereafter the retiring Chairman of the Section shall take the place upon the committee of the retiring member. It shall be the duty of the Executive Committee, in conjunction with the Chairman and Secretary, to give special attention to the interests of their own Section. Thus they shall secure the annual republication from the JOURNAL of the work of the Section, its papers and discussions, lists of officers, lists of all members of the Section, with their addresses, and rules adopted by the Section for the conduct of its work, securing from the Section the funds needful for the performance of this purpose. They shall carefully edit all publications of the Section, and secure a creditable mechanical execution of the same. They shall also take such measures as in their judgment will secure the cordial coöperation of all reputable workers in their special fields in North America.

The several Executive Committees of the Sections shall meet together and form a General Business Committee of the Association, with powers and duties described under the head of the General Business Committee.

The Chairman of each Section, in addition to his duties as a presiding officer and a member of the Executive Committee, shall read a short address at the opening of the session on the first day. In conjunction with the Secretary, he shall secure from members papers to be read, and arrange for the discussion of the same. This order of Section work he shall communicate to the Secretary of the Association at least one month before the annual meeting.

No paper read before the Sections shall occupy more than twenty minutes. If it be longer, the writer should make such an abstract as will bring it within the limit, and present it for discussion. No person shall discuss any paper more than once, or speak longer than fifteen minutes without unanimous consent.

No paper shall be read before any Section that is not in such condition as to pass at once from the reader's hands to the Executive Committee of the Section. Within thirty days said Committee must forward the entire work of the Section to the editor of the JOURNAL, with such recommendations as it deems proper. But no paper shall thus be sent by an Executive Committee that does not fall under one of the following heads:

1. Such as may contain and establish new facts, new modes of practice or new principles of real value.
2. Such as may contain the results of well devised, original experimental research.
3. Such as present so complete a review of the facts on any particular subject as to enable the writer to deduce therefrom legitimate conclusions of importance.

Other papers containing material of more or less value shall be returned to their authors, to be published as they may desire, with the statement that they were read before said Section of the American Medical Association.

In general, it is expected that each Executive Committee will make every effort to secure for its special Section, papers and discussions which will fairly represent the active workers in their department of medicine, and to promote cordial good will among the several workers therein.

PUBLICATION OF PAPERS AND REPORTS.

All papers and reports must be so prepared as to require no material alteration or addition at the hands of authors. All Section work must be in the hands of the editor of the JOURNAL within thirty days after the annual meeting. Proofs will be sent to authors, but they should be returned at the earliest possible moment, and unless returned within two weeks, the paper may be omitted from the JOURNAL. Every paper requiring it shall be illustrated at the expense of the Association, should it accept the same for publication. Every paper accepted is understood to be contributed exclusively to the Association JOURNAL, though brief abstracts of the same may be published elsewhere. In case of an article that is of especial value, the result of expensive research or experimentation, the Trustees, at their discretion, may compensate the writer in accord with the usual price of such work.

The Editor and Board of Trustees has the power to reject any paper referred to it, unless especially instructed to the contrary by the Association.

DUES.

Each member of the Association shall pay the annual subscription to the JOURNAL of five dollars before receiving from the Committee of Arrangements the membership ticket to the annual meeting. The evidence of this shall be the Treasurer's receipt for the five dollars. Any member failing for one year to pay this subscription shall be dropped from the rolls.

DELEGATES.

The President of the American Medical Association is authorized to appoint members, desiring such appointment, as delegates to the several medical and scientific bodies that are in sympathy with the Association.

DUTIES OF MEMBERS.

No members shall be permitted to address the Association unless they shall first have given their name and address, which shall be distinctly announced from the chair. If desirable the member may be required to go forward and speak from the platform.

Failure to do special committee work shall cause the offender to forfeit a continuance of the same appointment, or a place upon any other, unless satisfactory excuse is offered.

It is expected that every member will, in every available way, promote the interests of the medical profession as represented in the Association, and will conform to all its regulations in spirit and letter until they may be altered by the action of the body which formulated them.

THE PREVIOUS QUESTION.

When the previous question is demanded, it shall take at least twenty members to second it. When the main question is put under force of the previous question and negated, the question shall remain under consideration, the same as if the previous question had not been enforced.

NEW BUSINESS.

No new business, or resolutions by members, shall be introduced at the general session of the Association, except on the first and fourth days of the meetings.

ELIGIBILITY TO OFFICE.

In the election of officers and the appointing of committees by the Association and its President, they shall be confined to members present at the meeting, except in the Committee of Arrangements.

MEDICAL AND SURGICAL EXHIBIT.

There shall be no medical and surgical exhibit, under the authority or recognition of the American Medical Association, other than that made before the several Sections under the supervision of the Business Committee. All that is new and of value to the scientific or practical physician can thus find an appreciative audience. Experience has shown that all other exhibits detract from the work in Sections, and so lessen the attractiveness of the annual meetings to those whose presence is desirable.

Dr. H. D. Didama, of New York, presented and read the minority report. [Not furnished by the Secretary.—Ed.]

Dr. E. D. Ferguson, of New York moved the adoption of the minority report.

After some discussion by Drs. Quimby, Bergstein and G. F. Jenkins, a vote was taken, resulting in 160 ayes to 70 nays.

The President announced that by this vote the minority report became the report of the Committee.

Dr. M. M. Walker, of Virginia, moved that the report be now adopted.

Dr. Bergstein, of Nevada, moved that it be read by sections, and compared with the present laws. This was negatived by 100 ayes to 158 nays.

Dr. W. E. Quine, of Illinois, protested against the adoption of the report.

Dr. X. C. Scott, of Ohio, spoke in favor.

Dr. Henry P. Newman, of Illinois, offered the following rule, which was adopted: That no one shall speak more than once on this subject, and for only three minutes; the one who offered a motion to have five minutes.

Remarks were made by Drs. H. O. Marcy, of Massachusetts; Edw. Jackson, of Pennsylvania, and E. D. Ferguson, of New York, when Dr. J. W. Graham, of Colorado, moved to lay the whole subject on the table. This was lost by 84 ayes, 128 nays.

Dr. X. C. Scott moved the previous question, which was sustained.

The ayes and nays being demanded, the roll of delegates was called by the Permanent Secretary, resulting, ayes 151, nays 64. Total vote 215.

Dr. J. B. Roberts, of Pennsylvania, appealed from any decision by this vote on the ground that the laws required a three-fourths vote of *all the delegates in attendance*. The appeal was not seconded.

The President having examined the report of the vote decided that it lacked the necessary majority, and was not adopted.

Dr. E. D. Ferguson offered an amendment to the By-Laws to insert the words, "annual subscription to the JOURNAL of the Association," for "annual dues" wherever it might occur. This was unanimously adopted.

The Association adjourned until Friday, 10:30 A.M.

FRIDAY, JUNE 8.

The President called the Association to order at 10:30 A.M.

The Chairman of the Committee of Arrangements announced a number of communications.

The first business in order being the action upon the By-Laws. On motion of Dr. J. B. Roberts all the amendments as announced were postponed until next year.

Dr. H. D. Holton read the report of the Committee on Revision of the Code of Ethics.

It is proper that a word should be said in explanation. To this Committee appointed at the Detroit meeting, was referred the revision of the Constitution and By-Laws, as well as the revision of the Code of Ethics. Those of you who have ever served on a committee living at such distances from each other, know how difficult it is to arrange for the meeting of such committees. When we did meet, we found that our first meeting was used up in the consideration of the revised Constitution and By-Laws. Although three-fourths of all letters received on the subject desired some change in the Code, there were certain questions that we felt required more study, before we should formulate anything concerning them. At the Milwaukee meeting we so reported, and in that report indicated the lines upon which we believed the revised Code should be written. With an almost unanimous vote that report was accepted, and the Committee continued, with instructions to proceed with the work of revision as indicated. The Committee then felt that they were under specific instructions to perform a particular service, and that the lines along which they were to render this service were plainly indicated. Now what were the lines indicated in that report and which we were directed to follow? They were as follows:

1. We would omit all sections of the Code that describe the obligations of patients to their physicians, and of the public to physicians. The reason for this suggestion is that the Code is not designed either for patients or the public, and so the sections are superfluous. This omits the ten sections under Art. II, on pages 5, 6, 7 and Art. II, on page 20.

2. We suggest the placing in the same list with the copy-righting of medical books and other similar work, the patenting of all mechanical appliances used in medicine or surgery. The Code says nothing respecting the copy-righting of medical publications, and we find no good reason why it should say anything respecting the patenting of mechanical devices.

3. We recommend the more accurate definition of the term, "consultation," as we find good reason to believe that serious estrangement has arisen between physicians because of the different ideas they attached to this term. The Code of Ethics, page 14, second line from the top, says that in a "consultation" the responsibility must be equally divided between the medical attendants—they must equally share the credit as well as the blame of failure. With this statement before us, it is clear that there can be no consultation when one physician meets another for the purpose of obtaining from him an account of the case, or pertinent facts of family history, or a record of the past management of the case, in order that he may more intelligently assume the entire responsibility of its future conduct. Thus the existing Code of Ethics of the American Medical Association defines a consultation substantially as a meeting of doctors to discuss a case, to the end that they may equally share in its further management. By the same authority, a consultation is not a meeting of physicians with a case, in which one gets all the facts possible from the other or others, as a preliminary to his assuming entire responsibility in its future conduct.

From these data it is clear that usually the specialist does not consult with the general practitioner. He simply obtains all the facts the general practitioner possesses, preparatory to assuming full control of the case.

There are many other occasions for the meeting of medical men in connection with cases of sickness, that are in no sense consultations according to the existing Code. Hence we think that in the interest of scientific accuracy, there should be a discrimination made in the study of consultations, as present conditions differ widely from those of forty or more years ago.

Having promised this much, your Committee recommends the alteration of Art. IV, Sec. 1, page 11, Code of Ethics, to read as follows: "A thorough medical education furnishes the only presumptive evidence of professional abilities and requirements, and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless as the good of the patient is the sole object in view, and this is dependent upon personal confidence, no intelligent practitioner who has a license to practice from some medical board of known and acknowledged legal authority to issue such license, and who is in good moral and professional standing in the place in which he resides, should be refused consultation when it is requested by the patient."

4. It is suggested that it would be wise to re-write the Code, in phraseology so plain as to make it a practical common sense document for daily guidance in the performance of our various duties, and an aid in meeting responsibilities incident to our professional life.

We have followed the lines of these four recommendations and have also aimed,

1. To arrange, so far as practicable, all topics of the same nature under the same heading. As the Code now is, cognate subjects are scattered promiscuously through the entire document.

2. To make the different headings more definite in their designation of the subjects contained under them.

3. To separate questions of ethics from those of etiquette.

4. To make the Code correspond with and acknowledge the immense changes which have taken place in the profession since it was first written.

5. To avoid all reference to medical sects and irregular practitioners; because such reference sullies the dignity of the Code, and because it is a recognition of the existence of that which we believe should not exist, and because it is the most efficient means of perpetuating the objectionable condition.

6. In view of the fact that there are so many women practitioners of acknowledged learning, reputation, and skill, the language of the revision omits all reference to sex.

Finally, the fundamental requirement of the Code is the possession of such a liberal education, training and culture in the humanities, the arts, and the science and art of medicine itself, as will make every member of the profession a gentleman and a scholar, the peer of the members of all the other learned professions, and in that way to establish the

dignity of the profession on a surer basis than can be reached by hedging it in with any system of penal enactments.

For two months the work of the Committee has been before this Association. In that time a feeble attempt has been made to criticise this work. First, by following the custom of certain attorneys when their case is especially weak, to fall to and abuse the attorney of the other side. These critics have insisted that the Committee ought not to have presumed to have performed the task assigned them, but should have kept silence. This the Committee could not in honor do. They were directed to do a certain thing. Of letters received by the Committee upon this subject, more than three-fourths of the writers desired some change in the existing Code. We all know that in the last few years there has sprung up several large national societies to discuss the various phases of medical science. That they number in their membership some of the brightest scientific minds in the profession, some of whom formerly met with us and all of whom ought to be with us. In their articles of organization I do not find anything about our time-honored Code. If this Association is to hold the place for which it was originally organized, that of leading the profession, it has got to divest itself of such rules and regulations as have become dead letters and which it has not enforced for more than a decade because it could not. We may ostrich-like hide our heads in the sands of bigotry, and imagine that we are safe, while we listen to those sirens who chant of the sacred halo which forty-seven years has thrown around our Code. But we shall find that the bacilli of progress is, and has been at work in the profession at large, until this sacred halo of age can not eradicate them. This sleepy bigotry which would accept no change because present methods have answered well enough for the last half century, if applied to the different branches of our profession, would have prevented the wonderful triumphs of aseptic surgery. It would have left to some dim future the achievements of our professional gynecologists, and subjected us to the ridicule of the world. The eternal principles of truth and justice do not change, but the application of them does change as the environment of man changes.

The principles of law remain the same as in the days of the Roman Empire, but their application to the changed conditions of commerce and business varies with each stride of progress.

You may vote it down, as has been the cry of some, but like Banquo's ghost it will not down. For twenty years it has annually haunted us. In the centennial year of our Republic, that great and good man, justly eminent and held in the highest esteem, not only on this continent but by the whole civilized world, the then President of this Association, J. Marion-Sims, in his address to the Association, as if with prophetic eye, said in speaking of the Code of Ethics: "I know there are many, indeed a large majority, of this Association who believe it to be as perfect as the Decalogue, and as incapable of improvement. It is looked upon by some of its high priests as the holy of holies, and not to be desecrated by the touch of vulgar hands. . . . Pardon me if I ask you, 'Is the Code of Ethics up to the requirements of the times?' Under our Code, all consultations are secret and confidential, and the friends of the patient are never to know that there was a difference of opinion between the consultants. But was there ever such a difference that it did not leak out, sooner or later? Why should it not be so? Why should honest consultants act out such a deception as our Code falsely teaches? . . . The Code of Ethics is violated every day, either wilfully or ignorantly. Not only by the rank and file, but by men high in the profession. Men who are considered leaders, advanced thinkers and workers. There is not a man within the sound of my voice who can not call to mind some violation of the letter or spirit of the Code of Ethics, that has occurred under his own immediate observation. Indeed, when we speak of violating the spirit of the Code we may all, as one man, cry out: 'He that is without sin among you, let him first cast a stone!'"

"The time will come when your organic laws, like the Constitution of our country, will require modifications and amendments to suit a higher intelligence, a broader education and a greater destiny. Remember that when our Code, was adopted we had no telegraph, no ocean steam navigation and but few railroads; the profession was not educated up to its present level, medicine was more of a mystery than it is now, and the press was not the organized power in the land it is to-day. Modern thought and modern progress, keeping pace with the physical development of the age, will never be content with the slow, uncertain movement of olden

times." Has not the time arrived for the fulfillment of the prophecy of this wonderful man? As Holmes has said:

"In opinion look not always back;
Your wake is nothing, mind the coming track;
Leave what you've done for what you have to do;
Don't be 'consistent,' but be simply true."

HENRY D. HOLTON, Chairman.

Dr. H. D. Didama read the minority report.

REPORT OF THE MINORITY OF THE COMMITTEE ON REVISION OF THE CODE OF ETHICS OF THE AMERICAN MEDICAL ASSOCIATION.

SAN FRANCISCO, JUNE 8, 1894.

One year ago, at the meeting of the AMERICAN MEDICAL ASSOCIATION, the minority of the Committee on Revision reported against any kind of revision of the Ethical Code:

"1. Because the language of the Code is clear, concise and accurate, and conveys to the mind the soundest ethical principles derived from the maxims of all civilized nations, compiled and admirably arranged by practical men of acknowledged ability and wisdom.

"2. Because the Code is explicit, liberal, broad, humane and founded on truth, justice and reason, and is free from magisterial assumption or oppressive exaction.

"3. Because the Code contains full particulars, without superfluous details, for the guidance of all physicians, for the instruction of beginners and for the information of the people."

A careful examination of the revised Code, as published by the Majority Committee in the JOURNAL a few weeks ago, has served only to confirm the opinion expressed by the Minority Committee at the Milwaukee meeting.

It would be a needless and wearisome consumption of the valuable time of this Association to point out the omissions from, alterations of, and additions to, the Code which have received the signatures of the Majority Committee. You are familiar with them all. You know that whole Articles, such as those relating to the "Obligation of Patients to their Physicians," and of the "Public to the Profession," have been stricken out.

You know that the Article on the "Duties for the Support of Professional Character" has been emasculated by removing "the section which enjoins a high standard of moral excellence and purity of character on the part of the physician."

It can not have escaped your notice that certain varieties of advertising condemned by the present standard Code are commended in the revision, and that the patenting of surgical instruments and the prescribing of secret nostrums forbidden by the standard are intentionally ignored by the revisers.

And you have read—many of you, possibly with surprise and grief—the statement in the proposed revision that the possessor of a *license* granted by a board of acknowledged legal authority should not be refused consultation when requested by a patient.

Some of you, of your own free will and accord, and as loyal representatives of State societies which have spoken with no uncertain sound, undoubtedly hold the opinion that legality and fitness are not interchangeable terms. Notwithstanding the ingenious arguments of the eminent gentlemen who constitute the Majority Committee, you are not convinced that consultations of regular physicians with irregular practitioners are proper or beneficial to the patient. The irregular may be honest and sincere. He may have received a collegiate education. He may be a pillar in the church. He may thoroughly know anatomy and chemistry and biology. He may be able to speak with the persuasive tongue of eloquent men and of angels. And yet if he, by ignoring, or rejecting the rational *materia medica* and therapeutics upheld by all regular physicians throughout the world, and professing to be governed in his practice by a metaphysical dogma, demonstrates that he and the regular doctor have absolutely nothing of any practical importance in common, some of you steadfastly believe that a pretended consultation in these circumstances would be, even if the patient desired it, an imposition and swindle which no sophistry can rectify, no plea of liberality palliate, no fee recompense or excuse.

Abstaining from all argument, after the example of our excellent President in his address, the Minority Committee ventures to express the conviction, founded on abundant observation and experience, that the adoption of the Majority report would conduce, not to the welfare and harmony of the Association and the profession, but to the injury and degradation of both.

Respectfully submitted,

HENRY D. DIDAMA, M.D.

Dr. E. F. Ingals, Illinois, moved to lay the minority report on the table. This was rejected.

Dr. X. C. Scott, Ohio, moved that the minority report be substituted for the majority report. This was adopted.

Dr. J. H. Parkinson, California, seconded by Dr. Scott, moved that the consideration of the report be indefinitely postponed; this was withdrawn by the mover, with the consent of the seconder.

Finally, on motion, the report was laid on the table. Ayes, 135; nays, 30.

The Addresses on Surgery and on State Medicine were by request of their authors, (both being absent) read by title.

The report of the Committee on Nominations was presented by Dr. J. Cochran, Chairman, as follows:

REPORT OF NOMINATING COMMITTEE.

The Nominating Committee herewith submits its report: President, Donald Maclean, of Michigan. First Vice-President, Sterling Loving, of Ohio. Second Vice-President, Wm. Watson, of Iowa. Third Vice-President, W. B. Rodgers, of Tennessee. Fourth Vice-President, F. S. Bascom, of Utah. Treasurer, Henry P. Newman, of Illinois. Permanent Secretary, Wm. B. Atkinson, of Pennsylvania. Assistant Secretary, G. H. Rohé, of Maryland. Librarian, Passed. Place of Meeting, Baltimore, Md. Chairman Committee of Arrangements, Julian J. Chisholm, of Maryland.

Board of Trustees:—Jos. Eastman, Indiana; J. T. Priestley, Iowa, and D. W. Graham, Illinois (full term); John E. Woodbridge, Ohio (unexpired term); J. W. Graham, Colorado, *vice* D. C. Patterson, (deceased).

Judicial Council:—D. W. Crouse, Iowa; R. C. Moore, Nebraska; T. D. Crothers, Connecticut; G. B. Gillespie, Tennessee; W. T. Bishop, Pennsylvania; C. H. Hughes, Missouri; I. J. Heiberger, District of Columbia, and H. Brown, Kentucky (unexpired term).

Address on Medicine, William E. Quine, Illinois.

Address on Surgery, C. A. Wheaton, Minnesota.

Address on State Medicine, H. D. Holton, Vermont.

(Signed.) JEROME COCHRAN, Chairman.

On motion of Dr. B. R. Cole, California, the report was received, and declared to be approved.

On motion, the President and Permanent Secretary were authorized to appoint delegates to foreign societies.

Dr. Edw. Jackson, Pennsylvania, offered the following:

WHEREAS, The interests of the JOURNAL of the Association require that it should command the confidence of the members of the societies in affiliation with this Association; and

WHEREAS, The JOURNAL of the AMERICAN MEDICAL ASSOCIATION has continued to publish unethical advertisements, like those of "Antikamnia," "Labordine" and other secret nostrums, and that of the American Physicians' Sanitarium Company, offering one hundred dollars worth of stock to physicians sending it patients; and

WHEREAS, The Trustees of the JOURNAL have defended such a course on the grounds that the money from such advertisements was needed to publish such a journal as they thought creditable to the Association,

Resolved, That the various State Medical Societies in affiliation with this Association are hereby requested to inform this Association whether their members approve the policy of admitting such advertisements to the pages of the JOURNAL of the AMERICAN MEDICAL ASSOCIATION.

Dr. X. C. Scott moved to lay it upon the table. Lost, 102 to 113.

After discussion by Drs. Cochran; Dickson, of California; Hamilton, Illinois, Dr. Jackson agreed to strike out the preamble. Finally on motion of Dr. Cochran, the resolution was referred to the Judicial Council.

Dr. H. O. Marcy, Massachusetts, moved to take from the table all questions as to the Constitution, By-Laws and Code of Ethics. Adopted, 100 to 91. After some discussion, he moved to indefinitely postpone the entire matter. The previous question was called, sustained by a sufficient number,

and being put, Dr. Marcy's motion was agreed to by a large majority.

Dr. W. T. Bishop, Chairman of Committee on the President's Address, made the following report:

The Committee to whom was referred the Address of our President, James F. Hibberd, M.D., LL.D., Richmond, Ind., respectfully report:

The change of date from May to June, 1894, is approved. Credentials might be issued in duplicate, one copy given to delegate, and one copy or list of delegates with power of substitution forwarded to Secretary of American Medical Association, and he to furnish list of recognized bodies to Committee of Registration, the effort to be, as the President suggests, to get all members of the regular practice into the American Medical Association through State and county societies.

With the President we can not approve the turning of the Association over to the control of the sections; the sections should remain as they are and have their own officers, etc., as now provided for, the Nominating Committee representing men who are in the general or special practice of their several States and counties are sure to select proper officers, having done it for fifty years, the Association not being bound to accept the officers named having the power to amend the report of the Nominating Committee or refer it back for correction.

The American Medical Association should invite the attention of the Congress of the United States of America as represented in the Senate and House of Representatives, to the fact that we are opposed to the reduction of medical men from 125 to 90, or any other number less than at present provided for, 125 assistant surgeons; let the officers of our Association and the officers and members of State and county societies at once act; this is a matter of great importance to the Army and the country at large.

The appropriation to Index Catalogue and Library should be increased, as before the proposed reduction, to \$10,000.

The whole profession in this country, as well as Europe, are interested in this subject.

We urge the continuous effort for the Department of Public Health, but recognize that if organized it, like bills organizing State Boards of Medical Examiners, will either lack much that we desire or contain much that we do not desire. We want a Department, and can repair or improve it afterwards. This last may take time, and all will require some money to secure what we wish,—the money and labor, etc., now spent must be secured by further effort.

The effort should be made at all times to promote vaccination and establish proper sanitary conditions—the physician in his daily practice has much to do with preventing disease; the large population that is "on the move" makes it necessary that every good citizen should be on guard to prevent the spread of disease and crime.

Since our last meeting some States have provided for a Board of Medical Examiners, who will examine all who come into their State to practice medicine; the Board to be composed of members of the profession, but not connected with any teaching institution.

The medical profession and the world at large require from the practitioner more than ever before, knowledge founded upon education. The microscope and the cultures of the investigator make certain what was once surmised.

The attention is called to the constant amendments that are being offered to the Code and Constitution, and the members are warned to avoid ill feeling in the discussion of these questions.

The Address in general is most heartily approved.

W. T. BISHOP, Chairman.

REPORT OF THE BUSINESS COMMITTEE, JUNE 6, 1894.

The Business Committee recommends to the Association the adoption of the accompanying resolution of Dr. Marcy which was referred to it. It also recommends the adoption of the agreement with the Newberry Library of Chicago in regard to the transference of the Library, with the alteration made upon it, that the future deposit of books, etc., be optional with the Association and not obligatory.

The Committee also recommends the adoption of the following resolution in regard to the issuing and printing of the official program for the annual meeting:

Resolved, That the official program containing the appointments for the general sessions and the work of the sections shall be printed at the office of the JOURNAL of the Association, and in order that this may be accomplished, the officers of the Sections and the Committee of Arrangements shall

transmit the program of the business and scientific proceedings so that it shall be in the hands of the Permanent Secretary of this Association at least one month before the date of each annual meeting. The list of entertainments shall be prepared by the Committee of Arrangements and as far as practicable shall be included in the official program.

The Business Committee also ask if they are empowered to receive business directly from the sections before it has been presented to the Association, and if such is not included in their present authority, ask that the same be granted, as it believes that much time will thus be saved, and the work of the Association forwarded.

L. DUNCAN BULKLEY,
Secretary Business Committee American
Medical Association.

The Business Committee, to which was referred the suggestions contained in the Treasurer's report, recommend as follows:

1. That the Constitution be amended in that portion relating to the necessity of electing to office only those who are present at a meeting, so that the Treasurer be not thus included.

2. That the Treasurer receive compensation commensurate with the services required of him, and recommend that three hundred dollars (\$300) be appropriated for that purpose.

The third suggestion, regarding delinquency in the payment of dues, the Committee consider has been already met by the change in Constitution passed yesterday, so that no further action thereon is necessary.

The Committee recommend that the Board of Trustees appropriate three hundred dollars (\$300) for the salary of the Permanent Secretary.

The officers for the ensuing year are: Chairman, Dr. E. E. Montgomery, Philadelphia; Vice-Chairman, Dr. J. M. Duff, Pittsburg; Secretary, Dr. L. Duncan Bulkley, New York

L. DUNCAN BULKLEY, M.D.
Secretary Business Committee.

On motion, the report was adopted and the Committee were discharged.

On motion of Dr. X. C. Scott, the Trustees were instructed to publish each week the Explanatory Declaration relative to the Code of Ethics. (See pages 19 and 20 of Code.)

Dr. J. T. Priestley, Iowa, offered an amendment to the Constitution, which was laid over.

Dr. I. N. Quimby, New Jersey, offered an amendment to Section 5, Art. I, page 9, to strike out "surgical instruments, or." Laid over as an amendment.

The report of the Committee to Act with the Committee of the American Public Health Association was presented, accepted, and the appended resolution adopted:

The report of Dr. C. G. Comegys, Ohio, as Chairman of Committee on Secretary of Public Health, was laid before the members.

REPORT OF THE SPECIAL COMMITTEE APPOINTED TO PETITION
CONGRESS TO CREATE A DEPARTMENT AND SECRETARY
OF PUBLIC HEALTH.

Mr. President and Members of the American Medical Association:—Your Committee has endeavored, since the last session at Milwaukee, to advance the work committed to our charge, and beg leave to report progress. In the course of our efforts to secure the passage of our original bill which has heretofore, both at the annual sessions at Detroit and at Milwaukee, been laid before you, and which was introduced into the Fifty-second Congress in both Houses, in December, 1891, we found that a strong opposition was made to its favorable report from the committees in the Senate and House of Representatives by the Chief of the Marine-Hospital Service, because it seemed to him to encroach upon the functions of his office as Director of quarantine affairs, and that it would greatly embarrass his work. This was not intended at all by your Committee; therefore, as our bill appeared to lie dormant in the hands of the congressional committees, and as the dread apprehension of the entrance of Asiatic cholera through our commercial intercourse had so aroused Congress to the necessity of

strengthening the quarantine service, making it apparently unnecessary to extend legislation in the direction of public health at that time, we were advised by friends in Congress to cease further efforts until the second session. At the opening of the second session, in December, 1892, it was found that one of our important friends in the House Committee was ill—in fact, was unable to take his seat at any time during the session.

Your Committee then determined to await the opening of the Fifty-third Congress, in December, 1893, for a renewal of our activity. In the meantime the great Pan-American Medical Congress met in Washington, in September, 1893, and we took advantage of the assembly of that body of eminent medical men to bring before it the importance of the creation of Departments of Public Health in all governments, under the direction of a secretary appointed from the medical profession, who should be on a parity, in the Cabinet of the President, with the Secretaries of other Departments. Our proposition was referred to the Committee on State Medicine and, after a most thorough discussion by eminent practitioners of different States, was adopted with but one dissenting voice.

Your Committee next, after due consultation, concluded that, in order to avert the opposition of the Marine-Hospital Service, it would be wise to reconstruct our bill so as to leave out any reference to the supervision, by the Secretary of Public Health, of the quarantine service; merely referring to it as an available source of information for the general purposes of public health, on the same plane as that furnished by the Surgeons-General of the Army, Navy, the State Boards of Health, and all municipalities, hospitals and asylums throughout the country.

Therefore, we re-drafted our petition and bill, in regard to the establishment of the Health Department and the Secretary of Public Health (copies of which accompany this report), and they have been introduced into the present Congress—in the Senate by the Honorable Mr. Gray, of Delaware, and in the House by the Honorable Mr. Goodnight, of Kentucky—and have been referred to appropriate committees. Our report and petition have been published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, commended by the Editor, and also by other leading journals, and have been favorably spoken of by a multitude of eminent men in our profession everywhere.

We regret to say that there are members of the profession who are inimical to this movement of the Association to obtain increased rank and dignity in the affairs of the general government, not on account of what we specify as the true relation of the profession in the body politic in regard to its capabilities in preventive medicine, but because such a high office may involve us at length in the mire and filth of partisan politics, and we shall be made a low section of what is called the "political machine." This is an astonishing view to take of a profession that in its career in all history, and exceptionally so in the nineteenth century, is conspicuous in its service to the people, for its moral purity and broad and generous liberality. We protest against this consideration of our probable influence in public affairs. These hesitating friends seem to be willing enough to obtain the establishment of a Bureau of Public Health under the supervision of the Secretary of the Interior or of the Treasury; why should not the same apprehension of defilement attach to these Departments as to a Department of Public Health?

There are numerous medical men in every State in the Union whose intelligence, statesmanship and moral character is as strong as that of the men who are usually at the head of other Departments in the Cabinet.

There are others who say that this attempted elevation to a representation in the Cabinet of the President is too sudden and startling; that an office of such eminence can only be acceptable to public opinion after a lengthy novitiate as a commission of public health shall have shown its necessary utility in affairs appertaining to the health of the people; that its expenditures will become an additional burden to our tax ridden people, and this tendency to centralizing power in the Capital will be an additional limitation of the rights of the States in the Government.

The provisions of our bill answer sufficiently all these objections and show, on the contrary, that our influence for the promotion of preventive medicine will become greatly enlarged; in fact, that by no other method can the influence of our profession for the promotion of public order, comfort and virtue be as thoroughly displayed.

Our success has been greatly compromised by the action of the New York Academy of Medicine in their endeavor to frustrate our movement by the preparation of bills to obtain

an action of Congress to extend, in various ways, the existing quarantine laws and to keep the profession under the autonomy of either the Secretary of the Treasury, or the Secretary of the Interior; and their plan has been urgently pressed upon the attention of the State and medical societies and State Boards of Health throughout the Union. It is proper to say that, in the early part of our undertaking, we made an appeal to an eminent member of that Academy to bring our petition and bill before the Academy and to request its potent cooperation in our behalf. That member treated our communication courteously and we thought that he felt a warm sympathy with the movement; but, at length, he replied that there was an unwillingness on the part of several members to have it presented to that Society. This was a serious disappointment to us and was much regretted. For that Society is composed of distinguished medical men and is doing a notable quantity of scientific work; but we think it must be conceded that the AMERICAN MEDICAL ASSOCIATION, which for nearly fifty years has been holding its sessions in all the chief cities of our country and has been sustained by the greatest minds in medicine, has a stronger claim to represent the profession in the Congress of the United States than the very eminent local organization in the city of New York.

It is not probable that any bill can pass at this session of Congress, but the ASSOCIATION should at this time direct that a renewed effort should be made so as to be ready to make the most powerful effort possible to secure the passage of our bill at the next session. Such consolidated effort can only be made effective by an organized effort in every congressional district in the Union.

In conclusion, we beg to offer the following resolutions:

Resolved, That the AMERICAN MEDICAL ASSOCIATION renews its appeal to the Congress of the United States to adopt the bill now in its possession for the creation of "A Department and a Secretary of Public Health."

Resolved, That the Committee proceed as soon as possible to secure subcommittee in each congressional district of the country to obtain a favorable action on the part of their Senators and Representatives for this measure.

Resolved, That a committee be appointed to endeavor to secure the friendly cooperation of the New York Academy of Medicine.

Resolved, That a sum not exceeding four hundred dollars be appropriated to defray the necessary expenses of the committee in carrying on their work.

All of which is respectfully submitted.

C. G. COMEGYS, M.D.
N. S. DAVIS, M.D.
U. O. B. WINGATE, M.D.
J. C. CULBERTSON, M.D.
W. B. ATKINSON, M.D.
L. H. MONTGOMERY, M.D.

REPORT OF THE COMMITTEE APPOINTED BY THE AMERICAN MEDICAL ASSOCIATION TO ACT IN CONJUNCTION WITH A COMMITTEE OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

Mr. President, and Members of the American Medical Association:—Your Committee appointed at the last meeting of the American Medical Association, held in Milwaukee in June, 1893, "to act in conjunction with a Committee of the American Public Health Association to make efforts to induce the Congress of the United States to establish a Medical Bureau and Commissioner, who shall be the Chief Executive Officer of the General Government," would submit the following report:

Your Committee met with the Committee on Legislation of the American Public Health Association at Chicago, where the annual meeting of the Association was held, Oct. 9-14, 1893.

Dr. J. H. Parkinson, of California, not being able to be present, requested the President of the American Medical Association to appoint some one to act in his place. The President of the American Medical Association, Dr. James F. Hibberd, of Indiana, being present, by request and universal consent of both Committees acted on your Committee in the place of Dr. Parkinson.

After considerable discussion there was a disposition shown to take no action further than what the American Public Health Association had formerly taken in regard to the matter, but it was finally decided that the Association should place itself on record in some manner to show that any legislation aiming for a lesser object than that of providing for some national head with general sanitary authority, should not be encouraged.

A portion of your Committee believed, and still believe,

that no lesser office than that of Secretary of Public Health in the Cabinet of the President should be encouraged, but as it was impossible to convince the members of these two Committees that such course was the only advisable one to pursue, the following resolution was submitted and adopted by the American Public Health Association as a compromise between the two factions of the joint Committee:

Resolved, That the American Public Health Association again urge upon Congress the necessity of the appointment of some officer with general sanitary authority in connection with the National Government;

That the functions of such an authority are of sufficient importance to demand the exclusive attention of the best instructed sanitarian;

That such authority should be enabled from time to time, and under proper regulations, to secure the advice and cooperation of the State Boards of Health.

Respectfully submitted,

U. O. B. WINGATE,
JAMES H. PARKINSON,
JEROME COCHRAN.

Dr. Jerome Cochran presented the following from Alabama:

Resolved, That the Medical Association of the State of Alabama, which is also the State Board of Health, is earnestly in favor of the passage of the bill now pending in Congress, to establish a Department of Public Health, and recommends said bill to the favorable consideration and support of the members of Congress, Senators and Representatives from Alabama.

