The coating and fur upon the surface of the tongue are liable to be discolored by the expectoration, ingesta and vomited matters. In one of my cases the tongue presented a remarkably fine olive green coating.

In many cases the tongue is broad and flabby and shows the markings of the teeth.¹⁰ In these cases the color is apt to be gray, leaden or bluish. In other cases the tongue presents a strawberry-and-cream appearance which is very striking. Sometimes an albuminous exudation appears in patches upon the surface of the tongue. The tissues beneath the patches are inflamed and often ulcerate. This is usually an unfavorable, though not necessarily fatal sign.¹¹ Ulceration under the tongue¹² has been noticed by Baginsky.¹³ I have not seen ulceration of the lingual frenum in any case uncomplicated by pertussis. Herpes of the tongue¹⁴ was present in three of my cases.

In one of my cases the lingual herpes was unilateral, a group of five vesicles being arranged upon the right side. There were also herpetic vesicles at the angle of the mouth on the same side.

The temperature of the tongue is somewhat increased in the early part of the attack. It is lowered in cases attended with pronounced cyanosis or as a fatal termination is approached.

Although the condition of the tongue¹⁵ is a very important consideration, it can never teach us so much as the ancients believed. Thus Hippocrates¹⁶ claimed to be able to locate the disease by the coating upon the tongue. Stoll¹⁷ thought himself able to distinguish the pains of pneumonic fever from those of rheumatism¹⁸ by the moisture of the tongue.

During the height of the fever the secretion of saliva is diminished and in rare cases almost suppressed. A free secretion of saliva assists in keeping the mouth and tongue clean and is a favorable symptom.

Inflammation of the parotid gland is a rare complication of pneumonic fever. When it occurs the subjects are usually young—very rarely the aged. It comes on early in the attack and pursues a very acute course, attaining its full intensity in from one to three days. It is usually unilateral and tends to early suppuration. The pus, unless afforded early egress, inclines to burrow deeply and to find vent at distant points. Often but little pus escapes on incision and gangrene and sloughing are apt to result. This is a grave and dangerous complication and indicates that the general system is laboring under a heavy load of septic infection.¹⁹

As showing the rarity of this complication it may be

stated that Huss,²⁰ Fisser²¹ and Juergensen²² never met with a case. It occurred but six times in 5,738 cases treated in the Vienna General Hospital. One case is recorded in the Roosevelt Hospital Reports,²³ and Holt²⁴ has reported one occurring in Bellevue Hospital. Stortz²⁵ met with it once in 259 cases, Samter²⁶ once in 331 cases, and Schapira²⁷ once in 173 cases. I have met with a single example of this complication.

A boy, aged 7, in March, 1879, suffered an attack of *febris pneumonica sinistra*, with suppuration of the left parotid gland. The patient was of delicate build, was subject to frequent attacks of catarrhal pharyngitis, and eighteen months before had had diphtheria. The pulmonary inflammation pursued an ordinary course for a week, after which the local symptoms began to decline, while the constitutional ones continued unabated, although in a changed form. In the beginning the symptoms were marked by vigor and activity, whereas they were now of a low, dragging nature. On the eighth day a hard, painful swelling appeared in the left parotid region which rapidly increased in size, became reddened and livid, and "pointed" on the eleventh day, when it was incised at several points, giving exit to about a drachm of purulent matter. Pus continued to discharge for about ten days, after which the wounds healed. Previous to incising the abscess there was a high range of temperature, with at times chilliness, profuse perspiration, vomiting and a decided tendency to somnolency. These symptoms gradually subsided, although the patient continued weak and emaciated for several weeks.

Stomatitis, a softened state of the mucous membranes of the mouth—bleeding easily on touch—with ulceration, gangrene and sloughing may occur in rare cases, especially infantile.²⁸ Scurvy, with ulceration of the gums and loosening of the teeth was a feature of the Nantes epidemic in 1840.²⁹

Naso-pharyngeal inflammation is not very rare. In these cases the soft palate may be relaxed and the uvula swollen and elongated; diminution or abolition of sensibility is frequent and deglutition difficult. The posterior wall of the pharynx may be seen, in some of these cases, dry, glazed, ridged and furrowed. To this dried and insensitive surface particles of the expectoration are apt to adhere, giving rise to foul odors.³⁰ The patient sometimes complains of stiffness of the throat, with a creaking sensation on deglutition.³¹ False membrane may cover the tonsils, pharynx, larynx, esophagus, etc., in rare cases. This occurred in three of my cases.³² Alarming, or even fatal impediment to respiration may arise from edema³³ or laryngeal spasm.³⁴

In one of my cases laryngismus stridulus occurred. A child, 2 years of age, had had a cough for several days, when she awoke from sleep at 10 p.m., with a frightful fit of dyspnea, and cramping of various sets of muscles. Cyanosis was extreme; the eyes rolled outward; she became limp, and seemed as if dead. She gradually revived and no more dyspnea was observed. Examination revealed consolidation of the upper lobe of the left lung. The disease pursued a severe course, with a high range of temperature, but recovery eventually ensued.

The appetite is always impaired, and is usually lost,³⁵ especially in the earlier days of the attack. With the beginning of convalescence the appetite gradually returns and soon becomes quite keen.³⁶ During the entire course of the disease fluid food is more readily taken than solid.

Digestion is often held in abeyance, and food sometimes lies for a long time in the stomach as an undigested, sour mass, to be finally gotten rid of by vomiting or catharsis.³⁷

Thirst is almost always a prominent symptom in this disease.³⁸ It is always considerable and may be excessive. Ziemssen³⁹ has known even children to imbibe more than a quart of water in the twenty-four hours, and I have known adults to exceed this quantity several fold. Cold and slightly acidulated and

aërated drinks are usually relished by the patient, although plain, cold water is the one of which he tires least readily. The thirst is caused, in a great measure, by the loss of blood serum, and is proportional to such loss. It is therefore greatest when there is profuse perspirations, diuresis, diarrhea, loss of blood or extensive hepatization. These symptoms being present without thirst the prognosis is rendered doubtful. The absence of thirst in cases accompanied by stupor or other cerebral symptoms is also an unfavorable circumstance.⁴¹

Nausea and vomiting are very frequent and prominent symptoms of pneumonic fever, being observable, particularly at the onset, in a majority of cases.

Vomiting was present in 60 per cent. of my cases, taken *seriatim*, and in 85 per cent. of the children. This in excess of the proportion given by Rilliet et Barthez,⁴¹ 33 per cent.; Ziemssen,⁴² 40 per cent.; and Gerhard,⁴³ 60 per cent.—all referring to children.⁴⁴

It is usually one of the very earliest symptoms⁴⁵ and is limited to the first days of the attack,⁴⁶ although it may, in rare cases, continue for a long time.⁴⁷ It is aggravated or excited by overfilling the stomach with food and drinks⁴⁸ and by assuming the upright position. The vomited matters consist at first of the ordinary contents of the stomach and afterwards of bilious matters, mucus, food, drinks, etc.⁴⁹

One of my patients vomited, at different times and in various amounts, a peculiar, dark, bluish-green mucus which jellied when water was added in excess—a quart of water to a gill or half-pint of the vomitus. The patient, a female, was the subject of chronic gastro-ectasis.

At first the vomiting may not cause much distress, but later there is distressing retching and suffering. It greatly aggravates the thoracic pain and the nausea prevents the ingestion of food. Louis⁵⁰ considers it an element of danger, but this opinion I can neither confirm nor deny.

Hematemesis may be present in rare cases⁵¹—once in my collection.

A boy, aged 8, was taken, Sept. 18, 1875, with chilliness, followed by fever, cough, pain in the epigastrium, expectoration of sanguineous mucus and with dullness and tubular breathing over the base of the right lung. Vomiting, first of the ingesta and afterwards of mucus and bilious matter, was a prominent symptom from the beginning. On the morning of the second day the vomited mucus was streaked with blood, and later in the day he threw up a gill or more of dark coffee-ground matter. He recovered fully but afterwards developed a hemorrhagic diathesis and died, two years later, as the result of numerous severe hemorrhages.

Hiccough is an occasional and a very distressing symptom,⁵² especially in those cases complicated by diaphragmitis. It is often very persistent, continuing for several days,⁵³ or even weeks and months⁵⁴ in rare cases. It is probably due to an irritation of the pneumogastric nerve, acting upon the spinal cord and thence reflected to the phrenic nerve.⁵⁵

Mulreany⁵⁶ reports a very interesting series of cases of pneumonic fever with hiccough as a prominent symptom.

A robust farmer, aged 40, had pneumonic fever locally affecting the right lung. There was no cough, the pulse was almost natural and the stomach retained food pretty well. There was hiccough for twelve days, with recovery of the patient.

A thin, delicate blacksmith aged 56, had pneumonic fever, with hepatization of the base of the right lung. Pain was severe and extended to the shoulder and ear. The cough was embarrassed and hiccough preceded each expiration. He obtained only occasional and short snatches of sleep. The singultus continued for twenty-six days, terminating in recovery of the patient.

A muscular man, aged 21, had pneumonic fever, locally affecting the base of the right lung. There was a rapid

pulse, hurried respiration, incessant vomiting, anxiety of mind and a constant and harassing hiccough. There was no cough, neither was there pain, even on deep inspiration, but a severe lancinating pain was elicited by intercostal pressure. The vomiting and hiccough persisted for seventeen days, but gradually ceased with improvement in the chest symptoms. Recovery ensued.

A tall and muscular man, aged 22, was taken with a rigor, followed by intense headache, sopor, vomiting, profuse perspiration, high temperature, hurried respiration, cough and a scanty rusty expectoration. On the second day the breathing was very rapid and hiccough accompanied every second or third expiration. The patient daily went from bed to worse, he could not lie in the horizontal position, hiccoughed with every expiration, obtained no sleep and died, with a clear mind, on the fifteenth day.

I have met with prolonged severe hiccough only once in my experience with this malady.

A farmer, aged 30, was taken, May 10, 1870, with a severe chill, followed by fever, cough, pain in the left side, oppressed breathing, anorexia, nausea, vomiting and expectoration of rusty sputæ. I saw him first on the third day and found the entire left lung hepatized, the skin dry and harsh, cheeks dusky, tongue heavily coated, abundant labial herpes, great thirst, severe headache, loaded urine, bilious diarrhea, the pulse 140, respirations 40 and temperature 102.5 degrees. He had ridden a distance of six miles in an open wagon and through a broiling sun and returned to his home in the same manner. Upon arriving at his residence quite exhausted an intense burning pain developed in the epigastrium, with rigidity of the abdominal parietes, great dyspnea, agonizing efforts at vomiting and a persistent and distressing hiccough. The vomiting continued two days and the pain, although constantly present, became less intense after the sixth day. The hiccough persisted, with only the scantiest intervals of rest, for ten days when it ceased quite suddenly. Two days later as he was being removed from the bed to a chair, he instantly expired. The physiognomy of the patient when the singultus was at its height was pitiable in the extreme. With each spasm the face assumed a sardonic grin; the eyes were bloodshot; the skin was bathed in perspiration; the countenance was haggard and careworn, and the expression was one of deepest anxiety and a mute and pathetic appeal for succor.

Organic disease of the stomach is met with in some cases.⁵⁷ This organ, in infrequent instances, is enormously distended,⁵⁸ and it may be ulcerated or covered, in patches, by false membrane.⁵⁹ Gangrene is a peculiarity of some epidemics.⁶⁰

The bowels are generally somewhat costive,⁶¹ especially in the early days of the attack.⁶² If allowed to take its natural course the constipation is often relieved by a very copious evacuation after a few days, to be followed by more or less looseness of the bowels. This change occurs earlier in children than in adults. In some cases diarrhea is a prominent symptom,⁶³ even, it may be, from the start. A fetid diarrhea is characteristic of some epidemics.⁶⁴ The evacuations may be thin and watery, with but little color, whitish and foamy, yellowish, bilious, black and tarry, scybalous, mucus, hemorrhagic, fetid, etc.

The diarrhea may be distinctly inflammatory in character.^{64a} I have met a number of cases in which the pneumonic fever was ushered in by a dysenteric diarrhea.⁶⁵

A widow, aged 60, had had dysenteric diarrhea, cough and indefinite pains in the chest for a week, when, on April 25, 1881, she had a slight chill, followed by fever, vomiting, severe pain in the left side and extreme prostration. All the ordinary symptoms and signs of a grave, low grade pneumonic fever were developed, but the prominent feature of the case, from the beginning to the end, was the fetid, dysenteric, uncontrollable diarrhea. From day to day it varied in profuseness and character, but it was always present. During the first week the stools numbered from ten to twenty daily, and they were scybalous, bilious and somewhat dysenteric. During the second week they were more frequent, yellow, gelatinous and very fetid. During the last two days the evacuations were involuntary, unconscious

and incessant. She died on the thirteenth day, and the autopsy disclosed a gray hepatization of the entire left lung, the tissues being very soft and breaking down with the lightest touch; and ulceration of the lower portion of the ileum, cecum and ascending colon. One of the cecal ulcers had perforated the coats of the bowel, but the peritoneal surface had become adherent to a loop of the small intestine and no extravasation of the intestinal contents had occurred.

Perforation of these ulcers may incite a fatal peritonitis.

A man aged 20, contracted pneumonic fever, locally affecting the lower lobe of the right lung, from which he convalesced in the usual length of time. Rather sudden death occurred and at the autopsy, in addition to the evidence of pulmonary, pleuritic and pericardial inflammation there was found ulcerative enteritis, with perforation.⁶⁶

Peritonitis, especially purulent, has been noticed in a considerable number of cases,⁶⁷ independent of perforation. It is a very fatal complication.

The post-mortem examination, however, does not always disclose organic alterations to account for the diarrhea, even when most obstinate.

A sailor, aged 32, who had been ill for several days, was exposed to a hailstorm at sea, which was followed by chill, fever, thoracic pains, anorexia, sleeplessness and profuse diarrhea. On admission to the hospital on the third day he was thoroughly prostrated, had a short and hacking cough, scanty muco-sanguineous expectoration, a pulse of 126, temperature of 104 degrees and respirations of 42. There was a "total absence of respiratory murmur over middle and lower lobes of right lung; tongue, dry and brown; bowels very loose, requiring the stool every thirty minutes; urine free, but very dark in color." On the following day there was great dyspnea. "Crepitant ronschus could be heard all over the ward, the patient crying out for breath and sleep." He died during the night. At the autopsy "on opening the thorax considerable straw-colored serum escaped; about 1000 c.c. serum in thoracic cavity; fibrinous pleuritic adhesions throughout the right pleura, also slightly in left pleura; right lung collapsed and bathed in yellow pus; lower lobe of left lung inflammatory; right lung color of liver tissue; heart normal and perfectly healthy; liver, spleen and pancreas normal; intestines distended with flatus, but perfectly healthy."⁶⁸

Gaseous distension of the bowels is occasionally enormous,⁶⁹ impeding respiration and becoming an element of danger.⁷⁰

Diarrhea coming on late in the attack, with adynamic symptoms, is of evil import,⁷¹ and this is especially the case if the discharges are fetid or dysenteric in character, or if they are involuntarily evacuated.

In my series of cases there were fourteen in which there were involuntary or unconscious evacuations of the bowels as a prominent symptom. Of these ten died and four recovered.⁷² In one of the successful cases the diarrhea was hemorrhagic.⁷³

A young lady, 17 years of age, who had had an attack of pneumonic fever, five years previously, was taken February 23, with headache, alarm and muscular tremor, continuing three hours and terminating in chilliness and drowsiness, followed by fever and the ordinary symptoms of pneumonic fever with hepatization of the entire left lung—the inflammation beginning above and extending downward. For seven days the temperature ranged from 102 to 104.4 degrees, gradually declining to normal on the evening of the ninth day. The pulse, when the patient was first seen was 120, but did not again exceed 92. The respirations ranged from 24 to 32. Profuse diarrhea began on the fourth day. At first the stools were olive-colored and scybalous, but afterwards they were liquid, bilious and very offensive. On the sixth day the bowels moved only three times but the passages were unconscious. On the seventh, eighth, ninth and tenth days there was a constant, unconscious and uncontrollable passage of feces. On the ninth day there was a considerable discharge of fluid and clotted blood. On the seventh, eighth and ninth days the urine was also passed unconsciously—constantly dribbling away. The urine and feces were so acrid that the vulva, nates and upper part of the thighs were greatly irritated. The mind

remained remarkably clear throughout the attack. The case was one of the greatest severity; a physician of long experience and fine abilities, on the eighth day, pronouncing death inevitable. She recovered after a tedious convalescence.

Hemorrhage from the bowels is a rare complication.⁷⁴

During an attack of pneumonic fever intestinal worms, if any are present, are apt to be discharged, and this may be a prominent feature of some cases or epidemics.⁷⁵ Helminthiasis is most common in patients from 3 to 10 years of age, being infrequent in infants and youths and very rare in adults⁷⁶ and the aged. Lumbrici are sometimes present in immense numbers⁷⁷—"more than 1,000" being present;⁷⁸ the intestines being literally crammed with them⁷⁹—and large numbers of them may pass away at the same time. In one case 460 were passed in a fortnight.⁸⁰

In March, 1880, I attended two children, brother and sister, aged respectively 5 and 7 years, who were simultaneously attacked by pneumonic fever. The fever was ardent, with marked cerebral symptoms in both. On the fourth day I was shown two matted masses of lumbrici, each larger than a large orange which had been passed by the two children respectively during the preceding night. Improvement in all the symptoms began at once and both promptly recovered.

Some of the older authors considered it a very unfavorable sign to have these worms discharged, arguing that they instinctively anticipate danger, and, like rats fleeing from a sinking ship, hasten to desert their host.⁸¹

Jaundice, either preceding, accompanying or following the attack, will be encountered in a certain proportion of cases.⁸² This proportion will be large or small, as the observer classifies every shade of yellowness of the conjunctivæ and skin as examples, or only those which are more clearly and distinctly marked. Inasmuch as a slight tinge of jaundice may arise from hepatic congestion from any cause it is quite common in this disease⁸³ in which such congestion is often present.⁸⁴ Severe icteric manifestations, on the contrary, are not very frequent⁸⁵ and depend, most probably, upon duodenitis, inflammation of the bile ducts or other obstructive causes. It is a prominent feature of some epidemics.⁸⁶

It has been thought that jaundice occurs with greater frequency in those cases in which the pulmonary lesion is located upon the right side,⁸⁷ especially when at the base, but this does not accord with my experience.

Thus in my series of cases marked icterus was noticed in twenty-eight cases—5.7 per cent. Of these the pulmonary lesion was located in the right lung in thirteen, in the left in nine and in both in six cases, which is almost the exact proportion in which the local lesion is found in all cases. It may therefore be said that jaundice occurs oftener in connection with right-sided hepatization, because such inflammation is most common in pneumonic fever.

It might be readily supposed that the circulation in the blood—already surcharged with other excrementitious matters—of the biliary principles as is the case in severe jaundice would have a deleterious influence upon the course of the disease and the fate of the patient, and such is indeed the case.

Mosler⁸⁸ lost eleven of fifteen cases—73 per cent.—in which icterus was a marked feature, and he, with Traube⁸⁹ and others,⁹⁰ regards this as one of the most dangerous symptoms that can arise during the progress of pneumonic fever. Fisser⁹¹ puts the mortality in these cases at 20 per cent., which is about the average in general, but is slightly above that of his own cases. On the contrary, Huss⁹² lost only 8.7

per cent. of his cases, and Grisolles⁹⁸ but 15 per cent. of his twenty cases—both below their averages. My own opinion is that it is a most undesirable symptom and either makes or marks a grave case. This is based upon a loss of 36 per cent. of my cases and witnessing severe and grave manifestations in nearly all of the remainder.

Leyden⁹⁴ has called particular attention to the solvent action of the biliary acids upon the red blood corpuscles, and concludes that herein lies the true explanation of the known deleterious effects of the bile in the general circulation.⁹⁵

Secondary inflammation,⁹⁶ abscess⁹⁷ or cirrhosis⁹⁸ of the liver are some of the rarer accompaniments and sequelæ of pneumonic fever.

Enlargement of the spleen is a marked feature of some cases,⁹⁹ localities¹⁰⁰ and epidemics.¹⁰¹ When accompanied by softening¹⁰² it may become an element of danger. It usually returns to its normal condition after the fever declines, although some enlargement may remain permanently.¹⁰³

GENITO-URINARY SYSTEM.

Micturition is more or less modified, but differently in the two sexes. It is usually painful and there is a burning sensation as the urine flows along the urethra. The urine may be so irritating as to cause excoriation of the external surfaces with which it comes in contact.¹⁰⁴

This is mentioned as having occurred in nine of my cases—all females—and it may have been present in a lesser degree in others. In one case the vulvar excoriation was very extensive and gave rise to much distress.

In general, micturition is infrequent, the urine being passed only once or twice in twenty-four hours, especially early in the attack, although frequent micturition is not uncommon. There is usually some hesitation and delay in starting the stream of urine and the flow is retarded. This difficulty is sometimes so great that the bladder is only relieved *guttatim*,¹⁰⁵ or by the catheter. Patients have described the sensation as being one of increased resistance to be overcome by a diminished *vis-a-tergo*. The condition is due to excessive irritability of the sacral plexus or a diminution in the functional activity of the hypogastric plexus, or both.

A blunted intellect is also responsible for a certain proportion of these cases of dysuria.

This fact is mentioned in my notes but once. In this instance the patient, an adult male, was so dull and drowsy that unless means were taken to keep him aroused, he would, whilst passing the urine, relapse into a state of lethargy, with stoppage of the flow. There was no impediment to the flow of urine so long as he was awake.

I have been unable to find a parallel case in the medical literature at my command, although they have most probably been observed by others.

Retention may occur,¹⁰⁶ either from vesical paralysis or dullness of intellect, but the circumstance must be rare as it was met with but once in my series of cases.

A female child, aged 5 years was taken, Sept. 1, 1875, with the symptoms and signs of pneumonic fever, locally affecting the apex of the left lung. Vomiting and helminthiasis were prominent symptoms. From the first, the urine was passed with difficulty and on the third day there was complete retention. The catheter was used and a large quantity of urine withdrawn. Retention did not recur. There was only slight impairment of the mental faculties. Crisis occurred on the fifth day, with the extrusion of a very large number of round worms. Convalescence proceeded rapidly to complete recovery.¹⁰⁷

In females, especially those of advanced age or those who have borne children, there is, not infrequently, incontinence of urine with the efforts of

coughing. The symptom is one indicating more than ordinary danger. Such incontinence is seldom encountered in young girls or unmarried women, although I have given a case on a preceding page. It is very rare in male adults.¹⁰⁸

The urine of pneumonic fever patients is invariably altered in constitution.

Writers have generally employed the phrase, "the urine is usually altered in its constitution," but as the result of a very large number of examinations, both during the progress of the disease and after recovery, I am in a position to positively assert that whilst the malady is raging the characteristics of the urine are *invariably* other than those pertaining to health.

In quantity it is usually diminished,¹⁰⁰ although under peculiar circumstances it may be increased, as e.g., in the Tregagno epidemic.¹¹⁰ The volume of urine passed, however, depends largely upon the amount of fluids ingested, and the quantity of these diverted into other channels.

The urine may be suppressed, which is a very grave symptom, although complete suppression has continued for considerable periods with recovery. Uremia¹¹¹ often, but not invariably,¹¹² accompanies prolonged suppression.

The urine is usually foamy¹¹³ and highly colored. It may be of a dark straw color, but it is oftener that of beer. Rarely it is smoky, oily, sticky, whitish, greenish or olive. It is heavily laden with excrementitious material and has a high specific gravity.¹¹⁴ The amount of urea excreted is largely increased,¹¹⁵ indicating an active retrograde metamorphosis of tissue¹¹⁶ and a defective assimilation of the ingesta.¹¹⁷ Urea continues to be excreted in large quantities up to the beginning of resolution, and very often for several days longer. The quantity of urine is generally too small to hold the urates in solution at a temperature below that of the body and they are thrown down, together with some of the uric acid,¹¹⁸ as a reddish or fawn-colored precipitate upon the urine becoming cold.¹¹⁹ The amount of uric acid excreted is also, sometimes greatly increased.¹²⁰

In Zimmermann's cases the average was, during the incremental stage, 15 grains, during the decremental stage 13.5 grains and at the crisis 37.7 grains.

Poland¹²¹ considers imperfect respiration the cause of the presence of uric acid in excess in the urine, but this is uncertain.¹²²

The proportion of hippuric,¹²³ sulphuric¹²⁴ and phosphoric¹²⁵ acids are not perceptibly altered in this disease as evidenced by the salts excreted.

Simon¹²⁶ and Becquerel¹²⁷ long ago noticed a diminution of the chlorids in the urine in several inflammatory disorders, but to Redtenbacher¹²⁸ is due the credit of calling attention to the fact that in pneumonic fever they are entirely absent in a great majority of cases and are diminished in all,¹²⁹ even when they are largely ingested. This diminution or absence is most marked at the height of the disease, and they reappear with the cessation of the exudative process and the beginning of convalescence.¹³⁰ Inasmuch as the pneumonic exudate is peculiarly rich in the chlorid of sodium it is believed that this salt is diverted from the urine to the inflammatory exudate. So long then as the chlorids are diminished or absent in the urine we may be sure that the local lung trouble is in an actively progressive state, but when they begin to appear abundantly we may safely conclude that the inflammatory process is stationary or declining.

The quantity of chlorid of sodium excreted in the urine by a healthy adult is about one hundred and fifty-four grains in twenty-four hours.¹³¹ It is derived from the blood and it follows that if the salt is deficient in this fluid it will be likewise diminished in the urine. Now it is found that in pneumonic fever the blood is deficient in these salts, and it is generally believed that this is attributable to the exudative process going on in the lungs.¹³² Beale,¹³³ who studied this subject exhaustively, came to the following conclusion: 1, chlorid of sodium is totally absent from the urine of pneumonic patients at the period of complete hepatization;¹³⁴ 2, it reappears during resolution; 3, it exists in the blood in the greatest abundance when it appears most largely in the urine and *vice versa*; 4, it exists in large quantities in the pneumonic sputa; 5, there is reason to believe that it is determined toward the inflamed lung and is re-absorbed on the resolution of the process.

Chlorid of sodium appears scantily in, or is absent from the urine in other diseases besides the one under consideration, *e. g.*, bronchitis,¹³⁵ pleurisy,¹³⁶ phthisis,¹³⁷ cholera, rheumatism, typhus fever, cerebral abscess,¹³⁸ etc.

Albumen is present in the urine in a considerable number of cases¹³⁹—especially severe and lingering ones—of pneumonic fever.¹⁴⁰

Becquerel¹⁴¹ found albumen present in 9 of 21 cases, 42.8 per cent.; Caton¹⁴² in 4 of 85 cases, 5 per cent.; Finger in 15 of 33, cases, 45.4 per cent.; Fox¹⁴³ in 10 of 32 cases, 31 per cent.; Griesinger¹⁴⁴ in 63 of 121 cases, 52 per cent.; Metzger in none of 48 cases; Parkes¹⁴⁵ in 6 of 13 cases, 46 per cent.; Solon¹⁴⁶ in 11 of 78 cases, 14 per cent., and Ziemssen¹⁴⁷ in 2 of 24 cases, 8.3 per cent. It occurred in about 10 per cent. of my cases.

It may appear at any time, but is oftenest noticed at the beginning of resolution, and continues several days.¹⁴⁸ It is an unfavorable symptom.¹⁴⁹ It has been a prominent feature of some epidemics, as *e. g.*, those of Tregagno¹⁵⁰ and Moringen.¹⁵¹

In pneumonic fever the latent albumen is sometimes not shown by the ordinary tests, but if the urine and nitric acid are boiled together and the tube be then plunged into very cold water a precipitate appears which does not re-dissolve on boiling.¹⁵²

The albuminuria is due to an acute parenchymatous nephritis, which is a not infrequent complication.¹⁵³ As a rule the nephritic inflammation subsides with the progress of convalescence and terminates in complete recovery,¹⁵⁴ although chronic Bright's disease occasionally results.¹⁵⁵ In such cases dropsy ensues.¹⁵⁶ In nephritis the urine may be dark and smoky, with a deposit of casts, blood globules and other morphologic elements.

Peptonuria may be present,¹⁵⁷ especially in the final stages of the disease, in direct proportion to the activity of the absorption and elimination of the exudation material.¹⁵⁸ It has been thought that peptones in the urine denoted suppuration, and indeed it may well give rise to such suspicion when it is persistent, without any indication of resolution and general improvement. In a case of pneumonic abscess, observed by me in 1885, peptonuria was a marked symptom for several weeks. Peptonuria is not confined to pneumonic fever, but is met with in a variety of other diseases.¹⁵⁹

The presence of peptones in the urine is readily discovered by Randolph's test. This test is based upon the fact that acid nitrate of mercury causes a red precipitate when added to a cold solution of iodid of potassium. If, however, peptones or the biliary salts are present the precipitate is yellow.¹⁶⁰ The question as to the presence of the biliary salts is readily eliminated.

The urine may contain bile pigments, especially in those cases accompanied by jaundice.¹⁶¹ Elements of the blood may also be found, and in rare cases the urine may be actually hemorrhagic.¹⁶² Poisonous alkaloidal substances—ptomaines and leucomaines—are sometimes found in abundance in the urine of

pneumonic patients,¹⁶³ and such urine is highly toxic.¹⁶⁴

The vesicle mucus is increased in quantity and there is a tendency in the urine to early decomposition.¹⁶⁵ Senger¹⁶⁶ "found micrococci in almost every case which he examined," but Seitz,¹⁶⁷ Neumann¹⁶⁸ and others have obtained negative results in their search.

Melaturia may be present, either as a symptom¹⁶⁹ or as a preceding condition.

In a certain proportion of persons, sugar, in small quantity is present in the urine for a long time without giving rise to any marked symptoms and without being in itself a dangerous condition, yet as a rule such persons will not survive an attack of pneumonic fever.¹⁷⁰

Acetone may appear in the urine,¹⁷¹ especially in those cases accompanied by high fever. It is more dangerous in adults than in children, but it is always of grave import. In these cases the breath exhales an acetous, fruity odor which is very characteristic.

Kreatinin in the urine is increased in amount during the acute stage,¹⁷² but is diminished during the decline of the disease, especially if there is rapid wasting.¹⁷³

With the beginning of the disease and until convalescence is declared, sexual desire is either impaired or abolished.¹⁷⁴ With recovery it returns with renewed vigor.

In one of my cases, a male, aged 24, a masturbator, after exposure to cold during convalescence, had epididymitis and nocturnal emissions. The semen stained the linen a light, but distinct, blue.¹⁷⁵

The cremasters and scrotum are relaxed¹⁷⁶ and the penis flaccid. Edema of the genitals may be present.¹⁷⁷

tion in later years on account of the allurements of visceral surgery, and the rewards of work and study in the newer fields.

A conviction that there are established facts and available knowledge respecting this disease, which are not fully reflected in the views and the practice of to-day, is sufficient justification for an effort to ascertain and correlate what is known of the cause and nature of carbuncle, and for urging a more rational and radical method of treatment.

The observation has often been made and should be reiterated that the names, anthrax and malignant pustule, should no longer be used interchangeably with carbuncle. To avoid confusion the latter term should be reserved exclusively to designate the disease under consideration, while the former should be applied only to that disease of the lower animals which is contagious, sometimes communicated to man, and is caused by the anthrax bacillus.

Etiology.—Carbuncle is a disease of microbic origin, like all of its class. This has been demonstrated by the researches of Garré,¹ Bockhart,² Baum and others. The microorganism most frequently found is the staphylococcus aureus. In the minority of cases there are present also the staphylococcus albus or the streptococcus pyogenes, or the two together with the former, but always outnumbered by it. The coccus may enter the skin through the hair follicles, the sebaceous gland ducts, the sweat glands or an abrasion of the epidermis.³ The organism may enter also through the alimentary canal or the respiratory tract. We are nowhere more in bondage to the traditions of the elders than in the belief that this disease is of constitutional origin. The notion that it is a disease of the cachectic, the alcoholic, the tubercular and the diabetic was easily believed and necessarily prominent before local causes were demonstrated. The most that can be rightly claimed for the constitutional factor is that it increases the vulnerability of the tissues and predisposes to acute suppurations in general, rather than to carbuncle in particular. Even the diabetic, so prominently associated with carbuncle, does not often have the disease. The writer believes, with others, that the systemic vices are greatly overrated as etiologic factors, and though no statistics are at hand to prove it, it is even believed that the disease is not found more often, relatively, in the cachectic classes than in those of good health. The association of these constitutional conditions with carbuncle, in a causative relation, is probably partly accounted for by the fact that statistics used by writers and teachers have been collected more from the older large public hospitals and almshouses rather than from private practice and the smaller modern private hospitals. Whatever may be the exact facts in relation to this question it is certain that whoever ignores the local origin and local nature of the disease is handicapped and disarmed for the proper treatment of his patient.

Carbuncle is a disease of middle life, while its near relation, furuncle, is preëminently a disease of the adolescent, a clinical fact which is to be accounted for on the ground of histological variations in the skin at these periods of life as given below.

Anatomy and Pathology.—Nosologically, carbuncle is one of the acute suppurative inflammations of connective tissue, and hence is generically related to osteo-myelitis, parenchymatous abscess, acute abscess and furuncle, as well as other suppurative dis-

CARBUNCLE: ITS ETIOLOGY, PATHOLOGY AND TREATMENT.

Read before the First Pan-American Medical Congress.

BY D. W. GRAHAM, A.B., M.D.
CHICAGO, ILL.

ATTENDING SURGEON TO PRESBYTERIAN HOSPITAL.

Carbuncle was formerly looked upon as a peculiar mysterious disease having a pathologic process of its own, with little or no relationship to any other disease, either in its etiology, its pathology, or its indications for treatment.

The teaching and especially the practice of the present day indicate that we are still in bondage to the traditions of the older pathology with respect to carbuncle, chiefly because it is one of those more common diseases which have received scant atten-

eases of the skin. The essential unity of the group is shown when we consider that all have a local origin, all involve the same histologic structure, and all are due to the invasion of the same pus coccus; or at least one of the pyogenic cocci. The differences in clinical history, the divergence in pathologic process and the various modes of termination which are found when we compare the several diseases of this generic group with each other, are determined by differences in the anatomic structure of the region or organ concerned. These differences are quite as marked in the skin of different regions of the body when they are compared with each other, as are those found in one organ when compared with other organs. These variations in histologic anatomy relate to thickness, density, toughness, elasticity, vascularity, the surrounding attachments and the amount and mode of disposition of the adipose tissue.

It is these variations in histologic structure of the skin in different regions of the body, or the structural differences in the various strata of the skin in a given region, that determine whether in a given case of invasion by the pyogenic coccus we shall have a superficial pustulation, as impetigo; or a deeper and more extensive suppurative process, as furuncle; or a still more deeply seated and extensive one, as acute subcutaneous abscess, or carbuncle, as the case may be. When the coccus invades the mouth of the hair follicle, sebaceous gland or sweat gland, and is arrested there, we have impetigo² or one of its congeners. There is little tension, no stasis, no obstruction to the outflow of fluids or pus and no slough.

When the deepest part of the epithelial structures of the follicle, or the sebaceous or sweat gland is invaded a true furuncle is the result.² Here there is a degree of obstruction to the outflow of fluids and pus on account of the depth and partial closure of the passage way. Hence we have tension, stasis, liquification (pus), a limiting wall, and in the center a cone-like slough which consists of the remnants of the gland or follicle surrounded by as yet undigested connective tissue, especially fibers of the yellow elastic tissue.

But when the pus coccus passes beyond the epithelial layer of the skin into the cutis vera, the result is either an acute abscess² with its circumscribed cavity filled with digested connective tissue and inflammatory products, or, on the other hand, a carbuncle with its dense infiltrated mass of undigested connective tissue, without any circumscribed cavity. Whether it be an abscess or a carbuncle will depend on the histologic structure of the skin of the particular region invaded. The region of predilection of carbuncle is "the dense and fibrous integuments over the posterior median line of the body." The skin of this region is characterized by:

1. Its extreme thickness, especially the relative thickness of the cutis vera.
2. The aponeurotic-like density of the papillary layer and its having few and small openings.
3. The more direct connection of the subcutaneous tissue with the reticular part of the true skin, as one continuous structure.
4. The number and size of the polygonal spaces found in the subcutaneous and reticular strata, caused by the diverging and interlacing bundles of dense and not easily dissolved fibrous tissue which make up the framework of these strata. These polygonal spaces are chiefly occupied by adipose

tissue constituting the *panculus adiposus*, and a delicate network of fine easily digested connective tissue.

5. The presence of Warren's fat columns, extending from the adipose tissue below, to the base of the follicles of the lanugo hairs above, with their horizontal branches.³

6. The dense, tendon-like, cone-shaped fibrous bundles which extend from the base of the adipose columns obliquely to be inserted into the muscular fascia beneath.

The pus coccus having passed down and invaded these tissues, a focus of inflammation is begun and we have all the factors and conditions necessary for the production of a typical carbuncle. The delicate network of areolar adipose tissue succumbs readily and liquifies, and as tension increases pus is forced to the surface through the slender adipose columns into the hair follicles as the only means of escape. Thus we have the numerous pus points, and eventually the cribriform condition of the surface of the skin so characteristic of carbuncle⁴. As tension increases, the inflammation is forced to extend laterally further and further from the original focus through the polygonal spaces and channels occupied by the rapidly dissolving delicate connective tissue and fat. Thus we have the characteristic peripheral extension and the broad, flat indurated mass pressed between the still resisting dense papillary layer above, and the muscular fascia beneath, which are still firmly bound together by the tendon-like cones of fibrous tissue. If now an incision be made into this mass there would be seen the numerous small pus points and channels but no proper pus cavity; both of which conditions are well-recognized features of carbuncle. The process continues until the skin over the original focus becomes necrotic and sloughs away, thus reducing the tension and peripheral pressure and we have the first step towards the natural limitation of the disease. But if this infiltration and induration have already extended so far as not to be influenced by this diminution of tension it will continue to spread indefinitely or until the sloughing process following in its wake has gained on it sufficiently to entirely arrest the peripheral tension. After all the long-resisting, dense, fibrous parts described above, which began to die with the skin, have yielded and sloughed piecemeal, we have the crater-like cavity co-extensive with the indurated mass.

It is said carbuncle may occur on any part of the body, but this is not correct of true typical carbuncle conforming to a fixed definition. We can not have a typical carbuncle without continued surgical tension in inflamed tissues, one part of which resists the digestion or liquifying process of suppuration longer than other parts.

Many cutaneous inflammations are loosely called carbuncles, when they are simply abscesses. But as the characteristic features of the carbuncular skin are only typical in certain regions of the body, and are found more or less perfectly or imperfectly in other regions, it will often happen that a suppurative inflammation of the skin and subcutaneous tissue can not be definitely classed either as a carbuncle, an abscess or a furuncle; or that the characteristics of one predominate while those of the others are present in some degree.

Treatment.—The general indication for treatment is the same as in any other disease, viz.: To limit

its extent and duration. The special indications are to arrest suppuration and to prevent septicemia.

The history of the means and methods of treating carbuncle would fill a volume. Palliative means are useful and to be recommended if nothing better can be done. Many good surgeons advocate a purely expectant course and discard all active means, relying on internal medication, and treating it as a self-limited disease, not to be interfered with. Most surgeons, however, recognize the necessity of doing something to hasten the sloughing in order to relieve tension, and thus limit the extent of the disease and prevent absorption of diseased products.

Caustics, incisions—single, multiple, subcutaneous and the time-honored crucial incisions are relied on. These are to be recommended, also, if nothing more efficient can be done, but they are all inadequate to fulfill the indications, although they accomplish something. Scraping, as advocated by Page and Owen⁵, and Mr. Teale, of Leeds⁶, and even the "excision and scraping" as advocated by Rushton Parker⁷ are valuable means in certain stages, after sloughing has begun. But these means are properly applicable only to those cases where the disease has ceased to extend, and are to be considered only as adjuvants to the incisions and caustics.

The injection of various antiseptics into the mass before sloughing has begun, as advocated by some, would hardly be relied upon by any one who had an adequate conception of the anatomy and nature of the disease. But it is not my purpose to review and compare discarded or prevalent methods. As a substitute for all of these, I would advocate total extirpation of the indurated mass, as we would remove a benign tumor. If this is done early the entire skin can be saved. If it is done later, there will be some loss of skin over the original focus but the patient will be saved from all the dangers of septicemia—the cause of death in carbuncle, usually miscalled exhaustion. If the patient already have septicemia and there remains a ring of indurated tissue beyond the sloughing center, extirpation is still the best means of saving the patient's life. It should be resorted to in all cases, whatever the stage of progress, except those in which the disease has clearly run its course, when the excision and scraping of Rushton Parker would be sufficient.

It is a rational, life-saving and time-saving method, and will commend itself to all who try it. All the reasons that call for amputation of a gangrenous limb can be urged in favor of total extirpation of carbuncle. The writer has practiced total extirpation in all suitable cases for the last five or six years.

The technique of the operation requires but few words. Anesthesia is required, which should be as brief as possible and not profound if the patient already suffers from septicemia.

A crucial incision should extend to just beyond the borders of the induration. The four flaps are to be dissected up to the limits of the disease, which can usually be made out easily, contrary to what is generally taught. Then with the volsella forceps and a knife the mass is readily dissected from its attachments to the deep fascia and removed entire or in sections, according to its size and condition. The four flaps are then stitched together toward the center, more or less closely, according to the amount of necrosis and sloughing. When the extirpation is done early, there will often be no loss of skin and

but little subsequent discharge. There are no blood vessels in or under the skin in the carbuncular regions that should terrorize any one.

UTRICULITIS; A CONTRIBUTION TO THE PATHOLOGY OF THE PROSTATIC UTRICLE.

BY WILLIAM T. BELFIELD, M.D.

CHICAGO.

It is well known that the genital organs of the adult vertebrate are developed from two primitive organs of the embryo, the bodies named for Wolff and Müller; and that the sex of the individual varies with the relative development attained by these organs. In the future male animal the Wolffian duct furnishes the genital canal—epididymis and vas deferens—while the Müllerian duct suffers more or less complete atrophy; in the future female, on the other hand, the Müllerian duct furnishes the genital canal—Fallopian tubes, uterus and vagina (to the

Fig. 1.—Internal genital organs of male guinea pig. 1, testicle; 2, vas deferens; 3, seminal vesicle; 5, orifice of vas deferens into urethra; 6, verumontanum; 7, testicle displaced to show extremity of uterus; *ut*, right masculine uterus (Müllerian duct). Prostate not represented.

hymen)—the corresponding portions of the Wolffian duct suffering atrophy. In the most highly organized mammals, the male genital canal acquires certain accessory sexual glands not constantly found in the lower vertebrates—seminal vesicles, prostate, Cowper's, urethral and preputial glands—while the Müllerian duct exhibits marked atrophy; in man there persist regularly only the two rudimentary extremities of this duct, the hydatid of the testicle and the prostatic utricle.

Yet in some species the Müllerian-tract retains in the male, side by side with the fully developed Wolffian canal, a high degree of elaboration; among the many species of mammals that I have personally dissected, none presents a clearer picture of the complete Müllerian duct in the male than the familiar guinea pig. In this animal the testicles are abdominal organs, lying somewhat below the kidneys; the usual organs of the male mammal are well developed, but in addition there are found two large

tapering tubes, each arising as a blind extremity behind the testicle, describing almost a complete circle, passing behind the urinary bladder, and after receiving the ejaculatory duct opening into the urethra at the side of the verumontanum (Fig. 1). Each tube is therefore the complete Müllerian duct, whose homology with the internal sexual organs of the female guinea pig becomes apparent by inspection of Figs. 1 and 2; the ovaries differ from the testicles in their greater proximity to the kidneys; the Müllerian ducts (uteri) retain separate cavities until they reach the vagina.

In the human male, the lower end of the Müllerian duct persists as the so-called masculine uterus or prostatic utricle; though it is evident from comparative anatomic study that this rudiment represents the vagina rather than the uterus of the female. The term "prostatic utricle" conveys a second misconception, derived from human anatomy, as to the relations between prostate and utricle—namely that the latter is merely an appendage of the prostate. While this is usually the anatomic relation in man,

Fig. 2.—Internal genital organs of female guinea pig. 1, ovary; *ut*, left tube and uterus; 2, vagina; 3, kidney; 4, portion of ureter.

yet a study of their relations in various mammals shows this relative significance in the two organs to be reversed, *i. e.*, that the prostate is really an appendage of the utricle, an accessory and by no means constant gland of varied size and shape, always located—when present—at the orifice of the uterus (Müllerian duct). It is significant that in certain male mammals, *e. g.*, the ram, whose utricle is usually atrophied into a solid cord, the prostate is lacking entirely. In others—hare, squirrel, prairie-dog, for example—the prostate is a purely glandular structure which does not surround the urethra as in man, but lies entirely below this channel, being attached to the under surface of the utricle (Fig. 3); even in man the prostate is sometimes entirely suburethral—Dittel has dissected three such instances; and in the usual human prostate the glandular structures retain the original suburethral position, adjoining the utricle.

In a few animals, notably man, the prostate acquires an additional function—that of a vesical sphincter—quite foreign to its original universal office, that of a sexual gland; this is secured by the extension toward the bladder of muscular bands which encircle the urethra, *between this channel and the utricle* (Fig. 4).

This interposition of a complete muscular sphincter between utricle and urethra leads to the apparent burying of the utricle in the prostate; yet careful dissection will usually show that the body of the utricle is not surrounded by prostatic tissue; that it lies behind the prostatic sphincter (the "third lobe" of Sir E. Home) and between the upper ends of the lateral lobes, which separate to accommodate it (Fig. 5).

Fig. 3.—Part of bladder, prostate and urethra of hare, showing sub-urethral type of prostate found in many species. 1, bladder; 2, prostate; 3, urethra.

In other words its posterior surface and upper extremity are bordered, not by prostatic tissue but by the pelvic connective tissue. The clinical significance of this anatomic arrangement is apparent; a suppurative process in the utricle—and these must be frequent as extensions from the deep urethra—is separated from the pelvic connective tissue only by the thin wall of the utricle; it would seem *a priori* that peri-prostatic infection would be easier through the delicate extremity of the utricle than through the thick muscle and firm capsule of the prostate proper.

Fig. 4.—Longitudinal section human prostate, patient dead of consumption, aged 24. 1, urethra; 2, lateral lobe; 3, "third lobe" (between urethra and utricle); 4, utricle.

Though the pathologic and clinical possibilities of the utricle in man have been almost unnoticed, yet in a few cases the persistence of a large part of the Müllerian duct has been recognized; thus Martin records the persistence of Müller's ducts in a fetus at full time, and refers to a case wherein Boogard discovered at the autopsy of an adult man, two complete Müllerian ducts extending from kidneys to urethra (Fig. 6). Rémy and Barth found in a 5-year-old boy a canal extending from a suprarenal capsule to the verumontanum, open from the summit of the

trigone; retention of urine requiring the use of the catheter, had repeatedly occurred. Reliquet found a complete Müller's duct in a man of 45 years. In Franque's case the Müllerian ducts of an adult man were found united into tubes, uterus and vagina opening into the prostatic urethra (Fig. 7).

Persistence of the entire Müllerian canal in the human male, as recorded in these cases, is doubtless a rare occurrence, a teratologic curiosity beyond clinical recognition or relief; but the distal extremity of the duct, the prostatic utricle, is a constant anatomic factor in man, to whose clinical importance it is the object of this paper to direct attention.

I have been able to find but one allusion to this topic in the literature accessible to me—the article of Englisch, who found in five out of seventy autopsies of new-born infants the utricle more or less distended, sometimes rivaling the urinary bladder in size; he suggests the probable dependence of urinary retention in the new-born upon the urethral obstruction due to this distended sac. There are recorded, however, several cases of retro-vesical cysts in adults, which, though apparently distended utricles, were assumed by the observers to have originated in the seminal vesicle. Thus N. R. Smith described as a

Fig. 5.—Rectal surface of human prostate (same as represented in longitudinal section in Fig. 4). 1, right lateral lobe; 2, left lateral lobe; 3, triangular space between upper extremities of lobes, occupied by utricle; 4, bristles passed into ejaculatory ducts.

“hydrocele of the seminal vesicle” in an adult, a pyriform tumor rising above the umbilicus and at first mistaken for a distended bladder; puncture per rectum evacuated ten pints of brown serous fluid. The description strongly suggests a distended utricle, the possibility of which is not mentioned by the observer. Ralfe records as a “cystic tumor of the left seminal vesicle” in an adult, a sac which was found on autopsy to have no communication with the vesicle, but arose from the prostate—probably a distended utricle; (evidently neither Smith's nor Ralfe's was a case of hydatid cyst, not uncommon in the male pelvis.)

The undistended utricle in man is a chestnut-shaped sac lined with mucous membrane in which are imbedded numerous racemose glands; its pointed extremity opens into the urethra through a narrow orifice in the verumontanum; its rounded base lies between rectum and bladder, and between the upper ends of the prostatic lobes laterally. Its depth, stated by anatomists to be one to one and one-half centimeters (four-tenths to six-tenths of an inch), I found to average in

twenty-seven adults nearly one and one-half centimeters; the greatest depth I have observed is two and one-half centimeters, though Adams has measured a utricle over three centimeters deep. Occasionally distinct bifid prolongations—vestiges of the separate Müllerian canals—have been observed. In man, the ejaculatory ducts usually run in the lateral walls to separate exits into the urethra; sometimes one and rarely both ducts open into the utricle—a more frequent arrangement in other animals.

The utricle might, therefore, be expected to exhibit two morbid conditions: 1, distension of the sac with its own secretion after occlusion of its narrow urethral orifice; and 2, suppurative inflammation by extension from the deep urethra; in this case septic infection of the recto-vesical connective tissue surrounding the upper extremity of the utricle—“peri-prostatic” inflammation and abscess—would be a natural possibility.

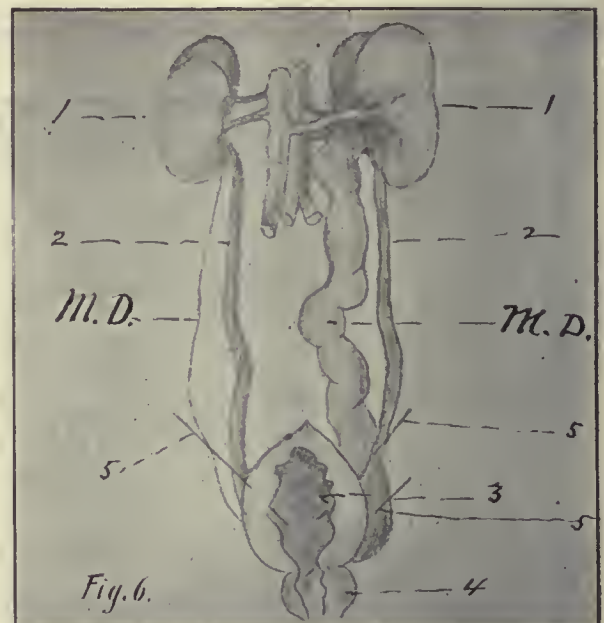

Fig. 6.—Müllerian ducts in adult man (Boogaard). 1, kidney; 2, ureter; 3, bladder; 4, prostate; 5, bristles in ureters and ducts; M.D., persistent Müllerian ducts (the right atrophied to a mere cord).

The first of these, the distension with physiologic products, has been proven by the observations of Englisch and others already mentioned; that suppuration in the utricle and vicinity is the explanation of cases of chronic prostatitis, prostatic and peri-prostatic abscess, seems evident from the following personal observations:

Postmortem.—As prostatic suppuration is not commonly fatal, opportunity for postmortem observation is limited; only two cases have come under my observation since my attention has been directed to this subject:

1. A patient of Dr. J. C. Cook, of Hyde Park, Ill., about 40 years of age, had long suffered from the symptoms usual to vesical calculus; at intervals, bladder irritation and straining would become extreme, then several drachms of thick pus would be expelled from the urethra, after which the vesical symptoms would abate for a time, until the process was repeated—in short, a prostatic abscess seemed to

fill and discharge repeatedly. I saw the patient once with Dr. Cook; no stone was detected and a cystoscopic examination was agreed upon, but never executed. The patient dying a few weeks later of cystopyelitis, the bladder and prostate were kindly sent to me. There was a fibrous polyp of the fundus of the bladder; the utricle was over an inch deep, distended with pus, and projected nearly half an inch above the prostate; the surrounding recto-vesical tissue hard, the seminal vesicles somewhat distended but not inflamed.

2. A man 62 years old, upon whom I made suprapubic cystotomy for stone, died six weeks later of chronic uremia; the symptoms of vesical irritation persisted after operation. Autopsy showed chronic cysto-pyelitis; the utricle presented the appearance of an evacuated abscess cavity and extended almost to the level of the summit of the trigone; the recto-vesical connective tissue was brawny and contained a small abscess contiguous to, but apparently not communicating with, the utricular cavity.

Clinical.—While a clinical diagnosis of utricular abscess lacks the certainty of anatomic demonstration, yet the following cases seem incapable of other explanation:

A commercial traveler, aged 40, was referred to me by Dr. H. M. Lyman, of Chicago, in December, 1890. For three years he had had the usual history

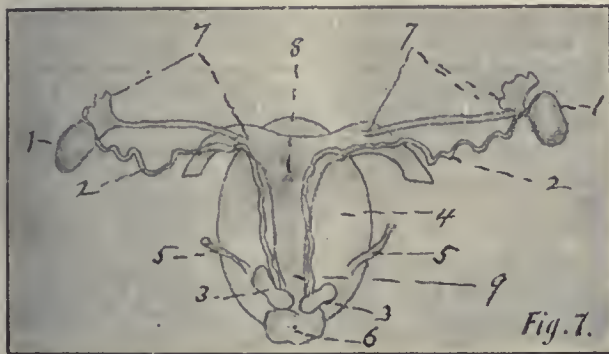

Fig. 7.—Müllerian ducts (tubes, uterus and vagina) in adult man (Franque). 1, testicle; 2, vas deferens; 3, seminal vesicle; 4, bladder; 5, ureter; 6, prostate; 7, Fallopian tube; 8, uterus; 9, vagina.

of chronic prostatitis in a marked degree, with much rectal irritation, though repeated examinations had failed to disclose any morbid condition of the rectum; no anterior urethritis in eighteen years. In December, 1890, after a severe jolting, the symptoms were aggravated, culminating ten days later in complete retention of urine. While straining to urinate he had a sensation as of "something breaking," immediately followed by a discharge per urethram of an ounce or more of thick, offensive pus; urination became at once possible.

I first saw him a few hours after this episode; the prostate was symmetrically swollen and tender, the space between the seminal vesicles tense and tender, the vesicles themselves not especially sensitive.

For several months, in spite of irrigations, injections and instillations of the deep urethra, the abscess cavity kept filling and at intervals discharging (with the urine) quantities of extremely fetid pus. I then made, in the Presbyterian Hospital, a perineal urethrotomy, expecting to find and curette a prostatic abscess cavity; but the prostatic urethra appeared to the finger quite normal. The operation

and subsequent drainage caused no appreciable improvement in the symptoms. About this time the probability that the utricle was the abscess cavity occurring to me, I passed a narrow knife from the perineum into the bladder between the upper extremities of the lateral prostatic lobes so as to pierce the utricle; a small drainage tube was left in the track of the knife, and the cavity irrigated with hydrogen peroxid. Complete healing was secured; urine and urination became normal and so remained a year later, when patient was last seen.

I can recall several prior cases which probably belonged to the same category, though unrecognized at the time; cases in which, as in the instance just related, perineal urethrotomy and drainage failed to relieve a chronic prostatitis, or even to reveal any morbid feature of the bladder neck (tuberculosis having been certainly excluded); and in two cases of prostatitis apparently due to early prostatic enlargement, thorough stretching of the prostate and drainage through a perineal incision failed to relieve, even temporarily, any of the symptoms. In one of these, complete relief followed the spontaneous emptying of a "prostatic" (perhaps utricular) abscess some months after operation. Two years ago while examining for Dr. Henrotin, of Chicago, a man 60 years old, suffering from prostatitis attributed to prostatic enlargement, I compressed the recto-vesical tissue between a sound in the bladder and a finger in the rectum; the urine passed immediately afterwards contained a quantity of fetid pus. The symptoms of cystitis, which had been pronounced and constant for a year, entirely disappeared within two weeks; and fourteen months later urine and urination were still perfectly normal.

With Dr. W. K. Harrison, of Chicago, I saw a man 65 years old, who for several years had had the usual history of a prostatic; during the last six months urination had become practically dependent upon the catheter; the urine contained some blood but only a little pus. The prostate and recto-vesical tissue were swollen. Two days later I made a perineal urethrotomy; the exploring finger found a swelling at the floor of the urethro-vesical orifice which burst under pressure, discharging perhaps an ounce of pus; the empty cavity was found to occupy the position of the utricle. There was no decided hypertrophy of the prostate.

Such experiences have led me to think that utriculitis is often a factor in the production of the prostatic and vesical symptoms attributed to prostatic enlargement as well as of the apparent enlargement itself, which is certainly at times edematous and inflammatory rather than hypertrophic; and that operative measures for the relief of prostatic enlargement should provide for drainage of the prostatic urethra and of the utricle. I have elsewhere (JOURNAL AMERICAN MEDICAL ASSOCIATION, April 7, 1894) described, as "posterior prostatic-cystotomy," an operation which seems to possess certain advantages over the supra-pubic incision; among others it affords access to the utricle, seminal vesicles and prostatic urethra, whose morbid conditions are apt to be confounded with "cystitis."

Summary.—1. The rudimentary extremity of the Müllerian duct in the human male, commonly termed the prostatic utricle, is not wholly inclosed by the prostate, but is partly bordered by the pelvic connective tissue.

2. It presents two morbid conditions: *a*, distension with the products of its own glands; and *b*, suppurative inflammation; the latter may infect the contiguous recto-vesical connective tissue.

3. The almost complete inclosure of the utricle by the prostate results in a community of morbid processes, and of clinical symptoms.

4. In cases of prostatic-cystitis from any cause, prostatic and peri-prostatic abscess, the possibly important rôle of the utricle should be considered.

5. Because of the minute size and frequent occlusion of the urethral orifice of the utricle, the usual methods of medicating the deep urethra can not be relied upon to influence a morbid process in the utricle itself.

6. The utricular cavity can be reached (aside from the possibilities of the endoscope) in three ways: *a*, through an aspirating needle passed from the perineum into the triangular space between the upper extremities of the lateral prostatic lobes; *b*, through a puncture with a narrow knife passed from perineum to bladder through the triangular space mentioned, with appropriate drainage; this can be readily added to the ordinary drainage of the bladder by perineal urethrotomy; *c*, by incision into the ischio-rectal fossa and separation of rectum from prostate.

7. Disease of the utricle seems to have been erroneously attributed to the seminal vesicle.

CLINICAL HISTORY OF THE CASE OF PRESIDENT JAMES ABRAM GARFIELD.

BY ROBERT REYBURN, A.M., M.D.

PROFESSOR OF PHYSIOLOGY AND CLINICAL SURGERY MEDICAL DEPARTMENT HOWARD UNIVERSITY, WASHINGTON, D. C., AND ONE OF THE ATTENDING SURGEONS IN THE CASE OF PRESIDENT GARFIELD.

(Continued from page 549).

August 24, 8:30 A.M. Temperature 98.5; pulse 100; respirations 17. August 24, 12:30 P.M. Temperature 99.2; pulse 104; respirations 17. August 24, 6:30 P.M. Temperature 100.7; pulse 108; respirations 19.

August 24 8:30 A.M. The President passed a very good night awakening at longer intervals than during several nights past. He continues to take liquid food by the mouth with more relish, and in such quantity that the nutritive enemata were suspended for the present. Shortly after the noon bulletin was issued, an incision was made into the swelling on the right side of the President's face for the purpose of relieving the tension of the swollen parotid gland and giving vent to pus, a small quantity of which was evacuated by the operation. The seat of the incision was sprayed with carbolic acid, but no anesthetic was given him, and he bore the operation well. He has not suffered from nausea to-day. 6:30 P.M. His temperature this afternoon is, however, higher than yesterday at the same hour, and his pulse somewhat more frequent.

The President continues to be very anxious to leave the White House. To-day he asked Dr. Bliss

if he could be removed by the time cold weather came. Dr. Bliss told him he would be removed as soon as his stomach was all right. "It's all right now," said the President. "I want to get away. If we can't go to Mentor, I want to go down the river on the *Tallapoosa*." (Steamship.) The President slept most of the night, but his sleep was broken and disturbed. Professor Agnew, who had returned to Philadelphia on the 23rd inst., was telegraphed for, and joined in the morning consultation of the 25th.

August 25. This morning the President is taking liquid food in sufficient quantity so that the nutritive enemata have not been renewed. August 25, 8:30 A.M. Temperature 98.5; pulse 106; respirations 18. August 25, 12:30 P.M. Temperature 99.2; pulse 112; respirations 19. August 25, 6:30 P.M. Temperature 99.8; pulse 112; respirations 19.

Many statements having become current to the effect that the condition of the President was greatly influenced by the miasma generated by the marshes which existed south of the White House; the matter was carefully considered by the attending and consulting surgeons this morning, and they issued the following bulletin after the morning dressing of the wound:

AUGUST 25, 9:15 A.M.

The subject of the removal of the President from Washington at the present time was earnestly considered by us last night and again this morning. After mature deliberation the conclusion arrived at by the majority was that it would not now be prudent, although all agree that it will be very desirable at the earliest possible moment at which his condition may warrant it. We are, moreover, unanimously of the opinion that at no time since the injury has the President exhibited any symptoms of malaria.

(Signed)

FRANK H. HAMILTON,
 D. HAYES AGNEW,
 D. W. BLISS,
 J. K. BARNES,
 J. J. WOODWARD,
 ROBERT REYBURN.

A little more pus came from the incision in the parotid gland to-day, but the swelling of the gland remains stationary. During the past three days the President's demands for his removal to some other locality have been frequent and almost imperative. He is most anxious to go some place, but not to the Soldiers' Home. He will not think of that. He has been very restless over the subject, and his determination to be taken to another place has been the cause of much anxiety in the sick room. Upon that subject alone he has refused to be guided by his physicians and friends. He refuses to pay any attention whatever to statements that it was impossible to take him away from the White House. After he had been told that he could not with safety be removed, he would not be in the least convinced, but would still as earnestly and persistently say that he must get away. Mentor is where he specially wants to go. Next to that he wants to be taken on board the steamer *Tallapoosa* for a cruise upon the salt water. His persistence in this matter may perhaps be explained by the fact that whenever he went upon a sea voyage he was always greatly benefited thereby. At 6:30 P.M. the wound was dressed as usual, and no unfavorable change has been observed in his condition. He has taken by the mouth a sufficient supply of liquid food.

August 26, 8:30 A.M. The President slept most of the night, awakening at intervals of half an hour to an hour. On first awakening there was, as there has been for several nights past, some mental confusion,

which disappeared when he was fully aroused, and occasionally he muttered in his sleep. These symptoms have abated during this morning, as on previous days. At present his temperature is slightly above the normal, and his pulse a little more frequent than yesterday morning.

August 26, 8:30 A.M. Temperature 99.1; pulse 108; respirations 17. August 26, 12:30 P.M. Temperature 100; pulse 118; respirations 18. August 26, 6:30 P.M. Temperature 99.9; pulse 116; respirations 18.

After awakening this morning the President's mind seemed perfectly clear, and he conversed rationally with the surgeons about the condition of the inflamed parotid gland. At the morning dressing of the President it was observed that pus from the parotid swelling had found its way spontaneously into the right external auditory meatus, through which it was discharging; some pus was also being discharged through the incision made over the swollen parotid gland, and also into the mouth, having dissected its way along the course of Steno's duct.

His wound looks as well as it has done for some time past. His pulse and temperature are at the present higher than at the corresponding hour for some days past. He continues to take by the mouth the liquid food, and it seems to be assimilated without difficulty, nevertheless we can not but regard his condition as extremely critical.

August 26, 6:30 P.M. The President's condition has not materially changed since the noon bulletin was issued. He occasionally asks for food, and since yesterday forenoon, commencing at 11:30 A.M., the nutritive enemata have again been given at regular intervals, as a means of administering stimulants as well as nutrients. The President seems drowsy and slept a considerable part of the day.

August 27, 8:30 A.M. The President slept from half an hour to an hour or more during the night. He continues to retain the liquid food given by the mouth, and the stimulating enemata; nevertheless his pulse has become more frequent since midnight, and at 6 A.M. this morning was so flickering and irregular that it was impossible to count it. He is evidently feebler this morning than yesterday.

August 27, 8:30 A.M. Temperature 98.4; pulse 120; respirations 22. August 27, 12:30 P.M. Temperature 99.6; pulse 120; respirations 22. August 27, 6:30 P.M. Temperature 98.9; pulse 114; respirations 22. At the morning dressing no material change was observed in the wound, and the parotid swelling appeared to be in the same condition as yesterday. The temperature which was slightly subnormal in the morning, rose a little over one degree (Fahrenheit) by noon, and during the morning the pulse was somewhat fluctuating.

August 27, 8:30 P.M. There was no improvement in the condition of the President at the time the noon bulletin was issued; during the afternoon, however, his symptoms showed a slight amelioration. His pulse became less frequent, and his temperature a little lower (98.9 F.). The mental disturbance mentioned in yesterday morning's bulletin has disappeared. The parotid swelling has discharged a little pus by the opening spontaneously formed into the ear as well as by the incision made, but it is not perceptibly smaller. The liquid food given by the mouth and the enemata continue to be retained: 10:30 P.M. The President seems more comfortable.

This has been a gloomy day at the White House. The surgeons and attendants were on duty all night, and for almost the first time the President expressed himself in terms of discouragement about his own case, and inquired anxiously about his symptoms. His mind is perfectly clear.

August 28, 8:30 A.M. The amelioration in the President's symptoms announced in last evening's bulletin continued during the night, and since midnight some further improvement has taken place. The pulse has progressively diminished in frequency. The stomach has continued to assimilate the liquid nourishment administered, and last evening he asked for and ate a small quantity of milk toast. Stimulating and nutritive enemata continue to be retained. There has been no mental disturbance during the night or this morning.

August 28, 8:30 A.M. Temperature 98.4; pulse 100; respirations 17. August 28, 12:30 P.M. Temperature 99.5; pulse 104; respirations 18. August 28, 6:30 P.M. Temperature 99.7; pulse 110; respirations 20.

August 28, 12:30 P.M. At the morning dressing of the President several yellowish points were observed just below the ear over the swollen parotid, and an incision being made about a teaspoonful of pus escaped. There was also some discharge of pus through the two openings (into the ear and the one made by the incision) mentioned in previous bulletins. The wound looks rather more healthy than it has been doing for several days past. Since the morning bulletin there has been a slight rise of temperature though but little increase in the frequency of the pulse.

August 28, 6 P.M. The improvement in the President's condition still continues. He continues to take willingly the liquid food given him, and also retains the stimulants and nutrients given him by enema. His pulse is stronger than it was at the same hour yesterday, and but little rise in temperature has taken place since noon.

August 28. This day (Sunday) was intensely hot, the thermometer ranging over 98 degrees F. during the entire day, and the cooling apparatus was put in operation to the great relief of the suffering President. This day prayers were offered on behalf of the President in all the churches of Washington City, and indeed in nearly all the churches in the country. During the evening I told him of the prayers so universally being offered in his behalf. With a sad and pathetic smile he answered: "I am glad of it; I have need of them."

August 29, 8:30 A.M. The President's symptoms this morning are as favorable as they were yesterday at the same hour. Last night was spent much more comfortably by the President than the previous one. He was restful and there was none of the hacking cough that had disturbed him the night before. He slept (awakening at intervals) the greater part of the night. At these intervals he took and retained the liquid nourishment administered. His mind continues perfectly clear.

August 29, 8:30 A.M. Temperature 98.5; pulse 100; respirations 17. August 29, 8:30 A.M. Temperature 98.6; pulse 106; respirations 18. August 29, 6:30 P.M. Temperature 100.5; pulse 110; respirations 18.

August 29, 12:30 P.M. At the morning dressing another small incision was made in the lower part of

the swelling on the right side of the President's face, which was followed by a free discharge of pus. A similar discharge took place through the other openings. The swelling is perceptibly smaller and looks better. The wound remains in an unchanged condition, and during the dressing this morning, the catheter used in injecting and cleansing the wound passed downwards to a depth of twelve inches. There has been little rise of temperature since the morning, but the pulse is more frequent.

August 29, 6:30 P.M. The President has been comparatively comfortable during the day. He has taken the usual amount of nourishment by the mouth, with stimulating enemata at stated periods. His rise of temperature this afternoon is one degree F. less than yesterday at the same hour, and his pulse is less frequent than at noon to-day. The parotid swelling has been discharging more freely, and is continuing to diminish in size.

Queen Victoria through Minister Lowell sent on Saturday a message to Secretary Blaine saying: "I am most deeply grieved at the sad news of the past few days, and would wish my deep sympathy to be conveyed to Mrs. Garfield."

August 30, 8:30 A.M. Last night was an uneventful and quiet one for the President, as he slept the greater portion of the night. The rise in temperature last night was due no doubt to the accumulation of pus in the swollen parotid, and subsided as soon as it was evacuated.

August 30, 8:30 A.M. Temperature 98.5; pulse 102; respirations 18. August 30, 12:30 P.M. Temperature 98.9; pulse 116; respirations 18. August 30, 6:30 P.M. Temperature 99.5; pulse 109; respirations 18.

August 30, 12:30 P.M. At the morning dressing another small incision was made in the lower part of the swelling on the right side of the President's face, which was followed by a free discharge of pus. A similar discharge took place through the other openings. The wound in the body remains in an unchanged condition. There has been a very slight rise in the temperature since the morning dressing, but the pulse is more frequent. In other respects his condition remains about the same.

August 30, 6:30 P.M. The President has had a fairly comfortable day. The only solid food given him was a little soft milk toast, with occasionally a spoonful of chicken jelly. He took his liquid food as usual with the nutritive enemata. The President complained this afternoon of pain in the parotid gland, which is discharging freely, and is continuing to diminish in size. His temperature this afternoon is a degree (F.) less than it was yesterday at the same time, and his pulse is less frequent than at noon to-day. The pus in the track of the wound in the body is dissecting its way downwards towards the right iliac fossa and a probe can be easily passed downwards to the extent of twelve inches. This channel was kept free from accumulations of pus by being irrigated with weak solutions of carbolic acid or permanganate of potash twice a day; while doing this the catheter was carefully withdrawn so as to avoid undue distension of the track of the wound.

August 31, 8:30 A.M. The President passed a very tranquil night. The sensitiveness of the parotid gland of which he complained yesterday afternoon abated, and he was without pain from that cause. In addition to the liquid food given him, he received a

small piece of steak of which he swallowed the juice.

August 31, 8:30 A.M. Temperature 98.4; pulse 100; respirations 18. August 31, 12:30 P.M. Temperature 98.4; pulse 95; respirations 17. August 31, 6:30 P.M. Temperature 98.6; pulse 109; respirations 18.

August 31, 12:30 P.M. At the morning dressing the parotid gland was found to be discharging freely. It has materially diminished in size, and the openings made in it show evidences of the formation of granulations around their edges.

August 31, 6:30 P.M. The President has passed a better day than he has had for some time past. He has taken his food with increased relish, and the usual afternoon rise of temperature did not occur. At the evening dressing the solution of permanganate used to wash out the parotid abscess found its way to the mouth, which it did not do this morning, showing that an opening into the mouth has spontaneously occurred.

During the past two weeks a number of pustules of acne, many of which suppurated appeared in the axillæ, and later four or five appeared on the trunk of the body; these were about the size of large peas, and were opened as soon as they suppurated. These were evidently due to the septic condition of the President's system. The small carbuncle mentioned in the report of the autopsy upon the body of the President was no doubt due to the same cause. The above were the only suppurating surfaces, excepting the incisions made into the wound, and four small superficial bedsores formed on the sacrum, which were observed on the body of the President during his illness.

Professor Agnew returned to Philadelphia to-day, and was relieved by Professor Hamilton.

September 1. About 9 P.M. last evening the President became restless and somewhat feverish. His pulse was somewhat irregular and fluctuating, and varied from 108 to 116 per minute. This condition which was unaccompanied by rigors or sweating, had subsided by midnight and after that time he slept fairly well.

September 1, 8:30 A.M. Temperature 98.4; pulse 100; respirations 17. September 1, 12:30 P.M. Temperature 98.6; pulse 108; respirations 18. September 1, 6:30 P.M. Temperature 99.4; pulse 108; respirations 18.

September 1, 12:30 P.M. At the morning dressing of the President the abscess of the parotid was found to be discharging freely and continuing to diminish in size. The state of the wound remains the same. His general condition is not materially different from what it was yesterday at the same hour, except that the pulse is somewhat more frequent. This morning in addition to his liquid refreshment he took a little beefsteak (swallowing the juice) and some gruel.

September 1, 6:30 P.M. The condition of the President has not materially changed since the noon bulletin, except that there has been a moderate rise this afternoon amounting to one degree (F). The question of the removal of the President to a more salubrious and cooler location was discussed at the meeting of the surgeons to-day, but on account of the absence of Professor Agnew the final settlement of the question was deferred until his arrival, which will take place the day after tomorrow. The President slept well during the night, and his condition was much more satisfactory than during the previous night. He waked at intervals, and at such times was

given more nourishment than usual. There was but little fever during the night. The condition of the parotid gland and wound remains the same.

September 2, 8:30 A.M. Temperature 98.4; pulse 100; respirations 17. September 2, 12:30 P.M. Temperature 98.7; pulse 100; respirations 18. September 2, 6:30 P.M. Temperature 99.2; pulse 104; respirations 18.

Among the many suggestions made respecting the removal of the President, one is for his removal by the Pennsylvania Railroad to Elberon, and the other is for a trip by water on the steamer, *Tallapoosa*.

The mails each day bring hundreds of letters containing all manner of plans for removing the President, and suggestions as to where he should be taken. After the noon examination to-day by Dr. Bliss, General Swaim, Colonel Rockwell, Ensign Hunt and Private Secretary Brown drove down to the Navy Yard to inspect the *Tallapoosa*, and see what quarters and accommodations there would be for the President on board the vessel.