Resolved, That we believe the bill would be materially improved by the insertion of an additional clause in the following words: "He shall once in every year, call to meet in the city of Washington, a conference of State Boards of Health, to be composed of one delegate from every State Board of Health in the United States, and to be for the purpose of discussing questions of public health, and for concerting plans of sanitary administration."

On motion of Dr. C. Denison, Colorado, the report was received, the addition proposed by Alabama accepted, the resignation of Dr. Comegys as Chairman accepted, and Dr. Cochran appointed Chairman.

The reports of the Business Committee were received and on motion accepted.

A notice from the Section on State Medicine, relative to Dr. J. H. Rauch, Illinois, deceased, was presented and adopted.

Mr. President and Members of the Section of State Medicine of the American Medical Association:—Your Committee appointed by the chair to draft and offer suitable resolutions upon the death of one of its honored members, the late Dr. John H. Rauch, of Illinois, beg leave to submit the following:

WHEREAS, Dr. John H. Rauch, an old and active member of the American Medical Association, a sanitarian of more than national reputation and worth, one whose entire professional life was identified with and devoted to State Medicine and sanitary science, and to whose personal efforts and perseverance the present existence of this Section is largely due, who at all times exhibited enthusiastic interest in its work and welfare, has recently been called to his final rest; therefore, be it

Resolved, That the Section of State Medicine by the death of Dr. Rauch painfully realizes that it has not only lost an active, earnest and devoted member, but that the science of sanitation and of medicine in general sustains an equally deplorable loss. Moreover, on account of Dr. Rauch's long and active connection with the American Medical Association, his unselfish devotion to his profession in times of war, peace and pestilence, and because of his national reputation, so deservedly won, we deem it only right and proper that we recommend to the American Medical Association at its present session, that it take some appropriate notice relative to the death of so distinguished, faithful and honored a member.

(Signed)

LISTON H. MONTGOMERY,
H. D. THOMASON,
C. A. RUGGLES,

Committee.

The foregoing preamble and resolution were unanimously adopted by the Section of State Medicine this p.m.

LISTON H. MONTGOMERY, Secretary.

The following from the Section on Materia Medica and Pharmacy was presented, and on motion adopted:

Resolved, That the American Medical Association directs the attention of the medical colleges of this country to the general neglect of the study of botany by medical students, and that it is the sense of this Section that the teaching of general descriptive botany should be made a part of the curriculum of study in every medical school. The delegates present at this meeting from the American Pharmaceutical Association concur in this action.

Resolved, That the American Pharmaceutical Association be invited to contribute to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION reports of and examinations of proprietary and secret nostrums, made under its direction. The officers of the Section on Materia Medica and Pharmacy to act with a committee to be appointed by the American Pharmaceutical Association, as a Committee of Conference in order to carry this resolution into effect.

As delegates to British Medical Association, Drs. C. A. L. Reed, Ohio; A. L. Hummel, Pennsylvania, and L. S. McMurtry, Kentucky were named.

Dr. Plummer, Chairman of Committee of Arrangements, announced that the number of those who had attended exceeded the expectations of the Committee. Twelve hundred delegates, visitors and ladies had been registered, and he thanked all for their presence at the meeting in San Francisco.

Dr. H. D. Holton, offered the following:

Resolved, That the most cordial thanks of this Association are due and are hereby tendered to the profession of California, the medical societies, the citizens of San Francisco, the Directors of the Midwinter Fair, the railroad officers, and all who have so generously contributed to make our visit to the Pacific Slope successful, pleasant and a memory that will live to cheer us during all our lives.

Resolved, That the thanks of the Association are hereby tendered to the President, Secretary, and other officers who have contributed to make this one of the most successful meetings in the history of the Association.

These were seconded by Dr. Marcy, and unanimously adopted.

The Permanent Secretary read as officers of sections.—

PRACTICE OF MEDICINE:

Chairman, E. W. Kellogg, Milwaukee, Wis.
Secretary, W. E. Quine, Chicago, Ill.

SURGERY AND ANATOMY:

Chairman, Jos. Ransohoff, Cincinnati, Ohio.
Secretary, Reginald H. Sayre, New York.

OBSTETRICS:

Chairman, F. H. Martin, Chicago, Ill.
Secretary, X. O. Werder, Pittsburg, Pa.

STATE MEDICINE:

Chairman, L. H. Montgomery, Chicago, Ill.
Secretary, C. H. Sheppard, Brooklyn, N. Y.
Executive Committee, C. A. Lindsley, New Haven, Conn.;
H. S. Orme, Los Angeles, Cal., and J. J. Kinyoun, Wash-
ington, D. C.

DERMATOLOGY AND SYPHILOGRAPHY:

Chairman, A. E. Regensberger, San Francisco.
Secretary, D. H. Rand, Portland, Oregon.
Executive Committee, L. D. Bulkley, New York; L. A.
Duhring, Philadelphia, and A. H. Ohmann-Dumesnil, St.
Louis, Mo.

DENTAL AND ORAL SURGERY:

Chairman, M. H. Fletcher, Cincinnati, Ohio.
Secretary, E. S. Talbot, Chicago, Ill.

OPHTHALMOLOGY:

Chairman, Edward Jackson, Philadelphia.
Secretary, H. V. Würdemann, Milwaukee, Wis.

NEUROLOGY AND MEDICAL JURISPRUDENCE:

Chairman, Daniel R. Brower, Chicago, Ill.
Secretary, W. J. Gavigan, San Francisco, Cal.
Executive Committee, John W. Givens, Blackfoot, Idaho;

T. D. Crothers, Hartford, Conn.; A. E. Regensberger, San Francisco, Cal.

LARYNGOLOGY AND OTOTOLOGY:

Chairman, J. F. Fulton, St. Paul, Minn.
Secretary, T. J. Gallaher, Pittsburg, Pa.

DISEASES OF CHILDREN:

Chairman, Edward H. Small, Pittsburg, Pa.
Secretary, Geo. W. McNeil, Pittsburg, Pa.

MATERIA MEDICA AND PHARMACY:

Chairman, W. L. Whelpley, St. Louis, Mo.
Secretary, Geo. F. Hanson, San Francisco, Cal.
Executive Committee, F. Woodbury, Philadelphia; F. E.
Stewart, Watkins, N. Y.

PHYSIOLOGY AND DIETETICS:

Chairman, E. H. Woolsey, Oakland, Cal.
Secretary, Chas. G. Chaddock, St. Louis, Mo.
Executive Committee, I. N. Love, St. Louis, Mo.; W. T.
Bishop, Harrisburg, Pa., and Ephraim Cutter, New York.
President Hibberd appointed Drs. H. D. Holton and L.
Cooper Lane to escort the President-elect to the platform.

Dr. Donald Maclean, of Michigan, the President-elect, in accepting the office, thanked the members and asked their aid in making the next meeting a success.

Dr. Hibberd, in retiring, thanked the members for their courtesy and general efforts in the success of this session.

The Association then adjourned to meet in Baltimore, Md., in June, 1895. W. B. ATKINSON, Permanent Secretary.

Address of Welcome to the American Medical Association, on the Occasion of its Visit to Cooper Medical College, June 6, 1894.

BY L. C. LANE, M.D.

PRESIDENT OF COOPER MEDICAL COLLEGE.

I extend to you a cordial welcome and sincerely thank you for this visit to Cooper Medical College; and its Faculty unite with me in this greeting. And further, let me thank you for your friendly act in visiting this State so remote on the sunset side of our Continent. You have learned how much time, labor and money it costs to reach us; and when I remind you that it has always cost us the same to reach you, I am sure you will find a satisfactory reason for the usual absence of the most of our profession from the annual conventions of this ASSOCIATION in the East.

The AMERICAN MEDICAL ASSOCIATION may be compared to a planet of spacious orbit; and like Jupiter or Saturn in the heavens, it requires many years to complete this orbit; and as it has again reached its aphelion I am happy to chronicle that from its strength, vitality and unimpaired activity one sees assurances of enduring life as far as he can project his vision into the future; so that our ASSOCIATION may fear no eclipse nor penumbral obscurity. And though ethical or other turbulent agency may, volcano-like, cause occasional disturbance, yet such disorder will be local and limited, and cause no digression from the established orbit. For an association having purposes such as this one, viz., the advancement of that knowledge which will alleviate the sufferings of afflicted humanity, has within its bosom the inherent elements of life; since inasmuch as in the Book of Existence, Fate has recorded against every birth and life, disease and death, the tasks of medicine will never end.

Your visit, gentlemen, to a medical college is eminently appropriate; for one of the objects which was had in view by the originators of the AMERICAN MEDICAL ASSOCIATION was to elevate the standard of medical education in the United States. And to the honored founder of this ASSOCIATION, Nathan S. Davis, chief credit is here due; and if a suitable chaplet were given him for his services for elevating medical teaching in our country, such a wreath should be woven of the olive, the laurel, the pine and the parsley; thus combining all grades of honor which were awarded to the victors in the ancient Grecian games. In him we see the happy union of precept and example; for in the presence of a powerful rival, he founded the first medical school in which a graded course was pursued and the curriculum of studies extended. The tree planted by Dr. Davis has grown until its branches overspread our continent; until, to-day, the most of American medical colleges have adopted a course of three years; and a few have gone farther and

adopted a curriculum of four years. A course of four years has been adopted, and is in action, in Cooper Medical College. And whether this change will lessen or increase the number of students is not a matter which renders our Faculty uneasy, since for the last fifteen years, its members have contributed their portions of their income from teaching to a common fund which is used, from time to time, for the purchase of instruments and other apparatus required for aid or illustration in teaching.

It is most desirable that the Association should continue its praiseworthy action in elevating our schools to a high degree of excellence in their work, until all colleges shall adopt a quadrennial curriculum, of two terms each year; and such curriculum to be complete, requires that in the several departments the lectures and instruction should be logically articulated and differ from each other in the several years. When our medical schools thus do their work each will become a luminary of trustworthy light; and such luminous centers scattered across our Western world will recall a sublime scene recorded in epic verse when it was agreed between the Greeks before Troy and their friends at home, that when Ilium should fall the news should be conveyed by signals of light; and the description of this event, as torchlight flashed to torchlight from peak to peak, and from vale to vale, is one of the most sublime and exciting pictures which has come to us from antiquity.

I heard Prof. Erichsen say after his return from visiting the medical institutions of the United States, that the time was not remote when English students, instead of going to the Continent to continue their medical studies, would go to America. Twenty years have elapsed since that time; and in the meantime medicine has made such upward strides with us that the European medical student has now much more to attract him to America; and especially is this true for the English student, who in his visit to France and Germany rarely so learns the language that he understands the foreign speaker.

In the standard of medical education which our Faculty has established here, the latter has indulged the hope that students might be attracted here from the East. In our literary school at Palo Alto, in which California has much pride, I may add that such a hope of the founder has been realized; you will find there many students from the Eastern States.

Realizing that theoretical teaching without a practical application of the principles taught, soon vanishes from the student's memory, and is nearly valueless to him, this school from its commencement has had a dispensary in connection with it, in which what is taught is actually verified. Last year about three thousand cases of disease were here treated. And this work combined with the opportunities for observation of the sick in our City Hospital which our students enjoy, will, in future be further enlarged by the additional clinical field which will soon be opened to them in the hospital which I have erected adjacent to Cooper College, and which will soon be ready for occupancy.

A fact or two in reference to the difficulties under which the hospital has been erected will not be uninteresting to you. It should be premised that there has always been the most irrational antagonism to the erection of hospitals in San Francisco. As the city enlarged, ordinance after ordinance has been enacted by the municipal authorities, extending the limits within which such institutions should not be erected; and these bounds to-day are so enlarged that it is forbidden to build any more hospitals on the Peninsula of San Francisco, unless certain conditions are complied with, which are of a nature which so hamper and discourage the applicant, that except the present building, all individual enterprise in this field has been deterred. Municipal authority, and the more illiberal portion of our people have come to regard hospitals, even those for non-contagious diseases, as a thing to be dreaded like a pestilence. A city father who was the author of an ordinance which excluded hospitals from this part of our city, as rejoinder to my plea against such enactment, said to me: "If you wish to build a hospital there is room for it across the bay in Alameda County." But it is an ill wind that is not fair for some one; and the result of this anti-hospital mania with which the popular mind is here infected, has had the result to drive those who felt disposed to do such work, to seek another field for their charitable enterprise, and instead of going to Alameda County as the Teuton supervisor counseled me to do, they have crossed the Rocky Mountains, and one of them, Michael Reese, has given Chicago a million of dollars for the erection and endowment of a hospital in that wiser and more liberal city. And a second refugee to a sphere where the munic-

pal statute book is marred by no enactment against hospitals, is the fortune of General Halleck, which has given a hospital for the treatment of cancer in New York city. These two great institutions which might and should have been ours, have found a more congenial home elsewhere, where they are giving relief and solace to the suffering; and in the one to which Mrs. Halleck has prescribed a specially defined line of work, viz., the treatment of cancer, it is probable it will open the way for the better treatment, if not the cure, of this scourge of our race.

A thing which will strike your attention, gentlemen, during your stay with us, is the international character of the medical profession in San Francisco. A reference to our medical register shows that we have representatives of every cultivated people of the earth; almost every medical school has here its graduate. And when you become acquainted with these physicians, as a rule, you will find that they are men of character; men who would have been successful in whatsoever land they should have sought a sphere for the exercise of their talents. Great Britain, France, Germany, Belgium, Austria, Hungary, Italy, Spain and Mexico have sent us creditable examples of their respective nationalities. These men were not long in abandoning the isolated exclusiveness that would naturally exist among men who were so different. And to-day the bond of fraternity is probably quite as strong as it would have been had they been of a common national blood.

The fraternity which has grown up here is the offspring of the essential nature of medicine itself; for the truths of medicine are the common heritage of an international brotherhood, which comprises all members of the healing art, wherever civilization has uplifted the race. All medical knowledge is common property; every fact which is discovered in medical science and art must by the finder be thrown into the common treasury; and thence every hand can draw and use. Among the other professions and callings of men, no such abnegation of self exists; a caveat or patent reserves all rights to the inventor or discoverer. This community of rights is the golden link in the ethical chain which binds the members of our profession together. These are the altruistic articles of faith to which each one of us has subscribed, in which the rule of action prescribed is to do more for others than for one's self.

Besides the medical institutions of our State which offer themselves for your observation, California has much else that I am certain will both interest and please you. Her resources of natural scenery are so vast, that many weeks would be necessary to visit the leading points of interest. In the excursion around our bay, the valleys and highland of the Coast Range of mountains presented in panoramic succession can not fail to delight and awaken admiration. And this range, as well as the more distant mountains, in form and appearance differ much from what exist in the East; in fact the difference is so great, that it seems as if the Pacific coast in its physical conformation, belongs to another continent. The mountains near the coast are often nearly destitute of forests except where their sides are entrenched by deep gorges which usually abound in oak trees. The smooth brown slopes of those high hills, diversified with the evergreen oak-clad gorges, constitute a leading feature of the Pacific landscape; and this form of landscape predominates until one has reached a long distance down the Mexican coast.

As you are aware, California has made two valuable contributions to our *materia medica*, viz., the *grindelia robusta* and the *cascara sagrada*. Some years ago when on a visit to Jalapa in Southern Mexico, I was anxious to see the plant, jalap. Yet I found that though I was in the city which gave the name to the plant, yet no living specimen could be found in the place; and I was informed by a druggist that if I wished to see it I would have to ride a distance of several miles to a deep gorge in the Cordilleras Mountains. I took his word for the fact and did not see the plant. But if you are anxious to see the Californian plants to which I have referred, you will have an opportunity. During your excursion to our neighboring naval station, you will find on Mare Island an abundance of *grindelia* growing there naturally, as it does in many parts of the State. And should you visit Yosemite, which none should fail so to do, who desires to see the sublimest scenery of California, you will here and there pass the *cascara* shrub. It grows, however, in the greatest abundance in the hills which surround Clear Lake, in Lake County. The shrub is likewise found along the high mountain road, by which the traveler reaches the geysers. But as the road closely skirts to the edge of a canon down which it makes the uninitiated traveler dizzy to look, the latter is

too much absorbed in personal matters to be occupied in the study of the flora.

Lest I may have inadvertently awakened apprehensions in any who are thinking of traveling over our mountain roads, let me assure such, that journeying there is more exempt from accidents than is travel on our city railroads with which you are familiar.

Let me again repeat my welcome to you, and thank you for the honor you have done Cooper College in paying it a visit; and in concluding these words of welcome, in looking on this assembly the felicity of the hour is saddened by the retrospective thought that many of those who visited us before, are now absent, and that in the green laurels which they then wore, the dark cypress has since been entwined; but with more cheerful augury for the future let me now express the hope that when two decades shall recall the honored sons of medicine to visit us again, each one of you will be present in that august assemblage.

This address was followed by Dr. E. R. Taylor, Attorney-at Law, who read extracts from a poem of great excellence entitled the "Hospital," lately written by Henley, the Scotch poet. In this poem the writer has depicted with vivid fidelity the dramatic scenes which are enacted in the surgical ward; scenes in which the action of an anesthetic, the operation, the patient's subsequent hours of doubtful event and his final emergence into the sunlight of life and health are portrayed; and though the license of a poet has been indulged in and fancy given full sway, yet the descriptions are singularly real, and akin to those soon to be enacted in the new building adjacent to the College, which the assembly was invited, presently, to visit.

The address of welcome was replied to by Dr. H. O. Marcy, of Boston; in a brief, but eloquent address, in which a high tribute was paid to the hospitalities which with lavish hand have been showered on the ASSOCIATION during its stay in San Francisco—words very pleasant to the ears of Californians, but in which a slight gilding of exaggeration might have been detected by the disinterested auditor.

The foregoing addresses were followed by a collation at which were served some of the choicest specimens of the wines of California, which were presented by members of the Viticultural Association, which has an exhibition at the Midwinter Fair. These wines, in their amber or ruby tints, were of rare beauty and exquisite flavor, and convinced the visitors that the productions of the vine-clad hills and valleys of Pomona, Napa, Tehama, Contra Costa and San Gabriel are not surpassed by the vintage of the Old World; in fact, that the wines of the Occident need but to be known and the powers of some genius gifted in lyric verse, to endow them with a celebrity equal to that which has been given to those of antiquity by the Latin muse, when Horace, reclining beside his much-loved Mæcenas and Pompeius singing his golden lyrics, exclaimed, "*Ciboria exple!*" and in matchless numbers gave immortality to Massio and Falernian.

The reception ended by the assembly separating into groups and visiting the various sections of the College and Hospital.

In reference to the erection of Cooper Medical College and its annexed hospital, as there has been a statement that the structures mentioned owe their origin to money left by Dr. Elias S. Cooper. The following sworn statement of Mr. Joseph Reay, executor of the estate of Dr. Cooper, is offered, with the hope that it may aid truth in supplanting untruth.

STATE OF CALIFORNIA,
CITY AND COUNTY OF SAN FRANCISCO. }ss.

JOSEPH W. REAY, being duly sworn, deposes and says he is a resident of the City and County of San Francisco, and has been for more than forty-three years past; that he was intimately acquainted with Dr. Elias S. Cooper during his lifetime, and lived with him in the same house, during all the time he was a resident of the State of California and the City and County of San Francisco, and for many years he was his business agent; and after his death, which was in October, 1862, he was an executor of his will, and duly qualified and acted as such executor without compensation or commissions from the estate. In his will Dr. Cooper bequeathed his entire estate to his relatives; and he left no means either by bequest in his will or by verbal request for the erection of a medical college in this city or elsewhere.

Deponent further says the total value of the estate left by Dr. Elias S. Cooper, deceased, was eighty-five hundred dollars, as more fully appears by the record of the Probate Court of this City and County.

Deponent further says that Dr. Levi C. Lane advanced and contributed out of his private funds the sum of \$1,162.76 to pay some of the claims against Dr. Cooper's estate.

Deponent further says upon his information and belief that the building in this city known as the Cooper Medical College was erected by Dr. Levi C. Lane, from his own private means, and was so named to honor his relative, Dr. E. S. Cooper.

Further affiant saith not.

J. W. REAY,

Subscribed and sworn to before me this 18th day of December, 1893.

JOHN P. POOLE, Notary Public in and for the
City and County of San Francisco, State of
California.

LEVI COOPER LANE.

SEAL

SELECTIONS.

The Conduct of the Journal of the American Medical Association as a Business.—There has come from Pennsylvania long-continued and persistent criticism of the advertising portion of the ASSOCIATION JOURNAL. It is significant that this has largely and mainly emanated from the *Medical News* and its editorial writers. When it is remembered that the *Medical News* is owned by a large publishing house, it is apparent that any damage of the ASSOCIATION JOURNAL as a business enterprise would profit its rivals. In this connection it will not be forgotten that many years ago the publishers of the *Medical News* greatly desired to secure the publication of the ASSOCIATION JOURNAL under their immediate control. Bearing these facts in mind, and remembering that the other great weeklies—the *New York Medical Journal*, the *Medical Record*, the *Boston Medical and Surgical Journal*—have no similar criticism, the reader must conclude that there must be some special reason why the *Medical News* desires to cripple the business resources of the JOURNAL.

The call is made that the trustees of the JOURNAL be "bounced" because they admit just such advertisements as are admitted by the *Medical News* itself, the *Medical Record*, the *New York Medical Journal*, and the *Boston Medical and Surgical Journal*. In so far as we are aware, the trustees one or all, are quite indifferent as to longer service for the ASSOCIATION as trustees, and hence are quite willing to devote their energies to other labors just as soon as the ASSOCIATION so desires. Meantime some common sense is desirable of such as wish prosperity to the JOURNAL.

When the ASSOCIATION started the JOURNAL, it entered upon a business enterprise. The laws of success in that enterprise it was compelled to obey, in order to succeed. It saw the old publishing houses of Henry C. Lea & Co., D. Appleton & Company, William Wood & Company, conducting their weekly medical journals in a certain manner, which was approved by the ASSOCIATION and the medical profession in general; it also saw the *British Medical Journal*, representing the British Medical Association, conducted in a similar manner—and all attended with large measure of success. The trustees therefore concluded that they were safe in following the methods of the old weeklies. In following these methods a considerable measure of success came to the ASSOCIATION JOURNAL. At Detroit, however, by one of those snap judgments so characteristic of the action of the general meeting, the ASSOCIATION ordered the trustees to cease publishing advertisements of articles whose composition was unknown. Their records show that the trustees took immediate action and directed the editor to follow the command of the ASSOCIATION. He affirms that he has followed this command, and that the composition of all substances advertised in the JOURNAL is known. But the critics are still not satisfied. They want all copyrighted and proprietary articles excluded, even though their composition be public property.

The effect of such exclusion would be the reduction of the

income of the JOURNAL by more than \$8,000 yearly. This doesn't look like business. If the members of the ASSOCIATION were not interested in these advertisements, the advertisements would not be offered to them. As the members own the JOURNAL, it would seem as if the JOURNAL should advertise such articles as they are interested to see. In such matters the majority should rule. The vote at the ASSOCIATION meetings and the voices of a few members do not count against the fact that such advertising pays when placed in the ASSOCIATION JOURNAL.

Personally we wish that all proprietary and copyrighted medicines, and every sort of secret remedy, were utterly and forever excluded by every doctor from the list of articles employed by him in his professional work. In the ideal state of medicine such will be the fact. To attain this end, doctors should be taught when they are students, either under a preceptor or in a medical college, that the use of such remedies is unwise and unworthy of a student of science. A crusade which would in this manner strike at the root of things would meet the endorsement of common sense. Meantime, ere this the matter will be considered by the ASSOCIATION at its San Francisco meeting, and doubtless wise counsels will prevail. It is hardly to be expected that the ASSOCIATION will advise that the JOURNAL be deprived of an income of \$8,000 yearly, by refusing advertisements which its rival weeklies accept and which a large proportion of its members prescribe as occasion offers. It will either continue the existing course or direct that with each advertisement a statement of its composition shall appear. We think the editors of the JOURNAL have done well in always refusing any of the so-called "reading notices" or the publication of matter edited by advertisers, or in any way giving the reading pages of the JOURNAL to the advertisers. Nearly all other medical journals are more or less guilty of one or more of these concessions to their advertisers.—*American Lancet*, June, 1894.

Can the Advertisements in a Reputable Medical Journal Promote Quackery?—This question has been raised in a paper honored by an audience before the Pennsylvania State Medical Society. The paper was intended to convict the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of the charge of promoting quackery. This special point we shall not consider now—only the broader one in the above heading. In the case in point it is not claimed that the reading pages are used in any manner to endorse the statements found in the advertising columns. Hence we have the question fairly as stated: "Can the advertising pages of a reputable medical journal promote quackery?"

1. The advertising pages of a reputable medical journal are read only by physicians, who by long and severe training have been taught to distinguish between the true and false in all medical matters. Grant that an advertisement of a fraud appears in the advertising pages of his journal, what are his previous training and experience good for if they do not enable him to detect the falsehood? If he can detect this, certainly he will not be misled. If he is not misled, then quackery will not be promoted through the physician who reads the journal.

2. If it is claimed that physicians are so badly educated as to be unable to detect the falseness of statements in the advertising pages of reputable medical journals, and so are led astray by these statements, the fault should rather be laid at the door of the medical college or licensing board which issued the license to practice medicine.

3. If, in the manner indicated, the journal of the ASSOCIATION promotes quackery, then do also the *Medical News*, the *Medical Record*, the *New York Medical Journal*, and the *Boston Medical and Surgical Journal*. The talented author of the paper referred to is a contributor editorially to the *Medical News*, and so himself aids a medical journal engaged in the work that he terms "promoting quackery." It were wise to think several times before affirming that the list of medical journals above is engaged in promoting quackery. Even

that paragon of excellence (in the minds of many), the *British Medical Journal*, is full of just the sort of advertisements complained of by Dr. Cohen. So also is the *London Lancet*. In the name of good sense, why should not the business management of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION do those things which all the medical journals of its class do?

4. For reasons indicated, we think it impossible for the advertising pages of a strictly medical journal to promote quackery. At the same time, we wish that nothing were printed in these advertising pages other than clean-cut scientific truth respecting drugs or preparations or appliances supposed to be useful to some physicians.—*American Lancet*, June, 1894.

Pure Cocain.—Though cocain has been known as a valuable agent for some years, it is only lately that knowledge of the physiologic effect of its accompanying amorphous bases has been materially widened.

Concerning the principal alkaloid, cocain *per se*, it is not necessary to speak, because it is familiar to the medical profession the world over in the form of a salt; but of the number of so-called secondary or amorphous alkaloids, chemists even at this late date are somewhat doubtful. There are known to be several, and recent researches on the part of Liebermann, Liebreich, and others, prove that one of these amorphous alkaloids, viz.: iso-atropyl-cocain, is a most violent cardiac poison. This alkaloid occurs in coca leaves in very minute quantity, as a rule, but some specimens contain far more than others; its separation is most difficult, and it enjoys the reputation of being the least easily detected of all the coca bases. Even if we were not positive that the secondary bases exhibited a pernicious effect, they must be looked upon as suspicious, and a cocain demanded from which they are removed. As a matter of fact, we do know that the presence of even small quantities of these amorphous bases is responsible for untoward and seemingly inexplicable results that often follow upon the administration of supposedly pure cocain preparations.

Recently the editor of the *Medical Age* learned of two apparently mysterious deaths which were in reality the result of the use of impure cocain by dentists for its benumbing effect in the extraction of teeth—in both cases the drug was injected into the gum. In one instance death occurred within a few hours after the teeth were drawn; in the other the lady lingered for about thirty-six hours, and all the resources of the medical art were unable to stimulate a heart that had been fatally poisoned owing to a preponderance of iso-atropyl-cocain.

Such facts as just cited should prove sufficient to put the practitioner on his guard and induce him to demand a cocain that is free not only from secondary alkaloids, but from such inorganic substances as sodium, calcium, etc., that are necessarily employed in the process of manufacture.—*Medical Age*.

Abuse of the Bandage.—The first abuse of the bandage comes through its clumsy, unskilled application, by the inexperienced, hasty or careless. The second, through its too firm adjustment, when the circulation is impeded or as sometimes happens, it is totally strangulated, the tissues beyond becoming asphyxiated, mortified and destroyed. This latter occurs most commonly in cases of fracture. As many as five or six such cases have come under my observation in my time, and I have been informed of others, in which the bandage got in its deadly work, though, they were frequently entered in the hospital records as cases of "acute mortification." A fractured limb which is at all firmly bandaged should be closely watched for the first twenty hours; until, in fact, the subsidence of primary inflammation and swelling and the bandage relaxes its grip. It often becomes a matter of great difficulty to permanently adjust widely separated fragments, without risking a firm bandage to fix them. These difficulties and dangers could be largely obviated if we would go back to the practice of our fathers; and, after carefully adjusting the fracture leave it alone and not permanently "set" it until primary swelling has subsided.—*Medical Summary*, June, 1894.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual subscription to THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

SATURDAY, JUNE 23, 1894.

THE FORTY-FIFTH ANNUAL MEETING.

The forty-fifth annual meeting of the ASSOCIATION was one that will long be remembered. The extraordinary efforts that were made by our brethren in San Francisco to make the social features successful were the subject of much remark and of sincere admiration.

The private receptions in addition to the official ones were numerous, and the hospitality of the Californians was as generous as it was general.

The President was singularly happy in his efforts to expedite business and banish dissension, and the turmoil that was threatened and even predicted by some, was averted. The question of revision of the Constitution was sought to have considered separately from the question of Code revision, but it proved impracticable to do so, and the whole matter was indefinitely postponed. One amendment, however, escaped the common fate; the one changing the "annual dues" regulation to one providing for annual subscription to the JOURNAL. This was made necessary by the construction put upon the postal laws, whereby society publications can not *per se*, be classed as second class matter, and granted postage at newspaper rates. With the adoption of the new regulation, the ASSOCIATION has complied with the law.

The action of the Trustees in accepting the same class of advertisements as other reputable medical journals accept was approved. We publish in this issue an excerpt from our esteemed contemporary, the *American Lancet*, which seems to show that the attack on the management of the JOURNAL is only a part of a serious and long-continued effort to break down the JOURNAL, for reasons which seem curious, to say the least.

The resignation of DR. R. J. DUNGLISON, after seventeen years' faithful service, was one of the surprises of the meeting. It is understood that the

wishes of DR. DUNGLISON were complied with in the appointment of his successor, DR. HENRY P. NEWMAN, whose residence near the publication office will make it easier to transact the ASSOCIATION business, which during the last few years has been especially burdensome. During DR. DUNGLISON'S incumbency of the Treasurer's office he has seen it grow from a comparatively few members to one of the largest, and the Sections have grown and developed into vast sub-conventions devoted to special topics.

The scientific business before the Sections was of considerable volume, and unusually varied. He would indeed be hard to please who would cavil at the work done in the Sections.

Among the many enjoyable entertainments "not writ down in the bills" was the breakfast given by the Gynecological Society of San Francisco to the members of the Obstetrical Section. DR. W. H. MAYS presided, and speeches were made by A. LAPHORN SMITH, of Montreal; I. N. LOVE, of St. Louis; H. O. MARCY, of Boston—a little fun was interjected into the proceedings by the introduction of DR. MARCY as "HERNIA O. MARCY, of Boston"; F. H. MARTIN, of Chicago; ALEX. J. STONE, of St. Paul; J. M. DUFF, of Pittsburg; JOSEPH EASTMAN, of Indianapolis; HENRY P. NEWMAN, of Chicago; DR. DELFF, of California; R. BEVERLY COLE, San Francisco, and JOHN B. HAMILTON, of Chicago.

The annual banquet of the American Medical Editors' Association was unusually interesting. At the business meeting just preceding, a letter from the genial Secretary, DR. GEO. M. GOULD, of the Philadelphia *Medical News*, was read, in which, in his usual happy and courteous vein, he congratulated the assembled medical editors on the high plane they should and did assume in the conduct of their branch of journalism. At the banquet, PRESIDENT HUGHES read the address elsewhere printed in this issue, which is a tribute to the work of the profession and a plea for its just recognition. He thinks here, as in his Mississippi Valley Medical Association address of last year, that the profession has been too generally derelict in non-assertion of the just claims of the medical profession to popular respect in this country.

The usual round of toasts followed; the toastmaster, DR. LOVE, performing that duty in his usual style, which in that, as in all other matters coming under his supervision, was performed with judgment, skill and taste. Speeches were made by DRs. LEVI COOPER LANE, R. BEVERLY COLE, R. H. PLUMMER, of San Francisco, and WINSLOW ANDERSON, of the *Pacific Medical Record*. Several of the members responded to toasts, including the host, MR. R. E. QUEEN.

The action of the Medical College Association in expelling two of its constituent colleges for failure

to comply with the rules governing the graduation of medical students was severe, but was done by that body as one of the surest means of convincing the country that they are sincere in their efforts at educational reform.

Taking the meeting all together, it is doubtful if its many-sided interests were ever more fully considered or represented.

As the question of amendment of the Constitution was left unsettled, it is more than probable that it will become a perennial one, until the amendments are separately formally adopted or rejected.

THE PLAGUE IN CHINA.

Doubts as to the identity of the disease reported to be Asiatic cholera in Canton and Hong Kong, noted in the JOURNAL of the 9th inst., are resolved through recent advices by the Pacific steamers. It is obviously an epidemic of bubonic plague and one of marked severity. The disease appears to have originated in Hong Kong and to have made its appearance in Canton about the end of April. Some idea of its ravages may be formed from the reports of a resident missionary in Canton, who made systematic investigations which showed a total of 6,000 deaths among the Cantonese in the first eight days; and its virulence and fatality may be inferred from the returns of one hospital, in which out of 393 cases received there were 320 deaths.

The symptoms of the disease, as reported by a district physician to Colonial Surgeon AYRES, are as follows: "With or without premonitory warning in the shape of malaise or chill there is a sudden onset of fever rising to 105 degrees or over; there is much headache and cerebral disturbance, accompanied by stupor; in from twelve to twenty-four hours glandular swellings occur in the neck, armpits or groin, rapidly enlarging to the size of a fowl's egg; these are hard and exceedingly tender; with or without a decline of the fever the patient sinks deeper into a condition of coma and dies, usually at the end of forty-eight hours or sooner; if six days are reached recovery is hopeful; the glandular swelling shows no signs of suppuration; in some cases epistaxis or vomiting of blood occurs; petechiæ appear in a few, but no regular eruption."

This is a fairly accurate portrayal of the fulminant form of the Oriental plague—the bubonic or glandular, as differentiated from the Indian or Pali plague, in which gangrenous inflammation of the lungs is a common lesion, while it rarely occurs in the bubo plague above described. This fulminant form occurs chiefly during the beginning of an epidemic; as the epidemic progresses cases increase in number in which there are well-marked stages of invasion,—fever, glandular involvement and convalescence, with a corresponding decrease of mortality. The etiology

of the disease is summed up in the term given to it by CABRIADIS, in his report to the Constantinople Board of Health on the outbreak in Astrakhan, 1878-79, namely, *miseriæ morbus*, the malady of the miserable, the plague of the poor. It is a disease of poverty and of the insanitary evils which poverty begets; overcrowding and want of ventilation, personal filthiness, improper and insufficient diet, etc.