September 2, 6:30 P.M. The President passed a comfortable day, and this evening appears to be better than for some days past. He has taken a larger quantity of nourishment than usual, and manifested greater relish for it. The parotid gland continues to diminish in size. Wound shows no change.

September 3, 8:30 A.M. The President was somewhat more restless than usual during the early part of the night, but slept better after 1 A.M. This morning his general condition does not differ materially from what it was at the same hour yesterday, except that there is a slight increase in the frequency of the pulse. He is a little weaker than yesterday, but otherwise there is no change.

September 3, 8:30 A.M. Temperature 98.6; pulse 104; respirations 18. September 3, 12:30 P.M. Temperature 98.4; pulse 104; respirations 18. September 3, 6:30 P.M. Temperature 99.6; pulse 102; respirations 18.

Professor Agnew arrived this morning. There is a general agreement among the medical attendants that the condition of the President is unfavorably influenced by the excessive heat of the weather, and by the noxious emanations from the Potomac River flats immediately south of the Executive Mansion. The rank vegetation which fertilized by the city sewerage, and stimulated by abundant water and hot sunshine, covers these flats during the summer, is now beginning to decay, and since yesterday morning a faint malodorous mist has hung over the river on the south side of the Executive Mansion grounds to the Long Bridge. The prevailing winds in Washington are southerly during the summer months, and these winds brought the emanations from the flats (or marshy grounds) directly to the windows of the President's room. The risk incurred in removing the President did not seem to the surgeons to be as great as it would be if he was retained in his present location in the White House. Besides his liquid nourishment the President to-day took a little milk toast, and some of the breast of reed birds. His general condition remains the same as yesterday. After consultation it was unanimously agreed that the sea voyage on the steamer *Tallapoosa* would not be advisable, nor likely to result in any permanent benefit to the President.

September 4, 8:30 A.M. The President vomited once late last evening, and once an hour after midnight. Notwithstanding this disturbance he slept

well most of the night, and this morning has taken his food without any nausea. His pulse is a little more frequent, but in other respects his condition is about the same as at this hour yesterday.

September 4, 8:30 A.M. Temperature 98.4; pulse 108; respirations 18. September 4, 12:30 P.M. Temperature 98.4; pulse 106; respirations 18. September 4, 6:30 P.M. Temperature 99; pulse 110; respirations 18.

September 4, 6:30 P.M. The President has passed a comfortable day. He has taken his food with relish, and has had no return of the irritability of stomach mentioned in this morning's bulletin. The parotid swelling is now so much reduced that the contour of the face is restored. The rise of temperature this afternoon has been very slight, but his pulse is more frequent. He seemed more exhausted than usual after the dressings of his wound, and is perceptibly weaker. He is becoming quite impatient in his desire to leave the White House for Elberon. The tenacious mucus which has been discharged in great quantities from the right side of the President's mouth has been to him a great source of annoyance and distress. This was coincident with the inflammation of the parotid gland, and as it will be remembered resulted in the formation of an abscess, which opened spontaneously, through the external auditory canal of the right ear, on August 26, and on August 31 discharged itself into the mouth. During the early stages of the inflammation of the parotid there was such rigidity of the masseter muscle that the jaws were so firmly fixed as to preclude the possibility of opening the mouth sufficiently for satisfactory examination. An interesting fact was observed that the inflammation of the mucous membrane of the mouth seemed to extend by continuity to the mucous membranes of the pharynx, larynx, trachea and bronchia. The physical signs developed the fact that acute bronchial catarrh was the sequel. Hypostatic congestion of the lungs was observed for some weeks before the President was taken to Elberon, more extensive on the right side than on the left, on account of decubitus. On the right side of the body it extended to the sixth rib posteriorly, while on the left side it was comparatively slight.

September 5. The President was restless during the early part of the night, but slept fairly well after midnight. There was no recurrence of the vomiting in the night nor was there any this morning. His pulse fluctuated during the night a good deal, and he was feverish and restless. In the night he commenced talking about the arrangements for his removal, and although every effort was made to pacify him, he persisted in talking of the matter and arranging the details of his departure. Dr. Bliss and the other surgeons told him that all arrangements were being made as rapidly as possible, and that as soon as they were completed, they would start on their journey. This morning he took beef extract and chicken broth for breakfast.

September 5, 8:30 A.M. Temperature 99.5; pulse 102; respirations 18. September 5, 12:30 P.M. Temperature 99.5; pulse 104; respirations 18. September 5, 6:30 P.M. Temperature 99.8; pulse 108; respirations 18.

The first thing the President asked Dr. Bliss this morning when he went into his room was: "Well, is this the last day in the White House?" Dr. Bliss

tried to quiet him, but he said: "No, no, I don't want any more delay." About 2 A.M. this morning the special train which is intended for the conveyance of President Garfield and the party accompanying him to Elberon arrived at the Baltimore & Ohio depot. It will be composed of an anthracite coal burning engine No. 569 (selected on account of its absence from dust), President Roberts' special car, two Eastlake cars and a baggage car. Car No. 33, which is to convey the President, has been thoroughly renovated. The seats were all taken out and a false top was placed a few inches above the roof of the car, in order to give the air an opportunity to circulate between it and the roof, so as to keep the air cool. Wire gauze was fastened on the outside of the car, completely inclosing the parlor for the President, thus keeping it free from dust. The inside was hung with heavy curtains, and Brussels carpet was laid on the floor. The method of removal of the President determined on was to take him from the White House on a stretcher in a covered wagon to the corner of Sixth Street and Pennsylvania Avenue, where he will be lifted into the car provided for his reception. To make this possible, Chief Engineer Walters had on the ground this morning a force of three hundred men, who at once proceeded to lay a temporary railroad track from the east side of Sixth Street to the main railroad track, a distance of over three hundred yards. In less than two and a half hours the rails were in place, and a train with gravel to ballast it was ready to work. Professor Hamilton preceded the rest of the party, and went to Elberon in advance, so as to have everything ready before the President's arrival. Notice has been given to all conductors and engineers to be on the lookout for the warning of the coming of the Presidential train. Immediately on the receipt of information that the train has left Washington, the trains going south on the Baltimore & Potomac Railroad will be stopped or switched off, until the train containing the President has passed by. It is intended that no noise of passing trains shall disturb the President, and for that reason trains going in opposite directions will wait until the special Presidential train has passed them. It having been decided by the surgeons that the President should be removed to Elberon, situated near Long Branch on the coast of New Jersey, the journey took place to-day. The details as to the precautions taken to secure his safe transit were of the most minute character, and every provision was made to meet such emergencies as might arise; even to the extent of providing places on the road for his removal from the train, during the journey, in case he should show symptoms of exhaustion.

(To be continued.)

Minority Report on Revision of the Constitution and By-Laws of the American Medical Association.

To the President and Members of the American Medical Association:

Gentlemen:—At the last meeting of the ASSOCIATION the Minority Committee made a preliminary report against the Majority Committee's revision, and now proposes, as a substitute for the Majority Committee's work, the following constitution and by-laws, to which are appended some explanatory notes for the convenience of delegates.

AMERICAN MEDICAL ASSOCIATION.

PLAN OF ORGANIZATION, CONSTITUTION AND BY-LAWS.

WHEREAS, The Medical Convention, held in the city of New York in May, 1846, has declared it expedient, "for the medical profession in the United States to institute a National Medical Association"; and inasmuch as an institution so conducted as to give frequent, united and emphatic expression to the views and aims of the medical profession in this country, must at all times have a beneficial influence, and supply more efficient means than have hitherto been available for cultivating and advancing medical knowledge; for elevating the standard of medical education; for promoting the usefulness, honor and interests of the medical profession; for enlightening and directing public opinion in regard to the duties, responsibilities and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession; and for facilitating and fostering friendly intercourse between those who are engaged in the practice of medicine; therefore be it

Resolved, In behalf of the medical profession of the United States, that the members of the Medical Convention, held in Philadelphia in May, 1847, and all others who, in pursuit of the objects above mentioned, are to unite with or succeed them, constitute a National Medical Association; and that for the organization and management of the same they adopt the following regulations:

CONSTITUTION.

ARTICLE I.—*Title and Objects of the Association.*

SECTION 1.—This organization is known as, and shall be designated the American Medical Association.

SEC. 2.—The objects of the Association shall be:

1. The cultivation and advancement of medical knowledge.
2. The elevation of the standard of medical education.
3. The promotion of the usefulness, honor, and interests of the medical profession.
4. The protection of public health.
5. The enlightenment of the people concerning the duties, responsibilities and requirements of medical men.
6. The encouragement of emulation among members of the profession.
7. The furtherance of concert of action in the profession.
8. The establishment of friendly relations among members of the profession.

ARTICLE II.—*Members.*

SECTION 1.—The Association shall be composed of members of the medical profession who shall be known as: 1, delegates; 2, permanent members; 3, members by invitation; and 4, members by application. These several classes of members shall collectively represent the common interests of the medical profession in every part of the United States.

SEC. 2.—The delegates shall receive their appointment from permanently organized State medical societies and associations in affiliation with the American Medical Association, from the medical departments of the Army and Navy, and from the Marine-Hospital Service of the United States.

SEC. 3.—Each delegate shall hold his appointment one year, but may be appointed every year, and shall be entitled to take part in all the affairs of the Association.

SEC. 4.—State medical societies and associations in affiliation with the American Medical Association shall be entitled to appoint delegates in the proportion of one for every ten of their regular members, and one for every additional fraction of more than half of that number.

SEC. 5.—Any medical society or association that

fails to adopt the American Code of Ethics, or that has intentionally violated or disregarded any article or clause thereof, shall not be entitled to representation in the American Medical Association.

SEC. 6.—The Medical Corps of the United States Army, Navy, and Marine-Hospital Service shall each be entitled to appoint four delegates.

SEC. 7.—The permanent members shall be those who have served as delegates and continue to comply with the requirements of the by-laws and ethics of this Association.

SEC. 8.—Permanent members may take part in the scientific and social proceedings, but shall not be entitled to vote.

SEC. 9.—Permanent members are authorized to introduce, by letter or in person, to the Committee of Arrangements, regular physicians of good repute who indorse the Association's ethics and who may wish to attend a meeting of the Association as members by invitation.

SEC. 10.—The members by invitation shall be regular physicians, in good standing, from foreign countries and from sections of the United States which are not represented by delegates or by permanent members at the meeting to which they may be invited by the Association.

SEC. 11.—Physicians who are proposed for membership by invitation shall be introduced to the Committee of Arrangements and vouched for by three members in attendance, or by letters from three absent delegates or permanent members.

SEC. 12.—Members by invitation may take part in the scientific and social proceedings of the Association, but shall not be entitled to vote; their connection with the Association shall continue until the close of the meeting at which they are received.

SEC. 13.—The members by application shall be such members of societies and associations entitled to representation by adopting the American Code of Medical Ethics, as shall make written application for admission to the Treasurer of the American Medical Association.

SEC. 14.—Each application shall be accompanied with the amount of the annual dues, and a certificate of good standing signed by the president and secretary of the society of which the applicant is a member.

SEC. 15.—The names of members by application shall be placed upon the roll of membership of the Association; these members shall have all the privileges of permanent members and shall retain their membership on the same terms.

SEC. 16.—Graduates of such regular schools of dental and oral surgery as require of their students a high standard of preliminary and general education, and a term of professional study equal to that demanded by the best class of medical colleges, and embrace in this curriculum all the fundamental branches of medicine; differing chiefly by the substitution of practical and clinical instruction in dental and oral surgery, in place of practical and clinical instruction in general medicine and surgery, shall be recognized as members of the regular profession of medicine, and be eligible to membership in this Association on the same conditions and subject to the same regulations as other members.

ARTICLE III.—*Further Conditions of Admission to Membership.*

SECTION 1.—All classes of members shall subscribe to the American Code of Medical Ethics.

SEC. 2.—All classes of members whose dues are fully paid shall receive gratis the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

SEC. 3.—Every delegate, prior to the permanent organization of an annual meeting, shall exhibit his credentials to the proper committee and sign these regulations, inscribing his name and address in full, and giving the title of the institution from which he has received his appointment. He shall not be entitled to take part in any of the proceedings until he shall have complied with these requirements.

SEC. 4.—None of the other classes of members shall take part in the proceedings to which they may be entitled until they have signed these regulations; inscribing their names and addresses in full and specifying the capacity in which they attend: Whether as permanent members, as members by invitation, or as members by application.

SEC. 5.—No physician who shall be under sentence of expulsion or suspension from any medical society, or whose name shall have been dropped from the rolls for non-payment of dues, shall be received as a delegate to this Association, or be allowed any of the privileges of a member, until he shall have been relieved from the sentence or disability, or shall have paid all arrears of membership dues; nor shall any person not a member and supporter of a local medical society, where such exists, be eligible to membership in the American Medical Association.

SEC. 6.—No member expelled from this Association shall be received as a delegate or member, except by a vote of three-fourths of the delegates present at the meeting to which he is sent or at which he is proposed.

ARTICLE IV.—*Titular Officers and Committees.*

SECTION 1.—The titular officers of the Association shall be: A President; four Vice-Presidents; a Permanent Secretary; an Assistant Secretary; a Treasurer, and a Librarian. With the exception of the Permanent Secretary, these officers shall serve for the period of one year.

SEC. 2.—The committees shall be: Five standing committees; one special committee, appointed by the delegates, and as many other special committees as may be required.

SEC. 3.—The standing committees shall be: a Judicial Council; a Board of Trustees; a Committee on American Medical Neurology; a Committee of Arrangements, and a Committee on Scientific Contributions.

SEC. 4.—The special committee, appointed by and from the delegates present, shall be known as the Nominating Committee. Such other special committees as may be necessary shall be appointed by the President of the Association.

ARTICLE V.—*Amendments.*

SECTION 1.—No part of this constitution shall be amended, altered, rescinded, or abolished, and no addition shall be made thereto, except at a regular annual meeting of the Association, after due notice of such amendments, alterations, excision, abolition, or additions shall have been given in writing by a delegate, at the preceding annual meeting, and then only by a vote of three-fourths of the delegates present.

ARTICLE VI.—*Enactment of the Constitution.*

SECTION 1.—This constitution shall go into effect immediately.

SEC. 2.—All sections or parts of sections of the prior constitution or by-laws, and all ordinances, declarations, or resolutions not in harmony with this amended Constitution are hereby repealed.

BY-LAWS.

ARTICLE I.—*Meetings.*

SECTION 1.—The regular meetings of the Association shall be held annually and shall last at least four days.

SEC. 2.—The particular place and time for each yearly meeting shall be determined by a vote of the Association on recommendation by the Nominating Committee.

SEC. 3.—Special meetings of the Association may be called, for urgent and extraordinary occasions, by the Judicial Council, but to decide the question of meeting, at least a three-fourths vote of the Council shall be required. For this end each member of the Council shall be polled through a printed communication, approved and signed by the President and Permanent Secretary of the Association together with five members of the Council, stating the particular object or objects, the place, time and duration of the meeting, and ending with, Are you in favor of holding this proposed special meeting?

SEC. 4.—Whenever the Judicial Council shall have determined the place and time of a special meeting, the Secretary of the Council shall make an announcement thereof in the JOURNAL of the Association at least three weeks in advance of the time of meeting.

SEC. 5.—No business other than that stated in the announcement shall be transacted at any special meeting.

SEC. 6.—At annual meetings of the Association there shall be two sessions each day, a morning and an afternoon session.

SEC. 7.—During the morning session of each day the general affairs of the Association shall be transacted; addresses shall be delivered; reports of committees made; communications from the Secretary read; and miscellaneous questions examined or referred to standing or special committees.

SEC. 8.—During the afternoon session of each day, beginning at 2 o'clock, essays, reports and communications of a scientific character may be presented by all classes of members. For these purposes the Association shall be divided into the following named Sections:

1. Practical Medicine and Physiology.
2. Obstetrics and Diseases of Women.
3. Surgery and Anatomy.
4. State Medicine.
5. Ophthalmology.
6. Diseases of Children.
7. Dental and Oral Surgery.
8. Medical Jurisprudence and Neurology.
9. Dermatology and Syphilis.
10. Laryngology and Otology.
11. Materia Medica and Pharmacy.

ARTICLE II.—*Nominations.*

SECTION 1.—During a recess of twenty minutes at the first morning session of the Association the accredited delegates shall meet in groups representing each of the States and Territories, the District of Columbia, the Army, the Navy and the Marine-Hospital Service; each group being authorized to

select one delegate who shall serve as a member of the Nominating Committee.

SEC. 2.—The chairman of each group of delegates shall, as soon as practicable, report the name of the delegate, chosen as member of the Nominating Committee, to the Permanent Secretary who, before adjournment of the morning session of the first day, shall announce the formation of the Committee, the names of its constituent members, and the hour and particular place of the meeting.

SEC. 3.—The Nominating Committee thus constituted shall open its first session on the afternoon of the first day and elect a chairman and secretary.

SEC. 4.—It shall be the duty of the Nominating Committee to recommend to the Association for action: The President; the four Vice-Presidents; the Permanent Secretary, when that office shall be vacant; the Assistant Secretary; the Treasurer; the Librarian; the names of delegates to fill all vacancies in the first four Standing Committees, the names of three members, the first of whom shall deliver an address on general medicine, the second on general surgery, and the third on State medicine—each of these addresses not to exceed one hour in its delivery which shall be during a morning session of the Association, and to suggest the place and time of the next annual meeting.

SEC. 5.—The selection of titular officers and standing committees for nomination shall be made only among delegates present at the meeting, except in the case of the Committee of Arrangements, of the Committee on American Medical Necrology, and of those members who shall deliver addresses at the general sessions of the Association. In these cases the Committee shall act at discretion.

SEC. 6.—The Nominating Committee shall make its report to the Association during the morning session of the third day whenever practicable.

ARTICLE III.—*Duties of the Titular Officers.*

SECTION 1.—The President and Vice-Presidents shall assume the duties of their respective offices at the close of the meeting at which they were elected.

SEC. 2.—The President shall preside at the meetings, preserve order and decorum in debate, give a casting vote when necessary, and perform all the other duties that custom and parliamentary usage may require.

SEC. 3.—The Vice-Presidents, when called upon, shall assist the President in the performance of his duties, and during the absence, or at the request of the President, one of them shall act in his place.

SEC. 4.—The Permanent Secretary shall record the minutes, and authenticate the proceedings of the Association; give due notice of the place and time of each annual meeting; notify all members of their appointment and of the duties assigned them; hold correspondence with permanently organized medical societies, both domestic and foreign; carefully preserve the archives and unpublished transactions of the Association, and deliver to the Trustees all materials ordered to be published. The Permanent Secretary shall be a member of the Committee of Arrangements.

SEC. 5.—The Assistant Secretary shall aid the Permanent Secretary in recording and authenticating the proceedings of the Association; serve as a member of the Committee of Arrangements, and perform all the duties of Permanent Secretary temporarily whenever that office may be vacant.

SEC. 6.—The Treasurer shall have the immediate charge and management of the Association's funds, and shall, through the Board of Trustees, present an annual report, in detail, of the state of the treasury, and a duly authenticated account of receipts and expenditures during the current year. He shall give bonds to the Board of Trustees for the safe keeping and proper use and disposal of his trust.

SEC. 7.—The Librarian shall receive and preserve all the property in books, pamphlets, journals and manuscripts presented to or acquired by the Association; record their titles in a book prepared for that purpose; and acknowledge receipt of all property to him transferred.

ARTICLE IV.—*The Judicial Council.*

SECTION 1.—The Judicial Council shall consist of twenty-one delegates elected by the Association on recommendation by the Nominating Committee. The term of office of members of this Council shall be three years.

SEC. 2.—The Council shall appoint one of its members as presiding officer and another as secretary, who shall keep an accurate permanent record of the Council's proceedings and prepare all reports to be presented to the Association.

SEC. 3.—It shall be the duty of the Council to take cognizance of, and decide all questions of an ethical or of a judicial character that may arise in connection with the Association.

SEC. 4.—All subjects that do not pertain to the Board of Trustees, to the Committee of Arrangements, or to other committees; all questions of a personal character, including complaints, protests and irregularities in credentials; shall at once and without debate, be referred to this Council whose decisions, on these and all other questions shall be final and shall be reported to the Association at the earliest moment.

SEC. 5.—The Council shall hold its annual meeting on the day before the first morning session, and such other meetings as may be necessary during or after morning sessions of the Association. In the course of the current year, urgent questions may be settled by correspondence on the same plan as that indicated below in Section 2, Article V.

ARTICLE V.—*The Board of Trustees.*

SECTION 1.—The Board of Trustees shall consist of nine delegates elected by the Association on recommendation by the Nominating Committee. The term of service of members of this Board shall be three years.

SEC. 2.—The Board shall hold its annual meeting on the day before the first morning session, and such other meetings as may be necessary during or after morning sessions of the Association. In the course of the current year, urgent questions may be settled by written votes, provided that the questions to be determined be presented in writing, or in type, and in identical language, to each member of the Board.

SEC. 3.—The Board shall appoint one of its members as presiding officer, and one as secretary, who shall keep an accurate record of the proceedings and prepare all reports to be presented to the Association.

SEC. 4.—It shall be the duty of this Board to provide for and superintend the publication and distribution of such proceedings, transactions and memoirs of the Association as may be ordered to be published, in such manner as the Association may

direct; to cause to be printed all these proceedings, transactions and memoirs in the form of a weekly publication which shall be styled THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION; and to appoint an editor and such assistants as may be needed to carry on the publication and distribution of the JOURNAL. The Board shall be authorized to determine the pay of the editor and of all subordinate persons engaged in the work of printing, proof reading, publication and distribution of all the Association's documents.

SEC. 5.—The editor of the JOURNAL shall not publish editorially, expressions contrary to the objects, ethics or discipline of the Association. Such expressions shall be regarded as disloyal to the Association whose principles he shall voice.

SEC. 6.—The secretaries of the several Sections, during the annual meetings, or as soon thereafter as possible, shall deliver to the Board of Trustees, or to its accredited agent, all papers, discussions, addresses and other documents designed for publication in the JOURNAL.

SEC. 7.—All propositions for the appropriation of money shall be referred to the Board of Trustees, with instructions to inquire closely into the nature and objects of such propositions and report thereon before final action by the Association.

SEC. 8.—Moneys derived from the business of the JOURNAL or accruing from other sources, to the benefit of the Association, and received by the Board of Trustees or its agents, shall be paid to the Treasurer of the Association.

SEC. 9.—Every order on the Treasurer for the disbursement of money in connection with the work of publication, or for the payment of other accounts against the Association, shall be indorsed by the presiding officer and secretary of the Board of Trustees.

SEC. 10.—The Board of Trustees shall hold the official bond of the Treasurer, shall annually audit and authenticate his accounts, and shall embody a statement thereof in his yearly report to the Association.

SEC. 11.—The Board of Trustees shall cause to be printed in the JOURNAL, once yearly, a list of the members, the Constitution and By-laws and the Code of Ethics of the Association, and to be inserted at the beginning of each volume of the JOURNAL the following disclaimer: The American Medical Association, although accepting and publishing the reports of the several standing committees, and memoirs, essays and discussions of members, assumes no responsibility whatsoever for the opinions, theories or criticisms therein contained, except when otherwise decided by special resolution.

SEC. 12.—No address, paper, or report shall be entitled to publication in the JOURNAL for the year in which it shall be presented to the Association, unless it be placed in the hands of the Board of Trustees, or of its accredited agent, on or before the first day of July. The document shall be so prepared as to require no material alteration or addition by its author.

SEC. 13.—Authors shall be required to return proofs of their compositions within a week after receiving them; otherwise they may be omitted from the JOURNAL.

SEC. 14.—Every paper received by the Association and ordered to be published, and all plates or other means of illustration, shall be the exclusive property

of the Association and shall be published and sold for the benefit of the Association.

SEC. 15.—The Board of Trustees shall have full discretionary power to omit from publication the whole or a part of any paper that may be referred to it by the Association, or by any of the Sections, unless specially instructed to the contrary by vote of the Association.

ARTICLE VI.—*The Committee on American Medical Neurology.*

SECTION 1.—The Committee on American Medical Neurology shall consist of one member from each State, and from each of the other interests entitled to representation in the Association.

SEC. 2.—The chairman and other members of this Committee shall be recommended by the Nominating Committee to the Association for election.

SEC. 3.—It shall be the duty of members of this Committee to procure memorials of the dead among eminent and distinguished physicians of their respective States and Territories, and transmit these memorials to the Chairman of the Committee on or before the first of April of each and every year.

SEC. 4.—The Chairman of the Committee shall make an annual report to the Association.

ARTICLE VII.—*The Committee of Arrangements.*

SECTION 1.—The Committee of Arrangements shall consist of not less than seven delegates, including the Permanent Secretary and the Assistant Secretary of the Association. The Chairman of this Committee and the Assistant Secretary, together with four delegates, shall be elected by the Association on recommendation by the Nominating Committee, and shall all be residents of the city where the meeting of the Association shall be held.

SEC. 2.—The Committee of Arrangements shall be authorized to increase the numbers of its members whenever there is need of such increase, and to hold such conferences as may be necessary prior to the annual meeting of the Association during the whole of which the Committee shall be in session.

SEC. 3.—It shall be the duty of this Committee to provide suitable accommodations for the meetings of the Association; to verify and report upon the credentials of membership; to issue credentials of membership to such physicians as fulfill the required conditions; to publish the rules governing the reading and discussion of papers, and the order of business of the general and sectional meetings; to receive and announce the titles of all papers and communications to be presented; and, with the aid of the Secretaries of the several Sections, determine the order in which the papers shall be read and discussed.

SEC. 4.—This Committee shall cause each member, of whatever class, to register, upon a blank prepared for the purpose, his name, address, source of appointment, place of residence during the meeting, and the name of the Section with which he wishes to be identified.

SEC. 5.—The Committee shall prepare a separate roll, by State and other interests represented, of all delegates present, for convenience of calling the ayes and nays when these are demanded during a morning session.

SEC. 6.—The Committee of Arrangements shall be authorized to invite distinguished laymen and also foreign medical men to take part in the scientific and social proceedings as guests of the Association.

SEC. 7.—The Association shall pay all necessary expenses for the announcement of the meeting, the publication of the programs, the cards of membership, the rental of a hall for the general meetings, and the rooms for meetings of Sections. If the Committee of Arrangements incurs other expenses it shall meet them from its own resources. The chairman of this Committee shall make his annual report at the first general session of the Association, and such special reports thereafter as may be necessary.

ARTICLE VIII.—*Dues of Members.*

SECTION 1.—The dues of all classes of members shall be five dollars a year. This shall entitle each member to receive gratis the JOURNAL of the Association for the current year. The payment of their dues shall be made by these members before they shall be entitled to take part in any of the Association's proceedings. Members not in attendance shall send their dues to the Treasurer.

SEC. 2.—Any member who shall fail to pay his dues shall no longer be entitled to receive the JOURNAL and, unless absent from the country, shall be dropped from the roll of the Association after having been notified of the forfeiture of his membership.

ARTICLE IX.—*Funds and Appropriations.*

SECTION 1.—Funds shall be raised by the Association to meet current expenses and awards, from year to year, but never with a view of creating a permanent income from investments. These funds shall be obtained from the annual dues of members, the business of the JOURNAL, and the sale of the Association's publications. Special funds may be raised through voluntary subscriptions for particular objects.

SEC. 2.—Funds may be appropriated: To defray the expenses of the Permanent Secretary in conducting the necessary correspondence of the Association, and his personal expenses in attending the annual meetings; to publish the Association's proceedings and transactions; to enable the standing committees to fulfill their respective duties, conduct their correspondence, and procure materials necessary for the completion of their annual reports; to encourage scientific investigation by prizes and awards of merit, and to defray expenses incidental to particular investigations under the instruction of the Association. Funds thus appropriated shall be paid by the Treasurer on an order from the Board of Trustees.

ARTICLE X.—*Ethics and Discipline.*

SECTION 1.—The Code of Ethics, adopted in 1847, as a condition of membership, and as it appeared with explanatory declarations in the JOURNAL of the Association, Nov. 19, 1892, shall constitute a part of the Association's laws.

SEC. 2.—The kinds and degrees of discipline of members, beyond dropping of names from the roll for non-payment of dues, shall be censure, suspension, or expulsion from the Association.

SEC. 3.—In case the Judicial Council shall be officially notified, by any organization in affiliation with this Association, of the expulsion from such organization of a member who is also a member of this Association, the name of such member shall be dropped from the roll of this Association, and he shall be notified of the fact and of the reason which led thereto.

SEC. 4.—The Judicial Council shall hear all complaints against members for conduct prejudicial to the interests of the Association or for violation of its laws. The Council shall notify any member against whom a charge has been preferred to appear in his defense, and shall at the same time furnish the accused with a copy of the charge or charges made against him. The accuser shall also be notified to appear with documents or witnesses and give evidence in the case. The accused shall be entitled to be aided in his defense by a member of the Association who shall act as his counsel, and the accuser shall likewise be aided in the prosecution by a member of the Association who shall act as his counsel. The Judicial Council shall appoint three of its members to sit as judges, who shall at the conclusion of the trial report the result thereof, for review, to the Council, whose decision shall be final.

SEC. 5.—A charge or charges against a member shall be made in writing, signed by the member making the charge or charges, inclosed in a sealed envelope, indorsed, "Charge or Charges against a Member," and shall be sent to the Secretary of the Council, to be by him presented to the Council.

SEC. 6.—The Council shall investigate all apparently flagrant violations of the Code of Ethics by a member, even without receiving formal charges from another member, and shall proceed with and decide the case as provided in Section 4 of this Article.

ARTICLE XI.—*Order of Business at the General Sessions.*

SECTION 1.—The order of business at the general sessions of the annual meetings of this Association shall, at all times, be subject to the vote of three-fourths of all the delegates in attendance; and, until permanently altered, except when for a time suspended, it shall be as follows:

1. Calling the meeting to order by the President or, in his absence, by one of the Vice-Presidents.
2. Report of the Committee of Arrangements.
3. Reception of guests.
4. Election of permanent members.
5. President's address.
6. Reports of special committees.
7. Voluntary communications, their reference to appropriate sections.
8. Recess of twenty minutes, on the first day, for the appointment of members of the Nominating Committee.
9. Announcement of the formation of the Nominating Committee.
10. Address on medicine, second day; address on surgery, third day; address on State medicine, fourth day.
11. Reports of the standing committees.
12. New business, first and fourth days.
13. Report of the Nominating Committee, and selection of the place of next meeting, third day.
14. Unfinished and miscellaneous business.
15. Reading of the minutes by the Secretary.
16. Adjournment.

ARTICLE XII.—*Rules of Order.*

Rule 1.—One hundred and fifty delegates, representing not less than twenty States, shall constitute a quorum for the transaction of business at the general sessions of the Association.

Rule 2.—Each member wishing to address the Association shall first give his name and that of his State

(or, if a Government officer, his title) which shall be distinctly announced from the chair. The member may then be required to speak from the stand, but not more than ten minutes.

Rule 3.—Any member appointed on a special committee who, accepting the appointment, fails to act, shall not be continued on this Committee, and shall not be appointed on any other committee unless he offer a satisfactory excuse.

Rule 4.—No new business or resolutions by members shall be introduced at the general sessions of the second and third days, except reports of committees as otherwise provided.

Rule 5.—When a motion is under debate, no motion shall be received except motions to adjourn, to lay on the table, for the previous question, to postpone, to refer, or to amend, which several motions shall have precedence in the order in which they are enumerated in this rule.

Rule 6.—A motion for the previous question shall not be entertained unless it be seconded, and supported by at least twenty delegates. When the main question is put under force of the previous question and negated, the question shall remain under consideration, the same as if the previous question had not been enforced.

Rule 7.—Motions to adjourn, to lay on the table, and for the previous question shall be decided without debate.

Rule 8.—Every delegate present shall vote on all questions unless excused from voting by the President with the consent of the Association.

Rule 9.—The ayes and nays on any question, when called for by five delegates, shall be decided without debate, and shall be recorded in full in the minutes of the Association.

Rule 10.—After a question has been decided in general session, except one of indefinite postponement, any two delegates who voted with the majority may, at the same or any subsequent general session of the same meeting, move a re-consideration thereof, without which no discussion of such question shall be allowed.

Rule 11.—Every delegate shall have the right to speak once on any question under consideration, but not oftener, unless by permission of the Association.

Rule 12.—All questions of order not provided for in these rules shall be determined in accordance with the rules of order embodied in Cushing's "Manual of Parliamentary Practice."

ARTICLE XIII.—*Delegates to Foreign Medical Societies.*

SECTION 1.—The President shall be authorized annually to appoint delegates to such foreign medical and other scientific societies as are in sympathy with this Association.

SEC. 2.—Suitable credentials signed by the President and Permanent Secretary of the Association will be given to those members who desire to represent abroad the American Medical Association.

ARTICLE XIV.—*The Sections of the Association.*

SECTION 1.—The several Sections of the Association shall be composed of all the classes of members. At the time of registering his name, on the blank supplied by the Committee of Arrangements, each member shall signify, in writing, the Section whose meetings he purposes to attend and with which he desires to be identified.

SEC. 2.—The Sections shall hold their sessions

during the afternoon of each day of the Association's annual meeting, beginning at 2 o'clock.

SEC. 3.—The officers of each Section shall be a Chairman, a Secretary, and an Executive Committee.

SEC. 4.—A new Chairman and a new Secretary shall be elected every year by each Section, on recommendation by a Nominating Committee appointed on the first day by the Section. On the second day the Committee shall make its report, which shall include the nomination of the Executive Committee.

SEC. 5.—The Executive Committee of each Section shall consist of the Chairman, the Secretary and three members chosen by the Section Nominating Committee, among members who have been in attendance at the sessions of the Section for at least two consecutive years. The first named shall serve one year; the second, two years; and the third, three years, so that one vacancy only shall need to be filled on each succeeding year.

SEC. 6.—The several Section Executive Committees shall unite to form one standing committee which shall be named the Committee on Scientific Contributions, and which shall annually elect one of its members as Chairman and one as Secretary.

SEC. 7.—The Committee on Scientific Contributions thus constituted shall hold daily meetings during the sessions of the Association, and such conferences at other times as may be deemed necessary.

SEC. 8.—Only questions that relate to the proper conduct of the affairs of the Sections shall be referred to this Committee, whose duties shall be solely in the direction of forwarding the scientific interests of the Sections; such as the selection of essayists, and the institution and arrangement of discussions on questions of a scientific and practical character.

SEC. 9.—The chairman of this standing committee shall make a report of its proceedings to the Association once yearly.

SEC. 10.—The chairman of each Section, at its first session, shall deliver a short address on the recent advances in the constituent branches of his Section, including suggestions of improvement in methods of observation, of study and of treatment.

SEC. 11.—As soon as elected, the chairman of a Section, aided by his Executive Committee, shall begin preparations for the annual meeting at which he shall sit. (While the Association is in session, he will be likely, by giving notice in his Section or by personal interview, to secure some very desirable papers for his Section, and thus save time and avoid extended correspondence.)

SEC. 12.—The titles of papers to be read and of communications to be made at Section meetings shall be sent to the chairman of the Committee of Arrangements one month before the annual meeting.

SEC. 13.—No paper shall be read longer than twenty minutes. In case more than this specified time be required to complete the reading, the author shall omit such parts of the composition as to bring it within the prescribed limit, but the paper may be published in its entirety if the author wishes. No member shall discuss any paper more than once, or speak longer than fifteen minutes without unanimous consent.

SEC. 14.—No paper shall be read before any Section that is not in such condition as to pass at once from the author's hands to the Executive Committee of the Section. This Committee, within thirty days, shall forward the entire work of the Section to the Board

of Trustees, after having carefully edited every document, and with such recommendations as may be deemed proper. But no paper shall thus be sent by an Executive Committee unless such paper embody some of the qualities set forth as follows:

1. A clear and succinct statement of the establishment or restoration of valuable discoveries, principles and modes of practice.

2. The results of well-devised original experimental research.

3. A critical and analytical review of any particular subject, such as is likely to enable the author to deduce therefrom conclusions of much value and importance.

SEC. 15.—Other papers, containing materials of more or less value, shall be returned to their authors, to be published as they may desire, with the statement that they were read before — Section of the American Medical Association.

ARTICLE XV.—*Medical and Surgical Exhibit.*

SECTION 1.—There shall be no medical and surgical exhibit, under the authority or recognition of the American Medical Association, other than that made before the several Sections under the supervision of the committee on scientific contributions. All that is of value to scientific and practical physicians can thus find an appreciative audience, experience having shown that all other exhibits detract from Section work, and so lessen the attractiveness of the annual meetings to those whose presence is desirable.

ARTICLE XVI.—*Amendments.*

SECTION 1.—No part of these by-laws shall be amended, altered, rescinded, or abolished, and no additions shall be made thereto except at a regular annual meeting of the Association, after due notice of such amendments, alterations, rescission, abolition, or additions shall have been given in writing by a delegate, at the preceding annual meeting, and then only by a vote of three-fourths of the delegates present.

ARTICLE XVII.—*Enactment of the By-laws.*

SECTION 1.—These by-laws shall go into effect immediately.

SEC. 2.—All sections or parts of Sections of the prior By-laws or Constitution, and all ordinances, declarations or resolutions not in harmony with these amended by-laws are hereby repealed.

EXPLANATORY NOTES.

NOTE 1.—In the Minority Report, the plan of organization of the Association is not changed, because it is of historical value, and because it consists of resolutions, the amendment of which should not, even if it could, be effected.

NOTE 2.—In order that the objects of the Association may be clearly understood at a glance, the Minority Committee has reproduced them in the Constitution and re-arranged them in a separate Section with distinct sub-sections suitably numbered.

NOTE 3.—In Article II of the Constitution revised by the Minority Committee, it will be seen that four classes of members are enumerated. This is necessary for the proper government and prosperity of the Association; the members classed as delegates giving it its distinctively representative character. The whole profession in the United States can thus be as well and as equitably represented by delegates from the several States as the whole people of this

country is represented in Congress by Members and Senators from the several States.

NOTE 4.—The revised Constitution of the Majority Committee contains by-laws and details of the duties of committees which should have no legitimate place in this Constitution. The Minority Committee has therefore endeavored to put things in their proper places, and to formulate a constitution designed as the framework upon which to construct the by-laws. The Constitution is therefore the generalization, and the By-laws consist of the particularization of the rules governing the Association.

NOTE 5.—In the revised By-laws of the Majority Committee no provision is made for special meetings. Circumstances may arise demanding a special meeting, and the Minority Committee has accordingly provided therefore by adding three sections, but with the purpose of making it difficult to call a special meeting which should never be held unless required to meet a very extraordinary emergency.

NOTE 6.—The Nominating Committee is given the prominence it so well deserves. Its abolition would be a grievous wrong to the several States and to their societies which send delegates to this Association. The Majority Committee's intrusion of the Business Committee to supersede the Nominating Committee is practically attempting to make the Sections rule the Association, although that Committee disclaims any such intention. It is partly on account of this attempt that the Minority Committee suggests the change of name from General Business Committee to Committee on Scientific Contributions, and endeavors to restrict the duties of the Committee and make it subordinate to the Association. The Sections being the offsprings of, should be governed by, the Association through a committee the formation of which is authorized by the Association.

NOTE 7.—The Minority Committee's revision of the By-laws contains an Article on Ethics and Discipline rendered necessary in view of the known existing circumstances. The first Section of this Article is an additional protest against any kind of revision of the Code, and the Minority Committee hopes that no change whatever will be made in this National Code of Medical Ethics. Moreover, the Minority Committee believes that if this revision of the Constitution and By-laws is adopted, it will settle forever the ethical disputes which have so much disturbed the profession, and that it will greatly enhance the harmony, prosperity and usefulness of the Association.

HENRY D. DIDAMA,
Chairman Minority Committee.

SOCIETY PROCEEDINGS.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 552).

ON THE ACTION OF ELECTRICITY ON UTERINE FIBROMATA.

DISCUSSION.

DR. A. LAPHORN SMITH had found the galvanic current arrest hemorrhage in nearly every case of this kind, even in the most desperate ones where almost every other known remedy had failed. It nearly always relieves the pain, and the failures are usually due to errors in diagnosis. Subsequently to the electrical treatment he operated in one of his cases, and found a sarcoma in which the uterus was embedded. Under such circumstances, it was impossible by palpation to

make a differential diagnosis. The pressure symptoms he had found invariably relieved, most probably by the tonic action of the current on the circulation. Steady digital pressure on a fibroid for a few minutes will show the formation of an indentation. The current also improves the action of the intestinal muscles, and relieves constipation. Strength and nutrition are as a rule also improved, partly from the action on the sympathetic and partly from the arrest of hemorrhage. In about half of his cases the growth had been arrested, and in half of these it had diminished in size; in only one case was he sure it had entirely disappeared, and in this one there was no doubt about the diagnosis. One constantly hears the operators in the Philadelphia Obstetrical Society say that their most difficult cases of fibromata were difficult because of the previous treatment by electricity, but this is not true. In one case he gave one hundred applications of the galvanic current, and obtained a symptomatic cure, but the patient was not satisfied with this, and insisted on an operation. On performing laparotomy, it was found to be entirely free from adhesions. On the other hand, he had frequently been present at operations where electricity had never been used, and yet the adhesions were very extensive.

He saw no difference between a fibroid and areola hyperplasia and he maintained that a fibroid comes by obstruction of the circulation, which causes a migration of cells around the blood vessels, and change into fibrous tissue. These people are always extremely constipated, and hence there is venous obstruction. If electricity cures a fibroid it does so, he believed, through the circulation in the veins and arteries or lymphatics.

As to the contra-indications, he was in favor of taking out both fibroid and tubes when there is tubal disease, as he did not think it wise to use electricity where there is reason to suppose there is pus in the tubes. The treatment should always be so conducted as to avoid pain and not interfere with the patient's avocation. The sittings are usually from seven to ten minutes, twice a week.

If a strong current is used, patients are required to lie down for a short time, but if moderate doses have been given, even this precaution is quite unnecessary. He had never given a case of this kind more than one hundred applications, and he usually observed marked improvement after about fifteen applications.

DR. CLEAVES said that she had found the treatment of especial value in intra-mural growths, and that in this class of tumors the pressure symptoms were invariably relieved, the general health improved, and in hemorrhagic cases there was an arrest of the hemorrhage. In a limited number of cases there was anatomic retrogression, but in no instance had she observed a complete disappearance of the tumor. She believed that the arrest of the hemorrhage was as largely due to the cataphoric action of the current as to the chemic cauterization. She called attention to the experiments made by Mr. Stewart of Owen's College Laboratory, by which he had demonstrated the increase of liquids at the negative pole and also an accumulation of salts at the negative pole. In order that there should be such an accumulation, it was necessary that first there should be a decomposition and redistribution of the salts. Fibroid tumors and inflammatory products, are rich in salts, especially in chlorid of sodium, and are very largely dependent upon the presence of these for the maintenance of their nutrition and growth. The experiments to which she referred, go to show that the removal of a considerable proportion of the salts, even if that removal were temporary would result in the destruction of the tissue, while the removal of a small proportion would affect its nutritive activity. That the contractile action of the current upon the unstriped muscular tissue of the uterus exerted a powerful influence both in controlling hemorrhage and interfering with nutrition, she believed.

Every one accustomed to making intra-uterine applications of the constant current is conscious of this, not only in the bearing down and expulsive pains complained of by the patient, but in their action upon the electrode, forcing it from its position unless carefully held there by the finger of the operator. These contractions serve to empty the blood vessels.

The action of the absorbents in removing the products of inter-polar electrolytic action must not be lost sight of. She had found the induced and static induced currents of very great avail as an adjuvant in the treatment of fibroid growths by means of the constant current. Cases in which the static induced had been used noted a marked sense of buoyancy and lightness in the pelvis, as well as a general sense of well being.

G. BETTON MASSEY, M.D., read a paper on

THE ELECTRICAL TREATMENT OF FIBROID TUMORS.

The invitation to participate in this year's discussion on the electrical treatment of fibroid tumors was a most welcome one, as it is a subject of daily interest to me. To those among you equally interested in it with myself, the annual recurrence of this discussion suggests far more than the threshing over of old straw; it suggests rather a new harvest of ideas and practical points, to which each of us may contribute our sheaf of information.

Before referring to the special points arranged for the discussion I shall allude to the

VALUE OF EARLY DIAGNOSIS AND TREATMENT OF INCIPIENT FIBROSIS.

This convention should call the attention of the profession to the importance of an early diagnosis and early treatment of this condition.

Case after case of large growths are referred to us, but where are the little ones? Each large growth has been small at one time, though its presence has as a rule been unnoted until its relatively large bulk called attention to it physically. Its earlier manifestations were possibly slight, since I have known some tumors attain the dimensions of a small cocoa-nut without giving rise to symptoms, but it is more likely that the earlier symptoms were mistaken for something else. I do not doubt but that there are scores of women to-day in this city with undiscovered fibrous nodules within the uterine substance varying from the size of a pea to a hickory nut, who are under treatment by gynecologists for such supposed affections as displacements, chronic metritis, menorrhagia, menorrhagia, laceration of the cervix, cellulitis and ovarian disease. I know this mistake is being made by reputedly good diagnosticians, and the evidence is contained in the histories of my cases, nearly all of whom were treated for some one of these conditions during the first three to ten years of the tumor's growth. Corroborative evidence has even been furnished by myself, in the discovery that in several cases in which an enlarged uterus had been diagnosed as chronic metritis or subinvolution, galvanic treatment led to a shrinkage of the organ everywhere but in one spot, where a small tumor was then evident.

These small growths should be searched for in obscure cases of pelvic pain, uterine enlargement, etc., and the patient placed promptly under electrical treatment when they are discovered, thereby saving her from years of misery, and at best a more prolonged treatment.

The early treatment of these tumors can not be other than advantageous as compared with late treatment. Their incipency and smaller size are decided helps to a method that acts only by inducing retrogressive changes; yet there is another reason for early diagnosis and early treatment. All fibroid tumors are amenable to electricity in their early stages, while some, by reason of degenerative changes in the later stages of their growth, become finally unfit for it.

This slurring over the diagnosis of fibroid growths is probably due in part to the former attitude of the profession which looked on the affection as neither requiring radical measures for surgical relief, nor amenable to any other form of treatment. Patients were simply told to wait for the menopause, in the hope that change of life would bring relief. Surgeons at the present day pay but little attention also to small incipient growths, for patients at this stage seldom consent to an operation. To the electrical worker, only, the early discovery of fibroid growths is of interest, not to mention the paramount importance of early discovery to the patient to whom it may mean a still existent possibility of relief from electricity that would not be possible after time had permitted a degeneration of the growth.

1. *Hemorrhage.*—Of eighty cases under my care thirty-four have been hemorrhagic. Other cases had been troubled with this symptom at previous dates in their history, but thirty-four were markedly hemorrhagic at the inception of the treatment, some of them being in dangerously weakened conditions because of the extreme loss of blood. Each one of the thirty-four were cured of this symptom, so far as my investigations into their after condition can reach. In some of the cases a prolonged treatment was necessary to insure this result, but I have been fortunate in obtaining the co-operation of the patients in most instances. By prolonged treatment I mean an active treatment of three or four months, followed by a more desultory series of applications for three months or a year longer. During the continuance of the active treatment, frequent applications are made in order that an alterative effect may be obtained throughout the cavity. This sometimes temporarily aggravates the flow,

or at least leads to a constant dribbling, but it is essential in order that a control of the case may be obtained. The desultory treatment following is applied twice or once a month, and like the earlier applications is very thorough, using from 100 to 200 milliampères. Sectional carbon electrodes are used when they can be inserted at first, but after the hemorrhagic feature has been somewhat controlled I prefer to use an elastic cotton-covered electrode as causing less irritation to the cavity. The active pole is invariably positive.

I have never yet been compelled to dilate the cervix to facilitate the insertion of an electrode, and would regard such a necessity as a confession of inexperience.¹

A recent case of a large hemorrhagic growth was so exsanguinated and weakened as to be brought in a chair. There was a history of a recent pelvic inflammation, and the temperature on admission to the Sanatorium varied between 101 and 102, indicating the possibility of peri-uterine mischief. Notwithstanding this contra-indication to electricity something had to be done, and it was soon seen that currents of 100 milliampères were well borne. During a period of rest following the active treatment the periods became almost normal, eight pounds in weight were gained and the health greatly improved. The treatment was given in this case to a lady continuously confined in bed, with an evening temperature varying from 99.5 to 101, with excellent results. The temperature became normal under the treatment.

This case has been specially mentioned, as it is decidedly against the rule to apply such currents during the existence of temperature variations of that extent. The wisdom of neglecting the rule in that particular case was verified by the results, but it should be borne in mind that the applications were tentatively begun, most closely watched, and prosecuted under the most favorable conditions for careful work.

2 and 3. *Pain and Pressure Symptoms* were present in nearly all of the cases treated and were among the earliest accompaniments of the tumors to disappear under treatment. The symptomatic cure was complete in seventy-two cases out of eighty. Of the eight failures, one was an extremely large growth in the abdomen, hanging pendulous above the pelvic brim and totally inaccessible by the vagina. Further treatment by abdominal puncture is contemplated. One case, a cystic, intra-uterine growth, succumbed to sepsis. Another was subperitoneal, loosely attached to the uterus and inaccessible to treatment. The remaining five cases fell into surgical hands after the more or less complete failure of electricity to relieve, and only one survived the operation of removal. Of these cases thus operated upon I consented to the operation in two, and the other three were operated upon either against my will or without my knowledge, and the operations were in my opinion totally inadvisable.

4. *Strength and Nutrition.*—The general health was completely restored in each of the seventy-two symptomatic cures.

5. *The Growth* was affected as follows in the seventy-two cases:

a. Arrest	10
b. Retrogression	49
c. Disappearance	7
d. Recurrence	1
e. No change	13

6. *Kind of Current.*—A continuous milliampère current has been employed in all cases, varying in strength from 30 to 400 milliampères, usually from 50 to 150. The rapidly successive induction currents from powerful primary faradic coils were used in a few muscular myomas, resulting in temporary but distinct contractions of the growths. The galvanic currents only have seemed to yield permanent results, though at present I frequently employ faradic currents simultaneously by means of a combiner, and am convinced that they do much to relieve patients of the, at times, unpleasant sensations accompanying and following the galvanic applications.

7. *Properties of the Current.*—a. *Electrolytic.* The mode of action of electricity on fibroid tumors embraces other elements of value than mere electrolysis. Electrolytic disturbance of tissue cells is probably the prime cause of arrest and regression of these growths, but it should by no means be supposed that the mode of action is by the

¹ Since writing the above, I have been compelled to use the dilator to insert an electrode within the os in a case of atresia caused by the improper placing of the electrode by a previous attendant. He had simply cauterized the mouth of a cavity that was four inches deep and capacious.

electrical decomposition of the growth into acids and bases. This occurs to some extent, but by far the greater part of the growth is removed by an apparent quickening of the metamorphic and sorbefacient processes, and this quickening will be found by experience to be not necessarily correlated in degree with the degree of electrolytic decomposition induced. Relatively weak currents, in other words, will accomplish more change in some cases than stronger ones. Another practical application of this fact enjoins us to exercise care not to nullify or interfere with the post-operative effects of one application by giving another too soon afterwards.

b. Cataphoric. I have had no practical experience with the cataphoric administration of medicaments in fibroids, but aside from this possibly fruitful question, I may say that electric osmosis is an important factor in the Apostoli treatment. The positive pole, for instance, checks hemorrhage largely by drying the tissues within the region of its polarity. With a strong current this desiccation may extend some distance from the point of contact, a whole tumor being partly deprived of its moisture, which is carried through the tissues towards the negative pole. The desiccation immediately beneath a small electrode surface is at times so great when strong currents are employed that a very powerful battery is required to keep up a sufficient current strength through the rapidly increasing resistance at this point. At the negative pole there is an increase of moisture in all galvanic applications in exact proportion to the loss at the positive pole. This physical fact renders it easier to maintain the current strength from a weak voltage when the negative pole is a small active surface; the current tends in fact, to creep upwards after being turned on to a certain point. Another practical application of the fact is the value of the negative pole in maintaining drainage from the uterus and in promoting the menstrual flow.

9. Dosage.—As before mentioned, the currents in my work have varied from 30 to 400 milliampères by the monopolar method, usually averaging from 50 to 150. The doses, are on the whole, smaller than I used at first, as it is my practice to be satisfied with moderate progress if unaccompanied by irritation. In an intra-uterine, sessile, vasculo-cystic tumor recently destroyed successfully by bipolar electrolysis I employed as much as 700 milliampères repeatedly in conjunction with continuous irrigation.

Polarity.—No cases were treated exclusively by one pole, except the distinct vascular growths, in which the positive pole was rigidly adhered to. Other growths were treated mainly by the negative application within the uterus.

Length of Sessce.—The duration of each application has been from three to ten minutes, usually three.

Frequency of Application.—Twice a week or once a week is the usual rule of frequency, daily vaginal applications being interspersed by preference. In the latter stages of prolonged cases one treatment a month has been the rule.

Duration of the Treatment.—My cases have been under active treatment from six weeks to six months, with periods of desultory treatment usually added, lasting three months to three years longer.

Contra-indications.—Cystic growths, purulent accumulations within the adnexæ.

DISCUSSION.

DR. ENGLEMAN thought it unfortunate that the discussions on this subject had been almost entirely from one side or the other; the surgeons ignore the electrical treatment, and the electro-therapeutists the surgical treatment. He had secured the arrest of hemorrhage and relief of pain; arrest of growth, and in some cases reduction. In inoperable cases which were doomed to suffer, the galvanic current gave more relief than any form of medication, and restored the patients to a useful life. He did not doubt that the tumors could be reduced provided the treatment was fortunately begun at the right time, but he had seen some striking instances of retrogression occurring without any treatment, and this has been the experience of many surgeons. He cited a case in which an enormous tumor had gradually disappeared, but it could not be attributed to the treatment. In another case, there was such a terrible hemorrhage that it was necessary to postpone the contemplated operation. The tumor was observed from time to time by Dr. Hodgeman and himself, and it first underwent fatty degeneration, and eventually was completely absorbed. He had come to the conclusion that we should limit our treatment with strong currents and by puncture to tumors in a healthy state of growth or of retrograde metamorphosis;

but if a solid growth of any kind shows a tendency to malignant metamorphosis, electrical applications will aggravate this tendency. The specimens of fibroids which had been removed by Martin, of Berlin, seem to show that if malignant degeneration be present, electricity will hasten it, just as it will hasten fatty degeneration and absorption.

In the early days he used Apostoli's platinum trocar, yet he had seen no discomfort following such treatment, although there would be some hemorrhage. While using the coulombmeter for investigation, and as a matter of interest sometimes in clinical work, he saw no practical advantage in its use, for a current of a certain density—100 to 150 milliampères is essential.

THE PRESIDENT said he did not hesitate to operate upon cases which did not yield to electricity, provided the symptoms warranted the complete removal of the tumor—not simply the removal of the appendages, which he regarded a useless procedure. One of the principal uses of electricity in certain fibroids of the uterus is to build up the patient's health sufficiently to admit of resorting to a surgical operation when it is demanded. We may confidently expect from electrical treatment, a symptomatic cure—the control of hemorrhage, and the relief of pain and pressure symptoms. The arrest of the growth is assured if the conditions for treatment are favorable, *i. e.*, in interstitial fibroids and in subperitoneal growths situated favorably for vaginal puncture. He had seen considerable retrogression under certain conditions, but he had never observed complete disappearance. The galvanic current is the only one suitable, and his impression was that a more profound effect was produced by strong currents of short duration than by mild currents for a longer time. Usually twice a week is sufficiently often for intrauterine applications and once a week where puncture is employed. The choice of the pole depends upon the case; in soft myomatous growths and where hemorrhage is a prominent symptom, the positive pole should be used, but where the growth is hard and fibromatous, the negative pole is more appropriate. This he considered important. He thought little could be accomplished short of six months, and the treatment should be continued so long as progressive retrogression and improvement is observed. In recent growths and in myomata we may expect more retrogression than in fibromata.

He directed attention to the danger of producing cervical stenosis, as he had seen this condition quite often in cases which had come to him from other operators. This had occurred in some instances after the use of currents of only fifty milliampères negative when the treatment had been continued for a long time.

DR. SMITH asked if there had been any evil effects from this stenosis.

DR. GOELET replied that in one case there was complete stenosis, so that it was quite impossible to introduce an electrode or sound into the cavity, and the pain was so severe that it became necessary to do a hysterectomy.

DR. HAYES said that for some twenty years Dr. _____ used the induced current with the positive pole directly over the tumor, and with a sufficient current to produce decided muscular contractions. The induction apparatus used by him had a large wire so as to produce a current of low voltage and slow interruption; in short, very decided muscular contractions.

When he had patients with fibroids, he employed the Apostoli method, and after two or three days gave a bath with the induced current in order to favor metabolism. For the relief of pain he had been using statical electricity, an electrode being introduced into the vagina or uterus, and a large diffusion electrode placed on the abdomen, and the current being broken in the metallic circuit by a modified Morton electrode. He thought this treatment altered cell action, and acted as a useful adjuvant to the Apostoli method, giving the best results in the shortest time.

DR. KELLOGG, in closing the discussion, said that from experiments he had made upon living rabbits, and on beef-steak, he had found that a feeble current will after a long time produce very nearly the same electrolytic effect as a more intense current will in a shorter time.

Sufficient attention is perhaps not given to the danger of puncturing the uterine wall in this method of treatment, for the reason that sometimes in the growth of the tumor a portion of the uterine wall may become very much stretched and attenuated. He mentioned this because of the paper which had been read this afternoon on passing a sound into the Fallopian tubes—an operation which he would never attempt. As a rule the opening of the tube is not large enough to admit a bristle, and hence it is extremely likely that the

tube will be punctured, and the electrode brought in contact with a loop of intestine, which it will destroy. Stenosis of the cervical canal may be to a great extent avoided by insulating the cervical portion of the electrode by a piece of gum catheter, but unless one produces stenosis, he hardly thought one would be successful in curing these cases of fibroids, this being the natural condition occurring at the menopause.

EVENING SESSION—THIRD DAY—SEPTEMBER 14.

The meeting was called to order at 8:30 P.M.
J. MOUNT BLEYER, M.D., and M. MILTON WEILL, M.D., of New York city, read a paper on

THE PRIMARY ACTION OF THE GALVANIC CURRENT—IT INCREASES THE AMOUNT OF OZONE IN THE BLOOD AS SHOWN BY CHEMICAL TEST OF THE BLOOD IN THE ARTERIES—WITH OUR THEORY OF ANIMAL ELECTRICITY.

Schönbein, in drawing his conclusions regarding the nature of ozone, assumed that oxygen was capable of three distinct conditions, viz.: ozone, electro-negative, antozone, electro-positive, and neutral oxygen, which, as its name indicates, has no polar distinction, but could be polarized and depolarized at will.

Of these three so-called forms of oxygen, the investigations of the observers since the day of the great Basle chemist have much changed our views. To-day we admit the existence of only two forms of oxygen—ozone and neutral oxygen, and for the sake of elucidation we give you the graphic construction of the molecule as we believe it to be:

Assuming, as he and the aftercoming observers did, that oxygen in its free state was neutral, and it so proved to be, he reasoned, and it is within the pale of all researches, even up to our own time, that as soon, or rather as we have found it, just before this oxygen enters into combination with either organic or inorganic substances in the presence of moisture it becomes polarized.

Carrying these conclusions into the field of physiologic chemistry, he became convinced that the corpuscles like phosphorus were possessed of the power of polarizing the oxygen in the lungs, and further of splitting up the molecules and rearranging them in the form of ozone. His idea was that ozone existed in the blood, that it was the vital oxidizing agent by means of which the recuperative changes in the tissues were wrought, yet the years of careful work he devoted to searching, failed him in finding the slightest trace of ozone in the blood.

In his later years he became equally emphatic in his assertion that the resolution of ozone—its oxidation was so rapid that in the blood and the moistened tissues surrounding the capillaries where the real respiration is accomplished it would be next to impossible to chemically detect the presence of ozone by the most delicate test. He even went so far as to doubt its existence in the blood, that is to say, he believed that it was ushered into existence and was used up in performing its function so quickly that it was not possible to chemically isolate it, that in the blood of the capillaries—presumably the radicals, although he does not so put it—where the pressure conditions are such as to allow of the free interchange of the gases of the blood with the tissue elements, ozone no longer existed.

Like many other great minds Schönbein was right in many of his claims, but in many other of his theories he allowed himself to fall into error, for in justice to those who come after him to study this question of the physiologic significance of ozone, and with no discredit to his greatness Schönbein left much to be cleared up and explained. The ever changing and improving chemic facilities and knowledge make this task far more easy. With the advantages afforded by the chemistry of his day, Schönbein accomplished an Herculean task. That famous physiologist, His, who had grown up in the shadow of Schönbein's laboratory and influence also failed to discover ozone in the blood.

At the very time His was engaged in his futile efforts, Alexander Schmitt was at work upon the same question—ozone in the blood.

We need not rehearse the details of Schmitt's methods; suffice it to say his experiments were elaborate and carefully made, and showed beyond doubt that ozone existed in the blood; but the quantity, apparently, was very small.

Not long afterwards Kühne, improving on Schmitt's tests, proved that ozone existed in the blood in readily appreciable quantity, and the question was forever settled in the affirmative.¹

Kühne concluded, and his deductions were not far from approximating the truth, that the red corpuscles greedily absorb ozone under the natural formation of carbonic acid, and decompose water as free oxygen is liberated.

Our experiments on the blood with the galvanic current are in a line with those of Kühne and Schmitt, only a short step in advance of those observers, a mere completion of their unfinished tasks. Whatever value the results we have obtained may have, there can be no doubt that the galvanic current applied to the living body, whatever else its action may be, increases the amount of ozone both in the corpuscle and the plasma.

Before entering into a rehearsal of the details of our experiments, let us briefly touch upon the physiology of the blood and the function of its gases; for here it is that we suspected the seat of first physiologic action of the galvanic current, and here, too, we were led to trace to its source, animal electricity, and observe its function as we suppose it, in the human economy.

The Blood—Its Gases and Solids.

The gases in the blood, the carbonic acid, the nitrogen and the oxygen, which interests us in particular, need not be gone into at length.

The oxygen in the blood exists in two forms: 1, that which is held in solution by the plasma; and 2, that which enters into combination with the constituent elements of the corpuscle.

The first variety commands our attention for the reason that to all appearances, the galvanic current first acts upon this freely dissolved oxygen and which naturally, therefore, first undergoes the transforming change from O₂ into O₃.

With a single exception, that of defibrinated blood, the blood obeys Dalton's well-known law of the absorption of gases by liquids. In vacuum 100 volumes of blood give up a trifle over 72 volumes of gas, of which in arterial blood 20 volumes, upon analysis, consist of oxygen, while in venous blood the volume is reduced to between 8 or 10.

The plasma simply holds the oxygen in solution, while the hemoglobin, which by actual weight makes up 90 per cent. of the dried corpuscle, enters into partial combination with the oxygen, although we have observed, and the observations are in keeping with those of other observers, that the oxygen in the hemoglobin is in such a loosely combined state that it readily solves its bonds of union, and under the slightest provocation goes over to the other elements for which it has affinity as soon as the pressure conditions of the plasma are changed so as to permit of a loosening of its bonds.

Plasma, or to be more accurate, fresh serum, will, upon exposure to the air, absorb no more gas than ordinary water under similar conditions, some three volumes; defibrinated or whipped blood, however, contrary to what might be expected, takes up considerably more. This will suffice for the behavior of the gases of the blood. Now a word about its solid constituents.

In general, in the plasma they are serum—albumen, globulin and crystallizable fatty and nitrogenous matter which, as we shall endeavor to show, are rendered more diffusible by this very transformation of oxygen into ozone, caused by the polarizing action of the existing animal electricity of the body, and rendered even more diffusible by the action of the galvanic current.

In the larger vessels, for example, the carotid artery which we have chosen as the seat of our experimentation, not only because it is accessible and convenient, but rather because it is a direct branch of the aorta where both the plasma and corpuscles are equipped with all the oxygen they can carry, the blood is charged to its full capacity with those elements which it is commissioned to give up to and upon which the tissues depend, particularly oxygen.

All physiologists agree that in these large vessels carrying arterial blood the hemoglobin in the corpuscle is in the form of oxyhemoglobin which signifies simply that the hemoglobin has entered into partial combination with as much oxygen as it can hold, and that it is ready to transfer this oxygen to the tissues as soon as the oxygen of the plasma has become exhausted, and the pressure conditions become so reduced as to permit the giving up of the gas.

(To be continued.)

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, APRIL 21, 1894.

ELMIRA REFORMATORY.

For many years this institution has led all others in the world in scientific studies and treatment of criminals. The application of modern theories of the disease of criminology, has been very strikingly illustrated in the physical and mental training of the inmates of this prison. The success of these new methods has so far exceeded the expectations of its advocates, that it has attracted a worldwide interest. These methods are briefly, physical culture, baths, industrial and military training, exact life and living, mental culture and rewards and punishment as an incentive. The inmates are treated by building up the physical and mental; and the crime is assumed to be a part of his physical degeneration, to be reached and controlled by the application of exact physical measures. Experience has built up a system of means and appliances and proved their value by practical application at this reformatory, far in advance of any other in the world. Pioneer work and pioneer men always encounter savage opposition. Not unfrequently the work is halted and put back to another period.

Such a storm has just passed over the Elmira institution. It began in wild newspaper charges and concentrated in an investigation by a committee of the State Board of Charities. The chairman of this Committee died at the beginning of the investigation; the second member, a noted physician, after a few hearings went off to Europe and failed to return, and the remaining member, an impractical lawyer, continued the investigation alone and made the final report. A student of history could have formulated the charges against this institution and its management without any knowledge whatever. Such charges invariably begin with the officers, who are called cruel, unjust, unlawful, inhuman, etc.; as a result, mismanagement, incompetency, and neglect

follows. Then follow charges of financial disturbances and dishonesty. Thus history was repeated in the charges in all its details in this investigation.

The financial workings were found correct, and the storm gathered round the methods of punishment by spanking. It was found from thirty years' experience by the management, that blows by a broad strap on the nates were the most effectual method of procuring obedience. This had been carried on for years under the Superintendent's direction, and proved to be an effectual stimulant to the small proportion of rebellious prisoners. Over a thousand pages of the report are devoted to the testimony concerning the horrors of this mode of punishment. Minute evidence gathered from convicts in State prisons who were former inmates and discharged prisoners, ex-keepers and others, all witnesses of the most unreliable character, is presented with a gravity that is farcical. The assertions that reddened skin from blows on the buttocks are "inhuman" and "brutal," reflects sadly on the wisdom of parents and the home experience of many centuries.

The testimony of two hundred witnesses has been spread over thirteen bound volumes of nearly four thousand pages, costing over ten thousand dollars, and finally culminating in conclusions of the opera bouffe style.

The Superintendent is found guilty; spanking is a very brutal punishment, and if persisted in, the prisoner should be so protected by a stout leather jacket, that no unnecessary injury be done him; that the Board of Managers should be discharged for disrespect to the Governor and over-confidence in the ability of the Superintendent; that nepotism is injurious, that more chaplains are essential, and a new institution is required.

The list of findings and recommendations is a fitting conclusion to an investigation based on press sensations, and conducted by non-experts, in an aimless and unreasonable way. There is not a jail, prison, asylum or hospital in the world that is managed to the satisfaction of all its inmates. There is always a class of critics, both in the press and professional circles, who assume far more perfect knowledge of any subject, than practical men who are giving their life work to it.

While the Elmira Reformatory will not suffer in any general way from this investigation, the thoroughly farcical character of such inquiries reflects on the intelligence of the community. Outside of all political sensationalism there is a scientific aspect to the subject that should not be overlooked.

Criminology has come into the realm of science, and belongs to the province of the physician. The Reformatory at Elmira has an eminent physician as President of the Board of Managers, and its resident physician is a recognized scientific student in this

field, whose papers and reports take rank with the work of the great leaders of penology. The Superintendent has been a practical worker in charge of convicts for over thirty years.

It is from such experience and training that we can hope for progress in this field. Institutions of any class under the control of politicians or non-experts who are not students of these subjects, never make any real advance, and are always open to all forms of abuses. Physicians everywhere should insist that penal institutions should have medical men to direct, and that the convict have the full benefit of all that science and experience has taught of the means and methods of cure.

It is a cause for great hopefulness that at least one pioneer work in the world is managed above political levels, by trained men and along lines of their best experience. This investigation has brought into greater prominence than ever, the folly of trusting to sensational stories of abuses in asylums, that come from inmates who have some purpose to accomplish, or some feeling of revenge to gratify. Also where a just suspicion exists of abuses, let the investigation be conducted by competent men who have only the truth to ascertain, truth that is above all doubt or question.

SANITO-VETERINARY INVESTIGATIONS.

Veterinary medicine and surgery is rapidly coming into prominence in many of the older States. Veterinary doctors are often highly educated, having medical diplomas from the best schools, but from choice turn their attention to animals and their diseases.

In a report to the Connecticut State Cattle Commissioners by DR. NOAH CRESSY, an expert veterinary surgeon, occurs many very suggestive facts, which open up new fields of research. The struggling physician who feels the pressure of keen rivalry, should consider that a wide field of great usefulness is open in the treatment of diseases of animals; also where highly honorable and thoroughly scientific work can be pursued, with a more assured hope of reward. DR. CRESSY presents some additional evidence showing that the virus of smallpox in passing through the animal organization, undergoes some modification by which it is deprived of its malignancy. He asserts that cattle and other animals suffer from typhoid fever germs, and that some of the low exhaustive distempers which occur in animals have their origin in these germs.

Foul water supplies to animals are in many ways equally dangerous, and while all the facts are not clear, there is a strong probability that animals suffer the same as man. Also that animals suffering in this way may pollute the water supplies and be sources of infection to man.

Animals should always be cremated and never be permitted to undergo the slow process of decomposition, either on the surface or under the soil. Especially animals suffering from tuberculosis. The soil over the graves of animals dying of these diseases has been found to be alive with germs that can be communicated to others producing in favorable conditions similar diseases. Diphtheritic germs are found to be equally dangerous, and not uncommon among animals. Although not recognized, yet the evidence of their existence and danger is very clear in many cases.

The bacilli of cholera, typhoid, tuberculosis and diphtheria, are all distinguishable and preventable in both man and animals. The water supplies, the soil, the absence of cleanliness and sunlight, and bad insufficient food, are all mediums for their growth and propagation. Animals suffer the same as man from these scourges, and the same general principles of hygienic and preventive treatment apply. Tuberculosis is the most common and dangerous source of disease in animals at present. The bacilli of this is transmitted in both milk and meat, and the diagnosis is not clear except by the microscope. The animals may give but little evidence of their real condition, and no treatment has been found available.

Extermination is so far the best plan to limit the evils. A constitutional disease, called acute anthropoid edema, is mentioned, and cases are given, and some remarks are made of cattle tick pathology.

This report is a striking confirmation of many facts observed in human diseases, and the author suggests that the germicide remedies should be used by farmers in many ways, to great advantage. He very properly protests against the use of patent secret nostrums as in all cases worse than useless, and urges a more sanitary care of animals.

It is a pleasure to note the rapid advances in this field, and along lines of scientific inquiry, and the consequent disappearance of the old vociferous horse doctor, whose coarse drugs and coarser treatment was always a source of disgust to the physician. It is equally interesting to consider that these dreaded germ diseases so common in every practice, extend to animals and possibly in many unknown ways, may be sources of transmitting these germs. Clearly a very wide field of research opens up in this direction.

THE CHINAMAN VIEWED FROM THE SURGICAL STANDPOINT.

DR. JOHN C. THOMSON, of Hong Kong, has written in the *China Medical Missionary Journal* regarding the fortitude of the Chinaman under the surgeon's knife. It often happens in China that the surgeons are called upon to operate in isolated localities, where the suitable anesthetic is wanting or where the

proper assistants are not at command. In a large proportion of minor operations, anesthetics are not exhibited. Under a variety of such circumstances the author has observed among the Celestials a degree of unflinching endurance of pain that would be scarcely possible in the more highly developed nervous constitution of the people of the West. There are many considerations among the Chinese that render the latter reluctant to surrender their surgically disordered members to the knife of the foreign surgeon, but when once their feelings of reluctance have been laid aside, the Chinaman becomes a "good patient." In explanation of some of the bedside experience DR. THOMSON has met with, the paper continues as follows:

"The fact is to be discounted that, in the case of the poorer Chinese, a prolonged course of low living and practical starvation has frequently added its results to the original trouble (while the native practitioners are doing their best or worst) before the case is submitted to the Western surgeon, and this materially affects the progress of many of our patients. Other things being equal, recovery and convalescence are very much more rapid and complete in the average Chinaman than in the average Englishman. Reasons for this difference are not entirely obvious, but the opinion may be hazarded that the simpler feeding habits of the Chinese and their equable mental constitution form, at least, some of the causes of the higher vitality of their tissues. The popularly accepted notion that the Chinaman lives on rice is very far from the truth, since even the poorest manage to add a few green vegetables and a little fish or pork to the rice, which is the staple national diet; but, taken all round, the Chinaman's food is certainly more simple, and probably more nutritious, than the food of an Englishman under analogous circumstances. His use of alcohol is also much less injurious to his tissues than is its use by a large proportion of Europeans. The native spirit, *samshoo*, is very extensively consumed, but it is invariably in minute quantities and never excepting with meals, intoxication being a thing practically unknown in China. The tranquillity of the Chinese mind is proverbial. A Chinaman is never in a hurry. Provided he be given a hope of ultimate relief, it rarely matters to him whether his stay in hospital is to extend over a week or a month, and this absence of all worry probably goes far, along with the other facts I have stated, to account for the kindly reaction of his tissues under the surgeon's knife."

MR. JONATHAN HUTCHINSON'S CLINICAL MUSEUM.

The President of the Royal College of Surgeons has shown anew his partiality for the pictorial element in teaching. He has developed from his atlases and archives an extensive museum of clinical surgery that bespeaks our admiration of its author's originality, industry and liberality. In this museum he has collected the experience of many years. It has, at first sight, the appearance of a pathologic picture gallery, but it is more than that. The upper parts of the walls are covered with pictures, while on shelves below them are the books pertaining to the same subjects, so that the building is rather a library with inserted illustrations than a simple museum. It is a

kind of spread-out atlas of medical subjects. The pictures are not hung, but are allowed to stand on narrow shelves, so that they can be taken down or moved from place to place for examination or comparison. In the library subdivision of the museum there are two hundred thick scrap-books, into which are pasted the current literature, taken from journals and pamphlets, germane to the illustrations. Each of these books has its own subject, and each is independently indexed. All of MR. HUTCHINSON'S periodicals are remorselessly cut into for material suitable for these two hundred reservoirs of current information.

TO MEMBERS OF THE ASSOCIATION.

The editor of this JOURNAL recently received a polite letter in faultless type-writing as follows:

PHILADELPHIA, March 12, 1894.

My Dear Doctor:—I see by the program of the Section on Surgery of the AMERICAN MEDICAL ASSOCIATION that you are to read a paper on, ——. I hope you will let us publish this in "The ——" We will gladly furnish you reprints free of cost and if you send us the MS. in time will have it set up in galley proof so that you can read from this at the meeting.

Very sincerely at your service, _____

In response to which we have the honor to reply that the By-Laws of the ASSOCIATION forbid the publication in the Transactions of articles previously printed elsewhere.

Papers read at the meetings of the ASSOCIATION become the exclusive property of the Section, and if previously printed elsewhere can not be printed in the JOURNAL OF THE ASSOCIATION until the other articles shall have first been printed. This rule led to the exclusion from the JOURNAL of some valuable papers which the authors had printed elsewhere last year, and it is hoped that gentlemen furnishing papers will this time remember the By-Law and decline requests of the character quoted.

THE MARRIAGE CERTIFICATE OF BELGIUM A MEANS OF EDUCATION.—The following paragraph from the Paris *Herald* shows how vital statistical stationery may be made instructive:

"In Belgium it is the custom to give certificates of marriages in the form of little books, which also contain a summary of the marriage laws, and among a mass of other miscellaneous information directions for the feeding and care of infants. There are also places for entering the names and birthdays of the children of the marriage, the authorities considerably affording space for twelve such entries."

JOURNALISTIC ENTERPRISE.—We congratulate our esteemed contemporary, the *New York Medical Record*, on its cable reports of the Eleventh International Medical Congress. The first instance of the kind, we believe, attempted in American medical journalism.

CORRESPONDENCE.

Revision of the Code of Ethics.

To the Editor:—Members of the ASSOCIATION being privileged to discuss in the pages of the JOURNAL, the reports of the Committee on the Code of Ethics, Constitution and By-laws, the following notes of a general examination of the Committee's work are made to call attention to the moral as well as the literary character of the "revision:"

1. After divers conferences, the Committee on Revision being divided, the majority made a report at Milwaukee in 1893, in which it gave only a vain excuse for not presenting the "revised" Code, and now prints it so late as to leave little time for publication of the objections of many members who do not regard revision as necessary. Since only seven numbers of the JOURNAL can appear before the June meeting, the opportunities for criticism will necessarily be very limited. It is not likely that the Committee was sure of giving an unexceptionable revision in spirit and letter; otherwise the profession would have been invited, several months ago, to examine it in the JOURNAL. The long delay in the appearance of the "revision" is therefore significant of lack of confidence of the "revisers" in their own work, and of fear of unfavorable criticism. Nearly two years have elapsed since the appointment of the Committee to perform a duty which could have been accomplished in three months, so far as it related to the Constitution and By-laws; but this Majority Committee seems to have consumed the greater part of these two years in endeavoring to pervert the Constitution and By-laws, and in making abortive attempts to "improve, abbreviate and illuminate" that admirably accurate and exemplary, concise and lucid statement of the most exalted moral maxims known as the American Code of Medical Ethics. At last this unenviable Majority Committee has completed and published, not changes or amendments, but a monstrous metamorphosis of the entire Code!

2. Bad, in all its senses, does not seem to fully qualify the "revised" Code. Its spirit is evil, its letter is execrable, and both are superlatively absurd. It is like a parody upon the original, and a contribution to ethical and ceremonial disorder and rhetorical monstrosity presented to the profession by the iconoclastic Majority Committee as an example of its instinct for destruction, its incapacity for reconstruction and its quaint gift for the invention of rules of misconduct, as well as the outcome of the greatest efforts of which it seems capable, for "ideal" codification, classification, emendation and literary composition.

3. Countless members of the profession and of the ASSOCIATION, who have been waiting patiently to know the result of the ethical and linguistic experiments of the Majority Committee, will read the revised Code with uncommon interest, and will be likely to look upon the success of the experiments as problematical; they may perhaps be so emboldened as to assert that the "revision" is no improvement over the original Code, and say that even if it were equal to the original it would then be a work of supererogation. They will probably regard this "revision" as infinitely inferior to the original, and go so far as to suggest that the question of revision be dismissed from further examination, and that the Committee be discharged with thanks for having given such a thorough demonstration of the futility of attempting to improve the original Code. A second reading will surely confirm these views and carry the conviction that dismissal would be a wise disposal of the revision agitation.

4. Declamation, dispute and disorder were for a time irrepressible at the Detroit meeting in 1892. Advantage was

taken of the ensuing confusion, on the seventh day of June, to induce a member to offer a resolution that the President appoint a committee "to whom the Code of Ethics shall be referred for such changes or amendments as they may deem it wise to recommend, if they should decide that any change is required." The Committee was duly appointed, and met, but was soon divided because its members were not unanimous as to the alleged necessity for changes in the Code. At the meeting of the ASSOCIATION in June, 1893, a majority report and a minority report were presented; the majority favoring changes, and the minority being against changes. No decisive action was taken, and it was proposed to test the vote of the affiliated State organizations.

5. Each member, or rather all the members together of the Majority Committee in assuming the rôle of revisers might have done serious mischief had they made only a few changes, but went much farther and blunderingly carried their excesses to the point of striving to demolish and then to remodel the lofty monument of wisdom erected by able, faithful, good and true men, and have thus greatly exceeded their instructions, which ended with, "if they should decide that any change is required," they might recommend such change. They were not authorized to transmogrify the Code. The resolution did not imply any intent, on the part of the mover or the ASSOCIATION, to change the character of the maxims or the plan and phraseology of the Code. The result of the Committee's work shows the influence if not the direction, of an enemy bent on demoralization, disorganization and destruction. In consequence of their being thus ill advised, the radical "revisers," failing to take advantage of their lore in ethics, logic and rhetoric, have substituted bad morals stated in slovenly style, for good morals stated in scholarly style.

6. For an example of the "revisers'" ethical as well as literary acumen, the proem is worth reading; it is the stamp of all that follows! The affixion to the Code of a composition, such as this proem, is an offense to the intelligence and discernment of even beginners in medicine. Besides, it adds to the number of platitudes and to the multitude of inaccuracies contained in the "revised" Code and renders it ridiculous from the beginning. To an "abbreviated" ethical code any kind of a proem would seem like a superfluity.

7. Gross and ludicrous are the blunders of the "revision" Committee, but none is so glaringly absurd as their introduction of details of preliminary and medical education, which have no place in the letter of an ethical code. The spirit of the original Code implies the highest qualifications. Physicians who uphold the American Code are expected to be scholarly gentlemen, well versed in the science and art of medicine. The excellence of the original Code is owing largely to the discrimination and learning of its framers who were thoroughly acquainted with "languages, mathematics, literature, history, philosophy and logic."

8. Have not the "revisers" separated too widely, medical etiquette from medical ethics? Should not rules of action be closely followed by rules for guidance in the ceremony of the action? It does seem convenient and proper that rules of etiquette, either stated or implied, closely follow, or even sometimes are incorporated with, ethical rules, and it does not seem rational that they be widely separated. The selection of the plan of arrangement of rules of ethics and etiquette adopted by the framers of the original Code is one of the many evidences of their sound judgment and wisdom.

9. In keeping with their crafty policy, the "revisers" imposed many obligations upon physicians, but few upon clients and, in their unwisdom, thus lead clients to believe that physicians have no rights which need be respected. How many times will it be necessary to point out that the Code was made for the information and protection of the

public as well as for physicians, and that their obligations must necessarily be reciprocal? One of the objects of the ASSOCIATION, distinctly stated in the plan of organization adopted in 1847, is "for enlightening and directing public opinion in regard to the duties, responsibilities and requirements of medical men." This object can be effected only by making the public acquainted with the ethical rules and other laws of the associated profession. To say that the "Code is not designed for patients or the public," is a confession of the grossest wilful ignorance of the principles of ethics and therefore of justice. That part of the Code which points out the reciprocal relations of clients and physicians is so clear and just that no intelligent layman who reads it will question its propriety and necessity, and all thoughtful readers will surely approve other parts of this original Code which relate to the public and the State. It is not easy to follow the vagaries of the Majority Committee both in its "revision" and its report of 1893 on the Code. In the report the Committee says that the original Code contains superfluous articles and sections of articles, and that "it would be wise to re-write this Code in phraseology so plain as to make it a practical common sense document," implying that it is senseless and does not fulfill its office. In another paragraph the Committee thinks that further inquiry should be made as to whether "alterations are warranted in view of the changes incident to the last half century," whatever this may mean. In the same report, page 692 of the JOURNAL for June 24, 1893, the Committee acknowledges that the original Code "contains the essentials for the successful conduct of a medical career, as these have been learned by the actual experience of the best members of the medical profession, from the earliest dawn of history to the day on which it was written." The frequent shiftings of this Committee's views show how unfit it is for the work it so rashly undertakes. First, the Committee thinks that the Code contains superfluous articles; second, that it is senseless and its phraseology is not plain; third, that there is a doubt whether alterations are warranted, and fourth, that the Code contains what is essential for the conduct of physicians throughout their career. It may seem strange, to those who have not studied the psychical state of the disorganizers, that after the last declaration the "revisers" persist in spoiling the Code, but to others, who know the spirit by which they are misguided, the ironical import of the declaration is plain. Toward the conclusion of its report on the Code the Committee says that it "deprecates all efforts to abolish, belittle, distort, ridicule or otherwise lessen its hold upon the profession." But despite this deprecation, the Committee gives a "revision" which, if adopted, would surely abolish the original and belittle in the extreme the ASSOCIATION adopting such a ridiculously distorted monstrosity.

10. Justice demands not only a general statement of the moral, but of the literary character of the Majority Committee's labors. Its "revision" is couched in pitifully inaccurate language which abounds in misused and misplaced words, bombastic expressions, and redundant phrases, besides uncounted inanities; while the few ideas are chimerical, and the style is inflated, inelegant, and hypnotically tedious.

11. Keen may be the wits, great the erudition, eminent the scholarship of the "revisers," but it is apparent throughout their document that they made use of none of these gifts in attempting the work of "revision." Among the glaring instances of carelessness, if not of designed perversion, is the distorted paraphrasing of some of the maxims that the Committee has seen fit to extract from the original Code.

12. Let the reader examine the files of the JOURNAL and

he will learn that among the "reforms" proposed by the "revisers" and their advocates, was to be an extraordinary abbreviation of the Code. They were "determined" to give the ASSOCIATION "a clean-cut set of short rules," to make the "revision" a highly compressed statement of only "necessary maxims," and to avoid "redundancies." But notwithstanding these boastful promises, and although they "omitted ten sections of Article II, on pages 5, 6, 7 and 8, and Article II on page 20," of the original Code, the "revisers" really omitted the whole of the original, and now give a "new code" which is about four-fifths the length of the original. This "newly revised" Code is indeed well adapted to the views of the disorganizing faction by which it was inspired. Its worse than sophomoric proem, its superfluous and disingenuous rules, its profuse flux of empty words and its sorry obstipation of ideas, constitute the kind of exhibit that was expected from the would-be reformers. To bring their ridiculous propositions to a climax, the "revisers" recommend a "more accurate definition of the term, consultation!" This seems as if the definition of the "term, consultation," in the best lexicons of the English language were as unsatisfactory to them as the statement of the maxims in the original Code; rejecting the one, they reject the other for the same lack of reason. To those members who uphold the National Code, the definition of consultation, given in general and medical lexicons, is sufficiently accurate, clear and satisfactory.

13. Many and great are the difficulties sometimes met with in striving to amend even what may be improved; but how much greater and more numerous must have been those which the "revisers" constantly encountered when, in their folly they undertook the emendation of the excellent moral and ceremonial maxims contained in the original Code! The signal failure of these "revisers" was not unexpected, particularly since the publication of their pitiable endeavors to sophisticate the Constitution and By-laws, which naturally led the reader to question their fitness for the work intrusted to them. Failing in the accomplishment of the lesser task, they were not likely to succeed in the greater. It is evident they did not recognize the fact that a document, such as the original code, so pregnant with clearly and concisely stated maxims, was written for all time and is not susceptible of betterment, for it was, is, and always will be, the wisest, safest and best guide of professional conduct to all general physicians of either sex, or to specialists, however great and diversified may be the changes in medicine and its votaries.

14. Nothing in literature is more difficult than the classification of subjects, the concise statement of facts, and the right disposition of propositions. This may have been realized by the "revisers," but apparently too late to take advantage of the knowledge. Had they made use of the information obtained from their early reading of history and general ethics, they would not have lost sight of the fact that even the sages of antiquity did not find it easy to formulate moral maxims. Had they remembered that, as a general rule, each moralist of old made but few contributions, and that systems of morals are usually made up from the maxims of the many, collected, selected, edited and arranged by able classifiers, they would have rightly appreciated the value of the framers' work on the original Code, would not have had the temerity to invent absurd rules of conduct, and would have abandoned their feeble attempt at "revision." They must have known, though they seemingly ignore, with what patient intelligence the committee of 1847 labored to gather, from divers collections of good maxims the materials which were essential to its wise purposes. What a woeful lack of discernment is manifested by the disorganizers in their estimate of the grand outcome of the studies of such learned, honorable and devoted phy-

sicians as those who were members of the memorable committee of 1847, and how irrational and unjust the "revisers" are to strive to abolish the admirably written system of morals unanimously adopted by the ASSOCIATION as a condition of membership! It is more than likely that any man who, in future, may be so rash as to endeavor to change the maxims, language or arrangements of the American Code of Medical Ethics, will be the subject of general opprobrium and derision.

15. One or two more notes will terminate this general examination of the "revised" Code. It does not seem possible for any individual or committee to improve the fundamental maxim of the Code which is, "be just," and is the basis of all codes of good morals. Any deviation from this maxim which is probably as ancient as the first aggregation of men, must necessarily be bad, for it will inevitably resolve itself into—be unjust.

16. Peace is not likely to be restored in the ASSOCIATION until the disorganizers are out-voted, the transformed Code is rejected, the original Code is preserved in its integrity, ethical wrangles are discouraged, and the revision question is disposed of forever.

17. Questions such as these can not always be discussed without warmth, particularly when they are raised by disturbers of the peace of a large and respectable body of men. Made in the interest and for the welfare of the ASSOCIATION whose objects would suffer by the adoption of a perverted Constitution, and whose dignity would be offended by an immoral, ill-composed and ridiculous Code, this criticism is of necessity unsparing. The writer regrets to have been compelled to use the strong expressions which the iniquitous revision agitation seem to justify, but was prompted to do so entirely for the defense of justice against injustice, without any attempt to conceal his indignant sorrow for those who are willingly led by designing demagogues, without desire to omit any demonstrations of grievous pity for them, and without power to suppress the distressful feeling that the ASSOCIATION will see evil days if the wrong-doers prevail. In his defense of good morals the writer found it necessary to point out the blunders in both the spirit and the letter of the "revised" Code, and to bring to light the enormities of the disorganizers and the incapacity of the revisers, not as individuals, but all together as the willing agents of a turbulent and mischievous faction.

A CONSERVATIVE MEMBER.

"The Texas Medical Law."

To the Editor:—I have to thank you for calling my attention to an editorial article in the current number of the *Texas Medical Journal*, in which the Illinois State Board of Health is accused of having made "a bad break with regard to the law in Texas," in its report on medical education, prepared by the present writer. Since that report has not yet been published the *Texas Journal* must refer to an article originally published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, March 10, 1894, under the title "Legal Requirements for the Practice of Medicine in the United States." It is, therefore, proper that this notice of the *Texas Journal's* charges should appear in the same columns.

The article consisted substantially of "a *résumé* of the legal requirements for practice in each State and Territory of the United States in force Jan. 1, 1894," and in it appeared the following:

"TEXAS.—A license issued after examination by a District Board of Medical Examiners. Diplomas confer no right to practice."

This was stated to be the law in force in Texas, Jan. 1,

1894—the "legal requirement" for the practice of medicine in that State.

The *Texas Medical Journal* now asserts that this is a mistake due to ignorance, for which there can be no excuse, and adds:

"It is notorious that the Texas law requires nothing but a diploma (a license can be procured by virtue of it alone) and the clerk of the county court is the judge of that diploma, even though it be written in Latin and he is unable to read it."

The Texas Civil Statutes, in force on the first day of January, 1894, has the following under "Title 73—Physicians":

Article 3632. *Duty of board to examine applicants, etc.* It shall be the duty of said board [one of the District Boards of Medical Examiners authorized to be created by a preceding article] to examine thoroughly all applicants for certificates of qualification to practice medicine in any of its branches or departments, whether such applicants are furnished with medical diplomas or not, upon the following named subjects, to-wit: Anatomy, physiology, pathological anatomy and pathology, surgery, obstetrics and chemistry; but no preference shall be given to any school of medicine. (Const. Art. 16, § 31; Act Aug. 21, 1876; 15 Leg. p. 221.)

There is no disposition on the part of the writer to evade responsibility for any sins of omission or of commission in the report on medical education; doubtless there are such, but the *Texas Medical Journal* is not dealing with one of them in this instance. The report must be judged for what it is, not for what it might be. In the *résumé* in question it was undertaken to state what the law required of medical practitioners—not whether the law was good or bad, efficient or inoperative, well enforced or neglected.

As a matter of fact, so stated in previous reports on medical education by the Illinois Board since 1883, the Texas law is a dead letter—whether so through the supineness or indifference of the profession it is not undertaken to say. But it may not be out of place to suggest that one, if not the only, difficulty in the enforcement of the Texas medical law as it stands to-day on the statute books—requiring a thorough examination of all applicants, "whether such applicants are furnished with medical diplomas or not"—has arisen from the acts of the compilers of the Penal Code of Texas.

The penalties for practicing before having obtained and recorded a certificate or license from the proper District Board of Medical Examiners, as provided in the article above quoted, are referred, in Article 3638, to the Penal Code. In the compilation of this Code in 1879, three years after the medical practice act went into effect, there appears a chapter entitled, "Ch. 3.—Unlawful Practice of Medicine." It consists of four articles, framed, as is specifically stated, upon the medical practice act of 1876. The first article, numbered 396 in the Code numbering, prescribes the penalty for practicing without having obtained the certificate of qualification; 397 defines what constitutes a separate offense; 398 fixes the penalty for failing to file the certificate; 399 defines the classes of practitioners who are exempt from the provisions of the Act—those qualified under the Act of 1873, those in practice five years prior to Jan. 1, 1875, and midwives.

It will be seen that the important articles are 396 and 398. Article 396 is as follows:

"If any person shall practice for pay, or as a regular practitioner, medicine in this State, in any of its branches or departments, or offer or attempt to practice without first having obtained a certificate of professional qualification from some authorized board of medical examiners [or without having a diploma from some accredited medical college, chartered by the Legislature of the State, or its authority, in which the same is situated], he shall be punished by fine not less than \$50 nor more than \$500."

As already stated, the compilers of the Code distinctly announce that the Articles composing this chapter "are framed upon the Act of Aug. 21, 1876."

Nowhere in that Act, either directly or by implication, is there any warrant for the phrase above bracketed in the quotation of Article 396. Not only is there no warrant in that Act for recognizing as an alternative qualification "a diploma from some accredited medical college," but the Act expressly forbids such recognition. All applicants for license to practice medicine in Texas are required by the law (Article 3632) to submit to be thoroughly examined in certain specified branches, "whether such applicants are furnished with medical diplomas or not." Article 3637 categorically defines the classes which are exempt from this examination; holders of diplomas are not therein exempted. Article 3638 is cumulative on this point.

The bracketed clause is an unwarranted and mischievous interpolation. The only other important Article of the compilers (398) was held by the court (French vs. S. 14 App. 75.) to be inoperative because "irreconcilably in conflict with the Act of 1876," and a modification was made to bring them in harmony. Can it be doubted that if the question was raised, Article 396 would also be held to be "irreconcilably in conflict," not only with Article 3632 but with the expressed purpose and policy of the Act as a whole?

F. W. REILLY, M.D.

Ex-Sec'y Ill. State Board of Health.

Chicago, April 16, 1894.

From a Woman Physician.

AN OPEN LETTER TO DR. W. W. PARKER.

CONANT, LAKE CO., FLORIDA, April 6, 1894.

With the courtesy of a Virginia gentleman, and there are none more courteous, and with the fairness of age and experience, will Dr. Parker listen to my story, and hear my plea, before he utters sentence against me—a woman physician?

My first year as doctor was spent as interne in a hospital conducted by women for women. During the year there were nearly one hundred births, two-thirds of which were illegitimate. The rules of the institution admitted only unfortunate girls who were primipara. No mother was permitted to leave without her child, nor child without its mother, if both were living. There I heard their stories; shall I repeat them?

An ignorant child of fourteen a mother! What is the age of legal consent in your State? A domestic chloroformed in an institution having male physicians; a girl overpowered in a reputable physician's office. These for variety, with the host of deceived by promise of marriage.

Afterward, I was the woman physician in an institution employing one woman and several male physicians. Complaint after complaint was poured into my ears by young women patients, of insult and vile insinuation from one of the doctors. Reporting to headquarters, as I learned from my predecessor's experience, called for an occasional apology on the part of the offender and then was made the subject of merriment and rude jest. Could Dr. Parker have stood in my place and noted the obscene look and unhallowed touch in the gynecological consulting room, I believe he would have felt like striking. Babes were not in the program there. I would not insinuate farther, for my position and opinions were too thoroughly understood for me to know more. When the situation became unendurable I was told that if these things were the cause of my resigning I would not better myself, as I would find the same conditions everywhere. One of the younger physicians who seemed a Christian gentleman, told me that he had been as much shocked as I, at first, but had found that all men told their jokes and their dirty story, and he had come to tell his with the rest.

I learned afterward of his death. The immediate cause

was said to have been grief over the death of his young child from blood poisoning.

Settling in a town with upwards of a dozen male practitioners, I was asked by one what I would do if appealed to by an unfortunate girl. I replied: "Murder is murder. I would as soon take a child from its crib and dash its brains out, as to destroy the youngest fetus." He replied: "There is not a doctor in town but has and will do it. You are no friend to your sex." I had no reason to contradict his first statement, but as to the last I loved woman too well to help her add murder to her other sin. If mother love and the touch of baby fingers did not save her to God and womanhood nothing could. That it could, I had proof in many cases where forsaken mothers had, in spite of all, carved for themselves and their fatherless children an honorable place in the world.

He gave me to understand that he had two abortion cases on hand and had asked with a view to my helping him out.

In a practice of thirteen years, I can remember being appealed to just twice—both times by women who had never seen me before—one a girl; one a wife with the consent of her husband. The unfortunate girl vanished as she came, plus the memory of a few earnest words. The wife was delivered of a fine child in due time.

The Doctor strikes a strong blow in a much needed direction when, in reference to "the preventive treatment against children," he says: "We are standing upon the mouth of a volcano wider than Vesuvius." And with all my woman's heart and brain I honor him for it, as I reverence and honor the God-like in man, but since as a girl I cried with my pet cat over her dead kittens—killed by a neighboring tom cat—I have never seen cause to hold the male element less responsible for the slaughter of the innocents than in the days of Herod.

Then, as now, men seem to fear the coming of Christ horn of woman, to dethrone earth's sensuality and cruelty.

This is my plea: "What God hath joined together let man put asunder," in the medical profession or elsewhere.

Let men and women join forces under the banner of Him who said: "He that is without sin among you, let him first cast a stone at her;" and also: "Neither do I condemn thee; go, and sin no more."

Let us join forces all along the line, and fight this hydra-headed monster to the death and save our nation.

O. E. WORCESTER, M.D.

For a Medical Jury.

BRACKETTVILLE, TEXAS, April 15, 1894.

To the Editor:—I hasten to the support of the suggestion of your New York contributor (in No. 13 current volume) for a revision of the statutes in a manner to provide for "a jury of medical men in all cases where medical evidence is required." I would establish at least one such jury in every county. I would arraign for trial all professors of clinical morphology, wherever they may be found at large, and all speculators on the psycho-physical relations of man, whether in the East or West. I would not try them by rule of law, but simply attempt to find out what is the matter with them. "If it is the physician's business intelligently to treat disease, then here is a fine field for future development." The jury would be required to clear and determine such questions as this: What is the mental condition of a medical man who writes about another to the JOURNAL that "his work was fruitless, not because it did not have all the elements of truth, active and professional disgrace (to quell); but because of the apathy of the profession itself." And again, "he ate largely of oatmeal which of itself is a paralyzing food." And again, "while it is right to use all

peripheral means of treating gynec diseases the central or centrifugal one of a proper diet should not be neglected." And again, "sweets are at a premium because of ethical esthetic taste. Women grown on society diet can not have full development. Hence, in my opinion, the decline of the birth rate," etc. The birth rate probably is diminishing under this kind of thing and the jury should look to it, taking care that the State suffer no injury. Oatmeal is not the only paralyzing food in the United States.

The psycho-physical man asks of the JOURNAL: What distinguishes the practice of our profession in treating the diseases and repairing the injuries of the *genus homo* from that of the veterinarian? Thereafter he affirms "that excessive feelings of displeasure, when protracted, produce a deficiency of innervation and quite a list of pathologic conditions have been attributed to this cause, *e. g.*, muscular debility, dyspnea, typhus, amenorrhea, chlorosis, dropsy, scurvy, tuberculosis, scirrhus and medulla sarcoma." The placing of "medulla sarcoma" in such a list as that is probably a menace to public health. But that is a question of fact for the jury while they are engaged with the matter of drawing the line between veterinary medicine and psycho-physics. Let us have the jury. The woods are full of medical cases which otherwise will fail of proper adjudication. Medical men demand it. Legal men would hail it with joy. Ecclesiastical men would find in the operations of such a tribunal the beneficence without the terrors of the holy office.

TEXAS M.D.

Railroad Rates.

FLINT, MICH., April 9, 1894.

To the Editor:—I wish to emphasize all that Dr. Daniel Lichty, of Rockford, says in your issue of the 7th inst., in reference to railroad transportation for members of our ASSOCIATION and their families, who have in the past, and who want to attend in the future the annual meetings of the ASSOCIATION.

Joining the ASSOCIATION myself at the New Orleans meeting in 1869, and attending its annual gatherings quite regularly for several years thereafter, I found that the comparatively small rebate in railroad fares afforded members, together with the necessary drafts upon time and purse, were a serious consideration when contemplating a trip to the place of meeting, each year, and have been among the absentees for several years past.

The first meeting of the ASSOCIATION in San Francisco was held when money was plenty and the U. P. and C. P. railroads were new, and the desire to see these roads, the vast tract of diversified country through which they were made, coupled with a desire to see the metropolis of the Pacific Coast, induced many physicians to put forth great efforts to attend that meeting. But much of this is now changed, and I greatly fear that, unless a *tempting fare* is offered to us, we may remain at our posts, still, doing more than any other class of people to ameliorate the condition of mankind, and thereby rendering a service directly and indirectly which, in over forty-five years of practice, I have found railroads loth to acknowledge and appreciate.

HENRY C. FAIRBANK, M.D.

Rates to San Francisco.

PITTSBURG, PA., April 10, 1894.

To the Editor:—Considerable space has already been taken up in the JOURNAL on the subject of transportation to the ASSOCIATION meeting, and I am reluctant to presume upon you, but I feel that unless there are some concessions made on the part of the railroad authorities the attendance from the East will be very small. I interested myself some time since in getting up a party to go by special train, with the expectation of low rates, and had secured the names of fifty-six. To-day with the present prospect of increased rates I can only get twelve of this same company to say they will

go. Leaving out of consideration the fact that perhaps to no other body of men are the railroad companies under greater obligations than to the medical fraternity, as a matter of business, looking at it in a mercenary manner, it would pay them to reduce the rates one-half on account of the larger number of passengers.

Can not a more determined effort be made to make the rates more satisfactory?

Yours sincerely,
JOHN MILTON DUFF, M.D.

Refilled Prescriptions.

RUSTON, LA., April 11, 1894.

To the Editor:—Has a druggist the right to refill a formula for a patient without the knowledge or consent of the physician? Has the patient the right to obtain a copy of formula from the druggist without the knowledge or consent of the author? In the event the patient is going to leave the community and take up residence in some distant part, has he the right then to obtain a copy of formula, and has the druggist the right to give it with the knowledge of the prescriber?

Very respectfully,
R. F. H.

Endorses Dr. Cohen et alii.

DENVER, COL., March 19, 1894.

To the Editor:—There are members of the ASSOCIATION outside of Pennsylvania who indorse most cordially Dr. Cohen's recent criticism of the policy of the JOURNAL in regard to advertisements of proprietary articles. I, for one, give an unqualified assent to all that he has said, and in addition consider the editorial attitude of the *Medical News* and the *Pittsburg Medical Review* most commendable. They take the only stand that honorable adherents of our Code of Ethics can take.

Very respectfully,
WM. P. MUNN, M.D.

Supports Dr. Cohen.

ALMA, MICH., March 19, 1894.

To the Editor:—Please record me as an ardent supporter of Dr. Solis-Cohen's contention against advertising quack remedies in our JOURNAL.

Yours,
I. N. BRAINERD.

BOOK NOTICES.

The International Medical Annual and Practitioner's Index: A Work of Reference for Medical Practitioners. Edited by WM. ALEXANDER, M.D., F.R.C.S., and thirty-nine collaborators. New York: E. B. Treat. 1894. Price \$2.75.

This is the American edition of the well-known *Annual* published in Bristol, England, for the last twelve years. The object of the *Annual* is to present its readers with "an exact and impartial record of the advances of medical science." In the rather successful effort to make the work truly cosmopolitan, the *Annual* has for some years past included among its contributors many American writers. For this volume we note the names of Hobart A. Hare, Wm. T. Buell, Paul F. Mundé, G. M. Hammond, H. D. Chapin, E. F. Frost, Frank W. Jackson, John Ridlon, J. Madison Taylor, Irving S. Haynes and John B. Hamilton. The *Annual* does not assume to make a report on *all* the medical literature of the preceding year, but takes note only of the "advances," or the progress made in medical knowledge of the subjects within the scope of the work.

Charaka-Samhita, Translated into English. Published by Avinash Chandra Kaviratna, Calcutta. Part VIII.

In our issue of September 23, we commented editorially on the character of this work, its great antiquity and its interest to all physicians.

This fasciculus concludes the nineteenth lesson, and gives

a translation of the twentieth, twenty-first and a part of the twenty-second. In the twenty-first lesson the physical faults are said to be: 1, excessive tallness of stature; 2, excessive shortness of stature; 3, excessive hairiness; 4, excessive baldness; 5, excessive darkness of complexion; 6, excessive whiteness of complexion; 7, excessive obesity; and 8, excessive leanness. The last two are especially damaging. The illustrious son of Atri had a very practical knowledge of his subject, for he says:

"Of the two, viz.: excessive corpulency and excessive emaciation, the latter is rather tolerable; for though the corpulent and the emaciated are equally situated, yet if disease assails both of them, it is sure to afflict the corpulent man more than the emaciated one."

For the cure of these evils, dietary regulations, exercise, and regulation of sleep are commended. This fasciculus is not less interesting than its predecessors.

A Text-Book of the Diseases of Women. By HENRY J. GAR-
RIGUES, A.M., M.D. Containing three hundred and ten
engravings and colored plates. Philadelphia: W. B.
Saunders. 16mo., cl., pp. 690. 1894.

This volume, which is dedicated to Dr. Abraham Jacobi, has been written for physicians, especially that class who "have not had the advantage of hospital training, and who go to a post-graduate school in order to learn gynecology;" and also for "that larger class who would like to go to such an establishment but who find it impossible to leave their practice;" and finally, for "undergraduates studying in medical colleges."

The work is therefore intended to be one for the general practitioner and medical student, but the surgeon will find much to interest him, and he will turn to this work for hurried consultation much oftener than to some of the more elaborate "text-books" and "systems." The later and standard operations are described concisely. A chapter on sterility and its treatment concludes the volume. The illustrations are excellent, many of them original, and the book is well printed.

NECROLOGY.

CORYDON L. FORD, M.D., of Ann Arbor, Mich., April 14. Dr. Ford's death was the result of an attack of apoplexy which he suffered while on his way home from the medical building. He was in his 80th year, having been born Aug 29, 1813, in Lexington, N. Y. His diploma was obtained from Geneva Medical College, where after graduation he was appointed Demonstrator of Anatomy. In 1846 he was appointed Demonstrator of Anatomy at the Buffalo Medical College. In 1854 he was invited to the Chair of Anatomy in the Medical Department of the University of Michigan, where his best work was done. At the various medical colleges with which Dr. Ford has been connected he has delivered 109 courses of lectures. During the past quarter of a century Dr. Ford has been considered one of the best authorities in anatomy in this country. His death has cast a gloom over the University, and by it that institution has suffered an irreparable loss.—N. M. Perry, M.D., of Troupsburg, N. Y., April 3.—Hulbert Agnew, M.D., of Philadelphia, April 6, aged 32. He was a cousin of the late Prof. D. Hayes Agnew.—Chas. Cawood, M.D., of Knoxville, Tenn., April 7, aged 32.—P. Harold Hayes, M.D., of Buffalo, N. Y., April 9. He was born in Bristol, Ontario County, New York, in 1823, and he was graduated from the Jefferson Medical College at Philadelphia in 1848. He practiced in Binghamton for many years. He went to Buffalo in 1892 where he has since resided.—Carl F. Rudden, of Joliet, Ill., April 9, aged 62.—James M. Hoyt, M.D., of Walled Lake, Minn., April 10.—John E. Wilcox, M.D., of Hoosic Falls, N. Y., April 10.—Thornton H. Flemming, M.D., of Canton, Ill., April 11, aged 85.—Alex. C. McChesney, M.D., of Chicago, April 14, at Nice, France, aged 53.—Chas. W. Davis, M.D., of Chautauqua, N. Y., April 9.

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Rio Grande Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville, Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland, thence east by way of the Northern Pacific R. R. to St. Paul. C. M. & St. P. R. St. Paul to Chicago. A stop over at Yellowstone National Park for those who desire it has been arranged, and it has been understood that at several places on the journey there will be short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentrating on this train should be effected at Chicago and St. Louis. For all information relating to this train, fares, etc., address J. M. Connell, 212 Clark st., Chicago, or any agent of Santa Fe line in other cities. Rates promised are the lowest excursion rates at time of departure.

This is the only route on which arrangements have been perfected by the Trustees.

Section on Practice of Medicine of the American Medical Association.—The officers of the Section on Practice of Medicine for the meeting of the Association in San Francisco will be glad to receive the titles of any papers which gentlemen desire to read at that meeting.

A large number of papers have already been promised for the meeting by members of the profession on the Pacific slope, and it is earnestly desired that an equal number of contributions should come from Eastern portions of the country.

H. A. HARE, Chairman,
222 S. Fifteenth Street, Philadelphia.
W. H. WASHBURN, Secretary,
803 Grand Avenue, Milwaukee, Wis.

Section on Neurology and Medical Jurisprudence.—Additional papers in this Section.

"A Study of the Ocular Symptoms of Friedrich's Disease," by Chas. A. Oliver, Philadelphia, Pa.

"Two Cases of Brain Tumor," by Anne Burnet, Wausaw, Wis.

"Dyspepsia, a Nervous Disease," by Chas. H. Hughes, St. Louis, Mo.

"The Forensic Aspect of Sadism with a Case," by W. L. Baum, Chicago, Ill.

"Lesions of the Sensory Portion of the Internal Capsule," by H. G. Brainerd, Los Angeles, Cal.

"Acute Mania," by John W. Givens, Blackfoot, Idaho.

A paper by Sarah Hackett Stevenson, Chicago, Ill.

"The Post Active Treatment of Narcotic Habitués," by J. B. Mattison, Brooklyn, N. Y.

FRANK P. NORBURY, M.D., Secretary.

Section on Obstetrics and Diseases of Women. Preliminary Program.—Address of the Chairman of the Section.

"Treatment of Fibroid Tumors of the Uterus," by Franklin H. Martin, M.D., Chicago, Ill.

"Recto-Vaginal Fistula, its Etiology and Surgical Treatment," by Augustus P. Clarke, M.D., Cambridge, Mass.

"Suspension of the Uterus in Extreme Anterior Displacements," by H. R. Holmes, M.D., Portland, Oregon.

"Placenta Previa," by Llewellyn Eliot, M.D., Washington, D. C.

"The Pedicle in Abdominal Hysterectomy," by A. H. Cordier, M.D., Kansas City, Mo.

"The Influence of Gestation upon Chronic Diseases of the Kidney," by T. Ridgeway Barker, M.D., Philadelphia, Pa.

"Tetanus Puerperum," by Allison Maxwell, A.M., M.D., Indianapolis, Ind.

"A Case of Didelphic Uterus, Unilateral Hematometria, Hemasalpinx and Hematocolpos," by X. O. Werder, M.D., Pittsburg, Pa.

"Removal of Fibroid Tumors through the Abdomen," by E. E. Montgomery, M.D., Philadelphia, Pa.

"Some of the Uses of Strychnia in Obstetric Practice," by John Milton Duff, M.D., Pittsburg, Pa.

The American Medical Association.—San Francisco is justly proud of her harbor, and since it is probable that the delegates and visitors to the AMERICAN MEDICAL ASSOCIATION will be given an excursion upon its waters, it will be of interest to many to learn something of its beauties. We will imagine we are upon one of the large excursion steamers and are starting upon our day's outing. The usual rush through the gates for the boat at the last moment is over, the inevitable half-minute-too-late man has been left behind and is sorrowfully wending his way back to his hotel, regretting the good time and the free lunch that have departed from him, and the boat with her load of guests has drawn out of the slip into the green bay, and with prow pointing northward is gathering headway for the journey.

It is not yet time for the usual afternoon breeze. The sun is shining brightly through a sky that will rival in depth of color and purity of tone the more famous skies of the old world; to the right the green slopes of the Coast range of mountains, looking blue in the distance, rise gradually from the shore until having reached the sky the vision is interrupted and the beyond is left to the imagination, while to the left the receding city with its undulating outline is growing gradually less distinct, and its rumble and roar is being replaced by the sound of churning waters from the wheels and the hum of happy voices. On the upper deck and forward is a good position from which to note points of interest.

To the eastward is Goat Island. This was formerly called Yerba Buena. Its present name doubtless arose from the fact that during the early forties it was used as a goat pasture. At present it is one of Uncle Sam's possessions. The Oakland and San Francisco ferry boats run just south of this Island and many tragedies are said to have occurred near its shores. Occasionally one reads in the papers of "the demon of Goat Island." If any are curious as to the legend, inquire of some native son or daughter and be enlightened. Alcatraz Island lies to the north. It belongs to the United States and is used as a fort and military prison. It seems too bad to appropriate so bright a spot to such use as the latter, but government and sentiment are not usually very closely related. Over to the left on the main shore is Fort Mason—commonly called Black Point, while further westward is Fort Point, backed by high bluffs that have recently been strongly fortified. The dirt mounds on their summits, covered with waving wild oats, look innocent enough, but hidden in their depths are engines of destruction so placed as to fully command the entrance to the harbor.

About equi-distant between the forts, the Pacific Coast headquarters for the Army is located. The neat quarters of the officers are almost covered by trailing vines and climbing roses that partly obscure their outlines. Soon after we have passed Alcatraz all eyes will be turned to the westward to drink in the view presented. In the center, like a mighty river, lies the Golden Gate; beyond is the limitless expanse of the Pacific Ocean; to the north the Mission Hills rise abruptly from the shore to culminate a few miles away in Mt. Tamalpais, while on the south the gentle slopes of the Presidio, dotted with evergreen trees, lead backward toward the city.

Our boat moves on, and new scenes shut this one out, but the impression made will long remain.

With a long sweep in toward Saucelito, nestling among the trees at the mountain's base, we have turned to the east, and are steaming along past Belvidere and Tiburn. Angel Island, which we are now approaching, is of some interest to this company of sightseers; here is located the quarantine station, and perhaps we will be given an opportunity to land and make inspection, but probably our boat will be headed for Raccoon Straits through which we will pass and cruise about in the broad bay above.

Here we will have an opportunity to point out Red Rock, Two Brothers, Hen and Chickens, McNear's Landing—the most delightful picnic place on the bay—the Chinese village of shrimp fishers and other places with which we may be familiar.

Our objective point is Mare Island. This is the Government Naval repair and supply station for the Pacific Coast.

Through the kindness of Surgeon-General Tryon and Surgeon Wood, of Mare Island, we will be permitted to land and inspect all that is of interest. Many famous old vessels have been refitted here, and perhaps some are lying in the offing now. After having spent an hour at this place we will board our steamer and start on our return.

There yet remains much to be seen, but the sun is gliding over toward the west, and we must hasten or it may be dark before the circuit is complete. We steam back past Vallejo, Port Costa, with its immense grain depots, Berkeley, our State University town, Oakland, the City of Churches, and Alameda the charming residence suburb. It will be of interest, as we cross the bay on our way home, to notice the Spreckles Sugar Refinery, the Union Iron Works, where have been constructed such war vessels as the *Charleston* and *San Francisco*, and the Pacific Mail Steamship docks, where the Chinese coolies were at one time landed by the thousands. The sun is dipping into the western waters, and as our boat glides into the slip, the twinkling lights of the city invite us back to our accustomed duties, refreshed and invigorated by our day's outing, and ready for whatever of entertainment may yet be in store.

R. L. RIGDON, Secretary.

SOCIETY NEWS.

Eleventh International Medical Congress.

To the Editor:—I send you a list of the delegates from America to the Congress at Rome, by request of Dr. T. H. Manley. Should you wish to describe the Congress itself, simply add chaos to confusion, with plenty of Italians who are placed in the halls to impart information; these never answer a question till the "tip" appears. The Latin races will not listen to the English tongue. We are the envy of the English Section because we have an executive committee who placed our members where they belong and have seen that the American papers were read. The Italian is indolent and apparently lacking in executive ability. One little incident will show you something of this: The managers published maps of the buildings—which are very large—and when the mistakes, which are frequent and gross in these plans, were pointed out, there was simply a shrug and a reply that everything was very clear.

One of the newspapers had a correspondent here for thirty days before the opening, and he has not found any Italian secretary or manager who had any conception or knowledge of any fixed plan. The truth is, there were no plans. Three time tables would give three different times of meetings. But the Americans have been on hand all the time. Trusting you can use the list, I remain very truly yours,

DOUGLAS H. STEWART, M.D., New York City.

The following is a list of American physicians at the Eleventh International Congress at Rome:

Austin, H. W., Washington, U. S.	Lowman, John H., Cleveland.
Maribes.	Lynch, John B., New York.
Ainley, Daniel, Halifax.	Landesburg, Max, Philadelphia.
Belcher, Sarah, New York.	*Link, John Eph., Indiana.
Baldwin, A. A., New York.	*Moise, Bettinidi, New York.
Brown, Adelaide, San Francisco.	Manley, Thos. H., New York.
*Bleyer, J. Monnt, New York.	Miller, A. M., Pennsylvania.
Borden, M., New York.	Mannem, Earnest, Illinois.
Bohn, H., Philadelphia.	Mallory, P. B., Boston.
Bradfield, G. M., Philadelphia.	*Moore, James, Minnesota.
*Bernays, A. C., St. Louis.	Miller, Wymond, Montana.
Blake, C. J., Boston.	*Murphy, J. B., Chicago.
Brown, A. A., Montreal.	Nuttall, Geo. H. F., Baltimore, Johns
Barnes, J. Steele, —.	Hopkins College.
Corlett, Wm. T., Ohio.	Owen, A., Indiana.
*Cannadays, C., Virginia.	Pyne, J. H., —.
Cohen, E., Minneapolis.	Parker, Carter A., Connecticut.
Cornu, Felix, Montreal.	Preble, Robert, Chicago.
Carlucci, Francesco, New York.	Price, John P., Pennsylvania.
Cunningham, John, Connecticut.	Patton, Stewart, West Virginia.
Caldwell, M., Wisconsin.	Pellou, P. C., Minnesota.
Campbell, H. A., Syracuse.	Rawlius, J., Florida.
Cannon, J., Iowa.	Ring, Frank, St. Louis.
Dickey, J. L., Virginia.	Richardson, J. J., West Virginia.
Dubois, Frank L., Washington, U.S.	Rice, W. B., Boston.
Navy.	Sochatzy, M., New York.
Dick, Alfred, Buffalo.	Sarton, H., California.
*Davis, J. C., —.	Simpson, John D., Minneapolis.
Engleman, J., St. Louis.	Sneve, Haldor, Minneapolis.
Field, H. A., Brooklyn.	Stoddard, Chas., Chicago.
*Frank, Jacob, Chicago.	*Smith, Joseph R., New York, U. S.
Furbeck, Peter R., Indiana.	Army.

Flour, Thos., Baltimore.
 Griscom, M., Philadelphia.
 Goldstein, M. A., St. Louis.
 Granger, D., —.
 Gay, Geo. W., Boston.
 Girard, A. C., Chicago, U. S. Army.
 Hayden, S. H., Chicago.
 Hoeck, K., Minneapolis.
 *Hewettson, J., Baltimore.
 *Irwin, B. J. D., Washington, U. S. Army.
 Jeffries, Horace, Boston.
 *Jacobi, A., New York.
 Joseph, L., Cincinnati.
 *Judson, Daland, Philadelphia.
 Keane, Francis, Boston.
 Koser, S. S., Pennsylvania.
 Kistler, O. F., Peru.
 Kreider, Geo. N., Illinois.
 Kee, A. H., California.
 Kitchen, E. E., Canada.
 *Kay, T. W., Pennsylvania.
 Keller, Thos. F., Ohio.

Those marked thus * read papers.

Dr. A. Jacobi, of New York, President; Dr. Wm. Tobin, of Halifax, Secretary for Canada; Dr. Douglas H. Stewart, of New York, Secretary for United States.

Executive Committee: Dr. Thos. H. Manley, New York, Chairman; Dr. G. C. Simmons, Sacramento; Dr. J. Engleman, St. Louis.

DOUGLAS H. STEWART, M.D., Secretary.

Pennsylvania State Medical Society.—The following is a list of the addresses and papers which have been appointed to be read or have been secured by the Committee on Scientific Business for the forty-fourth annual meeting of the Pennsylvania State Medical Society, to be held in Philadelphia, May 15 to 18, inclusive:

Annual Addresses: "Medicine," Dr. W. S. Foster, Pittsburg; "Surgery," Dr. G. D. Nutt, Williamsport; "Obstetrics," Dr. E. E. Montgomery, Philadelphia; "Mental Disorders," Dr. T. M. T. McKennan, Pittsburg; "Hygiene," Dr. J. H. Wilson, Beaver; "Ophthalmology," Dr. Geo. E. de Schweinitz, Philadelphia.

Medical Papers: "Hydrophobia," Dr. Charles W. Dulles; "Dietetics," Dr. H. F. Slifer; "Unique Cases in Practice," Dr. John M. Batten; "Therapeutics of Whooping Cough," Dr. W. C. Hollopeter; "Colorado Climate for Consumptives," Dr. William P. Munn (Denver, Col.); "Subcutaneous Emphysema," Dr. R. G. Curtin; "Diarrheal Diseases," Dr. John Aulde; "Acroparesthesia," Dr. Wharton Sinkler; "Typhoid Fever," Dr. Adolph Koenig; "Tapping of Abdominal Effusions as a Therapeutic Measure," Dr. W. E. Hughes.

Surgical: "Radical Cure for Hernia," Dr. E. Laplace; "Modification of Pirogoff's Amputation," Dr. F. Le Moyné; "Surgery of Gall-bladder," Dr. X. O. Werder; "Section of Tendo-Achillis in Fractures and Dislocations," Dr. T. S. K. Morton; "Appendicitis," Dr. John B. Deaver; "Amputation Near the Ankle," Dr. G. G. Davis; "Stricture of the Urethra," Dr. O. Horwitz; "Treatment of Fractures at the Lower End of the Humerus," Dr. Charles W. Dulles; "Acute Intestinal Obstruction," Dr. J. M. Barton; "Ocular Exploration of the Bladder and Urethra," Dr. Edward Martin; "Thyroidectomy," Dr. John B. Roberts.

Obstetrical and Gynecological: "Puerperal Eclampsia," Dr. J. C. McAllister; "Uterine Fibroids," Dr. Charles P. Noble; "Acute Endometritis," Dr. J. M. Baldy; "Studies in Obstetrics and Gynecology," Dr. Anna M. Fullerton; "Symphyseotomy and other Procedures," Dr. Horace Fox; "Cholecystoenterostomy," Dr. B. F. Baer.

Eye and Ear: "Corneal Ulcers," Dr. S. L. Ziegler; "Diseases of the Ear," Dr. S. MacCuen Smith; "Surgical Treatment of Internal Strabismus," Dr. H. F. Hansell; "Eye Strain," Dr. Charles H. Thomas; "Tympanic Vertigo," Dr. Charles Burnett; "Massage Methods in the Relief of Tinnitus," Dr. Louis F. Lautenbach; "Capsulotomy after Removal of Cataract," L. Webster Fox.

Nose and Throat: "Intra-nasal Surgery," Dr. W. H. Daly; "Naso-pharyngeal Catarrh," Dr. William R. Hoch.

Skin: "Clinical Observations," Dr. J. V. Shoemaker; "Epithelioma of the Skin," Dr. M. B. Hartzell.

Tuberculosis: Arrangements have been made for a discussion on "Medical and Surgical Tuberculosis," and papers will be read on "Medical Tuberculosis" as follows: "Curability and Treatment," Dr. S. S. Cohen; "Psychical Phases," Dr. J. M. Taylor; "Contagiousness," Dr. A. M. Cooper; "Prophylaxis," Dr. L. F. Flick; "Medical Tuberculosis," Dr. Hugh Hamilton; "Strychnin Treatment of Pulmonary Consumption," Dr. T. J. Mays; "Case of Tubercular Meningitis," Dr. D. Longaker.

Spring, C. B., California.
 Steadman, Thos. L., New York.
 Stannard, Frank, Chicago.
 Sumner, C. J., Buffalo.
 Sell, Edward, New York.
 Strong, Walter, Philadelphia.
 Simmons, G. C., Sacramento.
 Siegfried, Chas., Washington, U. S. Navy.
 *Stewart, D. H., New York.
 Shepherd, E. J., Montreal.
 Senouse, D. W., Iowa.
 Tobin, Wm., Halifax.
 *Tyner, T. J., Texas.
 Torrison, Geo., Kentucky.
 Tattelbee, J. B., Chicago.
 *Turek, J. F. B., Chicago.
 Von Klein, Carl H., Cleveland.
 Wolff, Jacob, Chicago.
 Warner, W. R., Philadelphia.
 Williams, H. A., Buffalo.
 Wardsworth, W. S., Philadelphia.

The following members of the Society have announced their wish to take part in the discussion on "Medical Tuberculosis": Drs. J. H. Musser, W. B. Ulrich, J. C. Wilson, J. S. Cohen, W. E. Hughes.

The following papers on "Surgical Tuberculosis" will be read: "Tuberculosis of the Fallopian Tubes," Dr. C. B. Penrose; "Treatment of Tubercular Caries of the Spine," Dr. H. A. Wilson; "Case of Tuberculosis of the Knee-joint," Dr. E. B. Haworth.

The following members will take part in the discussion on "Surgical Tuberculosis": Drs. J. B. Roberts, DeF. Willard, G. G. Davis, J. K. Young, J. M. Barton, B. F. Baer.

"Tubercular Manifestations of the Skin" will be discussed by Dr. H. W. Stelwagon.

Besides these the following papers on general subjects are announced: "Christian Science and the Medical Profession," Dr. H. H. Longsdorf; "Should the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION be used to Promote Quackery," Dr. S. S. Cohen; "Reasons for the Revision of the Code of Ethics," Dr. E. Jackson; "Cramming in Medical Schools," Dr. O. H. Allis.

The Committee has obtained the consent of Dr. Benjamin Sharp, of the Academy of Natural Sciences, to exhibit to the Society his beautiful series of lantern pictures of the Leper Settlement at Molokai, Sandwich Islands, and of lepers in various stages of the disease.

The Tennessee State Medical Society.—The Tennessee State Medical Society held its annual election of officers at Memphis April 11, which resulted as follows: President, Dr. F. L. Sim, Memphis; Vice-President for West Tennessee, Dr. G. B. Gillespie, Covington; Vice-President for Middle Tennessee, Dr. G. C. Savage, Nashville; Vice-President for East Tennessee, Dr. D. E. Shields, Morristown; Secretary, Dr. S. S. Crockett, Nashville; Treasurer, Dr. Ambrose Morrison, Nashville. Dr. Dulaney, of Bristol, is the retiring President, and as such becomes a member of the Judicial Council.

Morgan County (Illinois) Medical Society.—The regular meeting of this Society was held Thursday, April 12, in the Society Hall, Jacksonville. S. B. M. Griffith, of Springfield, Ill., member of the State Board of Health, read a very thorough and scientific paper on "The Salient Points in Preventive Medicine." A free discussion followed. A committee consisting of Drs. F. P. Norbury, G. V. Black and H. F. Carriel was appointed to prepare suitable resolutions relative to the death of Dr. Jno. H. Rauch, late Secretary of the State Board of Health.

The Tri-State Medical Society (Illinois, Iowa and Missouri) will hold its next meeting at Jacksonville, Ill. This Society has grown rapidly into one of the foremost in the West, and promises to be a vigorous, working Society. Its meeting in Kansas City April 3, 4 and 5 was a great success, both in attendance and work done. The physicians of Kansas City were especially hospitable and entertained the visiting members royally.

The Dubois Medical Society held its annual meeting at Jasper, Ind., April 3. The following officers were elected for the ensuing year: B. B. Brunnock, of Jasper, President, and C. R. Ramsbrok, of Huntingsburg, Secretary and Treasurer. Dr. W. R. McMahan was appointed a delegate to the AMERICAN MEDICAL ASSOCIATION.

MISCELLANY.

At the fifteenth annual commencement of the Arkansas Industrial University, April 5, thirteen graduates received the degree of M.D.

To be Mayor of St. Paul.—Dr. Chas. A. Wheaton, of St. Paul, has consented to accept the nomination for Mayor by the Republicans of that city.

Surgeon-General Fulton.—Dr. John F. Fulton was yesterday commissioned Surgeon-General of the Minnesota National Guard to succeed the late Dr. Murphy, April 6.

New Medical Journal.—We have received the initial number

of a new medical monthly published at Rochester, N. Y., and edited by H. Bronson Gee, M.D. It presents a neat appearance and is filled with interesting matter.

A Queen's Thoughts Concerning the Medical Art.—In her little book, called "Pensees," the Queen of Roumania offers the following comparisons between theology and physic:

"It is better to have a physician for a confessor than a priest. You tell the priest that you detest mankind; he answers: 'You are not a Christian.' The physician gives you a dose of rhubarb, and you love your fellow-being. You tell the priest that you are tired of living. He answers: 'Suicide is a crime.' The physician gives you a stimulant, and immediately you feel life supportable."

Smallpox in Illinois.—In Illinois, outside the city of Chicago, there have been eighteen places infected during the period between January 1 and April 18, 1894, with a total of sixty cases and ten deaths. At the latter date there were eight infection centers with eleven cases remaining. In fifteen places the outbreak was limited to the original case or cases; only in the poorhouses of Madison, Warren and Grundy Counties and at Harvey in Cook County, did the disease spread beyond the houses first infected. In all places the rules and regulations of the State Board of Health were promptly enforced and the record reflects credit upon the Board.

In Chicago, up to noon of the 17th, 226 cases were reported for the month of April and the spread of the disease continued unabated. The situation is grave beyond precedent. The pesthouse is overcrowded and newly-discovered cases are retained at their homes until places are made for them by death or recovery. Smallpox corpses awaiting burial are almost daily found by the inspectors, this being the first intimation of the existence of the disease. An inspector of the Tenth Ward reports finding two corpses on the 14th and three on the 15th. Work has been at last begun on an extension of the pesthouse, for which an appropriation of \$25,000 has been available for some time. The County Hospital has been again quarantined, there being on the 16th two cases of smallpox and six "suspects" in the building refused admission to the pesthouse until some of its inmates "die or recover." An emergency meeting of the State Board of Health was held in the city on the afternoon of the 17th, at which the Mayor and Health Commissioner were present. Beyond appointing a committee of the Board to inquire of the Governor what funds of the State were available to assist the city in its efforts to suppress the disease no action was taken—the city authorities, while confessedly unable to cope with the situation, refusing to make a direct appeal to the State Board for assistance.

An "East Side" Census in New York City.—The Church Temperance Society has recently made a social census of forty-seven city blocks, the approximate center of which is the intersection of Chrystie and Stanton Streets. The census was taken by eight ladies, who had already had experience in this field. The census-takers were, as a rule, courteously received in their districts, and were enabled to report more or less fully on 90 per cent. of their lists of questions. The population of the section is, in round numbers, 55,000; of which 25,000 souls are of American birth, the remainder being Russian, Polish or German; the real excess of alien Jews over Americans is stated at 5,517. The number of dwellings is 529, of tenements 1,775. Of these latter 180 are of the baneful variety known as "rear tenements." The proportion of the people who dwell in tenements is probably not below 90 per cent. One subdivision of the district, containing 40,000 souls, has 192 saloons, or one saloon to every 200 of the population, inclusive of children, women and men. In another smaller subsection, there is one saloon to every seventy-seven persons. One of the objective points of this movement will be to secure a reduction in the number of saloons, so that there shall be not more than one of these institutions to every 500 of the population.

Regarding the tenement system, the following observations are made in the report:

"The New York tenement house is a necessity begotten of its conditions and surroundings. It is not necessarily bad. It may be built with due regard for light and fresh air.

The evils, in our opinion, are the rear tenements; back to back tenements, known as double-deckers; front tenements, badly constructed as to light, drainage or both.

"In all reforms requiring large powers coupled with large expenditures, naturally the municipality is intrusted with the power because it can obtain the necessary capital at the cheapest rate. The present condition of the city, because of the baneful influence of Tammany Hall, precludes the possibility of large purchase, large clearing and the erection of sanitary dwellings thereon. The defeat of Tammany Hall and the installation of an honest, reputable and representative city government is a condition precedent to any real, full and effective dealing with the tenement, rear, front, and back to back."

Hospital Notes.

THE NEW city hospital at Dallas, Texas, will be ready for occupancy May 1, and will be furnished with "all modern improvements."

THE ST. LAWRENCE STATE HOSPITAL, at Ogdensburg, N. Y., will receive over one hundred thousand dollars this year for the following purposes: Grading grounds, \$20,000; cold storage, \$4,000; two cottages for disturbed patients, \$24,740; cottage for convalescents, \$44,168; propagating house, \$3,150; vegetable and sub-cellar, \$4,000; steam boiler, \$2,500; piping and motors for laundry, \$935.

THE PUBLIC SERVICE.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from April 7, 1894, to April 13, 1894.

Capt. OGDEN RAFFERTY, Asst. Surgeon, is hereby granted leave of absence for one month, with permission to apply for an extension until the 20th of May next.

The following named officers of the Medical Department will report in person, for temporary duty until further orders, as follows: First Lieut. CHARLES WILLCOX, Asst. Surgeon, to the commanding officer, Angel Island, Cal.; First Lieut. CHARLES E. B. FLAGG, Asst. Surgeon, to the commanding officer, Alcatraz Island, Cal.

ORIGINAL ARTICLES.

TRADITIONAL TREATMENT OF LEPROSY IN JAPAN AND CHINA.

BY ALBERT S. ASHMEAD, M.D.
NEW YORK.

"Kattai no kasa urami."—*urayami*—(the leper's envy of a syphilitic.)—*Japanese Proverb.*

There is a Japanese treatise on syphilis and leprosy published by Katakara Genshiu, Tokio, 1781, on which I wish to make a few observations. The preface of this book also alludes to the oft-quoted anecdote which seems to imply that leprosy existed at the time of Confucius. It is said that one of the great man's disciples being ill, his master went to see him, but staid outside and contented himself with shaking hands through the window casement, expressing his regret that his friend should have "that hateful disease." It is generally supposed that he meant leprosy. The preface of our book approves the cautious conduct of the master. "For, it is said, in later times special hospitals and houses were erected for lepers, so that their disease might not be mixed with other maladies."

(The work on syphilis has a preface of its own in which it is stated that this disease first received its special name in the early part of the Yuen dynasty, (A.D. 1260-1368). Katakara Genshiu says it is not mentioned as *yo-bai-so* (syphilis) in the most ancient Chinese medical books; the "*So-mon-nai-kei*" a Chinese medical book the most ancient of all), the "*Rei-shin-sho*," (Chinese book of medical marvels), the "*Kinki-sho-kan-ron*" (Golden Chest, A.D. 200), the "*Shin-no-kei*" (Method of Schoochuke, Chinese Hippocrates),¹ the "*Byo-gen-ron*" (Theory of Disease), the "*In-sho-ku*," (Diseases of Penis) and the "*In-so*" (Sores of Penis).

Syphilis appeared first in the swamps of Southern China; in Japan it made its first appearance in the province of Hijien. It was not so widespread in those remote times, as it is in our days. It is more generally cured now than formerly. It seems that five out of ten people are syphilitic in China as well as in Japan.

The author understands syphilis perfectly; its causes, its transference by inoculation, its transmission to the offspring, the danger of infection through cutaneous disease, especially itch. The author in describing secondary and tertiary syphilis confounds evidently mercurial salivation with the latter; for he speaks of the putrefaction of the gums, pains in the tongue, cracks on the side of the tongue, a continuous flow of saliva, bell-like sounds in the ears, etc. Describing the various forms of syphilis, he declares that, in spite of the great variety of appear-

ances, the poison in all cases is identical. He knows the danger of transference from the mouth. He mentions also the late manifestations of syphilis.

In the preface to the volume on leprosy, we read that a method of cure had been adopted in the time of the Sung and Yuen dynasties (A.D. 960-1278 and A.D. 1260-1368). As to his own method, the author assures us that it will cure the patient in the space of three months. This method of cure of the author consists in driving out noxious insects by medicines, and eliminating bad blood by *moxæ* and acupuncture. He tried his method on his own showing with excellent results in various provinces (Yamashiro, Settsu, Isé, Kii).

Among the causes of leprosy he mentions putrefaction of the blood by heat. He refers to some authors as having placed the origin of leprosy in the veins afflicted with catarrh. The writer, and all the authorities which he quotes, consider leprosy as related in some obscure way with cold; it may owe its origin to sleeping in the open air, or in swampy places, being exposed to the vitiated air emanating from water closets. Eating fat aliments, excessive sexual intercourse, neglecting to clear out the bad blood after childbirth, are also incriminated. But in all these cases, there has been, for several years before the outbreak, an insect in the body, whose presence is indispensable to the operation of the exciting cause; possibly he means a bacillus.

People of beautiful white complexion are very prone to contract the disease; however caused, the disease yields always to the same treatment.

The author cautions all doctors not to confound certain forms of alcoholism with leprosy; these forms of alcoholism are unknown to us.

Some of the Chinese names of leprosy embody the belief in an origin of the disease through cold; great cold wind, great paralyzing cold wind, great wind eruption, hateful great wind, great skin catarrh, influencing or favoring catarrh (influenza), unfavorable catarrh, penetrating catarrh, leaking catarrh, wet catarrh, incurable catarrh, filth catarrh.

Other denominations emphasize the influence of humidity: Swamp-filth poisoning, wood, or forest-filth poisoning,² fire-filth poisoning,² metal filth-poisoning,² earth-filth poisoning,² water-filth poisoning,² cricket or swamp-insect poisoning, rain-filth poisoning. There are some other names: Numbness poisoning, human insect poisoning, black disease poisoning. It is also called Confucius disciple (Hakugin) disease, from the student before mentioned; mutilating disease, insect-mutilating disease, bursting melon disease are other names. The most commonly used is the great wind catarrh disease.

Some cases are absolutely incurable; it is useless to attempt to cure a patient whose eyes have a yellow hue, whose finger nails have no white crescents at the

¹ Author of the *Shookaaron* (Treatise on feverish diseases) composed 350 years before Christ.

² Referring to the five elements.

bottom, whose hands are wholly anesthetic, whose palm or sole bleeds, whose eyeballs are ulcerated, whose penis is putrified, whose hands or feet are clawed, whose skin is spotted with black, whose fingers have melted off, leaving frog-foot shaped ends, whose body hairs fall off, whose nose is gone, whose bones are poisoned and putrified, drunkards and debauchees, a too frequent bather, men who contract the disease after their fortieth year, people with very emaciated bodies.

Chinese and Japanese character for leprosy.

This is a combination of the

character = disease,

and character = wind or catarrh.

Treatment.—The disease is to be treated in accordance with the condition of the temperature, and the degree of the disease, whether severe or mild. Apply moxæ below the eleventh vertebra three times a day, and various Chinese medicines, of which we know nothing.

In mild cases draw the corrupt blood by acupuncture. The needles must be used within the circumference of the spots; in severe cases they are to be heated, and applied red hot inside the margins of the sores. But, unfortunately the manner of using these hot needles as Dr. Chan used them is, in a measure lost; the most effective part of it, at least, that is the shape of the needles. The needles used by the writer are, says he, different from the ancient sort, and he uses thirteen in number, instead of the prescribed number, whatever that might have been. The length of the needle is seven and one-half inches (Japanese inch is ten inches to the foot). The end of the needle is sharp and round, the handle is hexagonal in shape, three inches long. One of the thirteen needles is flat-

headed. They are made of ordinary iron which in Japan is magnetic.

The manner of application is as follows:

Let the patient sit down naked, in a darkened room; burn camphor as a light, and examine the entire surface of the body. In this way the poison under the skin, may be seen plainly by the physician. Circumscribed blood spots of various shapes, round and square, oval and irregular will appear beneath the skin. If they are scarlet, the poison is not severe;

if dark purple, it is of great strength. The physician marks with ink the circumferences of these spots as they are seen by the reflected camphor light. The spots are mostly on the face, hands, feet and neck; very few of them are found on the chest and abdomen. Open the windows and puncture the spots with the red hot needles, the latter heated in a charcoal fire, are used one by one within the marked places. Generally there is no bleeding, nor is there any pain felt; if there is bleeding and pain the spot operated on is not leprous. The needles may be introduced even to the depth of an inch, without causing any pain. After these operations, the patient's body shows high temperature, his face reddens, his mouth is dry, and there is headache and intense thirst. Give him warm water to drink, and apply the hot flat-top needle to his bald vertex with a quick touch; thereupon he feels relief.

The needles are used three days in succession; on the second day, the acupunctures are made in the intervals between the first day punctures, when, how-

ever, the needle can not penetrate deep without causing pain; on the third day again, puncture in the existing intervals.

There is a test for leprosy which the writer makes before he operates. He pulls out some hairs, and if they yield easily, the patient is leprosy. After the operation the hair, in this case, is not so easily pulled out, which the author considers as a proof that already the blood has acquired additional strength.

At the first outbreak of the disease, the sufferer loses the skin sensibility, and feels an itching sensation like insects crawling under the skin; coldness in the finger-tips, cold and hot flashes over the body, severe pains in hands and feet, pinching pains in thighs, formications all over the body. If the skin is scratched there forms a scab. The outside of hands and feet turn as cold as ice, while scurf develops on the skin; loss of sensibility in little finger and little toe; swellings appear on trunk and hands. Under these circumstances the author advises the burning camphor skin-illumination, the use of three-cornered needles, and the application of his own special Chinese medicaments. The cure may be expected in forty or fifty days.

In a severe case of leprosy, the body becomes tuberculated, the color of the skin turns into purple; eruptions of egg or cannon-ball size appear, and their places swell near a fire. After a few days, the top of the eruptions break and yellow water oozes out; it looks very much like a burn. Now the eyebrows and lashes fall out, and there is a strange flash in the eyes. The skin becomes like the bark of a tree, the fingers bend, the expression of the face loses all brilliancy and turns ashy white; swellings and pains in bones; voice becomes rasping (leper's croak); ringing in the ears; total anesthesia. The eruption may disappear in one place, and reappear in another. No pain felt when hairs are pulled out. In these cases the author is confident that by using his method, and applying the needles for three days, a cure will be achieved. During the treatment a special diet is prescribed.

A leper must be precluded from sexual intercourse, and deprived of fatty food; these two rules are *sine qua non*.

Warm springs, says the author, have a most deleterious effect upon lepers, because they elicit the deep seated poison and spread it over the skin. Some persons appear to become leprosy in consequence of alcoholism; but this is only an appearance. A mild case of leprosy might be mistaken for syphilis. Therefore be careful of diagnosis before using the needles. The season most favorable for acupuncture is from the beginning of summer to the first days of autumn, because the chances of catching cold are less.

The author mentions some facts which have seemed to me worthy of reproduction:

In Nara near Kioto, there is a leper village which he has visited (the author made a visit to it in 1777 A.D.), inhabited by many hundred families. He quotes a Chinese doctor who gave it as his opinion that leprosy was transmitted in the sexual act, by the passage of an insect at the time of coition, either from the male to the female body, or *vice versa*;³ the Chinese physician recommends, in the intercourse between a leper and a healthy person, the interposi-

tion of a lotus leaf. He knows, in Southern China, of the existence of a leper village, built by the Government, whose population have to report, under penalties, the appearance of all new cases of the disease. He speaks of leper hospitals, which were built "in times of yore," in order to isolate the lepers. Most of the lepers in China seem to dwell in the wet districts which extend at the foot of the South Mountains. In Japan, not only the southern parts, but all the provinces, are infected. The cities are comparatively free from leprosy, though much afflicted with syphilis. These two antagonistic forces never occupy the same spots; it has been so in Japan for eight hundred to fifteen hundred years. In recent times syphilis became more prevalent in the country, and forthwith leprosy decreased.

After expatiating on these facts the author thinks fit to return to the subject of the cure of leprosy. He mentions now another treatment: The use of turpentine or boiled pinewood. The author thinks that such patients as are able to eschew fat and live cleanly have a good chance to be cured by this method. The remedy was known and used two thousand years ago (quotes a leper anecdote from a Chinese book of philosophical doctrine, "Ho-bo-kushi," written by Kakko).⁴ It is mentioned in the "Byo-gen-ron," the Chinese theory of diseases. We find it also in the "Thousand Golden Remedies," the "Sen-kin-ho," written A.D. 618-90, date of book A.D. 640. The method is described in the Chinese "Diet Cure of Diseases," as follows: "Take some pure turpentine, boil it in a clean pan with spring- or rain-water; keep stirring it; when it becomes muddy and bitter pour into cold water. Boil repeatedly until the liquid turns white and loses its bitterness. Dry in the shade; grind into powder, and make it fine. Use it thus: Make a soft boiled rice, mix the turpentine thoroughly with it, and eat freely of it. Eat it until it purges. If the patient feels thirsty let him drink nothing but pure water mixed with the turpentine powder. After ten days' use, vomiting and purgation come on; they are favorable symptoms. Resume the treatment from time to time. Mushrooms, and any plant growing in swampy places must be excluded from the patient's diet, not only during treatment, but forever after."

The pinewood treatment is also referred to in the Chinese history of the Jo River country ("Jo-sui-yen-dan").

Acupuncture in leprosy was certainly used in China under the Ming dynasty, (1368-1644 A.D.). It is mentioned in the "Dan-san" (collection of stories by To-fok).

PERSONAL EXPERIENCES OF THE AUTHOR.

1. A farmer of Aomi, in the province of Sagami; age 30; since about a year ago lost the sensibility of his little finger, and the same became crooked; legs became also anesthetic; boring pains at intervals. Case diagnosed as leprosy. Patient taken into a dark room; camphor illumination; congealed blood appears plainly under the skin. Three-sided acupuncture needles stabbed into several eruption places, without causing pain. Purgings during fifteen days, and then again for three days. He passed five insects.

⁴ Kakko wrote A.D. 330, a book entitled, "Chin-yo-ho," (prescriptions behind the elbow). The true meaning of this title is as follows: In mythological times, sages carried charms around the elbows to ward off evil spirits. In theological books, eminent Buddhist clergymen are referred to as priests who have charms around the elbow. It must be observed that the elbow part of the sleeve is the Japanese pocket.

³ Based, very probably, on the fact that leprosy occurs only at or after the age of puberty.

Medicaments ingested during twenty days; re-application of the three-sided needles. A cure was effected.

2. A student, 22 years old, province of Satsuma, contracted three years previously a gonorrhœa. One year after its cure the little finger of his right hand became anesthetic; spots appeared on hands and feet and on the face. At last all the fingers of his right hand became crooked. His case was incurable because treatment had not been demanded in time; his hand remained crooked, but the acupunctures could still prevent the falling off of the nose and the droppings of his fingers.

3. A rich man's cousin, aged 25, of Nishioka village, a province of Yamishiro, had been a leper for five years. Half of his eyebrows had fallen; his hands and feet were crooked; spots on face, feet and hands. Loss of feeling in both legs. The author visited this case in the leper village, ten miles from Kioto. He was atrophied, and the white crescents of the nails were absent; he had the usual flashing eyes; the fingers were not crooked much. Although, by the author's rule, the case was incurable, as the patient had not subjected himself to the warm springs treatment, and as he was young and had what the proverb calls, an iron-like heart, the author examined him by camphor light, outlined his spots and applied the needles for three days. He was then purged and passed fourteen worms a foot long. On the same day the fingers became more movable. Spots now appeared on his chest and acupuncture was there applied. For fifteen days after this treatment the wounds discharged pus, then granulated by degrees and healed. The fingers became quite free; the eyebrows and moustache grew again, and he was discharged cured.