It is the very type of the infective diseases, and herein lies the sole practical interest of this country in the Chinese outbreak. It is capable of being conveyed by vehicles of commercial intercourse, and while it has never appeared in this country it has repeatedly invaded Europe through commerce with the countries of its autochthonous origin. Sanitary authorities claim that preventive medicine has achieved no other work comparing in magnitude and importance with the extinction of the plague in Europe, through the development of the quarantine system with reference to the indigenous habitats of the disease. HIRSCH, in his "Hand-book of Geographic and Historic Pathology" says: "I can not, in fact, understand how any one, criticising the facts without prejudice, and having regard to the state of the plague in the East, can for a moment hesitate to attribute the chief cause of the disappearance of the plague from European soil to a well-regulated quarantine system." This country must rely upon the health authorities of the Pacific slope, both British and American, to see to it that this scourge of the far East obtains no foothold on our shores.

A SINGULAR PLEA FOR THE UNFIT.

In a recent address before one of the oldest State Medical Societies on the subject of cramming in our medical schools, the speaker made an argument which should commend him to the favorable regard of the average medical student. That such was not his intention goes without saying; but it remains, nevertheless, that the address was, in effect, a plea for the survival of the unfit.

Detailing the higher standard of medical education now in vogue as compared with that of a few years ago—the change from two short terms of repetitional lectures to three years' attendance upon a graded course; the increase in the length of the term itself; the increase in the teaching staff; the increase in laboratory work, class demonstrations, bedside ward-training, and special and general clinics—all to end in making the diploma, when obtained, only a passport to a State Board of Medical Examiners, the question is asked and answered:

"And what has been the result of the great increase of professional chairs, the rivalry for hospital appointments, and the creation of a State Board of Medical Examiners? The answer is only too apparent, viz., to increase the hardships of the medical student. Hard and unsatisfactory as it was when he could get his degree in two years, it is

doubly hard and far more oppressive under the extended course."

Then follows a harrowing picture of the quiz system and of the student's "long hours of work, often in foul and ill-ventilated rooms; the long tension of mind, unrelieved by the slightest relaxation; the magnitude of his work, with increasing perplexities every year, and the constantly menacing horror, that after all he may fail of getting his diploma"—all of which "rob him of sleep and render him almost imbecile at the moment when his faculties should be freshest and brightest" for his final examinations. And so "10 per cent. at least of every graduating class fail to get their degree; 10 per cent., after paying for three courses of medical instruction, three years' maintenance and three years' loss of time."

This setting forth of the results of the higher medical education is curiously interesting, but no less so are the reasons given "why so many fail."

Briefly, these are, first, because the preliminary examinations by the "medical schools are notoriously farcical. Think of 'throwing' a man at his final examination because he can not spell or write grammatically!" The JOURNAL knows of at least one licensing body which undertook to ascertain of graduates whether they had sufficient general education when they began the study of medicine, but the comical cart-before-the-horse feature of the attempt soon compelled its abandonment; but that medical colleges generally make their "preliminary" examinations at the end of the three years' course and 'throw' a man at his finals because of defects in his "three Rs," then first discovered, will be news to most faculties.

And the second reason is like unto the first: The professor "knows little or nothing of the student until he appears before him for his final examinations."

The serious feature of the address, however, is in the remedy proposed and recommended:

"If the law compels a young man to study four years it ought to give him some guarantee that he will be fairly dealt with. Were our medical schools compelled to refund one-half the expenses of the student who fails to get his diploma (*i. e.*, one-half the cost of three years' maintenance and of three years' loss of time), if the schools were obliged to refund *all* moneys expended on lectures, the graduating class would not be reduced in numbers, but the 10 per cent. that fail at their final examinations would have some redress."

This is just the kind of a proposition that would be apt to strike favorably a certain class of legislators, and it would not be in the least surprising to see it, in the near future, embodied in "An act entitled an act," etc.

Meanwhile, the JOURNAL commends to the attention of the author of the address under consideration, the following cold facts which have already appeared in these pages: In round numbers, there

are upward of 118,000 doctors in this country, which with a population, also in round numbers, of 65,000,000, gives an average of one doctor to every 550 men, women and children; this population increases at the rate of about 2.5 per cent. per annum, but every year we add over 5 per cent. of new doctors.

It does seem that we might worry along without making it any less "hard and unsatisfactory" to become a doctor—for the present, at least.

ANOTHER COURT ON PHYSICAL EXAMINATIONS.

Following very closely upon the handing down of the decision of the General Term of the New York Court of Common Pleas in the case of *Lyon v. Manhattan Railway Company*, concerning physical examinations under New York's new law, announced in the JOURNAL of May 26, comes its affirmation by the Court of Appeals of that State (advance sheets of 37 *Northeastern Reporter*, pp. 113-115), three justices dissenting therefrom. But in the latter Court, it is to be noted, the counsel for the plaintiff did not rest the case wholly upon the reasons given by the general term, but attacked the new statute as in conflict with the Federal State and constitutions. He insisted that such conflict arose from the fact that the plaintiff was required, as a condition of prosecuting her action in the courts, to expose her person against her will; that the statute in question, in effect, deprived her of the sacredness and privacy of her own person, and of her liberty and natural rights and the equal protection of the laws. The argument, though perhaps novel, the Court admits is not without interest. It is disposed of by the Court simply holding that the statute enacts a rule of procedure, the purpose of which is the discovery of the truth in respect of certain allegations which the plaintiff has presented for judicial investigation in the courts of justice. Prescribing a method of aiding the court and jury in the correct determination of an issue of fact raised by the pleadings, does not violate any of the express or implied restraints upon legislative power to be found in the fundamental law which controls it. According to the common law, as remarked by MR. JUSTICE GRAY, in the Supreme Court of the United States: "The inviolability of the person is as much invaded by a compulsory stripping and exposure as by a blow. To compel any one, and especially a woman, to lay bare the body, or to submit it to the touch of a stranger, without lawful authority, is an indignity, an insult, and a trespass." This statute, the Court of Appeals says, has changed that law, but it is not so certain that it will ever change the general sentiment of mankind which was expressed in that remark. The power conferred, it admonishes, should never be used in such a way as to leave any doubt as to the fairness and good faith of the proceeding, otherwise it may prove to be a sword instead of a

shield. It should be a fair and open inquiry after truth, in which both sides are or may be participants. If it is used only for the purpose of enabling the defendant to prepare expert witness to give testimony at the trial it will be hardly possible to keep the fact from the jury, and it is easy to see how such an element in the case might be used to excite sympathy, stimulate prejudices, and in some cases possibly to enhance damages. The physical examination being authorized, how is it possible, the Court asks, for medical experts to make the same, in any case, by merely observing the external marks or indications of personal injury or disease? The term itself implies not only such observation, but an inquiry by means of questions and answers, as to the cause, nature, character and extent of the disability. Mere external appearances are, in themselves, of no consequence unless identified and connected with the accident as the cause; and hence disclosures such as ordinarily occur between patient and physician must necessarily accompany the inspection of the injured parts. For this reason, this new New York enactment provides that the physical examination shall be procured in the same way and as part of an examination of the party before trial. The referee becomes something more than a mere spectator at an idle ceremony. He may take the plaintiff's testimony upon the issue, and report to the court. He has power to administer an oath and to authenticate the proceedings, and the plaintiff is bound to appear before him, and answer all proper questions with respect to the nature and extent of the injuries, whether framed by the medical experts from their own examination, or by the counsel present. It becomes a fair struggle for truth, and both parties may participate. The record of the examination is placed on file, and both sides know just what must be met if it is introduced in evidence, as it may be by either party.

AUTHORITY OF PHYSICIANS FOR RAILROADS.

Railroad companies have come to make arrangements with physicians all along their lines to care for injured persons, and especially employes, who require immediate attention. Mere appointments of this kind, however, carry with them but little implied authority. This fact is illustrated by the decision of the Appellate Court of Indiana in the case of the Chicago & Erie Railroad Company v. Behrens, rendered April 6, 1894. The evidence showed that a physician, regularly appointed by the Railroad Company named, was, under the terms of his contract, required to do the medical and surgical work of the Company in a prescribed territory, and to care for the patients while in his charge. An injured employe was brought to him, by the conductor of a train, to look after and attend as a surgeon.

The character of the employe's injuries was such as to require immediate attention, and, under the direction and at the request of the physician, he was removed from the car, on which he was brought to the place, to a house where he could be cared for and treated. Board and care were there furnished, at the request of the physician, with the implied understanding that they should be paid for by the Railroad Company. Under these circumstances, it is held, reversing a judgment of the Porter County Circuit Court against the Company for these services, that the physician had no implied authority to bind the Company for such board and care. Had it been affirmatively shown that the employe was injured by the Railroad Company, or that he was injured while engaged in the performance of some duty for it, it is intimated that perhaps a promise might be implied on the Company's part to pay for his care while disabled.

THE PUBLICATION OF THE MINUTES.

The publication of the minutes of the ASSOCIATION Meeting in the JOURNAL is usually delayed from one to three weeks according to the location of the place of meeting. The publication in the JOURNAL is the only official one, and it must be correct and complete. We can not therefore hasten its publication without detriment to the interests of the ASSOCIATION.

ASSOCIATION SUBSCRIPTION.

Members of the ASSOCIATION who have not already paid for the current year, will please pay their annual subscription forthwith without waiting for formal notification, to the ASSOCIATION Treasurer, DR. HENRY P. NEWMAN, Venetian Building, Chicago, Ill., or if they prefer, to the JOURNAL office direct.

CORRESPONDENCE.

EDITORIAL CORRESPONDENCE.

Leaflets from the Editorial Logbook.

On Saturday May 9, at 5 P.M., Drs. Montgomery, of Philadelphia, and Baker, of the *Cleveland Medical Gazette*, the new ASSOCIATION Treasurer, and others beside myself, left in advance of the ASSOCIATION train for the return trip via the "Shasta" route, and the Northern Pacific. We were assured by Mr. Austin, the special agent of the Northern Pacific, that trains would run through regularly by the time we reached Spokane and we would be passed through safely. On this assurance we started, and took a last look at the Golden Gate as we passed along the Bay shore. We woke up in the morning, June 10, with the train speeding along the Sacramento Valley far up in the mountains. No little river could be more picturesque as it rolled and sparkled, frothed and fretted at the rocks in its path. No mountains could be more rugged and few lift their heads higher than the Sacramento Range which merges into the Siskiyou and pierces the clouds with snow-tipped Shasta. We had an excellent breakfast at Shasta, and we stopped at Shasta Springs and drank the waters of the wonderful soda spring. Here the Mossbrae Falls rush foaming down the mountain

side over a mossy pillow, over which the shining waters spread as if loth to leave so sweet and fresh a pillow, to mingle with the vehement Sacramento. The Southern Pacific road with that kindly regard for the comfort of their passengers that had distinguished them from the time of arrival in California put on an observation car, which we were all free to use as we liked. All enjoyed the scenery which was grand beyond description, and the day was enjoyed by all, barring a mimic snow storm through which we passed while on the summit of the Divide.

June 11, at 8:20 A.M., we arrived at Portland. Here we took leave of Dr. Newman who left immediately for Alaska, in the midst of a pouring rain. For the first time we realized the loss of our special train with its genial company, the gentlemanly agent, Mr. Connell, and the efficient Pullman conductor, Mr. V. H. Coffin. The rain kept showering, but notwithstanding this fact, we hired a boat and viewed

the town, the principal business part of which was under water. Boards placed on trestles such as are used by carpenters and plasterers, served for sidewalk, and we thus had a practical demonstration of the actual working of that latest device for relief of congested city streets, *i.e.*, elevated sidewalks. The Willamette River was said to be five feet higher than ever, being a rise of thirty-five feet. The citizens seemed to view the matter with admirable *sang froid* and looked upon it as only a temporary setback to their prosperous and handsome city. The Northern Pacific agent on whom we called by boat, rowed by a stalwart Chinaman, assured us that from Spokane we would be sent forward on our journey with only little delay, and that it was possible we might go through without a break as the road might be repaired by the time we reached there, or at least forty-eight hours later; and so with some misgivings we left on the boat *Tacoma*, down the Columbia at 4 P.M. On our way down

the river we saw evidences of devastation on every hand. Houses, barns and lands submerged, some careened by the flood, and only in occasional instances did we see any living thing and then we could see that some plucky soul was living in the second story of some partially submerged building. On arrival at Kalama, the destruction by the flood was complete.

The railway dock was broken and partly under water, the raging current filled with floating driftwood covered the track, and the tops of the telegraph poles with their little cross pieces were all that could be seen of them. We passed down the Columbia and finally turned the bow of the *Tacoma* into the Cowlitz River, and we steamed up toward Kelso with the melancholy spectacle on either bank of the Cowlitz, of ruined homes, flooded farms, and wrecked industries. At Kelso we were once more on *terra firma*, and found our sleeping car awaiting us. We set off for Tacoma where we arrived about 1 A.M., June 12. Our train crawled along toward

the Yakimaw country, and it was three hours later when we awoke. We were in the midst of a dense pine forest and snow-capped peaks in sight from almost every point of view. We wound in and out along the water courses, climbed mountains, rushed down gorges, and reached the Yakimaw Valley. We descended that uninviting stream from Ellensburg, a handsome and flourishing mountain town, quite down to its emptying into the Columbia. A little below that point we crossed the Columbia and soon reached Pasco City. From Pasco City (a "city" of a dozen frame shanties) we moved slowly over the barren heights leading to Spokane, where we arrived about 5 P.M. We went to the Hotel Spokane where we found fair accommodations but poor cookery; an excellent proof of the wisdom of the old French proverb that "however certain it is that Heaven sends us our food, it is beyond doubt that the devil sends the cooks." As soon as possible after reaching Spokane we sought the Northern Pacific agent, who finally informed us that there was no pos-

sibility of our passing eastward for at least four days, and then we would be obliged to take a steamer on the Cœur d' Alene Lake, and a probable stage ride over washouts on the eastern slope of the Rockies; so we bought transportation over

the Union Pacific as we were unable to arrange a transfer, and were ready to start home by that line.

The falls at Spokane are among the most beautiful, and the city itself is a gem worthy of its setting in the magnifi-

MT. HOOD.

cent Colville Range—a spur of the Cœur d'Alene. The buildings are patterned after some of the best in Chicago, but are apparently about a decade beyond the present needs of the city. The street railways (trolley overhead wires) run everywhere, even out into the pine woods, but can scarcely be profitable at present. Dr. Doolittle and Dr.

Thomson entertained some of our party while at Spokane. On Wednesday, June 13, we resumed our journey, winding downward in a serpentine course toward the Snake River, which we crossed about 4 p.m. An hour or two later we arrived at a village called Starbuck, where we were given the worst supper that our suffering pilgrims had yet encoun-

BLACK BUTTES FROM BISSON'S LAKE

tered. We reached Walla Walla about 9:30. The country from Spokane to Walla Walla is an excellent grazing region but barren, dusty and unattractive in appearance, with alkali dust, and scarcity of water. As we left Walla Walla, with our train for the first time headed homeward, the travelers were happy; and a concert was started in the smoking car led by the Actor Stuart, who happened to be on board; his voice is a high tenor, and all were charmed with his comic and sentimental songs, but our pleasure was of short duration for three of our cars were suddenly derailed, and our Pullman was thrown sideways in a way that was unpleasant to say the least. A broken rail, mashed ties and warped brakes gave rise to much growling, but, as nobody was hurt, the *status quo ante accidens* was soon regained, a fire was built of broken ties along side of the track and story telling was resumed. Many speculations were indulged in regard to the cause of the accident. Some had noticed a cross-eyed man get aboard the train at the Snake River bridge; the brakeman acknowledged in a moment of confidential candor that a friend of his had given him an opal ring that day, with the cheerful assurance that his train would be ditched before night, and however near the mark these speculations may have come, a hard matter-of-fact passenger declared after examining the rail that it was "structurally defective," having been an old rail refaced, and that the ties were spongy with dry rot. As the speaker was a railroad contractor of much experience, this seemed to settle it, but the brakeman was seen to turn his opal ring to the inside of his finger where he could now and then cast deprecatory glances at it unobserved. As for the cross-eyed passenger, he disappeared shortly after the wreck, and was seen no more. Our train was after a while righted and we again started, chastened in spirit but not cast down. June 14 a dining car was put on the train at Pendleton, Oregon, and we breakfasted with comfort. All day long we were engaged in crossing and re-crossing Snake River, inhaling alkali dust and looking out on the hot arid wastes of sage brush and sand. We saw the mining shafts in the side hills near Baker City, where the placer mines are fairly productive, and just above Huntington we came upon the prison camp where a portion of the Coxy tramps are serving out a sentence of the Federal Court under guard of a detachment of regular troops from the Fourth and Fourteenth Infantry. The commanding officer in conversation informed us that these people were the toughest of their class. They were kept in a small level area of about four acres between the embankment of the railroad and the river, with high alkali hills on either side, without shade and exposed to the violent rays of a scorching sun. Notwithstanding their condition the majority absolutely refused to work when lumber and materials were furnished them for the construction of a barrack for their own accommodation—14 men out of 175 were willing, and began to put up the barracks, but were obliged by the remainder of the "unemployed" to cease work. The commanding officer then detailed a guard to protect them while at work and the building of the barracks was in progress as we passed. It is safe to say that our "boys in blue" were not enthusiastic about the nature of the duty. June 15 our train arrived at Montpelier, Idaho, at about 7 A.M., and barring the mosquitos, which were the most vicious of their class, we were in a pleasant region; snow-capped mountains surrounded us, and Bear River, a clear and beautiful trout stream, was full to its banks. The remainder of the journey was without incident and we arrived in Chicago June 17.

South Carolina Practice of Medicine Act.

AIKEN S. C., June 9, 1894.

To the Editor:—In the issue of your paper March 10, 1894, page 355 in the article, "Legal Requirements for the Prac-

tice of Medicine in the United States," you have the law for South Carolina wrong; please correct it as it is apt to mislead doctors wishing to come in the State to practice.

The Legislature of 1893 passed a law which went into effect Jan. 4, 1894. The law provided for the appointment of a State Board of Medical Examiners to be composed of seven members, whose duty it is to examine all candidates who wish to practice medicine in the State and who were not registered Jan. 4, 1894. The candidate must first show his diploma and he is then given a written examination of two hours on each of the seven principal branches. The next meeting of the Board is Oct. 9, 1894, at Columbia, S. C.

Yours truly,

C. F. MCGAHAN.

The Physicians' Sanitarium.

SAN FRANCISCO, June 8, 1894.

To the Editor:—There is an error in the announcement of the Physicians' Sanitarium which appeared in your issue of May 5 and possibly in subsequent issues.

I am not connected with that institution in that or any other capacity.

While I did contemplate connecting myself with that enterprise and deem such an institution, conducted on ethical lines, a proper enterprise in which physicians might and should engage, I declined permitting my name to be used in connection therewith upon seeing a circular emanating from a business manager thereof, and though the circulars have since been withdrawn I have yet no connection with that institution.

I make this statement with no intention to reflect upon the present management of the said institution, which I believe to be now ethically conducted.

Respectfully,

C. H. HUGHES, M.D., St. Louis.

Correction.

OTTAWA, CAN., June 6, 1894.

To the Editor:—It has but just come to my notice that there are several unpleasant typographical errors in my paper on Physiotherapy in the JOURNAL of May 26, and which I corrected in revised proof. I presume you did not receive proof before going to press. Besides errors in the Greek lettering, in spelling two or three proper names and in punctuation, especially in breaking with a period and a capital the last sentence (a long one, to be sure) in the first paragraph, there are errors in the last paragraph which would lead a hasty reader to think it was I who had started the "water cure." Instead of, "I placed myself under the care of a Mr. Brown, who had during the time of Priessnitz a popularity which extended to the uttermost parts of the earth; and started a . . . 'water cure,'" kindly make it read: "Brown, who had during the time of Priessnitz's popularity, which extended, etc., started a 'water cure.'"

EDWARD PLAYTER.

NECROLOGY.

WILLIAM T. BRIGGS, M.D., of Nashville, Tenn., June 13. He was born at Bowling Green, Ky., Dec. 4, 1828, and received his literary education in the schools of his native town. He then graduated in medicine at the Transylvania University at Lexington, Ky., when not 21 years of age. He returned to Bowling Green, Ky., and entered the practice of medicine with his father. He remained there three years when he was elected Demonstrator of Anatomy in the Medical Department of the University of Nashville. This was in 1852 and he removed to that city at once and has lived there ever

since. Soon after going to Nashville, he formed a partnership with Dr. John W. Watson, one of the most eminent physicians of his day. This partnership continued up to Dr. Watson's death in 1866. In 1856 Dr. Briggs was made a joint Professor of Anatomy with Dr. Thomas R. Jennings, Professor of Anatomy in the University. The University suspended during the war, but in 1865 when it was reopened Dr. Briggs was elected to the chair of surgical anatomy and physiology, which he held until transferred to the chair of obstetrics and diseases of women and children made vacant by the death of Dr. Watson. In 1868 he succeeded Dr. Paul F. Eve, Sr., as Professor of Surgery, and this position he continued to hold with marked ability in the consolidated medical departments of the University of Nashville and Vanderbilt University up to his death.

Dr. Briggs was a member and ex-President of the AMERICAN MEDICAL ASSOCIATION. He had been honored by this Association on several occasions, being elected a vice-President in 1881, President in 1890, delegate to the International Medical Congress of London, England, and was recently elected one of the Association's delegates to attend the International Medical Congress of Rome, Italy. He was one of the founders of the American Surgical Association, and was its President in 1885. He was chosen President of the Section on General Surgery in the International Congress held at Washington in 1887. He has several times been honored with the presidency of the State Medical Association.

In 1850 Dr. Briggs married Miss Annie E. Stubbins, of Bowling Green, Ky. His wife died about a month ago. By this marriage four children, all of whom are living, were born. They are Dr. Charles S. Briggs, Professor of Surgical Anatomy and Operative Surgery in the medical departments of the University of Nashville and Vanderbilt University; Dr. Waldo Briggs, of St. Louis; Miss Virginia Briggs and Dr. Samuel S. Briggs, a young physician of this city.

Dr. Briggs was author of quite a number of valuable publications. Principal among them were: "History of Surgery in Middle Tennessee," "Tetanus Treated by Chloroform," "Successful Amputation of the Shoulder Joint," "Traumatic Aneurism of the Internal Carotid, the Result of a Puncture," "Ligation of the Common Carotid and then of the Internal at the Seat of Injury."

E. ALLEN WOOD, M.D., was born March 24, 1834, at Woods Run, Washington County, Pa., and died at Philadelphia, June 4, 1894. His immediate death was due to cerebral hemorrhage. He for several months suffered from an atheromatous condition of the cerebral vessels. He went to Philadelphia to attend the meetings of the Pennsylvania State Medical Society then in session; while there he became worse and entered the Medico-Chirurgical Hospital where he remained. Dr. E. Allen Wood was a son of Joseph and Sarah Allen Wood. He had one brother, Captain Thos. J. Wood, and two sisters, all of whom survive him. His early education was obtained in the public schools, and later, at the academy, at California, Washington County, Pa. His earliest ambition was to become an artist, but he afterward turned his attention to medicine and graduated from the Western Reserve Medical College, of Cleveland, Ohio. His preceptor was Dr. James Gordon, of Temperanceville, Allegheny County, Pa., a prominent member of the profession at that time. Dr. Wood was married in 1859 to Miss Lizzie Hopkins, of Brownsville, Pa., who survives him. After graduating he located at Library, Pa. This field soon became too narrow for a man of his ability, attainment and ambition, and he removed to McKeesport, Pa. After practicing there for two years he again removed to Birmingham, Pittsburg, where he remained until 1892, when he removed to East End, Pittsburg, and opened an office on Sixth Avenue, but still retaining his office in South Pittsburg in connection with his partner, Dr. J. E. T. Martin. He was held in high esteem by both laity and profession. He was the organizer of the South Side Medical Society, the oldest medical organization in Pittsburg and was one of its early Presidents. He was also President of the Allegheny County Medical Society, and in 1886 was President of the Pennsylvania State Medical Society. He was a member of the AMERICAN MEDICAL ASSOCIATION and was for several years Chairman of the Committee on Dietetics. He delivered several lectures before the ASSOCIATION upon Dietetics. As a lecturer and public speaker

he was eloquent and original. He delivered a course of lectures before the New York Academy of Anthropology. He was one of the organizers of the Western Pennsylvania Medical College, of Pittsburg, and was the first Professor of Dietetics in that institution. He was beloved by the students for his earnest, witty and practical lectures. He was an honorary member of the Mississippi Valley Medical Association. He was one of the original members of the Mott Medical Club of this city, and was for years Division Surgeon of the Pennsylvania National Guard. During President Cleveland's last term he was one of the Pension Examiners for the Twenty-second District of Pennsylvania. He was from his early professional life interested in educational matters, and as in medical circles, he was a leader. He was for many years school director and also served in councils from this ward. He was elected to the Senate of Pennsylvania in 1875 from the Forty-fifth Senatorial District—a Republican stronghold, but he a Democrat. He was instrumental in framing the Anatomical Dissecting Act which has secured to medical students dissecting material. He was also active in the organization of the State Board of Health, and was for many years a member of the local board. He was a delegate to the National Democratic Convention that nominated General Hancock and was a personal friend of Tilden, Hancock, S. J. Randall and many other prominent Democrats. At the time of his death he was President of the Lotus Club of the South Side, Pittsburg. Dr. Wood was widely known for his literary ability and was passionately fond of music and poetry. He was a lover of nature and delighted in hunting, fishing and rambling through green fields and mountain forests. Some of his literary efforts have been widely read. He has published "Tancredi," "Tom and I," "The Phantom Coaches," "Bimini," the libretto of the "Lion of Peru," "Karl, the Prize Winner," now being played on the stage, and was also author of many other poems, novels and librettos still in manuscript. He wrote for recreation and for the pleasure which it afforded. He was for many years an ardent worker in the AMERICAN MEDICAL ASSOCIATION, and his hatred of hypocrisy and outspoken plainness made him respected and beloved by his associates.

CHARLES P. JAMES, M.D., of Brooklyn, May 22, 1894. Dr. James was a native of Brooklyn, having been born in that city nearly twenty-seven years ago. He was a graduate in medicine from the Long Island College Hospital in the class of 1891. He had been sick with gastritis and was under treatment by a neighboring physician. He was a member of the Kings County Medical Society.

SOCIETY PROCEEDINGS.

Cincinnati Obstetrical Society.

Meeting of April 12, 1894.

The President, T. P. WHITE, M.D., in the Chair; E. S. McKEE, M.D., Secretary.

CÆSAREAN SECTION.

DR. C. A. L. REED reported a case of Cæsarean section. The case emphasized some important clinical features, and proved the possibility of saving the child under very unfavorable circumstances. The child was saved but the mother died.

DR. G. E. JONES inquired how soon after the death of the patient the microscopic sections were made.

DR. REED replied as early as one hour and as late as six hours after death.

ABSCESS.

DR. JONES reported the following case: A young woman came into Christ's Hospital with an abscess three inches above the pubes. Why it was there was a puzzle. She had been operated on eighteen months prior for an ovarian tumor by Dr. Reed. The probe passed down behind the pubes for a considerable distance. With the curette this portion of the ligature (shown), which had been put on the stump, was fished up. The question is, are we not imposed on in our ligatures? In this specimen there seems to be a mixture of linen thread and silk.

DR. THAD. A. REAMY (examining specimen)—I think this is impure silk.

DR. REED—The silk is manifestly impure. I have had this

same thing to happen to me several times. Generally there is some infection, followed by an abscess or sinus. Sometimes these ligatures, when once contaminated, will feed a sinus indefinitely.

INDUCED LABOR BY INJECTION OF GLYCERIN.

DR. BYRON STANTON reported a case of induced labor by injection of glycerin in the cavity of the uterus. The labor, which was induced on account of a small pelvis, came on in two and one-half hours. In a former case reported to this Society four hours were required. The amount of glycerin injected I do not consider important, as its hygroscopic action is very great, one-half ounce having caused labor. Glycerin is found to act much more promptly than water. I pass a catheter into the uterus as far as possible and inject with a uterine syringe, using sterilized glycerin. The end of the catheter beyond the eyelet is filled up with plaster-of-paris, so as to avoid the injection of air.

DR. J. L. CLEVELAND reported a very disastrous result from the injection of water into the uterus, in the hands of another practitioner. He did not think any air had been injected, and while he does not think this accident so likely to happen in the use of glycerin, we should be very careful to exclude air.

DR. REAMY—I have never used fluid of any kind to induce labor, for fear that I might inject air. Why can it be necessary to induce labor at once except in the case of convulsions? I am unable to appreciate why we should bring on labor in two or three hours, when two or three days are not objectionable, but probably better. I have not for years practiced any other method than to dilate the cervix with the finger and detach the membranes. The hand in the vagina should be sterilized and the woman placed in the lithotomy position. This means will succeed in every case in two or three days. You will be surprised to find what amount of dilatation can be obtained in twenty minutes' time by the use of the finger. Frequently, when called to attend a woman when the cervix does not dilate, by the use of the finger I bring on the labor to my convenience. I can not but realize that it is safer to use the finger than glycerin.

DR. C. D. PALMER said we must recognize the intra-uterine injections of glycerin as an efficacious means to induce a premature labor. Certainly the glycerin should first be sterilized, drained, and care taken that no air is injected into the uterus at the same time. Perfectly pure anhydrous glycerin would do better work than ordinary shop glycerin. The great advantage of its use is its promptness of inducing uterine contractions, and this may call for its use at times. I have used the method spoken of by Dr. Reamy, but have not found it uniformly successful. The use of the solid elastic gum bougie (never the female catheter) has never failed with me in inducing some uterine action within twelve hours. On two occasions I have been obliged to introduce another and larger one, to increase labor pains on the opposite side of the uterus. To avoid the attached placenta, and prevent any detachment of the same, the best position for these bougies is along the anterior and lateral uterine walls.

DR. STANTON—I think Dr. Palmer has had an unusually fortunate experience in the use of the bougie. In my case it has required from one to two days. I think it is an advantage to bring on labor in a short time, three, four or five hours being much better than twenty-four or forty-eight. Labor induced by glycerin is, I think, as nearly natural as any method. The separation of the membranes by the finger has sometimes failed, and the assistance of a sound or catheter has been found necessary to separate the membranes higher up.

DR. E. G. ZINKE reported a case which occurred at the college, the patient being past her expected time. At the suggestion of Dr. Palmer, separation of the membranes was made every day for two weeks, and still labor did not commence.

DR. REAMY—If you did this every day you did wrong; you kept up a constant irritation and did not give the uterus time to respond. I think if you had separated the membranes higher up you would probably have induced labor.

DR. RUFUS B. HALL questioned the propriety of bringing on labor before it commences, as a matter of convenience, and he did not think it devoid of all danger or responsibility, especially in the hands of incompetent persons.

DR. PALMER—I realize as much as any one the inconvenience of obstetrics, conflicting as it does, with other engagements and with sleep. I have often been tempted, but so far have always waited.

DR. REAMY—A young man without experience should not hasten labor by dilating the cervix. No one should do it without much experience. Many have not the mechanical touch or conception, and never attain it. I am only speaking as to whether it is justifiable to make the dilatation when the woman is within a few days of confinement. A skilful man selecting his case, it is perfectly proper to bring on labor four or five days before it is due; it is better for the woman and better for the physician. I have done it many times when the patient did not know it; it is even better that she should not know it. I prefer to use the fingers rather than Barnes' bags to dilate the cervix. The labor will be brought on more quickly at seven months than at full term.

MULTILOCLAR OVARIAN TUMOR.

DR. REAMY reported a case of plain multilocular ovarian tumor. Some of the fluid, which was colloid in nature, was discharged into the peritoneal cavity by the rupture of the cyst, due to the struggles during the process of anesthetization. There were no adhesions. Peritonitis set up in spite of the fact that all the fluid had been carefully removed, and the patient died of peritonitis in two days.

DR. ZINKE said it frequently happens that cysts rupture during the operation, either from adhesions or thinness of the cyst walls. He reported a case which happened in the practice of Mr. Tait. The fluid was all washed out and the patient recovered, with union by first intention. I believe that the contents of cysts are ordinarily not septic.

DR. HALL—I can recall the case of an old Welsh woman who was successfully operated on by Mr. Tait. Had the case reported by Dr. Reamy been mine I would have drained. My experience leads me to know that in those cases where fluid is turned out, it acts as an irritant to the peritoneal cavity and causes it to throw out more material.

DR. REAMY—I did not drain because there was no hemorrhage, and feared none. The fluid was all over the peritoneal cavity. I thought of drainage, but reasoned that if this fluid did harm it would cause general peritonitis. Best authorities consider that the drainage tube drains only the peritoneal cavity. I thought it best that this cavity should be hermetically sealed.

PUBLIC HEALTH.

Cholera on the Continent.—It is predicted that the spread of Asiatic cholera from Russia into Austria and Eastern Germany and its continuance in the western departments of France will cause a considerable part of the Continent to be infected during the present summer. It is believed that the disease is more prevalent in France and Belgium than is reported; there has been a recrudescence of last year's outbreaks in L'Orient and Quimper, port cities of Finisterre and Morbihan, the infected western French departments, and sporadic cases are reported in Paris.

Smallpox on Staten Island.—New York City is undergoing a newspaper "scare," based on the existence of smallpox at Stapleton, S. I., where, it is alleged, variola has been diagnosed as varicella for several weeks, during all which time smallpox convalescents have been visiting New York daily. Dr. A. H. Doty, Chief Inspector of Contagious Diseases of the New York City Board of Health, has visited Stapleton and most positively asserts that the disease is smallpox and that the metropolis is in danger from the infected place. Health Commissioner Edson should welcome this occasion for securing further vaccinal protection for his own bailiwick. Properly utilized there is much virtue in the occasional "scare."

Is this a Sanitary Utopia?—Imagine the following as an item of official intelligence from Washington, D. C., U. S. A.: "The German Cultus-Minister has, in response to repeated stimulation by a sanitarian deputy, consented to organize systematic courses of instruction in matters appertaining to public health, for the especial benefit of members of the German Legislature; lectures are to be given in the Legislative Chamber itself by the professors of hygiene of the

ADDRESS.

SOME SURGICAL SINS.

The Chairman's Address read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY JOHN B. ROBERTS, A.M., M.D.
PHILADELPHIA.

A very significant fact in the surgical literature of recent months has been the evidence of reaction against an over-hasty adoption of operative methods of treatment. The general conviction of the relative certainty with which operative attacks could be freed from septic consequences quickly bred a crop of surgeons whose surgical learning scarcely kept pace with their operative zeal and the force of whose dogmatic assertions was only equaled by their rapidity in publishing tables of cures.

The low death rates of the new surgery made such a contrast with the mortalities recorded in accepted text-books that the men who believed the new gospel—naturally the young—were enchanted by the safety with which they could operate for conditions that older and more cautious surgeons hesitated to so treat. Many of us have stood appalled at the temerity, and astonished at the pathology, of these operative members of the profession. An omen of true progress can be seen in the tendency of even these to so restrict the use of the knife, and to reflect that the true surgeon must have accurate pathologic knowledge and good surgical judgment as well as operative dexterity. Of what advantage is it to a patient to undergo an operation, within the scheduled number of seconds, or with the loss of the promised minims of blood, if the operation was not demanded? Who cares whether he carries a scar one or two centimeters in length, if he could have been equally well cured without scar, and without the necessity and expense of a surgical procedure? "Look at the dozens of operations done by me this year without a death," says the operator. His less enthusiastic neighbor thinks of the proverbial kinds of falsehoods, "lies, damned lies, and statistics," and replies: "Reports of large numbers of cases subjected to operation seldom fail to beget a suspicion of unjustifiable risk."