4. A soldier of Kumamoto, age 40. Eruptions on upper parts of cheeks, flat and scaly, letting escape a yellow fluid, and spreading gradually all over the face. In spring and summer the fluid flows abundantly; it dries up in winter and turns flaky. These conditions had prevailed for four years. He was a leper. He was cured in sixty days.

5. A curio-dealer, age 38; a drunkard and fish-glutton; very fat, with rosaceous nose. A year before treatment scaly spots had appeared on his face in various shapes, like ringworms. He had lost his eyebrows. Case diagnosed as *wet and heat tropho neuritis*. Under acupuncture treatment he recovered in thirty days.

6. A little boy, son of a pawnbroker, age 8, had an eruption on the back of the neck, four or five spots of the size of a peach-stone. Gradually these spread over the whole body; scaly desquamation; eyebrows and hair of head fell out about one-half; left hand crooked; appetite lost. Case diagnosed as inherited syphilis. In forty days he was cured.

7. Man aged 35; had syphilis three years before. Offensive gland sores in axillæ; eruptions on face and other parts of the body; entire skin affected; eyebrows and moustache entirely gone. Diagnosed as syphilis. After some months, the eyebrows grew, the symptoms disappeared and he was discharged.

8. A man, brothel-keeper, aged 27. When he was a boy, a severe itching was suddenly felt in the little finger of the left hand; he bit it off, and the doctor who was sent for applied a moxa to the wound and stopped the bleeding. The wound healed, but sometime afterwards an eruption appeared on the small toe of the right foot, and the outer edge of both feet

became anesthetic. Another eruption on the elbow; comes and goes. He understood now that he was a leper. After many years he became emaciated; his left fingers crook; the nail crescents had disappeared; the soles of the feet ulcerated. For eighteen years these miseries continued. The author thinking him incurable declined to treat him, but finally consented to use the acupuncture, when the patient suddenly died.

Katakara Genshiu mentions another doctor who uses acupuncture, combined with cupping and leeching, Dr. Yoshio, of Nagasaki. It is supposed by our author that this practitioner learned the latter additions from the Dutch barbarians. After puncturing with the needles he pours wine into the sores, or uses a leech to suck the blood. Genshiu mentions that cupping and leeching is also used in China.

The book closes with some curious remarks on a certain brilliant complexion which indicates the presence of yet unmanifested leper poison in the body.

LONGEVITY.

Read before the Tennessee State Medical Society, April 10, 1894.

BY D. E. NELSON, M.D.

CHATTANOOGA, TENN.

The subject of the paper I bring before you is longevity; a subject that has been a fruitful and profoundly interesting theme of discussion, not only in our profession, but among thinkers and students in every department of knowledge and in every age. Even the comparatively unlettered masses of mankind have not permitted it to pass their observation without their quota of crude, confusing and altogether irreconcilable opinions and conjectures. There seems to be a peculiar fascination attaching to it, that instinctively challenges attention and stimulates mental activity until our faculties are not satisfied without, at least, a voyage of discovery. Like everything in existence, the deeper it is immersed in mystery, the greater our curiosity to solve it, or, at least, to make the effort, and to satisfy ourselves whether or not it may be a new departure in the course of human events, or a piece of charlatany utterly unworthy the valuable time and precious thought spent upon it. If it is governed by any specific law, that law is as yet undiscovered. If it is subject to any particular regimen, that also, remains hidden.

Is it not surprising that, notwithstanding all that has been written on the subject of longevity, so little is really known of the causes and conditions of long life? Statistics show that a majority of those living to be more than one hundred years old are women. Sir G. C. Lewis, who carefully investigated this subject positively denied that any *man* ever reached a hundred years, though he was nearly convinced that there were in his day some authentic cases of *female* centenarianism. His argument for his position, was that since the Christian era, no person of royal or noble birth was ever alleged to have reached that magic limit. The lives of the centenarians swell or diminish in length as we advance or recede from prehistoric times. If it be argued that men in high official positions are exposed to greater dangers and more exhausting labors than other men; that the cares of state, the fierce contentions of politics, the brainwork incident to tangled affairs cut short their

days, it may be urged on the other hand, that the higher the station the better the medical attendance, the food, air, clothing and all other conditions on which health and longevity are supposed to depend. It must be admitted that the higher a man's rank, the greater is the chance of accuracy in respect to dates; and that if in all the cases which can be easily attested, centenarianism has been found to be a myth, then there is a strong presumption against the obscure centenarians who grow up in places where the system of registration is unknown, and where skepticism is less common than credulity and love for the marvelous. The presumption, however, is liable to be rebutted by facts; and we think they exist in sufficient abundance, not only to overthrow it, but to prove centenarianism beyond a doubt. Flourens was of the opinion that thirty years is the age of man's maturity and that it marks one-third of his life.

We are justified in saying man has a normal life of ninety to one hundred years, and that by reason of strength he may reach one hundred and ten years. The Biblical expression: "His days shall be one hundred and twenty years," has been thought to mean that this should be the extreme duration of life; others think it meant the average. Judging of the subsequent facts the latter appears to be the correct interpretation. Abraham lived one hundred and sixty-five years. Joshua one hundred and ten. An inscription on an Egyptian monument states the extreme duration of life in that country to be one hundred and ten years. This was the age of Joseph. In the time of David a man of eighty was considered very old. The great prophet king himself, reached only seventy-five years. In the ninetyeth Psalm, tenth verse, it is said: "The days of our years are three-score years and ten, and if by reason of strength they be four-score years, yet is their strength labor and sorrow, for it is soon cut off and we fly away."

Seventy in the Middle Ages, was considered a great age, which few attained, but it is a fact that in modern times the average is greatly increased. But if normal longevity is thus established what does science teach as to possible longevity? To what period may exceptional lives extend? May not individuals be endowed with matter of life so largely and have so slight expenditure, that life may be extended far beyond the limits now fixed by various writers? Is one hundred years the extreme limit of human life, and may we not, under favoring conditions, extend life to variable periods much beyond one hundred years? In the patriarchal age man led a natural life. He lived principally out of doors and took moderate exercise. The tax upon his nervous system was moderate, his food was simple and nourishing, and his digestion consequently good. Accident and old age were then the principal causes of death. At the age of seventy-five, Abraham migrated with all of his possessions. Isaac was born when his father was one hundred and his mother ninety years of age. Abraham was over one hundred and twenty years when he bore the great trial of his faith. Jacob lived one hundred and forty-seven years, notwithstanding his troubles.

To go back to the Romans, Pliny states from the record of a census taken during the reign of Vespasian that there were living in the year 76 in Italy, in a certain district, one hundred and twenty-four

persons who had attained the age of one hundred years and upward. Haller, long ago declared that over eleven hundred persons had been known to have lived to various ages, between one hundred and one hundred and sixty-nine years.

Thomas Bailey's book, "Records of Longevity," published in 1857, contains the names of about four thousand centenarians, and Dr. Van Owen has collected notices of six thousand, two hundred and two. Of the latter we have the names, country, conditions and date of ninety-nine, who reached the age of one hundred and thirty; of thirty-seven, who lived to be one hundred and forty; of eleven who reached one hundred and fifty; of seventeen who exceeded a century and a half. Lord Bacon says that the Countess of Desmond lived one hundred and forty years and cut three sets of teeth. Allen's "American Biographical Dictionary" gives the names of more than two thousand centenarians; among them are Abraham Bogart, who died in Tennessee in 1833 at the age of one hundred and eighteen, and Francis Age who died in Pennsylvania in 1767, aged one hundred and thirty-four. Judge Basil Hamilton, of Kalamazoo, Mich., who died a few years ago aged one hundred and three, was one of a family of twenty-three children, and he himself, had seventeen of his own. Dr. Archer Atkinson in the *Virginia Medical Monthly* for February, 1894, in an article on longevity, says that Lucy Kennon, of Kentucky, was still living in 1876 and aged one hundred and twenty-three years; that Rosetta Washington, of Louisville, Ky., aged one hundred and twenty-one years was still living in 1888. Stephen Goodale, of York, Maine, died ten years ago aged one hundred and eighteen. Antoine Save, a native of Normandy, lived to be one hundred and thirty years. Joseph Crele, of Wisconsin, died aged one hundred and forty years. Samuel Stocker, born near Clarksville, Tenn., February, 1783, is now living in good health at Toledo, Ohio. George Foster, colored, died in Chattanooga April 17, 1892, aged one hundred and twelve years. Catherine Patton, colored, is now living in New York city, aged one hundred and eight, and has two daughters living, aged respectively seventy-four and seventy years.

Without considering further the arguments brought forward to establish normal and possible longevity, we may state it as a truth accepted by scientific men that man can, to a great extent, control both. The above cases taken together, however incredible some of them may be, seem conclusive. Granting that many of them are open to suspicion, yet after the utmost allowance has been made for errors, misstatements, and wilful exaggerations, enough still remains to establish the truth of ultra-longevity beyond all rational doubt. It is so generally admitted that the duration of life has increased during the present century as to call for no proof. But what are the conditions of long life, so far as can be gathered from the known cases? Happy and calm will be the sleep of those, who on their pillow, can muse on the consolations of the Gospel, and resign themselves implicitly and without wavering into the keeping of a Heavenly Protector and Father. Arbuthnot said: "The instances of longevity are chiefly among the abstemious;" "More men dig their graves with their teeth than with the spade."

Are agricultural districts more favorable than manufacturing, the fresh open country than the crowded

city, mild climates than those whose skies are perpetually scowling? Statistics, well authenticated reports on sickness and mortality say rural districts have, at most, the advantage of one in two hundred deaths above city districts and one in five hundred above the town. Against the overcrowding, the bad air, excitement, and the liability to accident in the cities, are set the better water, the greater variety of food, the better knowledge of the laws of health, the more accessible and skilful medical aid, so that the advantages and disadvantages are nearly balanced. The dweller by the sea naturally selects the mountain for his diversion in the summer, and the mountaineer in turn goes to the seacoast and comes home again in the autumn as to a haven of rest; or if he must labor it is with something like glee that he rejoins his work. After all, we are constrained to say: "There is no place like home." Hot climates have no superiority over cold; China is no more unhealthy than Norway, Iceland or Greenland. Is exercise a vital condition of longevity? Some have said not, in view of the fact that a vicar, cited by the *London Quarterly Review*, Rev. Wm. Davies, reached one hundred and five, though his only exercise for the last thirty-five years was to slip one foot before the other from room to room. Men have lived a hundred years and upward, who only taxed their physical powers to walk one hundred yards a day from house to office and back. Some of the strongest constitutions have been possessed by old soakers. Daniel Bull McCarthy, of Ireland, who drank freely of undiluted rum and brandy during the last seventy years of his life, died in 1752, aged one hundred and eleven. George Kirton, of Yorkshire, a hard drinker, lived to be one hundred and twenty years old. But these are only exceptional cases.

Is a proper diet a *sine qua non* of longevity? All writers on health denounce newly made bread and especially hot bread, and not a few denounce tea and coffee, but, can not each of us call to mind the names of very old people who have been for the greater portions of their lives free users of the same? Shall we declare in favor of frequent bathing or personal cleanliness? Animals get rid of the outer layer of skin in some way. In some species, certain reptiles for example, the outer skin is shed entire at certain seasons. Birds cast their feathers and fish their scales; and at each casting off of his kind, the vital processes are afterwards carried on with more energy, because the drains and sluice-ways of the surface are not blocked up at their mouths by broken down epidermis; so in man, the skin is removed; only the process in a state of health is gradual and less startling in its visible signs. What shall we say of "Lady" Lewson, a London widow, who never washed her rooms, nor bathed, and declared that people who bathed were constantly taking cold; but she habitually smeared her face and neck with hog's lard. It is said of the Icelanders, that though they are very uncleanly and suffer much from skin diseases, especially leprosy, their longevity is greater than that of the nations of Europe.

The one great question of sanitary science is to secure to each individual, death from old age. On every hand we witness the prodigal waste of human life. Of the children born, what a vast percentage never see the anniversary of their birth! What a large percentage die under five years of age! And how few, comparatively, reach the age of ten! At

twenty the generation has dwindled to an insignificant minority, and at thirty-three to forty-five disappears altogether. The science of life reveals to us the stupendous fact that man is born to health and longevity and that disease is abnormal and death, except from old age, is accidental, and that both are largely controllable by human agencies. We find that physiology teaches that in every tissue and in the corporate whole, there is inherent death.

It is evident, therefore, that the question of longevity is to be determined by estimating, correctly, vital endowment and vital expenditure. In man, the tendency to individuation is strongest and the degree of evolution is the highest. Man being omnivorous, can secure his food from many sources. He can sustain vigorous health on the products of the soil, or the river, or the forest. Nor need he expend his strength unavailingly in search of food, for by his ingenuity he can devise means of securing it with but slight effort. By suitable protection, man may and does husband his native resources and reduce to a minimum the expenditure of his vital forces. Consider also, by what skilful appliances he continues to repair the wastes and inroads of decay or accident upon his bodily organs and functions. It is a fact that the average length of human life has gradually increased in many civilized communities.

In 1665, in London, one twenty-third of the people of that city died, but now the rate of mortality has been reduced to one forty-fifth annually. Is this not proof of man's advance in civilization, which enables him to live with less expenditure of vital force, which leads him to see his own highest welfare in the common effort to promote the advance of sanitary science?

Mr. Mathews says that health is not a condition of long life, and that long life is no more dependent upon health than upon great muscularity. He cites as proof that the Tom Hyers and Heenans, great prize fighters, and heavy weight lifters, who could fell an ox with their fists, were always ailing and rarely lived to be more than fifty or sixty years old; and that Dr. Winship, of Boston, who could lift three thousand pounds, died aged forty-two. The celebrated Galen had a weak and delicate constitution, yet by strict temperance and evenness of temper, lived one hundred and forty years. It is said that his rule in eating was to rise from the table before his appetite was satisfied. Dr. Southy, in the *London Lancet*, ten years ago, said that the three oldest people he ever knew were women, who reached respectively, eighty-nine, ninety-eight, and one hundred years, and were nearly all their lives of infirm health. And thus I might go on and cite numerous other such cases, but this is enough to bring within the scope of this paper.

In spite of all these facts, it is hard to believe that virtuous habits, abstemiousness, exercise and cleanliness do not conduce to longevity. But the one thing that outweighs all other favorable circumstances is what is called, "a certain bodily and mental predisposition to longevity." Sir Thomas Brown wrote: "There are persons who are prefigured unto a long duration." Some persons are born with a genius for long life, but it is a gift which can be cultivated and like any other it may be destroyed. Those who have this inherited gift will commonly reach old age, though they trample on the laws of health; while those who have it not will die comparatively young

in spite of the strictest precaution against disease. How is it that in a race of beings having such a power over its destiny and striving by every means to obtain long life, but three in every thousand dying, reach their pre-ordained longevity? Within one's own observation he sees a vast array of causes abridging life. In his own makeup he sees sickness on a perpetual warfare with his vital forces.

According to the last United States census, nervous and digestive troubles cause nearly one-third of the deaths. Every point of man's system is subject to attack from disease. The earth and air teem with the germs of disease; we eat them and we breathe them. It is believed by both civilized and savage nations that disease is the expression of the Almighty's disapprobation of man's immoral conduct, and granting this to be true, may we not add that it is the penalty inflicted for the disregard of that Biblical precept: "Cleanliness is akin to godliness?" The most destructive diseases are of man's own creation. The principal condition which shortens life is, first, and above all others, the expenditure of vital force, and it is scarcely necessary for me to mention the various ways by which the vital force may be expended. At maturity the passions ripen into full activity and have their full play, and if not held under control they rapidly exhaust the vital strength. Man may yield to all his passions and appetites and perish at maturity or be decrepit at thirty. He may so order his life as to fully and healthfully develop his passions and appetites so that they shall culminate in a prolonged and vigorous old age, and thus leave death as a subject of accident. It is an axiom of enlightened statesmanship, that the great want of any country is, and ever will be, a healthy, robust and long-lived yeomanry. Public health means public wealth, honesty and morality. Our Government can in no way better promote the interests of the people than by diffusing knowledge on these points.

One of the most sensible sayings on the art of longevity that has fallen under my notice, so far as longevity can be considered attainable, was that given by an Italian in his one hundred and sixteenth year. Being asked the secret of his living so long, he replied:

"When hungry, of the best I eat,
And dry I keep my feet;
I screen my head from sun and rain,
And let few cares perplex my brain."

In these lines, especially the last, we have the quintessence of all the advice that has been or can be given on the subject. The deadliest foe to longevity is excitement. "To live long," said Cicero, "is to live slowly."

The careful stock-raiser shows his faith in heredity by strict examination of the pedigree; and why so well demonstrated a great physiologic truth escapes notice when a human being is concerned instead of a horse, is in the nature of a conundrum to all thoughtful minds. He who lives extensively, who avoids all stimulants, takes light and agreeable exercise, indulges no exhausting passions, feeds his mind and heart with no exciting material, has no debilitating pleasures, "keeps his accounts with God and man daily squared up," is sure if he has a good organism, to spin out his life, barring accidents, to the longest possible limit.

The poet, William Cullen Bryant, when asked the secret of his health and vigor at upwards of eighty,

answered: "It is all summed up in one word, *moderation*." The ancients laid much stress on gastronomy, as many idioms in all languages attest. "Heaven sends the food, but the devil sends the cook," is an old saw that is more forcible than elegant. How many a young man squanders on a holiday or an evening's entertainment an amount of nervous energy which he will bitterly feel the want of when he is fifty. It is true that overwork of the eye at fourteen may necessitate spectacles at forty instead of at sixty. Even warm affections are prejudicial; they subject the owner to constant anxiety, and are as unnerving as the excitement produced by politics or gambling. Nothing is more exhausting than anxiety for a sick wife or child, or nursing a friend through a long sickness, unless you can truthfully say that you take no interest in the result. When a "fine old man" was mentioned in Swift's presence, he exclaimed angrily: "There's no such thing; if his head or heart had been all right they would have worn him out long ago." Wadsworth at eighty, complained:

"Oh, but the good die first
And we whose hearts are dry as dust,
Burn to the socket."

Our fine enthusiasms, if they rise into intensity, are costly and lessen the number of moments we have to live. Some years ago a gentleman in England set about ascertaining the causes of the premature deaths of his acquaintances who had been cut off within twelve years. Of forty individuals, he found that twenty had died from excessive mental labor or excitement, and twelve of these were not intellectual laborers, but men of the world. Sydenham tells us that one of the severest fits of gout he ever suffered from, arose from great mental labor, undergone in composing his treatise on that disease.

Providence has appointed the succession of labor and rest by the alternation of day and night, yet how many violate this beneficent law by turning night into day and day into night. They sleep while the sun is shedding his life-giving beams and work amid the deadly influences of the night. Many do not toil at their callings in the night-time, yet imagine that they do a full day's work and afterwards, with impunity, spend half of the night in charitable labor, or in the pursuit of pleasure or knowledge. But nature can not be so cheated. Occasionally she lets an offender escape for forty or fifty years, but she is evermore "shadowing" him and hauling him up at last, inflicts her penalty just when and where he least expects it. It should be remembered that one can walk farther than he can run.

While all excess is injurious, it must not be inferred that hard brain-work apart from other causes tends to shorten life. Mental labor, apart from grief and fears, from forced or voluntary stinting of the body's needed supply of exercise, food or sleep and the mind's supply of social intercourse, rather prolongs life than cuts it short. Even overwork of the brain is probably far less injurious than underwork. Nine-tenths of the students and professional men who are supposed to break down from intense toil, wear themselves out, not by repletion of study, but by a vicious misapplication of their moral, physical or intellectual forces.

Lord Brougham lived eighty-nine years. Lord Lyndhurst wore out at ninety-one. Epimenides, the seventh of the wise men, is said to have lived to one

hundred and eighty-four. Hippocrates reached ninety-nine, Pythagoras reached eighty, and was murdered. Dr. Franklin was eighty-four. Montgomery, the poet, lived to be eighty-two. Sydney Smith lived to seventy-six and Sir Isaac Newton to eighty-five. The Right Hon. William E. Gladstone, who retired from the Premiership of England only a short time ago, was last December, eighty-four years old. Dr. Beard, of New York, in an able paper on the "Longevity of Brainworkers," has proven beyond even the shadow of a doubt that the world's hardest workers, so far from being short-lived, show a very high average of life; a far higher average than the world's drones, and those who had added nothing to its accumulated capital of happiness, knowledge, goodness and truth. It is an established fact that not a few of the long-livers might materially lengthen their days by taking more exercise and sleep, and by economizing more carefully the expenditure of intellectual and moral energy.

It is known by every scholar that mental application is one of the most effective means of relieving bodily pain, and that it is especially fitted to soothe the ruffled spirit and to mitigate the asperity of corroding anxiety and care. Bacon, in his "History of Life and Death," is emphatic in declaring the religious and literary to be among the forms of life most conducive to longevity. "There are," says he, "in religious life, leisure, admiration and contemplation of heavenly things, joys not sensual, noble hopes, wholesome fears, sweet sorrows, continual renovations by observances, penances and expiations, all of which are very powerful to the prolongation of life." There is a popular notion, which has long been deeply rooted, that precocity of intellect is unfavorable to longevity. It has been shown conclusively, that as a rule, a brain of exceptional force is united to a constitution of exceptionally good fiber, and that precocity, so far from being premonitory of early decay and death, is almost a mark of vast undeveloped abilities, and of a prolonged existence crowded with triumphant usefulness.

Three of the most precocious geniuses of their day were Bishop Thirlwall, Lord Macaulay and DeQuincy, yet they lived to the ages respectively of seventy-eight, fifty-nine and seventy-four. Of all the qualities of mind that conduce to longevity, none are more vitally essential than contentment, cheerfulness and hope. Worry kills more men than the most exacting work, whether physical or mental. Legitimate work develops force, while worry checks its development and wastes what already exists. The physician should be engaged to protect the household and individuals from the assaults of disease, to detect and meet the first and very slightest indications of disorder; and thus, we shall certainly see life prolonged.

There is no doubt that long life, if it be virtuously and happily spent, is a blessing most earnestly to be coveted. The mere lapse of years, however, is not life; "knowledge, truth, love, beauty, goodness and faith give vitality to the mechanism of existence." The value of time is purely relative; and if we count it by heart-beats, not by tickings of the clock, or the shadow of the dial; if, "he lives longest," as Baily says, "who knows the most, thinks the wisest, acts the best;" then many who were rich in years have really died young, while others whose lives measured by the calendar, were cut short early, have been rich in life.

Shakespeare, who died at fifty-two, lived ten times as long as poor old Parr who could boast of his one hundred and fifty-two years. Mere old age following an oyster-like existence, during which one has droned away his life in his shell, never buffeting the waves for himself or others is a questionable blessing; but the serene old age which is secured by temperance, sobriety and the conquest of vicious appetites and passions, the long mellow autumn of life, in which are harvested the fruits of years of useful toil, is to be coveted and striven for by all.

"Men deal with life, as children with their play,
Who first misuse, then cast their toys away."

OPHTHALMIA NEONATORUM.

Read before the Cambridge Medical Improvement Society.

BY AUGUSTUS P. CLARKE, A.M., M.D.

CAMBRIDGE, MASS.

Among the duties and responsibilities which the obstetrician has in large measure to assume, is the treatment of cases of ophthalmia occurring in the newborn. The disease is by no means infrequent; its course and termination have so often resulted unfavorably that public attention has been directed to the consideration of the subject. Perhaps it would not be unsafe to say that upward of 40 per cent. of all cases of total blindness has had its origin in this condition. The affection seems to be caused by acrid or septic discharges from the mother's tissues, coming in contact with the eye of the fetus during its descent or expulsion from the vulvo-vaginal outlet. The stimulus of light to the infant's eyes may be an exciting cause in those cases in which a purulent or gonorrhoeal infection is present. Sometimes other agencies may lend their influence in exciting inflammation; want of cleanliness, a strumous constitution, exposure to cold, and an insufficient nourishment are factors that may hasten the attack and lead to the dire result. Sometimes only one eye is affected, but in the severer cases the inflammation attacks both eyes. This may be either by the direct contact with the invading bacteria, or by the presence of germs with the lymph current in its course from the vitreous chamber through the sheaths of the vessels of the retina and through the sphenoidal fissure to the cranial cavity. From this point the bacteria may be hastened along between the optic nerve sheaths or coverings to the perichoroidal space of the other eye, and then passing with the current from the interior of the cranium into the subvaginal space of the optic nerve. That such a posterior lymph stream is developed in man as in the lower animals has been deemed by writers as highly probable.¹

In my own practice I have met with a considerable number of cases of purulent ophthalmia, and in almost every instance I have been able to get either a history of a gonorrhoeal attack occurring in the mother, or I have been able to obtain evidence to warrant a suspicion of the existence of that condition. Among the more prominent symptoms occurring in the early stages have been a peculiar florid condition of the palpebræ; these have often been agglutinated. The secretion from the inflamed conjunctiva becomes profuse, thick and purulent, some of which is discharged, but more is retained, induc-

¹ Further contribution to the subject of sympathetic ophthalmia by Howard Gifford, M.D., Vol. III, Ninth International Medical Congress, 1887.

ing distension and edema of the palpebral tissues beneath. In the milder forms, the inflammation is for the most part confined to the conjunctiva of the lids; in the severe forms, however, the inflammation extends beyond the fornix to the conjunctiva bulbi and to that of the caruncula lacrymalis. When the inflammation extends to the ocular portion, infiltration and ulceration of the cornea are liable to take place. In some instances the child appears to suffer but little, while in other instances the local and constitutional symptoms give rise to much fretfulness and really physical disturbance. This is especially so when any attempt is made to separate the eyelids and to remove the purulent exudation which is constantly taking place and which is liable to exercise undue pressure upon the orbicularis muscle, and to cause a permanent eversion and even an ectropium of the upper lids; this feature of the lids was termed by the ancients, lagophthalmia. The exudation often assumes different shades of a greenish or yellowish hue; sometimes the discharge is sanguineous or ichorous, resembling somewhat the gleety exudation of chronic gonorrhoea of the urethra.

One of the most marked or characteristic symptoms of gonorrhoeal cases is the chemosis or the edema of the ocular portion of the conjunctiva. The most careful examination, aided by the use of the wire speculum, does not always reveal the existence of ulceration going on in the marginal or in the central portion of the cornea. A hazy condition of the cornea may continue for some days without exciting the occurrence of ulcerative processes. One of the dangers to be apprehended is the taking place of interstitial deposits and a complete opacity of a portion or of the whole of the cornea. This in the later stages will be characterized by the development over more or less of its entire aspect, of a bluish gray film, the result of a proliferation or of an infiltration of tissues.

Authors speak of minute ulcers forming on the cornea after a hazy condition has taken place, as indicative of gonorrhoeal infection. Such a condition in young girls I have repeatedly observed without the least history, or even suspicion, of the presence of such a factor. These cases have occurred as the result of catarrhal inflammation or epidemic influences, and have yielded under appropriate treatment without leaving any untoward results; in some cases, if not in the most, when ulceration occurs the marginal portion of the cornea is first attacked; the morbid process extends in a crescentic form toward the central portion. This condition interrupts the nutritive processes of the corneal tissue and causes the loss of its vitality.

Ulceration may be so extensive as to lead to the escape of a portion or of the whole of the aqueous and sometimes of the vitreous humor, and to the collapse of the bulb. In cases in which opacity or ulceration of the eye is only of a limited extent, adhesions may take place between the cornea and the iris; minute points of opacity may form in the capsule of the lens. These conditions may lead to loss or impairment of vision. The corneal tissue may be so affected by ulceration or sloughing that the crystalline lens will escape through the opening or, instead, will become infiltrated with deposits of earthy phosphates which, by impinging on the ciliary processes and the iris, may give rise to severe neuralgia. Occasionally the disease may cause permanent en-

largement of the globe. There may be a staphylococcal projection of the cornea or of the sclerotic. The cornea may have been destroyed, leaving only the iris covered by a fibrous or a cicatricial tissue. These unsightly projections, or adventitious masses often become the source of much inconvenience. The child suffers so much from the irritation thus induced that he can not be easily restrained from a constant rubbing of his hands and fists against the protruding or hyperboloid tumor. Sclerotic staphylomata are the result of a gradual increasing distension of the attenuated fibers of the tissues involved; this usually takes place by the excessive accumulation of the aqueous medium. It may result from an iridochoroiditis. Such a condition may lead to an undue development of the vascular tissues which, though exceedingly minute, abound in the normal condition of these structures of the eye. In sclerotic staphyloma the enlarged eyeball has a bluish or a dark leaden color.

The indications for the treatment of ophthalmia are to remove as much as convenient, at short but regular intervals, of the purulent exudation. This may be done by syringing. Prolonged irrigation with antiseptic washes may be resorted to with much advantage. Mr. Edgar Browne² uses a half per cent solution of trichlorophenolate of magnesium. This is applied through perforations of fine silver tubing which can be made to penetrate the conjunctival sac. Mr. Jones,³ of the Liverpool Eye Infirmary, used Panas' solution of biniodid of mercury. This was applied either through Mr. Browne's irrigating lid retractor or through other devices which could be made to pass well into the sac of the conjunctiva. This means of treatment, though affording much relief in cases of ophthalmia and dacryocystitis resulting from the presence of pyogenic cocci, was found to be too severe as a routine treatment for cases of ophthalmia neonatorum. In conducting the treatment for a case of such ophthalmia whether catarrhal, blenorrhoeal, gonorrhoeal, phlegmonous or purulent, the important measures to be taken are to remove or to wash away the exudation and to change the tissues and products of secretion from a septic to an aseptic condition, without adding to the morbid process or doing violence to the epithelium and to the structures beneath. In my earlier practice I used, as local applications, acetate of zinc in the proportion of one scruple to four ounces of water; I also used acetate of lead and alum. A solution of nitrate of silver was formerly a favorite remedy in my practice. A solution from four to seven grains to the ounce was used, whether the exudation was purulent or gonorrhoeal. I have used as high as fifteen grains to the ounce in cases in which the distension of the tissues was marked. McKenzie's solution of bichlorid of mercury has occasionally yielded excellent results. The formula of this collyrium was as follows:

Hydrargyri bichloridi	1 gr.
Ammonia hydrochlorid	6 grs.
Water	16 ozs.

The employment of nitrate of silver in solution as a local application was for a long time much resorted to, especially as a preventive of ophthalmia in the newborn. That renowned obstetrician at Leipzig, Prof. Credé, was always accustomed to advise the

² Braithwaite, Vol. c., pp. 204-5.

³ Op. cit.

use of a 2 per cent. solution; a few drops of the lotion were applied to the eyes as soon as the funis was cut, and the eyes were cleansed from the smegma and the maternal secretion. I can testify from my own personal experience while I was in this great master's clinique during my later student days, with what enthusiasm and minuteness of detail every such procedure of his work was carried out. At the Dresden Clinique⁴ for women, thorough irrigation with a solution of perchlorid of mercury was frequently repeated during parturition. As soon as the infant was born, the eyes and parts adjoining were washed with cotton or lint moistened in tepid water. The solution of nitrate of silver was then applied. A similar method of treatment was adopted at the Jessop Hospital for Women, in Sheffield. As a means of prevention of ophthalmia in the newborn this method of treatment for patients in the larger hospitals may prove to be highly efficacious; in private practice, however, such a course as a routine practice may seem unnecessary, except in the cases occurring among the poorest, or among those in whom there may be evidence, or a history, or a suspicion, at least, that the mother's tissues are in an unhealthy condition.

Cases now and then occur, in which the most approved practice fails to afford favorable results. In some cases I have achieved successful results by the employment of the mild chlorid of mercury. This I use freely between the lids after the eyes have been cleansed. Sometimes I have used iodoform instead of the mild chlorid, but this in two instances signally failed me. I have used Panas' solution of biniodid of mercury, and have been highly pleased with the results obtained. When I have found that its free application caused too much smarting or irritation, I have reduced the strength. The best method for employing it is by irrigation. In a case in which ulceration of the cornea had occurred, the patient recovered without impairment of sight. The following is the formula for the solution which I have employed:

Hydrargyri biniodidi	1 part.
Absolute alcohol	400 parts.
Distilled water reesterilized	20,000 "

This solution, as will appear, is only a mild collyrium; the liberal use of it will prove, nevertheless, that it is an antiseptic and that it has a due degree of potency for overcoming pyogenic cocci. In those exceptional cases in which ulceration or sloughing of the cornea has taken place with consequent impairment or loss of vision, surgical measures for relief of the irritation or for lessening the deformity will have to be instituted. Certain morbid conditions of the eye may require the removal of the ball, especially for the arrest of disease on account of the occurrence of sympathetic irritation or of other severe disturbing processes. Sclerotic staphyloma, which may be the result of a gradually increasing distension of the fibrous structures through an excessive formation of the aqueous fluid, is not infrequently met with. For the relief of this condition some authors advise total extirpation of the globe. In some few cases I have had recourse to this procedure. In performing such an operation the cataract knife should be passed through the staphyloma in such a manner as to form a flap; this should be seized with a forceps and then be removed by another incision.

Should the incision be carried back to the margin of the ciliary region the humors may be expected to escape, and the remaining portion of the bulb will collapse and undergo nodular degeneration.

On Oct. 2, 1893, I was called to see a child aged 10 months who had a large staphyloma of the left eye, caused by a severe attack of gonorrhœal ophthalmia. Owing to the loss of sight, the disfigurement and the consequent irritation I at first determined to effect partial if not total extirpation of the ball. The knife, however, was only carried through the corneal projection, and the operation was completed by the second incision; a large amount of aqueous fluid escaped and the eye appeared to be totally collapsed. The application of dressings with iodoform was made to the wound; the operation had the effect of relieving all the local symptoms. On removing the dressing after the fourth day I was pleased to find that the normal humors, which had so long been subjected to the inordinate pressure from the staphylomatous accumulation, were re-forming, and that indications were favorable for complete restoration of the bulbous development. In the operation for this case I was careful that the incision should not be carried through the entire depths of the corneal structure, but only through the anterior basal membrane or lamellæ, the posterior laminae having, as I then believed, been crowded unduly backward by the excessive accumulation of fluid in the interlamellæ spaces.

On January 19, I operated on the right eye for a slowly developing staphyloma which was causing much local irritation. The incision was made as in the other operation, but the fluid in the areolæ between the basal tissues was not as profuse as in the other eye at the time of the first operation. I, therefore, did not have as favorable opportunity as before of witnessing an apparent restoration of the normal media. The operation, however, proved successful in overcoming the irritation and in lessening the deformity for which the operation was mainly undertaken.

TENORRHAPHY BY MEANS OF THE SUTURE À DISTANCE OF CATGUT, WITH REPORT OF CASE.

Read before the Chicago Pathological Society, April 9, 1894.

BY EMANUEL J. SENN, M.D.

CHICAGO.

INSTRUCTOR IN SURGICAL PATHOLOGY, RUSH MEDICAL COLLEGE; HOUSE-SURGEON, ST. JOSEPH'S HOSPITAL; MEMBER OF THE CHICAGO MEDICAL SOCIETY.

Injuries to tendons and their sheaths is of frequent occurrence, and a perfect knowledge of anatomy and method of repair of these structures for the requisite surgical treatment is of great importance to the practical surgeon. In studying our text-books of surgery, one is struck by the liberal space allotted to fractures; while the subjects of laceration of tendons and treatment are superficially dealt with in a few lines. Although injuries to tendons occur both in hospital and private practice far less often than fractures, this subject should receive comparatively more consideration from authors, both from a pathological and surgical standpoint. It is not in recent cases where tendons are simply divided that surgeons meet with difficulties; but it is in old cases as in ancient fractures, where pathologic conditions have manifested themselves and produce the many

⁴ London Lancet, 1891.

complications which call for difficult surgical intervention. Therefore, before considering the treatment by means of the *suture à distance*, I will comment lightly on the pathology and regeneration of divided tendons. Tendons are composed histologically of connective tissue. The cells are not round, but elongated into fibrils which are firmly bound together and give the appearance of white fibrous cords. They do not possess the quality of elasticity, and the vascular supply is very limited.

Tendons in performing their physiologic function, glide backward and forward; and like other parts of the body which are subject to motion are provided with a means intended to place friction at a mini-

mum, that is, protection and lubrication. The tendon sheath answers these two purposes well. In complete rupture of tendons there is a loss of function and a consequent atrophy; followed later by a degeneration of the extremities to a limited extent. It is a law of nature that where a tissue irrespective of histologic structure or vascular supply, and which has performed a customary amount of work is suddenly put to rest, either through trauma or otherwise, there is always more or less involution of its cells.

However, ruptured tendons differ from nerves in that the two ends only degenerate for about half an inch; while the medulla of the distal portion of a nerve degenerates into a granular mass, devoid of cellular organization. The sheath of Schwann

which is composed of connective tissue, alone remaining intact. This difference is most probably due to the different functions performed by the two structures and also to their difference in histology. The one composed of connective tissue whose function is entirely mechanical, namely, that of moving the bone to which it is attached, through the contraction of its muscle; while nerve cells are of a far more highly organized structure, and have vital properties for the transmission of peripheral and central stimuli. The cells of an injured tendon are surrounded by cells of their own kind, as connective tissue is omnipresent in the body and they accommodate themselves according to circumstances by union with surrounding structures; so that no matter how far the tendon ends may have retracted, there will likely be some function performed through contraction of neighboring muscles. On the other hand, the distal end of a nerve, provided collateral-anastomosis is not established, degenerates in the course of several weeks. This deterioration of nerve cells does not take place by reason of a deficient vascular supply, but as a result of loss of function. Cell life, either animal or vegetable, is only maintained when metabolism is in progress; and metabolism is only performed as long as the cell acts the rôle destined for it by nature. Although tendon tissue is scantily supplied with blood vessels, it differs from cartilage in being endowed with great intrinsic vegetative capacity. This is well demonstrated in tenotomy of the tendo-Achilles for talipes equinus, where the tendon ends are oftentimes widely separated, and no attempt is made by the surgeon to facilitate regeneration by art; but within a short period this great gap is filled in with new tissue from the tendon ends and sheath. Regeneration of tendons, although not given as much individual attention as was given to other structures, nevertheless was made the subject of some experimental investigation. It takes place by the production of embryonal cells from the mature cells of both extremities, and also probably to a lesser degree from the tendon sheath. In injury of tendons there is generally hemorrhage from neighboring blood vessels simultaneously cut or lacerated. This depends upon the anatomic location of the trauma.

M. Saint Germain speaks of a hemorrhage continuing eleven days after subcutaneous division of the tendo-Achilles.

Blood filling up the intervening space between tendon ends, naturally suggested the "organization" theory of Hunter, who maintained that the coagulum became vascular and in time was directly transformed into new tissue. This theory was supported by d'Ammon in 1837, Thierfelder in 1852, and Jobert in 1864; although not without some modifications. While they thought it very probable that blood was gradually merged into tissue, they were positive that it was the active factor in cicatrization. Later Pirogoff, Dembrosky and Volkmann gave insufficient blood extravasation as a cause for incomplete regeneration. Pirogoff asserted that blood between the tendon ends acted like a sequestrum in bone necrosis by stimulating tissue proliferation. Very recently Walter also encouraged this idea by recommending in tenotomy, non-ligature of vessels, in order to produce a clot as devised by Schede in the treatment of bone cavities. The inter-tendinous bloody effusion disappears by absorption about the fifth or sixth

day according to observations of Lebert. Bouvier in 1837 insisted that regeneration was affected by the cellular sheath, which through a process of corrugation and thickening, developed into a tendinous cord.

The blastema theory for a time found many adherents, championed by Henle in Germany, Robin in France and Brodhurst, Adams and Paget in England. This hypothesis was founded on the supposition that protoplasm was spontaneously developed into cells. This reasoning rested on a weak foundation when it came to practical demonstration and was soon exploded. Bizzozero in 1868 already looked upon the principle of this theory in the light of a second rôle. Cohnheim made a step in advance toward the true law of regeneration when he affirmed that leucocytes which had emigrated from the blood vessels surrounding the interval between the two tendon extremities were changed into granulation tissue through their own innate powers. The cellular theory is the last promulgated and has been faithfully defended by Türcher, Donders, Virchow, Remak, Kölliker, Cornil and Ranvier. Regeneration of connective tissue is analogous to regeneration of any other tissue, in that it can only generate from mature cells of its own kind. The blood clot acts in a passive manner by forming a temporary matrix for the immature cells and also in the capacity of an irritant; thus provoking a hyperemia which is favorable to the production of new tissue. The iodoform gauze tampon accomplishes the same effect; only one is artificially produced, while the other is nature's effort to accomplish the same purpose.

After injury there is always more or less para-vascular extravasation of blood; which is not essential for regeneration, but is a great auxiliary. Karyokinetic figures are seen in the cells of the tendon extremities and also in the tendon sheath within forty-eight hours after the trauma, followed by the production of bud-like processes which extend into the blood clot. These are embryonal cells and being of connective tissue origin, are called fibro-blasts. They are round or angular in shape, multi-nucleated and are composed of the elementary matter of all animal and vegetable life, protoplasm. All proliferation is followed by vascularization, that is extension of blood vessels from the neighboring mature tissue into the mass of granulation tissue. Cicatrization next becomes manifest. The embryonal cells after having supported themselves through metabolism for a certain length of time, by their own natural inherent quality evolve into mature cells or fixed permanent tissue. The large round or angular cells gradually merge into fibrils. In this metamorphosis each cell draws its neighbor into closer relation; thereby producing cicatricial or scar contraction. In this instance nature again centers her efforts to a good purpose; for by the mechanism of contraction the two tendon extremities are brought nearer toward each other.

The *suture à distance* as a means of establishing communication between ruptured tendons was inaugurated by Gluck in 1884. He operated successfully upon a case where the extensor tendon of the index finger was separated eight centimeters. This mode of suture was studied experimentally by Forgin, Assaki, Jeannel and Van Haecke. Where the divided ends are not too far apart, a plastic operation should always be resorted to; that is the procedure devised by Czerny, of splitting the tendon upon one

side for some distance, and turning the divided flap over to its fellow of the opposite side and suture. If the flap does not reach, the other tendon should be treated in the same manner and both flaps united end to end. In cases where approximation can not be secured, the *suture à distance* is the most useful, in fact it is the only operation which can be resorted to under the circumstances. An absorbable suturing material, such as sterilized catgut or kangaroo tendon should be used. The tendon ends are united *à distance* by several sutures in order to make a firm bridge-work. Catgut becomes entirely absorbed by phagocytosis in a short time. The operation meets several important indications, namely: 1, It prevents the tendon ends from retracting through elasticity of the muscle; 2, it forms a passage way for tissue proliferation; 3, it establishes a barrier, by which the embryonal cells secure protection from atrophy, caused by pressure of surrounding parts; 4, the suture being a foreign body, acts as a stimulant to the mature cells.

The following case is of interest, as there was extensive loss of substance of the extensor tendons of the hand, and this was entirely remedied by the absorbable *suture à distance*.

Mr. G. H., young man, English, miner by occupation; residence Northern Michigan. Entered St. Joseph's Hospital Jan. 6, 1894. Three months previously while at work in a mine, he accidentally thrust his wrist against a jagged, sharp rock, making a complete transverse incision of the extensor communis digitorum tendon at its junction with the muscle just below the middle of the fore-arm. The extensor indicis tendon was also severed. After the accident the integument was stitched and the wound bandaged. According to the patient's statement no attention was given to the deeper structures. The dressings were removed several days later and the wound found healed; but the three fingers supplied by the extensor communis digitorum were absolutely useless as far as extension was concerned. The patient waited three months in the hope of again recovering the use of his disabled hand, but to no avail.

Operation: Incision of three inches in the area of the old scar, parallel with the tendons. After carefully dissecting away the scar tissue, the proximal end was found. It did not consist of connective tissue, but was true muscular structure. Then came a tedious search for the four distal extremities, the three tendons of the extensor communis digitorum and the extensor indicis. After searching for some time without success, I carried the incision further in the distal direction and found the tendon ends about two inches above the metacarpo-phalangeal line. The perplexing problem of securing union between the distal ends and the proximal end now presented itself, as the intervening space was four inches in length. Splicing after the method of Czerny could not possibly be practiced here, and under the circumstances, I resorted to multiple *sutures à distance*, as the means of indirect approximation. Medium sized catgut, sterilized according to Bergmann's method was used. I made eight sutures, connecting the extensor communis digitorum and the extensor indicis tendons to the extensor communis digitorum muscle. The external wound was closed with an interrupted row of silkworm sutures and a continued row of catgut. No provision was made

for drainage, as hemostasis had been well effected by ligature and hot water irrigation. The hand was dressed in an extended position upon an anterior splint. The dressing was removed upon the fourth day and the wound presented a favorable appearance, except for a small suppurating focus around one stitch. This suture was removed and after thorough disinfection with a solution of bromin and insertion of a small iodoform gauze tampon, the dressing was re-applied. The wound was irrigated the subsequent three days and I succeeded in aborting a diffuse suppuration, the wound healing intact. The sutures were removed upon the ninth day. On the twelfth day the patient could extend the three fingers upon the splint with slight effort. He speedily recovered the use of his fingers and at the end of a month was discharged from the hospital with function entirely restored. Patient could lift a glass of water to his mouth and even write with perfect ease.

Remarks:—Although I did not have the opportunity of making an examination *in vivo* of the regenerative process which took place, I am satisfied that there was new tendon tissue produced to the extent of over four inches. When the patient made extension, by placing a finger at the muscle extremity, the impulse was perceptible along the whole route of the tendons, showing that there was direct communication. The new fibrous cords when in action would bulge and become prominent to such an extent as to become visible through the skin. These tests were convincing proofs. This case is also of pathologic interest by reason of the sutures uniting muscle with tendon. Muscle cells are endowed with very limited intrinsic vegetative capacity, and do not extend further than an inch from the ruptured end; so that in this case proliferation from the distal extremity was the prime factor in effecting reposition, as connective tissue is the most prolific of all tissues. I wish also to dwell on the importance of making as many sutures as possible in order to construct a canal, thereby securing a line of least resistance for the embryonal cells. If I had secured each tendon with but one suture, I am certain that there would have been very probably an obliteration of the canal by neighboring tissues, and consequent failure of the operation. An interval of four inches is an unusual occurrence. It is seldom that tendons become separated for more than one or two inches at the most; and when united by this method, the operation will yield encouraging results.

RAPID METHOD OF DEMONSTRATING TUBERCLE BACILLI IN SPUTA.

BY JOHN D. KALES, M.D.

DEMONSTRATOR OF BACTERIOLOGY IN THE MEDICAL DEPARTMENT OF
NORTHWESTERN UNIVERSITY.

Those who have been engaged in the demonstration of bacteria, and the use of the various methods of staining them, have doubtless been prompted to simplify the technique as much as possible. They can thereby attain a much greater percentage of successful preparations when the work is being done by a large class in the laboratory.

A method that is carried out with ease and success by many students working together in a laboratory, must of necessity possess certain advantages that would favor its adoption by every practitioner who realizes the diagnostic value of detecting tubercle bacilli, and has the necessary optical apparatus.

The writer has for several years stained sputa for tubercle bacilli by a rapid method, one quite generally adopted at present. It consisted in using the cover-glass as if it were a dish, and while holding it with a pair of forceps, the various staining fluids were boiled upon its surface, the cover-glass being held in the smokeless flame of an alcohol lamp or Bunson burner. The usual carbol-fuchsin solution was used, and decolorization accomplished by any of the well-known means, *i. e.*, Orth's solution¹ or nitric acid and water 1-4. If Orth's solution is used, decolorization is slower and seems to yield preparations which have little tendency to fade.

Recently the following method has been found still more convenient. However, in all methods where the flame is applied directly to a cover-glass for the purpose of heating or boiling a staining fluid, there is great need of using only the best quality of glass. This should be very thin, white and well annealed. The whiteness may be determined by looking at the edges of a package of glasses; these should show no greenish tinge. Their brittleness may be estimated by bending one between the fingers; it should stand considerable flexion before breaking. In buying cover-glasses it is necessary to observe these conditions, for a large number that are sold are not fit to use in rapid staining methods where the flame is directly applied.

It is also very important that the forceps used for holding the cover-glass be of the right kind. The best are the curved fixation forceps made for oculists. Their blades are so set that fluids are not drawn between them by capillary attraction. They grasp the cover-glass firmly and may be locked. The teeth are of no use and can be smoothed off with a file.

One should be provided with a saturated alcoholic solution of fuchsin, which is made by adding dry fuchsin to a quantity of alcohol until no more will be dissolved; the excess will settle to the bottom of the fluid and should be allowed to remain there. A pipette bottle is most convenient for this solution, which keeps indefinitely. A 5 per cent. solution of carbolic acid in distilled water should be at hand and is best kept in a pipette bottle also. For decolorizing, a 25 per cent. solution of nitric acid is placed in a wine glass.

Suppose we use a thin, clean and perfectly dry cover-glass of good quality, three-fourths of an inch square, the film of sputum being fixed upon it in the usual manner; then it will be found that twelve drops of the 5 per cent. carbolic acid solution will cover its surface. This is dropped on while the glass is held in the forceps, then with care the fuchsin solution is added, drop by drop. The first two drops make a blood red precipitate in the carbolic acid solution, the third tends to clear this slightly, while the fourth should cause the precipitate to disappear entirely. Thus when twelve drops of the 5 per cent. carbolic acid are used, four drops of fuchsin will be found necessary. Other sizes of cover-glasses will require a different quantity of the stain, though the proportion between the two fluids will be practically maintained as 4-12 or 1-3. Whatever size glass is used it must be completely covered with the carbolic acid solution, and it is well to add a few extra drops. This will prevent evaporation leaving any portion of the glass dry. We may ignore the above proportions

¹ Strong hydrochloric acid, 1 part; alcohol, 30 parts; water, 70 parts.

and always drop the fuchsin until the precipitate that first forms, clears.

Holding the cover-glass in suitable forceps, the staining fluid is boiled upon its surface, but never long enough to dry on the glass. Wash the glass in a stream of running water, still holding it with the forceps, and then wave it back and forth in the decolorizing solution until all color is lost; this may take twenty or thirty seconds. Wash again in running water, dry with the help of blotting paper and heat. If desired, counter stain with cold saturated aqueous solution of methyl blue; if not, invert the dry glass on a drop of glycerin, balsam or water for examination.

The entire process of fixing, staining, decolorizing, etc., may take from two to four minutes, and during this time the glass has been held continuously in the forceps.

There may be conditions when the application of a cold stain for tubercle bacilli—the cover-glass being left in the fluid for twenty-four hours—would be advantageous. The writer has seldom found such conditions necessary. But the above rapid process, which obviates the necessity for keeping on hand staining solutions liable to deteriorate, or obliges one to make up a stock solution whenever there is a suspicion that the one on hand has grown too old, has its advantages.

The overcoming of these difficulties may induce the general practitioner to avail himself more frequently of that method of detecting tuberculosis which has now grown to have a very considerable importance.

AN ABDOMINO-INGUINAL SUPPORTER. FOR USE AFTER HERNIOTOMY.

BY JOHN B. HAMILTON, M.D., LL.D.

PROFESSOR PRINCIPLES OF SURGERY AND CLINICAL SURGERY RUSH MEDICAL COLLEGE; PROFESSOR SURGERY CHICAGO POLICLINIC.

"The patient should not be allowed to get up until three weeks have elapsed after the operation and then only if the wound is sound. The question of a supporting bandage or a truss will then have to be considered."—Treves, "Manual of Operative Surgery," 1892, Vol. 2, page 530.

"A spring truss should not be worn after the operation as its pressure tends to cause premature absorption of the lymph, but the abdominal wall requires a certain amount of support for some months. In infants this may be managed with a skein of Berlin wool as already described; but for children and adults the form of appliance known as Harrison's truss answers best. It consists of a well fitting pelvic band and two short thigh pieces made of linen; like a pair of very short drawers fitting tightly and fastened with lacers; a perineal band prevents its ascending, and may in addition be furnished with a scrotal bag and with braces passing over the shoulders."—Moullin, "Surgery," 2d Ed. by Hamilton, 1894, p. 904.

"In all cases during more than six months, those who are subjected to the radical cure should be watched with care and on the first menace of the reappearance of the hernia a bandage must be prescribed, so as not to lose all the benefits of the operation."—Berger, *Traité de Chirurgie*, Duplay et Reclus, Tome vi.

My experience, now quite extensive, in operations for the radical cure of hernia, has convinced me of the general correctness of the view, that some kind of support is always indicated after herniotomy. The direction given in some of the recent writings on the subject, to cause the patient to wear a light spring truss for some weeks, is only less mischievous than the practice of discharging such patients without any support. In casting about for some apparatus that would approach the shape of the human hand in supporting the new cicatricial tissue closing the

inguinal ring, I thought a thin piece of flat sole leather slightly hollowed like the palm of the hand, covered with chamois skin, making uniform pressure on the abdomen, would fulfil the indications. To retain the broad pad in place I caused it to be sewed to a supporter made of silk elastic, with a thigh piece."

The cut shows the supporter as made for me by Truax, Greene & Co.

I have tried it on three cases, and with satisfaction to the patient in all.

With this bandage the pendulous abdomen may be well sustained, and the thigh piece keeps the pad in position. The bandage should be woven in a single piece, and the pad carefully fitted to the patient before permanent fastening. Care should be taken that the thigh piece is not too tight. The straps should be snugly buckled at the back. Patients wearing these supporters have been instructed to remove them at night.

Buena Park, Chicago, April 20, 1894.

ON THE AUTONOMY OF THE HEART.

BY GUIDO BELL, M.D.
INDIANAPOLIS, IND.

In the last number of the *American Journal of Medical Sciences*, Prof. I. M. Da Costa has published eight cases of weak heart, where the causation of neurasthenia and organic disorder, as valvular lesion or fatty degeneration had to be excluded.

He is inclined to attribute this weakness to the influence of the heart ganglia. Notwithstanding, Romberg¹ in compiling the recent experimental researches on the heart, has proven that the animal heart is active by itself and is regulated only by the sympathetic and pneumogastric nerves.

The heart's action never could be fully explained, neither in normal nor abnormal condition by its innervation. There was a supposition that Remak's ganglia promoted the activity of the heart; but embryologic researches revealed the fact that the heart is active before it is reached by these nerve centers, and, furthermore, that these centers spread out only sensory nerve filaments. Then nerve-cells in the heart muscle were looked for, but in vain.

If a man of high repute and large experience does not accept what seems to be an established law theoretically, it is in order to report all pathologic experiences which may be apt to sustain theory.

This is so much more justifiable in a case where a phenomenon can not be explained, except by assumption of what was found theoretically to be the truth.

In an article of the Cincinnati *Lancet-Clinic* of Sept. 19, 1891, I have reported three cases where a peculiar noise of the heart was heard at a distance during the shock. The sound was systolic and appeared not immediately after the injury, but later and stronger, according to the severity of the shock, and lasted until the organism revived and both sounds became audible again.

Both my cases recovered. I could not give a satisfactory explanation at that time, but in a paper read before the Marion County Medical Society in Indianapolis, March 28, 1893, I said that the peculiar noise of the heart heard at a distance during the shock can not be explained, unless the autonomy of the heart is accepted.

The heart meets an undue resistance in the collapsed arteries, and not being restrained by its regulating nerves is working excessively, thereby causing the undulations in the heart region visible through the bed-covers, and the sound audible at a distance of fifteen steps.

I also spoke of the following case: On Jan. 4, 1893, I was called to see John M., at 10 o'clock in the evening. I saw the man, who was 63 years old, half an hour later, lying in a bed without any sign of life.

He was walking the floor after an ordinary day's work, apparently well and in his usual way, when he fell backward without stumbling and lay perfectly motionless. This had happened a short time before 10 o'clock. I found him at 10:30 p.m. with eyes half open, pupils moderately dilated, immovable, lids languid, lips cyanotic, cold skin on face and extremities; temperature in axilla below 95 degrees F.; no respiration; different examinations were made; no pulse at the wrist, but the heart was beating regularly, not much weaker than in life, twenty-one beats

in fifteen seconds. I counted the heart's sounds seven times, and also my own pulse which was eighteen beats in fifteen seconds. The man was dead, notwithstanding the beating heart. I injected one one-hundredth grain of nitro-glycerin hypodermatically. A few minutes after 11 o'clock the heart's action became irregular and soon ceased.

These pathologic phenomena fully approve Romberg's statement of the autonomy of the heart.

Austin Flint in his text-book on "Human Physiology" says: "The heart seems to act without any palpable excitation." But if both experimental researches and clinical experiences forward such strong evidence, it seems not to be immodest to formulate Prof. Flint's assertion more positively by saying: "The heart does act without any palpable excitation."

FACIAL ERYSIPELAS—TREATED WITH
EXTERNAL APPLICATIONS OF
GUAIACOL.

BY CHAS. J. WHALEN, M.D.

INSTRUCTOR IN LARYNGOSCOPY, AND CHIEF ASSISTANT TO THE CLINIC
FOR DISEASES OF THE NOSE, THROAT AND CHEST, RUSH MEDICAL
COLLEGE; CLINICAL ASSISTANT TO THE CHAIR OF SURGERY,
CHICAGO POLICLINIC.

A review of the latest literature on erysipelas reveals, on the whole, a very unsatisfactory state as regards the treatment, and marked discrepancies exist in the writings of different authors on the subject. On this account I wish to place before you some observations based on a personal experience with this disease, treated by the external application of guaiacol.

Etiology.—Dr. J. M. Anders of Pennsylvania, gives elaborate statistics to prove that debilitating diseases greatly predispose to this disease. The primary cause is the streptococcus erysipelatosus discovered by Fehleisen. Jordan is of the opinion that the specificity of Fehleisen's erysipelococcus is questionable, and that its identity with the streptococcus pyogenes is probable. He has studied this subject carefully with reference to this question, and has drawn from his observation the conclusion: That erysipelas is etiologically not a specific disease; that, as a rule, it is caused by the streptococcus pyogenes, but that it may be provoked also by the staphylococcus pyogenes aureus.

These cocci which are so nearly identical with the streptococcus pyogenes, are found chiefly in, and spread along the capillary lymphatics of the skin. Recklinghausen and Lukowsky found them in the lymphatic vessels and connective tissue spaces in the structure affected by erysipelas. Fehleisen found cocci in chains constantly present in bits of skin excised from the spreading edge of an erysipelas rash; they lay in the lymphatics chiefly of the superficial part of the corium, never in blood vessels, and only exceptionally in the connective tissue spaces, or in the immediate vicinity of blood vessels.

Erysipelas spreads along the superficial lymphatics, but not necessarily in the direction of the lymph current, which may be temporarily arrested by blocking of the interior of the lymphatics with cocci. As this microbe is non-motile, its transportation in a direction opposite the lymph current can only occur by reproduction.

In the facial form, when no wound is visible, it is

¹ In Berlin Klin. Woch., March 27, 1893.

probable that infection takes place through some small abrasion, though auto-infection may possibly occur, the organism having been previously absorbed through the respiratory or digestive tract. This, however, seems improbable.

As an addition to our knowledge of the effects of guaiacol in the treatment of this disease, I hope that the following may be of interest:

Case 1.—J. E. S., age 30. I saw the patient November 8. He complained of having had tonsillitis two weeks previously, but he had not regained his strength. Three days before I saw him he began to suffer from headache and appeared to have fever in the afternoon. When first seen by me, he was suffering from nausea, headache and constipation. He had a severe chill the preceding day. I found the temperature 103.5 degrees F., pulse 100. I noticed a slight red blush near the lachrymal duct which had every appearance of the beginning facial erysipelas.

I ordered pure guaiacol applied to the affected area and for some distance beyond, in the hope of preventing further extension. The following day the patient claimed that he had experienced instantaneous relief from the application, that his headache shortly afterward disappeared and the fever gradually subsided, so that he was able to sleep for the first time in four nights.

His appearance, however, was much worse than on the preceding day. The rash had spread laterally to the ears, and had extended over the forehead to the border of the scalp. The eyes were completely closed from edema caused by escape of inflammatory exudate into the loose cellular tissue in this region. There was considerable delirium. At 10 A.M. temperature 104 degrees F., pulse 100. Again applied guaiacol with the same satisfaction as before. The nurse found it necessary in this case to make three applications daily for the next four days.

Three hours after the application of the guaiacol, the temperature was 97.5 degrees. At 5 P.M., 100.5 degrees F.

November 11, temperature, 10 A.M., 99 degrees F.; 5 P.M., 100 degrees F.

November 12, temperature, 10 A.M., 98.8 degrees F.; 5 P.M., 99.5 degrees F.

November 13, temperature, 10 A.M., 98.6 degrees F.; 5 P.M., 99 degrees F. Patient discharged cured.

Case 2.—I was called December 16, to see Mrs. S., mother of preceding patient. Had several previous attacks of erysipelas. At the time of my visit she had a temperature of 104.5 degrees F. Complained of intense headache, dry burning skin and constipation. The rash had extended over the entire face, ears and forehead. Bullæ had formed in the ears. I applied the guaiacol as in the preceding case with marked relief of the symptoms. At 1 P.M. temperature 102 degrees F. At 3 P.M. temperature 101 degrees F. At 5 P.M., 103 degrees F. Again painted the face, when the fever gradually receded to 101 degrees F. At 8 P.M., December 17, temperature 101 degrees F., pulse 98. Urine scant and contained albumen. Guaiacol was applied once a day for the four succeeding days.

December 18, temperature 101 degrees F., pulse 96. Albumen still present.

December 19, temperature 100.5 degrees F., pulse 110.

December 20, temperature 100.8 degrees F., pulse 106.

December 21, temperature 99 degrees F., pulse 80. Trace only of albumen found in urine. Patient made a slow recovery.

Case 3.—Mrs. H., age 27; eruption limited to the face. Bullæ had formed on the cheeks; considerable edema about the eyes. Patient was slightly delirious. At 9 A.M., temperature 103 degrees F., pulse 100; ordered pure guaiacol painted over the face. At 12 M., temperature 100 degrees F. At 2 P.M., 99.5 degrees. At 5 P.M., 100.5 degrees. At 8 P.M., 101 degrees, F., when the nurse was obliged to paint the face again. Guaiacol was applied twice a day for the five following days. Temperature ranged from 99.5 to 101.5 degrees F., when convalescence was established. No albumen found in the urine on repeated examinations. Patient was discharged cured on the sixth day.

Another case illustrates even more clearly the good effect of this drug:

I was called February 15 to see Mrs. F., age 40 years. I found that she had an erysipelatous rash covering the entire face, ears and forehead. Bullæ had formed on the cheeks and upper lip. Her temperature was 103 degrees F., pulse

120; dry brown tongue, teeth covered with sordes, bowels constipated; had two chills previous to my visit. Ordered hydrargyri chloridum mite and sodii bicarbonas, aa gr. 5 morning and evening for the bowels; and painted the face with pure guaiacol, from which the patient experienced marked relief. On the following day, at the time of my visit the patient was having a decided chill. I at once applied guaiacol and immediately the chill began growing less intense and within five minutes it entirely ceased. This treatment was repeated on subsequent occasions with the same happy results. Each chill being aborted by the guaiacol applied externally over the affected surface. February 18, patient had been delirious the previous night. Temperature 103 degrees F., was reduced in one hour to 101 degrees F. by guaiacol, applied externally.

February 19, temperature 101 degrees F.

February 20, temperature 98 degrees F.

February 21, temperature 99 degrees F. Convalescence now seemed established and progressed rapidly, much faster than is usual in such cases.

Dr. J. E. Rhodes has kindly permitted me to mention a case similarly treated by him, in which the facial erysipelas followed an intense inflammation of the nasal mucous membrane. The temperature which reached 105.2 degrees F. was promptly reduced. On one occasion profuse perspiration and marked alleviation of the symptoms immediately followed the application. This case ran its course in one week.

The chief points of interest in these cases are:

1. The short time that elapsed between the application and the resulting relief.

2. Repeated trials on the fourth case showed that a chill could be aborted by the external application of guaiacol.

3. Except in cases of extreme irritability of the skin, the application of pure guaiacol does not cause pain. In such cases the guaiacol may be diluted with alcohol, olive or any of the fixed oils to the desired strength.

4. The amount of guaiacol employed varied from 20 to 30 minims.

5. As might be expected, such a powerful effect was not without its drawbacks. In two cases I found a subnormal temperature. These figures suggest their own caution.

The action of guaiacol in controlling chills and fever, as in Case 4, I am inclined to believe is due to an anesthetic action on peripheral nerve endings. Absorption by a skin the seat of inflammatory changes is necessarily slow, and could not account for the immediate fall of temperature noticed in these cases. Experiments have demonstrated that the temperature is not affected in animals if the site of the application is previously anesthetized. Guinard bathed the hind limbs of two rabbits with guaiacol; in one, the sciatic nerve was cut four days before. Here the application caused no fall in temperature, while with the rabbit with nerves intact, the same fall was observed as before.

The same author in the *Province Medicale* for February 17, states: That if the parts are enveloped after the application, in two or three hours guaiacol may be found in the urine; and has drawn the following conclusion from his experiments: That guaiacol can penetrate through the epidermis; that this penetration appears to be the result of an absorption of the vapor; that the envelopment of the painted regions—thus keeping the vapor in contact with the skin—increases the proportion of guaiacol in the urine.

Dr. E. F. Ingals informs me that after my report to

him of the beneficial effects of guaiacol in erysipelas, he applied it in two cases of erysipelatous inflammation of the face associated with rhinitis; and in both cases succeeded in reducing the inflammation speedily.

I have for six months been using guaiacol locally to relieve the dermatitis of the arm, following vaccination, in which I found marked constitutional symptoms. These were generally relieved by one or two applications of 15 or 20 minims.

In regard to its action on the course of the disease, I am not prepared to state positively. In all cases convalescence began not later than the sixth day, although the disease was very extensive in three cases. Albumen was found in the urine of only one patient. Delirium was present in two cases. I am therefore inclined to believe that convalescence was somewhat hastened in all these cases.

After having treated numerous cases by the various methods advocated by different authors, I believe guaiacol to be the most efficient therapeutic agent that we possess at the present time. It is certainly preferable to any of the so-called antipyretics and anodynes usually used to reduce fever or to control pain.

36 Washington Street.

CLINICAL HISTORY OF THE CASE OF PRESIDENT JAMES ABRAM GARFIELD.

BY ROBERT REYBURN, A.M., M.D.

PROFESSOR OF PHYSIOLOGY AND CLINICAL SURGERY MEDICAL DEPARTMENT HOWARD UNIVERSITY, WASHINGTON, D. C., AND ONE OF THE ATTENDING SURGEONS IN THE CASE OF PRESIDENT GARFIELD.

(Continued from page 682).

The President was more restless than usual last night being evidently excited by the anticipation of the journey. This morning at 5:30 A.M. his temperature was 99.8; pulse 118; respirations 18.

• September 6 at 6 A.M. the President was tenderly lifted by the devoted friends, who had nursed him through his long and weary illness, and in company with his physicians, he was carried on a stretcher to the outer vestibule of the White House. Twice while being carried he waved his hand in recognition to those of his household he was leaving behind. The bed he had just left had preceded him. He was immediately placed upon it without the least apparent discomfort. The President seemingly enjoyed the proceedings until the car was reached. The hour was fortunately too early for any great congregation of people, yet many who had heard of his intended removal were present on the streets. In perfect silence with men guarding the heads of the horses (which by the way, were not attached until the President was safely in the wagon and were detached the moment the car was reached), we slowly wended our way to the waiting train. Twelve soldiers grasped the wheels of the wagon, as the horses were detached, and rolled it to the car containing the bed, to which the President was then transferred without the slightest disturbance. We left Washington with the President at 6:30 A.M. Owing to the admirable arrangements of the Pennsylvania Railroad Company, and to the ingeniously arranged bed designed by Mr. T. N. Ely for the use of the President, he suffered comparatively little and bore the fatigue of

the journey remarkably well. During the journey his temperature and pulse were taken occasionally, and the effect was noted of the varying rates of speed upon the comfort of our patient. The minimum of unpleasant motion seemed to be secured when the train was going at the rate of sixty miles per hour. Through that long hot afternoon no sound of bell or steam whistle was heard either from our own, or from the large number of trains we passed. It was indeed a strange and affecting journey, and as we silently sped along it almost seemed as if we were being transported by some invisible and noiseless force to our destination. At every station we were met by silent multitudes, who with uncovered heads greeted us, but spoke not a word. The car assigned for the use of the party contained besides the President, Mrs. and Miss Garfield, Mrs. Rockwell and Miss Rockwell, Mrs. Dr. Edson, Professor Agnew, Dr. Bliss, Surgeon-General Barnes, Dr. Woodward, Dr. Reyburn, General Swaim, Colonel Corbin, Colonel Rockwell, Secretary Brown and the two family servants.

The President seemed to enjoy the rapidity of the motion, and when the train was going at its greatest speed of over sixty miles an hour and he was asked if the motion was uncomfortable, he smiled and said: "Let them go." During the last hour of his journey he showed symptoms of exhaustion, which would have prevented his making any longer journey, had such been required to reach his destination.

The train reached Elberon at 1.09 P.M. A temporary railroad track had been laid from the railroad station at Elberon to the Francklyn Cottage which had been generously placed at the disposal of the President by Mr. Francklyn. On reaching the steep grade near the cottage the cars were detached from the engine and pushed by hand to the side entrance of the cottage, and from thence he was carried to the room in which he passed the remaining days of his life.

September 6, 6:30 P.M. During the last hour of the journey the President complained a good deal of fatigue, and after his arrival was feverish and restless. At present his temperature is 101.6; pulse 124; respirations 18.

September 6, 10:30 P.M. The President is sleeping quietly, and his fever which was evidently due to the exhaustion resulting from his journey, is gradually subsiding.

September 7, 9 A.M. The President slept the greater part of the night, awakening, however, as often as it was necessary to give him nourishment, which he took and relished very well. The fever reported in last night's bulletin had subsided by 11 P.M. This morning his temperature is normal, and he appears to have quite recovered from the fatigue of yesterday's journey. At the morning dressing the parotid abscess was found to be doing well. The visible part of the wound looks somewhat better.

September 7, 9 A.M. Temperature 98.4; pulse 106; respirations 18. September 7, 6 P.M. Temperature 101; pulse 108; respirations 18.

The sight of the ocean seemed to give the President great delight. He said to those about him, "it was refreshing to get where he could look at the sea." The room where he was placed is large and handsomely furnished. When the President was taken into the room he at once noticed that his bed was so situated that he could not look out at the sea. He immediately insisted that a change should be made

in the furniture of the room, by which he would have an unobstructed view of the ocean, which was accordingly done.

September 7, 6 P.M. Notwithstanding the exceptional heat of the weather (the thermometer in his bedroom rose to 94 (F) at half past three this afternoon) there was a breeze most of the day, so that the President was comparatively comfortable. He has taken his nourishment regularly, and has slept well at intervals during the day. At 12:15 P.M. his temperature was 98.4; pulse 114; respirations 18.

September 8, 8:30 A.M. The President was restless and wakeful during the early part of the night, but after midnight slept well until morning. His general condition appears to be more encouraging.

September 8, 9:30 P.M. Temperature 98.7; pulse 104; respirations 18. September 8, 12 M. Temperature 98.4; pulse 94; respirations 17. September 8, 6 P.M. Temperature 99.1; pulse 100; respirations 18.

September 8. The President, desiring to diminish the number of his medical attendants, Surgeon-General Barnes, Dr. Woodward and Dr. Robert Reyburn retired from the case on the evening of September 7. Dr. Bliss remains in charge of the case and the services of Professor Agnew and Professor Hamilton are retained as consulting surgeons. The wear and tear of the attendance upon the President has been perfectly frightful, and was beginning to tell very severely upon all the surgeons who had been on duty in the case. The constant fever of excitement we were under, the continued loss of rest we sustained in our endeavors to do all that we could to save the President's life, had nearly worn us all out. As before mentioned Dr. Bliss never slept a night in his own house from the time the President was shot until his death (except one night when he was compelled to go home on account of an attack of blood-poisoning from a cut received during the dressing of the President's wound). The consulting surgeons were not usually called on for duty at night, unless in case of an emergency; this left the chief burden of the night duty upon Dr. Bliss, and in a less degree upon Dr. Woodward and myself. Dr. Woodward and myself slept alternately one night at the White House and the other night at our homes. The room the surgeons occupied was immediately northeast of the one occupied by the President, and we relieved each other, so that he was never without medical assistance close at hand. During the latter days of the President's illness the weather was extremely sultry and oppressive, and after our broken rest each night, in the morning we could hardly muster energy enough to rise and begin our labors of the day in the President's room. It was the custom of Dr. Bliss to have brought over from his own house early each morning to our room in the White House some excellent coffee. After we had each drank a couple of cups of this strong black coffee, we were able to commence our day's work. It is probably known to most of the profession that all of the surgeons who were on duty in the case of President Garfield are dead except myself. It is my firm conviction that the lives of all these surgeons were materially shortened by their labors in his behalf. Dr. Woodward died a comparatively young man, and every one who knew Dr. Bliss will agree with me in the opinion that he would in all probability be living to-day if he had never taken charge of President Garfield. It was perfectly apparent to all the attending surgeons that the Presi-

dent's life could not be prolonged for more than a few days after the date of his trip to Elberon. There was a perfect unity of sentiment among the surgeons in the feeling that it was our duty to remain and minister to the President as long as he desired our services, at the sacrifice of our health, or even of our lives. When, however, it was deemed best to discontinue our services, it was with a feeling of the most grateful relief that we turned our faces homeward.

September 8. After the arrival of the President at Elberon the following bulletin was issued:

September 8, 6 P.M.

The President's temperature was 98.4; pulse 94; respirations 17. At the evening dressing, 5:30 P.M., his temperature was 99.1; pulse 100; respirations 18. He has taken a liberal amount of food (both solid and liquid) with apparent relish. By special request of the President it has been made our duty to say in this public manner, to Surgeon-General J. K. Barnes, Surgeon J. J. Woodward, and Dr. Robert Reyburn that in dispensing temporarily with their services as his medical attendants he was actuated only by a wish to relieve them from a labor and responsibility, which in his improved condition he could no longer impose upon them. Both the President and Mrs. Garfield desire us to express to these gentlemen personally, and in this public manner our high appreciation of the great skill and discretion which they have constantly exercised as associate counsel in the management of his case up to the present time

(Signed)

D. W. BLISS,
FRANK H. HAMILTON.

PRESIDENT GARFIELD'S SOJOURN AT ELBERON.