It seems to me that a revival of learning in surgery is upon us, a going back to the study of etiology, symptomatology, diagnosis and treatment, destined to restrain unseemly haste in adopting the scalpel as a panacea. If my observation of late events has been correct and unprejudiced, the operative madness has usually, though not always, been endemic among those whose preliminary educational training has been circumscribed and whose medical study and experience have been in one field rather than in all. Dogmatists in science and in religion are most usually found among those of limited scientific and

worldly knowledge. No one will deny the assertion that the best professional judgment would be found in a man who successively had had years of medical, surgical and special experience. The present breadth of medical science prohibits such experience in a human life; but the nearer a physician attains it the more valuable is he to the community.

The exaction of preliminary education, the lengthening of college courses and the association of doctors in meetings, such as this, are the correctives which will cure the specialist of his egotism, compel the conservative to know the value of new things, and drive the sluggard and ignorant to his medical journals and books. A true surgeon can not lack broad culture, modest self-denial, accurate judgment and unselfish regard for his patient.

This at least was the opinion of Thomas Vicary, Sergeant Chyrurgeon to Henry VIII., who well tells us "what properties and conditions a man must have before he be a perfect Chirurgeon." His advice in 1577 may well be studied in 1894. "The first (I sayde) he ought to be learned and that he know his principles, not onely in Chirurgerie but also in Phisicke, that he may the better defende his Surgery: Also he ought to be seene in Natural Philosophie, and in Grammer, that he speake congruitie in Logike, that teacheth him to proue his proportions with good reason. In Rethorike, that teacheth him to speak seemely and eloquently; also in Theorike, that teacheth him to know thinges naturall, and not naturall, and thinges agaynst Nature. Also he must know the Anatomie, for al Authors write against those Surgions that worke in man's body not knowing the Anatomie, for they be likened to a blind man that cutteth in a vine tree for he taketh more or lesse than he ought to doo."

"The ijd, I said, he must be expert: For Rasmus sayth he oughte to knowe and to see other men work and after to haue vse and exercise. The thirde, that he be ingenious or witty: For al things belonging to chirurgerie may not be written nor with letters set forth. The fourth (I sayde), that he must be well manered, and that he haue al these good conditions here following:"

"That a Chirurgeon must take heed he deceiue no man, with his wayne promises, nor to make of a smal matter a greate, because he woulde be accounted the more famous. Likewise, they shal geue no counsayle except they be asked, and then say their aduise by good deliberation, and that they be well aduised afore they speake, chefly in the presence of wise men. Likewise they must be as priuie and as secrete as any Confessour of al thinges that they shal eyther heare or see in the house of their patient. . . . And see they neuer prayse them selues for that redoundeth more to their shame and discredit than to their fame and worship: For a cunning and skilfull Chirurgeon neede neuer vaunt of his dooings, for his works wyll euer get credite ynough. Likewise

that they despise no other Chirurgion without a great cause: For it is meete that one Chirurgion should loue another, as Christe loueth vs al."

John of Arderne who wrote two hundred years earlier than Vicary appears to have been familiar with some of our nineteenth century tendencies. He was a specialist and, in accordance with the inherent tendency, wrote a treatise on anal fistula. After detailing the names and addresses of his patients and giving his own residence, he says, according to a fifteenth century translation of his Latin monograph:

"All these forseid cured I afore the making of this boke oure lord Ihsu ye blessed God knoweth that I lye *noght*. And therefore no man dout of this thof although old famous men and ful of clere (renowned) in studie haue confessed tham that thei fand nat the wey of curation in this case; for God that is deler or rewarder of Wisdom hathe hid many thingis from Wise men and *slighe* (cunning) whiche he vouchesafeth afterward for to shewe to symple men." "Therefore I pray that the grace of the holy gost be to this werke that he vouchesaf for to spede it; that the thinges whiche in wirking trewly I am ofte tymes experte I may plenevly (fully) explane tham in this litel boke. It is lefull forsoth for to sey that (what) is known and for to witnes that is seene.

"And this I sey that I know *noght* in al my tyme ne heard *noght* in al my tyme of any man nother (neither) in yngland ne in partiez biyonde the see, that kouthe cure fistula in ano outake (except) a frere minor that was withe the prince of Wales in gascon and gyan (Guienne) whiche rosed and bosted hym that he had cured the forseid sekenes. And at london he deceyued many men. And when he might *noght* cure som man he made suggestion to tham that no man might cure tham and that affermed he with swering that yif the fistule was dried that the pacient at the next schuld *noght* eschape dethe whiche forsoth ylefte and forsake of hym I cured perfityly."

Notwithstanding this author's characteristic vaunting of his own special skill he appears to have been too wise to speak against the general practitioners, for in his book on "Ye manere of ye Leche"—"the Conduct of the Physician,"—he gives this advice:

"He that skorneth other men shal not go away vnskorned. Yif ther be made speche to hym of any leche nouthur sette he hym at nought, ne preise hym to mich or commende hym but thus may he curteysly answeere, I haue *noght* eny knowleche of hym, but I lerned *noght* ne I have not herd of hym but gode and honeste; and of this shal honour and thankyngis of eche party encesse and multiplie to hym; aftur this, Honour is in the honorant and *noght* in the honored."

The cultivation of a habit of accurate statement, as well as of observation, would save many of us from criticism and teach us to be cautious about criticising others. Mr. Charles A. Dana in a recent address on journalism insisted that the faculty of seeing a thing as it is was one of the most precious ends of a good education, and advised newspaper men to tell what they knew accurately and without exaggeration or prejudice. It is usually a habit of inaccurate statement which impels a surgeon to say that an important operation is absolutely safe; and then calmly report a list of such cases containing several fatal operations. The surgeons who open an abdomen seven or eight times are almost as certainly lacking in judicious and accurate study of symp-

toms as the woman who permits it is ignorant of surgery. Yet a patient recently requested abdominal section at one of the hospitals with which I am connected, saying that she had already been subjected to seven such operations. I would think her statement untrue if my ears had not heard and my eyes seen similar things.

Due regard is not given by us to the influence of the nervous system upon the health. Many patients can be cured, by medicine or psychic remedies, of symptoms which would induce some surgeons to resort at once to mutilating operations. This statement does not apply alone to pelvic conditions but to affections of joints, muscles and viscera. My experience at the Woman's Hospital in Philadelphia, and in private practice justifies this assertion.

I am impelled to believe, though I dislike to do so, that the establishment and personal control of private hospitals by surgeons is a distinct evil. Such institutions seem, to me at least, to tend to warp the judgment; and make the surgeon's prospective income somewhat obscure the correct view of the patient's good. Practically it is rather difficult for a doctor to keep a hotel for patients without having his professional ethics a little blunted by a hotel proprietor's proper desire for many and long-staying patients. I regret that our human nature is liable to be thus tainted, because surgery can be better done, and sometimes more cheaply done, in a hospital than in a patient's home. I am convinced, however, that the truest ethical spirit is not developed by these private hospitals maintained for the pecuniary and professional advantage of one man. While some may do no harm, many tend to develop selfishness, theatrical operations, and a mercenary spirit foreign to the highest type of surgeon. I confess a similar distrust of private and corporate sanitarium. I know they frequently do much good for invalids, but the bestowal upon physicians by some of these institutions of shares of stock, proportionate to the number of patients sent for treatment, does not increase my confidence in the system.

Demanding unusually large fees for professional services is a surgical sin, which the increasing number of skilled surgeons is happily correcting. To send a bill for a large amount simply because the patient is wealthy does not appear to be just, and to obtain the money because the patient is in fear of death and dares not employ a less expensive attendant makes one think of the methods of the footpad who demands your money or your life. A high degree of skill and heavy professional responsibility undoubtedly deserve adequate pecuniary recognition, but the true surgeon will always recollect that practicing surgery for money alone degrades a noble profession to the level of a trade.

Declination to see a poor patient with a practitioner who desires the advice of a consultant is a similar wrong. Our common brotherhood teaches us to charge no fee for attending another doctor and his family. It is just as imperative that we go to his help when an obscure case gives him anxiety. A surgeon who will not aid another with his counsel because the patient can not pay the regular fee is a poor representative of the medical guild. Equally censurable is the hospital surgeon who allows insignificant causes to keep him from formal consultations called by his colleagues.

Not less destructive to the purposes of scientific

surgery is the use by many surgeons of secret nostrums. While many of these may have active ingredients, their use is unscientific and unworthy of us, because we have no knowledge of their *exact* composition, and hence can not treat our patients with accuracy and precision. A distinguished English surgeon once said: "The glory of surgery is precision." Very little precision characterizes the methods of the nostrum-employer; hence his surgery is usually far from glorious. Dr. J. T. Graham, of Virginia, has justly said on this topic: "Whenever a physician becomes too negligent to study his cases and prescribe well-known and tried remedies for definite pathologic conditions, he is no addition to his profession. As long as pure drugs are manufactured, as long as scientific works on materia medica and therapeutics are written, as long as ample facilities for acquiring a knowledge of medicine exist, there is no excuse for the physician acquiring the habit of prescribing patent medicines."

ORIGINAL ARTICLES.

A CRITIQUE OF THE SPOROZOAN THEORY OF MALIGNANT NEOPLASMS FROM A MICRO-TECHNICAL STANDPOINT.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY A. P. OHLMACHER, M.D.
CLEVELAND, OHIO.

PROFESSOR OF PATHOLOGY AND BACTERIOLOGY, MEDICAL DEPARTMENT UNIVERSITY OF WOOSTER, CLEVELAND, OHIO; FORMERLY PROFESSOR OF EMBRYOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO; AND OF PATHOLOGY IN THE CHICAGO POLICLINIC.

The present condition of the sporozoan theory of the etiology of malignant tumors in man and the higher animals is one of much confusion. The student of this subject is confronted by a multitude of imperfectly digested contributions from investigators of all ranks of excellence. It is astonishing to note the variety of objects which have been assigned to the class of cancer parasites by over enthusiastic workers. Almost every object which presents itself in the histologic study of malignant tumor tissue has been described as the carcinoma organism, from the blood elements on the one hand, to the tumor cells themselves, on the other. Red blood cells, leucocytes, blood plates, invaginated cells, endogenous cell formations, irregular nuclear division products, metabolic cell products, cell-degeneration products, capillaries filled with blood corpuscles, and other objects, familiar to the careful histologist, have been interpreted as parasites by some investigator in this field. The fact of the matter is that this mass of unscientific material, to which daily additions are being made, has brought the whole subject into ridicule and, instead of increasing our knowledge of this vital question, this worthless material has only served to burden and retard future research.

It is a difficult matter to assign all of the causes that have led to this distressing situation. One point, however, will impress itself upon the careful student of this question, and that is that the majority of contributions come from men of too narrow preliminary training; that is, the investigators may be too readily classified into the pure biologists or the pure pathologists. That is to say, of the pathologists, for instance, that while they have shown a

due amount of familiarity with the histologic structure and clinical manifestations of malignant neoplasms, they have shown a lack of fundamental knowledge of the morphology and life history of that class of organisms to which they have assigned the etiologic rôle; that is, the class *Sporozoa* of the sub-kingdom *Protozoa*. Conversely, the contributions of the biologists who have attacked this problem proclaim their familiarity with the comparatively little that is known of the life history of the various sporozoa; but their works exhibit an ignorance of the pathologic and clinical side of the study of malignant tumors. It is not uncommon, even in the very recent papers, to find the most absurd statements regarding the classification and zoölogic position of the sporozoa, to say nothing of the morphology and physiology of these organisms.

One thing at least is obvious, and that is that all investigators in this direction should thoroughly familiarize themselves with the peculiar organisms whose presence in tumors is suspected. Had not Koch been familiar with the considerable knowledge of bacteria accumulated at the time of his classical researches upon tuberculosis, it is doubtful whether his remarkable studies would have been given to medicine in the very complete condition which marked them a scientific masterpiece.

It is not within the province of this paper to enter into a detailed discussion of the foregoing statements, nor is it possible to touch upon the manifold aspects of the sporozoan theory of malignant neoplasms. The work thus far accomplished has been thoroughly reviewed upon several occasions, the most recent review being the very excellent bibliographical and critical summary of Stroebe,¹ to which the student may be referred.

The study of the parasitic organisms of tumors has thus far been almost exclusively confined to the microscopic examination of sections of fixed and stained tumor tissue. Under this head comes the work of the large majority of investigators who have attained prominence in the discussion of this subject. It is to this particular method of study that we shall direct attention.

There is a growing conviction in the minds of many students of biology and pathology that the wonderful advances in micro-technical methods of the last decade are becoming elements of serious danger. A reaction against the extreme tendency of the new microtomy is slowly finding expression. The fact that a host of microscopic methods are in vogue which rest upon purely empirical bases can not be denied, and these empirical methods must all come within the scrutiny of exact scientific research before their results can be accepted. It is scarcely too much to predict that a day of reckoning is coming in microtomy when many beautifully constructed histologic edifices will be rudely shattered; and in this destructive analysis American investigators, with their natural skepticism and keen criticism, will take no small part. The work has already begun in several contributions dealing especially with the anatomy and histology of the nervous system. The artificial products resulting from a mixture of numerous reagents of unknown effect, the artificial products of the mechanical aids employed in gross and microscopic anatomy, and the artificial products of our optical appliances—all of these so-called

¹ Cent. f. Allgem. Path. u. Path. Anat. V Band. Nos. 1, 2, 3, 1894.

"artefacts" must be rigidly analyzed and put upon firm scientific foundations before a good working basis shall have been reached.

Into this category comes all of the work upon the tumor parasites which is founded upon a microscopic study of the tumor tissue alone. In consulting the chapter on technique in each of the various papers upon the cancer parasite, it will be noted that all manner of combinations of fixing reagents and staining reagents have been employed. To one who has made an analytical study of reagent-effect in histology, it must at once occur that from this variety of technical processes a variety of effects have been produced in which the *reagents themselves* played a very essential part.

Upon two previous occasions I have endeavored to direct attention to the importance of a consideration of the reagent effect in the studies upon the sporozoan parasites of tumors. In the first communication² I tried to prove that the work of Podwysozki and Sawtschenko, and of Stroebe, was of limited value, because these investigators employed in their technique a combination of safranin and picric acid in staining, which, according to my experiments, gave rise to dangerous artefacts in the tissue elements. I found, for instance, that if safranin staining was followed by a washing out with picric acid-alcohol, minute crystalline artefacts were very frequently deposited in the section thus stained.

These very minute artefacts resembled in size, shape and color, the bodies described by Podwysozki and Sawtschenko, and by Stroebe, as segmentation products of their sporozoan parasites, and I could not resist the conclusion that they had these artificial products under observation.

In a second paper³ I described a new species of myxosporidia which I had discovered in the kidney of the common toad, and as a result of certain micro-technical studies upon these sporozoa, I again directed attention to the dangers underlying the carcinoma investigations. This second paper was supplemented by a communication from Dr. Whinery,⁴ who extended the description of the morphology of this myxosporidium, and who recorded further micro-technical studies.

Since the publication of my first paper I have continued the study of reagent-effect in tissues, and upon the sporozoan parasite of the toad, and I desire to bring a brief outline of this work to your attention.

My first observations were confined to an analytical study of reagent effect in normal tissues from a variety of vertebrate animals. The object of this work was to assign, if possible, the significance of the *method* in modern cytologic research. In this study the older methods of hardening and staining were discarded, and a series of fixing agents and staining agents, as advised by recent cytologists, was employed. Regarding this work I can only say here that the results were frequently astonishing, and that I was most profoundly impressed with the very great significance of technical modifications in all work of this character. It was in close connection with this study that I undertook an investigation of the carcinoma organism question, and it quite naturally followed that I was much inclined to scrutinize all of my work on this subject from the standpoint of the microtometist.

Upon the discovery of the myxosporidia in the kidney of the toad, I embraced the excellent opportunity afforded by these specimens for a comparative study of the reagents commonly employed by carcinoma investigators. Here was a good-sized sporozoan present in a matrix of animal tissue. What better opportunity for a control study of micro-technical effects could be desired?

In order to make clear the following summary of the experiments in the micro-technical reactions of these myxosporidia in the kidney tissue, it will be well to direct attention to the structure of these organisms, and to their relations to the host's tissue. In his paper, Whinery⁵ has given a very clear description of these myxosporidia, and he has accompanied the description by a good diagrammatic illustration.

These sporozoa were found only in their spore form. The spore is an oval structure, bounded externally by a striated, bi-valvular shell. Within the shell are found two spherical bodies, highly refractive in fresh preparations, and termed by Gurley, whose nomenclature we have adopted, capsules. Opposite the capsules lies a plasmatic mass, crescentic in shape, and containing in its substance several small, highly refractive bodies, the "nuclei" of Thelohan; this mass is called the sporoplasm. The myxosporidian spores lie in the tubules of the infected kidney, sometimes embedded in an albuminous secretion. The spores are frequently present in such numbers as to fill the entire lumen of a kidney tubule.

Pieces of kidney tissue containing the sporozoa were killed in a variety of fixing solutions, immediately after the death of the animal from chloroform. Of these fixing agents I directed especial attention to Flemming's solution, corrosive sublimate, absolute alcohol, Hermann's solution, Peryni's fluid, and Carnoy's solution. Concerning the behavior of these solutions upon the spores of this myxosporid, it may be briefly said that Flemming's solution, Hermann's solution, and Peryni's fluid, were very harmful to the spore structure. In other words, solutions containing chromic acid, or osmic acid, were unsuited to the preservation of these organisms. It must be remembered that these mixtures take first rank among the reliable fixing solutions of the cytologist, and that they are largely employed by recent carcinoma investigators. These three mixtures all produced a shrinking of the spore shell, and a distortion of the spore contents. Often this distortion of the spores was so extreme as to make it difficult to recognize these bodies in the kidney tubules. Not only did these fixing agents distort the spores as a primary effect of their application, but they interfered greatly with subsequent staining. With all of this harmful action on the myxosporidia, these fixing solutions preserved the cells and nuclei of the kidney tissue with their usual faithfulness.

Absolute alcohol, and Carnoy's chloroform acetic alcohol mixture gave very excellent results. The sporozoa were preserved without distortion, and the subsequent staining with appropriate dyes was very successful. With these media the kidney tissue elements were also well preserved.

Corrosive sublimate, while preserving the sporozoa and the tissue elements without harmful distortion was not entirely satisfactory, for the reason that it was washed out of the sections with great

⁴ New York Medical Journal Vol. lvi No. 23, 1893, pp. 660-662.

⁵ Loc. cit.

difficulty; and it was no uncommon occurrence to find, even after the most vigorous attempts to remove the sublimate crystals (treating sections with tincture of iodine and alcohol, as advised by Heidenhain), that these crystals still remained behind, particularly within the shells of the myxosporidian spores.

In this record of my experiments with staining solutions, I shall confine myself to a brief outline of the results obtained by those reagents which have found especial favor among the carcinoma organism investigators. I shall describe the combinations with absolute alcohol fixation in some detail, because this fixing agent gave a very faithful preservation of the kidney parasites. All of these descriptions refer to sections of tissue, cut after paraffin embedding, affixed to the slide by the water-albumen method, stained on the slide, and mounted in Canada balsam.

Absolute Alcohol; Ehrlich's Acid Hematoxylin, followed by Eosin.—With the low power (Leitz No. 3 objective) the myxosporidia can not be detected in the kidney tissue. The kidney elements are well stained. With high power (Leitz No. 7) the myxosporidian spores can only be recognized with difficulty. Were not their presence and location previously known, the detection of the spores in these sections would be a fruitless task. Kidney tubules filled with the organisms might easily be overlooked. The spores are massed together in an albuminous matrix; and they appear as faintly outlined, structureless bodies. Only occasionally do the spores show a faintly outlined, purple capsule. The curious feature about this staining combination is that the filaments (thread-like flagella projecting from the capsules through the spore shell, beyond the spore) of many spores are often deeply stained. In tubules containing a mass of spores, the filaments radiate in all directions, producing a prominent network of dark stained threads.

Absolute Alcohol; Ehrlich's Hematoxylin, and Babe's Safranin.—The kidney tissue shows a characteristic double stain, with a predominating purple color. The spores appear as brilliant red, shrunken bodies; and their contents can not be clearly outlined. The filaments are again prominent and stain a deep red color.

Other mixtures of hematoxylin gave essentially similar results.

Absolute Alcohol and Pfitzner's Alcoholic Safranin.—In sections well washed out with acidulated alcohol, after staining, the sporozoa appear as very prominent, deep red bodies, in a nearly colorless ground. The capsules stain with especial vigor with this solution, and stand out in the preparations with startling distinctness. The sporoplasm stains a light red color; while the shell and filaments remain unstained. This is the most successful stain of the series on account of its wonderful selective affinity for the capsules, and because, with good fixing agents (absolute alcohol, corrosive sublimate, and Carnoy's fluid,) it never deposits artefacts in the spores.

When Pfitzner's safranin is followed by aqueous methyl blue as a contrast stain, a beautiful double stain is produced. The kidney tissue stains blue; the capsules of the spores, brilliantly red; and the sporoplasm, a light blue. I have, in a former paper, directed attention to this marked dichromophilism of the spore contents of this organism. With this safranin staining, the spores appear small because the shells do not take the stain.

Absolute Alcohol; Babe's Anilin-Water Safranin.—In sections washed with acidulated (HCl) alcohol, the spores are prominent as large pink bodies. The capsules are stained a moderate red; the sporoplasm a faint pink; and the shell, itself, partakes of a light pink color. This staining of the shells makes the organism appear larger than in specimens stained with alcoholic safranin. Many of the shells exhibit the characteristic striation; and some show the valve junction line.

Babe's safranin, followed by picric alcohol (the method of Podwysoski and Sawtschenko) gave remarkable preparations. The spores appeared as prominent deep reddish-brown bodies. On examining these spores closely with a high power, it was found that the spore shells were filled with masses of deep red artefacts. I at once recognized these artefacts as the safranin picric acid crystals. These crystalline artefacts from their size, shape and location within the spore shell, might readily have been looked upon as segmentation masses (as "sickle-shaped embryos") had not this staining been controlled by numerous other combinations. I looked upon this experiment as a striking corroboration of my previous work on the safranin picric acid reaction.

Absolute Alcohol; and the Ehrlich-Biondi Reagent.—These preparations show the characteristically beautiful tissue staining of this reagent. Upon the sporozoa, however, the stain was a dismal failure. The spores appeared to resist the stain and only occasionally the sporoplasm of a spore would show a trace of dirty green color. The capsules and shells remained uncolored.

Absolute Alcohol; Russell's Carbol-Fuchsin, and Carbol-Iodin green combination.—This staining method proved excellent for the sporozoa. The capsules stained a deep red with the fuchsin; and the sporoplasm took a well marked green color. The shell was clearly visible in these preparations.

Absolute Alcohol; and Gentian Violet after Gram's Method.—The spores are prominent on account of their deep purple color. The shells are very heavily stained; so intensely, indeed, as to often hide the other spore structures. Many shells exhibit their striæ. In one preparation, after this method, the filaments were stained.

Corrosive Sublimate; and Carnoy's Fluid; in combination with the above-mentioned stains.—In a general way the results were similar to those obtained with tissue fixed in absolute alcohol. The only difference noted was the occasional interference of sublimate crystals, in preparations imperfectly washed. Contrary to my expectations, the Ehrlich-Biondi reagent did not give better preparations in sublimate fixed tissue, than in tissue fixed in absolute alcohol.

Flemming's Solution; Hermann's Solution; and Peryni's Fluid; followed by the above-mentioned stains.—Since these fixing fluids did not preserve the spores well, it naturally followed that the staining effects were poor. A variety of curious artefacts were produced in the stained spores, distorted by these fixing fluids. It is impossible to indicate these artefacts here, and we may dismiss this subject by saying that these three standard fixing solutions, together with all staining combinations, are absolutely unsuited for the preservation and demonstration of the spores of these myxosporidia.

All of these experiments, following closely upon a study of tumor tissue after the methods in vogue

among the carcinoma organism investigators, have impressed me very profoundly with the inadequacy of this kind of study; and I must again insist that with all their dangers, the methods of new microtomy can never, in themselves, aid us in solving the very important question of the etiology of malignant tumors.

THE CLINICAL RECOGNITION OF MALIGNANCY IN TUMORS.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY CHARLES A. WHEATON, M.D.
ST. PAUL, MINN.

This subject has invited the attention of some of the brightest minds of our generation. To attempt a delineation of the specific outlines of a clinical picture of malignant disease is an undertaking of no small dimensions. It is usually easy for the thoroughly trained student of pathology to distinguish between benignancy and malignancy when he has sections of each under his microscope; but it is often a very different matter when the cases are presented clinically, and he has to straighten out the tangled threads of his clinical story that he may advise and act judiciously. The microscopist may be able to tell us all about the histologic character of cancer in its various forms, but it is primarily the surgeon's function to formulate his plan of defense and attack, on gross appearances and the clinical history. Prof. Daniel Lewis, of New York, in his little monograph (edition of 1892) designates all malignant neoplasms as "cancer," and such a classification is eminently satisfactory because of its simplicity, and I shall adopt it here in my paper.

Modern pathology has practically renounced allegiance to the old constitutional theory of the origin of cancer. The physical idiosyncrasy which renders one individual more susceptible to the development of cancer than another may be acquired by heredity, and in our clinical research the genealogic tree should be carefully scanned, with a view to establishing this etiologic factor. Gross finds in 712 cases of breast cancer, 11.28 per cent. traceable to predisposition of this character. Mr. Herbert Snow, of London, in an able article on "Early Diagnosis and Practical Surgery of Cancer," states that malignant new growths are almost entirely restricted to women above the age of 34, and to men past 40. Further, they appear in organs which have fulfilled their functional purpose, *e.g.*, "the sexual organs of women; or in tissues whose vitality has become conspicuously impaired, such as the buccal mucous tract of men. Hence we are bound to look with grave suspicion upon any incipient tumor formation in these parts of the respective sexes; in people growing old; in those whose general health and energies have from any cause become markedly undermined."

It is a fact generally conceded by all surgeons of experience, that the ghastly records of the operative treatment of cancer are, in a large measure, the result of the tardy recognition of the existing disease. When we review the statistics of the Registrar-General of England, as made by Dunn, with reference to cancer, we are appalled at the record: "During the first decade in which the study was made, namely, from 1860 to 1870, the total number of deaths from cancer was 80,049, the annual average increase being

248; during the second decade, 1870 to 1880, the deaths amounted to 111,301, the annual average increase being 320. If, as is assumed by the writer, the average increase of population is about 1 to 10 during each succeeding ten years, it is evident that this dreadful malady is outstripping very much the numerical increase of population."

How important, then, it is that we as individual members of this noble profession, should attempt to familiarize ourselves with the disease in its manifold forms, in order that we may contribute our mite to minimizing these frightful ravages. Accepting Dr. Snow's dictum, we are constrained to consider as one of the most important of the clinical questions in the investigation of this disease, the age of the individual. As before stated, with reference to the hereditary predisposition to cancer, we can satisfy ourselves that there is some occult condition of the tissues which is thus transmitted, by consulting the statistics of such men as Sibley, of the younger Gross, of Paget, Baker, Broca and many other distinguished authors and teachers.

Dr. Snow states that "it may be laid down as a practical axiom that no average species of malignant tumor in the adult ever appears without an adequate and generally ascertainable existing cause." He says: "11.7 per cent. of cases of breast cancer follow sudden injury, a blow or a fall; the remainder are consequent upon some agency of a neurotic character impeding the normal devolution of the mamma."

In almost identical language the same opinion was entertained by the late lamented Prof. Agnew, of Philadelphia. On page 656 of the last edition of his work on "Surgery," Vol. III, he says: "The influence of emotional causes, as protracted grief, the nervous depression following loss of property, anxiety and worry as predisposing factors in carcinoma, has been forcibly impressed on my mind for several years, especially with reference to cancer of the mammary gland."

In this connection it should be borne in mind that females furnish a much larger excess of cases of this disease than males. The explanation is probably to be found in the fact of the places of election in the female subject, namely, the breasts and the uterus. The explanation is the vicissitudes entailed by maternity. It is a well attested fact that in breast carcinoma in women we often have an antecedent history of mastitis. The tendency to malignant changes in the cervix which has been the victim of laceration as the result of parturition, is also understood; and it is probable that corporeal disease of epithelial types, as well as other forms of malignant change, result from the same cause. The relative frequency of the disease in the sexes is estimated by some writers at about six cases in the female to one in the male. Taking the reports of the Registrar-General of England again in illustration, for three years, 1878 to 1880 inclusive, the deaths from cancer among females amounted in the aggregate to 25,890; while among males there were 12,851. It is thought by some writers that the greater the fecundity of the female the greater is the liability to cancer.

It is a well understood fact, as before quoted from Mr. Snow, that diminution or loss of function in certain organs in consequence of advancing age, seems to have a definite causative relation in the production of cancer. With reference to the various traumatic causes of carcinoma outside of those connected

with procreation in the female, we have the various causes of irritation, ragged teeth, vicious habits which exercise a deteriorating influence on the epithelial lining of the buccal surface, syphilis, tuberculosis and various other conditions. So commonly is phimosis associated with cancer of the penis, that it has been considered as one of the prime factors in its causation. Its *modus operandi* is supposed to be the retention of secretion, its decomposition and the balanitis following it as the result of a chemical irritation. In the rectum we often have cancerous degeneration following hemorrhoids, fistula, syphilis and other conditions which produce prolonged irritation in this part of the alimentary tract.

The pain of carcinoma is never sufficiently characteristic to be relied upon as a positive symptom, because of the fact that the situation of the disease often gives in its expressions of pain the nature of the tissue involved, as, for example, the subperiosteal sarcomas of the long bones; the pain is rheumatic in character, at times acute and often involves the whole limb, and, as we know, is often mistaken for rheumatism. The lancinating pains of hard carcinoma of the breast are often associated with that condition, but are not its invariable accompaniment, and may be produced by simple chronic abscess of the breast, simple adenoma, etc.

Again, the gross appearances of tumors when very deeply placed in the body structures are not to be relied upon. The weight of growths involving the breast or the testis often conveys a very correct idea of its nature. Where these neoplasms are so situated as to be beyond the application of this test, it is of no value. The consistency of a growth often bears very significant testimony as to its character. In the thin flabby breast it is often possible to make a very positive diagnosis as to the character of the new growth by palpation. In the fat full organ, however, we may be easily misled. The old text-book symptom of retraction of the nipple in connection with cicatrizing carcinoma, is always a significant indication when present, but unfortunately it is not present in those cases of malignant disease seated deeply in the gland, and oftentimes not apparent where the growth is superficial and near its nipple. Fixation of the skin over the tumor, with discoloration and puckering, should always excite suspicion.

The mobility is another very important consideration, and when taken in connection with the other clinical conditions, may throw a good deal of light on the character of the tumor with which we have to deal. The well known disposition of all carcinomas, with the exception of the sarcomatous varieties, secondarily involving the lymphatics in the known channels of absorption, usually stamps the primary disease as malignant. As a rule, we know sarcoma does not manifest this tendency. In estimating the value of this lymphatic involvement, we should always bear in mind that such a condition may arise from simple inflammatory conditions, or be associated with syphilis or tuberculosis; we should remember, as well, that all these conditions may be associated with malignancy.

To briefly recapitulate before taking up the consideration of special regions of the body, we can not do better than follow the suggestions of Mr. Snow. We believe in the local origin of the disease; we believe in traumatism of some character as a cause; we believe to a limited extent in the influence of heredity;

we believe that age in either sex is one of the most important factors for our consideration in determining as to the specific characteristics of the growth, as to its innocence or malignancy. From what has already been said, it is evident that age wields a wider influence in a diagnostic way than any other of the cited conditions which lead to malignancy. The enlarged gland in the neck or groin of a boy at 15, or an enlargement of the breast or thyroid gland in a girl of the same age, excites no special apprehension, because of the age of the individual; but carry these subjects thirty years farther along in their life journey, and these abnormal enlargements at once excite our suspicion.

The epitheliomatous variety of carcinoma, as we know, has a predilection for the mucous surfaces and outlets of the body. It is prone to implant itself upon many of the non-malignant diseases of the skin, such as warts, moles, simple ulcers, eczema of the nipple, as in Paget's disease, old cicatrices, etc. If we are to believe the teachings of Mr. Jonathan Hutchinson in an article on the origin of tumors, namely, that in every new growth there is a pre-cancerous stage, the onus of responsibility of those who assume to diagnose and dictate the treatment to be followed in these cases is indeed, one of great responsibility. Epithelial cancer is rarely seen under 40 years of age, oftener after 50. "In males the most common seats of the disease are the lower lip, some portions of the face, and the glans penis; in females, the uterus, the vulva, the anus and the face."—(Agnew). Again quoting from the same author, "it begins in various ways, sometimes as an indurated nodule, crack or fissure, and at other times in a papillary or wart-like prominence in the skin or mucous membrane. When the disease commences in the form of a hard mass or nodule, it is usually charged with great malignancy, passing soon into ulceration and invading the surrounding parts with great rapidity."

It is a well-known characteristic of epithelioma that when seated on the surface of the skin, its tendency is to extend superficially and not deeply, and it may exist for a long time without involving the subject in the systemic wreck which so rapidly follows its advancement upon the mucous surfaces. The explanation of this difference in the behavior of this growth in the two situations, as given by pathologists, is the resistance offered by the dense character of the tegumentary structures underlying the neoplasms. We have no doubt that this form of malignant disease may have been in existence for a long time, often a number of years, without any systemic involvement, and we also all know that so soon as the nearest lymphatic channels manifest by their enlargement that the disease has commenced its migration, that in the majority of instances the surgeon's knife shortens rather than lengthens life.

There is, perhaps no part of the body where early diagnosis would seem as easily obtainable as in the tongue, when attacked by malignant disease. And yet we often see epithelioma of the tongue which has been overlooked or disregarded until it has attained dimensions which preclude the possibility of relief at the hands of the surgeon. Within ten days a man, 74 years of age, applied to me, with an epitheliomatous tongue, which involved nearly two-thirds of its lateral surface; he told me he first noticed it six weeks before. It is probable that it had been in existence for several months.

Mr. Butlin in his recent work on "Operative Surgery of Malignant Disease" reiterates practically the teachings of Mr. Jonathan Hutchinson, in speaking of the pre-cancerous stage of diseases of the tongue, in the following very forcible language: "It is very important to bear in mind, not only for the purpose of more certain diagnosis, but in the prophylactic treatment, that carcinoma of the tongue is, in a large number of instances, preceded by some chronic affection of the surface of the tongue. Chronic superficial glossitis or one of the several conditions which are due to it, such as ichthyosis, psoriasis, leucoma."

The physical characteristics and the clinical behavior of epithelioma elsewhere in the cavity of the mouth, in the pharynx, or on the tonsils, or at the inferior outlet of the alimentary canal, or on the male or female genitalia, are practically the same and need no further consideration, except in connection with the uterus. Any woman who has attained to the age of cancerous susceptibility, who suffers from a menorrhagia or metrorrhagia, should undergo an immediate and thorough physical examination, and if she shall have passed the climacteric and should again bleed from the mucous surfaces of the pelvis, we are led at once to believe that malignancy is its cause.

The female breast furnishes more examples of malignant growths than any other organ of the body. The malignant tumors which are found in this situation are the different varieties of sarcoma and the hard and soft carcinoma, carcinoma being the more common. Sarcoma of the breast is usually a disease of early or mature life; it occurs somewhere between the ages of 20 and 35; more common among married than among unmarried women. The tumor is usually single, occurs in the breast at a time which we have been pleased to style, according to historical limitations, the pre-cancerous period of woman's life, grows with considerable rapidity, is moderately hard, is often lobulated in harmony with the conformation of the gland, shows little tendency to adhere to the skin or to ulcerate and break down, not often associated with much pain, and showing little disposition to involve the tributary lymphatics. This, briefly, is the description of sarcoma as ordinarily encountered.