September 9, 8:30 A.M. During last night the President was restless until after midnight when he fell asleep, and though occasionally awakening for a time, yet he slept a good deal. The conditions of the parotid gland and wound are improving. The emata and stimulants have been suspended during the past thirty-six hours. On the whole, the past twenty-four hours give evidence of favorable progress.

September 9, 8:30 A.M. Temperature 98.4; pulse 100; respirations 17. September 9, 6 P.M. Temperature 98.8; pulse 100; respirations 18.

A change was made to-day in the watchers upon the President; the four now on duty are Dr. Boynton, General Swaim, Colonel Rockwell and Mr. C. O. Rockwell. Two of these will be on duty each alternate night, and the day watch will be divided into periods of two hours each. The absence of the three surgeons who have been relieved from duty in the President's case is much felt by the remaining three surgeons, who are compelled to sit up with their patient each night, and get what chance sleep they can during the early morning or evening. This morning though cloudy and hazy is comparatively cool and refreshing. A gentle breeze is blowing from the sea, and the day is a decided improvement over the first three or four days of the week. The President's cottage has been rendered comfortable by fires made in the grates, so that no inconvenience will be felt by him should the temperature continue to decrease.

September 9, 1:25 P.M. The President is now sleeping quietly. The thermometer at noon registered 75 degrees (F). He expressed a desire to see this morning any of the members of the Cabinet who wished to call upon him.

September 10, 9 A.M. The President slept a good deal during the night awakening at intervals of one-half to one hour. There is a perceptible increase of strength with an improved condition of the digestive apparatus. The tumefaction of the parotid gland has entirely disappeared, and the suppuration from it has greatly diminished. The wound continues to

improve, and presents a more healthy appearance. He takes a fair amount of nourishment, and seems to digest it well. The surgeons agreed to allow the members of the Cabinet to visit the President, but to limit their stay to a few minutes. Secretaries Windom and Lincoln are to call this evening.

September 10, 9 A.M. Temperature 99.4; pulse 104; respirations 18. September 10, 12 M. Temperature 98.5; pulse 100; respirations 18. September 10, 6 P.M. Temperature 98.7; pulse 100; respirations 18.

The President's condition on the whole is not as favorable as it was yesterday. In the morning his temperature and pulse were higher but they diminished towards evening.

September 11, 8:30 A.M. Temperature 98.8; pulse 104; respirations 19. September 11, 12 M. Temperature 100; pulse 104; respirations 20. September 11, 6 P.M. Temperature 100.6; pulse 110; respirations 20.

The daily febrile rise occurred later than usual last night, and was prolonged over the greater portion of to-day. This was evidently due to a circumscribed area of lobular inflammation of the lower part of the inferior lobe of the right lung. The portion of the lung inflamed is quite limited in extent and the inflammation seems to be stationary, as it has not progressed during the day. The President's expectoration is more muco-purulent, and is rather scanty. No enemata are now given him, as he takes with relish a sufficient supply of both solid and liquid food. The President is bright and cheerful, and perfectly cognizant of all that is going on around him.

Dr. Bliss took his temperature at about 5 P.M. and found it to be a fraction over 100 (F). Dr. Agnew examined the President and said he thought the figures must be wrong, and requested that another test be made. Dr. Bliss replaced the thermometer, and as he did so the President said with a smile: "The figures are too high for you, are they? You wish to get them lower, if possible, I suppose."

In addition to his other food he has taken during the day three tablespoonfuls of brandy in the shape of milk punch. At the evening dressing quite a large slough of connective was removed from the region of the parotid gland.

September 12, 9 A.M. Temperature 98.4; pulse 100; respirations 18. September 12, 12 M. Temperature 99.2; pulse 106; respirations 18. September 12, 5:30 P.M. Temperature 98.6; pulse 100; respirations 18.

The President slept soundly last night from 10 P.M. to 2 A.M. this morning, when he awoke and took some nourishment, and immediately fell asleep and did not awake until 4 A.M. At that hour he was sponged off, and in the course of a few minutes fell asleep again, and did not awake until 7 A.M. at which time he apparently felt quite refreshed and rested. The suppuration from the parotid gland has almost entirely ceased, the openings from which the pus discharged are rapidly healing. The lobular inflammation of the lower portion of the right lung (broncho-pneumonia) spoken of yesterday seems to be the result of the parotid inflammation extending by continuity along the mucous membrane of the pharynx, larynx, trachea and bronchi. The cough is less to-day, and the expectoration has materially diminished. The President seems to feel better to-day; he has taken an ample supply of food without discomfort, and has

had several refreshing naps. His situation, however, is considered sufficiently grave to cause a postponement by the members of the Cabinet of their proposed trip to the White Mountains. Postmaster-General James goes to New York this morning, but will return this evening.

September 13, 8:30 A.M. Temperature 99.2; pulse 100; respirations 20. September 13, 12 M. Temperature 98.8; pulse 100; respirations 20. September 13, 5:30 P.M. Temperature 98.4; pulse 100; respirations 20.

The President passed a good night, sleeping most of the time. At 10 A.M. this morning the President was lifted from his bed to a reclining chair which he occupied for half an hour. He said: "This is delightful; it is such a change." He was placed in a position commanding a full view of the ocean, and his body raised to an angle of forty-five degrees. During the morning his pulse was irregular, and varied a good deal, but when he became quiet, settled down to the figures of the morning bulletin. The atmosphere is clear to-day, and the weather is cool and refreshing. The President is expectorating a good deal of muco-purulent material, and in his condition of great weakness he becomes much exhausted in his efforts to clear his throat of this tenacious matter. During these paroxysms of coughing his breathing becomes very rapid, and his pulse much accelerated. General and Mrs. Grant were here to-day, and in the evening General Grant spent some time in conversation with the surgeons anxiously inquiring concerning the exact condition of the President.

September 14, 8:30 A.M. Temperature 98.4; pulse 100; respirations 19. September 14, 12 M. Temperature 98.8; pulse 104; respirations 20. September 14, 5:30 P.M. Temperature 99.2; pulse 112; respirations 21.

The President passed a quiet night, sleeping comfortably the greater portion of the night. The day is bright and cheerful, and the President is in good spirits. In addition to the usual nourishment given him he ate a little fruit for breakfast. Soon after the morning dressing Secretary Lincoln was admitted to the sick room. He had not seen the President since the afternoon of the day on which he was shot, and was greatly distressed by his emaciated appearance and exhaustion. Drs. Bliss and Hamilton have decided on account of the great weakness of the President not to transfer him to the invalid chair unless he specially requests it. The President said just now, "that yesterday's experience at the window where he could see the green grass, the soldier walking his beat, the men and women in the summer house and walking along the beach, the fishermen at sea, the vessels on the ocean, and the bathers in the surf made him feel for the first time since he was shot that he was himself again."

Five pustules of acne have appeared upon the back of the President, and were opened to-day. This gave him much relief as they were quite an annoyance to him. September 14, 12:30 P.M. At the urgent request of the President he has been transferred from his bed to the reclining chair and is enjoying the scene very much. The weather continues very pleasant and invigorating, the atmosphere is perfectly transparent excepting over the ocean, where there is a beautifully tinted haze prevailing. After he had comfortably settled down in his chair he expressed

his sense of gratification, and remarked: "This should have been commenced three weeks ago." He remained in his chair about an hour and a half, and slept a portion of the time. He did not seem specially fatigued by the transfer or change of position though he had a slight febrile rise of temperature during the evening.

September 15, 8:30 A.M. Temperature 98.4; pulse 104; respirations 20. September 15, 12 M. Temperature 98.9; pulse 102; respirations 21. September 15, 5:30 P.M. Temperature 99.2; pulse 104; respirations 21.

The President slept until 3 A.M. when he was wakeful for a period of two hours, during which time his pulse rose to 120 per minute, but without the marked elevation of temperature which has characterized the febrile disturbances hitherto. After this time he slept quietly until morning. He had two rigors during the night. He expectorates a good deal, and is considerably exhausted by his paroxysms of coughing. His voice is weaker this morning, but he persists in talking, and thinks he is improving. He shows as much anxiety to know what the daily bulletins say concerning his condition as the general public does, and comments upon them, and discusses his general condition. Dr. Bliss took the 11 A.M. train for New York to-day, and will return at 5 P.M. and be present at the evening dressing of the wound. This is the only time since the President was shot that Dr. Bliss has been absent from his patient for any length of time. Drs. Agnew and Hamilton remained in charge of the President during his absence. Dr. Bliss said on his return: "Mr. President, I have been away for a few hours as you know, but they seemed like an age." He replied, "Doctor, you plainly show the effect of all this care and unrest, and I am glad you were forced to take this temporary relief. Your anxious watching will soon be over."

While the temperature of the President is not high this evening (99.2) yet the increasing frequency of his pulse and respirations, and more than this the excessive exhaustion he displayed, were sure tokens that the end of the weary struggle was near at hand. During the morning he took his liquid food and a small portion of steak. While his mind is usually clear, yet on first awakening from a sound sleep, he wanders a little for a short time.

September 15, 6 P.M. The President has passed the day quietly, sleeping a little, and coughing occasionally, the expectoration being purulent. He was placed on his reclining chair for three-quarters of an hour, and seemed to enjoy it very much.

September 16, 8:30 A.M. Temperature 98.6; pulse 104; respirations 21. September 16, 12 M. Temperature 99.8; pulse 116; respirations 21. September 16, 5:30 P.M. Temperature 98.6; pulse 104; respirations 21.

The President's condition causes a general feeling of despondency. During the past forty-eight hours he has made no favorable progress, and during the last twenty-four hours there has been a perceptible loss of strength. The process of repair in the wound has come to a standstill, and the discharge from it is thin and watery, and is small in quantity. The amount of lung tissue involved is considerably greater than it was forty-eight hours ago, and he is expectorating considerable quantities of purulent material. His attacks of coughing do not recur as frequently as they did a few days ago, but are more

severe and exhausting. The febrile rise during last night was not as high as it has usually been lately, but the pulse was quite frequent, at one time reaching 180 per minute. Three small bed-sores which had been previously healed have again made their appearance owing to the President's debilitated condition. His mind is not so clear to-day, and he shows evidences of hallucinations. A slight febrile rise occurred at 11 A.M. which had entirely subsided by 2 P.M. Nourishment and stimulants were given him freely during the day. Owing to the unfavorable news concerning the condition of the President, Postmaster-General James, Secretaries Hunt and Windom with their wives are now on their way from Boston to Elberon.

(To be continued.)

SOCIETY PROCEEDINGS.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Concluded from page 592.)

THE PRIMARY ACTION OF THE GALVANIC CURRENT—IT INCREASES THE AMOUNT OF OZONE IN THE BLOOD AS SHOWN BY CHEMICAL TEST OF THE BLOOD IN THE ARTERIES—WITH OUR THEORY OF ANIMAL ELECTRICITY.

This occurs in the capillaries. Until these are reached the pressure of the oxygen in the plasma restrains the hemoglobin from giving its oxygen. Here in the liquid moistening the fibrillæ of muscle that surround the terminal capillaries where the transfer of oxygen in reality begins, the tension of the oxygen is almost nil, since the tissue elements are steadily taking up the gas from the lymph surrounding them, and the plasma continues to give up oxygen through the walls of the capillaries until the tension falls too low for it to longer do so; then it is that a portion of the oxygen of the hemoglobin is freed and is dissolved in the plasma to take the place of that oxygen which it has given up and which in turn has passed out into the lymph on the other side of the capillary wall. This interchange continues until the pressure of the oxygen in the lymph equals that of the oxygen in the plasma, by which time the venous system of capillaries, the return circulation, has been reached.

One of the strong indications of the action of the galvanic current on the blood is the probability that it facilitates this transfer of oxygen to the tissues in active form, both chemically and physically. By rearranging the atoms of some of the molecules of oxygen in the plasma the volume of the oxygen held in solution is reduced, and the oxygen of the hemoglobin is at once transferred to the plasma instead of being doled out, as it were, to suit the constantly varying pressure changes that go on as the blood completes its circulatory round. This being the case, the transforming process is undoubtedly ushered into existence through the polarizing property of the animal electricity, of which we shall speak further on.

How far chemic change is wrought upon the diffusible solids of the blood by the generation and presence of such an increased amount of ozone we are unable to make precise answer, and we leave it to the thoughtful investigation of those observers who may take interest in our work and who are blessed with a more acute knowledge of physiologic chemistry and a more completely equipped laboratory than it is our good fortune to possess. To our mind there seems little question of the occurrence of just such a change as we have described. Our analyses thus far, have remained within the sphere of quality; it remains for others to continue in the more exact line of quantity. Reasoning by analogy, the galvanic current acts precisely upon the oxygen in solution in the plasma as it did in the jar filled with O₂ through which Schönbein passed the current and observed its transformation into ozone.

There is but one possible action of the ozone on the blood. It must hurry on the transfer of the oxygen to the tissues,

call into existence the oxidation of those constructive elements which the tissues require for their revivification. Doubtless these changes are more extensive than we have been able to determine.

Other Factors to be Considered.

The experiments of Guy-Lassan should teach us a valuable physiologic lesson. From his laboratory we feel that we can carry them over to that storehouse of chemic energy—the human body; and observe changes corresponding to those he observed in his jars filled with gases possessed of great affinity for one another which, however, remained quiescent and inactive until he prodded them with the stimulus of a galvanic current, which, as it passed through the gases, spurred into action, or awakened, as it were, their slumbering affinities, polarized their molecules and ushered into life the new something, the result of the three great potent factors—polarization, chemic action and affinity. We have tried to impress upon you the importance of these three conditions, for upon them depend all the chemico-physiologic changes—in short, all changes that go on within the human body.

We have observed them time and again in the course of our experimenting, and we have subjected them singly and together to the most rigorous test of verification.

Our observations point to the one conclusion, and that is, that chemic action, the feeder of life, can not go on unless there is present an electrical force, an energy that can polarize the molecules of the combining elements and prepare them for combining action. Affinity, catalytic force, the phenomena of contact in themselves are impotent without that ever preceding factor—molecular polarization.

It is the metabolism, the anabolism, the katabolism, the all, and more were it possible, of that cardinal nourisher of tissues, that feeder of life, the blood.

Animal electricity, and the important part it plays, we will reserve for a later chapter, and pass over to general details of our experiments upon the blood of the living animal in its normal state and under the stimulus of the galvanic current.

Preliminary Tests.

For a period of seventy-two hours before entering upon the examinations, we hung in various portions of our laboratory slips of specially prepared paper, saturated with a solution of the iodid of starch, and others moistened with tinct. guiac. These, as we all know, are acknowledged tests upon ozone. We kept the papers under careful observation, examining them in strong light at intervals of an hour, and as there was no evidence of a reaction at the end of the allotted time, we were justified in concluding that the atmosphere of the laboratory was free from ozone and the other gases which act upon starch and guiac. Next we directed our attention to nitrous compounds in the air, for the reason that they—if they exist in the slightest appreciable quantity—give us a reaction very much like that of ozone, and their presence must be excluded in order to give any sensitive test for ozone practical chemic value.

The test we applied for nitrous compounds is an extremely useful one, unusually sensitive, and we give its chemistry for the benefit of those who may desire to repeat our experiments. It is named Gries' test, after its discoverer. He observed that in sulphanilic acid and naphthylamine we have a reagent which acts on nitrous acid, but not on H_2O_2 or O_3 . This discovery Gries made while engaged in studying the action of diazo-benzene-sulphonic acid on naphthylamine.

He obtained his diazo-benzene-sulphonic acid by treating sulphanilic acid with nitrous acid, and calls attention to the extreme delicacy of the reaction, minute traces of nitrous acid sufficing to produce a dark red color in the presence of dilute sulphuric acid. The colored substance formed is an amido-azo derivative of the formula² $C_6H_5(SO_3H)N=N C_{10}H_6NH_2$ called azo-amido-naphthalene-benzene-sulphonic acid.

Prof. Slosvay,³ of the Polytechnic School at Buda-Pesth, increases the sensitiveness of the reaction by substituting acetic for sulphuric acid, and he can detect with it nitrous acid in aqueous solution in a dilution of one part nitrous acid to one thousand million parts of water.

The formula of the test is: $C_6H_5(SO_3H)N=N C_{10}H_6NH_2 + HNO_2 = C_6H_5(SO_3H)N=N C_{10}H_6NH_2$ sulphanilic acid and naphthylamine.

We availed ourselves of Slosvay's modification of Gries' formula.

A tank of a capacity of fifty gallons at a pressure of thirty pounds was filled with air from the laboratory. The air was sent through an air meter which registered one liter per minute, and from this into a test tube containing distilled water, through which it was allowed to bubble for ten minutes and then tested.

There was no immediate reaction, and only after half an hour's standing did we observe a tinge of color; so faint, however, as to be almost imperceptible in ordinary light. In order to see it, we were obliged to back the test tube with pure white filter paper and hold it to the sunlight.

In view of the delicacy of Slosvay's reaction, it was fair to assume that the quantity of nitrous acid in the air was so infinitesimally small that for practical purposes it could have no effect in interfering with the subsequent tests for ozone.

Ten liters of oxygen were treated in the same manner. The oxygen was first subjected to two washings in distilled water without giving any reaction to the nitrous acid test. The remaining forty gallons which were afterwards liberated in the laboratory were washed in caustic soda and dried with sulphuric acid (C P) and bubbled through distilled water. There was no reaction with Gries' test, thus showing that the gas was absolutely pure and free from admixture with nitrous and other gases.

This concluded the preliminary testing. The object of the careful analyzing of the air of the laboratory as you may already divine, was to devise means of testing for ozone in the open, and to avoid the less satisfactory method used by Schmitt, who treated his ozone in a balloon from which the oxygen had been removed as nearly as possible to do so, by means of carbon dioxide, or handling it in a similar glass receiver, from which all air had been exhausted, which was the manner in which Kühne conducted his experiments.

For several days work was suspended and resumed again Monday, August 21. On that morning we were treated to a genuine surprise, that caused us to ponder for a while. Dr. J. C. Dittrich, who, perhaps ranks first among the authorities on ozone in this country, and who kindly assisted us in the chemic portion of our work, prepared several specially sensitive test papers, which, on being moistened with distilled water, at once gave a reaction. The air of the laboratory was evidently charged with ozone, and we were at a loss to account for its presence. Speculation was soon set at rest when we recalled the violent thunder storms of the Sunday and Saturday before.

The ozone was the result of the intense static discharges of those days, and the amount that had been generated by the great Pluvius certainly was enormous and beyond measure. For that day and the three succeeding ones, work had to be deferred, with all the preliminary testing for naught.

On the following Thursday, on resuming operation, no ozone or nitrous acid was detected in the laboratory. The preliminary tests on being repeated gave results as already stated.

Testing for Ozone in the Blood.

A rabbit that had been well fed for a week was the subject of investigation—it was a big animal, in fine spirits, and weighed four pounds three ounces. It was brought into the laboratory, and both carotids cut through and the blood collected in a sterilized glass receiver. In all, sixty grams were extracted and defibrinated with sterilized glass rods. The operation requires nine minutes, and the fresh serum was subjected to test.

The serum was diluted with distilled water, in the proportion of one part of serum to four of water.

With the iodid of starch an immediate reaction was observed in the open air, and the same reaction faint at first, but gradually deepening in blue color, showed under a bell glass.

Testing with guiac. tincture of the officinal strength, which we reduced by adding an equal volume of absolute alcohol, responded more quickly to reaction of ozone. The blue ring around each drop of blood was marked and sharply defined. The same reaction continued when the test was made under the bell glass, and gradually approached its maximum of intensity at the end of half an hour, when, to all appearances, the ozone became completely exhausted.

The fibrinous clot, with the entrapped corpuscles, was likewise tested, and gave a far more distinct and marked reaction than the serum.

It was evident at a glance that the corpuscles contained a far larger amount of ozone than the plasma.

² Ber. d. Chem. Gesell., 12, 426, 15, 2191.

³ Bulletin de la Société Chimique de Paris, September and November, 1889.

The remainder of the defibrinated blood, about forty grams, which had been kept in a well-covered jar, was next subjected to electrification for five minutes.

A galvanic current of ten volts and fifteen milliampères was sent through the fluid. The electrodes used being strips of platinum an inch long and three-eighths of an inch wide.

In six seconds the meter dropped to eight milliampères, and the registration which was recorded at the end of each minute read as follows:

1 minute	7	milliampères
2 "	5	"
3 "	4.5	"
4 "	3.75	"
5 "	3+	"

Testing with iodid of starch and guiac. tincture showed the unmistakable increase of ozone. The rings around the drops of blood were of a deep blue hue, and the reaction continued with much greater rapidity than was the case with the unelectrified blood. As quantitative test was out of the question, Dr. Dittrich and my colleague made an approximation of the intensity of the action by comparing the rapidly deepening ring of blue with the chromatic scale, given by Dr. Fox, in his exhaustive work on ozone. They carefully noted the change of color as it progressed, availing themselves of the most advantageous light facilities, and agreed upon the estimate that the amount of ozone adequate to such reaction must be in the neighborhood of, at the lowest calculation, at least two and one-half times greater than the amount indicated by the reaction in the case of the unelectrified blood. The clot deposited around the electrode at the positive pole gave a more animated reaction, the ring of blue almost approaching indigo, showing a most marked increase over the former reaction.

Standing by itself this test of the blood outside of the body signifies but little, for it is the blood that circulates through the living organism unimpeded with which we have to deal, and in which physiologic conditions alone can be of any value in the study of the action of the galvanic current. Yet withal, when taken in connection with the tests that were afterwards made, the observations form an important link in the chain of evidence that it is animal electricity which is the polarizer of the atoms of neutral oxygen both in the plasma and in the hemoglobin.

Under normal conditions the transformation of O₂ into O₃ is slow and gradual, and the polarization of the neutral oxygen is proportionate to the polarizing force of the existing animal electricity.

Undoubtedly Schmitt, Houzeau, Meisner, Kühne and others were right in their assumptions, but it seems to us that they did not probe deep enough for a solution of the possible origin of this transformation of neutral oxygen into ozone within the human economy. It was due to the polarization of the atoms of the neutral oxygen, but how did it come about?

We have assumed in starting out upon the experiments the results of which form the title of the paper we have the honor of presenting to your consideration, together with the more exact details which we hope to announce at some future day, step by step, with the view of adding some light to the question, that this generation of ozone admits of a satisfactory scientific explanation.

During the years that my colleague and myself devoted to the study of ozone within the body, we have always regarded it with awe and veneration. We have woven theory after theory only to find that the strands broke precisely within the limits of the reasoning of the great observers to whom we owe all we know of ozone, and that to us as physiologists is indeed little.

That ozone can be found in the blood nourished by gases that contain no ozone is a fact beyond dispute, yet the problem of its generation is a problem that at first sight offers no easy solution.

In looking over the field of possible sources to explain this source of the formation of ozone it fastened itself upon us that one great factor that might afford an explanation had been overlooked. It was animal electricity, and we have tried to explain its function. There seems to be but one deduction to draw from the most careful observation and that is, that it is animal electricity upon which not only the polarization of the atoms of oxygen but all molecular polarization and chemic action in the body depends.

We believe that the transformation of oxygen into ozone within the body is brought about by this very animal electricity, which polarizes the neutral oxygen to such a degree

that a portion of the atoms rearrange themselves, attract and repel each other under this polarizing force until we get the ozone which we detect upon analysis. The function of the ozone is apparent to all of us. It gives the oxygen increased power to form combinations with the tissue elements and promotes oxidation.

This polarization of the oxygen seems to take place just as the gas touches the tissues where the conditions are favorable to such an action and where it closes circuit with electricity in the human frame. The unaffected molecules of oxygen under the vigorous spurring of this ozone become vitalized as it were, and at once begin the search for their affinities in the tissues and enter into combination with them.

The proof of this reasoning seems to us to be apparent from the fact that we have been able to appreciably increase the amount of ozone in the blood by passing very weak currents of galvanic electricity through the body, and it is the underlying theory upon which we based our experiments and which we hope to make clear to you.

Before dismissing this portion of our paper and passing over to an account of our experiments upon the blood of the living animal electrified by a current of galvanic electricity, permit us to advance another theory which we regard as justifiable from our findings, and we do so only in the hope that it will give rise to careful discussion, for it is at variance with some of our pet physiologic theories; it is

That oxygen in the blood stimulated by the polarizing power of animal electricity, and more so under the stimulus of the galvanic current enters into combination with the hemoglobin of the corpuscles with a partial transformation into ozone, and that in losing its combining bonds it undergoes a further partial transformation into ozone.

Experiments on the Electrified Animal.

This brings us to a record of the experiment upon the living animal with the galvanic current.

The animal chosen was also a rabbit, which was prepared by being fed on fresh vegetables for several days. He was in prime condition and was allowed to run at large until he was required for use. The batteries, two of the ordinary twenty-four cell medical machines of the Edison-Lalande pattern were used. The batteries were carefully tested cell by cell and the current measured with both volt and milliampère meter. A coil of a resistance of 400 ohms which had been placed in the circuit was removed after the measurement had been taken and we decided upon a current of a strength not to exceed forty milliampères.

Two cuts about half an inch apart were made into the skin of the animal and into these and for a distance into the body of the muscle, the platinum electrodes used in the previous experiment were inserted and a current of twenty volts turned on. The meter showed forty-four milliampères. This dropped quickly down to forty-one milliampères. The reading of the meter during the five minutes that the current flowed was as follows:

1 minute	40.5	milliampères.
2 "	38.	"
3 "	37+	"
4 "	35.8	"
5 "	35.—	"

At the end of five minutes both carotids were cut through and thirty-five grams of blood were drawn into a sterilized glass vessel and defibrinated as before with sterilized glass rods.

It was observed that the blood was of a brighter scarlet hue than that which flowed from the arteries of the unelectrified animal. Exposure to the air while the process of defibrination was going on did not affect the bright tint. Defibrination too, was not so easily affected and the fibrin slowly gathered around the rods.

Seven minutes after the blood was shed, a gram of the fresh serum was distilled with two grams of distilled water and subjected to test with both guiac. and starch iodid. The reaction in both instances was almost immediate, a trifle more active with the guiac. The ring of blue around the drops of blood was more pronounced and much deeper and kept on deepening both in the open air and under the bell jar as had been done with the blood from the first animal killed. At the end of twenty minutes the test papers, those saturated with guiac. and starch iodid, three of each variety being exposed to the air and a similar number under bell jars, indicated the termination of the action and they were taken out and carefully compared with the test records of the first experiment which had been preserved in air-tight

tubes. The blue ring was, even upon the most superficial examination, found to be several shades deeper and the ring of reaction more spreading, in some of the drops, almost half an inch wide and distinctly visible to the line of demarkation of chemic action. The fibrin also gave like results. A far larger amount of iodine had been set free in these tests than in the case of the first analysis. The quantity of ozone to give such reaction according to a most conservative calculation of both Dr. Dittrich and my colleague was estimated to be certainly three times greater than that which gave the reaction from the normal blood.

The increase in the amount of ozone was astonishing and far beyond our expectations. We had anticipated some difficulty in determining the increase if it proved to be trifling, but here we were met by a quantity far in excess of what we had hoped to find in the event of the most successful termination of our searching.

The action of the current on the oxygen in both plasma and corpuscle enmeshed fibrin was evident in the transformation of a portion of it into the more vital form of O_3 . That the current had accomplished this transformation, astonishing as it proved to be, was readily to be explained, but not so with the ozone in the normal blood. There was but one explanation for this, the polarizing action of the animal electricity.

Our Plain Views Regarding Animal Electricity.

The existence of animal electricity is acknowledged. The origin and action, however, are the points upon which electro-physiologists are not quite clear. Those who have given the subject some consideration dismiss it by establishing its connection between chemic action, heat and animal electricity. They rest content in discussing the three conditions without attaching the slightest importance to the precedence of one or the other of them. Chemic action we are told evolves heat, and so tissue metamorphoses and oxidation go on. They are satisfied with the evidences of the existence of animal electricity, that it can be measured, and that it is one of the great trinity upon which life rests.

It is in view of this condition of the investigations upon this question that we approach it with much trepidation and fear lest we be charged with being too radical in our deductions; we can almost see doubt written upon the faces of many of this distinguished gathering, and we can almost hear you say: "Well, are you going to settle the question?" Settle the question or not, still we have the boldness to advance a probable solution of the problem, and we ask you to follow closely our experimentation and the deductions we have drawn and based our opinion upon.

We will not take up your time by rehearsing the observations of the various electro-physiologists who have enlightened us in animal electricity. To do so we would in fairness to all be obliged to begin with Matteucci and so on up to the present day, without omitting a single one for each of the observers has welded a link in the chain of result, and to leave out a link would mean to destroy the integrity of the chain.

Let us for a moment consider the observations of Dutochet, and we may get a clue to the true function of animal electricity. He observed that if the positive pole of a battery be dipped into pure water and the negative in gum water, endosmosis continued more energetically.

Onimus later on discovered that with a reversal of this order of pole, endosmosis too was reversed. It is but fair, reasoning again by analogy, to assume that the electricity in the body exercises precisely the same physico-chemic action. We have already called your attention to the observations of Gay Lussan. Whenever the so-called catalytic action takes place in the living tissue, is it not equally fair to assume that animal electricity is the prime mover? Can there be any question that electricity, galvanic, with its electrolytic powers, the ready manner with which it decomposes the salts, coagulates albumen in the vessels of our laboratories, has a like action on the tissues and fluids of the living organism?

It is apparent, we hold, that animal electricity not only influences the whole system of nutritive operations, but also directs them.

Time and again we have electrified animals and observed that under certain conditions of electrification, the animals threw off a greater amount of urea and carbonic acid than under ordinary conditions.

Urea and carbonic acid! and what is the significance of such an increase in the waste products?

Nothing more than, and nothing short of increased chemic action, increased tissue metamorphosis, the increased evolution of

heat; but the electricity, the animal electricity—that remains unaccounted for.

Dutochet and Onimus showed us the action of the anode and the cathode in endosmosis, and left us to apply it to the physiology of nutrition. Now let us do so and account for the function of animal electricity if we can. As we have already intimated, the order of action is animal electricity first, and why, because we must have polarity before we can have chemic action and its natural result, heat.

Subject a solution of the iodid of potassium to electrification and you free the iodine. Inject a quantity of this fluid into the blood of a living animal and then subject the animal to electrification, and in a very few minutes starch papers held in contact with the parts surrounding the positive pole, will indicate that the iodine is set free by the action of that pole. Note the transfer of the chemic action from the laboratory to the living body; are the two not singularly alike?

Unfortunately we have not been able to isolate the poles of animal electricity, and hence it is that our tests on animals similarly injected, yet not electrified, give us such indistinct reactions, that we hesitate to announce them as positive results.

Yet all this points to the one conclusion, and the one deduction, that animal electricity comes first; that it is the prime factor in all the processes of change, of chemic action, or otherwise, within the living body. That without its stimulus of polarization, no chemic action can be called into life, and consequently none can go on; and tissue metamorphosis, which is life itself, must cease.

Before concluding, allow us a word or two upon ozone, its physiologic and therapeutic value, which are not under discussion, and are hardly properly to be considered in the limits of this paper. We have dealt with ozone generated from the oxygen within the body, and it is in this form that it plays its so important rôle in the oxidation of the tissues. There seems to be some doubt as to the possibility of introducing ozone in its pristine integrity into the system. It may be a feat within the range of possibility, judging from the voluminous literature upon the subject that has been published only within the past year or more, yet from our experience in handling it, we prefer to regard it as an agent that performs its most useful work upon the field where it is ushered into existence, where nature calls it into life because it is needed to perform important duties.

A paper was read by DR. WILLIAM JAMES MORTON ON
NOTE ON AN IMPROVEMENT IN INFLUENCE MACHINES, AND ON A
NEW TRANSFORMER TO BE USED WITH THESE MACHINES.

The improvements related to important points in mechanical construction and to utilizing Dr. Morton's discoveries for converting static discharges into currents. There are two directions in which influence machines are of use to physicians; one, the spark and its modifications; the other the Morton currents. The former are familiar to all; the latter exhibit the phenomena of high frequency high potential currents now familiarized by the labors of Tesla, Elihu Thomson and D'Arsonval.

As a result of continued medical work for thirteen years with static machines, the writer had had constructed by the Galvano-Faradic Company, of New York City, a machine which embodied in his opinion every modern advance. It was fundamentally of the Wimshurst-Holtz type; it had eight revolving plates, each one thirty inches in diameter; it was provided with a simple device, by aid of which the physician could employ at will the spark, spray, static induced and the transformer current. In its present shape the new machine answered every purpose in medicine to which influence machines could be put. It was known as the Morton-Wimshurst-Holtz machine.

Dr. Morton then exhibited the transformer, which consists of two flat spirals of wire placed in an ebonite box containing oil. The static induced current is led into one coil and from the other the current passes to the patient. This current produces a peculiarly vigorous, but painless muscular contraction.

DR. MORTON also read a paper on
NOTES ON MECHANICAL VIBRATIONS ACTUATED BY ELECTRIC
MOTORS WITH PRESENTATION OF THE INSTRUMENT.

A helmet was shown, such as was employed by Charcot in the treatment of disease by means of rapid percussion. The vibrations are produced by a small electric motor, called "The Premier," which can be procured almost anywhere at a cost of three or four dollars. By an eccentric action it is made to impart rapid vibrations to the interior of the apparatus.

The mechanical vibration idea dates back to 1734, and the method has been applied to all sorts of instruments. In 1878 experiments were made in vibratory treatment of the limbs of locomotor ataxia patients. Boudet de Paris, Gilles de la Tourette, Mortimer Granville and Allan McLane Hamilton are the best known of the more recent investigators in this field.

The helmet has been used with success in migraine and in insanity. Its action in insanity has been compared to the action of the alternating current passing through the brain. When placed on the head and set in motion, the first feeling is as though the heavy helmet were rising off the head; then the vibratory motion begins to extend to the eyes, nose and lips, and many patients feel a slight numbness creeping into the tips of the fingers. One uniform result of the application of the helmet is an almost immediate disappearance, at least temporarily, of the feeling of fatigue. In a severe case of migraine of twenty-two years' standing, the patient having at the time a severe attack in the left temple, the patient said after a few minutes that she felt as if she had taken nitrous oxide gas, and shortly afterwards she expressed a strong desire to go to sleep. In about fifteen minutes, the excruciating headache had disappeared, and although the pain returned in about half an hour, it was not nearly so severe. In another case of migraine in the midst of the attack, the patient fell asleep and the attack was cured absolutely.

DISCUSSION.

DR. WOOLSEY thought this relief was not due to hypnotism alone, as suggested by some, but to the influence on the spine. He was himself subject to a headache, which would be almost immediately relieved by a short horseback ride.

DR. MASSEY said that an intelligent patient of his who had read of this instrument was very anxious to have it tried on him, because he had noticed that when he had certain peculiar sensations of vertigo a ride in a railroad train would relieve him immediately.

The following paper was read by DR. ENGLEMAN ON

FARADISM AS IT WAS AND AS IT IS.—MY NEW APPARATUS, THE RAPID, CONTROLLABLE INTERRUPTOR AND PRECISED NERVE AND MUSCLE COILS.

The induced or interrupted current, as generated by my new apparatus, to which I wish to call the attention of this Association, is a very different agent from Faradism as now in general use; different in range, efficiency and effect, in precision and controllability, and I trust that this apparatus may be for the Faradic current what the milliamperemeter has been for the galvanic—the basis of progress and development.

I lay stress upon the apparatus because the faradic current, unlike the galvanic, depends altogether upon the generator for its character and efficiency, and the instruments in general use for therapeutic purposes have been such as to yield currents of limited value, without the possibility of varying their character, adapted to certain therapeutic purposes only, and imperfectly so at that; one differing from the other without means of record or comparison, so that even the most ingenious operator could derive but little positive benefit from their use, notwithstanding the satisfactory results occasionally achieved. The current was too vague and uncertain to be relied upon as a remedial agent: The attention of the observing practitioner and the scientific investigator was turned to more promising and efficient, more reliable and controllable, forms of electricity, and Faradism was cast aside. The striking results, however rare, which unquestionably followed its use now and then, gave a firm footing and a permanency to this current which Duchenne had so warmly recommended. It has always retained a certain status in the professional mind, which was not easily shaken, and it has been used more or less, usually in a vague way, as a mysterious agent or as a *dernier* resort, far more general than we might suppose, ever since the day of Duchenne, who, almost half a century ago, was far in advance of the general knowledge of Faradism as we find it at the present day. He not only gave us the induction current, but he perfected it as well, and the enthusiasm and perseverance, the physiologic and therapeutic research and experiment of this father of Faradism at once gave a high status to this form of electricity, which was received with favor; but as usual with a new agent, expectations ran too high, they were not realized, disappointment followed, so that the labors of Remak in behalf of galvanism were watched with interest, and his teachings fell upon fertile soil. The interrupted current was displaced, and permanently displaced, by the constant, and ever since the impetus

given to galvanism by Apostoli, since this mysterious fluid has been ranged among the controllable and recordable agents, scientific interest in Faradism seems almost to have ceased, but regardless of this the interrupted current continued in popular favor. No champion appeared for the cause, but the induction coil remained, regardless of the changes in the medical profession. Why was this? We may attribute it to some extent to the desire to test this mystic agent where other remedies have failed; to some extent undoubtedly to the good results now and then achieved by its use, results surprising or unexpected at times, and to such isolated successes we must ascribe the survival and persistence of the faradic current, vague as it was, without precision, without the possibility of record or dosage.

Medical science could hardly class so vague and uncertain a force among its remedial agents, no matter what the chance results now and then achieved by its use might be. The excellent work of Tripiet seems to have been without tangible results, and even the labors of Duchenne seemed doomed to oblivion. Practically, as I have already stated, far less is generally known at the present day of faradic electricity than was revealed and taught by Duchenne almost half a century ago. Faradism as known to the medical profession, the current as produced by the instruments in general use, was certainly not an agent to which the physician could resort with any positive expectation of success. The objections which were made, and correctly made, to the use of this current were above all its vagueness and uncertainty, not only the total absence of record and dosage, but the radical difference of currents from different instruments, so much so that the current from one might serve to alleviate pain, while this might be aggravated by the current from another. Moreover, there was no certainty of result, no means of comparing results from instruments of the same kind, and even from one and the same instrument; the effect was uncertain, as the current was a variable, constantly changing one. By means of my new apparatus the instrument I wish to describe to you and which is here for the first time presented to the profession since its completion I believe that I have succeeded: (1) in overcoming the existing objections; and (2) in increasing the efficiency and the therapeutic range of Faradism.

The objections which have justly been made against this form of electricity as hitherto known to the profession are obviated by the regular, thoroughly defined, precised and controllable current produced by this apparatus. Not only does this instrument enable us to control and dose the current, so as to render it a serviceable and reliable therapeutic agent, but it also enables us to so vary and modify this agent as to make it a useful and widely applicable one. The therapeutic scope of the current has been extended and new fields have been opened to it, by reason of the great range of current variations which it gives, variations in quantity and quality and in physiologic effect, made possible by the great rapidity of interruption, by changes in the rate of of that interruption and by variation in the character of the coils. These are the factors upon which the therapeutic success of the induction current depends, and which were prominent, but less perfectly developed in the Engleman battery manufactured by Waite & Bartlett for the past — years, in accordance with the suggestions contained in my first paper before the American Gynecological Society in 1886. In the instrument now before us, in which Dr. Waite has practically carried out my ideas in the most satisfactory manner, great improvements have been made. The apparatus with which I had been experimenting since the fall of 1892, was first demonstrated in March, 1893, in its crude form, at a meeting of the New York Electro-Therapeutic Society, and as it has proven eminently satisfactory, no material changes have been made in the construction of the instrument as now presented, although certain of the mechanical details have been simplified and improved by Mr. Harry Waite, who has assisted me so materially in the solving of the practical problems in the final carrying out of my ideas.

The characteristic features of this apparatus, which give to the current its controllability and extended range are:

1. The use of two motive powers, the separation of the primary flow through the coil from that which propels the interruptor; in other words a separation of the forces which serve to produce the interruptions and the current proper or the inducing flow which gives regularity of interruption with smoothness of current admits of perfect regulation and control of each independent of the other.

2. The interruptor, which is characterized by rapidity and

controllability: *a*, it admits of greater rapidity of interruptions than hitherto known; thus extending the physiologic and therapeutic efficiency of the current, and *b*, the control of these interruptions is perfect, making record and comparison possible.

3. The series of secondary coils, varying in the number of winds and the thickness of the wire used, each of known physical and physiologic power, adapted to its special therapeutic purpose, for reduction and stimulation; for effects on nerve and on muscle.

1. *The separation of Coil and interruptor Current*, the use of an independent force for the propulsion of the interruptor and the induction current proper overcomes some of the most important objections to the therapeutic use of the faradic current, by removing all irregularity and allowing of perfect control of each of its essential factors, the rate of interruption and the force of the induction flow proper. In the ordinary medical apparatus the same primary flow acts upon both, so that the resultant therapeutic current is constantly varying. The rapidity of interruption varies with the force of the primary flow, and varies with the position of the secondary coil, which is frequently changed as it is the essential element in determining the intensity of therapeutic effect. The rapidity of interruption with the same arrangement of the vibrator varies, then, not only with the force of the primary current, but with the pushing in or out of the secondary coil, the primary or the core, as the case may be, and the therapeutic or coil current again varies with the rapidity of interruption. Rapid interruption calls for a strong propelling force, so that a mild therapeutic current with rapid interruption can hardly be attained, but it is the constant variation which is the main objection, and by a separation of the forces the necessary regularity and controllability of each is attained. For the new apparatus by this separation of coil and interruptor current the most delicate or the most powerful inducing flow can be utilized with any desired rate of interruption, whether one or one hundred thousand per minute; whether it be the ordinary slow or rapid vibrator with muriate of ammonia cells or the new interruptor propelled by Grenet cell or storage battery.

I believe that I have satisfactorily shown that the rate of vibration is one of the most important factors in determining the therapeutic effect of the induction current, and not merely as it was formerly treated, a mechanical necessity for the production of such currents, and a very secondary part in the apparatus, as it has always been and still is in all faradic instruments for medical use. However, regularity of vibration or interruption is essential to a serviceable therapeutic current, and to obtain this we must not only have an interruptor acting with far greater regularity than the old-time vibrator as ordinarily constructed, but in addition the vibrator must be controlled by a separate force entirely distinct from the coil current, as it is in this apparatus. This separation of forces is essential to satisfactory work, to a simple and reliable controlling of the two most important factors of the therapeutic current. In no other way can precision be obtained, and I trust that ere long the better class of medical instruments will be arranged for a separate and distinct coil and interruptor current. The portable battery for general use, especially for stimulating currents, will probably, on account of the greater simplicity of construction, retain its present form with a single motive power or one primary current, which acts on the vibrator, producing the interruptions, and likewise the induction effects; but the stationary apparatus, from which the various phases of therapeutic currents are to be derived, must have a separate motive power for each, a storage or Edison-Lalande battery for the interruptor and four or, at most six, muriate of ammonia cells for the coil.

2. *Vibrator and Interruptor*.—It is needless at this time as in my earlier papers, to insist upon the therapeutic importance of vibration or alternation, an accepted fact since Mr. Tesla has demonstrated the marvelous mechanical results of rapid vibration, and D'Arsonval has proven the surprising insensibility of the system to currents of extremely rapid alternation. The remarkable results of vibratory action have been sufficiently demonstrated of late, and the varying effects of such vibrations of various mediums upon different nerves are the subject of physiologic and therapeutic experiment. The more varying the effect of different rates of vibration the more important is their perfect control, and this I believe has been achieved in this apparatus. The increased rapidity of interruption and the ability to control it gives a wide scope to the efficiency of the current, increases its sedative power, and renders the application of effective currents possible to the most sensitive tissues, cer-

tain results, especially decided vaso-motor effects, being produced by rapidly interrupted currents which are no longer perceptible to the sensory nerves. Whatever be the theory, whether it be true or not that the effect of the faradic current is mainly due to its mechanical influence upon the molecular constitution of the organism, the facts are that this variability, which is the very life and essence of faradic electricity, is likewise one of the most essential factors in determining its therapeutic efficiency. This is readily proven by observing the physiologic effects of the interrupted current. The effects of the slower rates of vibration, the highest obtainable by the spring vibrator,¹ are best demonstrated by the use of mild currents, but as such currents would cease to impress the sensory nerves, and would no longer be recognized by them if interrupted with greater rapidity, stronger currents must be used to test interruptions of greater rapidity.

The physiologic effect of the induction current slowly increases with an increase in the rapidity of interruption up to 2,500 or 3,000 per minute. The increase in the intensity of physiologic effect within these limits is not great, and

Engleman Faradic Apparatus, with rapid controllable Interruptor and Alternator.

observable only, as has been stated, in mild currents, hence of no great therapeutic value. The character of physiologic and therapeutic effect, however, does vary, so that it behooves us for medical purposes to note approximately, at least, the rate of interruption even within these limits, the limits as given by the spring vibrator, and this serves well as an exact control is unnecessary, unless for experimental pur-

¹ Great vagueness exists as to the rate of vibration of the average vibrator, and as a rule this is overestimated. An ordinary spring may vibrate 2-3,000 times per minute, 40 or 50 per second, and a better instrument at most from 4-6,000 per minute or from 60 to 100 per second; to determine this with precision by tuning fork is possible, but a difficult task for any but the skilled experimenter; the simple determination by the comparison of the note sounded is uncertain and subject to a most variable individual equation as well as other sources of error. My assertions are based on my own older Galfie instrument, which does not exceed 3,600, and on the comparison of results from the Waite and Bartlett spring vibrator with those from the controllable interruptor current. Moreover, at the suggestion of Dr. Mount-Bleyer, the lycopodium figures obtained upon the tense membrane by the vibrator and known figures of the new interruptor have been used as means of comparison, and by reference to the results obtained by these three methods the rates of vibration have been determined with approximate certainty.

poses, and this can be obtained by the new interruptor. For ordinary therapeutic purposes the methods of current interruption used in my portable battery may suffice; that is, the single impulse key for very slow interruption; the slow vibrator, which can be regulated so as to give from 100 to 1,500 interruptions per minute, and the rapid vibrator giving from 1,500 to 4,000 or at most 6,000 per minute. High rates of interruption, together with a perfect control of those interruptions, are obtained by the new interruptor, as seen in Fig. 1. The interruptions are obtained from the commutator upon the axle of a small motor propelled by a two-cell storage battery or six Edison-Lalande cells, per minute. We can thus obtain interruptions of known rapidity and perfect regularity, the rapidity being limited by the size of the apparatus only, any desired rate being obtainable. But I believe that the apparatus in its present form, with a limit of 50,000 to the minute, is ample for all therapeutic purposes in connection with the primary and secondary coils as now in use. This is a great change from the ordinary apparatus with the vibrator which averaged from 3,000 to 4,000 per minute, and all statements as to greater rapidity of vibration are based upon erroneous suppositions, not upon scientific experiment. The physiologic results obtained by experiments with interruptions between 50,000 to 100,000 per minute have not warranted their application to therapeutic purposes, so that higher rates still were not even tested; in fact, they would be useless, as such rapidity completely annuls the effect of currents obtained from four to six muriate of ammonia cells and ordinary coils. The higher the number of interruptions the greater is the current strength which is necessary to make an impress upon muscle or nerve, and with higher rapidities all physiologic effect would be lost. Up to 2,500 or 3,000 per minute there is a slight increase of effect both upon motor and sensory nerves. As the rapidity continues to increase the intensity of physiologic effect diminishes and its character changes.

I am not as yet prepared to give the results of my clinical work, and can only refer to physiologic experiment as a guide, bearing in mind that the physiologic effect of rapidity of interruption varies with character of coil and intensity of primary flow. I will merely cite an experiment with a primary current of four muriate of ammonia cells and coil 3 of my earlier apparatus (W. and B.). At 45 of the scale, or one-third of the coil in circuit, this will produce muscular contractions with from 45 to 100 interruptions per minute; this current grows stronger with an increase in the rapidity of interruptions up to 4,000 per minute, then soon decreases. Muscular contraction ceases at 5,000, at 6,500 its sensory effect is barely noticeable, and before a rapidity of 10,000 is reached it ceases to be felt altogether. A very strong current, such as one from No. 3 coil completely overlapping the primary, with an inducing power of four Leclanché cells, and applied through large moist electrodes—in other words, a current too strong for therapeutic applications with the ordinary vibrator at 3,000 per minute, is barely perceptible with 25,000 interruptions per minute, and ceases to be felt altogether at 28,000. The rapidity of interruption controls the physiologic effect of the current as perfectly as the sledge movement of the secondary coil, so that, all other conditions remaining unchanged, it is an index of current strength which may well be utilized. The therapeutic value of rapid interruption rests upon our ability to employ strong, efficient currents without discomfort, and is found in the nerve-quieting, sedative effects of these interruptions with fine coil currents.

Slow interruptions from 100 to 400 per minute are obtained from the large wheel in the center of the figure, which has 24 contacts, any and all of which can be eliminated at will, so as to reduce the number of interruptions in the revolution, and as these contacts are very distinct and clearly numbered, they will serve for the control of the rapidity of the motor and the number of interruptions from the rapid interruptor upon its axle, to the left in the figure, which revolves 210 times as fast; to the right is the alternator. Slow interruptions from 100 to 400 are obtained from the large wheel by moving the switch to the left to "S," and rapid interruptions from the commutator by moving it to "F."

The rapidity of the interruptions obtained from this instrument can be determined with precision by control of the revolutions of the slowly revolving large wheel, which always preserve the same relation to those of the commutator, as 1 to 210; the rate can likewise be deter-

mined by the use of the speed indicator and a noting of the propelling current force; hence the rate of interruption is under perfect control, either by observation of the number of revolutions of the slow interruptor or by a noting of the current intensity used after its effect has once been established by comparison with the speed indicator, a given current always producing a given number of revolutions and rate of interruption. Practically, it is the rheostat, (the switch to the right is the rheostatic) which regulates the rate of interruption and when the operator is once familiar with his instrument he can closely approximate the current intensity or rapidity of interruption by the resistance used, *i.e.*, by moving the rheostat switch from point to point.

The general laws governing rapidity of interruption are true of the primary as they are of the secondary or induced current, but in order not to enter upon too wide a field I will not here discuss the interruptions and alterations of the primary faradic which are readily obtained in the new apparatus; and moreover this current has lost in therapeutic significance since instruments are furnished with gravity coils of low electro-motor force, which I prefer to the primary, and which answer perfectly in almost all cases in which the primary coil was supposed to be essential.

3. *Coils.*—As physiologic effect depends upon resistance, diameter of wire, or current quantity and electro-motive force of the current, as determined by the number of winds in the secondary coil, I have devised a series of coils of known quantity and electro-motive force, so that each coil may determine a certain physiologic effect, and I believe that I have now at least approximated the physiologic and therapeutic extremes, since these coils have been developed after prolonged experiment and the winding of coil upon coil in accordance with theoretical reasoning and results previously achieved: The coils now determined upon represent certain forces and produce certain physiologic and therapeutic effects, motor and sensory, sedative and stimulating. Motor, to the exclusion of sensory effects, the painless influencing of the muscle, are most satisfactorily obtained by secondary coils of the lowest possible resistance with the largest possible electro-motive force, within certain limits, and within certain limits the efficiency of the muscle contracting current is increased by increased ampèreage, without any pain or sensory effect; this is proven by my coils notwithstanding theoretical statements to the contrary. Nerve effects, on the contrary, are most effectually produced by coils of higher electro-motive force, increased voltage with diminished ampèreage; counter-irritation, stimulation and painful effect upon the nerve by the greatest possible electro-motive force in short coils; the sedative, nerve-quieting effect by long coils of great electro-motive force, high voltage and low ampèreage. General nerve and muscle effects vary in character with resistance of electrode and rapidity of interruption by coils of moderately high electro-motive force and resistance. The various effects desired, calling for certain quantity and quality of current, can be satisfactorily obtained from individual coils only, quantity being necessary for action upon the mind direct, and electro-motive force for the influencing of the nerve; the endeavor to combine a variety of effects in one and the same coil is possible only to a limited extent, and perfect results can be obtained only from a continuous coil or its inner sections, and a variety of such coils is necessary if definite results are to be achieved.

The coils used in connection with the apparatus are:

A—For Motor Effects.

1. Coil I of the old series, the heavy wire coil, 0.8 ohms resistance, 528 winds, as high a voltage as is well possible, is a simple coil with considerable ampèreage.

2. Multiple coil of 32 wire, 6,500 winds, 4.1 ohms resistance, which gives even more efficient and entirely painless muscle contraction, by reason of the comparatively great ampèreage with high voltage.

B—For Stimulation and Counter-Irritation.

3. Coil II of the old series, 13 ohms resistance, 1751 winds, with penetrating and rather irritating effect, the current being a more painful one as ampèreage lessens and voltage is still moderate, comparative low.

4. Short fine coil, 40 wire, 180 ohms resistance, 528 winds, giving an extremely painful current without motor effects of any kind. An unusual relation of ampèreage to voltage, ampèreage is much less than in the previous case and voltage also lower. Comparing this with Coil I, same voltage, 528 winds, we see that high ampèreage, 0.8 ohms resistance gives effective and painless muscle contraction, whilst very low ampèreage, 180 ohms resistance causes great pain and no contraction comparatively.

² An improvement is now being made by Mr. Waite which admits of the direct count.

C.—General Nerve and Muscle Effects.

5. A coil of 32 wire, 7500 ohms resistance, 4500 feet, tapped at 3000 feet 500 ohms, 1500 feet 250 ohms.

D.—Sedative Effects.

6. Coil of 6,000 feet, 12,890 winds, 2,484 ohms resistance, tapped at 4,000 feet 9,685 winds, 1,656 ohms 2,000 feet 5,670 winds 828 ohms. This coil gives the most satisfactory sedative effect, acting rather upon the sensory nerves to the exclusion of the muscle, as far as this is possible, the first or 5670 winds section, with more ampérage being still serviceable for certain muscle effects; the full coil of 12,890 winds represent the extremes which can be used to advantage even for sedative purposes, 10,000 or 11,000 winds being almost sufficient. The coil has, however, been retained as it may in some cases yield results which could not be attained by lower electro-motive force, but higher voltage, more winds, are not only useless, but even less efficient with the battery force and primary coil; as now made the higher voltage with lowest ampérage affects the muscles least.

These coils represent definite physiologic and therapeutic effects as far as it is possible for this one factor to do: to develop the utmost possible current effect a combination of the various determining factors is necessary. The full effect of the motor coil is obtained by slow current interruption and the moist electrode, which reduces resistance to a minimum, giving the greatest possible current quantity; it thus gives an efficient muscle current without the greatest possible increase of ampérage possible with the given voltage yields the most efficient and painless muscle current effect upon the sensory nerves. The irritating effect of the short, fine Coil 4, is developed to its fullest extent by an increase of resistance, or diminution of ampérage, by the use of the dry metallic electrode and interruptions of moderate rapidity, whilst the sedative effect of Coil 6, with the highest possible electro-motive force, is developed by rapidity of interruption and increase of penetration by the moist electrode. Only by a combination of all the essential factors can the most perfect results be obtained, and it is readily seen how the physiologic effect may be varied by a variation in any one of these factors, especially by a variation of each one in the same sense.

A farther variation of the current is obtained by the rheostat, the switch to the right, which controls the coil current, varying its intensity without changing the relation of primary and secondary coil; the other rheostat controls the interruptor current and thus the rapidity of interruption or alternation.

In conclusion, let me again emphasize what I deem the essential features of the new apparatus, they are:

1. The separation of motive powers, an independent coil and interruptor current.

2. The precision and variation of secondary coils and current.

3. The rapidity, regularity and controllability of interruption; though rapid interruptions have been attempted by various means, they have never been practically controlled; thus the singing or ribbon vibrator, which is difficult to adjust and calls for a strong motive power, which means a powerful coil current; and while its vibrations can be varied to some extent, this variation of vibration is obtained only by a variation of coil current, and is within extremely uncertain limits. The regularity of interruption obtained by the revolutions of the commutator is perfect while every rheotome or vibrator varies constantly, almost with each of the ever-changing factors of a therapeutic application. The importance of a perfect control of the rate of interruption such as is possible in this apparatus is evident, and that rate of interruption can be determined positively at any moment, while the determination of the vibrations of the rheotome, possible only by comparison with delicately constructed tuning forks, is simply out of the question in the physician's office during therapeutic applications. The construction of the coils for the development of currents of known physiologic and therapeutic value is an equally important feature of this instrument; it is the noting of quantity or resistance and electro-motive force or number of winds of these coils, which enables the operator to indicate with precision the current quantity and quality, and it is this possibility of determining with precision each of the elements upon which therapeutic effect depends that a positive value is given to this agent, record and dosage is made possible, and upon this we must depend, as absolute measurement is of no therapeutic value. This I can now positively say since I have for some time measured therapeutic and experimental currents, and find that such physical measure is no indication of physiologic effect, as will be readily seen if we con-

sider merely this one fact: That the same current slowly interrupted may produce a powerful effect upon motor and sensory nerves, and when rapidly interrupted it is not perceived by either, yet physical measurement remains the same.

The interruptor which was devised in connection with this apparatus will serve other therapeutic purposes; being acted upon by its own individual motive power it may be used as a separate instrument for the purpose of interrupting or alternating the primary faradic or the galvanic current; and it may likewise be used for the purpose of producing atmospheric vibrations, by means of the telephone receiver or other vibrator, vibrations which will prove useful for various therapeutic purposes. One of the results of such independent use of the interruptor has been the muscle contracting current which is obtained by a combination of the galvanic and faradic apparatus, the mixed or high voltage primary current,³ as I have termed it, which acts powerfully upon the fiber, and may be used to contract the muscle in cases where the faradic proper has failed.

While the striking physiologic effects produced by the new currents warrant us to expect valuable therapeutic results I will merely say that I have been more than gratified by what has been so far accomplished by muscular contraction or interstitial massage in the painless stimulation of relaxed pelvic tissues by the muscle coil, the counter-irritation produced by the short, fine, wire coil, and above all, the sedative effects of the long fine coil, even with interruptions of moderate rapidity. Without entering into details, I will only say that the instantaneous relief obtained from the application of such currents in acute inflammatory pain has been surprising and warrants the highest expectations.

DISCUSSION.

DR. MASSEY said that there was still another objection to the ordinary coils, and that was the rapid oxidation of the contact points on the interruptor. A very few passages of the current suffices to oxidize these.

DR. HERDMAN said that the new apparatus was simple and efficient, and it not only gave very rapid interruptions, but the number of these could be very readily determined at any particular moment. It also did away with the objection mentioned by the last speaker, for the rubbing of the brake wheel suffices to prevent oxidation. He thought, however, that the physiologic limit had not yet been determined because of the lack of sufficient apparatus. He believed firmly that in view of the excellent work which faradic apparatus had done in the past, even in its crude form, in its improved form it should be capable of rendering very valuable assistance. Careful study by the graphic method, which is thoroughly scientific, will give a reliable basis for the comparison of future observations.

DR. MORTON thought Dr. Engleman's modification of the apparatus was a very desirable step in the right direction. These induction coils are very useful and serviceable, and they will probably be always more or less in demand. It is just such enthusiastic studies as these which are likely to bring forth good fruit. The mere fact that the number of vibrations can be recorded is in itself one of extreme importance. There is one advantage which the induction apparatus will always possess, and that is its great portability.

DR. ENGLEMAN, in closing the discussion, said he thought the physiologic limit had been already determined. The best physiologic and physical effects are obtained from a coil which has a trifle less than 13,000 windings. The coils which have been already constructed have been made purely on experimental data.

EXECUTIVE SESSION.

Communications were read by the Secretary from Drs. Apostoli, Tripiet and Gautier, of Paris; Drs. Henry McClure and Bruce Clark, of England; Dr. DuBois Raymond, of Berlin; Dr. La Torre, of Rome; Honorary Fellows, conveying to the Association an expression of their interest and sympathy in the work of the Association, and wishes for its success. Also from Drs. Campbell, Grier, Hutchinson and Munn, Fellows of the Association, regretting their inability to be present, and with wishes for a successful meeting.

The resignation of Dr. Anna Galbraith, of New York, was read by the Secretary, and on motion accepted.

Nomination of officers came next in order.

For President.—Dr. Morton said: It is a very difficult and delicate matter in an Association like this to make a

³ The interrupted high voltage primary or mixed current. Medical News, Feb. 3, 1894.

nomination for this office. Even though this Association be a most "vigorous infant," if we get the wrong wet nurse, the infant will lose much of its vigor. I would put in nomination the name of a man whom I think will promote the very best interests of the Association; a man who is an instructor, and who earnestly desires to have electro-therapeutists manufactured out of students who have received a fundamental education in the principles of electro-physics and electro-physiology. These students will come in time from Ann Arbor, and their teacher is not only well known to us, but he has graced every meeting, and by his personal qualities has endeared himself to all of us. I nominate PROF. W. J. HERDMAN for President.

The vote was unanimous, and Dr. HERDMAN declared President. DR. FRANKLIN MARTIN, of Chicago, was elected First Vice-President, and DR. A. LAPHORN SMITH, of Montreal, Canada, Second Vice-President. DR. R. J. NUNN, of Savannah, Georgia, was unanimously elected Treasurer.

DR. FRANKLIN MARTIN said that as no one could be more faithful than the present Secretary, he therefore nominated DR. CLEAVES as Permanent Secretary. DR. CLEAVES was unanimously elected.

EXECUTIVE COUNCIL.

Dr. A. H. Goelet, New York City.
Dr. Wm. J. Morton, New York City.
Dr. G. Betton Massey, Philadelphia.
Dr. Robert Newman, New York City.
Dr. Chas. R. Dickson, Toronto, Canada.

STANDING COMMITTEES.

On Standard Coils:

Dr. W. J. Morton, New York City.
Dr. A. H. Goelet, New York City.
Dr. W. F. Hutchinson, Providence, R. I.
Dr. G. J. Engleman, St. Louis, Mo.
Mr. A. E. Kennelly, Edison's Laboratory, Orange, N. J.

On Standard Meters:

Dr. Margaret A. Cleaves, New York City.
Dr. Emil Heuel, New York City.
Mr. W. J. Jenks, E. E., New York City.

On Standard Static Machines:

Dr. W. J. Morton, New York City.
Dr. J. H. Kellogg, Battle Creek, Mich.
Dr. G. Betton Massey, Philadelphia, Pa.
Dr. Margaret A. Cleaves, New York City.

On Standard Electrodes:

Dr. A. Laphorn Smith, Montreal, Canada.
Dr. Chas. P. Dickson, Toronto, Canada.
Dr. Plym. S. Hayes, Chicago, Ill.

On Electrical Illuminators for Therapeutic and Diagnostic Purposes:

Dr. Plym. S. Hayes, Chicago, Ill.
Dr. Margaret A. Cleaves, New York City.
Dr. H. H. Hahn, Youngstown, Ohio.

New York City was selected as the place of meeting for the next year on the last Tuesday in September.

THE PRESIDENT announced a proposed amendment to Article III of the Constitution, viz.: Every candidate for admission to the Association shall be required to present a paper to the Executive Council, at least one month before the annual meeting.

THE PRESIDENT presented the Association with a permanent gavel with the name of the Association and its Presidents engraved upon it. It was a static roller electrode which had been presented to the Committee of Arrangements last year for use during that meeting. He then thanked the members for their consideration and for their assistance in rendering the meeting pleasant, interesting and instructive. He declared that he was proud to be numbered one of the fathers of this Association and was gratified with the progress it had made. It showed by the work thus far accomplished that it is destined to be one of the most important of our American organizations. In resigning the chair, and bidding adieu to the members in his official capacity he said he knew of no one to whom he would rather surrender the office than to the newly elected President, Dr. Herdman.

DR. HERDMAN—In accepting the symbol of office, I do not propose to inflict upon you a speech at this late hour. Allusion has been made on several occasions to the "vigorous infant" which you have placed in my charge for the ensuing year. I accept the charge with considerable diffidence. I understand that it has a great many grandfathers, uncles, cousins, and other blood relations, and without such rela-

tionship the infant is going to die. I accept the responsibility only on the condition that sustenance and support and constant interest of these blood relations shall not be withheld. The Association has already enlisted the interest of many worthy ones in other countries.

When I was nominated for this office this morning in such a flattering speech, I was relieved somewhat when Dr. Morton put it on the ground of my position as an educator. We know that in order to become expert electro-therapeutists, a fundamental education in electro-physics and physiology is essential, and should be an established part of the curriculum of the schools. This has been with me almost a fad; I trust that every member of the Association will make himself a missionary in this cause. Within the last four or five years there has been an effort to meet this need in all our important medical schools, and I have received many letters asking about the methods to be pursued in carrying out this idea.

I only trust that in selecting me, you may not find that I have in any way disappointed you. I am a member of a small scientific society which names its presiding officer, "the principal servant;" it is in this capacity I wish to carry out the duties of this office.

DR. MARTIN.—I have a word to say. It is difficult to mix smiles and sorrows; we look upon the retiring President and sympathize with his departing glory; we say, "the king is dead; long live the king!"

I suspect that Dr. Goelet had a special design in having the names enrolled as he did on his gavel, for on it and occupying almost the entire space is written, Massey, Morton, Goelet, and he has just left room for Herdman. Obviously he desires to limit the number of names upon it. But, seriously, Dr. Goelet's name will long be graven on our hearts, as well as upon this emblem. Our meetings, I think, have never been presided over with more dignity and urbanity than by him, and on the whole we must admit that he has kept his word pretty well about not being "a talking President." Every thing has been harmonious and our papers have been of unusual merit.

A rising vote of thanks, upon motion of Dr. Morton, was then extended Dr. Goelet for the very able and efficient manner in which he had presided over the meeting.

DR. GOELET.—I assure you the remarks of Dr. Morton have overpowered me. I can say no more.

Adjourned.

SULPHONAL POISONING.—Stern (*Deut. med. Woch.*, March 8, 1894), discusses the renal lesions in this condition. An insane woman, aged 70, received 1 g. of sulphonal every evening, the dose having to be doubled in a month's time. This was continued for more than three months, with frequent intermissions amounting often to eight days. When the total amount taken was some 150 g. the urine showed a dark color due to hematorporphyrin. The drug was omitted at once. Fatal coma, however, supervened in a week's time. The kidneys were of a pale red color, with smooth surface, and contained deposits of lime salts. These changes were such as might be attributed to advanced age, but the microscope displayed a very extensive necrosis of epithelium, and also minute hemorrhages. These minute changes represent a toxic nephritis, and were unquestionably due to the sulphonal. There was a large gall stone in the gall bladder, and small friable concretions in the scarred cystic duct. Very slight jaundice was present during life. The poisoning occurred here, as in other published cases, in a woman, and after the prolonged use of the drug. The obstinate constipation, the age of the patient, and the changes found in the myocardium no doubt accelerated the result. During the use of sulphonal the urine should be carefully examined for albumen or formed elements, as when once hematorporphyrinuria appears the prognosis is unfavorable. In the presence of renal disease the prolonged use of sulphonal should be resorted to with great caution.—*Brit. Med. Journal*, April 14, 1894.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNOLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, APRIL 28, 1894.

THE SURGERY OF HENRI DE MONDEVILLE.

That accomplished *savant*, M. NICAISE, who recently published an edition of the "Chirurgie de Guy de Chauliac," has brought out an edition of the surgery of Master HENRI DE MONDEVILLE, which proves conclusively that MONDEVILLE and not GUY DE CHAULIAC, was the father of French surgery. DR. PAGEL (J. L.) gave a Latin edition of MONDEVILLE in 1892, and with that exception the work has remained unknown quite down to our time. The predecessor of GUY of Montpellier, by fifty years, he lectured at Paris in 1306 and 1312, and the volume now edited by NICAISE is the identical course on surgery delivered more than five centuries ago by Master HENRI DE MONDEVILLE. NICAISE is of opinion that while the work was written in Latin, MONDEVILLE gave his course in French. As proof of this hypothesis he cites the fact of the existence of the manuscript written in the life time of the author, in the Bibliotheque Nationale.

MONDEVILLE had been a pupil of the famous THEODORIC, of Bologne, who among other advanced notions held that the "formation of pus was not necessary for the cicatrization of a wound," and he used dressings of wine, dressings that were antiseptic exactly in proportion to the percentage of alcohol contained therein. MONDEVILLE, who was the surgeon of PHILIP LE BEL, sought to introduce the wine dressings of THEODORIC into French civil and military practice. But MONDEVILLE had much trouble; he thus writes in 1312:

"It is very perilous for a surgeon to make an operation otherwise than according to the custom of other surgeons; we have a proof; for the treatment of wounds according to the method of THEODORIC, MASTER JEAN PITART and me, who have been the first to bring this method in France, and we were the first to employ it at Paris, and in many wars, contrary to the wish and the advice of all, particularly the physicians. We have well endured the disdain and

shameful words on the part of the people and on the part of our confrères, the surgeons, and as well menaces and threats. From certain persons and physicians, every day, and at each new dressing, we have borne discussions and such violent words, that half vanquished, and fatigued by all this opposition, we had almost renounced this treatment, and would have completely abandoned it without the aid of the most serene COUNT DE VALOIS. But this Prince came to our aid, and also certain other persons, who had seen in the camps, wounds treated by this method. Furthermore, we have been sustained by truth, but if we had not been strong in the faith, and nominated by the King as Royal Physician, and not a few letters, it would have been necessary for us to have abandoned this treatment."

But the treatment, says NICAISE, "ceased to be employed after the death of MONDEVILLE," and GUY DE CHAULIAC, writing fifty years later, speaks "with a certain disdain and rejects the doctrine of MONDEVILLE on suppuration."

The wound treatment of THEODORIC, championed by MASTER MONDEVILLE, sought the immediate arrest of the flow of blood, and apposition of the lips of the wound; neither probe nor tent was allowed to be introduced, the wound was closed by suture, and a pledget soaked in wine laid upon it. The whole theory of treatment after the suppression of hemorrhage was based on exclusion of the air. MONDEVILLE frequently used a plaster of resin cerate or turpentine.

Ligature of arteries is mentioned as a matter of common practice, in the chapter on amputations. The teaching that we owe the introduction of the ligature to PARÉ is thus spoken of by NICAISE:

"This practice has remained, it seems, in the traditions of the Italian surgeons, where MONDEVILLE and perhaps PARÉ borrowed it. CELSUS spoke [of the ligature] also as a simple thing, and as well that ORIBASIVUS reported the practice of ARCHIGINUS of Apamia, who tied the vessels after amputations and placed a ligature at the root of the member during the operation."

In the treatment of wounds of the belly, where the intestines and omentum had escaped, MONDEVILLE recommended immediate reduction after washing them with hot wine. In event of the wounding of the epiploön he said that the "considerable arteries and veins should be tied so that the blood escape not, and then replaced." When the escaped intestines were wounded, he considered the case incurable, but if the wound were so small as to close itself without suture, it was favorable. He excepted wounds of the great intestine from this gloomy prognosis, and sutured them with a Glover's suture of silk. He wished always to exclude the air, "which is supplicative and cold," from these wounds.

His materia medica list was large, but purely empirical. M. NICAISE has done a great public service in rescuing this manuscript of the Middle Ages from oblivion, and bringing it to the front.

THE ANTISEPTIC DRESSING OF THE UMBILICAL STUMP.

Under this title, DR. JOSEPH EVE ALLEN, in the *American Journal of Obstetrics* for April, makes an earnest plea for more rigid care of the cord in newborn children. The author reiterates the fact, long since known, that the separation of the funis is effected by a process of desiccation and that, therefore, any ulceration or suppuration is proof positive that the physiologic process has been interfered with. The method advocated by the author is as follows: The cord is ligated temporarily or clamped till after the nurse has washed the child. The accoucheur, having previously washed his hands and the child's abdomen and cord in an antiseptic solution, releases the ligature, strips the cord, pressing out as much of the contained gelatinous material as possible, and re-ligates it with a silk ligature that has been rendered thoroughly antiseptic by being boiled in a strong solution of corrosive sublimate and afterward kept in a solution of iodoform in ether. The cord is then dressed with a piece of sterilized gauze, covered again with a pad of gauze soaked in chemically pure glycerin, and the whole retained by a sterilized flannel bandage. Each day the gauze pad is removed and a fresh one, soaked also in glycerin, applied; as often as the retaining band becomes soiled it is changed.

Under this treatment the cord often falls within three days, and the umbilical fossa should then be filled with aristol, a dry pad of gauze placed over it and the bandage re-applied. Repeated microscopic examinations of cords treated in this way, the author declares, failed to show the presence of any form of microbe.

This is but a step in advance of the practice of applying a piece of scorched linen to the cord, which has been in vogue for so long as to have descended to the place of an "old woman's remedy." And yet, like so many old wives' prescriptions, down at the bottom lies a grain of truth. The charcoal formed by the scorching was in fact an antiseptic to a very mild degree, and the heat rendered the linen aseptic. DR. ALLEN's procedure starts out by making the cord aseptic and keeping it so by the sterilized dressing and the glycerin—in itself a mild antiseptic. The glycerin also serves the secondary purpose of hastening the desiccation by its hygroscopic qualities.

It may be urged that the treatment is unnecessary and meddlesome. The same was said of antiseptic midwifery, and the profession of one generation has seen the criticism silenced and antiseptics practiced in all the maternity hospitals and by most of the physicians of the world. It is true that infection of the cord rarely occurs, but that it occurs at all is an argument in favor of preventing it as far as human means can. Perhaps in the true country districts,

with houses far removed from each other, with pure air and pure water, the risk of infection may be slight; but in the city, with its crowded tenement houses, its air loaded with particles of filth of all kinds from the streets, and its water of questionable purity, the necessity for care becomes imperative. The author's method may be too strongly antiseptic to suit some, but the main principle is good sound surgical sense; that the attendant should see to the dressing of the cord, having in mind the possibility of septic infection of the child, and not trust it to the unwashed hands of any old woman who happens to officiate as nurse.

"The danger of septicemia threatens every newborn babe, and can be certainly averted only by strict attention to asepsis; and the physician who does not practice its principles, and has septic diseases occur to infants in his charge, is derelict in his duty and is morally, if not legally, responsible;" such are the closing words of DR. ALLEN's paper, and they are worth while pondering over.

REQUIREMENTS OF THE TEXAS LAW.

The Court of Civil Appeals of Texas handed down on Feb. 28, 1894, in the case of KENNEDY vs. SCHULTZ, a decision of considerable importance to the medical profession, and especially to practitioners in that State. This was an action brought to recover for services rendered as a physician. The party suing alleged that he was a physician in Bexar County, and had been ever since May 1, 1890; that he was a graduate holding a diploma from a reputable American medical college, recognized as such by the AMERICAN MEDICAL ASSOCIATION; that he had never resided in any county in Texas but Bexar, and never practiced his profession in any other county in Texas; that there had not, since May 1, 1890, been a duly appointed and qualified board of examiners in Bexar County, and, if such board or boards were ever appointed by either of the district courts, that none of the members had ever qualified, and for that reason it had been impossible for him to obtain a certificate, as required by law, and to have the same registered.

The petition in which these declarations were made was specially excepted to because it appeared from the face of it that the services rendered were in violation of the civil and criminal statutes of Texas, because the party rendering them had not caused to be recorded the certificate permitting him to practice medicine or surgery, which exception was sustained.

The court first of all holds constitutional the State law concerning physicians. The conflict set up between the statute and the constitution was that the statute provided that the board of examiners must be graduates of some medical college recognized by the AMERICAN MEDICAL ASSOCIATION, and that this

ASSOCIATION was composed entirely of adherents to the "allopathic" school of medicine. This court said that it could not possibly know that to be a fact, and could not go out into the field of speculation in connection with that subject.

Coming to the main question in the case, which has never before been directly decided in Texas, the court holds, in harmony with the uniform decisions of many other States, that a physician practicing medicine in violation of the law can not recover for fees for his services.

To practice medicine in Texas without having obtained a proper certificate and without having it duly recorded, is in violation of the civil statute, and this failure, the court holds, can not be excused on the ground that no board of medical examiners had been appointed. A violation of law can not be excused on the ground that some one else has violated it; so that, if there was no medical board in Bexar County, as required by law, this physician, for example, should have applied to some other board for examination, or at least have had his diploma recorded, in order that others might see it, and ascertain whether it was from some "reputable American college."

SMALLPOX AND TRAMPS.

In times of the prevalence of smallpox the best efforts of the sanitary officers are nullified or baffled by the Wandering Willy and Dusty Rhoades of the community. The cities have in their low-browed cheap lodging houses, as well as the rural districts in their workhouses, a source of danger in the unvaccinated tramp that deserves especial attention. The jail, likewise, to which the dirty and homeless "rounder" gravitates two or three times in the smallpox season is another menace. The prison is ordinarily free from danger, it being the rule with nearly all wardens to compel all newcomers to go through the ordeal of vaccination. But in reference to the former places of temporary abiding of the homeless class, it is expedient that an official inspection for vaccination purposes be made once to thrice a week during epidemic crises. The following sensible observations, by DR. RICHARD H. LEWIS, in the *Bulletin* of the North Carolina Board of Health for January, are worthy the attention of all local sanitary officers:

"We have already called attention to the rapid spread of smallpox over the United States and sounded a note of warning. Since that time the disease has made its appearance in our own State—in Cherokee; but thanks to the prompt and vigorous action of the County Superintendent of Health looking to the quarantining of the patient he did not abide with us long. Rather than be quarantined he left the State, thereby demonstrating in a very practical and satisfactory manner the value to the community of an organized health department with

an alert health officer. Most fortunately also he came in contact with none except those who were protected by a previous attack of the disease, and we have good reason therefore to hope that he will not leave a trail behind him. There is no reason why a similar case should not crop out at other points in the State, particularly on the main lines of travel, which are now more than commonly infested with tramps. It is most unlikely to happen again that every one exposed is protected, and if not there is no telling, in view of the great number of unvaccinated persons to be found everywhere in the State, what a terrible scourge might then and there be originated. The danger is a real one, but how to get the people to realize it and avail themselves of the protection so easily obtainable is the question, and a most difficult question it is to answer. Most persons not acquainted with the temper of our people would say at once, Make vaccination compulsory. That sounds well, but it would be *vox et preterea nihil*. In the first place, in the opinion of the writer, our Legislature could not be induced to enact such a law; and if it could the law would, unsupported by public sentiment, be a dead letter. As to what public sentiment on this subject is the following will illustrate: At the conjoint session of the State Board of Health with the State Medical Society in Wilmington in 1892, one of our county superintendents reported that going to a public school house to vaccinate the children, according to a previous appointment, he found the house shut up and the entire school, teacher and all, taken to the woods. Again, more recently, an outbreak of the smallpox occurred in an adjoining State about fifty or sixty miles from one of our progressive towns. The Town Commissioners discussed the advisability of passing an ordinance making vaccinations compulsory. Whereupon certain citizens gave notice that they would remove from the town. Comment is unnecessary."

LICENSES MUST BE RECORDED IN ALABAMA.

The Supreme Court of Alabama holds, in the case of *Nicholson v. State*, decided Feb. 8, 1894, that the requirements of the Alabama Code, with regard to the recording of certificates, or "licenses," are mandatory and vital. It is provided that every certificate of qualification authorizing any person to practice medicine in that State, which shall be issued by any authorized board of medical examiners, shall be presented to the probate judge of the county in which such person resides, who shall officially indorse the same, seal it with the seal of the county, and cause it to be recorded in a book kept for the purpose. The very fact that no time is fixed to comply with these requirements, the court says, is a strong argument in support of the position that until they are complied with, the so-called "license" is waste paper conferring no right, perfect or inchoate. The language employed is equally positive and mandatory in respect of those requirements as in respect of the issuance of the certificate by the board of examiners, and there is as much room on the face of the statute, for holding the latter provision directory as the former. Until these things are done, the non-

inal licensee is as much without authority to practice medicine, or, as it was in this particular case where the question was raised, dentistry, as if the paper had never been issued to him. And upon familiar principles, there being not even an inchoate right to so practice until the statute has been complied with in the respects mentioned, such compliance can not relate back, and relieve the practitioner of the penal consequences of having previously engaged in the business.

CORRESPONDENCE.

LETTER FROM EUROPE.

Major Girard, Surgeon U. S. Army, to Professor Senn.
No. V.

THE INTERNATIONAL MEDICAL CONGRESS AT ROME.

ROME, ITALY, April 7, 1894.

Dear Dr. Senn:—When I promised you a letter from Rome, relating to the International Medical Congress, I did not realize the import of the promise. I had been at the International Congress at Copenhagen and found there no difficulty in following the work of one or two Sections; at least, made notes as the papers were read, and elaborated them at night, so that at the end of the Congress I had a fairly full report of the general sessions and of at least one Section ready for the press. I found matters quite different here, and have been obliged to postpone this letter to the end of the Congress in order to arrange my notes and collect material, when I could not be present in person.

I find that my account of this Congress can not be condensed into one letter, and will devote the first one to general considerations.

The Roman Executive Committee have had no easy task of it, and can not be held responsible for all of the many shortcomings of this Congress. It is evident that the attendance far exceeded their expectations and preparations, thus causing in the commencement great confusion. Over 7,000 physicians attended the Congress. A great majority of these were attracted to Italy by the reduced fares and the prospect of taking in the wonders of this land, while ostensibly attending the Congress. The first two or three days they felt in honor bound to visit the Sections to which they had attached themselves, without, however, earnestly becoming listeners. The result was a restless going in and out, causing such a continued noise that only the persons occupying the rows of seats nearest the speakers could follow the discourse. The place appointed for the general sessions accommodated only 300 persons, while the first two sessions were attended, not only by nearly all the members of the Congress, but by a large lay audience of Roman citizens. The jam occasioned by this enormous concourse can well be imagined. Soon, however, the sights of the great Italian metropolis proved a greater attraction than the scientific work and the Sections were but slimly attended, and the audience in the general sessions fell to about one-half of the capacity of the hall.

In his speech at the dinner given by Minister Baccelli after the third day of the Congress, Prof. Virchow characterized this change with satire. He reverted to the softening influence of Italy. Even Hannibal had lost the edge of his sword under the smiling skies of Capua. Thousands of physicians had wandered across the Alps with the earnest intention of devoting themselves to severe scientific work, but the irresistible amiability of Roman hospitality had

somewhat blunted the scientific zeal. He feared that the Congress would fare somewhat as Hannibal did in Capua.

There was another circumstance inimical to continued serious attention. The number of papers presented to the Congress was 2,700; of these more than one-half—perhaps three-fourths, were in the Italian language, which was understood by a small minority of the 3,000 foreigners. At first the papers were read regardless of the language, often compelling the majority of the audience to listen for hours to a tongue they did not understand. This naturally led to disappointment and indifferent attendance. In some of the Sections this was partly remedied by relegating the Italian papers to the latter part of the sessions, but the stream of favor had already been diverted to other channels and the attendance did not recuperate in numbers. Another great drawback was the distance of the Poli-clinico from the city. This building is a large hospital on the pavilion plan, completed, but not furnished in time for this Congress. While the first three days it was entirely inadequate for the vast attendance, it was very comfortable during the latter part of the Congress, but still its location caused a loss in transit of two hours a day, unless one took the slim chances of getting a luncheon in the restaurant established in the Administration building.

Now as to the papers presented. Either the reader of the proceedings, when once they are published, or the publishing committee, who will have to select the papers suitable for printing, will have a hard task of it to sift the wheat from the chaff. A general plan of subjects to be reported on and discussed, if such a one existed, was not followed, and if any particular subjects received more attention than others, they received it accidentally because they happened to be questions of the present fashion in medicine. At least 1,500 of the papers presented were of Italian origin. The majority of these papers could not be of any scientific value, as Italy, no more than any other country of equal size, has such a number of physicians capable or in position to manufacture mental food of quality sufficiently good to be worthy of presentation at an International Congress and preservation as a matter of record or a specimen of the progress in medical training.

I believe, therefore, that for immediate or remote scientific results this Congress is a failure, and that all international congresses, when the attendance can not be reduced to a conference of more select spirits, and when distractions can more than fill the week allotted to the meetings, will be equally barren, compared to the time and money devoted. Still, for all this, I would not condemn these gatherings as useless. We can always notice a nucleus of renowned men, who closely follow the work and, if they do not participate much in the discussions, they gather in what is worth keeping. Around these come in concentric layers the less distinguished, perhaps younger generations, who sooner or later advance to the inner layers.

In this manner, insensibly as it may seem, the men of similar caliber congregate, become acquainted, learn to gauge each other and their methods of investigation and reasoning. These little cliques, as we may call them are, however, limited by language, and when a congress is held in four languages, while but a very small part of the members have command of more than two, and the great majority of but one, as here, the congress ceases to be international as far as the scientific work is concerned.

I have prefaced this letter with general remarks, which properly belong to the epilogue, but deemed them of importance for a correct understanding of what may be said in the secular and medical press.

SOCIAL FEATURES OF THE CONGRESS.

As to the social amenities, of which, judging from the

above remarks, there must have been many, they are very creditable to Roman hospitality. When the fetes were general, with admission of a large concourse of invited residents, the arrangements were not sufficient to control and guide the multitudes assembled. Selected gatherings and dinner parties, however, were as exquisite as liberality and art could make them.

The festivities commenced with Sunday, on which various excursions to the Roman "Castelli" were arranged. I participated in one of the Military Section, to Tivoli, to visit the falls of the Arno, the Temple of Sibyl and the Villa d'Este, the country seat of Cardinal Hohenlohe, who had offered the use of the large castle for a luncheon to be given by the medical officers of the Italian Army to the medical officers of foreign armies, of which a large number were present; not less than sixty of the German Army. The Secretary of the Section, Dr. R. Livi, gave evidence of great organizing talent in this entertainment, as well as in others given by his Section; decorum was never lacking and the crush of other entertainments was avoided by personal attention to accommodation.

The same day a concert was given by the Mayor of Rome to the members of the Congress at the Constanza Theater. In the evening, Minister Baccelli, the President of the Congress, gave a magnificent dinner to the more distinguished members of the Congress, and to the official delegates of the several governments. I had the good fortune of being invited as delegate from the Army Medical Department.

One evening the vast ruins of the palaces of the Roman emperors on the Palatinum were illuminated with Bengal lights; several bands of music played during the evening; the King and his court were present on a special balcony; a powerful electric searchlight illuminated at a distance the thermes of Caracalla, the pyramid of Cestius, the aqueducts, the arches of Constantin, and of Titus, and the Coliseum, etc., the whole making a most splendid spectacle.

Another evening there was a reception in the museum of the Capitol—a most elegant gathering, but such a jam I have never witnessed. The Venus of the Capitol, generally acknowledged the best statue of the many Venuses of antiquity, was illuminated with rose-colored light and appeared life-like.

Tuesday afternoon the Queen of Italy gave a garden party at the Quirinal, to which a limited number of invitations were issued to distinguished members of the Congress and to delegates. Of the Romans, only those who were received at court were present. I was also among those fortunate. Presentations to the King and Queen, music by two fine bands, and luncheon served by the royal servants were the order of the day. The affair was very enjoyable.

The last day of the Congress was celebrated by the dinners of the several Sections. The one by the Section of Military Medicine and Surgery to which I was invited, was held at the Aquarium, a dome-shaped magnificent hall. Nearly every person of about 300 guests was dressed in full uniform with all their decorations. The United States Army uniform looked very plain among all these brilliant uniforms, but the spectacle was brilliant, the menu very good and the speeches in the various tongues cheering.

After the closing of the Congress a luncheon was given at the immense Roman baths, the thermes of Caracalla, at which 14,000 persons were present, with the jam usual on these general occasions.

A flower corso in the afternoon, at which over 3,000 carriages participated and a punch by the officers of the Italian Army, at their club, to the members of the Military Section, concluded the official festivities.

Numerous private balls, concerts and dinner parties were given during the Congress.

All the galleries and museums were open to the members of the Congress free of charge. It will be seen that it required an unusual sternness of purpose to steadily pursue the scientific work, and it will not be saying too much, if I assert that 90 per cent. of the members of the Congress fell more or less from grace.

A few words on the opening of the Congress and the organization of the Sections, and I will conclude this letter, hoping to find time during my return voyage to give you an extract of the scientific work.

The first day was the grand opening of the Congress, in presence of the King and Queen, their court, the foreign ambassadors and the members of the Congress at the Castanza Theater. The multitude present, inside and outside of the building, was enormous. The introductory address was made by Minister Crispi, followed by Baccelli, Ruspoli, Virchow, and others, upon which Maragliano, the Secretary-General made his report. This was followed by speeches of the representatives of the various nations, and presentations to the King and Queen. The Presidents of the nineteen Sections, all Italians, were announced and from the national committees of the visiting nations the following illustrious names were announced as Vice-Presidents: Virchow, Sir James Paget, Sir W. MacCormac, Stokes, Stockvis, Grainger Stewart, Kocher, etc., and last but not least, Jacobi of New York, for the United States.

The speakers at the general sessions to be held in the afternoon at 4 o'clock (or as the Italians say at 15 o'clock) were by Virchow, Brouardel, Babes, Foster, Nothnagel, Laache, Danilewsky, Bizzozero, Cujas, Kocher, Jacobi, and Stockvis. These sessions were held at the Eldorado, near de Hygienic Exposition, on the Via Nazionale, in the center of the city, while the sessions of the Sections were at the Poli-clinic, as mentioned above.

In the afternoon of the first day the Sections were organized; that of Surgery electing Durante of Rome, as President, with Spencer Wells, MacCormac, Stokes, Macewen, Konig, Mikulicz, Ollier, Péan, Championniere, Lorenz, Janny, Lavista, Rossandu, Kocher, Murphy as Honorary Presidents. The Section of Military Medicine and Surgery elected Cippalla as President, and as Honorary Presidents, among others, Col. J. R. Smith, Assistant Surgeon-General U. S. A., senior delegate from the War Department, and myself among the Honorary Secretaries.

The sessions of the Sections lasted from 8 to 12, and from 1 to 3, but soon the majority of the afternoon sessions were abandoned. A great haste was apparent, in order to get through the vast number of papers, and many of those who had announced theirs were anxious to present them, in order to follow the army of those who preferred sight-seeing to the scientific labors.

A. C. GIRARD.

What the General Practitioner Should Know About Diseases of the Eye.

CHICAGO, April, 1894.

Dr. T. A. Smith read a paper with the above title before the Tennessee State Medical Society, which was published in several medical journals. The object of Dr. Smith's paper was to define the minimum amount of knowledge the general practitioner should have before entering upon the practice of medicine. I took exceptions to his ideas in an article with the same title in this JOURNAL, Feb. 3, 1894. Dr. Smith replies to my criticism in an article in this JOURNAL of April 14, 1894.

In Dr. Smith's first article he says the general practitioner should not attempt to use the ophthalmoscope. On this statement I took decided issue with him, and in his article of February 14 he repeats his former statement. In my article of Feb. 3, 1894, I cited cases of glaucoma, cataract,

optic atrophy and albuminuric retinitis where the ophthalmoscope would have been very valuable in helping him make a diagnosis. In answer to the first and second, Dr. Smith says he does not need an ophthalmoscope. That any case of glaucoma can be easily diagnosed by the tension alone, as it does not require any great amount of skill if it is at all marked, and the ophthalmoscopic signs do not appear until late. The reference given below will show how misleading this is.

I do not maintain that the general practitioner should become an expert with the ophthalmoscope and tie his hands. Just because he can use the ophthalmoscope he need not be barred from using his fingers to test the tension. He might make a mistake were he to depend upon either alone. No doctor would ignore his stethoscope because he had a microscope and could examine sputum with it. If Dr. Smith's cases of glaucoma are all inflammatory, then he may get along nicely without an ophthalmoscope, but if he has, as others have, cases of glaucoma simplex and can make a diagnosis by the tension alone, I will give him the credit of having his sense of touch very highly developed.

Every one knows who does work in ophthalmology that we often see cases of glaucoma simplex where the tension is normal, or if it is elevated we can not detect it, and the patient has no pain or any symptom that would lead us to suspect glaucoma, except loss of vision. With such cases we use the ophthalmoscope or fail to find the trouble. If the specialist can not detect the tension I think it poor policy to advise the general practitioner to rely on it. To keep this from appearing as personal difference of opinion, I will quote a few works that are called good authority, *verbatim*:

Fuch's 1892, "Glaucoma Simplex," page 343: "In glaucoma simplex, the increase of tension sets in very gradually, so that no inflammatory phenomena are produced. The eye either looks quite normal externally, or it gives evidence of its lesion through the greater prominence of the disturbed anterior ciliary veins, and also through a somewhat dilated and sluggish state of the pupil. The tension of the eye is shown by palpation to be elevated, but not to any considerable degree. Often on the first examination no increase of tension is found at all; it is not until we examine the eye repeatedly, and especially at different times of the day, that we succeed in demonstrating that the tension is elevated. At these times a slight, smoky cloudiness of the cornea is also present, such as appertains to the prodromal attacks of inflammatory glaucoma. Finally, there are cases of glaucoma simplex in which the tension is never found distinctly increased; in consideration of the fact that in glaucoma simplex marked external symptoms, and sometimes indeed, any manifest increase of tension are wanting, and we are thrown back upon the ophthalmoscopic examination for the establishment of a diagnosis. Such an examination shows the presence of a total excavation of the optic nerve, the depth of which corresponds to the duration of the process."

Meyer, 1887, page 251: "Simple Glaucoma: In this variety of glaucoma the inflammatory symptoms are entirely absent, and the appearance of the eyeball does not materially differ from that of the normal eye. At most we may find, after some exciting cause, a slight pericorneal injection, and a slight turbidity of the aqueous humor, soon disappearing. In short, the patient does not complain of any pain, and the exterior of the eye preserves its natural appearance. It is often difficult in the early stages, and even throughout the disease, to decide by the sense of touch whether the eye be harder than usual. This is all the more difficult that the physiologic tension is subject to considerable variation. To the ophthalmoscope the media of the eye seem to be completely transparent; but we find the char-

acteristic excavation of the papilla and the arterial pulsations, which are either spontaneous, or easily produced by slight pressure of the fingers on the eye."

Noyes, 1890, page 506: "Patients often can give little account of the premonitory symptoms, although they have long existed. When well established it is often mistaken in old persons for senile cataract, especially because the lense in old age has a smoky hue. This explanation of failing sight is considered adequate, and a resort to skilled advice is discouraged. Under this mistake the patient is told to wait until the supposed cataract shall be ripe before going for relief, while the delay is simply affording time for the loss of all chances of recovery."

Page 509: "No dependence can be placed upon the external signs because the eye looks healthy, central vision may be normal or nearly so, and subjective symptoms are obscure or have been unheeded; tension may be doubtful. We are then confined to two symptoms, the appearance of the optic nerve and a careful scrutiny of the visual field."

(In Noyes work of 1894 the above is found, pages 551 and 554).

G. E. de Schweinitz, 1892, pages 373 and 374: "Chronic Glaucoma. This type of the disease is characterized by an absence of the signs of glaucoma in the anterior aspect of the eye, at least, on ordinary inspection. By careful examination a slight steaminess of the cornea may sometimes be detected, with a little lack of transparency in the aqueous humor. So, too, there may be some undue tortuosity of the perforating branches of the episcleral plexus. In general terms, however, there is an absence of congestive symptoms, and there is no pain. The tension of the eyeball is but slightly increased, and often it is difficult to decide whether it is increased at all. The media are clear, and the disease is detected with the ophthalmoscope by observing the characteristic cup in the nerve head, the halo surrounding it, and the spontaneous arterial pulse or its ready development by slight pressure." (The references I have given are copied word for word, so the general practitioner can see the weight of authority.)

No one will say a doctor ought not to take the tension of an eye, but why depend upon it and advise him not to attempt the use of an instrument that will assist him in making a diagnosis?

I am sure it would be better for the patients if the general practitioner knew how to use the ophthalmoscope, and infinitely better for the specialist, for then there would be found patients that needed a specialist much more often than there would if the general practitioner did not use the ophthalmoscope. Dr. Smith fails to say why the general practitioner should not use the ophthalmoscope in locomotor ataxia and albuminuric retinitis mentioned in my article. About 15 per cent. of the cases of posterior locomotor ataxia have atrophy of the optic nerves, and whenever we have atrophy it appears before the ataxic symptoms.

Dr. Smith in his first paper says the general practitioner should know when spectacles are supposed to be indicated. Let him use the ophthalmoscope and he would not have to suppose; *he would know*.

I would refer the general practitioner to Gower's work on medical ophthalmology to see the necessity for the use of the ophthalmoscope in functional nervous diseases, the main indications of which should be recognized by the general practitioner.

I do not write this article simply to get the last word, like two little boys quarreling, but for the good of the general practitioner, the patients that intrust their health and happiness to him and the specialist. The general practitioner, as a rule, does not use the ophthalmoscope, but it is unjust to him and his patients to advise him not to use an instrument costing so little, and of so much importance.

103 State Street.

W. A. FISHER, M.D.

Protection for Vaccinated Arms.

Mt. PLEASANT, IOWA, April 17, 1894.

To the Editor:—In our "Correspondence" of the JOURNAL, February 24, I hoped as a result of it to elicit some ideas, either suggestive or final, of value in the direction aimed; and perhaps also, that some one would bring up the subject for the same purpose next June, at the meeting of the AMERICAN MEDICAL ASSOCIATION. Of the former, there has been no result. Of the latter, it is yet too early to know what may be done.

Having myself concluded my opinion of the best plan of

protection to the vaccinated—the subject we have in consideration—I will advance it; and also as a reason for this second communication.

Cut two triangles out of any piece of cloth which may be at hand; a lesser triangle cut from the base of the first and larger triangle, and you have a V, the first letter of vaccine. Vaccination as a word is peculiar, in suggesting to the most illiterate that it begins with V, and V seen on the arm of a person is hence suggestive of *vaccinated*, and is at once a danger signal to the wearer. Railroads protect by signals their charges, and why should not the medical profession protect its vaccination train? Prophylaxis is considered by many to be the highest sphere in medicine; if this is so, is it not desirable to make it as perfect and complete as possible? Something cheap, simple, expeditious and efficient it seems to me is in this manner obtained. It is easy to make, easy to sew on (easier than a band), and no choice necessary (except, perhaps, to select the most conspicuous, if there is a choice), in selecting the kind of cloth.

Let us hope some one will present this subject to the ASSOCIATION, and something in this much needed direction be accomplished by the profession at its next National meeting.

Very truly,

H. L. GREEN, M.D.

Big Things.

To the Editor:—In a friendly chat with one of my medical friends, recently, I asked him why he did not take the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. His reply was as follows: "It is too full of *big things*." There is some truth in this assertion. The JOURNAL is often full of big things; my friend claims that the so-called expert and the specialist are allowed too much space in which to air themselves; that it requires too much effort upon the part of the country doctor to digest the "big things." He says the country doctor's time is better spent in reading a few practical *truths* than in trying to analyze a lengthy article on "Electro-anesthesia and Frequency of Induction Vibration;" "The Esoteric Beauty and Utility of the Microscope;" "Appendicitis with Original Report of One Hundred and Forty-one Histories and Laparatomies for that disease under Personal Observation." To the specialist these big things are really *big*, but to the average country practitioner they are too utterly too too. He has neither the time nor inclination to read these effusions, even if he had the ability to digest them. For the above reasons the country doctor will subscribe for a journal that deals in things not quite so big.

I take the JOURNAL because its contents are from the pens of the ablest men in the profession. (I write, occasionally, *myself*). But I never get on a high horse and try to say things that the reader can not possibly understand. I believe it was Josh Billings who pointed out the folly of learning too many things that were not so. Most of the *big things* in all the journals are examples of this kind of knowledge. I have often thought of writing an article on microbes; in fact did write a squib on the "Microbe of Drunkenness" and suggested the name of Cloridi of Dwightii or Goldii, I have forgotten now which, but it does not matter—*microbes* are *little things* and I am on another subject. But before I forget it, I will say that filth and vermin are often found together, therefore vermin are (or is) the cause of filth, or filth is the cause of vermin, I do not know which; but this is a very clear proof of the correctness of the germ theory. It is very plain to a man who understands it, but I don't understand it, you see.

The next "big thing" to which I call attention, is the nostrum vendor. This dare-devil worries me; every mail brings some of his diabolical literature or some of his infernal stuff, "all free gratis and for nothing." I will treat any doctor in the United States to a plug hat who will show me how to stop this fellow from writing me. One day he

tells me about tablets, the next about pills, the next about elixirs, and then comes the "Ines," "L—ine," "H—ine," "P—ine," "H—ine," "T—ine," "Y—ine," "M—ine," last but not least "B—ine," all of which are certainly *asinine*. If this monster can be killed off I would be glad to know it.

Kentucky has made a raid on him and I hope will rout him. Other States ought to follow suit. Recollect, I am not making war on the "Ines;" they are inoffensive *per se*.

What I object to is the knave who puts on the almanac attachments. "A—a" with its almanac attachment is no better (to me) than "Jayne's Expecto-rant." If a remedy will not sell without this attachment I'll never buy it. If quinin, morphin, opium, chloral, chloroform and calomel should be accompanied with an almanac attachment, together with all the lies that usually go with such, then they too would be stricken from my list of remedies. A remedy that will not sell on its own merits is like a doctor who depends upon a newspaper for his reputation. Neither one will do to trust (in my estimation). The genuine medicine needs no almanac attachment. The first class doctor never advertises. The nostrum vender is a big thing *as a nuisance* and ought to be abated. The advertising doctor belongs to the same category and if you will watch right close you will see these two fellows very close together. The newspaper doctor prescribes nostrums. "J—e," "O—n," "S—c," are favorites with him,—but I must close.

Respectfully yours,

W. P. HOWLE, M.D.

The Code and Railroad Corporations.

SAN DIEGO, CAL., April 16, 1894.

To the Editor:—I have hitherto refrained from discussing Code revision, though mentally applying to *some* of the diatribes forinst the dear old Magna Charta, that well-known couplet:

"No rogue e'er felt the halter draw
With good opinion of the law."

For more than thirty-five years I have associated it with the Decalogue and the Hippocratic oath, never realizing that either of them was particularly irksome, nor believing that all men could be induced to abide by them, however modernized. In elegance of diction and loftiness of sentiment I know of no instrument comparable with it. Its quaintness lends to it an additional charm, and I much fear if we begin to revise and amend it we shall leave nothing worthy the name. Perhaps a better solution of the problem would be to adopt the suggestion and the language of the poet as he saw vandals carrying off the good ship, *Constitution*, piecemeal. He wrote, as you remember,

"Ay, tear that tattered ensign down,
Long has it waved on high,
And many an eye has danced to see
That banner in the sky,
Nail to the mast that holy flag,
Set every threadbare sail,
And give her to the God of storms,
The lightning and the gale!"

But if the suggestion of the Committee, to drop the section covering the duties of the laity to our profession, shall prevail, I hope some equally good advice to railroad corporations will be substituted in its place. And this, in connection with Dr. Lichty's timely contribution to your April 7 issue, suggests a reminiscence, for which the indulgence of your readers is solicited.

In the spring of 1869, near Wasatch, on the U. P. Road, the writer was seated in one of five coaches that plunged down a thirty-foot embankment. Upon recovering his equilibrium he closed the door of a stove suspended above his head, to prevent a threatened conflagration, and walked out on the *ceiling* to a place of exit. Several persons were killed outright, among them the nephew of Chief of Police Crowley, of San Francisco, and many more sustained various injuries. For hours the doctor stood in the melting snow, treating all applicants until both of his pocket cases were exhausted, and possibly saving the Company thousands of dollars in the matter of suits for damages. Upon reaching home he was laid up for

three weeks with inflammatory rheumatism, caused by the fall and subsequent exposure, his business, meanwhile, suffering from neglect. The recital is not unique in the experience of our profession, as Dr. L. suggests, nor is the sequel. For he has never received the thanks, much less an honorarium, from the Company. Nor would the incident be recalled at this late date except to point the moral, that doctors, journeying as they annually do for the public weal, are entitled to something better than Midwinter Fair rates. Change the Code? No, but rather the consciences of men.

Faithfully yours,

C. M. FENN, A.M., M.D.

A Curlosum.

INDIANAPOLIS, April 21, 1894.

To the Editor:—Our Board of Health concluded to have a new pest-house.

Once on a morning, this month, our Mayor with his medical advisers and constables marched out, as in ancient times the burgomasters did, to burn the old pest-house. The old ground would become valuable and be sold at a price to purchase a new ground and to build a new house.

The foolish act was done with great dignity. But in the very afternoon a tramp marched in town with smallpox. Certainly the court house was vaccinated from the Mayor to the watch-dog, and so the station house. Then, with equal dignity, the whole city government sat down in a meeting: the Mayor, the Board of Public Safety, of Public Works, of Health and Charities, and all wise men of the town.

Whereas no bids for the old grounds had come in, it had been unanimously concluded to build new pest-houses on the same ground, but little ones, that the mistake may not appear too great.

Perhaps it is advisable to publish this incident as a warning.

G. B.

From Dr. Woodbridge.

YOUNGSTOWN, OHIO, April 20, 1894.

To the Editor:—I supposed that when I published my paper, "Can Typhoid Fever be Aborted," that I would immediately be buried under an avalanche of adverse criticism. It was, therefore, a great and very agreeable surprise when letters of commendation and inquiry began to pour in upon me from every part of the United States and Canada. I regret that I can not answer them, and at the same time (in addition to my other duties) prepare a paper for the San Francisco meeting. If the writers will excuse me until I return from the meeting of the AMERICAN MEDICAL ASSOCIATION I will employ a stenographer and will then take pleasure in answering, as far as I am able, every question.

Very respectfully,

JOHN ELIOT WOODBRIDGE.

Philadelphia County Medical Society.

To the Editor:—At a meeting of the Philadelphia County Medical Society held April 18, the following resolutions were adopted:

WHEREAS, The Code of Ethics of the AMERICAN MEDICAL ASSOCIATION declares it derogatory to professional character for a physician to dispense or in any way promote the use of a secret nostrum; and the AMERICAN MEDICAL ASSOCIATION by a resolution unanimously adopted at its meeting in 1892 forbade the advertising of such nostrums in its JOURNAL; and

WHEREAS, The JOURNAL of the ASSOCIATION has continued to advertise such nostrums and in defense of its course in this particular has published an anonymous personal attack on a member of the AMERICAN MEDICAL ASSOCIATION and of this Society;

Resolved, That the Philadelphia Medical Society respectfully demands that the Trustees of the JOURNAL shall in their public official acts, respect the spirit and the letter o

its Code of Ethics; and that the columns of its JOURNAL shall not be used for the anonymous personal abuse of its members in good standing.

Resolved, That a copy of these resolutions be transmitted to the Medical Society of the State of Pennsylvania; and to the AMERICAN MEDICAL ASSOCIATION; and to the weekly medical journals.

T. B. SCHNEIDEMAN, Secretary.

PUBLIC HEALTH.

Smallpox.—Except in Chicago, smallpox is fast losing its importance as a factor in the public health situation. The disease seems to have attained its maximum spread about the middle of March, when a total of 219 infection centers had been reported in twenty States and the Dominion of Canada. At the beginning of the present week there were reported as still remaining fifty-five infected points in the following States: Massachusetts, Connecticut, New York, Pennsylvania, Indiana, Illinois, Wisconsin, Minnesota and Iowa.

The lodging-houses continue to give some trouble in New York city, nearly all the recent cases being found in these unsanitary premises. Another inspection of them was recently begun, this time at night so as to secure the vaccination of all inmates. An occasional walking-case still turns up in the city public offices, and a clerk in an office on the ground floor of the City Hall was recently taken to the pest-house. The building has been again disinfected and all occupants and employes from the Mayor down to the scrub-women, have been again vaccinated or re-vaccinated. The disease, which was declared epidemic in Brooklyn in March, had almost entirely disappeared in that city during the early part of the present month. April 4, for the first time, in several months, no new cases were reported. There was however, a recrudescence of the outbreaks soon thereafter and the work of inspection and vaccination is still being vigorously prosecuted. Infected and suspected premises are rigidly quarantined, in one case fourteen whole blocks of buildings being in charge of a corps of vaccinators and disinfectors, protected by the reserves of five police stations, and the entire population of about 5,000 were vaccinated in a single night. Elsewhere in the State, tramps conveyed the disease into the Wayne County poor-house, April 1; into the police station at Syracuse, April 8; and into the county jail at Schenectady March 18, where the character of the case was not discovered until April 6 by which time six other cases had developed.

The arrival at New York of two of the Netherlands line of steamers with smallpox on board caused the Health Officer of the port to notify the Company that its vessels will not be allowed to enter, unless their crews have been vaccinated before clearing from Rotterdam, and to request the United States Consul at that place not to give clearances for New York to these steamers unless this provision is carried out and the passengers and crews are disinfected before the vessels sail.

In Pennsylvania there were reported fifty-nine cases in the State, all but two of which had been directly traced to Danville, where, as previously noted, the disease was declared epidemic March 23. Advices from Dr. Benjamin Lee, Secretary of the State Board of Health, announce that smallpox has disappeared from Tyrone Forges, Reading, Williamsport and Wilkesburg.

Dr. C. N. Hewitt, Secretary and Executive Officer of the Minnesota State Board of Health, reports that State free from smallpox except the cases in St. Paul, where there have been two infected houses—some half dozen cases in a suburban hotel, from which there has been no spread, and one case in a house in the city itself; this latter case was

that of a young woman in a private family, origin unknown and no connection with the first outbreak. "There is no likelihood of any spread from either of these cases."

Dr. Scott, Secretary of the Illinois State Board of Health, in his report to the Board at its meeting on the 24th inst., refers to the remark of his predecessor, Dr. Reilly, at the January, 1892, meeting of the Board, to the effect that Illinois was then in greater danger of a smallpox epidemic than of one of Asiatic cholera; and urging that, while proper precautions should be taken against the latter disease, the renewal of the vaccinal protection of the State was of even greater importance. To the work then begun, and since vigorously continued, he attributes the fact that, notwithstanding the infection has been carried into twenty-two points in the State, either by tramps or others from Chicago—in only one instance has there been any spread beyond the family or premises first infected, while in the majority of instances there has been only a single case. The exceptional instance is at a manufacturing suburb of Chicago, where three families have been infected. At the date of the report there were eleven infected points, with seventeen cases remaining, outside of Chicago. In Chicago from January 1 to April 21 there were 962 cases, apportioned among the several months as follows: January, 128; February, 233; March, 305; April (to the 21st), 296. The average for the first twenty-one days of April was 14 cases a day, and at this rate the total for April will be 420 cases, an increase of 30 per cent. over the previous month. Infection centers are widely distributed, cases having been discovered during the last week in twenty-one of the thirty-four wards of the city. The resources of the health department have been overtaxed; the smallpox hospital crowded beyond its limits, so that cases are now retained at their own homes. At the close of the week there were some sixty cases being treated at houses in twelve different wards in every division of the city, the majority, however, in the west division in the group of wards opposite the business district. There were twenty-six infection centers in the tenth ward alone—one of this group.

The municipal authorities have at last awakened to the gravity of the situation; the Health Department, crippled hitherto by want of funds, has been given *carte blanche* as to expenditures; a second 100-bed extension of the smallpox hospital is under way; an adequate ambulance service is provided; the city has been districted and each district is in charge of a qualified physician with unlimited authority as to men and measures necessary for the prompt suppression of the epidemic; inspectors are stationed at all railway stations and the house-to-house inspection is being repeated—this time by competent physicians,—the former inspections by policemen having proved worthless. In concluding his report, Dr. Scott adds:

"Meanwhile the wholesale vaccination begun by Health Commissioner Reynolds last year is being vigorously pushed, and it is upon this work that the greatest reliance is to be placed. More public vaccinations have been performed in the city of Chicago within the last few months than among any other equal number of people probably in the world, and if the work is continued it is only a question of time when the epidemic will die out for want of material."

Asiatic Cholera.—Recent reports of the westward spread of Asiatic cholera in Europe are by no means reassuring. It has been reported successively in Turkey, Poland, Belgium and Portugal—late cable dispatches announcing sixty-five new cases in Lisbon on the 22d, and 104 more, with three deaths, on the 23d. Spain has established quarantine along the frontier and has also dispatched a medical man to Lisbon with instructions to report the progress of the epidemic direct to Madrid—the Portuguese Government having suppressed information by wire. Inspector General Proust reported to the Council of Public Hygiene of Paris, three cases of the disease at Liege, Belgium, during the last week of March, but the fact was not made public until April 19. The disease has continued to spread in Constantinople, among its recent victims in the higher classes being the Director-General of the Tobacco Monopoly. The situation is being made the occasion of urgent appeals in the columns of the secular press for a rigid enforcement of the precautionary measures adopted by the recent International Sanitary Conference in Paris. These measures embrace a system of medical inspection and disinfection of

pilgrims for Mecca before embarkation, and also of the vessels upon which they are to be carried; each vessel is to have a qualified physician, is to be supplied with a *per capita* allowance of good drinking water, etc., and is to furnish a given amount of space for each person on board. The Turkish lazarettos are to be reorganized on the plans laid down by the Conference at the Venice and Dresden sessions. Most important are the measures to be enforced with the returning pilgrims; it is their filthy and often diseased condition, due to their mode of life in the "holy city," that constitutes the menace to public health, and which has so often been the means of importing cholera into Egypt, Algeria, Tunis, Bosnia and thence to the rest of the world. Strict sanitary measures are to be enforced with them, especially at the lazaretto in the Turkish dependency of El Thor in Arabia Petrea on the east shore of the Gulf of Suez, and the Sultan is urged to thoroughly reorganize his sanitary administration—a recommendation which it is believed, in view of the special mission already dispatched to the Yemen under Assaf Pasha, will receive prompt attention.

Quarantining Chicago.—Conferences of neighboring State health officers have been held at Chicago with a view of determining the necessity of instituting quarantine measures against the deportation of smallpox from the city. The impracticability of such measures seems to have been conceded after investigation by Secretary Probst of Ohio, Metcalf of Indiana, Scott of Illinois, Reeve of Wisconsin and Hewitt of Minnesota. Nevertheless Dr. Hoyt, Health Officer of St Paul, has asked the Mayor of that city to take steps to establish a quarantine against Chicago. The Mayor does not believe the situation warrants such action at the present time.

Tramps and the Public Health.—In the majority of the 219 smallpox centers thus far reported, the origin of the infection has been directly traced to tramps. It has been repeatedly urged that every municipality should have a standing order that, before giving shelter or other assistance to one of these gentry, he should be examined as to his vaccinal status and if this is not satisfactory, he should be vaccinated forthwith. The tramp is a serious menace to the public health in many ways, but, in respect to the propagation of variola, he may readily be made innocuous.

Fighting Vaccination.—Suits to prevent the enforcement of school vaccination orders are growing in frequency. In addition to those already reported in New York, Pennsylvania, Indiana and Illinois, similar proceedings have been begun in Connecticut, at New Britain, and at Beloit in Wisconsin. At the latter place the State Board of Health is defending the school board, and will probably be called upon to do the same for other boards in that State.

Coxey and Preventive Medicine.—Some of the divisions of "Gen." Coxey's army of "commonwealers" have submitted *en masse* to vaccination. This has been made a condition by some communities to the supply of provisions and shelter. If the precedent should be generally followed the cause of preventive medicine, so far as smallpox is concerned, would be a large gainer by "Gen." Coxey's "petition on foot."

BOOK NOTICES.

An American Text-Book of the Diseases of Children; including special chapters on essential surgical subjects. by American teachers. Edited by LOUIS STARR, M.D., assisted by THOMSON S. WESTCOTT, M.D. Philadelphia: W. B. Saunders. 1894. Pp. 1190. For sale by subscription only.

This elaborate text-book has been written by a syndicate of sixty-three authors, of whom about fifty are directly connected with a medical college. This practically insures the sale of the work to the medical students at the institutions where the "American teachers" teach. The steady increase in this manner of medical book producing, has some advan-

tages, but it is, in the long run fatal to individual authorship. It is true that the "text-book" being an exhibit of the current information, and therefore of temporary value, is better adapted to syndicate writing than most other books but the practice is of very doubtful utility to the profession.

The work is encyclopedic in scope and after the introduction is divided into thirteen parts, as follows: 1, "Injuries to birth and diseases of the new-born; 2, "The Diathetic Diseases;" 3, "The Acute Infectious Diseases;" 4, "General Diseases not Infectious;" 5, "Diseases of the Blood;" 6, "Diseases of the Digestive Organs;" 7, "Diseases of the Nervous System;" 8, "Diseases of the Respiratory System;" 9, "Diseases of the Heart;" 10, "Diseases of the Genito-Urinary System;" 11, "Diseases of the Skin;" 12, "Diseases of the Ear;" 13, "Diseases of the Eye."

The book is well printed, and the illustrations are excellent, some of them colored plates in the best style of the art. The prescriptions are all written in the old English system of weights and measures instead of the modern decimal system. The unusually copious index adds much to its value as a work of reference. While there is less weight given to antiseptic therapeutics in the treatment of the different diseases than one would expect, taking into consideration the existing state of bacteriological science as set forth in the pathological portions, yet the treatment fairly represents the current practice. In pathology the work is abreast of the most recent accepted facts. As a whole the book is highly creditable in every respect to American authorship, and a worthy companion to the other "text-books" of the series.

A Text-Book on Diseases of the Eye. By HENRY D. NOYES, A.M., M.D. Complete in one octavo volume of 816 pages, profusely illustrated with 269 wood-engravings in the text, five chromo-lithographic plates, and ten plates in black and colors. Second Revised Edition. Price, in cloth, \$6.00; leather, \$7.00. New York: William Wood & Company.

That the first edition of this work has been exhausted in three years, is the best of proof that the author has succeeded well in his endeavor to furnish the American medical student a good practical text-book on ophthalmology. In the revised edition the general arrangement has not been changed; but many additions have been made in order to embody in the book the more recent discoveries and well-established views in ophthalmology.

It deserves particular mention that the subject of eye-strain and its important relation to the nervous system is a great deal more thoroughly treated than in the first edition. The chapter on granular conjunctivitis has been partly re-written, and in its new form is one of the best expositions of the various phases of this complex malady. All through the book the great care and good judgment of the author is noticeable in the selection of additional reading matter. It is, therefore, much to be regretted that the author has not bestowed the same attention on a careful revision of the phraseology in order to expunge the many inaccurate statements and ambiguous phrases which occurred in the first edition. For instance, on page 89 we read: "Then sol. sulph. atropia, gr. iv ad ʒj, will be dropped into the eyes from three to ten times within one to three days." How are we to interpret these directions? Shall the drops be used three or ten times each day, or three to ten times in all?

On page 206 *loss of sight of the one eye* is mentioned as one of the conditions which influence the capacity of fusion of the separate retinal images! How can the patient have double images if one eye is blind?

In the treatment of ophthalmia neonatorum on page 324 the following instruction is given: "If the daily personal attendance of the physician is not possible, a solution (gr. v ad. ʒi) of silver nitrate may be dropped between the lids

three times daily, taking pains to insure its entrance beneath the upper lid by lifting it off the globe and at the same time avoiding contact of the caustic with the cornea." This is very bad advice in every respect; it is bad enough indirectly to admit that a physician could not see a case of ophthalmia neonatorum every day; but it is worse to let anybody use nitrate of silver solutions on the eyes under so critical conditions; and it is absurd to insist that the caustic shall not come in contact with the cornea when it is allowed to spread all over the conjunctiva of the upper lid. That is asking for a physical impossibility.

In a work intended to be a guide for students and physicians, accuracy and clearness in the expression of views is of the greatest importance; any ambiguity which puzzles the student's understanding of the author's meaning, mars the usefulness of a text-book. If in the next edition which undoubtedly soon will become necessary, these defects are removed, this work will be the perfect text-book on ophthalmology.

Gonorrhoea: Being the Translation of *Blenorrhoea of the Sexual Organs and its Complications.* By Dr. ERNEST FINGER, Docent at the University of Vienna. One volume, of 330 pages, octavo, illustrated by numerous wood-engravings, and by seven chromo-lithographic plates. Third Revised and Enlarged Edition. Bound in muslin, gold lettered, \$3.00. New York: William Wood & Company.

The author in this edition has given a statement of the advances which have been made since the appearance of the second edition. The author says in his preface: "The possibility of more ready culture of the gonococcus and greater precision in the question of mixed infections, constitute important achievements. On the other hand, I have been able, through the great kindness of Prof. Weichselbaum, to make the first systematic anatomic examinations of chronic urethritis. These points form the principal changes and additions to be found in the present edition."

This work is one of the most systematic in any language on this disease. The chapter on its history is especially interesting, and the author gives a *résumé* of the subject from the earliest mention in the Mosaic writings down to those of the recent bacteriologists. This portion of the book is marred by some errors in spelling, due to bad proof reading; as "Rhages" instead of Rhazes; "Abulcasem" instead of Albucasis or Albucasem (page 3); "Guido de Cauliac" instead of Guy de Chauliac. (It is only fair to say that the Latin spelling was "Guidon de Caulhiaco.") But these are minor errors. The work is well worthy of a place in the library of every progressive physician and surgeon.

Transactions of the Southern Surgical and Gynecological Association. Vol VI. Sixth Session, held at New Orleans, La., November, 1893. Published by the Association. 1894.

This JOURNAL published a fairly complete abstract of the proceedings of this flourishing Association shortly after the meeting; several of the papers have been printed in the JOURNAL and elsewhere.

The papers are specially noticeable for their practical character. Many physicians of highest standing in America, without regard to the line of Mason and Dixon, were among the contributors.

The paper of the most enduring value is that by L. S. McMurtry on "Ephraim McDowell." Dr. McMurtry, long a resident of Danville, Ky., the theater of McDowell's great pioneer work, has gathered in this paper all the local information obtainable, in addition to the published records of McDowell and his operative work.

The high class of the papers in this volume, the excellent typography, and the careful editing by the Secretary, Dr. W. E. B. Davis, make it fully equal to its predecessors, and a credit to the Society. The next meeting will be held at Charleston, S. C.

ASSOCIATION NEWS.

Section on Ophthalmology.—Members of the Section who have not yet forwarded the titles of their papers will confer a favor by sending the same to the Secretary.

Preliminary program: Address by Chairman of Section.

"A Clinical Study of the Myopic Eye—Its Genesis and Treatment," Dr. S. D. Risley, Philadelphia, Pa.

"Asthenopia," Dr. C. M. Hobby, Iowa City, Iowa.

"The Physiological Basis of certain Oculo-muscular Phenomena, incorrectly termed Anomalies," Dr. F. B. Eaton, Portland, Oregon.

"The Value of Retinoscopy as the Crucial test of the Correction of Refraction Errors," Dr. B. Alexander Randall, Philadelphia, Pa.

"Toxic Amblyopia," Dr. James A. Lydston, Chicago, Ill.

"Amblyopia," Dr. A. H. Voorhees, San Francisco, Cal.

"Are Low Degree Lenses of purely Mythical Value?" Dr. H. M. Starkey, Chicago, Ill.

"Great Value of Weak Lenses in the Correction of Eye Pains," Dr. Julian J. Chisholm, Baltimore, Md.

"Sub-conjunctival Injections in the Treatment of Eye Diseases," Dr. Wm. E. Briggs, Sacramento, Cal.

"Fractures of the Orbit," Dr. J. F. Fulton, St. Paul, Minn.

"Cyclophoria—Its Detection and Treatment," Dr. George H. Price, Nashville, Tenn.

"Status of Skiascopy," Dr. H. V. Würdemann, Milwaukee, Wis.

"School Children's Eyes—A Plea for the Examination of every Child's Eyes when commencing to attend School," Dr. W. F. Southard, San Francisco, Cal.

"Iritis and its Treatment," Dr. Louis F. Love, Philadelphia, Pa.

"Some Observations upon Gould's Method of Managing Exophoria," Dr. Leartus Conner, Detroit, Mich.

"Conservative Treatment of Injuries of the Eyeball, with Cases," Dr. Lewis H. Taylor, Wilkesbarre, Pa.

"Treatment of Purulent Ophthalmia," Dr. X. C. Scott, Cleveland, Ohio.

"Retinitis Pigmentosa," Dr. Dudley S. Reynolds, Louisville Ky.

"The Visual Zone of the Dioptric Media and its Study by Skiascopy," Dr. Edward Jackson, Philadelphia.

Report of the Committee on "The Value of Objective Tests for the Determination of Ametropia, Ophthalmoscopy, Ophthalmometry and Skiascopy," Dr. Edward Jackson, Chairman, Philadelphia, Pa.

ALBERT R. BAKER, M.D., Chairman,
122 Euclid Ave., Cleveland, Ohio.

LEWIS H. TAYLOR, M.D., Secretary,
41 S. Franklin St., Wilkesbarre, Pa.

Section on Dental and Oral Surgery.—The following papers are announced for this Section:

Address, by Dr. M. H. Fletcher.

"Professional Ethics," by Dr. Van Orden.

"The Lateral Incisor," by Dr. C. L. Goddard.

"The Teeth of our School Children—What shall be done to save Them?" by Dr. Jno. C. McCoy.

"Pyorrhæa Alveolaris." What it is and what the Dentist can do for it," by Dr. L. L. Dunbar.

"Pyorrhæa Alveolaris," by Dr. W. J. Younger.

"Remote Effects of Oral Lesions," by Dr. W. B. Sherman.

"The Systemic Factor in the Treatment of Dental Caries," by Dr. G. S. Dean.

"The Present and Future Status of the Dental Practitioner," by Dr. J. D. Hodgen.

"Operations on Congenital Cleft Palate," by Dr. Robert McLane.

"Random Thoughts on our Specialty," by Dr. A. E. Baldwin.

"Pathological Notes on Neoplasms of the Maxillæ, with Cases and Photographs," by Dr. Vida A. Latham.

"The Present Scientific Status of Hypnotism," by Dr. W. X. Sudduth.

Dr. R. J. Taft.

Dr. E. S. Talbot.

SOCIETY NEWS.

The Cleveland Medical Society.—Dr. William Pepper, of the University of Pennsylvania, will address the Cleveland Medical Society Friday evening, June 22, and will also give

a clinic on the following forenoon in one of the hospitals in the city, to which the profession generally will be invited.

OSCAR T. THOMAS, Secretary.

The Indiana Medical Society.—The forty-fifth annual meeting of the Indiana State Medical Society will occur in Indianapolis, Thursday and Friday, May 17 and 18, 1894. The sessions will be held in Plymouth Church, southeast corner of Meridian and New York Streets. The meeting will be called to order promptly at 10 o'clock Thursday morning, May 17. The program this year promises to be a valuable one, and it is earnestly desired that there be a large attendance at the meeting. Arrangements have been made with the Central Traffic Association whereby the usual one and one-third railroad rate may be secured by those desiring to attend the meeting. In securing railway tickets, full fare will be paid to Indianapolis, the purchaser at the same time requesting his ticket agent to furnish him with a certificate of such purchase. This will be signed at Indianapolis by the Chairman of the Committee on Arrangements, which will entitle the holder to a return ticket at one-third the regular fare. Failure to obtain a certificate will necessitate the payment of full fare both ways. Good hotel accommodations can be secured in Indianapolis for \$1.50 per day and upwards. All members expecting to present papers at this meeting must send the titles of such papers to the Chairman of the Committee on Arrangements not later than April 30.

FREDERICK C. WOODBURN,

Chairman of the Committee on Arrangements.

National Association of Railway Surgeons.—The following is the preliminary program of the seventh annual meeting of the National Association of Railway Surgeons, to be held in Harmony Hall, Galveston, Tex., May 8, 9, 10 and 11, 1894.

OFFICERS OF THE ASSOCIATION.

President: Surgeon W. J. Galbraith, Omaha, Neb.

Vice-Presidents: Surgeons E. R. Lewis, Kansas City, Mo.; Thomas H. Manley, New York, N. Y.; E. F. Yansey, Sedalia, Mo.; D. F. Stuart, Houston, Tex.; E. A. McGannon, Brockville, Ont., Can.; E. G. Cochran, Greenville, Tex.; W. R. Blakeslee, Forest City, Pa.

Secretary: J. M. Dinnen, Fort Wayne, Ind.

Assistant Secretary: J. H. Ford, Wabash, Ind.

Treasurer: R. Harvey Reed, Columbus, Ohio.

Executive Committee: Surgeons B. F. Wilson, Chairman, Slater, Mo.; J. B. Murdoch, Pittsburg, Pa.; G. L. Hoege, Fostoria, Ohio; Alexander J. Mullen, Jr., Michigan City, Ind.; J. B. Murphy, Chicago, Ill.; A. A. Thompson, Waxahatchie, Tex.; C. K. Cole, Helena, Mont.

Committee of Arrangements: Surgeons C. H. Wilkinson, Chairman, Galveston, Tex.; D. F. Stuart, Houston, Tex.; T. F. Wagley, Cleburne, Tex.; A. A. Thompson, Waxahatchie, Tex.; C. C. Barrell, Galveston, Tex.

Committee on Transportation: Surgeons W. B. Outten, Chairman, St. Louis, Mo.; J. B. Murdoch, Pittsburg, Pa.; C. M. Daniels, Buffalo, N. Y.; Mr. Harry P. Robinson, Chicago, Ill.

ORDER OF EXERCISES.

Tuesday, May 8—Morning Session—10 A.M.

Opening of the seventh annual meeting. Surgeon C. H. Wilkinson, Chairman Committee of Arrangements.

Divine invocation.

Address of welcome, by his honor, the Mayor of Galveston.

Address of welcome in behalf of the citizens.

Response to the address of welcome. Dr. Alexander J. Mullen, Jr., Michigan City, Ind.

Delivery of the gavel to the President. Chairman Committee of Arrangements.

President's address. Dr. W. J. Galbraith, chief surgeon U. P. Railroad, Omaha, Neb.

Annual report of the Treasurer.

Tuesday, May 8—Afternoon Session—2 P.M.

Contributions to the study of fractures:

a, "Conservatism in the Treatment of Compound Comminuted Fractures of the Leg," by Dr. Geo. R. Dean, Surgeon R. & D. Railroad, Spartansburg, S. C.; b, "Compound Fractures," by Dr. Milton Jay, Chief Surgeon C. & E. I. Railroad, Chicago, Ill.; c, "Plaster-paris Splints to Fractures Simple

and Compound," by Dr. J. G. Buchanan, Surgeon Pennsylvania Company, Pittsburg, Pa.

Contribution to the study of anesthetics:

a, "Anesthesia (local and general) and its Proper Production," by Dr. E. A. McGannon, Surgeon G. T. Railroad, Brockville, Ont., Can.

Wednesday, May 9—Morning Session—9 A.M.

Contributions to the study of spinal and nervous injuries:

a, "Fracture and Dislocation of the Spine," by Dr. Thomas H. Manley, Surgeon C. P. E. & W. Railroad, New York, N. Y.; b, "Diagnosis of Injuries of the Cord and its Envelopes with and without Fracture of the Spine," by Dr. C. H. Hughes, Surgeon Mo. Pac. Railroad, St. Louis, Mo.; c, "Treatment of Injuries of the Cord and its Envelopes with and without Fracture of the Spine," by Dr. W. B. Outten, Chief Surgeon Mo. Pac. Railroad, St. Louis, Mo.; d, "Medico-Legal Relations of Injuries of the Cord and its Envelopes, with and without Fracture of the Spine," by Clark Bell, Esq., Member Bar, New York, N. Y.

Contributions on miscellaneous subjects:

a, "Some of the Uses of Hot Water in Recent Injuries in Railway Surgery," by Dr. N. A. Drake, Surgeon C. R. I. & P. Railroad, Kansas City, Mo.; b, "Minor Surgery," by Dr. J. D. Myers, Surgeon C. & O. Railroad, Huntington, W. Va.

Wednesday, May 9—Afternoon Session—2 P.M.

Contributions to the study of injuries of the eye:

a, "Color Blindness," by Dr. D. Emmett Welsh, Surgeon G. R. & I. Railroad, Grand Rapids, Mich.; b, "Exhibition of New Tests for Simulated Blindness in One Eye," by Dr. James L. Minor, Oculist K. C. M. & B. Railroad, Memphis, Tenn.; c, "Evisceration vs. Enucleation, following Injuries of the Eye," by Dr. A. E. Prince, Surgeon Wabash Railroad, Springfield, Ill.

Contributions to the study of miscellaneous subjects:

a, "Rectal and Anal Surgery and its Relation to Railway Injuries," by Dr. S. G. Gant, Surgeon K. C. Ft. S. & M. Railroad, Kansas City, Mo.; b, "Should the National Association of Railway Surgeons become a Delegatory Body," by Dr. R. Harvey Reed, Consulting Surgeon B. & O. and Big Four Railways, Columbus, Ohio; c, "Quarantine and its Relation to the Railway Surgeon and Railway Surgeons Relation to Quarantine," by Dr. Van B. Thornton, Local Surgeon H. & T. C. Railroad, Hempstead, Texas.

Thursday, May 10—Morning Session—9 A.M.

Contributions to the study of spinal and nervous injuries:

a, "Litigation Psychosis," by Dr. Matthew D. Field, Surgeon Manhattan Railway Company, New York, N. Y.; b, "A Case that ought to have been one of Railway Spine and its Treatment," by Dr. C. M. Woodward, Surgeon C. M. & J. Railroad, Tecumseh, Mich.; c, "A Novel Case of Cerebral Traumatism," by Dr. J. R. Barnett, Surgeon C. & N.-W. Railroad, Neenah, Wis.; d, "A Case of Fracture of the Spine; operation followed by improvement," by Dr. John E. Sylvester, Surgeon C. H. V. & T. Railroad, McArthur, Ohio.

Contributions on miscellaneous subjects:

a, "The Evolution of Railway Surgery," by Dr. E. R. Lewis, Surgeon Wabash Railroad, Kansas City, Mo.; b, "Dressing of the Stump in Amputation," by Dr. A. B. Brumbaugh, Surgeon Pennsylvania Railroad, Huntington, Pa.; c, "Railways and Railway Surgery," by Clark Bell, Esq., New York, N. Y.

Thursday, May 10—Afternoon Session—2 P.M.

Contributions to improvements in appliances in cases of emergency:

a, "Improved Railway Stretcher," by Dr. R. Ortega, Chief Surgeon M. I. Railroad, Ciudad Porfirio Diaz, Mex.

Contributions on miscellaneous subjects:

a, "Thiersch's Grafts in Extensive Destruction of Soft Parts about Large Joints," by Dr. Henry W. Coe, Surgeon East Side Railroad, Portland, Ore.; b, "A Digest of 400 Consecutive Railway Cases," by Dr. Howard J. Williams, Surgeon Central Railway of Georgia, Macon, Ga.; c, "Management of Burns and Scalds, with Cases," Dr. C. K. Cole, Chief Surgeon Montana Central Railroad, Helena, Mont.

Contributions to the study of spinal and nervous injuries:

a, "A Case of Spinal Injury with Rupture of Intestine; operation; recovery," by Dr. I. N. Warren, Chief Surgeon S. C. & N. Railroad, Sioux City, Iowa; b, "Concussion," by Dr. Geo. W. Cox, Surgeon S. P. Railroad, Brownsville, Ore.

Friday, May 11—Morning Session—9 A.M.

Contributions to the study of shock:

a, "Shock—its Phenomenal Results," by Dr. Willis M. Wilson, Surgeon B. & M. R. Railroad, Curtis, Neb.; b, "Clinical Cases—Shock, Hemorrhage, Tendon, Suture," by Dr.

John Van Duyn, Surgeon West Shore Railroad, Syracuse, N. Y.; c, "Treatment of Shock," Dr. James H. Letcher, Chief Surgeon O. V. Railroad, Henderson, Ky.

Installation of officers etc.

Friday, May 11, 3 p.m. Excursions on the bay; excursion down the island; excursions over to mainland. All members and accompanying members of their families invited.

Saturday, May 12—7 A.M.

Excursion to Houston, Austin, San Antonio. Through the courtesy of the management of the Houston & Texas Central, Gulf Colorado & Santa Fe, International & Great Northern and Southern Pacific Railways an excursion has been arranged and will be conducted under the auspices of Dr. D. F. Stuart, Chief Surgeon of the H. & T. C. Railroad and Dr. W. B. Outten, Chairman Committee on Transportation, and Dr. C. H. Wilkinson, Chairman Committee of Arrangements. Receipts for the annual dues for next year will be accepted for the transportation of members and their families on this excursion, the same as last year.

W. J. GALDRAITH, M.D., President.

C. H. WILKINSON, M.D.,

Chairman Committee of Arrangements.

J. M. DINNEN, M.D., Secretary.

Nebraska State Medical Society.—The twenty-sixth annual meeting of the Nebraska State Medical Society will be held in the chapel of the State University buildings, Lincoln, Nebraska, May 1, 2 and 3, 1894.

Officers: President, A. S. Von Mansfelde, Ashland; Vice-Presidents, B. F. Crummer, Omaha, Geo. L. Humphreys, Kearney; Secretary, George Wilkinson, Omaha; Corresponding Secretary, B. D. Davis, McCook; Treasurer, W. M. Knapp, Lincoln; Committee of Arrangements, F. D. Crim, H. B. Lowry, M. H. Everett, Lincoln.

Call to order; payment of dues; report of the Committee on Credentials and election of new members; reading of the minutes; report of the Committee of Arrangements.

President's address: "The Constitution and Code of the AMERICAN MEDICAL ASSOCIATION—Individual and Society Relations Thereto."

Annual reports of a, Secretary; b, Corresponding Secretary; c, Treasurer. Business requiring early consideration; report of the Special Committee on Sanitary Science; report of the Special Committee on Medical Legislation; report of Committee on Grievances; report of Committee on Neurology; miscellaneous.

Practice of Medicine: "The Diagnosis of Valvular Disease of the Heart," Dr. H. B. Lowry, Lincoln. Discussion, Dr. A. R. Mitchell, Lincoln; Dr. E. M. Whitten, Nebraska City.

Surgery: "Some Observations on Tuberculosis of the Osseous System," Dr. J. P. Lord, Omaha. Discussion, Dr. J. S. Butler, Superior; Dr. G. L. Humphreys, Kearney.

Obstetrics: "The Responsibility of the Obstetrician from a Gynecological Point of View," Dr. Sherman Van Ness, Omaha. Discussion, Dr. P. L. Hall, Mead.

Gynecology: "Endometritis, Pathology and Treatment," Mrs. M. H. Jonas, Omaha. Discussion, Dr. F. D. Crim, Lincoln; Mrs. E. S. Daily, Omaha.

Nervous and Mental Diseases: "The advancement of the Care and Treatment of the Insane," Mrs. Sophronia N. Lane, Asylum. Discussion, Dr. S. C. Spalding, Omaha; Dr. G. W. Johnston, Fairmont.

Anatomy and Physiology: "The Anatomy of the Reflexes with their Interpretation in Rectal and Genito-Urinary Diseases," Dr. Charles Allison, Omaha. Discussion, Dr. A. R. Mitchell, Lincoln; Dr. F. E. Coulter, Omaha.

Ophthalmology and Otolaryngology: "Optic Neuritis following La Grippe," Dr. D. C. Bryant, Omaha. Discussion, Dr. J. W. Bullard, Pawnee City; Dr. W. L. Dayton, Lincoln.

Materia Medica and Therapeutics: "The Therapy of the Respiratory Tract," Dr. W. H. Christie, Omaha. Discussion, Dr. E. M. Whitten, Nebraska City; Dr. W. B. Ely, Ainsworth.

Medical Jurisprudence, Medical Chemistry and Toxicology: 1, "Medico-Legal Aspects of the Social Evil." 2, "On the Legal Responsibility of the Physician upon Whose Certificate a Sane Person is Committed to an Insane Asylum," Dr. M. V. B. Clark, Sutton. Discussion, Dr. Chas. L. Kerr, Falls City; Dr. Claud Watson, Nebraska City.

Pathology and Histology: "Etiological Factors that Cause Pathological Changes," Dr. Wm. Protzman, Lincoln.

Discussion, Dr. George H. Littlefield, Syracuse; Dr. W. F. Milroy, Omaha.

Public Hygiene and Medical Legislation: "The Medical Law of Nebraska and its Enforcement," Dr. J. V. Beghtol, Friend. Discussion, Dr. B. F. Crummer, Omaha; Dr. F. D. Haldeman, Ord.

Dermatology: "Eczema," Dr. E. E. Womersley, Omaha. Discussion, Dr. W. O. Henry, Omaha; Dr. A. B. Anderson, Pawnee City.

Laryngology: "Adenoid Vegetation with Illustrative Cases," Dr. F. S. Owen, Omaha. Discussion, Drs. H. S. Burrell and George Wilkinson, Omaha.

"The Treatment of Asthma," Dr. J. Lue Sutherland, Grand Island.

"Lessons from a Few Surgical Cases," Dr. W. O. Henry, Omaha.

"Ulceration of the Stomach," Dr. F. E. Coulter, Omaha.

"The Conservative Treatment of Pelvic Disease in the Female," Dr. B. F. Crummer, Omaha.

"The Surgical Treatment of Large Vascular Nervi," Dr. A. F. Jonas, Omaha.

"Brief Thoughts on Surgical Methods in General Practice," Dr. M. L. Hildreth, Lyons.

"Memoranda—The Course and Diagnosis of Acquired Syphilis," Dr. H. Clayton Sumney, Omaha.

"Remarks upon Recent Aids to the Diagnosis and Treatment of Diseases of the Bladder, Ureters and Kidneys in the Female," Dr. J. E. Summers, Jr., Omaha.

"Three Functions of the Liver Normally and Pathologically Considered," Dr. J. S. Foote, Omaha.

"Legislation for the Prevention of Blindness," Dr. H. Gifford, Omaha.

"Detection of Sugar in the Urine," Dr. F. Martin Mueller, Omaha.

Report of Standing Committees; miscellaneous and unfinished business; election and installation of officers; selection of next place of meeting; banquet, Thursday evening.

The following constitutional amendments will need attention at this meeting: Amendment to Constitution, Article II, Sec. 2, by Dr. J. E. Summers, Jr.:

"That any legally qualified practitioner shall be eligible for membership in this Society, whatsoever his source of education, provided that he or she proclaims in writing adherence to no particular dogma or line of practice other than rational medicine."

Amendment to By-laws by Dr. A. S. von Mansfelde. Add at the end of No. 2:

"Except the Committee on Credentials which shall be composed of one member from each Congressional District and the Recording Secretary, who shall be ex-officio chairman of such Committee."

Transportation—All of the railroad companies have granted a reduction in rates—one and one-third fare for the round trip—on the certificate plan. Take certificate from ticket agents from whom tickets are purchased in going to the meeting. Have it countersigned by the Secretary, which will secure a return ticket at one-third fare.

GEORGE WILKINSON, Sec'y.

MISCELLANY.

Medical Director Albert L. Gihon, U. S. Navy, delivered the address at the commencement of the Albany Medical College on the 18th instant.

Dr. M. L. James, of Richmond, Va., has retired from the professorship of Practice of Medicine of the Medical College of Virginia.

The Graham Matter of the Brain.—"Do you vegetarians claim that the use of unbolted flour bread is good for brain-workers?"

"Certainly. It stimulates the production of graham matter."—*Chicago Tribune*.

Dr. Corydon L. Ford, whose death was announced in the *JOURNAL* of April 21, left an estate estimated at \$250,000. His will bequeathed \$9,000 to the University of Michigan, the income to be used to purchase books for the general library and \$3,000 to the Students' Christian Association. The remainder of the estate is to be distributed among his relatives and certain specified religious and missionary associations of the Congregational denomination.

Honorary Presidents International Medical Congress.—The International Medical Congress has appointed its Honorary Presidents for the ensuing Congress in Russia. The list is as follows: For America, Dr. J. B. Murphy, of Chicago; for Germany, Bergman, of Berlin; for Switzerland, Kocher, of Berne; for Ireland, Stokes, of Dublin; for England and Great Britain, Sir William MacCormac; for Austria, Mikulicz, of Vienna; for Scotland, Macewen, of Glasgow. Dr. J. B. Murphy, of Chicago, the American Honorary President, is well known to the profession through his work in abdominal surgery and the success of the intestinal anastomosis button, of which he is the inventor.

The D. Hayes Agnew Memorial.—The D. Hayes Agnew Memorial Committee, organized a year ago to secure a lasting memorial of Dr. Agnew in connection with the University Hospital, have pleasure in reporting that subscriptions have been promised of sufficient amount to give reasonable assurance of the speedy and successful carrying out of the project. The plan includes not only the Children's Ward (for the building of which this Associate Committee was established and for which it is so earnestly laboring), but also an amphitheater and ward class rooms, with wards for men and for women,—the whole to be a model in perfection of details and completeness of appliances, and thus a fitting representation of the wonderfully full and complete work of Dr. Agnew.

The State Legislature, at its last session, made an appropriation of \$80,000 to the University Hospital for building purposes, provided that an equal sum of \$80,000 be raised by the friends of the Hospital, and paid in cash, available for construction purposes. The Managers of the Hospital, appreciating the eminent propriety of our movement, have consented to give to the entire wing the honored name of D. Hayes Agnew. Toward the additional \$80,000 to be so raised, about \$60,000 can now be counted upon as available in cash on or before May 1, 1894, leaving only about \$20,000 more to be secured by that time, so that building operations may begin this spring, and the State appropriation be drawn and expended within the two years contemplated in the Act.

It is to be hoped that, in addition to the building fund, there may also be secured a sum sufficient for the beginning of an endowment. Such a memorial will best attest the affection inspired by Dr. Agnew's life of usefulness and the example of devotion to his profession both as teacher and practitioner.

The grant by the Legislature is a recognition of the work done by the University and its Hospital, to which Dr. Agnew gave the best years of his busy life, and the subscription supplementing and securing that appropriation will show how his many friends, patients, and students honor his memory.

All those who desire to join in this memorial of a great surgeon and good man can do so by sending their subscriptions to the Treasurer, Mr. Eugene Delano, of Messrs. Brown Brothers, at the banking house, southeast corner of Fourth and Chestnut Streets, Philadelphia.

By order of the Committee,

J. S. MACINTOSH, D.D., Chairman,

J. G. ROSENGARTEN, Secretary,

WM. PEPPER, M.D., Provost of the University.

Resignation of Prof. Wm. Pepper as Provost of the University of Pennsylvania.—The following is the text of the letter of Prof. Pepper:

With deep thankfulness I recognize that the University has reached a stage of development and prosperity which justifies me in laying down the high office you intrusted to me more than thirteen years ago, and which I have held as long as it was possible to combine the administrative labors of Provost with the demands of medical teaching and practice. This time has now passed, and I beg, therefore, to tender my resignation to take effect after the coming Commencement.

The close of the current session will witness the completion of the formative period of the University. From a group of disconnected schools there has been gradually

organized a great academic body, complete in its unity and instinct with varied yet harmonious activities. Mutual confidence and coöperation have developed a system strong enough for effective central control, yet so flexible as to admit affiliation with many separate organizations. To our University is due the credit of establishing university extension in America, yet the important and successful society which controls this movement has no organic relations with the University, save that the Provost is *ex officio* the honorary president. The Wistar Institute of Anatomy and Biology, a magnificent memorial to the founder of American anatomy, has a separate charter and is not owned by the University, yet is governed by a board, the majority of whose members are appointed by yourselves. The University Hospital, which has grown so prosperously, is a special trust and administered by a board of twenty-two members, only four of whom are appointed by the Trustees of the University.

The Department of Archæology and Paleontology, under whose energetic operations there is developing rapidly a museum of high rank, is governed by a board of not less than thirty-six members, of whom only six are appointed by the Trustees of the University. Reference is made to these familiar instances to illustrate the admirable results which may develop under a system which excludes rigid control, and rests upon mutual confidence and a common devotion to a great cause.