The hard carcinoma, or scirrhus carcinoma, so-called, appears usually after the fortieth year of life. Prof. Gross, the younger, in his analysis of 642 cases found the average age to be 48, and stated that the disease was not at all uncommon after 60 or 65. It is more common among married women, and women who have borne children furnish relatively the larger number of cases of this form of cancer. It does not show the disposition to encapsulation that is found in sarcoma, but tends to disseminate itself through all the structures of the gland. In many of the circumscribed forms the tumor conveys the impression to the finger of being very hard; it is often irregular and knobby, and is usually tender to the touch, and often associated with sharp, lancinating, and at times agonizing pains radiating from the breast all over the affected side. As the disease advances the skin becomes adherent, puckered on the surface, soon becomes discolored and after a time undergoes ulceration; the nipple becomes retracted, sometimes early, sometimes at a late period, sometimes not at all.

In the soft or encephaloid variety of carcinoma we

have a growth whose life history is much more rapid; it runs a very swift course; it shows a disposition to skin adhesion, ulceration, early fungosities appear, systemic infection takes place, and in many cases a few months are sufficient to destroy the life of its unfortunate possessor. The behavior of soft carcinoma of the breast is very like that of sarcoma, but they differ materially in their anatomic relations with the structures in which they are placed; soft carcinoma infiltrates the gland, and sarcoma, as a rule, is encapsulated, and in palpating the breast so diseased it is often possible to distinguish between the two conditions.

The sarcoma and soft carcinoma when situated in other portions of the body than the breast, differs little in its clinical behavior, with the exception, perhaps, of the subperiosteal forms of sarcoma as found in the long bones. I have in mind a woman age 28, who had a subperiosteal sarcoma of the lower end of the femur, whose lower extremity I removed at the hip joint shortly after diagnosis became certain; there was at the time no appearance of any lymphatic involvement in any of the tributary channels. She made a rapid convalescence from the amputation. Two months later I removed all of the muscular covering of the os innominatum on the amputated side, which was the seat of extensive infiltration, and about three months later she died of hemiplegia, presumably from metastasis to the brain.

In another case of periosteal sarcoma of the ulna, an amputation at the elbow joint was followed in about five months by a paraplegia, which was brought about by a new focus of the disease in the brachial enlargement of the cord, and which rapidly became so extensive that it destroyed the laminae of the lower cervical and upper dorsal vertebrae, and a tumor the size of the fist developed upon the dorsal aspect of the spine in that situation.

In a third case of sarcoma of the lower third of the femur in a child 14 years of age, amputation at the hip joint was made in May; she died in September of metastatic deposits in the left upper jaw in the diploic structure of the calvarium and probably within the skull. These three sad cases demonstrate the atrocious virulence of this form of malignant disease.

It seems a cruel distortion of the munificent plan of the Almighty, when this disease finds its victims from among those of the human family least able by age or vitality to withstand it. Such, nevertheless, is frequently seen.

I have recently been very much interested in the recital of the clinical history of two cases of rapidly growing sarcoma of the kidney in very young children, reported by Dr. Robert Abbe, of New York. In his first case the tumor had attained to the weight of two and one-fourth pounds when the child had attained its second year of life. In the second case, it had reached seven and one-half pounds and the child was but one year and two months of age. A year ago this past winter, I removed a similar tumor from a child of 5, and the tumor weighed nearly nine pounds. My result, I am unhappy to say, was not as successful as Dr. Abbe's.

Malignant disease of the adult kidney is often impossible to determine, because of the deep situation of the organ and the uncertainty of its clinical manifestation. The microscopic clinician for years has been assiduously in pursuit of that *ignis fatuus*, the

cancer cell, in the human urine, with the view of demonstrating the contamination of that fluid by the presence of a neoplasm along the track through which it travels in its exit from the body. The perfected modern cystoscope has done much to aid us in arriving at definite conclusions as to the part of the genito-urinary tract involved, by eliminating the bladder and urethra from being responsible for the physical characteristics of the abnormal secretion. I believe the majority of all thinking students of surgical pathology are as enthusiastically imbued with the idea that *the* specific microbe will soon be revealed to us, as was the historical Micawber that something would turn up to *his* advantage.

Prof. Stockton, of the University of Buffalo, in a clinical lecture delivered in 1892, laid great stress on the diminution of urea in cases of abdominal carcinoma. He says: "I have seen it in cancerous disease of the kidneys, pancreas, liver, mesenteric glands, omentum, colon and other organs. The diminution of urea also holds good to a certain extent in reference to cancerous disease of other parts of the body, but it is especially important as a sign in cancer of the abdominal organs." Gastric and intestinal carcinoma are not to be positively diagnosed without a palpable tumor, and oftentimes only by ocular demonstration after opening the abdominal cavity. Until the later stages the clinical history is entirely subjective. The absence of free hydrochloric acid in the gastric juice is considered strong presumptive evidence of cancer in this organ.

THE NECESSITY OF EARLY SURGICAL INTERFERENCE IN MALIGNANT GROWTHS.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held in San Francisco, June 5-8, 1894.

BY R. A. McLEAN, M.D.
SAN FRANCISCO, CAL.

The fact of malignancy having been established in a suspicious growth, the question of its complete removal demands the immediate attention of the surgeon. Regarded from a purely practical standpoint, there can be no doubt of the superiority of extirpation by the knife over all other procedures, yet all candid surgeons will admit that many instances of recurrence have been met with after operations, which seemed at the time to be extensive enough to include all the diseased tissues. This tendency to recurrence after removal of malignant growths by operation, has influenced the laity, and not a small part of the profession, to delay radical treatment until the case has become hopeless.

It is the purpose of this paper briefly to point out the causes of failure of operative treatment, and to indicate, in a general way, the means by which a large proportion of cases of malignant disease may be permanently cured.

First in importance as a cause of failure of operative treatment in the majority of cases, is the large development of the growth when the surgeon is first consulted. In the carcinomata the surrounding tissues and neighboring lymphatics have already become deeply infiltrated; in the sarcomata, metastasis to distant parts has already taken place.

In not a few cases, ulceration has occurred; and to the exhausting effects of the discharges is added the presence of septicemia. Only disaster can result

from interference in such cases; and should the patient survive an attempt at extirpation he will certainly succumb later to recurrence. The mistake is frequently made by the medical man first consulted at the comparatively early stage of the disease, in not insisting upon radical treatment. It is usually the family physician who is first called upon to examine and prescribe for the suspicious growth. Upon him rests the grave responsibility in all such cases of deciding the question of probable malignancy. The temporizing policy usually pursued allows the disease to develop until operative treatment is inadmissible. The physician who is first consulted in a case of tumor or ulcer should promptly apply the usual tests to settle the question of malignancy. A broad consideration of the clinical features of the case will usually suffice to exclude the various non-malignant tumors and ulcers. In the majority of suspected cases the only element of doubt that need enter into consideration is the difficulty, in certain cases, of differentiating between malignancy, tuberculosis and syphilis. To reduce the question of doubt to still more narrow limits, it is only important to differentiate between malignancy and syphilis. A four weeks' course of mercury with arsenic and iodid of potassium will be a sufficient test. The question of tuberculosis is not important as governing the treatment, for extirpation is the most satisfactory method of dealing with all such tubercular manifestations as could cause suspicion of malignancy. A careful study of a suspected case for one month should be ample time to eliminate all doubt as to the proper course of treatment. The patient should be urged to undergo a radical operation without delay. If this course were followed, instead of the policy of delay, the surgeon could show statistics in which failure would be as uncommon as success has been heretofore. It is probable that cancer is increasing in frequency. It is to the family physician that the patient first goes for advice, and he should be alive to the importance of early recognition of malignancy in suspicious ulcerations and tumors. One cause of delay and loss of valuable time is the attempt to label the suspected growth with its pathologic title. Malignancy being probable, it should make no difference in treatment whether the case be one of scirrhus, or epithelial cancer, or one of the various forms of sarcoma. The surgeon has before him merely the question of extirpation of a growth which, if left to itself, will certainly destroy life.

In the early stage of malignant growths a relatively small portion only of the region or organ affected need be removed. The general health has not yet been affected and the patient rapidly recovers from a comparatively slight operation.

It should, therefore, be the first duty of the surgeon to insist upon early operation. Unfortunately, however, it is not until the growth has attained considerable proportions that the patient presents himself for operative treatment, and the surgeon is confronted with the task of removing the disease without sacrificing the life of the patient. It is probably the experience of most surgeons that cases of malignant disease do not apply for operation until the growth has involved a large part of the part or organ first attacked, and usually the neighboring lymphatics are extensively affected. In such cases it is unwise to attempt extirpation.

The following remarks are to be regarded as applying only to external malignant growths.

An early operation may be defined as one undertaken before any considerable extent of the part or organ originally attacked has been invaded. In carcinoma the lymphatics have not yet become affected, or only those in the immediate vicinity of the growth. The general health has not suffered. In sarcomata, no symptoms indicating metastasis have yet appeared.

It is in such cases that the surgeon may operate with a certainty of eradicating the disease. We now come to the most difficult part of the problem. How shall we decide in each case how far to carry the knife beyond the evidently diseased district? Instead of attempting to remove as little of the surrounding tissue as possible, it should be the rule to remove as much of the neighboring parts as can be done with safety, and with due regard for preservation of appearance and function. The direction and extent of the incisions will depend upon the course and proximity of the lymph vessels and glands, all of which should be removed with the overlying skin together with all of the connective tissue in which they are embedded.

The surgeon will never have cause to regret extensive abscission, not only of the tissues evidently diseased, but also of such parts as lie in the path of extension.

The experienced touch, carefully and deliberately practiced about the vicinity of the growth, with due consideration of the direction of the lymph vessels leading from it to the nearest lymphatic glands, will enable the surgeon to plan his incisions so that they will fall altogether beyond the probable limits of the infiltration.

After the growth has been removed and the vessels secured, the surface of the wound and its vicinity should be systematically palpated in order to detect any outlying indurated tissue or diseased lymph gland. This must be done with the utmost thoroughness, and the touch can be materially assisted by the use of a powerful hand lens. Infiltrated lymph vessels will by this expedient be detected which would not be evident to the touch.

In dealing with malignancy occurring in the vicinity of the bones of the skull, as much of the entire thickness of the bone should be removed as has been affected by the erosion. This should also be done if the overlying periosteum be infiltrated.

In carcinoma of the tongue or lower lip, the inferior maxilla should be removed in part with the growth, if the extension of the disease has caused erosion of the bone itself, or infiltration of the periosteum.

In dealing with sarcoma of the extremities, amputation should be the invariable rule. In these cases the conservative surgeon will advise operation only in recent examples, and before the occurrence of metastasis has placed the patient beyond the probability of cure. The amputation should be done through the continuity of the bone upon the proximal side of the articulation next above the growth. By this method alone can there be certainty of including all diseased tissue.

As an example of the advantages of a thorough removal of all neighboring tissue in carcinoma, I venture to present the following case:

Joel Simpson, 33 years of age, entered the City and

County Hospital in January, 1883, with an extensive ulcerating epithelioma of the entire lower lip and the greater part of the right half of the upper lip and right cheek. The surrounding tissues were greatly thickened and infiltrated, and the lymph glands and both sides of the neck were enlarged. His general health was good. He stated that a small lump appeared first upon the right side of the lower lip about eight months before, caused, he thought, by smoking a clay pipe. The outer surface of the body of the inferior maxilla was eroded and the incisor teeth were loose. It was decided to extirpate the diseased mass including the body of the lower jaw.

Both external carotids and superior thyroids were first ligated. The growth was then circumscribed by an incision, beginning on the left side near the angle of the mouth, through the lower lip down the left side of the neck in an oblique direction to the larynx, where it was joined by a second incision beginning near the median line of the upper lip on the right side, and carried in a curved direction upward and outward through the right cheek and then downward and inward along the neck to the larynx.

The body of the lower jaw was then sawn through on each side near the angle, and the entire mass, including the submaxillary glands and enlarged lymph glands, were dissected from the inferior surface of the tongue, the pharynx and larynx. A few outlying enlarged glands were then removed. The surface of the wound seemed to be perfectly free from disease, but it was thought best to defer any attempt to close it by a plastic operation. In order to lessen the suppurating surface remaining, the edges of the mucous membrane and skin were brought together by sutures where the incisions passed through the lips and cheeks. The remaining wound was dressed with borated vaselin spread on lint, over which was applied an ample absorbent dressing.

The patient lost but little blood during the operation. In six weeks the wound had almost completely cicatrized. A plastic operation was then done to remedy the deformity, and difficulty in swallowing and speaking, caused by the protrusion of the tongue and absence of the lower lip and right side of the cheek. After dissecting off the cicatricial tissue from the edges of the cheeks and surface of the original wound, the tongue was freed from its adhesions anteriorly. A flap of skin and connective tissue was then lifted from the right side of the base of the neck and shoulder, turned upon its pedicle and approximated to the raw surface below the line of the mouth. The upper margin of the flap served the purpose of the lower lip, and its extremity was attached by sutures to the edge of the original incision in the left side of the neck.

In about four weeks the flap had united, when its pedicle was severed and adjusted to the freshened edges of the incision in the right side of the cheek and neck.

In conclusion, the following propositions may be offered:

1. All cases of suspected malignant growths should be treated surgically in the early stages of their development according to the rules of procedure above outlined.

2. Excision should be done in all cases of malignant growths, however extensive, in which the general health has not been seriously impaired, or extensive lymphatic involvement or metastasis have not occurred.

3. Operation should be refused in cases of recurrent or primary malignancy, in which the general health is so much impaired as to render an extensive operation a serious risk to life; in all cases of extensive ulceration and infiltration of lymph vessels and glands; and in all cases of sarcoma in which there is a probability of metastasis having already occurred.

THE VALUE OF CAUSTICS IN THE TREATMENT OF MALIGNANT DISEASES.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association held at San Francisco, June 5-8, 1894.

BY JOHN PARMENTER, M.D.

BUFFALO N. Y.

The advocates of caustics in the treatment of malignant growths have made many claims regarding the method of action and the results to be attained from the employment of the same. Prominent among the advantages claimed for caustics is the one that after their use, recurrence of the malignant growth is less frequent. An assertion like the above is easy to make, but difficult to prove. It is equally difficult to disprove, and correct conclusions can only be made by careful and logical interpretation of the statistics of a large and well observed number of cases. Apropos of this, space permits only the remark that the general consensus of opinion among surgeons to-day is to the effect that caustics give no more exemption from recurrence than does the knife.

Another claim is to the effect that the value of caustics is due to a selective action, whereby only malignant tissue is destroyed by the agent employed. This erroneous idea naturally arose from the fact that caustics destroy malignant sooner than healthy tissue, the latter having more resistance than the former, and hence the appearance of selective action. Such a caustic would be ideal, and when it is found, perhaps the question of the treatment of malignant disease will be forever solved. That we have no such drug or combination of drugs, experience constantly reminds us, and therefore this claim must be declared unfounded.

Still another virtue attributed to caustics is their power to reduce enlarged lymphatics adjacent to the seat of disease. That this result is attained sooner and more completely than after extirpation with the knife, of the disease causing them, is certainly not the case. It, however, often happens that the removal of a slough, due to the application of some caustic, is followed by a decrease in the size, tenderness and other signs of inflammation of the adjacent lymph glands. This, however, occurs very commonly where no caustic has been employed and is probably due to the fact that better drainage results from the removal of the slough, and hence the secretions no longer pent up, cease to infect the glands so actively.

The value of caustics, then, is not to be found along the lines advanced by their advocates, but must be sought for in other directions. The less we know about the method of action of an agent, the more carefully must we observe the various phases of the action itself if we would learn to use properly and safely such agent, and experience has taught us that the value of caustics lies in a combination of two conditions, viz, the use of a proper caustic, and its intelligent application in suitable cases. What is a proper caustic, and which are suitable cases? A proper caustic is one which effects complete destruction and removal of the diseased tissue. Many substances classed as escharotics—such as silver nitrate, carbolic acid, zinc sulphate, and the like—are not sufficiently caustic and should not be used. They only serve to irritate the diseased tissue, stimulate the lymphatics and disseminate the infection, thus making a bad matter worse. So when caustics are used, they should be those whose action is both

rapid and thorough. Among these are the actual cautery, sulphuric acid, Vienna paste, Bougard's paste and zinc chlorid.

The actual cautery is a clean speedy agent for the destruction of malignant tissue, but it has seemed to me, in the few cases in which it was used, that there was quicker recurrence than was the case after using, say, Bougard's or Vienna paste.

Sulphuric acid is an active escharotic, but exceedingly painful and but little used now for this reason.

The alkaline caustics are among our most efficient agents and in some form or another are very commonly employed. The same is true of zinc chlorid in its various combinations. This agent is the principal ingredient of Bougard's formula, which according to Lewis (*Medical Record*, Feb. 13, 1892), "is by all odds the best (escharotic) we have at present." Its composition is as follows:

Wheat flour	60 grams.
Starch	60 "
Arsenic	1 "
Cinnabar	5 "
Sal ammonia	5 "
Corrosive sublimate	0.50 centigrams.
Sol. of chlorid of zinc at 52	245 grams.

In its preparation, Lewis suggests that each of the first six substances be separately reduced to a fine powder, then mixed in a mortar (glass or china) and upon the whole is poured the solution of zinc chlorid. The mixture is rapidly stirred to prevent the formation of lumps. A paste results, of which a thick layer is spread upon cotton and left in contact with the diseased tissue for twenty-four hours (caustic potash having been first applied to remove the outer layers of the diseased tissue and thus bring the caustic into quicker and closer contact with the remaining parts). After this time, warm poultices are applied to bring away the slough. This requires from three to nine days, according to the case. When the slough has separated, the wound may be dressed with some stimulating antiseptic ointment.

The space at my command does not permit me to describe the various other caustics and their method of application, so I have given a few details regarding Bougard's paste as fairly typical of the whole class of escharotics.

Whatever escharotic is used, common sense must be exercised in applying it. It must be proportionate in power to the necessities of the case; it must not be applied over too great an extent of surface at one time, one to two square inches being usually enough for a single application; it must be applied to all justly suspicious tissue, and the pain caused by it mitigated in all cases so far as possible. Especially is this latter important in persons enfeebled by age or disease, to whom loss of sleep and appetite are a serious matter. In short, the value of caustics depends in no small measure upon the intelligent way in which they are used and here, as elsewhere, the abuse of these agents leads to negative or disastrous consequences.

And now regarding the question, Which are suitable cases? In speaking of the proper kind of caustic the remark was made that it should possess the property of effecting complete destruction and removal of diseased tissue. It is equally important for us to select such cases as, from their anatomic situation, freedom from general infection, or infection of adjacent lymph glands, make it possible for an efficient caustic to exert its full influence. Without taking

the time and space to specify the cases which would naturally be excluded by such selection, we may say in general that malignant disease affecting bone, tissues intimately adherent to important structures (large vessels, etc.,) internal organs, or glands like the thyroid, are not suitable for treatment by caustics, viewed either from the standpoint of theory or of experience.

What of malignant disease of the breast, cervix and corpus uteri, tongue, tonsil, eyelids, rectum, or of the genital organs, and other similar and common sites of cancer? Experience again teaches us the futility and even positive danger of employing escharotics in the great majority of such cases. Now and then a caustic has cured a cancer of the breast or of some other part of the body, where the course of the disease is usually rapidly fatal; but this is most exceptional. Vastly more often their use results in increased suffering for the patient and an aggravation of the disease. This narrows the field down to cancer of the skin, the lip and the external ear. In other words, cancer usually limited in extent and easily accessible (two very advantageous conditions for the application of caustic). Lewis puts these cases in a distinct class, claiming that if taken early 95 per cent. should be cured, and in this statement the majority of surgeons will probably concur. When the time comes that surgeons shall have learned to properly select their cases, the statistics of caustic treatment will unquestionably show a decided and encouraging improvement. To-day it is to be feared that many surgeons have obtained indifferent results, due to obvious causes, such as late diagnosis, inefficient cauterization, poor technique and the like. This should change with time. Improvement in every way should follow. New agents more potent and of wider applicability may be found and used. Finally, even the long-awaited specific, in caustic form, may come to rid mankind of this terrible scourge.

The foregoing remarks seem to justify the following conclusions:

1. The value of caustics in the treatment of malignant disease depends upon the use of proper caustics and their intelligent application in suitable cases.
2. A proper caustic is one which completely destroys and removes the malignant tissue.
3. Mild caustics are inefficient and dangerous, and therefore to be avoided.
4. Bougard's paste is the most generally useful escharotic.
5. Proper technique in application accentuates the value of caustics.
6. The suitable cases are those which have a limited extent and are easily accessible, or in other words, cancer of the skin, lip and external ear, in their incipient stages.
7. The prognosis should be most excellent, cure resulting in the vast majority of cases when treatment is early and thorough.

Washington State Board of Examiners.—Dr. E. Van Zandt, of New Whatcom; Dr. Wm. W. Misner, of Tacoma; and Dr. John E. Bingham, of Walla Walla, have recently been appointed on the Washington State Board of Medical Examiners.

ON THE USE OF CAUSTICS IN MALIGNANT DISEASE.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY L. DUNCAN BULKLEY, A.M., M.D.
NEW YORK.

As is well known, the treatment of malignant disease by caustics has been practiced very largely by those who are known as "empirics and quacks," much to the discredit of the medical profession and often to the injury of patients. But that there is somewhat of a foundation for their use in the success which may often attend them is certain, and it behooves the profession to correctly understand and profit by the experience which has been gained in this direction.

That there is a foundation in science for this method of treatment, there can be no doubt to any one who has studied the subject and who has had experience in the same. On the other hand, that harm may be done by their injudicious use is also equally evident. It will be our object to consider very briefly the indications for the use of caustics in malignant disease, the method of their employment, and the cautions to be observed in regard to the same.

To appreciate rightly their value, some consideration must be had in regard to the nature of the disease which it is sought to remove. This has been very largely considered by those who have preceded me in this discussion, and I will not enter into the pathology or etiology of malignant disease, but will only briefly state a few propositions.

The success of the treatment must entirely depend upon the localization of the disease. If the malignant elements are so situated that they can be absolutely and thoroughly destroyed, even to the very deepest ramifications, there is no reason why the caustic which reaches to every part of the disease and destroys its life may not succeed in eradicating the same; consequently, it is in the earlier stages of malignant disease that caustics find their value; and to be of successful employment they must be so used that the destruction shall be absolute and complete. It is needless to say that when the adjoining glands have become at all affected, and when metastasis has occurred to other organs, it is worse than useless to attempt the destruction of the local trouble alone by caustics or other means. Caustics are therefore largely applicable during the formative period, and when one can fairly judge of the exact extent of the morbid process. A very large share of the reputation or celebrity which has come to certain cancer quacks is derived from results obtained under such conditions; for it is very common for patients, when the diagnosis of epithelioma or local cancer has been made, to go at once to them, from fear of the knife, and a thorough application of the caustic made by them will often prove completely successful; and undoubtedly also, as I have personally known to be the case, many other conditions are brought to them which are not cancer, which are easily removed and thus add to their reputation.

I will speak first in regard to the treatment of early epithelioma, especially on exposed regions and particularly on the face. As is well known, these often begin as very trivial affairs, from a mole or wart, or sebaceous concretion, which has been pricked or irritated until a scab forms, and then, the slight

ulceration, having failed to heal, takes on epitheliomatous degeneration.

In the early stages of the disease, what is known as Marsden's paste will often prove a most valuable application, and one which can be successfully applied, if the rules in regard to its use are carefully carried out. This paste is composed of arsenious acid and powdered gum acacia. I generally keep the two ingredients separate and mix them at the time of application. A small portion of each is taken, in about equal parts by weight, or fully twice as much of the powdered gum by measure, and thoroughly mixed in a saucer; a drop or two of water is then added, and they are rubbed together until a thick tenacious paste is made. This is then carefully laid over the affected area to the depth, perhaps, of an eighth of an inch in thickness, after having carefully removed any adherent crusts. Before the paste dries, a little absorbent cotton is gently pressed upon it, the edges being tucked in so that the application covers the area occupied by the diseased surface. The layer of cotton should be very thin, perhaps also an eighth of an inch in thickness when gently pressed down. Ordinarily, I do not care to make such an application over a space exceeding one inch in diameter either way. But others have used it safely over several square inches at a time.

After a few minutes the paste will harden, and no dressing is required over the cotton until later; at first there is not much pain but within a few hours there is a drawing sensation, and the parts begin to feel uncomfortable; some hours later a severe burning pain sets in which may prevent sleep, the first night. About twelve hours after the application of the paste, a flaxseed poultice is applied, quite warm, the flaxseed being enclosed in a small bag with its mouth open, so that the poultice comes directly over the cotton, without any intervening substance between. It is well to cover the poultice with oiled silk, in order to keep in the heat and moisture. It may be changed every two or three hours.

When the poultices are changed, care should be exercised not to disturb the original cotton, the idea being that by means of the moisture of the poultices the cotton absorbs the arsenic beneath it, and there is a prolonged, gently acting influence of the drug over the part for some days.

In a short period, within a day or two after the application of the poultices, the affected part has become quite swollen, and a distinct border of demarkation can be seen in the form of a slight yellow line which soon breaks down, forming a furrow around the diseased tissue. The time occupied for the complete formation and separation of the slough varies greatly in different cases according to the extent or depth of the epithelioma. In superficial growths it may separate in a week, but where the disease is of some depth the slough will sometimes adhere for two or three weeks. It is well not to interfere too much with the process of destruction, but to let the supuration completely detach the dead portion from the surrounding tissue; but when it adheres too long any shreds may be clipped off with the scissors. It is understood that the poultices are to be continued for some days, or for a week or two. The wound heals comparatively rapidly after the separation of the slough; I do not have it washed or cleansed in any way.

If enough of the arsenic paste has been laid upon

it, and the cotton allowed to adhere, a single application will generally be sufficient to eradicate most of the smaller epitheliomata; but if there should be signs of a portion of the disease left at any point, a second or even a third application of the paste may be necessary. Sometimes after the slough has separated, the wound will heal very kindly and quickly under the use of a mild zinc ointment; but I think the best results have been obtained when the poultices are continued until complete cicatrization had taken place.

If the arsenic paste has been applied strong enough there is really no danger of poisoning from the drug, for it so thoroughly destroys everything before it that absorption can not take place; the only danger lies in using it with too light a hand. There may be considerable pain during the first twenty-four hours after the application of the poultice and thus necessitate the use of opiates; but again the pain is often very slight. The cicatrix resulting from the healing with this treatment is often very small and supple. In many cases in which I have employed it, a single application has proved entirely successful, and there has been no return of the disease.

Thus far I have spoken only of the treatment of rather small and early phases of epithelioma; but this method of destruction may also be employed over larger areas than have been mentioned, which may be taken piecemeal if necessary.

Larger and deeper malignant growths have also been successfully removed by many, but the difficulties attending this method of treatment are often quite great. Cancer of the breast is constantly attacked both by empirics and by many in the regular profession, by the deeply acting caustics, but the pain attending this procedure is often very excessive.

Chlorid of zinc will eat its way through any amount of tissue and is relatively harmless in regard to any toxic effects. When once used this should be pressed on fearlessly, by one application after another, until the base of the tumor is reached and all is destroyed.

A valuable paste of chlorid of zinc is now used a good deal, under the name of Bougard's paste, composed as follows:

R	Farinæ tritici (wheat flour)	
	Amyli	aa ʒi
	Acid. arsenios. pulv.	grs. viij
	Hydrarg. sulph. rub	ʒii
	Ammon, mur	ʒii
	Hydrarg. bichlor. corros.	grs. iv
	Zinci chlorid. cryst	ʒi
	Aque fervid	ʒiiss
	℞	

This is spread directly upon the surface, or thickly on a bit of linen, and laid on, and left on for twenty-four hours or more. The application causes considerable pain. After removal of the paste the parts are treated by a simple ointment or water dressing, the slough separates, and if there is still some hard tissue the application should be repeated.

Caustic potash is also another destructive agent of great value in many cases, but is more apt to be followed by unpleasant cicatrization. With these three caustics; arsenic, chlorid of zinc and caustic potash, I believe that all can be accomplished which is possible with such means in malignant growths.

A few words may be added in regard to what should not be done in the treatment of this class of affections:

It is useless and worse than useless to attempt their destruction or removal by any mild means, for any

caustic agent which fails of utter destruction and removal of diseased tissue will certainly contribute to its growth. A most earnest protest should be raised against the practice, far too common, of touching malignant growths with "nitrate of silver." This is a very superficially acting caustic, and is utterly incapable of producing any great destruction. It coagulates the albuminous substances in the tissue, and thus produces a bar against its further penetration. Multitudes of cases of epithelioma which in their beginning were very slight and relatively unimportant, have been goaded on, by repeated burnings with the "nitrate of silver stick," until they are even past all surgical relief. Nor should any of the caustics be employed except such as will thoroughly penetrate and destroy the mass.

Pyrogallic acid is often spoken of as a most valuable remedy in epithelioma, but its action is quite superficial and seldom will serve alone to eradicate the disease. It is, however, a very valuable adjunct after curetting, and seems to have some elective affinity for epithelial structures. In many instances I thoroughly scrape out small epitheliomata with a very small and fine curette, searching out even the smaller ramifications of the same, and then after the bleeding has been stopped by pressure, I fill the cavity with powdered pyrogallic acid, cover with cotton and allow the surface to heal, not disturbing the dressing. At the expiration of a week the dressing may be removed, and perfect cicatrization will be found. The resulting scar is often a little blackened by the pyrogallic acid, but the stain will pass off in a few weeks.

A few words may be added in conclusion in regard to the relative value of caustics and other measures in the treatment of malignant growths.

The aim in all treatment is to go entirely outside of every possible extension of the disease. It has been well shown that malignant growths extend along lymphatic channels, even to some distance beyond what appears to be the seat of the disease. Excision will undoubtedly eradicate, and that permanently, a large share of malignant growths. But far too often after excision they recur again in the site of the cicatrix. This has resulted simply from not removing all outlying processes of disease, and herein lies the danger from the knife.

If the operation is not radical enough to include every possible line or group of degenerated cells, the caustic will to a very large degree follow out these lines or channels, and by producing inflammation around, as Robinson¹ has shown, destroy their vitality. Another favorable feature in regard to the employment of caustics is that the destruction of tissue and skin cicatrization is much less than would be requisite in producing the same effect by the knife. It is really surprising what a relatively small scar may result from the destruction by complete cauterization of even a large mass of disease.

On the other hand, I by no means advocate the use of caustics to the exclusion of operative surgery, for in many instances the latter is preferable. In the instance of epithelioma of the lip, unless it is very superficial and small, I almost always advocate a surgical removal. About the eye-lids the knife will often give better results, and avoid danger to the contents of the orbit which might arise from misuse of the caustic. Within the cavity of the mouth,

caustics are almost impossible of application. I am not myself at all inclined to use caustics in cancer of the breast, unless the lesion is superficial and relatively small. Localized sarcomata may often be removed advantageously by a caustic, but in a large share of instances it can not compete with the knife. In cancer of the internal organs, caustic treatment is entirely out of the question.

It will be seen, therefore, from what has been said, that I by no means seek to elevate the use of caustics in malignant growths above their true value; but I assert that their proper use has been neglected too much by the regular profession, for in many cases they have proved an adequate and desirable means of removing the trouble. They may often be employed satisfactorily in cases which, while suitable for the knife, can not be thus treated owing to the objections of the patient.

THE RADICAL CURE OF MALIGNANT TUMORS BY OPERATION.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY J. H. WYTHE, M.D., LL.D.

PROFESSOR OF HISTOLOGY AND MICROSCOPY, COOPER MEDICAL COLLEGE, SAN FRANCISCO.

By the phrase, malignant tumor, both the profession and the laity distinguish any new growth which has a direct tendency to destroy life. Malignancy is shown by the rapid invasion of adjoining structures, the enlargement of neighboring lymph glands in which the same kind of tumor is soon produced, and by the formation of similar structures in distant organs from the transfer of morbid germs through the lymphatics and blood vessels. In one or all of these ways, a virulent morbid growth will be manifested, according to the time it has existed and the activity of its growth.

Innocent tumors may recur, as well as malignant ones, if they are insufficiently removed by the surgeon, but they are subject to operation, not on account of their destructive virulence, but for the relief of pain, inconvenience or disfigurement. Operations for the removal of malignant tumors may also be useful as palliative, when all expectation of cure has vanished.

Since Virchow, in 1863, established the classification of tumors according to their minute structure, their study has been greatly simplified, yet the terms benign and malignant, survivors of the old clinical method of study, are used as convenient expressions of the tendencies of new growths. The anatomic arrangement of tumors was the direct consequence of the announcement by Müller, in 1838, of the law which is the foundation of all our knowledge of new growths, viz: "That the tissue of which a tumor is composed has its type in the tissues of the animal body, either in the adult or embryonic condition." Since this law has been fully confirmed by microscopic observation, no one dreams of looking for a specific cancer cell.

The term, malignant, is now usually restricted to the sarcomata or carcinomata, the first originating in the embryonic connective tissue cell, and the other, according to the generally accepted views of Waldmeyer, beginning in the more fully formed epithelial cell. In each form, the cells have a tendency to run wild, and, instead of producing an

¹ International Journal of Surgery, July, 1892.

orderly normal structure, greatly multiply themselves and accumulate in masses. These masses project and infiltrate into neighboring parts, whose nutrition becomes impaired and whose mutual pressure leads to ulceration and degeneration. Then comes absorption and transfer of germ cells to distant parts, when all hope of cure must be abandoned.

The cure by removal of malignant tumors depends on the fact that first they are of local origin. If they can be removed at an early stage of growth, together with all the neighboring cells which have a morbid tendency, they may never recur. Perseverance in removal after successive recurrences in the same place has also been greatly rewarded. Paget refers to cases where the tendency to recur was exhausted after many successive operations. Such patients had unusual intelligence and courage, with perfect reliance upon their surgeon, and deserved success.

My own observation of cures effected by the removal of malignant tumors has been limited to cases occurring in private practice, yet is sufficient to establish a favorable judgment. In such operations, two general principles have been influential: 1, to operate early, or as soon as the new growth showed signs of activity or irritation; 2, to remove with the tumor, a large amount of neighboring tissue, especially if the tissue had similar minute structure to that in which the neoplasm began. Thus, in several cases of epithelioma of the lip, I have not trusted to the curette or cautery, but have excised the growth with considerable tissue on each side of it. In no case did the disease return. In one instance, where the cancerous growth had spread from the lip to the gums and alveolar process, the lower jaw was excised and a new lip made by a plastic operation. Four years afterwards, the man died of delirium tremens with no sign of recurrence of the malignant growth.

In malignant tumors of the breast, I invariably remove the entire gland, as well as any affected glands in the axilla. Of eight cases, but two have recurred. One of these was a scirrhus cancer, whose removal was succeeded after some months by carcinoma of the liver. The other was a large sarcomatous tumor followed a year after removal by osteosarcoma of the thigh. After amputation it recurred again in the stump, with fatal result.

In February, 1891, I reported in the *Pacific Medical Journal*, a new method of hysterectomy by enucleating the inner and middle layers of the uterine wall. This operation commended itself to me on histologic grounds as a safe, easy and effective way of thoroughly removing an epithelial growth of the uterine cervix. Neither the peritoneum, or the uterine or ovarian arteries are disturbed by this method, but the new growth, together with the entire follicular layer in which such growths begin, and the muscular layer adjoining, are entirely removed. This is a more thorough operation than the ablation of a cone of tissue around the morbid neoplasm, as advised by some writers. In the *Medical News* of Feb. 10, 1894, Prof. Reyburn, of Washington, D. C., describes an operation somewhat similar, but in his case the entire uterus was stripped from the peritoneal layer. I leave a portion of the outer muscular layer, which contracts so as to prevent hemorrhage. Prof. Reyburn's case was perfectly successful, but he suggests that in a younger woman the ovarian arteries might require ligation. This would be quite unnecessary

in my method, as sufficient uterine tissue is left to avoid opening the peritoneal cavity.

I have operated in this way upon three cases of epithelioma and one of sarcoma, confirmed by both clinical and microscopic examination, and with no recurrence. One of the patients has been under observation for six years, and as she had passed the menopause before the operation, the remnant of the uterus has atrophied to a mere nodule. In the other cases the menstrual function continues as aforesaid.

This method of hysterectomy (for so it may really be termed) may be available in other gynecologic conditions, but it is referred to here as affording a practical and easy way of effecting a radical cure in a large class of malignant new growths if undertaken early, but which, if left long to themselves, or treated only by palliatives, are among the most distressing of maladies.

THE VALUE OF INOCULATIONS WITH SEPTIC OR TOXIC AGENTS IN THE TREATMENT OF MALIGNANT NEOPLASMS.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY JOHN A. WYETH, M.D.

NEW YORK.

My first experience with the action of toxic or septic agents upon malignant neoplasms was in 1884. J. W. Phillips, an innkeeper of Gainesville, Texas, at that time (May 20, 1884) 33 years of age, was directed to me by Dr. Conson, his home physician. Four months before he had noticed a small lump in the wall of the abdomen on the right side, about four inches above Poupart's ligament, just where he had been struck some weeks previously by the end of a billiard cue. The tumor grew rapidly and enlarged in all directions, but was not painful. In the last few weeks he lost flesh considerably. History of specific urethritis ten years ago and sores on penis six years ago, but no symptoms of constitutional syphilitic infection followed. He had always been a vigorous and healthy subject.

When he came under my care the tumor in the wall of the abdomen was about four by six inches in measurement, and seemed deeply attached or glued to the muscles of the belly. Under anesthesia I found it impossible to make a thorough extirpation of the mass without sacrificing so much of the abdominal wall that the patient would have had an enormous ventral hernia and been incapacitated from any business.

I removed a large section from the tumor and packed the wound thus made.

The specimen was studied carefully under the microscope by Prof. Wm. H. Welch, now of Johns Hopkins University; by Dr. Wm. L. Wardwell, a pupil of Conheim, and an excellent pathologist, and by myself. Each of us agreed that the tumor was a sarcoma, confirming the diagnosis which had been made from the history and gross appearance of the neoplasm.

I had read in a German journal, about that time, of three cases of sarcoma reported as cured by injections into the substance of the tumor of arsenious acid, and advised my patient to permit me to try it on him, which was done. I injected a small quantity every day for about ten days into various parts of the growth. The injections were quite painful and established a very severe degree of inflammation and suppuration, to such an extent that the patient begged the discontinuance of the treatment and it was abandoned. By this time his condition was very bad. I had no hope of his recovery. He was carried to Virginia, his native State, where for several weeks the process of suppuration continued, gradually ceasing until finally the tumor disappeared.

It is now ten years since he was treated, and there has been no recurrence of the growth. He is in excellent physical condition and I think he may be considered as cured.

The caustic action of the arsenic could not account

for the destruction of the tumor, for not more than one-twentieth of the mass was reached by the injections. The suppuration which ensued filled the inflamed area with shoals of streptococci and other septic products, and these destroyed the elements of the sarcoma.

There was no erysipelas in this case up to the time he left me, and I do not think the cocci of Fehleisen had anything to do with the cure. It was a positive case of sarcoma cured by the action of septic or toxic agents, the ordinary products of inflammation.

Shortly after this there occurred another remarkable case in the wards of Mt. Sinai Hospital:

A young girl was admitted on account of a sarcoma of the leg, for which an amputation was performed on the middle of the thigh. Several months later the growth recurred in the stump and Dr. Gerster removed the remaining portion of the extremity at the hip joint. A second recurrence took place in the line of amputation at the hip, and presented as it developed an extensive cauliflower-like mass, dirty, foul, granulating, and from which bleeding occurred at intervals. This patient was abandoned to die, but was accidentally inoculated with erysipelas in the stump. Large sloughing masses were cast off, the wound finally healed, all traces of the sarcoma disappeared, and she is now, more than five years after the attack of erysipelas, living and healthy with no sign of the terrible malady from which she so narrowly escaped, excepting the loss of the extremity.

A third case of large lympho-sarcoma of the neck in a man about 60 years of age in my service at Mt. Sinai Hospital in 1891, was accidentally inoculated with erysipelas, but perished in three days from the onslaught of the disease. When attacked he was in low condition, and died before any noticeable changes had occurred in the new formation.

The following case has been under my care since August, 1893:

J. J. L., 37 years of age, lawyer, of Pennsylvania, with excellent family and personal history. Two and one-half years ago a filled molar tooth in the right upper jaw began to ache, and the gum to swell. The nerve was killed by his dentist and this stopped the pain, but the swelling persisted and the tooth was extracted. Later the antrum was opened, and in August, 1893, I opened freely into this cavity and curetted it with Volkmann's spoon.

The presence of sarcoma of the upper jaw of this side was suspected, and Professor T. Mitchell Prudden, of New York, confirmed this diagnosis by the microscope.

Hoping to spare the patient the mutilation which the surgical removal of his jaw would cause, on Jan. 31, 1893, I inoculated him with the toxic products of erysipelas cultures. Under the influence of these injections the temperature would rise from 1 to 4 degrees (and on one occasion to 104 degrees F. within three hours of the injection), and then gradually decline to the normal. The pulse never went beyond 90. By February 16 the ptomaines secured by filtration of Fehleisen's coccus ceased to produce any impression and the pure serum drawn by aspiration from an erysipelous bleb was inserted under the skin, but without producing erysipelas or a temperature above the normal. This was repeated on three occasions in one week with a similar result. A plug of cotton saturated with erysipelas serum introduced into the antrum also failed to give the patient erysipelas.

On February 21 pure cultures of Fehleisen's coccus of erysipelas caused a red blush in the skin on the leg, the point of injection, and this spread on the body into a well marked erysipelas lasting for several days. As no impression had been made upon the sarcomatous jaw, the treatment was discontinued, and two weeks later I removed the upper jaw, pterygoid process of the sphenoid, and the floor of the orbit. The patient recovered.

The limitations of this paper will not permit me to give minute details of cases. Suffice it to say that the literature of surgery, especially within the last five years, contains a number of cases which prove that septic inflammation, and particularly the sepsis of erysipelas, has a remarkable curative effect upon sarcoma.

In the application of these agents the observations already made show that pure erysipelas produces the

most desirable curative effect, but that sarcomata will disappear as a result of inoculation with non-erysipelous septic products.

As erysipelas is not without danger and since several cases of death are on record following the injection of the pure cultures of Fehleisen's coccus of erysipelas, even when these do not produce typical erysipelas, it is advisable at first to try thoroughly the injections of the sterile toxic products.

Dr. Wm. B. Coley, of New York, and Dr. Alexander Lambert, of the Laboratory of the College of Physicians and Surgeons, have obtained a perfectly sterile liquid by cultivating cocci of erysipelas in bouillon for three weeks, and then filtering. No heat is employed in this process. This fluid with the occasional addition of a certain quantity of the *bacillus prodigiosus*, I have employed in several recent cases.

Upon carcinoma the influence of erysipelas or of the toxic products is not so appreciable. That the growth of cancer is retarded and in some instances the neoplasm disappears under the influence of these agents, there is no doubt, but in my limited experience, and in the cases reported so far, these happy results are rare.

In 1893 an elderly gentleman consulted me in regard to a small epithelioma developed from a congenital mole or wart on the face, immediately over the right zygoma. A few days later he accidentally acquired erysipelas in the ulcer, which spread over an area of several inches, and was arrested by scaring the skin just outside the limit of redness. The epithelial ulcer disappeared entirely with the erysipelas, but returned eight weeks later.

Dr. Wm. B. Coley has collected a series of nineteen cases of carcinoma in which eight, or 42 per cent., were well from one to seven years after the attack of erysipelas. In twenty cases of carcinoma three were permanently cured. Professor Spronck, of Utrecht, reports experiments on twenty-five inoperable neoplasms, eight sarcomata and twelve carcinomata. He employed a product made by "heating liquid bouillon cultures to 100 degrees Centigrade after adding 5 per cent. glycerin, then evaporating to one-tenth the volume and finally filtering through porcelain."

The results following the injection of this liquid were not so satisfactory as those reported by Coley, who obtains the toxic product without heating, while in Spronck's cases retardation was noticed and marked diminution in one or two instances, in no case was there complete disappearance of the neoplasm. In six recent cases of sarcoma reported by Coley, one entirely disappeared and had not returned in four months; another tumor of the pelvis and abdominal wall was reduced in six months from a diameter of seven inches to a small mass not over two inches in diameter. In four cases no well marked improvement was noticed.

Conclusions: Sarcoma may be cured by septic infection. The sepsis of erysipelas exercises the most powerful curative influence. Infection from the streptococcus pyogenes aureus will, in my opinion, also cure sarcoma. The injection of the sterile products of Fehleisen's coccus will also cause these neoplasms to disappear.

These agents act through the blood. Thus erysipelas attacking a breaking down sarcoma of the back, caused this to disappear simultaneously with a simi-

lar growth in another portion of the body of the same patient not locally infected. It is probably better to inoculate in the mass and get the local action of the inflammatory process when this is possible.

The lower the order of the structure of the sarcoma the less likelihood of a successful result. Thus in tumors of a myxomatous character the prognosis is less favorable.

Epitheliomata may also be made to disappear or their growth retarded by septic infection.

Adenoid carcinomata are only slightly, if at all susceptible, to cure or retardation in growth by these agents.

AMERICAN MEDICAL ASSOCIATION.—SECTION ON SURGERY AND ANATOMY.

The Section was called to order June 5 at 2 P.M., by its chairman, DR. JOHN B. ROBERTS, of Philadelphia, Pa. In the absence of the Secretary, Dr. Floyd W. McRae, of Atlanta, Ga., Dr. Reginald H. Sayre, of New York, was appointed temporary Secretary.

The Chairman read his address, "Some Surgical Sins."

The next in order on the program was the reading of papers pertaining to the subject of malignant growths. In the absence of DR. E. LAPLACE, of Philadelphia, his paper on "The Pathology of Malignant Growths" was read by title and referred to the Committee on Publication.

DR. J. H. WYTHE, of Oakland, Cal., read a paper on "The Radical Cure of Malignant Tumors by Operation."

"A Critique of the Sporozoan Theory of Malignant Neoplasms from a Micro-technical Standpoint," by DR. A. P. OHLMACHER, of Cleveland, Ohio, was read by the Secretary in the absence of its author.

Papers on "The Clinical Recognition of Malignancy in Tumors," by DRs. C. A. WHEATON, St. Paul, Minn., and HENRY W. COE, Portland, Oregon, were read by title.

DR. R. A. McLEAN, San Francisco, Cal., followed with a paper on "The Necessity of Early Surgical Interference in Malignant Tumors."

In the absence of its author, DR. JOHN PARMENTER, Buffalo, N. Y., his paper on "The Value of Caustics in Malignant Growths" was read by DR. H. O. MARCY, of Boston, Mass., and the Secretary did a like service for DR. L. DUNCAN BULKLEY, of New York, his paper being on the same subject.

DR. JOHN A. WYETH, New York, being absent, his paper on "The Value of Inoculation with Septic or Toxic Agents in the Treatment of Malignant Neoplasms," was read by title.

The same course was taken with the paper of DR. X. C. SCOTT, Cleveland, Ohio, and for the same reason, his paper being on "Non-Malignant Stenosis of the Pylorus and Duodenum."

DISCUSSION.

The discussion on the foregoing group of papers was opened by DR. H. O. MARCY, Boston, Mass., who said—Your presence in these large numbers shows the wisdom of the selection of this class of topics as a symposium for the day. It seems to me that hardly any subject could be brought up with greater profit for discussion than the accurate and proper understanding of what we might term the malignant growths by the common professional physician, as well as what shall be done with them by the surgeon.

As we are looking into it I take great pleasure in referring to the instructions, in this connection, of the late Dr. Bennett, of Edinburgh who, so far as I know, was the first to declare that malignant growths were 1, local; 2, constitutional. As I look around me I suppose the majority of

those I see were taught the contrary—that malignancy was a disease of the body and had its local expression, and consequently it mattered not how we cared for it, it would be sure to come back. Thanks to Dr. Bennett, as I believe, the profession is indebted to the great progress which has been made in this respect, and it is now accepted as the general consensus of surgical opinion, on both sides of the Atlantic that malignant disease is 1, local; 2, constitutional. Now, if this be true, it seems to us that we can have no two opinions regarding its early treatment. Dr. McLean was extremely fortunate in reading his paper and stating the views with such emphasis as he did in reference to the early diagnosis of malignant disease by the general practitioner, and he should then be equally competent and careful as to what should be done with the same. I am glad to feel that in a very large class of cases the general practitioner may help the surgeon because if he does his early detecting, as has been suggested to-day, you need not demand to be very extreme and need not demand that higher class of skill which belongs to the specialist in this direction, and would give further emphasis to the earnest work of the general practitioner upon whom we must all depend much for the early knowledge of this class of diseases. The question has been discussed with real interest by two of the writers as to what it is and how it is disseminated, and it becomes of equal interest to us all. I can not help believing that it is disseminated in large measure, whatever it is, through the lymphatic system, and hence the importance of our understanding, as has been already pointed out by one of the writers, the relationship of the local growth and the lymphatic system.

One word further; some of us have made careful preparations for attempting experiments that we might determine something in contribution to this subject, and there is one paper that was read that is of real vital interest to myself. In my early studies I had no difficulty in differentiating a certain growth, a growth not alone to be detected in microscopic knowledge, but that could be detected in bacteriology; as to its reproduction in animals, and I feel very sure I should not have been sorry if I had been made a committee of one to make the experiment upon criminals, for I can not help feeling that there is not so much difference between animals and the human race, so far as malignant growth is concerned. However, that is one suggested problem that has not been given to the profession to solve. But in its solution by local attack, shall we use the caustics? The paper which I had the honor of reading, the paper of Dr. Bulkley, an authority whom you all recognize in this country as of primary type, so far as disease of this kind is concerned, I can not believe that you will fail to accept. At the most the argument for this has been for limited conditions; disease of the ear, of the lip, those superficial, of the skin. May we not equally well and with a great deal better results effect those local operations by the use of the knife, carefully eliminating the use of so much of the tissue as Dr. McLean showed you that he had done, that we may be quite certain that the surroundings are removed in such a way as to make it far more intelligently corrected, more certainly effective than by any application of caustic, no matter how wisely made? What does the caustic do? Both the writers have told you that in many instances they are utter failures. You and I have seen it over and over again—no matter if you grant that they are carefully and thoughtfully and scientifically applied—we have seen utter failures in the control of this disease; and why should we subject the patient to this painful suffering? Why should we make an open wound subject to further infection? Why should we attack that growth on the superficial tissues when any permanent good results are so uncertain and it causes so

much suffering, when it is so easy with the knife, and we may expect permanent results almost without failure, with the aseptic measures which are at our disposal, and leave our patient practically cured the moment he or she shall leave the table? And if this is true, the plea for caustics is one that should be relegated, and will be, only to the men who do not thoroughly understand the subject, and such men I am sure you will agree with me have no right to practice upon this class of surgical patients, with the dangerous means of sure delay and sure death. (Applause).

DR. GEORGE F. SHIELS, San Francisco, Cal.—In the paper read by Dr. McLean he narrowed down the differential diagnosis, leaving aside tuberculosis, to syphilis and malignancy, and in reference to it spoke of the method of differentiation by treatment. Now we all know perfectly well that the differentiation between syphilitic growth and granulum, and of malignant growth of epitheliomas especially, may be made in a large majority of cases; but I want to call attention to a particular kind of condition which exists at times, and which makes this means of differential diagnosis impossible. Sometimes there exists gumma which do not undergo dissolution in the face of treatment by any of our known remedies. Large doses of iodid of potassium have been found to fail utterly in getting rid of a gummatous growth. Combined with mercury it has failed and even with arsenic it has failed in getting rid of real gummatous growth. I have seen such growths occurring in the tongue. Now, as we all know, in diseases of the tongue you sometimes have a tumor with enlargement of the submaxillary gland and where you have a great difficulty in making a differential diagnosis. In some of these cases you might give iodid of potassium in large doses and still fail utterly in getting a differentiation. You may have had a series of points brought to your attention which make you think or suspect that that condition is gummatous, and yet in spite of your iodid of potassium it does not appear. In other words there is a particular form of gumma, which is almost a simple primary type and without danger to life, and yet if you take this method of differential diagnosis described by Dr. McLean as your guide you might possibly cut out a man's tongue, when you perhaps could have saved it by other means. I do not believe much in throwing in any new method of treatment here, but I will give you a case. You have a case of ulcerating tumor of the tongue and enlargement of the glands. It seems to grow a little larger; you give all these medicines; you fail to make it go away; you have reason to suspect that it is a gumma—I have seen such a case, and have used different decoctions, Zithen's decoction—I don't care what decoction—what I want to point out is this: That there is a condition in post-syphilitic gummatous growths which does not allow of immediate cure by the use of iodid of potassium, and that one should give a very careful consideration, especially to tumor of the tongue of syphilitic history before he proceeds to remove the tongue.

I had intended to make some remarks concerning this question of caustics, which ought to have been entitled, the lack of value of caustics in malignant growth, but Dr. Marcy has covered that subject pretty thoroughly. One thing I would like to say is, that whenever you apply a caustic to a part, no matter how slight or how strong that caustic may be, with the hope of curing a malignant disease you are applying it to a tissue which is undergoing rapid cellular change, you change the cellular growth and are liable to make a non-malignant growth a very malignant one.

DR. E. GRISWOLD, Pennsylvania—Dr. McLean has remarked a fact in regard to the necessity of excision, and I think his remarks are very correct, but there are conditions—we

find cases in which it would seem that they ought to admit of a little variation. I have a case in mind. A patient comes to me with a tumor upon the breast, which is open, with the axillæ enlarged, and the patient seemingly can not live more than a year. She came to me five years ago last March and said: "Doctor, I have a lump on my breast and have come to you to get it cured, and if it can not be cured in any other way I will have it taken out." I looked at it and was obliged to tell her that she could not be cured at all, in any way. Well, couldn't anything be done for her? Yes, very likely your life may be prolonged by an operation, but a cure is impossible; your system is wholly involved—and, by the way, she was almost going to bed; her pulse was accelerated, she was emaciated and her appetite largely gone. I said: "If you choose to have the operation done I will do it." She thought it over three or four days and then sent for me. I performed the operation, took out a very large mass, the whole breast, and took out so much of the tissue that it was impossible to bring the wound together in any ordinary way. I put in wire sutures and made a slight incision in the skin at one point so as to make the cut surfaces come together, took out all the axillary glands, and after six weeks the cuts are completely healed except at this point where there was so much tension on account of the silver wires—and, by the way, the silver wires cut more than an inch before they were taken out. It all healed in a short time—the operation was done antiseptically—except at that one point. That woman is alive yet, and that operation was done five years ago. Now, that operation was optional. She had it done because I said it would prolong her life; nothing more was promised, nothing more was expected. She can't live a great while longer, but she has lived two or three years longer than she would have lived had no operation been done. I have had similar cases done by their wish after the patient had been told what could be expected and what could not be expected.

With reference to caustics, I have had a great many patients who had epithelioma mostly on the face, and sometimes on the hand and on the lip, and so forth, who would not submit to the knife—the knife was always my method if I could get the patient to submit to it, but rather than let them go on to destruction I would adopt any other method which I thought was practicable—and I got hold some years ago of a method of applying caustic, I scarcely know how, but better in my opinion than anything that has been presented to us to-day, and the treatment by it is done at one seance; one sitting does the work. It has to be done, however, in a peculiar and careful manner. The caustic made of sulphate of zinc, dried so that the water of crystallization is all driven off by heat, till it bubbles up after the water of crystallization is driven off, and then powdered in a mortar promptly and quickly so that it shall not absorb water from the air; put it in a bottle and pour in enough pure sulphuric acid, chemically pure, so that when it stirs up, it will make a paste so thick that when you put a little stick or little glass rod in it, a good sized drop will adhere to that stick or glass rod, and not drop off. Have plenty of absorbent cotton or plaster, and apply that all over the surface. It is a little painful but in about ten minutes it destroys the tissue to the depth of about one-eighth of an inch. Then take the point of your penknife and scrape it off until it begins to bleed, to the quick; then apply it again, and after four or five applications I have to use my judgment as to whether I have got all the cells out or not. I believe I have never failed in perhaps fifteen to twenty operations in getting a complete success the first time, except once, and that was on the hand where I was afraid of injuring the tendon. While scraping it that way you get all the cancer cells out and destroy them completely; it may take from an hour or an

hour and a half to two hours, according to the size of the epithelioma. Then you use any simple ointment you may happen to have and the pain is all over and there is no further trouble.

DR. MACLEAN, Mich.—I very much regret, indeed, that I was unavoidably detained and missed the principal part of this session, the more so that this is a subject which I think of the very utmost importance to the practicing physician and surgeon. There are one or two thoughts suggested to my mind in what I have heard since I came into the room that perhaps are worth presenting. In the first place, the question of diagnosis between benign and malignant tumors. A great deal of time and a great deal of genius and work have been devoted to this subject, and the profession has labored earnestly and honestly, early and late towards that point where we could be able to say, This tumor is malignant, and this tumor is simple and must be treated as a simple tumor. Of course the microscope and all the resources of histology and of chemistry, as well as those of the ordinary practice of surgery have been called to the aid of the practitioner in this matter. And after all I am afraid we must admit that we are far from having attained to a definite conclusion. Dr. Marcy referred to the teachings of Dr. Bennett, of Edinburgh, as to the local origin of cancer or malignant tumors. Now, I am perhaps the only man present who had the pleasure of listening to Dr. Bennett's teachings and arguments on that subject, and I remember also at the same time Prof. Symme was teaching on the same subject, and he had a very illustrative class of cases, namely the Highland shepherds, the men who spent a great part of their lives herding sheep in the Highlands, and the sole comfort of their days was their little clay pipe, which soon got broken down pretty nearly to the bowl, but it was all they had, and they had to use it. And the most common everyday cases that we met with in the Royal Infirmary in Edinburgh when I was a student there, was the Highland shepherd with his epithelioma of the lip. He smoked this little short clay pipe with the bowl close to the skin, and the epithelioma always appeared on the side of his mouth on which he carried his pipe. That seemed to be a very strong argument in favor of the origin of malignant disease from local irritation. If these cases came early enough and were excised clean and clear by the surgeon's knife and closed up, they healed within a few days, and we hardly ever saw the patient again; but if they were too late in coming, if the time had been allowed to pass on, and when the poor fellow arrived at the hospital he had enlarged glands under his chin or in the neck, no matter how carefully or how thoroughly the excision was made, a few months saw him back again with a great mass on his neck. There seemed to be a direct, straight, clear, undeniable history of malignant disease, commencing locally from local irritation and becoming gradually, general, constitutional, uncontrollable and fatal. But it is a curious fact that cases of tumors on the breast, cancers on the breast, tumors of various kinds come across our path every once in a while, where there seem to be all the characteristics of malignancy, and in which the result demonstrates that after all they were local, non-constitutional, treatable and curable, when other cases very similar, almost entirely impossible to draw the line between them, take an entirely different course. Now, then, what is the difference? What is the microscopic, physiologic, chemic condition which confers malignancy on one tumor and benignancy on another? In that direction I believe that sooner or later some great revolutionary discovery will occur by which we will be able to recognize the difference. I do not believe that at the present time, with any means we have at our disposal, we can speak with positive certainty as to the prognosis of a large class of tumors.

Certainly we can not say what makes one tumor malignant and another benign.

Now, as to the treatment of tumors by caustic. I have always been taught and always believed that that is a system of treatment used before the days of exact knowledge, in the days when the surgeon was afraid to use the knife because he did not know what trouble he might produce, and that he might get beyond his depth. And it has always seemed to me to a very large extent an unscientific, cowardly, unsurgical method of treatment. I have always thought it myself and I have always believed it and at the same time I am ready to acknowledge that under certain circumstances, in certain cases, the treatment by caustics may be the best that we can use. The treatment just described by my learned friend, by the use of sulphate of zinc, which he says himself he accidentally stumbled across, I think, in fact I have no doubt of the absolute fact, was taught in a little different way by Sir James Simpson when I was a student in Edinburgh. Sulphate of zinc was prepared in the same way but used as a fine powder, and used for ulcerating, open malignant growths; and while it was temporarily painful it certainly did tend to stay the growth and prolong the patient's life. And besides that I believe that we did once in a while come across a little growth, or at least of a suspected character, a growth in which we had reason to believe that there may be a basis of malignancy, in which an operation with the knife is difficult and unsatisfactory, where it is so situated that you can hardly make a proper or satisfactory incision with the knife, and where by some such method as has just been described, by the use of caustic carefully applied, it can be got rid of very thoroughly, very rapidly and very efficiently; but my own impression is that that class is small. I think it would be unjust for us as surgical authors to lay down the doctrine that the treatment of cancerous growths by caustics is always unjustifiable. While I do believe that in a vast majority of cases it is abused and misused and improperly used, I believe that the larger number of men who use that form of treatment are men who do not know anything about what they are doing, further than that they have got hold of some kind of treatment, and they are going to relieve the patient and get what money they can from him. I think it cruel and unscientific treatment in a majority of cases, but it is like a great many medical and surgical applications. I do not think it is possible to lay down a hard and fast cast-iron law and say, You shall not use caustic, you shall always cut, or *vice versa*. I do not think we are in a position to do that at the present time. I believe in caustics. I believe in the doctrine of the local origin and local nature of malignant growth to a very great extent. Still there are exceptions. I was going to explain one single case, and then I have done:

A patient came to me with a tumor which involved all one side of the lower jaw. It had grown rapidly. It started in the submaxillary gland and involved the jaw. I removed more than half of the jaw, and the patient apparently recovered and was in good health for twelve years; went about his ordinary avocations and had no trouble. At the end of that time he returned to me, his jaw healed up; he had a wire plate and false teeth and the scar was hardly perceptible. No person could see that there was anything wrong with him at all, but away back behind his tonsil, the same side from which I had removed his jaw, there was a great malignant growth, a lump that it was impossible to cure. After twelve years of good health between the two tumors. Now I say it is very hard to reconcile such a case as that, and I can stand here and give you many such. I think it is hard to reconcile that with the theory of a simply local nature of malignant disease. The fact is in my opinion that we do not know just exactly what we do mean by ma-

lignancy. I believe that there is something more for us to learn in that direction; I am perfectly certain of it. I believe that there is something yet beyond the reach of the microscopic lens or the chemic test, but something which the rapid and magnificent progress of modern science, surgic, pathologic and anatomic, will clear up and we will be able to apply more effective and more satisfactory treatment to them.

DR. J. W. COPENOR, Iowa.—I do not wish to enter into any discussion nor to report any cases, but I do wish to do this; to give briefly my conclusion upon this subject from my observation and experience. I believe that these cases of cancer that have been cured were not malignant cancer I believe that we have to look beyond any local application or the knife for any permanent cure upon cancer. Further, that the cases that are supposed to have been prolonged to any great extent or possibly cured by the means that have been suggested were not malignant cancer, and the means had not been used prior to their treatment to ascertain definitely as to whether they were or were not, which can only be done, not by the naked eye, not by any observation, but by the microscope and if necessary, even a more critical examination than we could get from the microscope, and that is the only way we have of ascertaining definitely what we have. In 50 per cent. of the cases you will find that it is simply some other tumor aside from a malignant tumor. Then your local application, then your knives will be of some benefit. But if it be truly malignant then we have to look for something beyond all local treatment and the knife for a permanent cure, and I fear that it will be some time before we ascertain that.

DR. L. DUNCAN BULKLEY, New York—I am sorry I could not hear the discussion entirely, but I am glad it has taken the turn that it has, because no one feels more than I do its importance; there is no one who has thought more than I have of the danger of caustics as they are commonly applied. I believe in my paper I stated that many a case which would have proved a very simple affair has been urged on by caustics until it became malignant and beyond control of either the knife or caustics. I believe there is no one who more strongly than myself, in a large number of the cases that have come under my observation, urges instant operation. Many cases I have shown in clinics where there has been harm by the light application of silver, and as I mentioned in my paper in most cases I have advised against the use of it in any possible way for fear of tumor that I thought might be epithelioma. It should never be done. But in epithelioma of the face or the hand you certainly can get results with Marsden's arsenic paste long before there is any danger of infection, I certainly should allow the paste to be applied in many a case in its early stages. But in many cases it is harmful, because the caustic has not been removed, because they have tinkered with it one way and another with irritating salve, and it has gone on until it has become too late for anybody to cure. In many of those cases you can get a better result than with surgery. As I stated in my paper, I believe the arsenic penetrates further than the surgeon will penetrate with his knife. I have had several cases operated on by surgeons—I do not operate myself—and I have repeatedly stood by and urged the surgeon to go further and he would decline to. I believe and I know that the arsenic follows down further than the surgeon will go. If you are going to cut out one of these things, go clear around it, beyond all possible penetration of that epithelioma, if you are willing to make a big scar—but upon the face and upon certain other localities you will not make a scar sufficient,—you will make the incision too small, and it will certainly come out on the outside as I have seen it time and time again. Suf-

cient paste put on rightly according to directions which are well recognized will penetrate further than the surgeon's knife. The scars from arsenic paste, used rightly—because every one has his own way of using these things, and he may not follow out all the details as another man would—the scar, I am sure, is preferable in a large number of instances to that left by operation. I have seen it leave a cicatrix that you can hardly see. The only point is to discover the proper paste, using it early and using it thoroughly, and I believe that you err greatly in supposing it, as some gentlemen have supposed it, below surgery.

DR. RANSONOFF, Cincinnati—The cases of cancer that get well are cases of epithelioma, and some get well without treatment. Cases of epithelioma will sometimes run on ten or twelve years and finally get well. It has been stated by the gentleman from Iowa that cases of carcinoma never continue after this operation, and if I remember the words rightly, that we still have to proceed somewhere beyond the operation in order to effect a cure. Dr. McLean in his paper stated that when we see these cases of malignant disease appear early an operation, not very extensive, is possible, that it is justifiable—I do not remember his exact phraseology, but that is the impression that I obtained from his very admirable paper. I think in that remark he follows Bangs very largely in that particular, though Butlin as determined by his work, shows that it has been very largely corrected and destroyed by what he says concerning the treatment of malignancy by incomplete operation; in other words, by the mere removal of the tumor itself, leaving the parts overlying the tissues, leaving a part behind of the underlying tissue, and not investigating the axillary glands. We know very well that recently Dennis has made an admirable collection of cases from his hospital and private practice in which he had obtained a recovery in 15 to 25 per cent., which was a good deal higher than the recoveries obtained through the work of Gross. Now, say that all these cases were not cases of malignant disease, 15 to 25 per cent. of recoveries can hardly be within the limit of fact, because unless there had been a microscopic section of every tumor that had been removed in that way, in that case there could be no question at all as to the malignancy of the growth. Now, regarding the removal of the tumor, leaving the breast. It is not nearly so difficult to remove the tumor. Everybody knows that, but we know that such cases usually occur at a time of life with patients when the breasts are no longer so important, there is no longer very much physiologic need for that part of the anatomy. In the next place, to remove only the tumor leaves the integuments over it, and leaves frequently some important fascia, and it is here we have the secondary local developments of the case. One of the speakers suggested to be careful about palpating; one certainly can not do it in the axillary region through the integuments. Most of these cases happen with women with a fair or excessive development of adipose tissue, and you can not do this through the layers of much adipose tissue. For that reason, the disease being of the lymphatic glands, they ought to be opened invariably. It has been shown that not more than 2 per cent. of women die after the operation of amputation of the breast, simple amputation of the breast, and the mortality from opening and removing all the axillary glands is not excessive; the operation is not at all difficult. So I think that every woman who is unfortunate enough to be subjected to this operation ought to have not only the breasts removed, but the integuments over it. We do not have the large open wounds any more, because they can be skin-grafted at once, and the axillary region at the same time cleaned thoroughly. It is ordinarily in the axillary glands that the lymphatic disease produces its secondary consequences. From 15 to 17 per

cent. of the cases of carcinoma of the uterus have this result, because all of the glands involved are not removed, and the same is true of carcinoma of the rectum, which when it is thoroughly removed does not ordinarily produce metastasis. I did not hear Dr. Wyeth's views here upon this subject, but I feel quite certain that if Dr. Wyeth had read his paper upon the radical treatment of malignant disease, it would not have been upon the use of superficial applications with caustics, but upon the use of methods; that he would have told us something about a method like amputating at the thigh, that is to say, going up just as far as you can, and then the mortality will be diminished to a minimum. I did not hear the paper which was recently read before the Maryland State Medical Society by Halstead, of Johns Hopkins, but somebody stated that Halstead presented quite a large number of cases of malignant disease operations in which the mortality was not more than 6 per cent. But in these remarks I merely wanted to take exceptions to the remarks made by one of the speakers namely, that in cases of recoveries from malignant disease of this class they are in the nature of an Irish bull; they are not malignant diseases at all.

DR. JULES ROSENSTEIN, San Francisco—In the discussion about malignant tumors, I have missed a necessity which I think is of paramount importance, in knowing which tumors are malignant—we have been talking here mostly of cancers. Cancer to my mind does not convey a very distinct histologic meaning. There are different kinds of malignant tumors, epithelioma, carcinoma; there are sarcomas, and among the sarcomas there are again different degrees of malignancy, the round-celled sarcoma and the spindle-celled sarcoma; we all know that the round-celled sarcoma is a much more malignant growth than the spindle-celled sarcoma; also that certain kinds are of local origin—in fact, originate from some local irritation. We have the epithelioma of the chimney sweepers in some parts of Germany, caused by sliding down the long chimneys and coming in contact with the soot, and which is removed without the danger of recurrence; the parafine epithelioma of the workers in parafine factories, which attacks only certain parts of the body that come in contact with certain material used in the manufacture of parafine. In fact, we have a theory which can be fortified by a great number of facts that constant irritation, be it by whatever cause, can stimulate the growth of the epithelial cells; that they become malignant. We know that at different orifices of the body, orifices that are exposed to constant irritation by the passage of food or other material, the different passages of the stomach, rectum, the mouth, and even the cervix uteri—all these are liable to be the first or the original seat of certain kinds of carcinoma. To throw all this together without any etiologic differentiation, without saying, this kind of tumor is malignant, this kind of tumor is easily infecting the general system, while that one is growing slowly, I think is a scientific matter. The fact is, that kind of tumor, epithelioma, slow-growing epithelioma, can be treated by early operation, and if the lymphatic glands are not infected we have a certain moderate assurance of a permanent cure. We can certainly not guarantee that after a time, be it long or be it short, the lymphatic glands in the neighborhood of the tumor will be free from infection from the original point, and we will not have any secondary growth of the same kind of tumors. Indeed, as one of the talented speakers just now remarked, it is certainly dependent upon the nature of the tissues, upon the anatomic relations. Some parts that have no great connection with the lymphatic glands in their immediate neighborhood will form their growth slower; others are surrounded by a network of lymphatics that will certainly be apt to make the infection more general.