It has been a chief aim of your Board to demonstrate to the people of this great Commonwealth that the University is truly the voluntary association of all persons and of all agencies who wish to unite in work for the elevation of society by the pursuit and diffusion of knowledge and truth. No less important has been the establishment of the principle that the University, so far from being a private and exclusive corporation, is essentially and organically a part of the municipality. The large future of the University was secured when, in 1872 and in 1883, City Councils voted, without a dissenting voice, the transfer to the University of splendid tracts of ground, in consideration of the establishment in perpetuity of fifty free beds in the Hospital for the poor of Philadelphia, and of fifty prize scholarships in the College, to be awarded to graduates of the public schools of Philadelphia. The subsequent accessions of territory which have brought the domain of the University up to fifty-two acres, in a compact body in the center of the city, have been the logical consequences of these great steps; and so faithfully have all the trusts and conditions been executed, that it has come to be recognized by the municipal authorities that it is more profitable to the city to give freely to the University anything in its power to bestow, which is needed for the development of that institution, than to dispose of it elsewhere, even at a great price. It needs only the resolute continuance of this wise policy to secure for the University full recognition as a branch of the city government, with a duly accredited representative of its great constituency in her Councils.

Progress has also been made toward the establishment of the essential principle that the University is in right, and should be in fact, the head of the educational system of the entire Commonwealth. We may fairly claim to have done much toward securing a recognition of the view that the encouragement of higher education, by the municipality and the Legislature, is as proper and important in the older communities of America as it has been decided to be in the newer States.

"While the unification of the University and the establishment of broad lines of policy may seem to be the most important work of the past thirteen years, it will be found that the resources of the University and the educational work in each department have been successfully promoted. In 1881 its property was fifteen acres, while at present there are owned or controlled by the University, in a continuous tract and solely for educational purposes not less than fifty-two acres. The values of the lands, buildings and endowment in 1881 may be estimated at \$1,600,000; it is now over \$5,000,000. Prior to the date of the late John Henry Towne's great bequest, the University had never received a single large gift or legacy. During the current year ending Sept. 1, 1894, there will be acquired in lands, buildings, money and subscriptions not less than \$1,000,000. The members of the teaching force in 1881 numbered 88, and the students in all departments 981; at this time the former are 268 and the attendance has reached 2,180, representing every State of the Union and no less than thirty-eight foreign countries. The College Department has attained a national distinction, and its complete re-organization, which has now been

accomplished successfully, gives sure promise of sound and rapid progress. The Medical School has been advanced to preëminence in equipment and prosperity, while plans now maturing will place it abreast of the great schools of Europe. The Law School has effected the prolongation and elevation of its curriculum, and has deservedly won national repute. Encouraging progress has been made toward providing an admirable building on an approved site, so that the future eminence of the school is assured. Gratifying reports may be made of the position of the Dental and Veterinary Departments; and well considered plans for their still further development need only time for their fulfillment. Upon this vigorous basis rests the Department of Philosophy, which although organized as late as 1884, and still without special endowment, has already 154 students. It represents the University in its highest and best intellectual life; it affords inspiration to teachers and students; it has enabled us to extend the richest privileges of the University to women on equal terms with men; it points the way to large endowment of rich research and advanced scholarship."

The necessity of dormitories to the development of the best university life has come to be clearly recognized by your Board, and generous friends stand ready to supply this important need.

It is pleasant, in these days of strength and prosperity, to reflect upon those of doubt and struggle, when ridicule met the assertion, the truth of which is now freely conceded, that nowhere can a great university be developed so favorably as in a great city.

In closing my term of service as Provost, I may be permitted to allude to the motives which impel me to this step. The labor of these thirteen years has been so severe, in connection with my professional duties in the Medical School and with the extensive medical practice necessary to provide the funds which have enabled me to initiate nearly all of the large movements undertaken during this time, that I have often felt that my life was specially preserved for the work. It has, however, been growing evident for several years past that the time was approaching when the immense extent of the University interests would demand the undivided activity of the most energetic man. It has now become necessary for me to choose between administrative work and medical science, and my devotion to the latter has determined the choice.

No official has ever been associated with more affectionate and indulgent colleagues, or has enjoyed more loyal coöperation than has been extended to me. I am confident that the choice of my successor will be wisely and promptly made. I do not leave the service of the University, but will remain, with more free hands, ready to serve her every interest with utmost devotion.

I invoke upon your continued labors in the government of this grand institution the richest blessings of Almighty God, who has in the past so signally guarded it.

April 23, 1894.

WILLIAM PEPPER.

THE PUBLIC SERVICE.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from April 14, 1894, to April 20, 1894.

Capt. OGDEN RAFFERTY, Asst. Surgeon, leave of absence granted is extended eighteen days.

Capt. ALONZO R. CHAPIN, Asst. Surgeon, will report in person to the President of the Army Retiring Board at Ft. Bliss, Texas, for examination by the Board. By direction of the President.

First Lieut. CHARLES WILLCOX, Asst. Surgeon, is relieved from temporary duty at Angel Island, Cal., and will rejoin his proper station, the Presidio of San Francisco, Cal.

First Lieut. HARLAN E. MCVAY, Asst. Surgeon, par. 2, S. O. 68, A. G. O., is so amended as to direct him, on being relieved from duty at San Carlos, Ariz., by First Lieut. STRAUB, Asst. Surgeon, to report for duty at Angel Island, Cal., instead of Ft. Huachuca, Ariz.

First Lieut. ALLEN M. SMITH, Asst. Surgeon, will be relieved from duty at Ft. Custer, Mont., at the expiration of his present leave of absence, and will report in person to the commanding officer, Ft. Reno, Oklahoma Ter., for duty at that post.

First Lieut. JAMES M. KENNEDY, Asst. Surgeon, is relieved from duty at Ft. Riley, Kan., and ordered to Ft. Custer, Mont., for duty.

Major PETER J. A. CLEARY, Surgeon, so much of par. 13, S. O. 79, A. G. O., as relates to him, is so amended as to direct him, on being relieved from duty at Ft. McPherson, Ga., to report for duty at Ft. Wingate, N. M., instead of Ft. Custer, Mont., for duty at that post, to relieve Major WASHINGTON MATTHEWS, Surgeon. Major MATTHEWS, on being so relieved, will report to Washington, D. C., and report in person to the Surgeon-General for temporary duty.

PROMOTION.

Capt. JAMES C. MERRILL, Asst. Surgeon, to be Surgeon with the rank of Major, March 13, 1894, vice BARTHOLF, retired from active service.

ORIGINAL ARTICLES.

THE MEDICAL HISTORY OF CHRISTOPHER COLUMBUS, AND THE PART TAKEN BY THE MEDICAL PROFESSION IN THE DISCOVERY OF AMERICA.

Read by the Author before the Section on General Medicine of the First Pan-American Medical Congress, Washington, D. C., Sept. 7, 1893.

[Published simultaneously in the Spanish language.]

BY A. M. FERNANDEZ DE YBARRA, M.D.

NEW YORK.

Corresponding Member of the Spanish Medico-Chirurgical Academy of Madrid, Spain; the Argentine Medical Circle of Buenos Ayres, South America, and the Society for Clinical Studies, of Havana, Cuba; Official Delegate of the Medico-Legal Society of New York to the First Medical Congress of the Island of Cuba; Executive Assistant Secretary-General of the First Pan-American Medical Congress.

"*Amicus Plato, sed magis amica veritas.*"—ARISTOTLE.

One of the most important events in the history of humanity, and perhaps second only to the birth of Christ in beneficial results, is without any species of doubt the discovery of America by the Spaniards under the leadership of Christopher Columbus. A number of times willing and unwilling visitors certainly did come before that date from the Old World to the New. In the fifth century of the Christian era, a few Buddhist missionary priests came, either directly from China to a country which they called Fusang, and known to us now as Mexico, or they first, and most probably, settled in Japan and afterwards crossed from there to the Pacific coast of America; the voyages of the Northmen in the tenth and eleventh centuries, the traditional narratives of which tell us of the deeds of the daring sailor, Eric the Red, and the discovery of Helluland, Markland, and Vinland by his famous son, Leif Ericsson; the story of the Venetian brothers, Nicolo and Antonio Zeno, the first wrecked in 1390 upon one of the Faroe Islands, his subsequent visit to Greenland and return, and the second embarking on an unsuccessful voyage of discovery in the Atlantic Ocean, about the year 1400, to verify some fishermen's reports of the existence of land a thousand miles or more to the west from the Faroe Islands; the old and often repeated rumors concerning the fancied Island of St. Brandan, which several Portuguese and Spanish captains imagined they had beheld beyond Madeira; the seemingly-truthful statement in regard to the Spanish pilot, Alonzo Sanchez de Huelva, who, sailing in 1484 (which should be 1474) "one year more or less," from the Canaries to Madeira, had been tempest-tossed by violent easterly winds upon an unknown island (the Island of Hispaniola or San Domingo), where he landed, took an altitude, and wrote an account of all he saw, and all that had occurred in the voyage; he succeeded in returning, arrived at Terceira (one of the Azores) sick and worn out, and soon after died, leaving

Columbus, who had hospitably received him in his house and nursed him, heir to his papers.

All these, and more, pre-Columbian voyages, legendary reports and fanciful descriptions of America are completely divested of true historical importance, and did not contribute a mite to our geographical knowledge or to the betterment of mankind. To speak of them as to implicate, in any sense whatsoever, that they constitute a *discovery* of America is perfectly absurd. To expatiate about them with the mental reservation of robbing Columbus of his well-earned title of discoverer of the New World is the height of folly. In 1492 the American continent was to a certain degree as unknown to the rest of the world as the nebulous inhabitants of the planet Mars are to us to-day.

On the present four hundredth anniversary of that paramount event in history, almost all classes and conditions of men have endeavored to bring forth their representatives who, in some way or another, had anything to do with it. Mariners are still singing the wonderful skill and intrepidity of their seafaring companions of the fifteenth and sixteenth centuries. The military have spoken of their famous captains, and with minute details referred to their heroic feats and glorious conquests, not always wise or even right. The clergy have told us of the first American bishops, large numbers of pious and lion-hearted missionaries, and the numberless martyrs sacrificed in our luxuriant forests. Politicians have pointed out the many examples of good, indifferent, bad, and very bad rulers, together with chieftains and leaders totally destitute of diplomatic tact. Lawyers have shown who were at that time eminent legislators, and put on record the notable judicial contests arising in consequence of the discovery of America. Physicians only have remained silent in this universal revival, when we, as a class, contributed very largely to the realization of the constant dream of a great genius, thought then by almost every one but a distinguished Italian physician and a modest Spanish village doctor to be merely a madman.

If modern anthropological science can justly boast of having made clear the intimate relations existing between the shape, volume, and minute structure of the internal organs of man and his outward manifestations, both physical and psychical, it is evident that in speaking of such a profoundly important historical figure as Christopher Columbus, an humble attempt to examine his personal appearance, temperament, physical ailments, and the cause of his untimely death may greatly help a more accurate appreciation of his mental characteristics and moral nature.

First, as to the date of his birth. This is a *vexata questio* which it would be out of my power in the limits of this short paper to discuss. Washington Irving, relying upon the evidence of Andrés Bernaldez,

an historiographer and intimate friend of Columbus, states it to be about 1435 or 1436. Don Fernando, the Admiral's second son and his most faithful biographer, relates that in a letter written by his father to the King and Queen of Spain, dated 1501, he declares that he had then been forty years at sea, and in another letter that he was fourteen years old when he first went to sea; so that allowing a year either way for probable inattention to circumstantial details, we get the date of his birth, fixed by his own hand, at about 1447. If we take into consideration that he did not go to sea during his seven years of patient waiting in Spain,—from 1485 when for the second time he entered that country from Portugal, to 1492 when he set sail westward on the Sea of Darkness—we must then acknowledge that in referring in 1501 to his being forty years at sea, he did not probably reckon the time spent in surmounting the difficulties encountered at the court of Ferdinand and Isabella. This would bring us to 1440 as the date of his birth; but if we make a calm and philosophical analysis of the expression, "being forty years at sea," from a sailor who had the year before arrived, a prisoner in fetters, poor, sickly and dejected, from his third voyage across an unknown ocean, and bearing in mind his former unequivocal statement that he had "followed the sea for twenty-three years without being on shore any space of time worth accounting," in which period he had been to and fro upon the Mediterranean, the Grecian Archipelago, France, Flanders, the coast of Guinea, the Canary Islands, Madeira, Porto Santo, the Azores, Cape Verde Islands, England, Ireland, Iceland, and sailed a hundred leagues beyond this "Ultima Thule" of Ptolemy, we will be forced to admit that that phrase only means a sailor of forty years' experience, the same as any old professor, architect, lawyer, or physician might express himself in like circumstances regardless of the few years spent in traveling, sickness, or some temporary occupation.

The place of his birth was the city of Genoa.

From the accounts of his personal appearance given by his son Fernando, Las Casas, Andrés Bernaldez, Pietro Martire d'Anghiera, the Portuguese historian João de Barros, Agostino Giustiniani, Antonio Gallo and others who knew him well, I gather that Columbus was a man of commanding presence, tall and well built, with fair ruddy complexion somewhat freckled, oval face with rather prominent cheek bones, broad and high forehead, medium-size mouth, aquiline nose, grayish-blue eyes, very light reddish hair and beard prematurely turned gray. He was of a genial disposition, courteous and graceful, his conversation agreeable and interesting to such a point that strangers were quickly attracted and felt at ease. An indefinable air of dignified command surrounded him, and the magnetism of his noble soul was perceptible in the tender glance of his glowing eyes, when his religious enthusiasm was kindled by the divine spark of genius that abided in him. Of a great nervous susceptibility, his mind was highly imaginative and poetical. Naturally religious, he was temperate in eating and drinking and puritanical in his habits.

My search for particulars regarding the life of Columbus prior to his arrival in Portugal is far from satisfactory. From the period of his first going to sea, which was about 1460, until the year some biographers say his vessel was burned near

the Portuguese coast not far from the city of Lisbon, nowhere in history have I met with a distinct mention of his name. We have positive evidence, however, that in 1472 he was in the city of Savona, Italy, from the fact of his signature being appended as witness to the will of one Nicolo Monleone, under date of March 20 of that year. It appears very probable that in 1469 he took part, under the command of a French vice-admiral of the name of Caseneuve, in a successful sea fight to capture several Dutch ships returning from the herring fishery in the Baltic. We find him afterward in a terrible naval engagement between Lisbon and Cape St. Vincent, trying to take possession of four richly laden Venetian galleys on their return from Flanders, the desperate struggle lasting from morning till evening, the hand grenades and other burning missiles used in the battle caused at last a general conflagration among the vessels, which having been lashed together with iron grappings, could not be separated, and the crews were compelled to leap into the water to escape the fire. Columbus' son, Fernando, goes on to say that "his father, who was a good swimmer, finding himself at the distance of two leagues from land, seized an oar, and by its aid succeeded in reaching the shore." It was close at hand to Lisbon, where he went and there made his abode. This happened in the year 1470 or early in 1471, and in 1473 he married the Portuguese lady, Philippa Moniz de Perestrelo, and went to live with her at Porto Santo, a small island on the Atlantic Ocean, twenty-five miles northeast of Madeira. There his son Diego was born in 1474.

The subject of the medical history of Columbus is a barren one, so barren indeed that it has never before been touched upon. I asked the present Duke of Veragua, and such living sterling biographers of the illustrious Genoese navigator as Mr. Henry Harris, Mr. José M. Asensio y Toledo, Professors John Fiske and C. K. Adams, Mr. Justin Winsor and Mr. Cesareo Fernandez Duro, and they all answered me that they did not know of anybody who had investigated the medical aspect of the life of Columbus. I consulted the librarians of the Smithsonian Institution at Washington, Lenox and Astor Libraries of New York and the Public Library of the City of Boston; I searched carefully all the old standard historical authorities, but mighty little did I find, and here it is embodied. I must, however, acknowledge my indebtedness to a recent monograph of Dr. Calatraveno, of Madrid, Spain, for many things I say in this paper about the part taken by the medical profession in the discovery of America. Nearly a year of constant inquiry and exploration in this unproductive field has resulted in what I venture to call my contribution to this first Columbian Pan-American assemblage of scientific men.

The piratical character of the seafaring life of Columbus' time, and the peculiar construction of the vessels, necessarily exposed its followers to unceasing hardships, privation and many unavoidable dangers to health. The severity of this early manner of living in a man of such a well-marked sanguine temperament as that of the immortal sailor must have very insidiously tended to undermine his naturally strong constitution, after "being at sea twenty-three years without remaining on shore any space of time worth accounting," and render him liable, at the age of 46 years, to the ailments and sicknesses he

subsequently suffered during his four voyages of discovery to America; to which must be added the grief, disappointment, mental anxiety and moral depression he endured, altogether combining in the production of the chronic disease that put an end to his imperishable career at a comparatively premature period of life.

Regarding hereditary predisposition to disease, I may safely say he had none. His father died at an extreme old age (in 1496 or 1498) and his mother a few years before. He was the eldest of five children, four boys and a girl, and not one of the others showed hereditary taint. His parents belonged to the healthy, sound, hearty and frugal types of the Ligurian peasantry.

On Friday, August 3, 1492, Columbus sailed westward from the little seaport of Palos de Moguer, Spain, to plough the Sea of Darkness in quest of a New World. On Friday, October 12 of the same year, he discovered America, and also on Friday, March 15, 1493, he dropped anchor, back from his mission, at the same little harbor of Palos. He spent 225 days in this first round trip to the Western hemisphere, in which time I have found no record whatever of his having suffered any sickness, except casual references to "sore eyes." This slight and transitory ocular affection which he often experienced afterwards, I consider to have been probably due to blepharitis, or styes, or to granular ophthalmia, brought on by straining the eyes in search of land in a diaphanous atmosphere where the sun's rays of light are most intense. Perhaps the Admiral's leaning toward albinism also contributed to it. His excellent eyesight at night seems to lend weight to this opinion of mine.

He undoubtedly suffered great anxiety, tribulation and mental anguish when the crews began to murmur, and finally became openly impatient and mutinous at not finding land; but this prejudicial moral effect on his health must have been entirely extinguished by the joy, satisfaction and pride of having succeeded in his stupendous enterprise. The two shabby tricks of Martin Alonzo Pinzon, captain of the caravel *Pinta*—by far the best sailer of the three—when on the 20th of November, sailing along the coast of beautiful Cuba, he treacherously deserted his chief, and on the 12th of February he surreptitiously abandoned him again to bring the news of the discovery home first, must have also caused Columbus no little pain and dejection.

He put to sea again, on his second voyage of discovery, from Cadiz, Sept. 25, 1493; this time with a fleet of three galleons or carracks and fourteen caravels, carrying 1,500 people on board, instead of the 120 who accompanied him in his former unparalleled hazardous cruise.

This large number of men—among whom were many aristocratic young fellows, daring, supercilious, irascible and obstinate hidalgos, left without occupation at the end of the war with the Moors—were placed under the medical care of Dr. Diego Alvarez Chanca, a distinguished practitioner of great reputation of the city of Seville, who was also Physician-in-Ordinary to the King and Queen of Spain, and had attended their firstborn, Princess Isabella (who afterwards became Queen of Portugal), during her serious illness the year before. Speaking of him in a memorial addressed to Ferdinand and Isabella, dated Jan. 30, 1494, Columbus wrote: "You will

inform their Highnesses of the continual labor that Dr. Chanca has undergone, from the prodigious number of sick and the scarcity of provisions; and that, in spite of all this, he exhibits the greatest zeal and benevolence in everything that relates to his profession. As their Highnesses have intrusted me with the charge of fixing the salary that is to be paid to him while out here (although it is certain that he neither receives, nor can receive anything from any one, and does not receive anything from his position equal to what he did receive and could still get if he were in Spain, where he lived peaceably and at ease, in a very different style from what he does here), I have, nevertheless, not ventured to place to the credit of his account more than fifty thousand maravedis (about \$725) per annum, as the sum which he is to receive for yearly labor during the time of his stay in this country."

The letter or report of this learned and magnanimous man to the Chapter of Seville, from which I quote two passages further on, is the first scientific monograph written about America, and worthy of careful perusal.

On the 27th of November the fleet arrived in the harbor of La Navidad, in the Island of San Domingo, and found the little fortress completely destroyed, and each and every one of the thirty-eight men left there on the first voyage had been massacred by the native Indians. Columbus caused to be built a neat little town, to which the name of Isabella was given, and remained in this island until April 24, 1494, when he put to sea again and discovered Jamaica (May 3), and visited Cuba for the third time; returning from there he passed by all the southern coast of Jamaica and Hispaniola, and discovered the little islands of Beata, Saona and Mona.

The day after leaving this last island, in the passage between San Domingo and Porto Rico (Sept. 25, 1494), worn out with the toil and hardships of a five months' cruise among people who, though very kind and generous, could not afford him the relief and comfort he so much needed, and in which time his incessant watching, nervous excitement and high hopes of finding large quantities of gold and spices had sustained him wonderfully, the inevitable reaction at last overtook him, and his whole system suddenly collapsed. "He lay in a stupor, knowing little, remembering nothing, his eyes dim and vitality oozing, until the little fleet sorrowfully, but gladly entered the harbor of Isabella." Columbus himself acknowledges that for thirty-three days he had slept next to nothing, when he began to feel very tired and fell into a lethargical state which almost deprived him of his life. He remained sick very nearly five months, under the care of Dr. Chanca.

In the early part of April of that year he had been seized with intermittent fever at Isabella, where the same principles of heat, humidity, porosity of the soil, and presence of decaying vegetable matter which gave an extraordinary fecundity to the uncultivated fields, worked havoc among the Spaniards. Many of them are also said to have suffered at La Vega under the torments of a disease called "the scourge" (syphilis?), the origin of which, whether American or European or Asiatic, has been a subject of great dispute for over three centuries. Dr. Chanca, in his letter to the Chapter of Seville, expresses himself on the situation thus: "One-third of our people have fallen sick within the last four or five days, which I think

has principally arisen from the toil and privations of the journey, and another cause has been the variability of the climate." In another place he says: "The Admiral had at one time determined to leave the search for the mines until he had first dispatched the ships which were to return to Spain on account of the great sickness which had prevailed among the men." Does he refer here to venereal diseases? I incline to the affirmative, but in the sense of gonorrhoeal and not syphilitic diseases. Concerning his first statement that one-third of the colonists had fallen sick in four or five days, I firmly believe it was due to the bad quality of the provisions brought from Spain, and to malarial infection, not very well understood in those days. The miraculous *pulvis febrifugus orbis americani* was not yet known to Europeans. The existence and wonderful virtue of "quinquina,"—which later on saved the life of Charles II, of England, Louis XIV, of France, and Friedrich the Great—were then only known to the native inhabitants of undiscovered Peru.

What was that dangerous disease from which Columbus did not entirely recover for nearly five months? Was it a disease of the nervous system? The only affections of that kind most likely to have developed are acute softening of the brain or idiopathic meningitis. But acute softening occurs always in very old persons, is apt to be preceded by mental confusion, a feeling of numbness, and some slight impairment of motion; and in idiopathic meningitis there are from the beginning an intense headache, vertigo, nausea and vomiting. These two diseases also run their courses generally in a short time, the usual termination in acute meningitis being death; cerebral softening always leaves behind permanent disorder of the mental, sensory or motor functions.

Could it have been scurvy? Decidedly no, because although scorbutus was in those days a very familiar disease among soldiers and sailors, arising from a deficiency of fresh meat or vegetable diet; and sometimes to be found also in badly ventilated, dark, and damp prisons, owing to the want of proper assimilation of food, neither insomnia, stupor, nor delirium form a part of the onset of this disease. Besides, scurvy is so slow and gradual in its development that the patients do not know when it begins.

In the absence of a clinical history of the case, let us scrutinize a little more the simple historical account of the disease. In going from Mona to Porto Rico, Columbus' fatigue and weakness and want of proper food "cast him into a dangerous disease between a pestilential fever and lethargy, which deprived him of his sense and memory." This is his own way of expressing his malady. It certainly was then one of the following three low-type fevers—typhus, typhoid, or relapsing.

We must not lose sight of the fact that he had just got over a protracted attack of paludal poisoning, which consequently left him in an anemic and debilitated condition at the time of embarking in this five months' cruise; thus offering an inviting soil for the favorable incubation of a specific, blood-disorganizing fever such as the above named ones.

Not knowing the exact bodily temperature, nor the characteristics of its daily variations (and for the best of reasons,—the clinical thermometer had not yet been invented), nothing whatever in regard to the peculiarities of the pulse, the actual condition of the skin, the tongue, the bowels, the presence or ab-

sence of eruption, epistaxis, lung symptoms, nausea or vomiting, the anomalies of the urinary excretion, etc., we can not make a good differential diagnosis between those three low, specific fevers. As a rule, we find in all of them the same symptoms of general malaise, weakness, drowsiness, at the beginning of the disease; but my opinion is, however, that it was typhus because of the prolonged convalescence, which must have been due to some pulmonary complication, partial paralysis, scurvy, dysentery, suppurative inflammation of parotid, submaxillary or inguinal glands, or more probably of the joints. There is another important circumstance which leads me to make the diagnosis of ship fever, and that is that Columbus, as a general rule, very seldom went ashore but remained on board while waiting at the different harbors, coves, anchorages, and roadsteads, thus necessarily exposing himself more to the infection than the average of his companions, whose nervous systems could not have been in such an unstrung and depressed state as his.

When Columbus recovered consciousness at Isabella, he found his dear brother Bartholomew, whom he had not seen for six years, seated by his bedside and tenderly nursing him. This happened on the 8th or 9th of October, which shows that the stupor lasted during the first two weeks of the disease—another diagnostic symptom in favor of typhus.

Early in March, 1496, the immortal navigator sailed for Spain; but he did not arrive there until June 11, having exhausted all their provisions and the famine was such that the crews came near eating up some of the thirty or more Indian captives whom they were taking to Spain. The haggard and starving party dropped anchor in the same harbor of Cadiz, from which many of them had joyously set sail with Columbus two years, eight months, and sixteen days previously.

Columbus started on his third voyage of discovery with a fleet of six ships, carrying about 200 men besides the sailors, from the little sea-port of San Lucar de Barrameda on May 30, 1498. On June 21, at the island of Ferro (the most westerly of the Canaries) the Admiral divided his fleet, sending three ships directly to Hispaniola, while with the other three he steered southwest. Prosecuting his voyage toward the Cape Verde Islands, in the last days of June, and "as he advanced within the tropics, the change of climate, and the close and sultry weather, brought on a severe attack of the gout, followed by a violent fever," says Washington Irving. On the 31st of July he discovered the Island of Trinidad, and caught a glimpse of terra firma at the delta of the Orinoco River; coming out from it through the passage which he named Dragon's Mouth (Boca del Dragon), during the second week of August, "he suffered a great deal from gout and ophthalmia," says Navarrete.

These two are the first distinct and positive historical references to Columbus suffering from gout. As for the transitory ophthalmia, I have already stated my opinion about it, only adding that it is a frequent complication of rheumatism but not of gout. Now I shall endeavor to prove that Christopher Columbus was never affected with gout, which is contrary to the firm belief of all accepted standard non-professional authorities.

Gout is more decidedly hereditary than rheumatism, and occurs in those who live high or drink

large quantities of malt liquor, or is seen in persons whose systems have been impregnated with lead. The greatest maritime genius of the fifteenth century was of too humble birth to have inherited the gouty diathesis, and too frugal in his habits to have acquired a malady the result of over-indulgence in the pleasures of the table, especially when cruising with very scanty provisions; surely there could not have been much lead in his system. Gout is characterized by the occurrence of paroxysms of severe pain in a small joint,—the great toe usually. Gout in the foot is called *podagra*; gout in the hand, *chiragra*; and gout in the knee, *gonagra*. But Columbus suffered pain in several joints, of the upper as well as the lower extremities, whose movement was slow, rigid, and jerking, so that it was accomplished with difficulty, and his disorder therefore could not very well be placed under any of these three Latin divisions of gout.

There are yet two very important diagnostic factors against the theory of gout, viz., the season of the year in which exists the greatest tendency to the occurrence of the seizures (winter), these two first attacks taking place in the middle of the summer, and moreover that we meet in the course of the distemper with no cardiac complication, at least no valvular affection, as so constantly happens in rheumatism, and which sequel was the ultimate result of the disease that launched Columbus into eternity; and furthermore, in complete possession of all his mental faculties, which does not occur in gout where the morbid changes induced in the kidneys give rise to cerebral symptoms at the time of death.

The Admiral arrived at Isabella on the 30th of August, was immediately put in irons and thrown into prison by Bobadilla, who had come from Spain a week before. While confined in prison, and deprived of intercourse with any one, loaded with fetters and chains, in the fort of the little town, he was sick for several days, probably with intermittent fever or rheumatic pains, improperly called gout. He was put on board a vessel and sent to Spain early in October, 1500, arriving at Cadiz on a December day, and as he passed, his stately and venerable figure burdened with shackles and chains, through the streets of that city, he awakened a great popular outburst of sympathy for him and indignation at his persecutors, which reproof immediately reperculated in the wealthy cities of Seville and Granada.

Fortunately the passage had been calm and fair, and of but moderate duration, rendered also less disagreeable by the kind treatment of Alonzo de Villejo, to whom he was given in custody.

While on board the ship he had written a long and eloquent letter, full of pathos, to Dona Juana de la Torre, the nurse (*ama*) of Prince Juan, a lady high in favor with Queen Isabella, to whom her brother Antonio, a fellow-voyager of Columbus, straightforwardly carried the epistle on landing. In studying the ideas and wording of this remarkable letter, I find that his reason was just beginning to lose equipoise under the strain of the great humiliation he was then enduring, and the disordered condition in which his unexpected, unwarranted, and unworthy arrest had thrown all his private affairs. This clouded state of his intellect suffered a more aggravated relapse on two or three other occasions, when in moments of despair and heartrending anguish his religious enthusiasm com-

pletely overpowered his understanding, and of which I will speak later on.

During the seventeen months elapsing between his arrival from the third voyage and his departure again on the fourth, not a word, that I know of, is said in history about Columbus being afflicted with gout, which is a strong argument against the theory of his suffering from that malady. When much better fed, in company of cavaliers and rich men, he should have had more paroxysms of that "eminently respectable disease," as Sydenham used to call it, than when living as a sailor on strange seas, short of the most necessary provisions.

The equipment of the fleet on the fourth and last voyage consisted of four small caravels with crews numbering, all told, 150 men. Columbus' brother Bartholomew, and his younger son Fernando, then a boy of fourteen, accompanied him. They sailed from Cadiz on the 11th of May, 1502, and on the 7th of November, 1504, after a tempestuous voyage and narrow escape from shipwreck, he landed back at San Lucar de Barrameda, so sick and thoroughly worn out that he could not personally go to Court to give an account of his new discoveries, but had to send in his place his youthful son, Fernando.

While sailing along the coast of Honduras, on the middle of August, 1502, there was an incessant tempest with heavy rains and such thundering and lightning that "it seemed as if the end of the world was at hand." The vessels had been so violently tossed about that their seams opened, and the provisions were damaged by the rain and by the leakage. During a great part of this time Columbus "suffered extremely from the gout, aggravated by his watchfulness and anxiety." His illness did not prevent him, however, from attending to his duties; he had a small cabin constructed on the stern of his vessel, from which, even when lying down on his bed, he could keep a lookout and direct the course of the ships. Columbus himself says that "many times he was so ill that he thought his end approaching."

The little fleet at last succeeded in passing the Cape Gracias á Dios on September 14, after struggling with the wind and the waves and the currents for about forty days. When on the coast of Veragua (Republic of Costa Rica), on the middle of October, many days of constant mental disturbance and nights of sleepless anxiety, preyed upon a constitution undermined by a slow blood poison, by grief and disappointment, by hardships, by unhygienic surroundings, and by want of proper treatment, finally producing an illusory vision, deemed by Columbus in his religious conceit of private revelation to be really God-sent and supernatural. In a letter to the sovereigns of Spain he gives a very solemn account of this hallucination, in which he heard in the course of a vivid dream a piteous voice reminding him of Scriptural passages to comfort and encourage him to trust in the Almighty. Such psychical perturbation can easily be explained if we take into consideration Columbus' highly imaginative cerebration, his exalted religious conceptions, his daily devotional exercises, and his deep-rooted belief that he was the chosen one from among men to carry the light of the true faith into far-distant, unenlightened and pagan lands. This favorable field, when well ploughed by a chronic and painful disease, and harrowed by the iron teeth of grief, could without difficulty produce a momentary phomania. Like the firm trust

of all impassioned religious or political reformers, his sublime reliance in his lofty predestination certainly served him to overcome the multitude of obstacles he found in his path. And here we find the proof once more of the undiscernible and undefinable boundary between insanity and genius.

Whilst visiting Jamaica in the latter part of June, 1503, in which island he was obliged to spend a year, Columbus suffered another attack of the so-called gout, and malarial fevers of long duration, on the shores of the harbor of Santa Gloria, known to-day as St. Anne's Bay, which rendered him a cripple.

During all this fourth voyage his mental and physical condition was very much weakened, though hope, to be sure, had not altogether departed from his ardent and sanguine nature; but it was a hope that had experienced many reverses, and its pinions were sorely clipped. His voyages of discovery always involved hardships enough to wear out the strongest human frame, having to navigate among unforeseen dangers, without chart or pilot or previous knowledge of the countries, their inhabitants or language; to keep a constant and anxious watch at all hours, in all kinds of weather, subject to the caprices of the wind and without proper food. Age was already rapidly making itself felt when Columbus undertook this, his last, and most disastrous cruise (55 years old), the ultimate ten years of which were filled with care, physical ailments, and troubles of many sorts. For several weeks before he landed back at San Lucar de Barrameda, his tiny ship was thrown hither and thither in mid-ocean by violent winds and hill-like waves, combined with tropical showers; all that time Columbus was suffering the most excruciating pains from his old malady, until his crazy and shattered little bark anchored in the harbor, with her haggard, emaciated, crippled and almost blind master aboard.

From San Lucar he had himself conveyed to Seville, where he hoped to enjoy the much-needed rest of mind and body, and to recruit his health; but fortune continued to frown upon him, for he ascertained on arriving at that city that all his private affairs were in a state of confusion and entanglement. Since he had been sent to Spain from San Domingo, shackled like the vilest of culprits, when his house and effects had been seized and confiscated by order of Bobadilla, his rents and dues had been unlawfully retained in possession of Governor Ovando, the successor of Bobadilla in command of the Island. He was, therefore, in actual penury. He remained at Seville during the rest of that winter and part of the following spring, a victim of his chronic and painful illness.

At the beginning of May, 1505, feeling a little better, he went with his brother Bartholomew to Court, then sojourning at Segovia, to personally plead for his rights. While there "he was once more confined to his bed by a tormenting attack of the gout, aggravated by the sorrows and disappointments which preyed upon his heart." From this couch of anguish he addressed one more pathetic appeal to the justice of the King, but ah, all in vain!

He sought consolation in devoutly reading the prophecies of the Holy Scriptures and the writings of the Fathers of the Church, and wrote a religious book and a final long letter, full of poetic mysticism, to that selfish and ungrateful King Ferdinand, the noble and magnanimous Queen Isabella having already expired the year before. In making a hurried

psychological study of these two opuscles, I find that for the third time the intellect of Columbus was clouded with delusion. The extravagances of his overwrought imagination must not, however, be entirely judged as they appear at the present day. They were in perfect sympathy with the quintessence of those times, when the spirit of the Crusaders was still rampant, when the conquest and fanatical expatriation of the Moslem had just been accomplished, and the Inquisition permeated, enslaved and terrorized the whole Spanish kingdom.

So poor and helpless at last he found himself, after uselessly following the Court from place to place, that he accepted the modest home offered him by kind-hearted and charitable Gil Garcia—a sailor—at Valladolid, Magdalen Street (now called Colón). There, propped up in his lowly bed, suffering just as much from the cardiac complications of chronic rheumatism as from mental anguish and dejection, and want of proper medical attendance; looking a great deal older than he really was, but with loftiness of heart, the religious enthusiasm of an old prophet, and Christ-like forgiveness for all his persecutors, under those long, curling white hairs of his, and the gray robe of the order of St. Francis—of whom he had been a great devotee—in which he begged to be clothed and buried, he was uttering words which, to anybody unacquainted with his life, would have seemed very strange indeed. For he was speaking to his two sons and his confessor, Fray Gaspar de la Misericordia, of little else but of another world—not the world of the unknown and unknowable, nor the house not made with hands, eternal in the heavens, to which he was soon to go—but of a New World on this planet of ours, where he had been; of which he was the first to give a faithful account, and to bring from it men of an unheard-of race, and most wonderful specimens of the animal and vegetable kingdoms; a world which should be forever associated with his name, and which will be without any doubt for all coming ages an inexhaustible field for commerce, for industry, for agriculture, for benevolence, philanthropy and liberty—a true material salvation of the whole human race.

He took his departure from this life on Ascension day, May 20, 1506, a servant satisfied of his work and honorably dismissed from the visible terraqueous globe, which he had very much enlarged, to go to the invisible and everlasting hereafter, whither all of us are marching on, pronouncing with great unction these sublime Latin words: *In manus tuas Domine commendo spiritum meum.*

What was the cause of Columbus' death, and what part did the medical profession take in the discovery of America?

I have just remarked that he died from the cardiac complications of chronic rheumatism, thus contradicting all the standard historical authorities who assert he was a victim of gout. My humble opinion is that the chronic form of poly-articular rheumatism was not developed slowly, but succeeded to an acute attack, and that this first invasion of the disease occurred on the last days of June, 1498, after Columbus left the Cape Verde Islands, on his third voyage. "The atmosphere was loaded with clouds and vapors; neither sun nor stars were to be seen; a sultry, depressing temperature prevailed," says Washington Irving. A little farther along in his narrative the same high historical authority adds that on July 13

the ships "had entered a region where the whole sea was like a mirror, and the vessels remained almost motionless, with flapping sails; the crews panting under the heat of a vertical sun, unmitigated by any refreshing breeze." The sailors lost all strength and spirits, and there was in the atmosphere, owing to drizzling showers, that combination of heat and moisture so well adapted for a genuine attack of acute rheumatism, and entirely unfavorable for the development of a paroxysm of gout. But the presence of the rheumatic poison was clearly evident in the accompanying "violent fever." Gout is not ushered in by high fever, and during the hours of severe suffering the skin usually remains dry, a general sense of relief being experienced just as soon as a profuse perspiration sets in. A warm climate exerts for that reason a beneficial effect on the occurrence of the seizures of gout. As for the peculiarity of the first attack making its appearance at night, between the hours of 12 M. and 5 A.M., I can not say anything, because the exact time at which it occurred is nowhere recorded.

Those writers who have minutely described the last few months of the life of Christopher Columbus state that when he was confined in bed *his body was extraordinarily swollen from the chest downwards*. Here we have the cardiac dropsy met with as the final and fatal result of an old inflammation of the endocardium, brought about almost invariably by an attack of acute rheumatism. The shrinking and induration of the valve curtains of the heart and their tendons, as a sequel of endocarditis, and the hypertrophy and dilatation of the cardiac walls to which these pathologic changes give rise, owe their chief importance to the purely mechanical disturbance of the blood circulation thereby induced, the action of the heart becoming more and more feeble every day until death at last closes the scene.

The cardiac complications of rheumatism (endocarditis, pericarditis, myocarditis) are by far the most frequent, being present in more than 50 per cent. of all cases, and constitute the commonest cause of death in this disease. Bouillaud was the first to recognize the frequency of such accidents, and his great discovery that "their occurrence is the rule rather than the exception in rheumatic fever," has stood the test of all subsequent observers, and remains to-day one of the best established facts in clinical medicine.

Having finished saying what I had to say about the medical history of the immortal discoverer of this New World of ours, I will end by putting upon record the names of those belonging to our noble profession who directly contributed to the realization of such a momentous event in history. The clear intuitions of Avicenna "the Prince of Physicians," as he was called; the advice and encouragement given to Columbus by the Florentine physician and distinguished cosmographer, Paul Toscanelli; the modest village doctor, Garcia Fernandez, who, as an improvised expert in mental diseases, won for the perambulating genius the respect and sympathy of the worthy prior of the Monastery of La Rabida; the very important fact that, although it is proved beyond doubt that no priest accompanied Columbus on his first voyage, there were two representatives of our profession among his followers—Maestro Alonzo and Maestro Juan—two ship surgeons or *fisicos*; and last but not least, the learned author of the very first

scientific report on America, Dr. Diego Alvarez Chanca, who came over with Columbus on the second voyage, and saved his life during a protracted and dangerous attack of typhus fever. All these facts, scattered in many old books and pamphlets, worm-eaten in dusty archives, are here collected and presented as *pieces justificatives* of the noteworthy part taken by the medical profession in the discovery of the Western Continent.

Almost every one who has written the life and voyages of the immortal Genoese navigator,—and their name is legion—speaks of the probable sources of his information about the existence of a western route to the East Indies. But none of them, that I am aware of, refers to the writing of Avicenna as a possible fountain of suggestion. This eminently successful physician and most wonderfully learned man was born at the village of Afshend, in the province of Bokhara, Turkestan, Central Asia, in 980 A.D., and died in 1037. Besides his resplendent medical knowledge, he was a profound philosopher, a skilful rhetorician, excellent geometer, well versed in astronomy and astrology, a shrewd theologian, an accomplished naturalist, and a very fine musician. During the last fourteen years of his life he wrote a considerable number of works on widely different subjects, among which his treatise entitled, "De Complexionibus," section 1, chapter 1, where he cites the opinion of Aristotle expressed in his work, "De Causis Proprietatum Elementorum," is an able speculation on the existence of the Antipodes.

Paolo del Pozzo Toscanelli was born at Florence in 1397, studied medicine in his native city and became one of the most famous astronomers and cosmographers of his time. On account of his great reputation in nautical science he was constantly consulted by bold navigators from different countries, who unhesitatingly followed his advice and the course marked down for them in the charts Toscanelli himself drew. He was thoroughly acquainted with the scientific and geographical literature of the Greek and Latin classics; became one of the keepers of the celebrated Florentine Library at the age of 30 years; erected, about 1468, the famous gnomon on the uppermost part of the dome of the cathedral at Florence; died in that city on the 15th of May, 1482. To this distinguished member of our profession Columbus applied, beseeching his opinion and advice in regard to his contemplated stupendous enterprise, as had also done a few days before, on the same subject, the powerful King of Portugal. Like the truly scientific and generous man that he was, not only did he immediately answer the two letters of the then obscure sailor, confirming him in his views of the figure of the earth and the practicability of a voyage westward to India, but also sent him a chart drawn by his own hands in which was marked and explained the course Columbus should follow to reach there in safety. This very chart was the one used by the Admiral on his first voyage of discovery. He showed it to Martin Alonzo Pinzon, captain of the caravel *Pinta*, while sailing on the *mare incognitum, tenebrosum*, and both frequently sat on deck discoursing upon it. The historian Las Casas, a contemporary and friend of Columbus, says he saw it and had it in his possession. But it has been irretrievably lost.

The ancient convent of Franciscan friars dedicated to Santa Maria de la Rábida—where Columbus halted, accompanied by his son Diego, hungry, thirsty,

-dressed in tatters, full of dust and tired from having tramped many miles—is situated at about half a league from the village of Palos de Moguer, in Andalusia, Spain. The humble physician of this little maritime town was Dr. Garcia Fernandez, who enjoyed the friendship and high regard of the respected Prior of the Monastery, Juan Perez de Marchena. This patriotic friar detained Columbus there as his guest, and, diffident of his own judgment as to the sanity of the distinguished-looking foreigner, sent for his scientific friend, the village doctor, to converse with him and inquire into his mental state. Dr. Fernandez was equally struck with the intelligent appearance and entertaining conversation of Columbus. He discussed with him several geographical and astronomical topics, and became convinced that he by no means was talking to a madman but to a genius. His clear discernment at once detected the possibility of the adventure Columbus was pursuing, and won for him, with his favorable report to the Prior, the good will and invaluable aid of that influential religious man. What the result would have been if that unassuming and kind village doctor had given an unfavorable opinion, nobody can tell.

Among the few brave men that dared accompany Columbus on his first voyage of discovery to America were two representatives of our philanthropical profession. Maestro Alonzo was the name of one, and Maestro Juan that of the other. The first seems to have been the better known of the two, and came over in the caravel *Santa Maria*, commanded by Columbus, while the second was more of a friend of Martin Alonzo Pinzon, and embarked in his vessel *Pinta*. This last remained at the little fort of Navidad when Columbus returned to Spain, being one of the thirty-eight men massacred by the native Indians of San Domingo, and thus paying with his life for his professional devotion. The small band of foolhardy Spanish colonizers were under his medical care.

I have already referred to Dr. Diego Alvarez Chanca, who came with Columbus on his second voyage, and saved his life and that of many hidalgos at the point of death in the Island of Hispaniola or San Domingo. The account given by this distinguished man of science to the municipal council of his native city is undoubtedly an unpretentious evidence of the wide range of his scientific knowledge, and constitutes the first sketch of the flora, the fauna, the ethnology and climatology of our dear American continent. He also wrote, on his return to Spain, a work entitled, "Comentum Novum in Parabolis Divi Arnaldi de Villanova," published at Seville in 1514.

In conclusion, we, as a class, have sufficient reason to feel proud of the active part taken by members of the medical profession in the discovery of this beautiful land of ours, where the "divine right of kings" is no longer possible, and when the great Chicago World's Columbian Fair has given imperishable existence to the memory of its discoverer.

194 West 10th Street.

CONTRACTION OF FINGERS.—Apply upon the palm of the hand a large quantity of the following ointment: White vaselin, 30 grammes (1 ounce); iodid of potassium, 2 grammes (31 grains); iodine, 1 gramme (15½ grains); cover with thick layer of cotton, rubber cloth, and moderately tight bandage. Renew application daily for three or four weeks. (VULPIAN, *La Presse Médicale*, Feb. 10, 1894).—*Universal Medical Journal*, April, 1894.

TRANSPORTATION OF WOUNDED IN WAR.

The opening paper of the Symposium on Transportation of Wounded, at the meeting of the Association of Military Surgeons, Washington, D. C., May 2, 1894.

BY CHARLES SMART, M.D.

MAJOR AND SURGEON, UNITED STATES ARMY.

In writing history it is necessary to begin at the beginning, thereafter following our subject along the stream of time until we reach either the end of its course or its present anchorage; but the beginning of our present subject is lost in the haze of the distant past. In the earliest dawn of history we find men fighting; and battles, no doubt, were fought even in the primitive days. The history of the human race is, in fact, a history of battles and their results. But history had no eyes for those who dropped out of the struggle; seldom are we told of the wounded. Nevertheless, we must credit these old time warriors with sympathies which led them to care for their wounded, so that our subject finds a beginning as far back and as undefined as history itself.

We may assume that slaves, servants, companions-in-arms, friends or relatives cared for the fallen as soon as the exigencies of war permitted, and that the methods differed with race and nation, mode of warfare, and an infinity of small or local conditions. We get an occasional glimpse of these in the chronicles of the past, but they have merely an antiquarian interest. In the feudal age each chief looked after the welfare of his armed vassals, if from no higher motive than personal interest, for his own power depended on the strength of his following. A victorious army imposed the care of its sick and wounded on the non-combatant population, whether friends or enemies, and the system of ransom which followed that of slavery often obtained for a fallen enemy greater care and consideration than he would otherwise have received. When the companies of feudal chiefs became replaced by commands recruited at large, provision was made for the wounded by the central power or government.

The outbreak of our Revolution brought us first face to face with this question. Our improvised army was modeled on that of England, and English medical methods necessarily influenced the elaboration of our own. These looked only to providing the army with intelligent medical men, efficient nurses, and the needful allowance of medical and surgical supplies. They were of infinite value when brought into immediate relationship with the wounded, but there was no special provision to insure that this would be effected. When a battle was in progress the medical men, nurses and supplies constituting the field or regimental hospitals, were somewhere in the rear of the army with its other impedimenta, for at that time the medical armamentaria were regarded as impediments pure and simple,—their value as preservative of the integrity of a line of battle being unrecognized. In Europe, where frequent wars had reduced the methods of the battlefield to system, the regulation distance of the impedimenta behind the fighting line was not less than one league. Here, during the battle, the medical men of the army attended such of the wounded as were able to reach them, or such special cases, generally officers of rank, as might be brought to them; and as in a general engagement there was usually no lack of such patients, the surgeons naturally considered themselves to be doing excellent and valuable work, although the poor fellows stricken on the field and unable to leave it without

assistance, derived no comfort from their proceedings. If defeated, the army withdrew, leaving the wounded to fall into the hands of the enemy; if victorious, arrangements were made to have them brought to the hospital. Servants, bandsmen, and camp followers were sent to the field, and a force, volunteer or impressed, of the inhabitants of the vicinity, with all needful or available wagons, was organized for this work of mercy.

This, the usual method of bringing off the seriously wounded, was that adopted at Spire, for the wounded of the French Army of the Rhine under General Custine in the autumn of 1792. Although time honored by the practice of generations of military men, it did not meet with the approval of a young surgeon, D. J. Larrey, who had recently joined Custine's command. He thought that some effort should be made to reach and assist those men who were dying from shock, exposure and needless loss of blood, and he was positive that lying uncared for on the field for twenty-four or more hours was not a desirable preliminary to amputation for gunshot injury. His disapproval of the regulation method became strengthened when, some time later, the wounded in an engagement at Limbourg had to be abandoned because before the arrangements for their removal were completed the defeated army received strong reinforcements. With the consent of General Custine he procured some light wagons and organized an *ambulance volante* or flying hospital, intended to bring assistance to the wounded and remove them from the field during the battle. Its first service demonstrated its value. A strong force had been thrown forward to guard a mountain pass against the advance of the Austrians, and Larrey, in anticipation of an engagement, accompanied it with his ambulance wagons. The Austrians discovered the isolation of this force and surrounded it; but the French, by a vigorous assault, broke the enemy's line and succeeded in rejoining the main body, bringing with them in the ambulance wagons the wounded who otherwise would have been left on the field. His ambulance for a division of troops consisted of eight two-wheeled two-horse spring wagons and four four-wheeled four-horse wagons for the wounded, with four store wagons and a *personnel* of over one hundred men, of whom fourteen were surgeons. Its value was so well appreciated that shortly afterwards Larrey was sent to Paris to organize ambulances for all the divisions of the army. He joined Bonaparte in his Egyptian campaign, and personally supervised the operations of the flying ambulances of the French armies from that time until the Napoleonic sun set at Waterloo.

Meanwhile another surgeon of these wars, Baron P. F. Percy, serving with General Moreau's command, was also endeavoring to solve the problem of prompt aid on the battlefield. As the hospital trains were not allowed on the field on account of the uncertainty of the issue, the risk of capture, and the certainty that they would be in the way of the troops during some part of the action, Percy's idea was to transport to the field the essentials of surgical aid, without blocking roads or impeding military movements. The surgical wagons which he constructed to effect this were modeled on those of the light artillery. The art of preserving life, he considered, should compete in activity and promptness with that of destroying it. Each was drawn by six horses, and carried eight

surgeons and as many orderlies, with instruments, stretchers and supplies. When a sheltered spot near the fighting line was reached, the surgeons gave professional aid to the wounded who gathered near them, while the stretchers attached to the wagon were put to excellent service by the orderlies and men temporarily spared from the combatant ranks. When the work was finished, the wagon was driven to some other part of the field where surgical assistance was in demand.

This wagon did much good during the short time it was in use. It gave aid to those who were able to reach it, but who could not have reached the hospital train two or three miles beyond; it gave vital assistance to many who otherwise would have died, and it brought aid and comfort to those who otherwise would have been exposed without either for hours; but particularly did it demonstrate how much good could be effected by the presence of medical officers, although the regulation hospitals and their supplies were miles away. It contributed as much as the ambulance volante to the immediate comfort and surgical safety of the wounded, but it left them on the field until the usual arrangements were made for their removal. Percy speedily recognized this inferiority of his system, and having abandoned the wagon he devoted his energies to adapting its *personnel* to work in connection with Larrey's ambulance.

When with General Moreau in Spain he organized a company of brancardiers or stretcher-bearers from selected volunteers from the regiments. Each man carried one-half of a litter as a part of his equipment. His lance or pike became a litter-pole by removing its head; his sash formed one-half of the bed of a litter when laced lengthwise to a similar piece by eyelets; and on top of his knapsack he carried a horizontal traverse having at each end a hole for the pole to pass through and a downward projection which formed one of the legs of the completed litter.

Percy's views, however, went further than the mere organization of bearer companies. In his efforts to provide for the wounded he at one time endeavored to effect a re-organization of the medical service in the field—defining the rank of its officers and their staff positions, with a major-general as the chief, three inspectors-general, sixteen lieutenant-colonels, etc. The Emperor declined to approve this proposition, as it failed to include the physicians and pharmacists of the general hospitals whom Percy seems to have intentionally omitted from his scheme; but the brancardier system was so successful that in 1813 it was formally adopted by the Imperial armies.

Some combination of bearer companies and ambulance wagons is now in use in all armies; but the minutiae of the system are in many instances imperfect. Up to the year 1821 the Army Regulations of this country were silent on the subject of transportation of the wounded. The Army Medical Department was apparently left to accomplish its ends by any available means, and presumably these would have been such as were known to have given satisfactory results elsewhere. In the year mentioned, however, the Regulations compiled by General Scott, prescribed the method of aid on the battlefield in language clear as to its provisions, and yet so elastic in its requirements as to leave the Department free to exercise full discretion in its management. The medical director was authorized to establish *field* or *movable* hospitals, and these in the revised edition published

in 1825, were called *ambulances*, in advantageous positions behind the line of battle, with smaller sections organized in like manner to follow detached columns and even to give succor to the skirmish line. The Quartermaster's Department was directed to provide the wagons after consultation with the Medical Director, but these wagons were to remain under the conduct of an officer or agent of that Department. The direction to employ hired labor for the purpose of manning the ambulance system was the weakest point in the program. It was, no doubt, a concession to military custom which up to this time had been broken systematically only by the organization of the *brancardiers* of the French army.

During the period of uninterrupted peace which occurred at this time, our War Department officials became absorbed in current work relating to the movements of small detachments of troops in the West. War on a great scale dropped from their consideration, and in consequence the 1821 provisions for battlefield service were omitted from the Regulations published in 1834, 1835 and 1841. The only provision for assistance to the disabled in these official publications shows the narrowness of mind contracted by official routine during those years: "For the accommodation of the sick and disabled, a wagon will be attached to the rear guard when necessary and practicable, and a surgeon will attend to give assistance and see that no improper persons are suffered to avail themselves of the accommodation."

The war with Mexico then came upon us so suddenly that in a hasty re-issue of the Regulations in 1847 there was no time to elaborate and incorporate a medical system for field service; and the Medical Department was left to do the best it could, trammelled, however, by its dependence for transportation on the Quartermaster's Department. System was evolved in the progress of the war, and the results were embodied in 1857 in the next issue of the Regulations. But in these there was a great lapse from the provisions of 1821. The latter made the Medical Department a free agent to enable it to sustain its high responsibilities and gave it the Quartermaster's Department for collaboration and assistance. In this way they were in advance of the methods of all other armies; but the Regulation issued one-third of a century later fettered the Medical Department with the bonds of slavery to a so-called ambulance corps. The surgeon dropped to the status held by him in foreign armies, as the mere attendant on the wounded, when permitted by the officers of another department to come into personal contact with them. Even the medical director, a director only in name, was ordered to take his post for professional work at the principal depot.

The Regulations of 1861 found us engaged in a great war, responsible before public opinion for the care of the wounded, yet unable to accomplish anything without the consent and active coöperation of officers who were not held to this responsibility. Many of these officers were volunteers, ignorant of their powers under the Regulations, and actuated, as were the regular officers of the Quartermaster's Department, by no petty jealousy of position, rank or power, but solely by a desire to accomplish the end in view of doing the best for the wounded under the conditions of the time. The medical work on the battlefields of the Civil War progressed therefore under an intelligent appreciation of what the Regulations

should have been, rather than of what they were—and as a result an ambulance corps was organized, a combination of Larrey's *ambulance volante* and Percy's *brancardiers*, the whole under the orders of the Medical Director, although officered for purposes of domestic economy and property responsibility, by details from the line of the Army.

Under these provisions the ambulance and field hospital service of the United States armies became models for the military surgeons of Europe. Their ability to deal with large numbers of wounded was fully demonstrated during the series of battles and marches, beginning with the crossing of the Rapidan and the Battle of the Wilderness and ending six weeks later with the commencement of siege operations at Petersburg, Va. On several occasions during this trying time the headquarter wagons of general officers were turned over to the Medical Department for field work; but this indicated no weakness of the system, merely a shortage of ambulance wagons—and it is to be observed that there would have been no shortage but for the imminence or the actual occurrence of an engagement during the temporary absence of some part of the ambulance train at the base of supplies. Ordinarily in the absence of railroad transportation, empty supply wagons were utilized for the evacuation of the field hospitals, but during this active campaign the wagons of the *ambulance volante* were called upon to do some duty *d'arrière* as well as their own special duties *d'avant*. Practically the work of the battlefield and field hospitals was done with the organization that we now have in the Medical Department of the United States Army; a staff corps of surgeons and a similar corps of enlisted men thoroughly educated in the principles and drilled in the practice of first aid. These corps did not then have a legal existence. They were extemporized by medical directors out of regimental and other surgeons, and regimental and other nurses, and hospital attendants. But since 1887 a special Hospital Corps, authorized by Congress, has been organized and educated. At the present time its members are scattered at 120 different posts, but if an order were to be issued for the mobilization of our Army, its Hospital Corps could be organized into bearer companies and field hospitals as quickly as the troops could be brigaded.

Instead of being a loose aggregation of regimental and hospital surgeons, incapable officially of doing anything but practice their profession when the military exigencies permitted or required them to do so, the Medical Department is now a compact body, responsible for the care of the sick and wounded, and having the powers of commanding officers over the *personnel* and material specially provided for carrying out its purposes.

Gentlemen, when I was asked to contribute to the history of the transportation of wounded men from the field of battle, my mind ran back to the esquire and his wounded knight—the officer brought off in his sash by servants, the Scottish Highlander in his plaid by clansmen, and the soldier generally in his blanket between two pikes or muskets or pic-a-back on the shoulders of a friend; but a little thought showed me how immaterial were these trifles as compared with changes in the status of the medical officer, and the power which he could exercise in providing facilities or in rendering them available. In this really and not in an improved ambulance

wagon or a modified litter sling, lies the progress and history of the transportation of the wounded from the field.

The car of progress moves slowly. For some undefined reason, medical men labor at a disadvantage in fields of practical work, although these may be allied closely to their own. It seems to have been assumed that because a man is intelligent enough to be capable of taking care of another in sickness or injury, he should be regarded as incapable of doing anything else with the ability that might be expected of one who has never been exposed to the deteriorating influence of medical knowledge. Although the French surgeons did so much to mitigate suffering and save life on the battlefield by suggesting and organizing new systems and testing and demonstrating their value, it was not until 1882 that the Medical Department of the French Army was given command of these organizations, nor until seven years later that it was empowered to control its supplies. During that long period its members remained merely doctors, caring for the sick and instructing nurses and stretcher-bearers, whose services were afterward controlled along with their own by officers who, in the interests of the wounded, should have been their assistants. And although Percy a century ago recommended a staff corps of military surgeons, the French still maintain their regimental officers and "soldats infirmiers" or regimental nurses, the former equivalent to our medical officers on duty at the first aid stations and the latter to our company bearers.

The Germans perfected their field medical service during the war of 1870. Besides special aid on the fighting line, they have a bearer company of about two hundred men to each division and a reserve company to each corps. To 36,000 men, forming a corps of two divisions, they have therefore about six hundred men for bearer duty; but the field hospitals of the corps are manned by as many more, so that exclusive of medical officers, the sanitary force is equal to over 3 per cent. of the troops in line. The Medical Department controls its men, transportation and supplies.

The conservatism of the British military authorities was slow to permit new ideas to modify the sacred customs of service, so that although the medical officers engaged in the campaigns against Napoleon were well aware of the advantages of the methods of Larrey and Percy, and made many appeals to the government to be permitted to do likewise, these were uniformly disapproved. The Duke of Wellington was chiefly responsible for this, as he would not hear of encumbering his army and impeding its movements with these wagons. Wounded Frenchmen were succored while the din of battle was yet in their ears, but their British opponents had to lie exposed, not only during the continuance of the struggle, but during the long watches of the night until arrangements were perfected for their removal. The available wagons of the supply departments and such as could be hired or impressed into the service were brought up along with the bandsmen, camp followers and hired labor to give the long delayed aid and transport the sufferers to the hospitals. The stretchers used in loading consisted of a canvas bed between two pikes or poles, with no cross-pieces to keep them apart. The long wars of the early part of the century improved the organization and internal economy of the British

field hospitals, but effected no immediately beneficial change in their methods of transportation. Nor was anything done until the outbreak of the Crimean war, when a Hospital Conveyance Corps was hastily organized and shipped with the troops. This was so decided a failure that the work of transporting the wounded had to be transferred to the train of the Subsistence Department. The wagons of the Conveyance Corps were too heavy; no provision was made for repair in case of accidents, and the men were old, broken down and dissipated soldiers weeded out of the regimental ranks, rather than selected on account of special fitness for important duties. After the Crimean war, a Medical Staff Corps was organized in order to provide a better *personnel* for the care of the wounded than could be obtained under the old system of regimental details. I need say nothing here of this regimental system, as our regular army officers are personally familiar with its objectionable features, some of which I delineated in a paper read at the last meeting of this Association. The Medical Staff Corps proved a failure on account of being composed of hired civilians. In 1873, however, an important change was effected. The British abolished their regimental system of medical appointments, and established a staff corps of officers and a hospital corps of enlisted men such as we have now in the Army of the United States; but these medical officers have one disadvantage yet to overcome. Their ambulances are not under their control,—the officers of the Army Transportation Corps command them.

And so in all armies we now find bearer companies and ambulance trains with unimportant differences in their composition, and more important differences in the control exercised over them by those most interested in the welfare of the wounded. Patriotic officers of corps other than the medical, may claim as much interest in their wounded countrymen as any man could have, when not bound by special ties of blood or friendship, and so far as their knowledge goes they are no doubt warranted in making the claim; but they have no knowledge of the interest of the medical man in lives or limbs susceptible of being saved. He is interested in the wounded on account of what he as an individual may be able to accomplish and also on account of what medical and surgical science may be able to effect; and to these interests, of which the Transportation Corps or Quartermaster's officer knows nothing, he may claim a full share of interest on behalf of patriotism.

But every system for the care and transportation of the wounded, no matter how carefully organized, may occasionally be crushed and paralyzed by the iron heel of war. Of what avail, for instance, were Larrey's ambulances on the disastrous march from Moscow when men, narcotized by cold, fell and were shrouded in snow before the heart had ceased to pulsate,—when they were cut off on the Berezina, and the great surgeon was, himself, saved only by being passed over the blocked, broken and enflamed bridge on the shoulders of the men, or when the Sisters of Charity at Wilna were endeavoring to rally him from his exhaustion at the end of that terrible march.

Thanks to the better parts of human nature, scenes of this kind will be of less frequent occurrence in war hereafter. To alleviate the sufferings of the wounded, commanding generals have sometimes made temporary arrangements for the neutrality and

safety of surgeons and others engaged in the humane work. The success of an agreement of this kind in 1743 between Stair and the Duc de Noailles led Baron Percy in 1800 to draw up a similar compact, which Moreau signed and sent to the Austrian General Kray, but the latter declined to entertain the proposition. Commanding generals have not plenary powers. Kray was, no doubt, tied down by the military power at Vienna. But an arrangement of this kind has now been effected on behalf of the wounded of all civilized nations by the influence of the International Red Cross Society. I need not dwell on the provisions of the various articles of the Geneva Convention, the practical operation of which has been tested in the wars of Europe since 1864.

During the past century much progress has been made in the evolution of the ambulance wagon. Larrey's two-wheeled vehicle consisted of an oblong box suspended from springs at its four corners, closed by folding doors in front and rear, and having openings with sliding shutters in the sides for the admission of light and air. On the floor were two padded litters on castors; and, to facilitate the handling of these when loaded, four iron handles were attached to the sides of each.

The first ambulance wagon officially recognized in this country was the Moses wagon, which was examined by a medical board in 1859. It was evidently intended to meet the special requirements of our Western service, the chief characteristics of which were long marches made by small commands. It was reported to be a kind of large omnibus fitted up as a traveling hospital, and capable of extending its shelter at night or in camp by the use of attached canvas so as to accommodate about thirty persons.

The Wheeling ambulance, weighing only 700 to 800 pounds, was used extensively during the Civil war. It was furnished inside with padded seats for eight, convertible into beds for two. By some, it was considered too light or frail for field service, but it was simple in construction, easily kept in repair, and a matter of fact in many of the divisions of the Army of the Potomac, it survived the war after participating in every campaign. Since then, I have seen it in Western service accompanying troops over mountain trails where none of the wagons of recent construction could have been taken. Our present ambulance wagon is an altered Rucker, converted into a medicine wagon in front by a well which contains two medicine chests. It is thus excellently suited for the current work of accompanying small commands on marches and such field service as we have on the Mexican frontier, but is wholly unfit for battlefield service in time of war. Ambulance wagons should be suited for the work required of them. Ambulance surgeons, civil as well as military, recognize this principle. This subject is on our program for discussion, but meanwhile I desire to say, as a conclusion from the study of its history, that if we again have to gather up our wounded from the battlefield by divisions and corps, it is not by means of our present wagons that we shall accomplish our object, but with shells on wheels, in so far resembling the Wheeling ambulance wagon that they can hover under shelter in rear of a skirmish line or line of battle irrespective of the presence or absence of macadamized turnpikes.

The evolution of the stretcher has kept pace with that of the ambulance wagon. The huge knife with

which the men of our Hospital Corps are armed, although under the terms of the Geneva Convention they should carry no arms, recalls the head of the brancardier's pike when worn as a side-arm; but all the other parts of the Percy litter have been consolidated into a single compact piece. Two of these, when open and in use, should fit and fill the floor of the ambulance wagon, and the handles should be long enough to keep the equipments of No. 2 of the litter squad, when engaged in actual bearer work, from bumping against the feet of the patient. Majors Harvard and Hoff, who have given more study to this subject than most of our regular medical officers, will by-and-by show us how far we have succeeded in getting away from the pike, sash and traverse of Baron Percy's brancardiers.

In this country we have had little experience on a war scale of any other mode of field transportation than the stretcher, the ambulance, and the army wagon, the last being the wagon of the general supply train, the "six-mule team" of the War of the Rebellion. Observe the use of the word, ambulance, in the last sentence, instead of the term, ambulance wagon. This is an Americanism which grew into our use of language during our civil war. Larrey understood by an ambulance an aggregation of light wagons, drivers, surgeons, attendants and supplies in aid of the wounded, and in Europe at the present time the word conveys the same meaning; but very generally in America it means merely one of the light wagons belonging to the European ambulance or field hospital. Here we have room for international misunderstanding. When I, as an American, speak of six ambulances I mean six ambulance wagons; but the military surgeons of Europe would understand me to mean six field hospitals, each having probably more than this number of the light wagons to which the term in my American usage of it has reference. It might be well for this Association to stamp an official impress on the word. To avoid misunderstanding, when the report of our proceedings is in the hands of foreign readers, I have been careful to use the word as an adjective, but in the sentence to which I have invited attention I have made use of it American fashion in order to introduce this suggestion.

In individual instances we have tried several modes of field transportation other than the hand-litter and wagon. Many of our officers, in the absence of wheeled vehicles, have taken a lesson from the Indian and brought off their wounded on improvised travois; and have thereafter given much thought to elaborating as a perfected and prepared piece of mechanism that which owes the whole of its value to the fact that it can be so easily improvised. Single litters based on a pack saddle or *aparejo* have been constructed by some of our officers, and cacolets and horse litters were tried in a small way during our war—but in every instance with unsatisfactory results as one grand disadvantage affected each and all of them, their utter valuelessness in the absence of mules or horses specially trained for their service. In the Crimea, Algeria and Mexico, cacolets were largely used by the French troops, and many favorable reports are on record concerning them. The cacolet method has indeed been characterized as "the most perfect system that has yet been devised for the transportation of the sick and wounded on the field." This shows what may be accomplished by care and

training notwithstanding the inherent difficulties of the method. American opinion, in so far as I have been able to gather it, is against the use of these many ingenious contrivances, for it is held that if a wounded man is unable to move off on foot, or to ride a gentle horse, he should be carried recumbent in an ambulance or other carefully prepared wagon or, in the absence of wagons, on a hand-litter if the distance is short, or a travois if it is long.

After the battle of Bautzen, Baron Larrey noted with much satisfaction the "convenient and expeditious" manner in which the wounded were conveyed from the field to the city of Dresden in wheelbarrows. This observation, no doubt, originated the wheeled litter and gave rise to many of the efforts that have been made to perfect it. But the wheeled litter did not occur to Larrey. His was a broad mind; and the incident showed him "how important it is for a surgeon-in-chief to study the facilities afforded by the country through which the army is passing." American surgeons have had few opportunities of acting on this suggestion. The Indian travois is their only development in this line. The loyal British subject points with pride to the fact that the sun never sets on the flag of his government. Medical officers of the British Army have studied the facilities for transportation in every quarter of the globe, and in many of its obscure corners. Their published works on this subject are filled with modifications of "native" methods. It is needless to do more than mention the palanquin, dooley, dandy, etc., because these are acknowledged to be valuable only under the conditions prevailing in the locality which originated them, and to compare unfavorably for the general purposes of modern warfare with the lineal descendants of Percy's stretchers and Larrey's ambulance wagons.

In future wars, all ambulance wagons drawn by animals except the light wagon for battlefield service, will be superseded by railroad transportation. An excellent system of hospital trains was in use at the close of our Civil War, although at first we had no experience in this line. Cars returning to the base of operations for supplies were frequently utilized for the removal of sick and wounded, with only such provision for comfort and the amelioration of suffering as could be extemporized by comrades or attendants. But after a time, on account of the frequent recurrence of movements of this kind, railroad transportation ceased to be regarded as an emergency measure, and improvements speedily followed, until carefully outfitted trains with kitchen, dispensary and office cars became a part of our medical service—and these continue to have a formal recognition in our Army Regulations.

Although we worked out our system of hospital trains by the light of our own experience, the subject had already been discussed in Europe. In 1859 a French surgeon, M. Périer, suggested an adaptation of the ordinary baggage car for hospital purposes, and in 1860 Prof. Gurlt, of Berlin, brought forward a similar proposition; but the question was first solved in practice in 1863 during the progress of our war. Since then great progress has been made in Europe, mainly through the efforts of the Red Cross Society.

The transportation of the wounded by ships of special construction and equipment, dates from the time of the Crimean War, when Great Britain provided a hospital fleet to bring her sick and wounded

to the general hospitals at Scutari and thence home. Early in the progress of our war, Mississippi River steamers were altered for hospital purposes, and later many vessels, some built specially for the service, were employed on the Atlantic and Gulf coasts. The Medical Department was at first liable to be deprived of these vessels at any time by local commanders who desired their use as transports for men or supplies; but an order subsequently issued gave the Department exclusive control of "all hospital transports and hospital boats properly assigned as such." The hospital boat, like the hospital train, is recognized by existing Army Regulations, so that in case of war the development of transportation by water, as well as by land, would depend on the energy of the Medical Department and the available appropriations.

I desire, in conclusion, to make a reference to the small caliber and tunneled bullets. Some officers consider that their disabling power at long range will prevent assistance from reaching the wounded until the battle has been fought. I by no means concur in this view. Battles are not fought on the dead level where every object within range would be struck, but on broken ground where every irregularity or swell affords more or less protection from the enemy's fire. I feel confident, therefore, that the Hospital Corps and its ambulances will be found close to the fighting line in the battles of the twentieth, as in those of the nineteenth century.

THE EXTINCTION OF TUBERCULOSIS.

The President's Address before the Medical and Chirurgical Faculty of Maryland, delivered April 24, 1894.

BY GEORGE H. ROHÉ, M.D.

President of the Medical and Chirurgical Faculty of Maryland; of the American Association of Obstetricians and Gynecologists; Professor of Therapeutics, Hygiene and Mental Diseases in the College of Physicians and Surgeons of Baltimore; Superintendent of the Maryland Hospital for the Insane, Catonsville, Md.

This Ninety-Sixth Annual Convention of this Faculty should be to us an occasion of congratulation. During the past year our losses in membership have been few, and our gains not inconsiderable.

The semi-annual meeting held in Annapolis last November was very successful, in point of attendance as well as in the character of the work accomplished.

In an address at the opening of that meeting, I said: "A legitimate object of organization is to use it as a power to secure legislation. Not legislation for our benefit as physicians, but legislation for the public good. The medical profession wants nothing for itself from the Legislature. The legislation in which the profession is interested is such as will be for the benefit of the whole people. Public health laws, medical registration laws, lunacy laws, were all intended for the good of the public, although always originated, and their enactment promoted by the efforts of physicians."

It gives me especial gratification to call your attention to some recent results of such organization in this State. During the last session of the General Assembly three measures were considered in which the medical profession were interested, and which had their origin in committees appointed by this Faculty. These measures were: The Amendment of the Medical Practice Act, the bill for an Additional Hospital for the Insane, and the Act for the Prevention of Blindness in Infants. Each of them passed

in essentially the shape in which it was recommended by the Faculty through its appropriate committees. Having watched the progress of these measures through the Legislature, I believe I may say that not one of them would have passed in satisfactory form if the members of the Legislature had not been impressed by the fact that the organized profession of the State, as represented in this Faculty, indorsed and supported them. In this connection I may be permitted to mention a circumstance which, I think, justifies this statement. When the bill for the prevention of blindness was put upon its passage in the House of Delegates there was a good deal of opposition to some of its provisions. The bill was eloquently and intelligently defended by the Baltimore City delegation and the Committee on Hygiene, but the opposition was so determined that for a time its success was problematical. It was not uninteresting to note that the only effective opposition came from those counties which are still unrepresented in this Faculty.

There is additional reason for congratulation in the fact that all the labor of getting a law passed through the Legislature was not rendered nugatory by unfavorable executive action, as has happened to the profession of this State heretofore. Having at present in the executive chair a Governor "noted for his common sense," as was happily said by Dr. Preston, in the discussion on the Care of the Insane at Annapolis, all our bills have been approved and are now laws.