As to treatment with caustics, I believe that ought to be relegated to ancient history. We certainly can not say that our caustics shall do effective work, shall penetrate the lymphatic glands and channels and shall clear out all the infected ones, and leave the others perfectly sound and perfectly unaffected. We must rely on a very much extended operation to protect our patients, operations that can be done with safety now with the antiseptic treatment, and operations which ought to be done to protect them against infection, operations that go into all the possible channels of infection and thereby extirpate all that we can reach, and then trust that the infection has not gone any farther. That is all we can do; all we ought to do, but not any more than we ought to do. Anything that we do less is a crime against the patient. And I think the more extended the operation in early cases that come into our hands, the more benefit we will do the patients that are intrusted to our care.

DR. BISHOP, Pennsylvania—It seems to me that there is a belief on the part of this Section, and we ought to be decided in the expression of our opinions in regard to the question of the use or non-use of caustics; and I think that we owe it to our practitioners, and to our patients both, that we should be decided in the expression and assume the responsibility so that we shall be deterred, you might say, from the use of caustics. Certainly the tendency is to do more hurt than it is to do good. The percentage which would be relieved will certainly be less than the percentage relieved by operative measures, and it looks like a measure in which the practitioner either is afraid to assume the responsibility of an operation, or he is afraid that he will lose a patient, and he makes concessions to the patient and lets the patient select the operation instead of having the courage to select it himself. It is a cowardly act, it seems to me, and the man ought to assume the responsibility, and the Society ought to assume the responsibility, and give a decided expression. I think we would make no mistake by doing that, and we do make mistakes by leaving it an open question as to whether the one or the other should be used.

DR. I. M. QUIMBY, Jersey City, N. J.—I think this differential diagnosis should have an important bearing. You take the case in which a local irritation has brought out or developed the disease, as by tobacco. These are the cases in which a different form of treatment frequently may be had. You take a case, on the other hand, where it seems to grow, a sort of imperceptible growth, without any definite or any positive local irritation there; I think you have something of a constitutional disturbance, and so you can not make your diagnosis more exact of all diseases. It has been laid down by some writers on tumors that they are all of local origin. I think that is a mistake. There are some that certainly are constitutional. You can not treat those with the same line or kind of treatment. I had a case of exuberant granulation that came to me—a burn after six or eight years' treatment with all sorts of mild caustics, burnt alum, and nitrate of silver; the local physician had used that for several years—the case came to me, and I found that I could do nothing with it and advised amputation. However, I sent him over to the hospital, thinking that Dr. Bulkley with his experience in a cancer hospital might say differently, but he thought nothing could be done but amputation. I simply mention this case to show the damage that may be done, a benign tumor, a non-malignant trouble, a simple burn that had been tortured into a malignant growth, and the man lost his arm. So we want to be right on the thing to be used, and use it thoroughly. I think the plan laid down by Washington Atlee several years ago is a good one, that all patients should be treated in a constitutional way, and if it is by the arsenical operation, for one or two or three months take the Powers' solution, which I have done

in several instances with marked success, and where there was no return. I operated upon a lady twenty-five years ago for a malignant growth on the lip. I treated her with mercury for a while, and then the potassium iodid, and then I put her on the treatment of the arsenical operation and kept her on that for three months. That was twenty-five years ago and the trouble has not returned, and I could give you a number of instances to illustrate what I think is the success of constitutional treatment after that operation, whatever it may be. As far as local treatment is concerned, I do not think we ought to be like machines to follow any one treatment, although I believe in the knife. It is the quickest, and I think it is the safest, especially with epithelioma of the lip. In flat cancers of the face perhaps paste may be important, but where you can amputate, excise, I think it is better, and the patients do not suffer so much. I have noticed in several instances where the patient has been treated with caustics his health seems affected from the constant irritation, and that does not occur with the knife. Therefore I give preference to the knife, and then constitutional treatment afterward.

The Chair appointed as a Nominating Committee, Drs. D. W. Graham, Chicago; H. M. Sherman, San Francisco; and D. Root, Connecticut; and as alternates on the Business Committee to supply vacancies, Drs. Joseph Ransohoff, Ohio; and R. H. Sayre, New York.

Adjourned.

SOCIETY PROCEEDINGS.

Colorado State Medical Society.

The twenty-fourth annual convention of the Colorado State Medical Society was held June 20, in Denver.

Dr. E. J. A. Rogers called the convention to order shortly after 10 o'clock. At that time there were present E. J. A. Rogers, S. A. Fisk, A. M. Bucknum, A. S. Lobingier, E. R. Axtell, V. P. Munn, W. F. McClelland, W. E. Wilson, J. N. Hail, John Chase, John N. Foster, J. W. Collins, Howell T. Pershing, I. B. Perkins, Jesse Hawes, Greeley; E. C. Rivers, Herbert Work, Pueblo; C. F. Shollenberger, J. W. Exline, A. Nickerson, T. M. Burns, J. Kelly, J. E. Waxham, D. E. Wetzels, George Cleary, C. P. Conroy, W. Weist, O. A. Pfeiffer, O. W. Mill, P. F. Gilder, Colorado Springs; A. J. Baker, P. D. Rothwell, W. J. Rothwell, C. K. Fleming, E. H. Fish, O. H. Simmons, Leadville; J. T. Beatty, Lupton; J. W. Collins, H. B. Whitney, J. N. Vroom, G. M. Black, E. H. Allison, F. D. Green, E. C. Rivers, E. M. Marbourg, Robert Levy, W. C. Bane, W. W. Bulette, Pueblo; R. F. Le Mond, E. J. Rothwell, Mrs. Exline and Mittie Bradner, J. C. Herrick, G. B. Packard, Una G. Roberts.

Dr. Hubert Work, of Pueblo, read the annual report, which showed healthy branches of the Society to be in existence in the principal towns of the State. Reports were also read from the Treasurer and the committees on publication, and medical societies.

The main business of the convention was then proceeded with. Papers on various diseases and their various methods of treatment were read, among them being these: "Operative Treatment of Granulated Lids," by John M. Foster, Denver; "Some Cases in Ophthalmic Practice," by F. D. Green, Pueblo; "Report of Two Cases of Removal of Cataract and of a Piece of Steel at the Same Operation," by E. C. Rivers, Denver; "A Report of Eleven Cases of Intubation of the Larynx in Denver, Colo., with Exhibition of a Lamp for the Sublimation of Calomel," by F. E. Waxham, Denver; "Dacryo-Cystitis and Its Complications," by E. M. Marbourg, Pueblo; "A Valuable Artificial Membrana Tympani," by Geo. Cleary, Denver; "The Treatment of Empyema of the Antrum of Highmore," by Robert Levy, Denver; "The Use of a Modified Nasal Trephine in Hypertrophic Rhinitis," by G. M. Black, Denver; "Ophthalmic Memoranda," by W. C. Bane, Denver; "Acute Otitis Media," by W. W. Bulette, Pueblo; "What a General Practitioner Should Know About Eye Troubles," by R. F. Le Mond, Denver; "Eczema Marginatum and Eczema Seborrhoeicum," by D. E. Wetzels, Denver.

The afternoon session opened with a symposium on obstetric difficulties. Dr. Jesse Hawes, of Greeley, read an interesting paper on "Rigid Os," which was followed by Dr. W. S. Bagot, of Denver, with an able and argumentative paper on "Extra-uterine Pregnancy." Another carefully prepared and statistical paper was that by Dr. Herbert Work, of

Pueblo, on "Maternal Impressions." The preponderance of opinion quoted by Dr. Work appeared to favor the theory that unusual mental or physical agitation of the mother during her term of pregnancy was almost certain to be transmitted to the child.

"Unusual Operative Procedures" was the title of an exceptionally practical paper by Dr. Neil McPhatter, of Denver. The woman and babe whose lives Dr. McPhatter saved were present at the session. Dr. McPhatter said: I believe the part assigned to me for discussion this afternoon is a consideration of the unusual methods or extraordinary measures that may legitimately be resorted to in difficult parturition, when the difficulties assume such proportions that the woman can not be delivered by any of the ordinary means. My sphere is limited to a still narrower margin than this, for I have been informed by the gentleman who so kindly invited me to participate in this discussion to endeavor to confine my remarks more particularly to that part of the obstetric art which calls for the use of cutting instruments, *i. e.*, when there exists such a disproportion between the natural passage and the size of the fetus as to render it absolutely impossible for the child to be delivered in the ordinary manner. Then we come upon a peculiarly interesting and tremendously responsible situation, for it is one in which the lives of mother and child are placed in imminent jeopardy, and one which calls for the highest and at the same time most evenly balanced judgment on the part of the attending physician. In the remarks to which I give expression I trust I shall approach the subject free from the thralldom of preconceived ideas, and unbiased in the advocacy of any one method of procedure only in so far as the merit of such a method demands.

Fortunately for mankind, more particularly for those who are obliged to bear the burdens and dangers of parturition, nature in her own inimitable ways and by ordinances that far surpass in beauty and perfection of design the imagination, is usually quite competent to fulfill this trying ordeal. Occasionally, however, the ordinances of nature are disregarded. Morbid influences in the pelvis of the mother or unnatural development on the part of the fetus may render it absolutely impossible for the woman to be delivered normally, and it is here that the cunning hand of the surgeon may be of the utmost importance to life. It is highly commendatory to the standing of the profession at the present time that the principles we advocate have been so beneficial to mankind. The method in vogue not many years ago of resorting to the operation of craniotomy with the appalling disasters that followed in its wake, forms one of the darkest pages in the history of obstetrics. When one contemplates the frequency with which this operation was resorted to in preference to others much less dangerous, it would seem that the spirit of scientific midwifery was long lulled to sleep and that nature had become emasculated. The operation of eviscerating the yet warm and quivering body of an innocent babe from its mother's womb should be reserved for very rare and exceptional cases, such as hydrocephalus, or where the child is already dead. Much more satisfactory and humane methods are the Cæsarean section and Porro's method of operating.

Porro's operation, unlike the majority of recent triumphs in surgery, is not one which has been resuscitated after having been performed and discarded many years before, but is of comparatively recent origin. The first successful case on record was performed in the year 1876 by Porro of Bavaria. It has since been performed a great number of times with comparatively good results. Heretofore, and even at the present time, this operation and the Cæsarean section had been indiscriminately advocated when the condition present called for one or the other method. I believe this to be a mistake. Whether the Cæsarean section can have any advantages over its recent rival rests wholly upon a question of morals. Certain it is that there are well defined conditions and complications in pregnancy when Porro's method is the only scientific course to pursue.

Each method may possess well-defined advantages over the other, and in estimating the relative values of Porro and Cæsarean sections a number of important conditions should be remembered. In all cases where pregnancy is complicated by tumors, such as fibroid of the uterus, ovarian, or dermoids, as was the condition in this case, hysterectomy is the preferable operation. Where labor has proceeded for a long time and the uterus becomes putrid, Porro's operation ought to be selected. In certain operations begun as Cæsarean sections, but which become complicated by difficulties in the detachment of the placenta, uncontrollable hemorrhage or complete atresia of the vagina, Porro's is the

operation indicated. These are some of the advantages that this operation possesses over the classical one. In straight, uncomplicated cases I doubt very much if the Cæsarean method is superior to the Porro. The advocates of the Cæsarean section maintain that because Porro's operation forever renders the woman sterile, the Cæsarean method has the advantage. This question again is one altogether of morals; but given a woman with a deformed pelvis and a contraction of its diameters, so that one or the other operation was absolutely demanded, and believe the fact that one would save her life equally as certain as the other, the one that would place her in such a condition that pregnancy could not again occur would be the preferable one. I look upon this point alone as a decided advantage of Porro over its rival. Such a proceeding would leave the life of the mother absolutely free so far as any future chances were concerned. I am well aware that this is at variance with the opinions of many able minds, but nevertheless it is one that I have long maintained, and is at least one of honesty.

There can exist no reason why this operation, if properly planned, carried out with as much care and precaution as other abdominal sections should not be almost entirely free from risk, as far as the lives of mother and child are concerned. It is to be regretted that in a great majority of instances the idea of the operation does not enter into the head of the physician until the patient becomes almost entirely exhausted from the reiterated efforts of the uterus to expel the fetus. An operation of this character above all others should be done opportunely and not left until the rough manipulations have exhausted the woman and materially reduced her chances. It can readily be understood why the mortality of this operation has remained so high, in view of the fact that it is usually done as a forlorn hope. On the 16th of last August I was called in consultation by Dr. E. J. Rothwell to see a patient who was eight months and a half pregnant.

History Given.—Woman had contracted pelvis, had previously borne twins weighing three and one-half pounds each. Last confinement craniotomy performed after repeated efforts of days; confined in bed for three months afterward. Upon examination I found conjugate diameter not over two inches. Cervix so high I could not detect it with my finger. I could, however, make out that the fetus was alive and that it was in fourth position. It was of large size, and we felt it was physically impossible to deliver the patient by the normal channel.

This we explained to her and her husband, and advised the removal of the child by abdominal incision as the method attended with the least risk. To this they willingly consented, and she was removed to my private hospital on Vine Street and was prepared for ovariectomy. We decided to operate several days before the expected time of labor. Thursday morning, August 23, she was put under the influence of anesthetic by Dr. Leavitt. The abdominal incision was made in the median line and was continued above the umbilicus. Bleeding points were caught up by pressure forceps and secured. The transversalis fascia was cut through to the extent of the abdominal wound. Before the incision into the uterus was begun, several warm flat sponges were placed between the uterus and the intestines, for the double purpose of keeping them from cooling and preventing fluid from escaping into the abdomen. The incision was vertical, beginning near the fundus, cutting toward the cervix about four inches. I went carefully through the whole extent of the incision, layer after layer, until I came to the membrane, which was intact. The uterine walls retracted, exposing the fetus as through tissue paper. I ruptured the membrane, and the uterus contracted, the child entered the world head first, crying lustily, and was turned over to one of the attending nurses. Here I was confronted by an unexpected complication of two tumors of the ovaries, and decided to remove them also, together with the uterus. As in hysterectomy for fibroid tumors of the uterus, experience has taught us that the extra-peritoneal method of fixation of the pedicle is one followed by the most favorable results. The simple method of converting the temporary elastic ligature into a permanent one is as good as any and saves time. The pedicle was now fixed in the lower part of the wound after all clots were removed from the Douglas cul-de-sac. In order to prevent the pedicle from retracting, a staple or two steel pins are passed through it, immediately above the constrictor. The peritoneum was then sutured separately. The deep sutures to close the abdominal wound were inserted subsequently. Stitches were inserted as in other abdominal sections and the wound dressed. The patient made a very satisfactory recovery. Her tempera-

ture remained normal for nearly two weeks. She now, as you may see, is enjoying the best of health.

At the close of the doctor's remarks and at his request the lady in question came up to the platform with her baby in her arms. As the President took the plump little fellow in his arms for a moment and held him up before the audience, the room resounded with hearty cheers for the youngster.

Dr. C. F. Shollenberger's paper on "Albuminuria" was discussed, the opening by Dr. Kate Lobingier, of Denver. The other papers which were discussed were: "Puerperal Fever, its Etiology, Pathology and Prevention," by T. A. Stodard, Pueblo; "Should Ergot be Used during Parturition and the Subsequent Involution Period?" by E. Stuver Rawlins, Wyoming; "Floating Kidney," by W. A. Campbell, Colorado Springs; "Cases of Floating Kidney," by W. B. Craig, Denver; "La Grippe During the Puerperal State," by T. M. Burns, Denver; "Nephrectomy, with Report of a Case and Demonstration of Specimen," by A. S. Lobingier, Denver.

The visiting members to the convention were entertained at a reception by the lady managers at St. Luke's Hospital. Afterward they went to Manhattan Beach in special cars and attended a performance tendered by Dr. J. M. Foster, of the Society.

Medical Society of the District of Columbia.

The Medical Society of the District of Columbia, June 21, continued the discussion of the prevalence of typhoid fever and a pure milk supply, so auspiciously commenced last week. The hot weather had a visible effect on the attendance. Though only a few were present the discussion, however, was earnest and interesting.

The meeting was called to order with Dr. S. C. Busey in the chair.

Dr. Robert Reyburn read a report in which he took exception to that portion of the committee's report in which they stated that cases of typhoid fever diminished as the city was more thoroughly sewered. He cited data to show that such was not the case, and claimed that while perhaps the increase in typhoid cases was very small, yet the sewerage system was increasing with great bounds, and this was an absolute proof of his claim. Dr. Reyburn then read a report of an investigation of certain alleys in the city. He referred to Cedar alley in particular. He spoke of improper water closets, and scored the health officer for his neglect of duty. In the course of his remarks Dr. Reyburn made mention of the pump at Sixth and O Streets, which was so universally condemned at the last meeting. Dr. Busey interrupted and said:

"That pump is closed."

"Indeed," said Dr. Reyburn; "since when?"

"Since last Wednesday night," said Dr. Busey, and the little sally was met with a laugh.

Dr. Benjamin C. Poole read an exhaustive report on the death rate from typhoid fever. He claimed that typhoid fever was not as prevalent as was supposed. He claimed that many deaths laid at the door of typhoid fever were due to malarial fever. He next attacked the committee's report on pumps. He declared that never had there been any authentic report of a case of typhoid fever resulting from well water. He called the report "untrue, illogical, and based on the misrepresentations and miscalculations of those who had made the investigation."

Dr. J. W. Chappell then said that he had gathered from what had been said that there was a very low percentage of deaths from typhoid fever. He objected to this, and said that he believed that it had increased, not because there was any real increase of typhoid, but because physicians had changed their diagnosis. He showed by figures that real typhoid fever, however, was on the decline. He said that in 1880 the death-rate was 107; in 1882, 141; in 1890, 122; and in 1892 it stopped at 98.

Dr. Chappell then went on to attack the belief that wells

were conducive to typhoid fever. He said his experience had not taught him that, and furthermore, he was a disciple of the theory that water filtered through the ground would be purified. He said that he believed that the wells in the city were no worse than in the country for this reason. He admitted that the ground in the city was more befouled than in the country, but claimed that the rule still held good.

Dr. C. G. Stone, of Brightwood, rose to antagonize the claim that an improved sewerage system checked typhoid fever. He said that in his district there was not a proper sewerage system. He added that there were not as many cases in his district as in the city. Despite this, he said, he wished to declare himself in favor of the sewerage system now under consideration by Congress, and would do all he could to push the matter along.

Dr. G. L. Magruder thanked the Society for their almost unanimous indorsement of the report of the committee as reported to the Society. He stated that at the outset the work appeared to be easy, but as time wore on its laborious details became evident, and the report was the result of hours and days of hard labor. He felt confident that the report was correct.

It was in every detail as faithful as it was possible to make it. Therefore he asserted again that typhoid fever was on the increase, and again that to wells this increase was due. He complained bitterly of the way in which certain members of the Society had hounded the report as a sensational bugaboo. He said that these things were true, and that it was better that the Society were awake to the fact and prepared to combat the disease, rather than to shut their eyes and allow the alarming growth of disease to pass unnoticed in order to lull an unsuspecting public into a sense of false security. Therefore he asked for the indorsement of the recommendations made by the committee.

Dr. W. W. Johnston said that he wished to reply to Dr. Smart, who had asserted that water in rivers was particularly conducive to typhoid fever. He said:

"It is not a question for us to settle. Authorities have settled the matter for us, and it is an absolute certainty that polluted soil and well water are prime factors in producing typhoid fever.

"It is an undisputed fact that the *pro rata* of typhoid fever is on the increase. It may be a few more or a few less than last year. Nevertheless it is on the increase, and it is for us to rise and try to overcome the disease. Now let us go to work, drop all differences, adopt this report, and go to work with a will to stop this evil."

Dr. S. S. Adams moved that the committee's report be adopted. The motion was carried.

The Society then took up *seriatim* the report of the special committee relative to the matter of unlicensed physicians practicing in the District. At this point the reporters were excluded from the room.

Upon a motion made by Dr. Adams the meeting adjourned until fall.

Medical Editors Banqueted.

[From the San Francisco Examiner.]

The banquet of the American Medical Editors' Association, which is annually held, took place June 4, at the Palace Hotel. It was the first event of the extensive medical congresses and meetings which are to be held during the week. Last night the editor-physicians were the guests of R. E. Queen, of San Francisco. About ninety doctors and their guests, many of them famous throughout the world, lined the three beautifully decorated tables in the banquet hall.

After the first few courses had been disposed of, Dr. C. H. Hughes, President of the Editors' Association, introduced as toastmaster Dr. I. N. Love, of St. Louis, Chairman of the Committee of Arrangements. After all, doctors know as well as secularists how to enjoy a banquet, and the President of the Association lost no time in beginning the fun.

"I take pleasure," he said, "in presenting you a toastmaster early in the evening, while I can vouch for him. He is all right now, though I can't say how he will be at 12 o'clock. But I have examined his head and find him thoroughly normal at present."

Dr. Love rose and got even on his introducer at once, and

then said the reason he appeared in a dress suit was because he had learned from experience to carry one in his pocket handkerchief when he went traveling. "Seven years ago," said Dr. Love, "the custom of holding these banquets was inaugurated at St. Louis. Long may it be perpetuated."

Dr. Hughes responded to the first toast, that of the Editors' Association. He greeted the assemblage as he had had the pleasure of doing last year in the Arlington Hotel in Washington. "We are going to see all the sights of Chinatown, Benicia Bay, the Midwinter Fair without the Plaisance, and last, but not least, San Francisco's warm-hearted and beautiful wives and daughters." He entered upon a eulogistic tribute to the value and importance of medical journals to the profession, and also to the outside world. "We help commerce itself," he said, "for we keep men in condition to get up and get a move on, and keep commerce lively."

In the absence of Dr. James F. Hibberd, President of the American Medical Association, who is eighty years old, ex-President Henry O. Marcy, of Boston, did the honors for the National Medical Association.

With the true gastronomic recklessness of physicians the banquetters plunged into sweetbread patties and all manner of indigestible dainties, and the speeches went on.

Dr. John Morris, one of the best known physicians of Baltimore and a great wag, told how he once met a seedy friend who asked for a loan. "I don't like to give you money upon the street," I replied, "but here is a ticket for a banquet—a \$10 affair. You can get enough for a week." "Any speeches?" he asked. "Oh, yes; Chauncy Depew, McVeagh and others—fine speakers." "Oh, Lord," he said pitiously, "I haven't eaten for three days, but keep the ticket; I would rather starve."

Dr. P. O. Hooper, of the American Medical Association, spoke, and was followed by John B. Hamilton, editor of the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, the largest of its kind in the country.

Winslow Anderson was the first San Franciscan to speak. He responded to "Our Guests," and bade the editor-doctors a hearty welcome to the Golden State.

Dr. R. H. Plummer, Chairman of Committee of Arrangements, seconded Dr. Anderson's remarks of welcome in a few well chosen words.

Dr. Lane, as President of the Cooper Medical College, told of the fine old physician who had first planted the tree of medicine in California, and then Dr. Taylor, of San Francisco, the retired physician and present attorney, answered to a sentiment which was fittingly expressed in Shakespeare's words: "An honest man he is who hates the slime that sticks on filthy deeds." Dr. Taylor spoke of the affection he bore the medical profession and how he always felt identified with it, in spite of the twenty-one years he had been pursuing a different calling.

"Woman" came in for her share of adulation under the able handling of Dr. Lyman Beecher Todd, of Lexington, Ky., and "The Medical Purveyor, Handmaiden of the Physician," was responded to by Dr. A. L. Hummel, of Philadelphia. Dr. R. Beverly Cole responded eloquently to "The Old Guard." The banquet did not break up until a late hour.

Those invited were:

A. Wyeth Hamilton, L. C. Lane, R. H. Plummer, J. F. Hibberd, C. H. Hughes, R. E. Queen, I. N. Love, R. B. Cole, J. A. Wyeth, S. Parkinson, E. R. Taylor, Warren Olney, J. D. V. Middleton, W. W. Kerr, W. F. McNutt, J. W. McLean, W. R. Cluness, J. F. Morse, J. L. Frazier, G. W. Woods, T. W. Huntington, W. E. Briggs, Walter Lindley, J. H. Wythe, W. A. Briggs, W. P. Redington, H. Michaels, A. Mack, J. Rosenstein, Washington Ayer, Clinton Cushing, C. N. Ellinwood, R. L. Rigdon, A. Hart-suff, W. S. Thorne, J. O. Hirschfelder, William T. Fonda, William Fini-ger, J. C. Queen, L. B. Todd, B. L. Coleman, E. D. Ferguson, Justin Steer, S. Pollak, Robert Levy, P. O. Hooper, I. N. Quimby, F. C. Greene, A. C. Cotton, H. Brown, W. B. Rogers, — Jerome, Donald Maclean, J. M. Duff, W. F. Jarvis, A. L. Smith, John Morris, S. Loving, G. W. Stoner, J. J. Mulheron, W. W. Imrie, George M. Gould, M. F. Shrody, Winslow Anderson, S. O. L. Potter, N. F. Essig, F. W. Sultan, B. T. Whitmore, M. M. Walker, J. D. Griffith, W. R. Ballard, W. W. Watkins, C. G. Chaddock, George Wilkinson, F. P. Foster, A. L. Hammond, J. King, G. B. Shattuck, E. W. Cushing, L. B. Edwards, W. F. Winn, H. A. Hare, E. Martin, A. W. Brayton, Theo. Potter, J. E. Minney, J. V. Shoemaker, H. Bert Ellis, J. C. Denise, J. B. Hamilton, F. L. Simon, A. L. Fulton, Frank Woodbury, W. H. Hancock, J. G. Kirvan, F. S. Parson, J. E. Harper, E. Lanphear, E. S. Briggs, A. J. Stone, F. D. Crothers, H. O. Marcy, W. Wyman, I. C. Scott, C. W. Smiley, Dr. Barnet, J. W. Keating, F. W. Mann, A. R. Baker, E. Walker, H. P. Newman, George Wilkinson, H. D. Holton, A. C. Bernays, E. H. Hughes, R. T. Morris, W. H. Evans, H. N. Moyer, L. A. Duhring, H. C. Coe, J. C. LeGrande, E. O. Shakespear, E. F. Ingals, E. Montgomery, P. H. Millard, A. Garcelon, W. B. Atkinson, J. W. Duff, J. S. Marshall, G. C. Stockton, L. D. Bulkley, H. McGuire.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO. 68 WARASH AVE., CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual subscription to THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

SATURDAY, JUNE 30, 1894.

SCHOOLS OF PRACTICE.

In the trial, still pending before a Circuit Court in one of our largest cities, of a petition for a writ of mandamus against a State Board of Health—which is also a medical examining and licensing body—to compel the Board to issue its certificate, authorizing the petitioner to practice medicine and surgery in the State, the plea is made in support of the petition that the Board is actuated, in its refusal to issue such certificate, by hostility to the school of practice of which the petitioner is an adherent; and, is moreover, dominated by members who are identified with colleges which are competitors and rivals of the college of which the petitioner is a graduate. It is not necessary, for the purpose of this article, to indicate more definitely the State Board which is thus attacked, nor to advertise more widely the institution which is seeking to pose as the victim of oppression and persecution. The suit, in itself, is referred to only as the occasion for pointing out some defects in the practical execution of legislative attempts to regulate the practice of medicine.

It too often happens that, as in the present instance, licensing and examining bodies embrace in their membership those intimately connected with teaching and graduating institutions. It is, perhaps, natural that this should be so; the appointing power, in casting about for *materiel* for such bodies, is very apt to be attracted to those who have already attained prominence in the profession as teachers and educators; and, other things being equal, the appointment of such prominent individuals seems, *prima facie*, to be fit and proper. But when it is considered that these gentlemen are called upon in the discharge of their duties as examiners and licensers, to sit in judgment, not only upon their own graduates, but upon the graduates of other and often rival schools, such appointments are seen to be eminently unfit and improper.

The logical tendency of all serious effort for a

higher standard of qualification for the practice of medicine is toward the absolute divorcement of the teacher from the examiner and licenser—the devotion of the medical college to its legitimate function as an organization of instructional agencies, pure and simple; the creation of an examining and licensing body to judicially determine the results of that instruction. Obviously, the *personnel* of these two agencies may not be identical without the risk of lending color to such charges as those set up in the suit which is made a text for these comments.

Another and a much more readily cured defect in the current system of licensing and examining, is that which grows out of taking cognizance of “schools of practice.” In this mandamus suit it is plausibly urged as a sufficient reason for the Court’s interference that, while there is representation on this Board of the regular, the “homeopathic” and the “eclectic” schools, there is none of the particular school to which the petitioner belongs. With a court, still more with a jury, such a plea will undoubtedly have weight; and whatever of plausibility it may have is gratuitously furnished by the Board itself.

Unlike the laws in some States, the law creating this Board and defining its duties, etc., does not require it to take cognizance of any school of practice; but in its rules and regulations it is provided that if an applicant for license on examination “has special views of theory and practice of medicine or of therapeutics a special examination in such branches will be held.” It is urged upon the Court in this case that there is no member of this Board qualified to examine the petitioner on the theory and practice and therapeutics of his school; that the members one and all, are prejudiced against his school and its practice, and that great injustice is thereby done him and those like-minded unto him in this respect.

Why have “special examinations” in these branches? Why have any examinations at all in theory and practice, *materia medica* or therapeutics?

If, upon examination, an applicant for the license to practice, be found well grounded in anatomy, physiology, chemistry, pathology, surgery, obstetrics, gynecology and hygiene—the branches of medical science common to all schools—his qualifications for the practice of medicine have been sufficiently demonstrated; his views and theories on the etiology of disease and on the action of remedies may be safely eliminated from the examination.

Practice and therapeutics are expressly excluded from the examinations in many States—notably in Alabama, where the regulation of medical practice is, probably, more thoroughly systematized and with more benefit to the profession and to the public than in any other State of the Union. Where the law does not require otherwise, boards of examiners would do well to follow this example and thus re

move the pretext for future charges of "intolerance," "proscription" and similar terms addressed to the ears of the groundlings.

THE TERM NEUROSIS.

The uses made of the term "neurosis" in the medical literature of the present day strongly suggests a certain indefiniteness in the concept it conveys to the average medical writer on the necessity of a new definition. In the latest and most elaborate medical dictionaries we still find its principal signification given as "a functional nervous disease, without ascertainable structural lesion," though some, like Billings and Thomas, also allow it in one sense to cover all nervous disorders in general. If neurosis, however, is used in this sense, it can not at the same time be applied to any special class of these affections, as would seem to be usually the case. The neuroses are very commonly spoken of as a class apart, a special type of nervous disorders, and among them we find included not only hysteria (which is really a psychosis in the medical sense of the word) and neurasthenia, with their manifold phases, epilepsy, chorea, migraine, exophthalmic goitre, and other diseases of undetermined pathology, but also infectious diseases like tetanus, disorders with observed structural lesions like paralysis agitans, acromegaly, certain trophic affections, and even club feet and hare-lip and various other structural defects of degeneracy. The widest signification of the term can only include these last, in the sense that they are more or less the results of nervous defects, and this they share with every possible form of congenital or developmental malformation. Genius is said to be a neurosis; beauty and deformity might equally well be thus designated.

The fact seems to be that in the progress of pathologic research the old class of functional nervous disorders is dying out, or rather medical men are losing faith in it and they are becoming looser in their usage of the terms that belonged to it. The general and the special meanings of the word, neurosis, are used confusedly; when one is employed there is also a flavor or suspicion of the other, and the scientific definiteness of the term is sacrificed. This has been particularly noticeable in some recent papers, and it is not an advantage in any respect.

It is questionable whether a new definition of the word is desirable, and whether we have not yet a use for it in the special meaning it has hitherto held. It need not be, as some have claimed, merely an expression of discreditable ignorance, or a limbo for the results of inefficient diagnosis; there will always be some forms of disease of undetermined pathology, and there is no harm in grouping them under a common name and of using the same, if we only guard against the too common error of assuming that giv-

ing a name to a thing implies its full explanation. Neurasthenia, hysteria, and the more general term "neurosis" can still be used scientifically, and meet a want; what we need is more accuracy in their employment. The usage and not the vocabulary needs most to be reformed.

THE CLERGY AND THE MEDICAL PROFESSION; THE MEDICAL CODE A TONIC.

It has long been recognized that the best supporters—on paper—of quack medicines are the Protestant clergymen. No class of persons, except it be the conductors of the religious weeklies, concoct more false testimonials for belts and nostrums and anti-drink specifics than do the average clergymen. Why this is so, is sought to be explained by SIR JAMES CRICHTON-BROWNE, at the opening of the Sheffield Medical School.

"Quackery," says SIR JAMES, "is patronized in high places; it is supported not only by the dull and ignorant, but by the presumably educated and intelligent. It may flourish in our manufacturing centers, such as Sheffield, but the very hot-beds of it are our fashionable watering places and health resorts, and I am assured that, while our skilled artisans are least of all given to quackery, our learned clerics are most addicted to it. Well, I think our learned clerics should seriously reflect, that in giving countenance to the nostrums of the empire, they exhibit a credulity and superstition that must seriously impair their usefulness in their sacred calling, with all thoughtful men. Great may be the faith, but small must be the wisdom of the man who believes he derives benefit from a non-electric belt! What exegetical insight is possible in him who swallows patent pills? They should remember—these learned clerics—the commendation of the Bereans, and they should search the Scriptures, that is to say the newer scriptures of science and common sense, to see if these things be so."

But if this they fail to do, they must, as SIR JAMES shows, await a day of judgment according to the rule of right. His contention is that there is "above and beyond any special code of honor appertaining to the medical profession, the general code of ethics, to which that and all professions are amenable, and as regards that general code, I would say that medical practice is daily demonstrating to those engaged in it, its reasonableness and wisdom. To those who faithfully pursue it, medical practice affords an ethical training and discipline of the best kind; it opens a refuge from pessimism in the opportunities it gives for the relief of sorrow and suffering; it unveils, in the tender ministrations of the sick-room, some token of the angel as plainly as competition discloses vestiges of the tiger and the ape, and it fosters that wide sympathy that yields hope for the future of our

race. 'The man shall die,' said DAVID, 'not because he did this wrong, but 'because he had no pity'.'

Concerning that branch of ethics that we call "our Code," DR. CRICHTON-BROWNE is free to admit that the majority of his colleagues are competent to pursue the path of rectitude without a printed guide-book, but for the weaker brethren, "a code of honor supplemental to the general ethical code is an *admirable tonic*." Let those who are strong, and need not a physician or a prescription, remember there are always the weak with us and the Code is their best tonic.

INTERNATIONAL MEDICAL MISSIONARY INSTITUTE, NEW YORK.

In New York city, a training school for indigent young men and women, desirous of fitting themselves for life in foreign lands, has been in operation about twelve years. It is conducted by DR. GEO. D. DOW-KONTT at two houses on East Forty-fifth Street. The present accommodations suffice for students not in excess of twenty, whereas eight times that number are on the books as applicants for admission. The trustees, having obtained subscriptions amounting to \$100,000, look forward to the construction of a new building with room for two hundred, or two hundred and fifty pupils. They will be ready to break ground as soon as there shall be \$250,000 on their subscription list, and men of large means and practiced liberality have expressed their favorable opinions of the work in hand. The last annual report of the institution says:

"We believe we have found a solution of the problem of true missionary work in the establishment of a fully equipped medical missionary college. Our society is incorporated and has a board of eighteen managers of various denominations. The average annual income for the last six years has been about \$10,000. In addition to training students born in this country, the society has had in training the natives of twenty foreign countries. We shall begin putting our plans into execution as soon as the site is obtained. For the completion of the necessary fund we look to the generosity of those interested in true missionary work."

SUBJECTS ON WHICH OPINION EVIDENCE IS INCOMPETENT.

Evidence in the nature of expert or opinion testimony, is not competent, and can not be received, the Supreme Court of Nebraska holds, in the case of the Atchison, Topeka & Santa Fe Railroad Company v. Lawler, decided May 2, 1894, upon a subject of inquiry which is of such a kind or character as to be within the knowledge of men of common education and experience, and to require no special skill, knowledge, or experience in considering or forming an opinion upon it, as the jury will be presumed, if all the facts are before them, to be competent to draw the inference and form the opinion from such facts.

SECTION REPRINTS.

Gentlemen desiring copies of section reprints of particular sections will please send their names to the JOURNAL at once, unless they subscribed at the meeting. No section book will be published unless there are at least fifty subscribers for the volume.

CORRESPONDENCE.

STAFF CORRESPONDENCE.

A Visit to Yellowstone National Park.

After the sessions of the ASSOCIATION had adjourned *sine die* and the San Francisco meeting had passed into history, some of the members took their way southward as far as Los Angeles and Coronado Beach, or visited the famous Hotel Del Monte at Monterey, and admired its magnificent park and gardens. Some climbed Mt. Hamilton to see the famous Lick Observatory, and returning, drove out to inspect the great Leland Stanford University at Palo Alto and the stock farm in the vicinity, where the equine aristocracy reside. Others turned northward to Portland and Tacoma, to explore the Sound regions, the scenes of the recent floods, and from thence went to Alaska, or turned their faces eastward in the direction of the Yellowstone National Park, which they ultimately reached after many vicissitudes that upset carefully laid plans and caused some vexatious delays. Our party took the Union Pacific direct to Ogden and Salt Lake City, where some of the local physicians distinguished themselves by their courtesy and hospitality to their guests. Many of the delegates and members on their way to the Park spent part of a day at Butte, Mont., where they were also warmly received and entertained by the physicians.

A brief account of a tour of the Park may prove interesting and not inappropriate, since the party of members of the AMERICAN MEDICAL ASSOCIATION who started for Mammoth Hot Springs on the morning of June 18 was the first this year to go over the Continental Divide to the Yellowstone Lake, and thus make the complete tour of the Park. This party consisted of C. A. Wheaton and A. Macdonald, of St. Paul; M. P. Van der Horck, of Minneapolis; Dwight W. Day, of Eau Claire, Wis.; O. Wellington Archibald, of Jamestown, N. D., and Frank Woodbury, of Philadelphia. Capt. George S. Anderson, U. S. A., in charge of the military post and Acting Superintendent of the Park, under authority of the Secretary of War, being acquainted with some of the party, kindly accepted a very pressing invitation to spend the week in going through the Park in their company. Capt. Anderson combines distinguished executive ability with great geniality and social qualities which make him a delightful companion, while his acute interest in everything pertaining to the Park, and his abundant information upon every subject which attracts the attention of visitors, constituted him a most desirable and important addition to the party.

All visitors enter the Park by way of Cinnabar, fifty-one miles distant from Livingston, which is on the main line of the Northern Pacific Railroad. Upon arrival of the delegates at Livingston, the railroad company very courteously made up a special train to convey them from Livingston to Cinnabar, where stages were in waiting to take them to the Mammoth Hot Springs, the first stop in the Park. In the vicinity of the hotel is the U. S. military post already incidentally referred to. The miniature hospital here is under the direct management of Capt. Chas. M. Gandy, M.D., who is an efficient officer as he is a refined and cultured gentleman. We were once more impressed with the

thought that the AMERICAN MEDICAL ASSOCIATION would be the gainer if all the medical officers in the United States service could become active members of our National medical association.

Near the Mammoth Hot Springs Hotel are the first evidences of geyser action in the form of springs of boiling water which deposit mineral salts, and here these deposits have in the course of ages formed immense terraces of travertine, which is almost pure calcium carbonate. In this formation various forms of algæ flourish which give color, and produce a pleasing variety of tints, to the formations known as the "Cleopatra Terrace," "Jupiter and Minerva Terraces," the "Orange Geyser" and the "Elephant." Starting from the hotel on the first day of the trip, the road passes the formation and enters Gardner Canon, through a defile called the Golden Gate. The road, which is an exceedingly good one, winds around the side of a mountain, having on one side the cascade of the river and on the other steep peaks extending upward to the region of perpetual snow. Evidences of volcanic action are numerous, but none is more striking than the cliffs of obsidian, or volcanic glass, which are passed a little beyond the canon. The scenery is very fine, the mountains being covered with trees up to the snow line; while here and there small lakes are seen, which resemble gems in their brightness of color, some being blue, others green or prismatic in their shades. The Twin Lakes, although lying side by side, are entirely different in their color, one being emerald, the other sapphire. Springs of cold water are frequently encountered, but rarely are any seen which so closely resemble the famous Apollinaris Spring as the one found near the obsidian cliffs, which furnishes a soda water of very pleasant taste, like that for which it has been named. At the Norris Geyser Basin a stop of an hour or more is made for lunch. Here there is a large mass of the formation already alluded to, in which there are frequent fissures which give vent to steam, or rivulets of hot water. In the sheltered places on the mountain side are patches of snow which furnish a marked contrast to the steaming plateau. This is noticed more particularly at the side of the road where the "Old Growler" geyser pours forth a constant volume of steam and hot water from the midst of a snow-bank.

Starting again after lunch, the party traversed the Gibbon Canon, where a fine view of the falls of the Gibbon River are obtained. A stop for the night was then made at Fountain Hotel, having travelled over forty miles the first day. Immediately in front of this hotel is the "Fountain Geyser" near which are the "Paint Pots," as they are called. The latter are small lakes of pigment of different colors, kept constantly in agitation by escaping bubbles of steam. The "Fountain" was the first real geyser we had seen. It spouts about every half hour, sending upward a large stream of water with vast clouds of steam, the exhibition lasting about five minutes. The hot water from the geysers is piped into the hotel for bathing purposes. As it is alkaline and somewhat sulphurous, it should have valuable medicinal effects; it certainly has a very pleasant action upon the skin. The second day was full of incident. After leaving the Lower Geyser Basin, Fire Hole River was soon reached. This is a large mountain stream stocked with rainbow and speckled trout, which we readily demonstrated by catching some two pounders of very gamey character. It is a strange sight, however, to observe streams of boiling water pouring over the bank, while a little beyond two geysers, the "Morning Glory" and "Riverside," at intervals threw large streams of boiling water out over the stream. Soon we came into a district surrounded by geysers, steaming and spouting like whales on every side, the place being not inappropriately termed "Hell's Half Acre," except as to area, which is

nearer ten acres. This probably was not in the mind of the author who wrote on "Ten Acres Enough," or he might have altered his title and pronounced it more than enough. Here fifty-one miles from Mammoth Hot Springs is "Old Faithful" which plays every sixty-five minutes, sending a stream nearly 200 feet into the air lasting about ten minutes.

Among the noted geysers in this field are the "Giant," "Grotto," "Castle," "Saw Mill," "Oblong," "Artemisia," "Lion," "Lioness," and "Cub." This being enough for one day's stock of impressions, we turned back eleven miles to the Fountain Hotel for the night. The third morning we passed the geysers again, and leaving the Fire Hole River, which is the commencement of the Madison, one of the sources of the Missouri River, we crossed the Continental Divide and soon came to the Snake River which empties its waters finally into the Pacific Ocean. In crossing the Divide, which is over 9,000 feet elevation, we found considerable snow in the road, which in places was above the hubs of the wheels, so that on the 20th day of June we were stuck in the snow and were obliged to get out of the wagon and walk on the frozen surface. The views of Shoshone Lake and the mountains were very impressive, and reminded us of scenery in Norway, the firs and hemlocks, and Kepler's Cascade completing the picture. Several elk were seen, including a young calf at the side of the road, which our party got out to pet, while the anxious mother viewed the proceedings from the adjacent hillside, where she was half concealed by the brush. We reached the Thumb, nineteen miles from the Upper Basin, in time for lunch. Near this place are boiling springs in which a fish or an egg can be cooked in a few minutes. The Thumb is a bay in Lake Yellowstone which, in its southern portion, is extended or spread out in inlets resembling a human hand. The lake is a beautiful body of fresh water some thirty miles in length by ten to twelve in breadth, and is bordered by snow-capped mountains which remind one of the Swiss Alps. There is a steamboat plying on the lake, which has the distinction of being the only steamboat in the world at this altitude. On this boat we took passage to the northern end of the lake near its outlet into the Yellowstone River. We here found a good hotel, the Lake House, where we stopped for the third night of our tour through the Park.

The following day we started about 9 o'clock for the Grand Canon, passing the beautiful Hayden Valley, in which we saw some groups of deer, and we also passed the "Mud Geyser," which is a cavern, in the recesses of which black mud eternally bubbles and boils like a witch's caldron, presenting a most gruesome and uncanny appearance. In the afternoon, we took a light wagon and drove over to Inspiration Point and Lookout Point. The views of the Upper and Lower Falls are entrancing, the latter having a sheer descent of 360 feet, which is double the height of Niagara Falls, but the views of the Grand Canon of the Yellowstone from Inspiration Point are almost unearthly in their grandeur, to which no words of description can do justice. At the bottom of the canon, a thousand feet below, the river pursues its tortuous course, like a green ribbon, between precipices and peaks of varied hues, crimson, yellow, white, and other shades which combine to produce a weird unnatural effect. On a peak below us, there is an eagle's nest in which the young birds are plainly visible, quite unconscious of their apparently perilous position. In looking down the canon, the view is seen which Moran has represented upon canvas, but which defies the artist's brush or the pen of the ready writer, to reproduce or describe its sublimity and unconventionality if we may use this word with such application. Leaving the Grand Canon with regret, but much refreshed by a good night's rest, we took stage again for Mammoth Hot Springs, our starting point, where we arrived

on Friday evening, having stopped at Larry's, at the Lower Basin, for lunch. The following morning the party left the Park and returned to the every-day work-a-day world through the Paradise Valley of the Yellowstone as we had entered it a week before. In reviewing our recent impressions, it was thought proper to express in a formal manner, our opinion of the resources of the Park from a medical and hygienic standpoint, and the following was accordingly drawn up and signed by the physicians who had just had such unequalled opportunities of inspecting the locality under the direction of its presiding genius and genial Superintendent, Captain Anderson.

The testimonial read as follows:

"MAMMOTH HOT SPRINGS, June 26, 1894.

The Yellowstone National Park, having an average elevation of about 8000 feet, an inland mountain climate, mineral springs of special value for medicinal purposes, and pure air ozonized by innumerable coniferous trees,—impresses us as being preëminently suited to be the site of a great sanitarium. Its mineral waters, which are of varied chemical composition, are in no way inferior to those of the celebrated European baths and springs, and we believe that they should be utilized, by the medical profession of the country especially, in the treatment of diseases for which such waters are commonly employed."

LETTER FROM EUROPE.

No. II.

PRAG, BOHEMIA, June 2, 1894.

To the Editor:—In all German schools of medicine, pathology is given a most prominent place. In accordance with this idea, the medical faculty of the Prag University obliges the student to give much attention to this subject and has a separate building for pathologic anatomy. This building is large, modern, well constructed, and admirably adapted to the work. The Professor, his three assistants, the demonstrators, have each separate rooms where they may work undisturbed. There is also a well equipped bacteriologic laboratory in connection with this department, entirely distinct from the one of the Institute of Hygiene, which is in another part of the city, and presided over by Hueppe. The room for microscopy where class instruction in pathologic histology is given is large, well lighted and well fitted for such work. Tables, chests, shelves, etc., are set apart in this room and in side rooms, for special workers in pathology. The autopsy room is so arranged that three autopsies can be made at the same time.

The museum of pathologic anatomy, containing about five thousand specimens, is a model of its kind. There is not a single specimen that can not be immediately used for demonstration. No dust has to be removed or change of alcohol made before it is brought to the class, for under the watchful eye of Prof. Chiari, the preparations are kept always ready for presentation. Scarcely a gross pathologic change can be mentioned that has not its representation here; and Prof. Chiari can step to the museum and aided by his wonderful memory, almost immediately lay his hand on the very specimen he desires to use to illustrate his point. New preparations are being constantly added. I was not aware until I came here of the extreme value, as an adjunct in teaching, of a well stocked, and well kept, museum. Too many of our museums, I fear, are mere unsystematic collections of pathologic curiosities and monstrosities, gazed at through the glass doors with half understanding eyes by a few students, or displayed to the curious visitor as one of the great possessions of the college, a treasure no well regulated medical institution should be without.

I may say here, while speaking of museums, that through the kindness of Prof. Rabl, I was enabled the other day to see the museum of anatomy in the Anatomical Institute.

Here, too, is a collection well utilized. At the time of my visit, at least twenty specimens were absent from their places on the shelves, as they were to be used the following hour to illustrate a lecture on the anatomy of the nervous system. And I noticed another excellent feature of the Anatomical Institute, viz., a study room for students where were skeletons, loose bones, charts, etc., to aid in the study of anatomy, and all freely accessible to the student. The advantage of studying anatomy with the bone directly before one or in one's hand is self-evident. I was interested in a preparation of the vascular system made by the celebrated Hyrtl in 1848, when he was the anatomist at Prag.

To return to the Pathological Institute. Every morning between 8 and 11 the autopsies are made by the Professor or his assistants. On an average about five or six autopsies a day can be seen. A week ago I saw nine in one day and on another day ten. At 11 o'clock all the specimens are reviewed by the Professor, who corrects errors in diagnosis, investigates further when necessary, criticises the work of his assistants, discusses the cases, etc. I find this one of the most enjoyable hours of the day. At 12 is the didactic lecture on pathologic anatomy. At 1 o'clock the specimens from the autopsies are demonstrated to the students, who, after the demonstration, can examine and handle the specimens as freely as they wish. Whenever a patient who has been before the clinic dies, a "clinical section" is made by Prof. Chiari himself, unless there are two or three to be performed at the same time, when assistants aid the Professor. A "clinical autopsy" is witnessed by the clinical professor and his class. To see a patient in clinic, listen to the clinical exposition of the case, have the opportunity of examining the patient in the ward, and then to witness the autopsy, is certainly the ideal method of studying medicine.

All specimens from surgic, gynecologic and obstetric clinics come to this Institute for pathologic diagnosis. Every day specimens of the most various descriptions—tumors, tubercular joints, gangrenous limbs, extrauterine pregnancies, extirpated glands, ovarian cysts, prematurely born fetuses, etc., are brought to Prof. Chiari for his diagnosis. A brief clinical history always accompanies the specimen. When the diagnosis has been made, and this necessarily often involves microscopic examination of the specimen, a card is made out and returned to the clinical professor with the pathologic diagnosis. It is, perhaps, needless to add that bacteriology as one of the important aids to diagnosis is freely made use of in the autopsy work and wherever necessary in the histologic examination of specimens from clinics. No post-mortem diagnosis leaves the Institute that has not been passed upon by Prof. Chiari.

It is somewhat comforting to find that we in America, are not the only ones who sometimes err in matters of diagnosis. I have seen here the best of the teachers make mistakes. Perhaps the most instructive feature of it all is to see the interest the diagnostician takes in the autopsy, and his eagerness and readiness to profit by his errors. The European teachers certainly have a great advantage in having their mistakes corrected by autopsy. The lesson of a mistake of this kind corrected, is of more value than the most accurate diagnosis. It was very amusing a few weeks ago, to see the expression on the face of a surgeon who witnessed the autopsy on the woman from whom, the day before he had removed the uterus with an enormous myoma, the patient dying, as the autopsy showed, from thrombosis of the pulmonary artery. During the operation he had separated the tumor from the under surface of the liver, to which it had become adherent, ligating several large vessels. The autopsy showed that what had been regarded as the liver was a large lobe or nodule of the tumor, entirely free from the liver and other organs, and showing plainly where its

connection with the main tumor mass had been severed by the surgeon. When this mass was slipped under the liver its edge just projecting, felt very much like that of the liver, even having a little indentation corresponding to the notch for the gall-bladder, so that one could clearly see how a mistake of this kind could be made. The surgeon's look of amusement, incredulity and chagrin as the revelation was made was worth remembering.

Other errors I have seen in all departments. In but a few instances could the error be regarded as one due to carelessness. Usually the error has been one of judgment. I mean that the utmost care is usually taken in examination of cases, more care than is usually seen in our hospitals. Too little importance is, at times, as it seems to me, attached to the anamnesis. And there is a tendency with some also, to be drawn away from some cardinal, vital symptom, by the findings of some of the newer methods of diagnosis whose value may not be, as yet, fully established or is, in part, theoretical, *e. g.*, some of the urinary or blood findings, or examination of the stomach contents.

Of the personal characteristics of the various teachers, here is not the place to speak; nor is it in good taste to institute comparisons. Yet I can not forbear to speak in the highest terms of Prof. Chiari, both as a teacher and a scientific man. His lectures and demonstrations are clear, terse, always up with the times. He knows as well what not to tell students as what to tell. He always creates the impression of having an immense reserve fund of knowledge, as telling you what was best for you to know and not all he knows. He works rapidly and accurately, and his post-mortem macroscopic diagnoses rarely have to be corrected by the microscopic or bacteriologic examinations. He is a strict disciplinarian, demanding of all who work under him quick obedience and the same fidelity and thoroughness that he exemplifies in his own daily work. He is personally watchful over all the details of the work in the Institute and is, as he himself says, very particular and pedantic. He is impartial in his praise or censure of all work done, according as it deserves the one or the other criticism. One who desires to do special work in pathology would find him a careful, inspiring and faithful guide. Were it permissible in a letter of this kind to say more concerning his personal characteristics, I should gladly pay tribute to the many charming and manly qualities of Prof. Chiari.

I can not forbear adding, as a sort of postscript to this letter, a description or rather a mere enumeration of the interesting post-mortem cases seen in the Pathological Institute this morning, June 4:

- 1, Tuberculosis of the lungs; secondary basilar meningitis in a child 9 years old;
- 2, broncho-pneumonia in a child;
- 3, carcinoma of the liver, probably primary in the liver; icterus gravis;
- 4, primary carcinoma of the common bile-duct; icterus gravis, etc.;
- 5, splenic-myelogenic leukemia with intercurrent erysipelas as the immediate cause of death;
- 6, congenital syphilis in a child with characteristic, well marked changes in heart, lungs, liver, spleen; osteochondritis in all the bones examined—femur both ends, tibia, humerus, ribs. Fracture of femur from version during parturition. Child dead ten minutes post-partum;
- 7, infiltrating carcinoma of the stomach with clinical history showing difficulty of diagnosis in so many of these cases, though it had been made correctly (Pribram) in this instance;
- 8, old appendicitis, suppurative phlebitis, pus still visible in vessels leading from appendix to mesentery, embolic abscesses of liver, pyemia, with retro-pharyngeal and double middle ear abscesses;
- 9, syringomelia; clinical course somewhat resembling tabes dorsalis; death due to typhoid fever developed during stay in hospital;
- 10, old echinococcus cyst of brain, right occipital lobe and encroaching, by pres-

sure, on posterior horn of lateral ventricle. The cyst, the size of a walnut, was surrounded by cicatricial tissue and a capsule so hard from calcification as to require the bone shears to cut it. Echinococcus hooklets found in the softened mass in the interior. History showed patient healthy up to 15, then epileptic attacks frequently recurring; no focal symptoms; gradually developing paranoia, death at 22 during an epileptic attack. Chiari's theory that at the time of the first attack, seven years before, the infection with the echinococcus occurred, certainly seems rational.

I felt as I witnessed the autopsies and saw these specimens, listened to the epitomized clinical histories and the clear and concise demonstrations of Prof. Chiari, that I had food for reflection and study for a week.

Very truly yours, JAMES B. HERRICK.

Woman's Hospital and Foundlings' Home.

DETROIT, June 22, 1894.

To the Editor:—Dr. Longyear, President of the medical staff of the Woman's Hospital and Foundlings' Home, has requested me to ask you to notice in your journal the following resolution, which was adopted at a recent meeting of the Trustees of that Hospital:

WHEREAS, The arrangement, providing that nurses from the Correspondence School of Health and Hygiene be allowed to practice in the Woman's Hospital and Foundlings' Home, was made without due consideration; therefore

Resolved, That such arrangement be, and is hereby discontinued from this date, and that a resolution to the effect that no relation whatever exist between the said Correspondence School of Health and Hygiene and the Woman's Hospital and Foundlings' Home be published in medical journals already specified.

MRS. KATHARINE V. H. WELLS,
Recording Secretary.

MUNICIPAL HALL, PITTSBURG, PA., June 14, 1894.

To the Editor:—Please insert the following in your journal:

To the Members of the Medical Board holding examinations in Pittsburg:—We, a committee representing the candidates from the various colleges, by joint resolution hereby tender for ourselves and colleagues our sincere thanks for the courteous reception extended and the fair treatment shown to us.

Resolved, further, that this resolution be spread in the medical journals of the various States.

Represented:—Drs. A. D. Davidow, Chairman, College of Physicians and Surgeons, Chicago; A. C. Davis, Secretary West Pennsylvania Medical College, Pittsburg, Pa.; W. F. Bayley, University of Tennessee Medical College; W. A. Clementson, Jefferson Medical College, Philadelphia, Pa.; R. B. Cunningham, Louisville Medical College, Kentucky; D. Molyneaux, Royal College of Surgeons, Dublin, Ireland; J. C. Walker, University Medical College, New York; W. J. Cooper, College of Physicians and Surgeons, Baltimore, Md.; Clemens R. Jones, Columbus Medical College, Ohio; John W. Kiger, Medical College of Ohio; Mary E. Chrystie, Woman's Medical College of Pennsylvania; McCurdy Bricker, Medical College of Indiana.

SOCIETY NEWS.

New Hampshire State Medical Society.—The annual meeting of the New Hampshire State Medical Society was held at Concord, June 18 and 19, 1894. The last day's proceedings were as follows:

Officers elected—President, Dr. David P. Goodhue, of Springfield; Vice-President, Dr. E. F. McQuesten, Nashua; Treasurer, Dr. H. M. Felt, Hillsboro Bridge; Secretary, Dr.

G. P. Conn, Concord; Executive committee, Drs. Charles R. Walker, Concord; Geo. D. Towne, Manchester; F. A. Stillings, Concord; W. T. Smith, Hanover; Dr. F. E. Kittredge, Nashua. Trustee for three years, Dr. Levi G. Hill, Dover; Anniversary chairman, Dr. Robert Burns, of Plymouth.

Delegates to Dartmouth Medical College: Drs. A. Noel Smith, Dover; Ira H. Adams, Derry Depot.

Committee of Arrangements: Drs. F. A. Stillings, D. Edward Sullivan, Arthur K. Day, Chas. W. Lovejoy, N. W. McMurphy, Concord.

Board of Censors: Drs. D. S. Adams, G. D. Towne, Manchester; Thomas Hilland, Concord; John W. Parsons, Portsmouth; C. B. Hammond, Nashua; C. B. Drake, West Lebanon; Leonard Jarvis, Claremont; J. C. Eastman, Hampstead; I. J. Prouty, Keene; M. E. Lathrop, Dover.

Council: A. G. Straw, D. G. Adams, Manchester; W. K. Wadleigh, Hopkinton; D. Edward Sullivan, Concord; H. A. Weymouth, Andover; E. L. Carr, Pittsfield; G. D. Frost, Hanover; S. N. Welch, Sutton; J. W. Staples, Franklin Falls; G. S. Gove, Whitefield; G. H. Saltmarsh, Lakeport; Edward French, Concord; J. F. Robinson, Manchester; J. W. Parsons, Portsmouth; S. M. Dinsmore, Keene; T. B. Sanborn, Newport; D. L. Slater, Rochester; H. M. Felt, Hillsboro' Bridge; C. B. Hammond, Nashua; C. A. Fairbanks, Dover.

Delegates to the State Societies: Maine, E. E. Graves, J. W. McGregor; Vermont, Edward Abbott, H. K. Falkner; Massachusetts, G. M. Kimball, H. T. Boutwell; Rhode Island, D. L. Stokes, F. W. Spaulding; Connecticut, A. W. Shea, W. R. Garland.

Committee on Publications: Drs. G. P. Conn, H. M. Felt. Orators: Drs. G. D. Frost, Hanover; S. N. Welch, Sutton. Substitutes, J. W. Staples, Franklin Falls; G. S. Gove, Whitefield.

Papers: Drs. Edward French, Concord; W. K. Wadleigh, Hopkinton; H. A. Weymouth, Andover; G. H. Saltmarsh, Lakeport; S. W. Roberts.

Report on Surgery: J. F. Robinson, Manchester.

Necrologist: John J. Berry, Portsmouth.

On account of the illness of President Carbee, the annual address was omitted and the time was occupied by Dr. G. P. Conn, of this city, with an interesting paper on "Sanitation in Mexico."

The anniversary dinner was served in the private dining room at the Eagle Hotel at 1 o'clock.

Dr. Ira A. Prouty, of Keene, anniversary chairman, presided, and after grace had been said by Rev. F. D. Ayer D. D., the following hour was spent in discussing the various items on the menu card, which constituted one of Landlord Pelren's famous spreads.

At the conclusion there were interesting post-prandial exercises, the sentiments and responses being:

"The New Hampshire Medical Society," President Goodhue, Springfield.

"The State of New Hampshire," Governor John B. Smith.

"Methods of Medical Instruction," Prof. Quackenbos, New York City.

"Our Lady Members," Dr. Ella Blaylock, Nashua.

"Our Brethren across the Connecticut," Dr. Hill, Bellows Falls, Vt.

"The Druggist, the Physician's Helpmeet," Dr. S. M. Dinsmore, Keene.

This concluded the exercises of the meeting which has been one of the most successful in the history of the Society.

The next meeting will be held May 30, 31, 1895.

Ontario Medical Association.—At the annual meeting of the Ontario Medical Association held in Toronto, Ont., the contract system of lodge doctoring was discussed. The special committee appointed for the purpose of considering the question reported that the Association consider all such lodge contract work unprofessional, and recommended that the medical council declare the practice as unprofessional under the statute.

This was put in form of motion and carried. The following officers were elected for the ensuing year:

President, Dr. Bruce Smith, Seaforth; First Vice-President, Dr. A. A. Macdonald, Toronto; Second Vice-President, Dr. Welford, Woodstock; Third Vice-President, Dr. Saunders, Kingston; Fourth Vice-President, Dr. Forrest, Mount Albert; General Secretary, Dr. J. N. E. Brown, Toronto; Assistant Secretary, Dr. Charles Temple, Toronto; Treasurer,

Dr. J. H. Burns, Toronto. The following committees were appointed to the chairmen named: Committee on Credentials, Dr. A. J. Johnson, Toronto; Public Health, Dr. H. J. Hamilton, Woodhill; Legislation, Dr. William Britton, Toronto; Publication, Dr. Charles Sheard, Toronto; By-Laws, Dr. G. Hodge, London; Ethics, Dr. J. W. Williams, Ingersoll; Advisory, Dr. J. D. McDonald, Toronto. It was decided to hold the next annual meeting in Toronto.

BOOK NOTICES.

An Illustrated Dictionary of Medicine, Biology and Allied Sciences, including the Pronunciation, Accentuation, Derivation and Definition of the terms used in Medicine, Anatomy, Surgery, Obstetrics, etc. And the various Sciences closely related to Medicine, Bacteriology, Parasitology, Microscopy, Botany, Zoology, Dentistry, Pharmacy, etc. By GEORGE M. GOULD, A.M., M.D. Based upon recent scientific literature. 1894. Pp. 1,633, half morocco. Philadelphia: P. Blakiston, Son & Co. Chicago: The W. T. Keener Co.

No period in the history of American medicine has been more prolific in the production of dictionaries than the present. The oldest work, that of Dunglison, has been supplemented by Thomas, Foster, Gould, Billings and Duane, and all have their good points. The dictionary of Dr. Foster, however, covers the medical terms used in the Latin, English, French and German languages, and is therefore of a different class from the others. The Century and the later editions of Worcester and Webster have given much more than the usual space to medical words.

The net result is, that the American physician of to-day is incomparably better equipped for the pursuit of medical literature than his predecessors. In the volume under consideration, the author has, so far as practicable, adhered to the reformed spelling. The author says: "I have usually recommended that in medicine the diphthongs æ and œ be supplanted by e; such usage is already well established as regards many words, and the suggestion is in strict harmony with etymology and the spirit of the language. . . . In the spelling of certain chemic words, the advice of the American Association for the Advancement of Science has, as a rule, been followed, and seems to be in the line of cautious and wise progress. The unanimous acceptance and practice of all these recommendations by the American Medical Editors' Association constitute a gratifying proof of progressiveness and freedom from irrational prejudice." The advanced and sensible views of the author in regard to spelling do not, however, seem to have influenced him in the pronunciation, and it is with regret that we observe his adherence to the English pronunciation of medical terms of Greek and Latin derivation. It would be admissible if Latin were so pronounced the world over, but when the English speaking race are themselves divided, and all the remainder of the world essentially agree in pronunciation it seems a pity to maintain a factional and provincial position. The same British, bull-headedness that insists upon calling Firenze, "Florence," Napoli, "Naples," and Livorni, "Leghorn," persists in mangling the sonorous Tuscan sounds by a British accent that is as unnecessary from a scientific point of view as it is unintelligible to all our Continental brethren. From other standpoints the work is to be commended.

Transactions of the Indiana State Medical Society.—Forty-fourth Annual Session, held in Indianapolis, May 11 and 12, 1893. Pp. 378. Cloth.

One of the most interesting papers in this volume is that of Dr. Wishard, of Indianapolis, on the medical men and medical practice in the early days of Indianapolis. The days of the pioneer have passed in nearly every portion of our now great Republic. The railway, the telegraph, the daily newspaper and the medical journal now go everywhere, and local tradition in most cases is all there is left to

inform us of the mode of life of our predecessors, the difficulties under which they labored, and the professional triumphs they met with, then unheralded by the medical press. It is, therefore, not only a pleasant task, but our medical societies should insist upon it as a patriotic duty, that the work of the medical pioneers should be rescued from the unmerited obscurity into which they have fallen. This thought seems to have animated many of our medical societies by the number of historical papers now appearing in the annual volumes of transactions. Many an operation, such as that recorded of Dr. J. L. Richmond, at Newtown, Ind., who in 1824 successfully performed the Cæsarean section by the light of a tallow candle, would be permanently lost to the world but for the work of the medical historian.

Among the other papers in the volume are many of scientific value and more than passing interest.

A list of members and a list of all papers presented to the Society from its date of organization to 1893 are included.

A Manual of Instruction in the Principles of Prompt Aid to the Injured, including a chapter on Hygiene and the Drill Regulations for the Hospital Corps, U. S. A. Designed for Military and Civil use by ALVAN H. DORR, M.D. New York: D. Appleton & Co. 1894. Chicago: A. C. McClurg & Co. Price, \$1.50.

This little book is an excellent one, but has no particular *raison d'être*, in view of the many excellent manuals already in existence on the same subject. There is nothing new or original in it, so far as we can judge. The illustrations are well executed and the typography all that could be desired.

The Care and Feeding of Children; A Catechism for the use of Mothers and Children's Nurses. By L. EMMETT HOLT, M.D. Pp. 66. Cloth. New York: D. Appleton & Co. Chicago: A. C. McClurg & Co.

The method of questions and answers for inculcating various kinds of useful knowledge is one of the most practical and useful. This sanitary catechism should be read by every one having the care of infants or young children.

The Nurse's Dictionary of Medical Terms and Nursing Treatment.—Compiled for the use of nurses. By HONORA MORTEN. Pp. 139. 32 mo. Cloth. Philadelphia: W. B. Saunders. London: The Scientific Press. 1894.

This is a handy little dictionary of the medical terms likely to be met with, or words that should be understood by nurses. It seems to be a selection from some of the larger dictionaries of the class of medical terms sought to be winnowed for the nurse's benefit. It is true that no learning may come amiss, but there are many words in the book that seem to have no special adaptation to the nurse's needs, especially as it is stated in the preface that "nurses are warned that this volume is merely meant to be used at the bedside as a temporary reference book until there is time to look up fuller works on the different subjects."

Transactions of the Fifteenth Annual Meeting of the American Laryngological Association, held at New York city, May 22, 23 and 24, 1893. Cloth. Pp. 165. New York: D. Appleton & Co. 1894.

This volume contains papers by Drs. Peyre Porcher, Delavan, Casselberry, Lincoln, Lefferts, Mulhall, Johnston, Farlow, Wright, Roe, Rice, Blois, Wagner, J. Solis-Cohen, Allen, Major, Bryan, Simpson and Robinson. All of which were published in the medical journals of that year. This volume also contains a well-written obituary notice of the late Franklin H. Hooper, M.D.

Saunders' Question Compend, No. 14.—Part I. Essentials of Refraction and the Diseases of the Eye. By EDWARD JACKSON, A.M., M.D. Part II. Essentials of Diseases of the Nose and Throat. By E. B. GLEASON, S.B., M.D. Second edition, revised, illustrated. Crown 8vo. Cloth. 1894. Philadelphia: W. B. Saunders.

However one may cavil at the whole brood of quiz compends, when they take the form of a catechism, there can

be no real objection provided that the student is clearly informed that only the outlines of the subject are given. The book before us has passed to its second edition, and will doubtless reach many more. It is an excellent instruction book on the topics named in the title.

PUBLIC HEALTH.

Congress of Hygiene.—A committee of which Sir Douglas Galton is chairman, has been formed to further the interests of Great Britain at the Eighth International Congress of Hygiene and Demography which will be held at Budapest, September 1-8, prox.

Saving of School-Life.—In his last annual report Dr. U. O. B. Wingate, Commissioner of Health of the city of Milwaukee, shows a decrease from 509 deaths in 1892 to 378 deaths in 1893, among children of the school ages—5 to 20 years. On the basis of population this shows a reduction of from 2.07 per one thousand of the population at all ages in the former year to 1.45 per thousand in 1893. In the absence of any other apparent reason the Commissioner says: "It is possible that the work done in overhauling the school buildings and putting them in better sanitary condition is bearing good fruit."

The Plague.—Later advices from Hong Kong are less sensational and more reassuring, although the gravity of the situation is fully recognized. The early mortality figures seem to have been grossly exaggerated, the total number of deaths in Hong Kong to the 16th inst. being now reported at 1,708, with an average of 70 to 80 daily at that date. The fatality of the earlier cases, however, seems to have been quite as great as stated in the *JOURNAL* of the 23d. Europe, and especially Great Britain through her intimate commercial relations with the infected region, are more directly concerned in the outbreak than is this country. Hong Kong is the distributing center for all China and, as was pointed out by the *British Medical Journal*, if it is true as stated, that 100,000 Chinamen have fled from that city, many of them presumably plague-smitten, and are let loose in Canton and all over the Kwantung and Fokien provinces, this would portend an irremediable spread of the pest, threatening all commercial intercourse with Chinese ports.

Cholera in Europe.—Except in Russia, Asiatic cholera is attracting little attention, and even in that country it has disappeared from all but two of the eleven provinces or governments which have been infected since the beginning of the year. All the Portuguese ports, including Lisbon, are officially pronounced to be healthy and the country is free from any suspicion of cholera. There appears to be some ground for concern in Brittany, but the disease has disappeared from Finisterre and it is denied that France is threatened. The outbreak in Upper Silesia, near the Austrian and Russian frontiers, has been officially investigated and found to have been caused by a female tramp from Russian Poland. Cholera bacilli having been found in the waters of the Vistula near Dantzic the river has been forbidden as a source of supply. The promptitude of enforcement and the efficiency of the measures relied upon for the prevention and suppression of the disease are shown in these and similar investigations and actions, and warrant the anticipation that Europe will escape any serious infliction this year.

Is Syphilis Diminishing?—Dr. J. H. Musser, of Philadelphia, believes that syphilis is diminishing in prevalence and is of a milder type than that of twenty years ago. He defended this thesis in a paper presented to the Association of Amer-