These successes should only render more forcible the appeal of the Committee on Membership for a larger representation of the profession of the State in the Faculty. There is room in this organization for every honorable regular practitioner in Maryland.

I will now invite your attention to some considerations showing the possibility of

THE EXTINCTION OF TUBERCULOSIS.

For over two thousand years a portion of the medical profession has believed in the contagiousness of consumption. A not inconsiderable proportion of the laity has likewise leaned to this view. So strong was this belief at one time that toward the close of the eighteenth century a law was promulgated in the kingdom of Naples, making very stringent regulations looking to the registration of consumptives, the segregation of the sick in hospitals and the destruction of infected articles. It seems that at the beginning of the present century the prevalence of consumption in Southern Italy was so great that the expression, "See Naples and die," could almost be taken in its literal sense.

About thirty years ago Villemin demonstrated the communicability of tuberculosis by a series of experimental inoculations upon animals. The results obtained by this investigator were soon confirmed by Chauveau and others. It was, however, not until the epoch-making discovery of the tubercle bacillus by Robert Koch, in 1882, that the value of the researches of the two distinguished French experimenters was generally recognized. Since that time the view that tuberculosis is an infectious and communicable disease has gradually pervaded the profession until to-day there are probably few physicians laying claim to common sense and current knowledge who would attempt to controvert it.

Coincidentally with the general acceptance of the infectious nature of tuberculosis have come experi-

ments to more definitely indicate the common methods of infection, and endeavors to restrict the disease within narrower limits. That this is a laudable striving must be conceded when we reflect that the annual mortality from tuberculosis in its various forms in the United States is 163,500, or nearly 450 per day; and that in this city the deaths from consumption of the lungs alone reach nearly 1200 per year, a ratio of 13.69 per cent. to the total mortality. If the deaths from tuberculosis in its various forms were included, the ratio would amount to over 14 per cent., or one in seven, which is the ratio throughout the world, as stated by Koch in his memorable paper announcing the discovery of the *bacillus tuberculosis*.

In accepting the infectious nature of this disease, we must not overlook the influence of the receptive condition of the individual in determining the time or place of infection. While the value of hereditary predisposition in determining phthisis is often overestimated, we can not ignore it altogether; neither may we undervalue the effect of an acute or chronic inflammation, a traumatism, or other weakening factor in rendering the tissues less resistant, or more receptive to the infective agent. These and many other conditions governing the infection of the individual must be recognized and accorded their full worth. The essential fact remains, however, that without the inoculation of the bacillus tuberculosis we can not have consumption, or any form of tubercular disease; and if by any means we can exclude this infective agent from the body the individual is safe from the disease.

There are two principal channels of infection in tuberculosis; one is by the digestive tract and the other, far the more important, by the respiratory organs.

Children are especially liable to infection by way of the digestive organs. An infant nursed by a consumptive mother, or one fed on milk from tuberculous cows may become tuberculous if the food contains the infective agent. It has been shown that the milk may contain tubercle bacilli, even though there is no recognizable local tubercular disease of the lacteal glands. It is highly probable that the frequency of tuberculosis of the intestinal canal, the peritoneum, the mesenteric glands and other abdominal organs in the young, is in most cases attributable to direct infection by tuberculous milk. In the adult this avenue of infection is likewise open. Meat from tuberculous animals, or other articles of food accidentally contaminated by the tubercle bacillus, may be the medium of communication. Secondary infection, from swallowing the bacillus-laden sputum from the lungs, is also not infrequent.

I need hardly say, however, that in the great majority of cases of tuberculosis the infection takes place by way of the respiratory organs, which also become the principal and generally the only, seat of the disease.

It is held by some, and I am inclined to consider the belief well founded, that the tubercle bacillus can not effect a lodgment in the tissues and begin its destructive action, unless these are weakened in their resistive power by an inherited defective organization, or by acquired conditions of lowered vitality. It is a result of clinical observation that a catarrhal pneumonia, for example, is often a forerunner of pulmonary consumption. It is assumed, with good reason, that the anatomical elements of the lining

membranes of the inflamed air-cells and finer bronchial tubes succumb to the attacks of the invading germ, carried in the inspired air, while in a state of health the tissues could resist the destroying organism. This simply emphasizes the importance of avoiding any factors tending to depress the vital condition of the organism or any of its parts.

The tubercle bacillus does not multiply under ordinary conditions outside of the body, and the fully developed organism when removed from the conditions favoring its growth in the body soon loses its vitality. But the spores of the bacillus, or the germs of the germ, as one may say, are extremely resistant and retain their power of growth and development for a considerable period. The dried spores are thus always potential sources of mischief if accidentally taken into the system by inhalation or swallowing. They may also be inoculated in wounds or traumatism, but this mode of infection is comparatively rare, and may be left out of account in the present discussion.

Careful investigations by Baer and Cornet have shown that the death-rate from consumption is four times as great in German prisons as among the free population of the same age. In convents, asylums, and similar institutions, tubercular diseases are also extremely prevalent. In the Maryland Hospital for the Insane, over 30 per cent. of the deaths are due to tuberculosis. I am confident that within the last two years at least three patients contracted the disease by infection in the wards. Efforts have been recently made to minimize this danger.

Dr. Lawrence F. Flick has shown by a patient and laborious study of the cause of death in the fifth ward in the city of Philadelphia, that certain houses in that ward are infected. He found that for a period of twenty-five years, from 1863 to 1887, all the deaths from tuberculosis in the ward occurred in less than one-third of the houses, while in 1888 over one-half of the tubercular deaths occurred in these same houses, demonstrating beyond a doubt that these houses were infected.

I can hardly think it necessary to adduce proof that the tubercle bacillus is in all cases of tuberculosis the active agent of the infection. Recent investigations, especially those of Cornet, have shown the manner in which infection occurs. The breath of consumptives contains no bacilli, and is not infective. Even when the lungs are full of broken down tissue swarming with bacilli, the latter are only in the rarest instances, if at all, exhaled in the breath. During a fit of coughing, small particles of pus and secretion containing bacilli may be carried along in the forcible expulsion of air from the lungs, but even this is probably rare. Ordinarily the air of rooms or of hospital wards occupied by consumptives is free from bacilli and may be breathed with impunity. It is only when the dust of the room, containing dried and pulverized sputa, is disturbed by sweeping, or shaking up the bed-clothing, or in other ways, that danger of infection occurs. Scrapings from the walls of rooms occupied by consumptives, inoculated into animals, produced tuberculosis in 20 per cent. of the latter. Control experiments showed that dust from the walls of houses, hospital wards and public buildings not inhabited by tubercular patients was not infective. Cornet showed also that the dust from the walls was in no case infectious when sputum cups were used to receive all expectorated matter,

although such expectoration was full of bacilli. Praussnitz has demonstrated the presence of tubercle bacilli in the scrapings from the interior of railway carriages on one of the German railway lines carrying many consumptive passengers. Thus is experimentally demonstrated a danger to which attention had previously been forcibly drawn by Whittaker, Gihon and others.

It is generally agreed among physicians that if the stools from a case of typhoid fever are disinfected before being thrown out where they may contaminate the drinking-water supply, there is little, if any, danger from further infection. The alvine excreta being recognized as containing the infective agent, the destruction of the latter renders the material innocuous. In like manner it may be accepted as demonstrated by recent researches that if the sputa of a case of consumption be disinfected as soon as expectorated, the consumptive patient is no longer a source of danger to his neighbor.

From the foregoing it becomes evident that the principal measures of prophylaxis against tuberculosis must be such as comprise, first, immediate destruction of the bacillus tuberculosis in the sputa, or in other excretions when the case is not a pulmonary one; second, the disinfection of clothing and bedding, or other furniture liable to be contaminated with the infective material. As accessory measures must be considered notification to the health authorities of all cases of consumption, public disinfection of infected houses and conveyances (ships, railway cars), and the establishment of special hospitals for the free treatment of indigent consumptives.

The first example of an attempt at a thoroughgoing restriction of tuberculosis, is the decree of the King of Naples in 1832, before referred to. According to De Renzi, quoted by Flick, this decree contained the following propositions:

1. The physician shall report the consumptive patient, when ulceration of the lungs has been established, under penalty for the first offense of 300 ducats, and upon repetition, of banishment for ten years.

2. An inventory shall be made by the authorities of the clothing in the patient's room, to be identified after his death, and if any opposition shall be made, the person doing so, if he belongs to the lower class, shall have three years in the galleys or in prison; if to the nobility, three years in the castle and a penalty of 300 ducats.

3. Household goods which are not susceptible shall be immediately cleansed, and those that are susceptible shall at once be burned or destroyed.

4. The authorities themselves shall tear out and re-plaster the house, alter it from cellar to garret, carry away and burn the doors and wooden windows and put in new ones.

5. The sick poor shall at once be removed to a hospital.

6. Newly built houses can not be inhabited before one year from their completion, and six months after plastering has been finished and repairing has been done.

7. Superintendents of hospitals must keep in separate places clothing and bedding for the use of consumptives. Other severe penalties are threatened to those who buy or sell objects which have been used by consumptives, to servants, members of the family, and to any transgressors whomsoever.

The discovery of the bacillus tuberculosis and its mode of propagation and transmission would almost seem to justify these harsh regulations. Indeed, their enforcement appears to have produced a marked reduction in tuberculous diseases. Dr. Flick, who has made a very thorough study of this question, estimates that in 1782 the mortality from tuberculous diseases in the Kingdom of Naples was ten per thousand of population. In 1887 the official statistics for the Italian States formerly comprised under the Neapolitan Kingdom showed that the death-rate from all forms of tuberculosis was only 2.05 per thousand living people.

The efficient carrying out of restrictive measures against consumption requires intelligent coöperation on the part of the public. Hence, the education of the laity upon the infectious nature of tuberculosis and the importance of individual measures of prophylaxis must precede any successful enforcement of legal enactments looking toward the restriction of the disease. There can be no doubt that the public press can give most effective aid in spreading such knowledge. The newspapers are always foremost in the dissemination of useful information. The press is the most powerful auxiliary of the sanitarian. The press makes public opinion. Public opinion makes laws, and until laws have the sanction of public opinion, it is futile to look for their successful enforcement.

Popular societies, like the French "Ligue préventive contre la phthisie pulmonaire," and the "Pennsylvania Society for the Prevention of Tuberculosis," are also useful and effective agencies in educating the people upon this subject. The organization of similar societies should be encouraged elsewhere.

Our current knowledge of tuberculosis and its means of prevention was effectively summed up in a report made to the New York City Health Department in the early part of 1889, by Drs. T. M. Prudden, H. M. Biggs, and H. P. Loomis, the pathologists of the department, and extensively published. In 1890, the Prussian Government issued a set of regulations which admirably cover the whole subject. This action was followed by the Kingdom of Wurtemberg in 1892. In the same year the State Board of Health of Michigan issued a pamphlet giving instructions for the disinfection of sputa, and in 1893 the same Board went a step further and adopted a resolution requiring consumption of the lungs and other tubercular diseases to be reported among "the diseases dangerous to the public health," this report to be made by householders and physicians to the local health officer as soon as the disease is recognized. The purpose of such report is to secure to the health officer information of the location of each case, "with the view of placing in the hands of the patient reliable information how to avoid re-infecting himself or herself, or giving the disease to others, and in the hands of those most endangered, information how to avoid contracting the disease."

The publication of the report of Drs. Prudden, Biggs and Loomis seems to have been the first official notification to the public by any health authority of the infectiousness and preventability of tuberculosis, since the Neapolitan decree before quoted. Within a few months the New York Health Department has taken a more aggressive step, and now requires all public institutions, such as asylums, homes, dispensaries, etc., to transmit to the Board

of Health the names and addresses of all persons suffering from pulmonary tuberculosis within seven days of the time when such persons first come under observation." Physicians are requested to notify the Board of all cases coming under their professional care. Hospital authorities are urged to separate consumptive patients from those sick of other diseases. Special inspectors are appointed to visit the residences of consumptives, deliver printed instructions containing methods of prevention, and practice disinfection when required. One of the municipal hospitals is to be set aside as a "Consumptive Hospital" for the exclusive treatment of this disease, and whenever requested by physicians, the Health Department will undertake the bacteriological examination of the sputum in doubtful cases.

Action in a similar direction was contemplated by the Board of Health of Philadelphia, but objection on the part of some physicians to the compulsory notification of the disease was so strong that it has been for the time abandoned.

Within two months the State Board of Health of Washington has placed consumption among the diseases required to be reported to the Board.

The Board of Health of the City of Baltimore is about issuing a circular to the public giving suggestions in reference to preventive measures against tuberculosis.

The Pan-American Medical Congress, in session in Washington last September, adopted resolutions recommending to the various National Governments represented, effective measures for the restriction of the disease, and the American Public Health Association, which has been studying the question for the past four years through a special committee, set its stamp of approval upon the work of the committee by the adoption of the following report and recommendations in Chicago last October:

1. "Tuberculosis has been conclusively demonstrated to be contagious by bacteriological experiments, by clinical observations, and by a study of the history of the disease.

2. "Tuberculosis is a preventable disease. Its preventability follows as a logical sequence upon its contagiousness, but has likewise been demonstrated in practical life.

3. "The contagium of tuberculosis resides entirely and solely in broken down tubercular tissue. A person suffering from tuberculosis, therefore, does not become a source of danger to others until he begins to give off broken-down tubercular tissue, either in the form of sputa from the throat or lungs, diarrheal discharges from the bowels, or matter from a tuberculous sore such as lupus, white swelling, cold abscess, scrofula or tubercular inflammation of a joint.

4. "A person suffering from tuberculosis can be made entirely harmless to those about him by thorough sterilization of all broken-down tissue immediately upon its being given off. With proper precautions it is therefore possible to live in the closest relation and upon the most intimate terms with consumptives without contracting the disease.

5. "Tuberculosis is not hereditary. A predisposition to the disease can be transmitted from parent to offspring, but this is more true of tuberculosis than it is of all other contagious diseases.

6. "A predisposition to tuberculosis can be created anew by malnutrition or by anything which depresses the nervous system.

7. "Tuberculosis affects animals as well as man, and is identically the same disease in both. In domestic life, human beings and animals mutually infect each other.

8. "The media through which human beings are ordinarily infected by animals are milk and meat.

9. "Houses in which consumptives have lived and in which immediate sterilization of all broken-down tissue has not been practiced, are infected houses and are liable to convey the disease to subsequent occupants.

10. "Spitting upon floors and into handkerchiefs, and permitting the broken-down tissue to dry and become pulverized, is a prolific cause of spreading tuberculosis.

11. "Temporary occupation of hotel rooms, sleeping-car berths and steamer cabins by consumptives in the infectious stage can infect them so as to convey the disease to subsequent occupants unless proper precautions are taken against contamination of the bedding, furniture and walls with broken-down tubercular tissue."

We recommend the following practical measures for the prevention of the disease:

1. "The notification and registration by health authorities of all cases of tuberculosis which have arrived at the infectious stage.

2. "The thorough disinfection of all houses in which tuberculosis has occurred, and the recording of such action in an open record.

3. "The establishment of special hospitals for the prevention of tuberculosis.

4. "The organization of societies for the prevention of tuberculosis.

5. "Government inspection of dairies and slaughter houses, and the extermination of tuberculosis among dairy cattle.

6. "Appropriate legislation against spitting into places where the sputum is liable to infect others, and against the sale or donation of objects which have been in use by consumptives unless they have been thoroughly disinfected.

7. "Compulsory disinfection of hotel rooms, sleeping-car berths and steamer cabins which have been occupied by consumptives before other persons are allowed to occupy them."

The City of London Hospital for Diseases of the Chest, and the North London Hospital for Consumption, the Royal National Hospital for Consumption, the National Sanitarium, the Manchester Hospital for Consumption and the Victoria Dispensary for Consumption, issue instructions to be observed by their patients to prevent spreading the disease. These all comprise the use of spit cups, disinfected cuspidors, the prohibition of expectorating on the floor indoors, or on the ground out of doors, and the avoidance of swallowing the sputa to prevent reinfection.

In the various sanatoria for tuberculosis in Germany and in many in this country similar instructions are issued. Some progressive private practitioners in this country have cards printed containing concise instructions for the disinfection of sputa, and other measures to prevent the further spread of the disease.

The various practicable measures for the restriction of tuberculosis may be summed up as follows:

1. Notification to the health authorities of all cases of tuberculosis, more especially of tuberculosis of the

lungs. This report should be made by the physician who becomes cognizant of the case in the line of his professional duty, and by the householder himself. In order to reach all cases, such notification should be compulsory. While it is probable that some cases would escape report through the negligence or wilful disregard of the medical attendant, these would be few and would diminish as soon as the benefits accruing from attention to this regulation became apparent.

2. All public institutions, as hospitals, prisons, schools, asylums, etc., should be required to promptly report through their managers or executive officials, under penalty, all cases of tuberculosis occurring in such institutions.

3. Upon the recovery, death or removal of a consumptive from one house or apartment to another, notice should be given by the patient or his guardian, the householder or the physician, to the health authorities in order that appropriate measures of disinfection of the vacated premises may be taken.

4. Concise instructions for the guidance of patients with pulmonary consumption, or persons coming into frequent contact with them, should be furnished free of charge by the health authorities, upon notification of a case, or at the request of any person interested. These instructions should cover especially the means for destroying or rendering innocuous the sputa. *The isolation of patients is not necessary; when the material containing the tubercle bacilli—in these cases the sputa—is destroyed, the consumptive is no longer dangerous to his most intimate associates.*

5. The health authorities should be empowered to employ special inspectors to visit all cases of consumption reported, instruct the patients themselves and the family, or those brought closely and constantly in contact with them in the best means of avoiding self-infection and the communication of the disease to others, and to disinfect the apartments occupied by the consumptive if found necessary. It may be objected that this will interfere too much with the rights and privileges of the attending physician, but the latter would doubtless often be willing to be relieved of the tedious details necessary. There could, of course, be no objection to the attending physician performing these duties himself, provided they were thoroughly done.

Neither the inspector nor any other officer of the health department should be allowed to comment on the physician's treatment or to offer any suggestions in this particular. I believe it will be generally conceded that sanitary officials conduct themselves with tact and discretion in their relations with physicians.

6. Municipalities should be urged to establish special hospitals for the treatment of indigent consumptives. General hospitals should provide special wards for patients with this disease, and enforce in them the proper measures for the limitation of infection.

7. Railway and steamship companies should be required to change and disinfect all bed linen and other materials liable to infection from consumptive travelers.¹ Dr Albert L. Gihon, in an address before the Pan-American Medical Congress, has graphically referred to the danger in steamship travel with con-

¹ It is reported that on one of the Hungarian railway lines, special railway cars will be furnished for consumptives. These will be renovated and disinfected after each trip.

sumptives, and Dr. J. T. Whittaker has pointed out the many sources of possible infection in the Pullman car.

Such are, in outline, some facts and suggestions that I have thought not inappropriate to present to you on this occasion. The facts are vouched for by leading investigators, physicians and sanitarians. The suggestions are legitimate deductions from the facts recorded. No one who studies the question without prejudice can resist the conviction that tuberculosis, "the great white plague" is a preventable disease; that by concerted action on the part of physicians, sanitary authorities and the public, it can be stamped out among all civilized peoples; that, like leprosy and the black death, it should be of interest in the future merely to the historian of human progress.

CLINICAL HISTORY OF THE CASE OF PRESIDENT JAMES ABRAM GARFIELD.

BY ROBERT REYBURN, A.M., M.D.

PROFESSOR OF PHYSIOLOGY AND CLINICAL SURGERY MEDICAL DEPARTMENT HOWARD UNIVERSITY, WASHINGTON, D. C., AND ONE OF THE ATTENDING SURGEONS IN THE CASE OF PRESIDENT GARFIELD.

(Concluded from page 624).

September 17, 8:30 A.M. Temperature 99.8; pulse 108; respirations 21. September 17, 12 M. Temperature 102.2; pulse 120; respirations 24. September 17, 5:30 P.M. Temperature 98; pulse 102; respirations 24. Up to midnight last night the condition of the President had not improved. At 11 P.M. his pulse was 130 per minute, and it varied from 116 to 130 during the night. At about 3 A.M. he fell asleep and slept until 6 A.M. When he awoke his pulse had receded to 106, and his temperature to 98 (F). His temperature during the night did not vary much from the normal point. He slept fairly well in the night taking nourishment at proper intervals. At 11:30 A.M. he had a severe chill lasting about half an hour, and his pulse ran up to 137, followed by perspiration. After 12 M. the temperature gradually fell with diminished frequency of pulse and respiration, so that they were nearly normal by 6 P.M. He slept most of the afternoon, and took liquid nourishment. The paroxysms of coughing were less frequent than usual. During a lucid interval last night the President called Dr. Agnew to him and said: "Doctor, am I not critically ill?" "Your condition is critical," was the frank response, "I thought so," rejoined the President. At the time when the President was attacked with the chill, he complained of very severe pain in the anterior mediastinum; this pain recurred at intervals of six or seven hours until the President's death. This pain is now believed to have been due to the rupture of the aneurismal sac developed on the splenic artery, as show by the postmortem.

September 18, 8:30 A.M. Temperature 98; pulse 102; respirations 18. September 18, 11 A.M. Temperature 100; pulse 116; respirations 20. September 18, 5:30 P.M. Temperature 98.4; pulse 102; respirations 20.

There was no perceptible febrile rise in the temperature of the President during the night, the pulse ranging from 102 to 112 per minute. The cough was less troublesome than on previous nights, and the expectoration is unchanged. He was able to

take the nourishment and stimulants required, without gastric disturbance, and there was no evidence of mental aberration during the night. This morning his temperature was six-tenths of a degree (F.) below the normal point, and he was immediately sponged with hot alcohol and wrapped in hot blankets. Enemata containing defibrinated beef blood and stimulants have been administered to him to bring about reaction.

September 18, 6 P.M. The President though quite weak has passed a very quiet day. There has been no recurrence of chill or mental disturbance during the day. At 9 A.M. a slight febrile rise took place which began to subside at 11 A.M.

September 18. To-day the President called Colonel Rockwell to him and said: "Do you think my name will have a place in human history?" The Colonel answered: "Yes, a grand one, but a grander one in human hearts. You must not talk in that way. You have a great work yet to perform." After a moment's silence he said, sadly and solemnly: "No, my work is done."

September 19, 8 A.M. Temperature 98.8; pulse 106; respirations 22. September 19, 12:30 P.M. Temperature 98.2; pulse 104; respirations 20. September 19, 6 P.M. Temperature 98.4; pulse 102; respirations 18.

The President's condition continues to be very unfavorable, and the end is evidently approaching fast. Shortly after the issue of last evening's bulletin, he had a chill lasting fifteen minutes. The febrile rise which followed lasted until midnight, during which time his pulse ranged from 112 to 130 per minute. The sweating which followed was quite profuse. The cough which was troublesome during the chill gave him little annoyance during the remainder of the night. At 8:30 A.M. another chill came on, on account of which the dressing of the wound was temporarily postponed. He slept most of the morning, coughing but little and with more ease.

September 19, 11:30 P.M. After the evening bulletin was issued at 5:30 P.M. the condition of the President remained about the same as during the afternoon, the pulse varying from 100 to 106 per minute, and with rather increased force and volume. After taking nourishment he fell into a quiet sleep. About thirty-five minutes before his death, and while he was asleep, his pulse rose to 120.

September 19, at 10 P.M. General Swaim who was watching in the room with the President heard him gasp, and make an effort to speak. He at once arose and came to his bedside. He stood there for a few moments looking at him as he apparently lay asleep. The President opening his eyes saw and recognized him and said: "Well, Swaim," and then immediately afterward, "Oh my! Swaim, what a pain I have right here," putting his hand to his heart. General Swaim leaned over and felt his pulse, and then finding himself unable to count its beats, sent instantly for Dr. Bliss, who was in the next room. It required but a glance to see what was coming. Death was at hand. Dr. Bliss sent immediately for Drs. Agnew and Hamilton, and called Mrs. Garfield, who was in the adjoining room. Within half a minute Mrs. Garfield entered the sick chamber. Nothing was said but the one question she addressed to Dr. Bliss, "Is there no hope?" "Madame," replied the Doctor gravely, "he is dying."

By this time Mrs. Rockwell and Miss Rockwell,

Miss Garfield, Private Secretary Brown, Colonel Rockwell and Dr. Agnew had entered the room. Mr. John Ricard, Mr. H. L. Atchinson and the four attendants were also present. The President was quite unconscious. His eyes were half closed, and the balls of them turned upwards, so that the lines of white showed between the half-opened lids. There was no sound in the sick room except his breathing, which at times was loud and stertorous, and then again could scarcely be heard. It was not many minutes (at 10:35 p.m.) before the life went out so gradually that it was hardly manifest when he was dead. When the limbs had assumed that eternal rigor which only decay can change, Dr. Bliss tried to feel the pulse, and endeavored in vain to hear the heart beats, and then said in a half whisper, "It is over."

V.

THE CAUSES OF THE DEATH OF PRESIDENT GARFIELD.

It is surprising, considering the large amount of medical literature in existence devoted to the case of President Garfield, to find so many members of our profession having very vague ideas concerning the cause of his death.

The immediate cause of his death was the spontaneous rupture of a traumatic aneurism formed on the splenic artery, probably as the result of the abrasion of the outer coats of this blood vessel by the bullet at the time of the shooting. This was a complication that could neither be foreseen or prevented, nor could it have been relieved by any exertion of surgical or medical skill on the part of his surgeons. The proximate cause of his death (and one that would have inevitably soon terminated his life even had the bursting of the aneurism not taken place) was the profound condition of septic poisoning (septicemia) which existed in the case of the President for a considerable time previous to his death. The initial point of this septic condition probably dates as far back as the period of the first chill (July 23), and though there were apparent symptoms of convalescence at various times, yet the course of this septic infection was practically continuous, and could only result in inevitable death. This brings up the grave and momentous question for consideration viz: Could this septic condition in the President have been prevented by a different method of treatment on the part of his surgeons? It is useless for me to tell how many weary days and wakeful nights I have spent in arguing with myself the various and opposing arguments on either side of this question. In order to give a calm and unbiased judgment in this matter, let us go back a little and study the course of the missile in the body of the President with the nature of the injury produced by it.

The bullet from the pistol of the assassin entered his body in a horizontal and slightly downward direction immediately over the eleventh rib about three and one-half inches to the right of the vertebral spine. Its course was deflected downward and somewhat to the left, and then it passed to the left, fracturing the eleventh rib; then it fractured the twelfth rib at a point slightly more to the left than the fracture of the eleventh took place, being still more deflected to the left by the rounded and curved surface of the twelfth rib. It then entered the upper part of the right side of the body of the

first lumbar vertebra, involving the inter-vertebral cartilage of the vertebra above (twelfth dorsal) in its course. The bullet emerged from the left side of the body of the first lumbar vertebra at a lower

Fig. 1.—Lateral view (right side) of bodies and spinous processes of twelfth dorsal and first and second lumbar vertebrae of President Garfield, showing wound of entrance in body of first lumbar vertebra.

point down than its point of entrance, and continuing its course to the left with diminishing velocity, passed behind the pancreas to a point just below its lower surface where it was found at the time of the

postmortem examination. The course of the bullet was wholly without the peritoneal cavity.

As will be seen by the engraving, the course of the missile after it entered the body of the President followed the line of an irregular, nearly S-shaped curve with its convex surface directed to the back of the President, and passing to the left and gradually downward to its termination. A consideration of this fact will show at once how impossible it was to obtain any information concerning the course of the bullet, or its location in the body by any examination made from the outside of the body. No probe could be passed through the wound in the body of the vertebra, (even if it had been considered advisable to attempt such a proceeding), and the purulent material formed in the wound as the result of bacterial action, gradually by the action of gravity dissected its way downward toward the right iliac fossa, and formed a false channel or sinus, which misled the surgeons, and made them suppose the bullet lay in

(The probe has been passed from above and somewhat downwards through wounds of entrance and exit).

that part of the body. The carious condition of the body of the first lumbar vertebra found to exist at the time of the postmortem was quite sufficient to account for the septic condition of the President during life. It may here be remarked that the spinal canal of the first lumbar vertebra was not opened by the bullet in its course through the body, nor were there any gross anatomical lesions found in the spinal cord at the time it was examined. It should be remembered, however, that the weapon with which the President was shot was an English revolver of what is commonly called the "bulldog pattern," that was capable of throwing a bullet with great propulsive force; and crushed and splintered the porous cancellated bony tissue in its passage through the body of the vertebra.

The lacerated condition of the cancellated structure of the first lumbar vertebra doubtless contributed largely to the production of the septicemic

condition, which was in no wise due to lack of proper or sufficient drainage. More favorable circumstances for its production than existed in the comminuted and softened cancellous tissue, with its open venous sinuses bathed in ichorous pus could scarcely be imagined. Dr. William White (Review of some of the more important surgical problems of President Garfield's Case, p. 15, 1882): "The fact that drainage was thorough and complete, and that no portion of the unfavorable symptoms was due to failure in this respect, was fully established by the absence of purulent collections, either along the track of the ball or in the passage caused by the burrowing of the pus. There was no time previous to the first operation (July 24) at which the accumulated pus did not pass freely out of the original wound. Its exit was favored by gravitation after the two incisions had been made, which

Fig. 4.—Antero posterior section of bodies and spinous processes of twelfth dorsal and first and second lumbar vertebrae of President Garfield, showing carious condition of the bodies of twelfth dorsal and first lumbar vertebrae.

brought the external openings to a lower level, and enabled them not only to drain the lumbar and iliac regions, but also to carry away any discharge that might have come from the fractured vertebra." Antiseptic treatment was employed throughout the case as carefully as it was possible to do so, and drainage tubes were used until it was evident that their use was unnecessary."

In attempting to reply to the above mentioned questions, much time and labor have been spent in reviewing the various authorities on this subject. The consensus of opinion of all the great masters of the art of surgery is to the effect that these injuries are almost necessarily fatal. Dr. Lidell, justly esteemed as one of our most experienced of American military surgeons, says (*American Journal of the Medical Sciences*, Vol. 48, p. 317): "Leaving out of the calculation such fractures as involve the spinous processes

Chart of the temperature, pulse and respiration of President Garfield from July 2, 1881 to September 19, 1881. By Robert Reyburn, M.D.
 1. Period of profound shock and internal hemorrhage. 2. First rigor (septic infection). 3. Opening made to drain the President's wound. 4. President removed to Elberon, N. J. 5. President died at 10:35 P.M.

alone, the writer has never seen a case of gunshot fracture get well, and he might add that he has never seen life prolonged for a month after the infliction of that injury."

In Circular No. 6, Surgeon-General's Office, 1865 (issued during our Civil War), it is reported that of 187 recorded cases of gunshot fracture of the vertebræ, all but seven proved fatal; six of these were fractures of the transverse or spinous apophyses. It is well known that fractures of the vertebral processes are not especially fatal injuries, and that a large proportion of them recover. Many of these have been recorded under the general head of fractures of the vertebræ, but evidently have no bearing on the case in question. Dr. Demme, ("Military Surgery," 1868) says: "Extensive injuries or lodgment of balls in vertebræ or in the cord give rise to death or incurable paralysis."

Fig. 5.—Oblique view (from the left side) of the twelfth dorsal and first and second lumbar vertebrae of President Garfield.

Professor Gross ("Treatise on Military Surgery," Vol. 2, p. 82) says: "Gunshot wounds of the vertebræ, with lesion of the spinal cord, are nearly always, if not invariably fatal. Of twenty-two cases of this kind in the English army in the Crimea, not one recovered. Even when the bones alone are affected the danger is generally very imminent, most of the patients thus affected dying in a short time."

Professor P. S. Connor (Ashhurst's International Encyclopedia of Surgery, 1882, Vol. 2, p. 203) says: "The prognosis of vertebral injuries, aside from the less severe forms of contusions and fractures of the processes, especially the spinous, is very grave, death usually resulting from lesion of the cord, from septic infection, from caries with abscess, or from associated wounds of a viscus or large vessel. As was declared by Ollivier, in gunshot cases the accidents are graver and death generally more rapid than in those otherwise caused. Of the thirty-two cases of verte-

bral fracture among the British soldiers in the Crimea, all proved fatal except four, which were either fractures of the transverse processes in the neck, or of the spinous processes only, and in the French army, 181 died out of 194 (93.3 per cent.). In the war between Prussia and Hanover in 1866, there were eight cases with six deaths. Of 628 cases tabulated by Otis, 349 or 55.57 per cent. ended in death, the mortality according to locality having been: For the cervical region 70 per cent. (63 out of 90); for the dorsal region 63.5, (87 out of 137); and for the lumbar region, 45.5 per cent. (66 out of 145); but in almost all probably, of the non-fatal cases, the fractures affected only the processes."

In the *Wien Medicin Wochen*, No. 47, 1881, Professor Max Schuller, after giving a complete history of President Garfield's case concludes as follows: "Taking into consideration all the circumstances

Diagram of posterior surface of body of President Garfield. 1. Point of entrance of bullet. 2. Location of bullet when found during the post-mortem examination.

connected with this gunshot wound, it is evident that the determination of the direction taken by the missile by probing would have been extremely difficult, and had it been possible, would have been accompanied by great danger to the patient. Among the symptoms which presented themselves immediately after the receipt of the injury, only the pain and disturbance of insensibility in the lower extremities, gave an indication of the true course of the bullet. If, however, the supposition had been entertained that the vertebral column was wounded, the question of the indication for treatment would not have been different from that instituted by the attending surgeons." He then continues: "To prevent sepsis in gunshot injuries, and to bring to a successful issue such a wound as that received by President Garfield, is one of the most difficult achievements, and can not always be accomplished, even

with the most careful and assiduous application of aseptic surgery."

Dr. John Ashhurst (*North American Review*, December, 1881, p. 594) says: "Looking at the whole case from beginning to end, I do not see that the treatment could have been altered in any way to the advantage of the illustrious patient; nothing was done that should have been omitted, and nothing was left undone that could possibly have been of benefit."

Dr. J. Marion Sims (*North American Review*, December, 1881, p. 300) says: "The President's surgeons did all that men could do, all that the present state of science would permit, and all that could have been done, even if they had first ascertained the course and direction of the ball." "Our whole medical literature does not contain a single well authenticated case of recovery from such a wound." "He had not the least chance of recovery under any circumstances or any treatment."

Dr. John T. Hodgen (*Ibid*, p. 610) says: "In reviewing the history of the case of President Garfield, I can find no reason for adverse criticism of any part of the management."

Finally, while it is difficult and perhaps impossible for any one to give a dispassionate judgment, in a case in which we were so deeply and personally interested as in that of the President, yet it is the deliberate conviction of the writer (as it was of all the surgeons in charge of the case) that the President was mortally wounded when he received the fatal shot. Freely confessing our errors of diagnosis, yet we believed that no different course of treatment could have saved his life. I know that I speak only the truth when I say that no wounded man ever received more tender, loving and devoted service, not only from his surgeons but also from the faithful friends who nursed him through his long and weary illness. We gave him this cheerfully and would have sacrificed even our lives for him, if by so doing we could have saved his. We would have done this not only because he was President, but because we loved the man. Poor patient, uncomplaining, suffering President. How our hearts ached for him; Member of Congress, Senator, President, stricken down at the time when he had received in rapid succession the highest honors his country could bestow, he passed through days, weeks and months of suffering, through the valley of the shadow of death, to that heavenly country, where there is neither sorrow, nor suffering nor pain. We can not understand why such things should be. We can only bow in humble submission to the will of Him who ruleth all things both in heaven and earth, and who doeth all things, well.

THE END.

A NEW APPARATUS FOR ADMINISTERING ANESTHETICS.

BY EDMOND SOUCHON, M.D.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY, TULANE UNIVERSITY,
NEW ORLEANS, LA.

THE ANESTHETIZER.

This new apparatus has for its object to force the vapor alone of anesthetics into the pharynx through a tube passed into the nose or mouth, or to force the vapor into a cone. I call this apparatus by the newly coined word, "anesthetizer," because such a

device requires really a new word to express its mode of action, which is active since the vapor is forced out of the receptacle into the patient by an agent which is outside of the patient, who is himself passive; whereas inhalers are passive and require the exposure to the air of the anesthetic for their proper working, and require also an active coöperation from the patient.

The apparatus consists of a receptacle or bottle of suitable size with a stopper traversed by two tubes, an inlet and an outlet tube, neither of which dips into the liquid anesthetic, but both stop close to the stopper. The two tubes are of the same diameter throughout and at both extremities, about one-quarter of an inch more or less. Stop cocks may be fitted to them to prevent the spilling or the evaporation of the anesthetic when the apparatus is not used. The inlet tube is connected with a compressible bulb which is fixed at both ends to the receptacle by a simple metallic frame, so that the apparatus can be readily held and worked with one hand, leaving the other hand free to take care of the pulse. A ring adapted to the frame on the side opposite to the bulb, and through which a finger is passed, assists in the working. A hook with or without a chain may be adapted to the frame so as to hook the apparatus to the vest or coat, as is used in some inhalers. The outlet tube from the stopper is provided with a rubber tube of suitable length which is connected with a cone, or is introduced through the nose or through the mouth, into the pharynx.

SOUCHON'S ANESTHETIZER

The receptacle or bottle is filled or emptied by simply removing the cork.

To guard against any possibility of forcing the liquid anesthetic through the outlet tube, and also to guard against any spilling, so as to enable the anesthetist to lay the bottle on the bed or table without any apprehensions as to the consequences, it may be well to fill loosely the bottle with sufficient absorbent cotton to imbibe and hold the anesthetic; a sponge or any absorbent material will do as well. This, however, may diminish somewhat the strength or quantity of the vapor at each pressure of the bulb. After the operation is over the anesthetic unused keeps in the bottle and cotton as well as in a separate bottle, provided the tubes are disconnected and the holes plugged tightly.

The bulb is detachable and can be renewed whenever this becomes necessary.

The advantages of this apparatus over inhalers of a more or less similar kind, consist: 1, in that neither the inlet or the outlet tubes dip down into the liquid anesthetic or come near to it, thus preventing the liquid anesthetic from being driven into the outlet

tube, thence into the face or pharynx; 2, the absorbent cotton prevents also against this same accident and against the spilling of the anesthetic when the bottle is laid on the side or inverted; 3, in the fixation of the bulb at *both ends*, making the fastening of the bulb more secure and the bulb more easy to work with the same hand that holds the apparatus; 4, the ring which assists in holding it; 5, its small size, about five inches in height by two in diameter; 6, its cheapness; 7, the facility with which one can be constructed *ad hoc*; 8, the thorough manner in which it does its work; 9, the impossibility of its getting out of order.

TUBO-NASAL ANESTHESIA.

Without such an efficient and simple apparatus it is impossible to make a *daily practical success* of maintaining the anesthesia through the nose or mouth in all operations on the face or its orifices, when otherwise the cone or wire mask has to be removed every few minutes to uncover the field of the operation to enable the operator to proceed with the operation. Soon after the inhaler is removed, the patient recovers from the effects of the anesthetic and the operator has to stop operating to allow the cone or mask to be applied over the face. With this anesthetizer, anesthesia is maintained uninterruptedly.

It is a great saving of time, pain, bleeding and shock to the patient, thereby contributing materially to the saving of life in operations which for the most part are long and bloody and often bring the patient to death's door. It is also a great saving of mental strain to the surgeon who can proceed rapidly and uninterruptedly with the operation.

The nasal tube should be introduced down into the *lower pharynx*, otherwise the patient breathing through the mouth may not inhale sufficiently of the anesthetic. By compressing the bulb at the onset of an inspiration is best; this rule compels a closer watch over the respiration. By compressing the bulb more or less rapidly and thoroughly, the amount of the anesthetic is regulated; this must be borne in mind lest too much anesthetic be given. It does not require much anesthetic to maintain the anesthesia after the *patient has been well anesthetized*. Any soft tube of whatever material will perhaps answer, but an ordinary soft red rubber catheter is the best, and is easily obtainable; this tube should be as large as the nasal cavity will admit. It is also important that all connections should be air-tight for obvious reasons. Care should be taken that no bends or kinks form on any part of the tubes, as this will interfere with the proper working of the apparatus.

The one who administers the anesthetic can place himself in any position where he will be best out of the way of the operator, even at the head of the table or sitting, without interfering with the proper working of the apparatus.

In case of emergency any powder-blower with a bottle will answer. Care should be taken that the long stopper-tube should not dip down into the anesthetic lest too much vapor and liquid be thrown in, even upon moderate pressure of the bulb, unless the absorbent cotton be used. The ends of both tubes should lie in the vapor only of the upper part of the bottle. Any atomizer will do also, provided the tube that dips down into the fluid be removed, otherwise the liquid anesthetic will be driven through the outlet tube; cotton may also be used in the bottle or not.

It is easy for any one to construct an apparatus *ad hoc*, out of any bottle of suitable size. The two holes through the cork are quickly burned through with a red hot piece of large wire; any pieces of tubing, glass or metal, or two goose quills can answer; the bulb of a Davidson syringe or any other obtainable bulb may be adapted; it requires little anesthetic to maintain the anesthesia after the patient has been well anesthetized by the ordinary method.

This apparatus was first exhibited in Ward Eight of the Charity Hospital, in connection with a patient upon whom Dr. Matas was operating for cleft palate.

It was employed throughout a whole operation by the author in a case of tumor of the superior maxilla which was operated upon by Dr. A. W. de Roaldes, in the presence of Drs. R. Matas, A. McShane, F. Landfried, P. Delaup and several others. It was the case of a boy 11 years old where a portion of the right superior maxilla had to be gouged for a most interesting case of odontoma. The patient was anesthetized by the ordinary method, but from the moment the operation began, the anesthesia was kept up by the above means, for over an hour, to the thorough satisfaction of all present. The operator did not stop one minute during the operation, until it was completed. The anesthesia was complete all the time. At one time the head had been lowered (Rose's position), and kept in that position quite a long time, without interfering with the administration of the anesthetic. Barely three-quarters of an ounce of chloroform was used.

The apparatus was also used in the amphitheater of the Charity Hospital on a patient from the service of the author (Ward Two). It was the case of a mulatto adult whose chin and lower jaw had been shot off, leaving a large gap which had to be closed by a plastic operation. Dr. Matas was kind enough to operate while the author administered the anesthetic with his apparatus. The operation was performed before the class of Tulane Medical College and of the members of the Polyclinic. The anesthesia lasted one hour and three-quarters with perfect satisfaction. No bad after effects followed in *either* of the two cases. The apparatus was later on used in other cases with equal satisfaction.

BUCCAL TUBO-ANESTHESIA.

Should the operation be on the nose itself, where the tube might be in the way, the tube could be introduced through the mouth into the lower pharynx, care being taken to prevent the tube being bitten, by using a wedge or a gag or by connecting the end of the tube with a metallic tube, or, best, with a disinfected male metallic catheter which the teeth could not mash.

FACIAL TUBO-ANESTHESIA.

The apparatus may also be used to replace the ordinary way of administering anesthetics for operating in general, by pinning the extremity of an outlet or discharging *long* rubber tube to the interior of the apex of a cone, made of a towel of several ply of paper; fasten the cone with strings tied by a bow knot around the head of the patient. Apply the base of the cone close and tight around the nose and mouth so as to exclude the air; enough air is thrown in coming with the bulb from the anesthetic. For that reason the wire mask does not answer well, as it allows too much air. Dr. A. L. Metz, Demonstrator of Practical Chemistry in the Tulane Medical College, says that

there are eight parts of air to one of chloroform forced out of the receptacle at each compression of the bulb. By pressing the bulb properly, anesthesia was duly produced and kept up in the cases where we employed it. There was no burning of the lips and nose. The motions of the head of the patient are unheeded because of the length of the tube and of the fastening of the cone. In case of vomiting, the strings are readily untied and the cone removed.

If the operation is to be on the face or its orifices, the facial process is abandoned as soon as the patient is anesthetized, and the tube is introduced through the nose or mouth into the pharynx as described above.

OBSTETRICAL TUBO-ANESTHESIA.

The apparatus is useful also in administering anesthetics during labor, using a cone and perhaps a longer tube than above described. As soon as a pain is about to commence, the quick compression of the bulb throws in all the vapor needed. The accoucheur has one hand free to make his examinations. He may trust the apparatus to any one present who will press the bulb only when directed by the accoucheur.

The accoucheur is also relieved of the painful position of stooping over the patient to manage the cone and the anesthetic. The patient may safely administer the anesthetic to herself by compressing the bulb herself, since when unconsciousness is produced she can no more work the bulb and take too much anesthetic. There is no danger of spilling the anesthetic, if the absorbent cotton has been properly arranged in the bottle.

SOCIETY PROCEEDINGS.

Georgia State Medical Association.

Abstract of the Proceedings of the Forty-fifth Annual Meeting held in Atlanta, April 18, 19 and 20, 1894.

FIRST DAY—MORNING SESSION.

The Association convened in Concordia Hall, and was called to order by the President, DR. W. H. ELLIOTT, of Savannah, at 10 A.M.

Prayer was offered by REV. I. S. HOPKINS.

An address of welcome was delivered by the HON. N. J. HAMMOND, of Atlanta, and PRESIDENT ELLIOTT responded thereto in behalf of the Association.

DR. J. B. S. HOLMES, of Atlanta, took the chair, and PRESIDENT ELLIOTT delivered his address. He selected for his subject the

DUTY OF THE PHYSICIAN TO HIS PATIENT.

He began by refreshing the memory of the members by not only a recital of the law, but asked attention to some practical applications of its precepts. He quoted largely from the American and English Encyclopedia of Law, and pointed out the obligations the law implies upon the physician. Directing attention to the Code of Medical Ethics of the AMERICAN MEDICAL ASSOCIATION, he said that this Code was formally adopted by the Constitution of the Medical Association of Georgia, and the fact of its membership made it binding upon the members. It was an obligation voluntarily assumed, and therefore they were bound by the highest dictates of honor to faithfully observe its injunctions. He closed by saying that the standard of responsibility was high, but that it should only increase our zeal to attain it. "If we regard our patients as men and brethren, we will, without the restraint of law and code, follow the Golden Rule and do unto others as we would have them do unto us. If we are faithful to this, what is our reward? Not only 'the promise of the life that now is,' but when the Son of Man, who was our brother here on earth, shall be the King upon his throne of his glory, he will say: 'Inasmuch as ye have done it unto one of the least of these, my brethren, ye have done it unto Me.'"

The address elicited considerable applause throughout its delivery.

The report of the Committee of Arrangements was then read by the Chairman, DR. WILLIS F. WESTMORELAND, of Atlanta.

DR. C. D. HURT, of Atlanta, followed with the report of the Committee on Program.

The reading of papers was then proceeded with, and the first paper was read by DR. W. C. HUMPHRIES, of Acworth, entitled

THE TREATMENT OF PNEUMONIA,

in which he confined himself mostly to the acute lobar variety. The majority of cases with which he comes in contact assume from the beginning the sthenic type and require active or depleting measures. If called to treat the patient in the first stage of the disease he resorts to moderately active catharsis, and an agent that will arouse the dormant secretions and assist nature to eliminate from the system the effete products produced by the disease. For this purpose he finds no better remedy than calomel, and usually prescribes from six to ten grains to an adult in combination with Dover's powders or some preparation of opium and bismuth subnitrate. His next effort is directed to reducing the force and frequency of the heart's action, and for this purpose he has tried several remedies, such as aconite, gelsemium, the coal tar derivatives, etc., but none of them have given so great satisfaction or such uniform results in his hands as veratrum viride. He uses this oftener than any other heart sedative in this disease and it seldom ever fails him. He does not give it to such an extent as to produce nausea, but in small and often repeated doses. With veratrum he combines turpentine in the form of an emulsion. The author then dwelt upon external applications in the treatment of the disease.

DR. O. H. BUFORD, of Cartersville, followed with a paper on the

FLUID EXTRACT OF JABORANDI AS AN ABORTIVE TREATMENT IN PNEUMONIA.

The author thinks that in this drug we have a remedy that in many cases will force a crisis when given early in the congestive stage. He had used it for several years with good effect. After giving fluid extract of jaborandi, he follows it with quinin and stimulants if indicated. The author then reported three cases in which he used this treatment.

DR. T. M. GREENWOOD, of Mineral Bluff, read a paper on the

ABORTIVE TREATMENT OF PNEUMONIA.

He said his mode of treating the disease was to apply a mustard plaster over the entire portion of the lung affected. He usually makes or has them made under his special directions, using the purest brand mixed with water only, letting the plaster remain on the patient for six hours. He next investigates the condition of the bowels, the secretions in general and, if necessary, gives a mercurial. If this does not cause a free evacuation of the bowels, he administers Epsom salts or castor oil. He next prepares a solution of salicylate of soda, containing about sixty grains of soda to an ounce of water, giving one teaspoonful every two or three hours, according to the intensity of the pain and the amount of fever. Expectorants in his hands have done little or no good, generally doing harm, the great objection to this treatment being, when long continued, its rejection by the stomach. He considered this treatment abortive, for in his hands it has either been abortive or curative. A trial of over fifty cases have given varying success without a single death.

DR. C. S. WEBB, of Atlanta, called attention to the fluid extract of ergot to reduce the temperature in the first stage of pneumonia. Ergot is to some extent a heart depressant. It slows the heart and reduces the temperature, and in his opinion is not so dangerous a drug as the fluid extract of jaborandi.

DR. R. R. KIME, of Atlanta, said it was absolutely essential in the treatment of pneumonia to distinguish between the first stage of the affection and that of absorption of the circulation after consolidation had taken place, and adapt the treatment to these conditions, otherwise failures would be made. Bleeding and the use of the coal tar derivatives should have a limited place in the treatment of the disease. It was worse than folly to tax the heart to its utmost capacity by the use of cardiac remedies. But the physician should increase the power of the heart, equalize the circulation in order to get rid of the material in the lung. At

this stage many cases could be tided over the critical period by the hypodermatic use of strychnin.

DR. W. H. DOUGHTY, of Augusta, formulated the treatment of the disease under four heads: 1, give the patient plenty of fresh air; 2, keep him clean; 3, feed him; and 4, come just as near as possible to letting him alone.

DR. WM. O'DANIEL, of Bullard, considered the disease self-limiting and advocated supportive treatment. The patient needs to be supported early; that if the physician waited for any length of time the loss could not be made up.

FIRST DAY—AFTERNOON SESSION.

DR. H. J. WILLIAMS, of Macon, read a paper entitled

A CASE OF SARCOMA OF THE ILIUM FOLLOWING A RAILWAY INJURY.

The patient was 32 years of age, strong and healthy, a trainmaster by occupation. There was a wreck on his division, and it was important that the roadway should be rapidly cleared, and so he went to the scene of the accident. A guide rope was attached by one end to a locomotive and by the other to some part of the wreck, so that the power of the locomotive could be used in removing the obstacle. The patient was standing by this rope, it broke under the strain, he became entangled and was dragged some distance by the engine, striking his right buttock against the corner of a cross-tie. He felt no inconvenience from the accident, except a momentary pain following a contusion near the exit of the great sciatic nerve, and returned to work. A month later he consulted Dr. Williams for a pain in the right buttock. One day while using deep injections the author thought he felt the end of his needle scraping denuded bone. This he mentioned to the patient and then received the first intimation of the injury received at the wreck. From this he constructed a theory that the bone had been injured, and denuded of periosteum was pressing upon the sciatic nerve at the notch in the pelvis. The doctor suggested the possibility of an operation, which at this time was declined. About six weeks or two months later he operated. Beginning his incision as for aneurism of the sciatic artery, at the posterior superior spine of the ilium, it was carried over the top of the larger tumor of the greater trochanter, and the tissues were dissected down to the tumor. It was situated on the flange of the ilium just above the exit of the sciatic nerve and attached to the bone, though unattached to the muscles over it. The upper and posterior third of the great sciatic notch was denuded of periosteum and a stellate fracture radiating from the notch upward and backward for an inch and one-half was found, the bone being pressed slightly inward upon the sciatic nerve. In attempting to cut out the tumor, a cavity in it was opened, followed by a gush of fluid, and a small clot. He feared he had opened an aneurismal sac. Running his finger into this sac to find the opening of the artery, he found the interior of the cavity incrustated with small spiculae of bone. There was no collapsing of the cavity nor any further escape of the fluid after the first gush from it. He removed several small pieces of denuded bone and as much as possible of the tumor. Not a drop of pus was found in the growth. The operation was a very bloody one and the patient was much depressed. The wound was packed with iodoform gauze and dressed antiseptically, the patient put between blankets, stimulants administered hypodermatically and hot bottles used to bring on reaction. Examination of the growth disclosed it to be a subperiosteal sarcoma of the mixed type. The patient did well for weeks following the operation, but died some forty-three days after the operation and nearly eight months after the accident.

DR. J. MCFADDEN GASTON, of Atlanta, read a paper entitled

OPERATION FOR FIBRO-CYSTIC SARCOMA INVOLVING THE RIGHT INFERIOR MAXILLARY BONE.

The patient, a colored woman, was 35 years of age, and presented herself with a reproduction of the growth, at the clinic of the Southern Medical College. Examination revealed a large mass involving the region from the angle to the mental curve of the right lower maxillary bone, extending upward to the zygomatic arch and inward to the root of the tongue. There was a protuberance on indurated substance in the middle and a tense elastic portion above, with a larger formation of the same character below. The entire cavity of the mouth on the right side was filled with the tumor. The previous operation was performed about two years ago, and the patient states that the growth commenced some six years prior to that time. An operation being advised and consented to, the patient was instructed to take

two compound cathartic pills night and morning to procure free evacuations from the bowels, and to refrain from food on the morning preparatory to undergoing the operation. At the outset of the operation a strong silk ligature was passed through the tongue and its ends knotted together so as to form a loop, which was to be made available to prevent the tongue from dropping back and interfering with respiration at a subsequent stage of the operation. This precaution was made requisite from the record of cases in which suffocation has resulted from its omission when the lateral attachments of the tongue have been severed. The next step was the extraction of two of the lower incisor teeth, where it was expected to divide the thick bony structure subsequently, either with the saw or bone forceps. This would effect its detachment in front and another section behind the angle of the jaw, through the condyloid would separate the bone behind, so that all the intervening portion of the lower maxillary bone on the right side should be detached with the tumor. Dr. Gaston's greatest concern in regard to hemorrhage connected with the operation was relieved by the expectation of leaving the condyloid process and thus obviating the risk of wounding the internal maxillary artery by its removal. Having planned to accomplish the incision and dissection, so far as possible, without entering the buccal cavity, and thus avoid the entrance of blood into the fauces, he first divided the skin from a point immediately below the middle of the lower lip along the line of cicatrix from the former incision back to the angle of the right lower jaw, and thence upward to the prominence of the zygoma, keeping away from the temporal artery in front of the ear. The skin was then dissected back on the lower side from the tumor and in like manner above to the zygomatic arch, thus exposing the exterior surface of the diseased structure without entering the buccal cavity. The few cutaneous arteries which were divided were secured with artery forceps in the course of the dissection on the lower border. Dr. Gaston outlined the further details connected with the operation. Following the operation there was a steady increase of coma, with a gradual decline of vital force until the death of the patient six days and four hours after the operation. With the favorable state of the wound in the progress of this case, and the final retention of urine, Dr. Gaston is disposed to consider the coma of uremic origin, but has not sufficient data upon which to base this opinion. The cause of death was given as septicemia in his certificate.

DR. M. B. HUTCHINS, of Atlanta, read a paper on

MALIGNANT GROWTHS OF THE SKIN: THEIR DIAGNOSIS AND TREATMENT.

in which he said that while not all the growths to be described are strictly malignant, in a literal sense, the term applies, in that they are either malignant or terminate in malignancy. We have the carcinomata of the skin with epithelioma as a related disease, and the sarcomata. Epithelioma being more frequently met with, Dr. Hutchins described this first: He said that authors described three varieties of epithelioma: the superficial, the deep-seated, the papillary. These three varieties were then interestingly described.

Coming to the treatment of epithelioma, he said this must be limited to local measures, as internal treatment has no value. Incomplete destruction or removal is liable to do more harm than good. Whether caustics, the actual cautery, the galvano-cautery, écraseur or knife are used, the operation must be thorough and the destruction of the growth complete. The means used must be governed by the size, extent and situation of the growth. The caustics are said to be best for superficial growths. Caustic potash may be bored into the diseased tissue, and into its border, any excess being neutralized by dilute acetic acid. It is not an exceedingly painful method. Pure carbolic acid, followed in a few minutes by nitric acid, is mentioned by Shoemaker. Chlorid of lime has been used, but it is very painful and has no advantages. Marsden's paste was referred to as an excellent application for certain forms of epithelioma, as the small, not too deep. The curette may be used for very superficial growths or preceding the caustic application.

Regarding the use of the knife, the author said there was a popular prejudice against it, and people would submit to anything in preference to its employment. There are recurrences after the knife but their frequency, their malignancy, and their terribly destructive action following inefficient or incompletely used applications remove none of the fear of the knife. For the majority of cases the knife is the only remedy, and it is to be preferred where not mechanically

contra-indicated. The deep-seated and the papular forms especially require excision. Every visible particle of the disease must be removed, and with it a perfect coating of healthy tissue.

DR. ARTHUR G. HOBBS, of Atlanta, read a paper entitled "Treatment of Corneal Ulcers with the Galvano-Cautery."

DR. J. W. HALLUM, of Carrollton, contributed a paper on

CHRONIC SORE LEGS AND HOW TO CURE THEM,

in which he said that chronic sore legs were the result of a disease that we often meet in our healing journey. In the remarks of his paper he excluded specific and malignant ulcers, and discussed a simply chronic ulcer that has refused to heal from all efforts of nature that have been brought to bear upon it. The author had been curing such ulcers by painting them with carbonate of lead and linseed oil, in the following proportion:

Pure white lead (ground in oil) ʒxv.
Raw linseed oil ʒvi.

Mix well and sign, paint the ulcer once or twice a day after washing it with warm water. Dry well before painting. The best thing to apply the remedy with is a camel's hair brush.

He was not able to tell how this application effects a cure; but carbonate of lead is sedative, astringent, and probably possesses disinfectant powers, all of which the author considers quite essential in the cure of these ulcers. The shortest time he has been able to accomplish a cure by this method was six days. The ulcer was two and one-half inches in diameter and of three years' standing, but had not penetrated the entire true skin.

SECOND DAY—MORNING SESSION.

DR. H. PERDUE, of Barnesville, read a paper on

DIAGNOSIS.

He said the ability to make an early and quick diagnosis should be sought and, if possible, attained by every physician. It enables one oftentimes to abort disease, and even when this can not be done the violence of the attack may often be modified, and its duration abridged. Thoroughness should be the aim of every physician. None should be satisfied with attainments short of the ability to make a diagnosis through scientific and practical methods of research.

DR. LUTHER B. GRANDY, of Atlanta, read a paper entitled "Suture of the Tendo Achilles," in which he reported a case and exhibited the patient. Similar cases were reported by Drs. Battey, of Rome, and Wm. O'Daniel, of Ballard.

DR. J. B. S. HOLMES then read a paper entitled

MAKING AND CLOSING THE INCISION IN ABDOMINAL SURGERY.

He said that many surgeons, in doing abdominal work, pay more attention to time than the details that are necessary to secure results that are free from sequelæ. This not only reflects seriously upon the surgeon, but leaves the patient in many instances a sufferer for life, requiring often a second operation to cure what might have been prevented. A smooth wound with no cicatricial tissue, no abscess scars and no ventral hernia, is a pleasing sight, not only to the surgeon but to the patient. He would not pretend to say that the sequelæ following abdominal operations can always be prevented, but certainly with proper care and attention to the technique of the operation, if not prevented entirely, they can be reduced to a minimum. The author then went into the details of closing the incision in abdominal operations.

DR. F. W. McRAE, of Atlanta, contributed a paper on

APPENDICITIS, WITH REPORT OF CASES.

The author presented some tentative conclusions and opinions culled from papers and discussions which had fallen under his notice within the last few months.

In the fulminant cases there was no question as to the proper treatment. Nothing but an early operation would save the patient; but in the milder cases there was much diversity of opinion as to how we should proceed. The author's personal experience was confined to six cases of well-defined appendicitis. He had seen several other cases where there were some indications of inflammatory trouble in the right iliac fossa, but no well-defined lesion. They all got well. Of the six cases one, a child of 2 years, died before he saw the case, after an illness of five days. From the history of the case and a careful examination of the body he had no doubt as to the diagnosis. Of the other five cases two passed through one attack, one through two attacks, and one through four attacks of well-marked appendicitis in his hands. In all, except one, he advised operation. All declined it. All except one are now in good health. The

one who has had four attacks he thinks will require an operation later, as there is a well-defined persistent tumor in the right iliac fossa.

DR. SAMUEL C. BENEDICT, of Athens, delivered the orator's address. He selected for his subject,

SUGGESTION AND ITS THERAPEUTIC USES.

By suggestion is meant simply an impression made from without, through one of the five senses, upon the cells of the cerebral cortex; it is a sensory impression by which either motor phenomena only are developed, or mental action such as revival of memory. In some instances a language used in childhood and long since forgotten, has been brought again into speech as clearly as though never lost. Auto-suggestion arises without external impressions and is typical in dreams or delirium. Now, as explanatory of such phenomena a working hypothesis has been formulated by Hudson which explains better than any previous theory the causes for such phenomena. His reasoning is that man has two minds, one of which he calls the objective, and one the subjective mind, and further, that the subjective mind, which is the store house of the memory and the seat of the emotions, is constantly amenable to control by suggestion, and is incapable of inductive reasoning.

DR. P. R. CORTELYOU, of Marietta, reported an interesting case of inflammation of external auditory canal following facial erysipelas in a woman, sixty-eight years of age.

DR. DUNBAR ROY of Atlanta, read a paper on

CHRONIC OTORRHEA, ITS SIGNIFICANCE AND TREATMENT.

This paper dealt with: 1, chronic discharges from the external auditory meatus; 2, polypi and foreign bodies; and 3, discharges originating from and dependent upon pathologic conditions of the middle ear or its contiguous cavities. With reference to the treatment, the author said that painstaking research into the history of every case; the correlation and comparison of all phenomena; a thorough knowledge of the normal and abnormal appearances of the parts, coupled with a sufficient amount of clinical experience were necessary for the treatment of all ear diseases.

DR. J. H. SHORTER, of Macon, read a paper entitled

TREATMENT OF CATARACT.

He said all operations for removal of cataract have been by one of three methods: Depression, decission, or extraction. These three methods were then described in detail and the indications for each method pointed out.

DR. H. McHATTON, of Macon, followed with a paper on

TEETHING.

No one denies that dentition is a physiologic process, *pari passu*. As the infant departs from its natural state, teething is increased in violence. The infant who is fortunate enough to have a mother who is physiologically perfect, and who treats her child as nature intended, does not teethe the first year, but is liable to, the second summer. The one who has to be partially fed, teeth oftener and earlier than the above mentioned. The one that is bottle-fed from the start, and exclusively, teeth as a rule, early, and in many cases fatally. The author knew that most practitioners would agree that dietetic errors are the cause of nearly all digestive disorders in the infant, and that these disorders are in the beginning and non-inflammatory stage most amenable to appropriate treatment, but by neglect they become the worst type of diseases that we have to contend with. The author then quoted from standard authors in regard to the subject of teething.

DR. RICHARD DOUGLAS of Nashville, addressed the Association by invitation on "Surgical Shock."

DR. R. H. TAYLOR, of Griffin read a paper on

AN OPERATION FOR HEMORRHOIDS.

He describes the operation as follows: "After preparing the patient for operation in the usual way, fix the hemorrhoid with vulsellum forceps or a stout tenaculum, which is firmly held by an assistant. Instead of cutting a groove around the base of the pile for your ligature in the usual way, make an elliptical incision through the mucous membrane, including the hemorrhoid in the ellipsis. Turn back a small flap of mucous membrane from the base of the tumor. Now, have the assistant make firm traction on the pile while you pass a double ligature of stout chromicized catgut through the pedicle, which may be much reduced in size in some instances by separating it from the muscular coat of the bowel from below upward. Firmly secure the ligature and cut away the tumor as close to the ligature as possible, only leaving enough stump to safely prevent slipping of the

ligature. Then close the flaps over the ligated stump with a suture of the chromicized catgut. This leaves you with a closed wound which if aseptic will practically heal in four days.

Dr. R. P. Cox, of Rome, read a paper entitled

SACRIFICIAL SURGERY OF THE OVARIES, TUBES AND UTERUS FOR UTERINE FIBROIDS AND UTERINE CANCER.

In the treatment of uterine fibroids and uterine cancer, radical interference is often the best hope for the one and always the only hope for the other. The rather indefinite, though usually given, moral ground of justification for excision of the pelvic organs is to save life, to preserve from destruction a patient's usefulness or her capacity for the rational pursuit of happiness, or to relieve serious and permanent impairment of these natural rights. The author said that any medical man who advises or performs these radical operations on vague indications, without the ability to give an honest and reasonably intelligent opinion as to the necessity and probable results and, in doubtful cases, without the sanction of skilful and conscientious counsel, has failed in his duty and dishonored his profession. The author concludes that in nearly all cases supposed to be operable carcinoma uteri, we should try to exclude cancer by the microscope, but if this examination confirms the diagnosis of cancer, we should proceed at once to amputation, or in a certain sense, excision, by the galvano-cautery, and not by vaginal hysterectomy. Abdominal hysterectomy is indicated only in certain cases where the malignant disease is complicated by enlargement, such as by myoma or pregnancy.

Dr. W. B. GILMER of Macon, read a paper entitled "Drainage of the Peritoneal Cavity with the use of the Siphon Pump."

THIRD DAY—MORNING SESSION.

Dr. R. M. HARBIN, of Calhoun, read a paper entitled TREPHINING IN HEAD INJURY WITH PARALYSIS OF OPPOSITE ARM FOLLOWED BY FUNGUS CEREBRI,

and reported an interesting case which he considered a distinct indication for operative interference. The patient was 25 years of age, and in a fight was struck upon the head with the heavy end of a thirty ounce billiard cue, and was carried home in an unconscious condition in about two hours thereafter, having vomited a number of times. The patient was seen on the third day after the injury with the left arm completely paralyzed, sensation being normal. A diagnosis of compression of the brain was made, probably due to a blood clot. Trephining was done on the seventh day after the injury.

Dr. Harbin drew the following deductions from the case:

1. That this patient would almost certainly have died in the first instance had not the clot been removed.
2. That there was a positive indication for trephining.
3. That it furnished a striking example of the practical value of the applied rules of topographical anatomy of the brain.
4. That the prevention of fungus cerebri is more important than the cure, and is not to be looked for with proper precaution.
5. That the occurrence of fungus cerebri is very unusual in such a small trephine wound without injury to the dura mater.

Dr. GEORGE H. NOBLE, of Atlanta, contributed a paper on "Phlegmasia Alba Dolens," and Dr. J. M. HULL, of Augusta, one entitled "Foreign Bodies in the Larynx."

AFTERNOON SESSION.

Dr. WALTER A. CROW, of Atlanta, read a paper entitled CANCER OF THE UTERUS, THE REMOTE RESULT OF OPERATIVE INTERFERENCE,

in which he reported a series of cases that had come under his care recently, and which served to impress two facts: 1, the common occurrence of this disease especially in women approaching the menopause, and 2, the great disposition to overlook their true nature or probable tendency, and to incline to use palliative measures until the disease assumes a malignant form, and we thereby lose our golden opportunity of effecting a cure in most cases.

Dr. H. W. STAFFORD, of New York, read a paper by invitation on

THE EXTRACTION OF CLEAR LENSES FOR MYOPIA,

and reported five interesting cases. Previous to describing the operations, he related the circumstances which led him to believe that the extraction of the lens, whether clear or not, would arrest the progress of myopia.

RESPONSIBILITY AND RELATION OF THE GENERAL PRACTITIONER TO GYNECOLOGY, PREVENTIVE AND NON-PREVENTIVE.

This was the title of a paper read by Dr. R. R. KIME, of Atlanta, in which he said to properly prepare for special work in gynecology requires years of practical experience in general medicine and obstetrics. The most successful practitioner is one who seeks to know and eliminate as far as possible the cause of disease. In gynecological work it is not so often a question of eliminating the primal cause of disease as it is to correct the results of antecedent causes. To illustrate: Pyosalpinx is not a primal cause, but the result of a previous inflammation simple, infectious, or specific. Pelvis peritonitis in the female is not idiopathic, but the result of diseased conditions elsewhere.

Having cited some of the many instances in which the general practitioner may prevent disease and injury to the female and lessen gynecological work, the author then pointed out a few instances in which his duty is reversed, and for the sake of brevity presented them in the form of *Don'ts*.

Dr. J. G. EARNEST, of Atlanta, reported a case of extra-uterine pregnancy in a woman, 32 years of age, the mother of three children.

Dr. J. C. AVERY, of Atlanta, read a paper entitled the "Tampon in Gynecology," and Dr. BERNARD WOLFE, of Atlanta, one entitled "A Plea for the Closer Recognition of Dermatology as a Specialty."

The following officers were elected:

President: Dr. Willis F. Westmoreland, of Atlanta.

First Vice-President: Dr. H. Taylor, of Griffin.

Second Vice-President: Dr. Wm. B. Tate, of Tate.

Treasurer: Dr. E. C. Goodrich, of Augusta.

Secretary: Dr. D. H. Howell, of Atlanta.

Dr. J. McFadden Gaston, of Atlanta, introduced the following resolution, which was unanimously adopted:

WHEREAS, THE AMERICAN MEDICAL ASSOCIATION at its last meeting provided for an expression in regard to the Code of Ethics from the different State Associations, to be laid before the forthcoming meeting at San Francisco; it is hereby

Resolved, That the Medical Association of Georgia reasserts its adoption of, and conformity to, the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION, as heretofore recognized by that body, and authorizes this record of its adherence to the same.

After drafting, introducing and adopting resolutions of thanks, the Association, on motion, adjourned to meet in Savannah on the third Wednesday in April, 1895.

NECROLOGY.

FREDERICK MOSSBACKER, M.D., of Saginaw, Mich., April 17, aged 54.—John Fisher, M.D., of Arcadia, Ohio, April 17.—Clark E. Chappell, M.D., of Canandaigua, Mich., April 12, aged 78.—T. M. Ebright, M.D., of Akron, Ohio, April 11.—Wm. A. Conway, M.D., of New York, April 17, aged 54.

MARY P. SAWTELLE, M.D., of San Francisco, aged 59, in New York city, April 22. She was a native of New York but moved to California and was the first woman to enter a medical college on the Pacific slope. In 1872 she originated the bill which gave women, married or single, residents of any Territory or of the State of Oregon, the right take up Government land.

CHARLES COREY, M.D., of Brooklyn, died at his home on the 4th ultimo in his sixty-fifth year. He was a pioneer specialist in that city, having adopted the rôle of a neurologist after a preliminary training in Bloomingdale Asylum and elsewhere. He was always a general practitioner but devoted to mental and nervous patients the greater part of his professional interest and work. He took up his residence in Brooklyn about thirty years ago, at a time when not more than one other physician of that city had embarked in specialism in mental diseases. He was early and largely employed in important cases, not a few of which became *causes célèbres* in the criminal or civil courts. He was a clear-headed observer, and made a telling medico-legal witness. He was a man of scholarship and popular in the profession as a consultant. He was a graduate in medicine of Dartmouth College, in the class of 1856, in which he was classmate of Dr. Benning Crosby, who was also, for a time, a well-known resident of Brooklyn. The death of Dr. Corey was unexpected, occurring as it did after a brief attack of pneumonia, while the Doctor was yet in the prime of his professional activity.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE. \$5.00
SINGLE COPIES. 10 CENTS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, MAY 5, 1894.

THE BRITISH SANITARY INSTITUTE AND THE
AMERICAN PUBLIC HEALTH ASSOCIATION.

The Sanitary Institute of Great Britain has taken a new departure in deciding to publish a journal of its proceedings instead of an annual volume of Transactions, following in this the example set by the British and the AMERICAN MEDICAL ASSOCIATIONS. The journal is to be, in the first instance, a quarterly. Its first part, April, 1894, has just been issued. The object of this alteration is to circulate to the members at an early date the papers read at the various meetings of the Institute, to afford an opportunity for recording information of general sanitary interest and to keep the members more closely in touch with the work that is being carried on.

The Sanitary Institute is the analogue of our American Public Health Association. The one was originated in 1876, the other in 1870. Usually we follow our British cousins on the track of sanitary progress. In this instance we led. The objects of both institutions are identical—the advancement of sanitary science and the promotion of organizations and measures for the practical application of public hygiene. Our Public Health Association has been remarkably successful in certain lines of its work. State and local boards of health have been called into being by the impetus it gave to sanitary progress. It was successful even in effecting the establishment of a National Board of Health; and its influence is felt in the protection from exotic disease which we now have through the agency of the Marine-Hospital service. The meetings of the Association have been as a liberal education in sanitary science and practical sanitation to health officers and others in attendance; and much excellent committee work has been done, sometimes involving, as in STERNBERG'S Committee on Disinfectants, a considerable amount of laboratory research. In its methods our Association followed

those of the medical societies. So also the Institute in so far as it held ordinary meetings at its headquarters in London and annual meetings or congresses in various provincial towns "to bring together those interested in sanitary science, to read papers and discuss questions affecting the public health;" but the prominence which the Institute gave to its educational line of work led to a speedy divergence from the time-honored methods of the medical associations. To educate the public, special attention was given at the meetings to the arrangements for the exhibition of sanitary apparatus and appliances for which medals and certificates were awarded. During the sixteen years that exhibitions have been held, a uniform system of judging the exhibits has been organized, and in the Transactions for 1893 an illustrated and classified list of all those to which awards have been made since the incorporation of the Institute has been published.

It was proposed also to examine those persons who were desirous of official positions as inspectors and surveyors under the local sanitary authorities, and to issue certificates of qualification when merited. During the first year only eight candidates appeared. Progress was slow in this direction; but after a time the examinations became popular and the certificates of the Institute appreciated. In 1890 the examinations, which up to this time had been held in London only, were extended to the provinces to make them accessible to candidates living at a distance; and now, by legislative enactment, sanitary inspectors appointed after Jan. 1, 1895, must hold the Institute's certificate of qualification. During the past year 510 candidates were examined. Meanwhile the examinations revealed the fact that candidates for appointment as sanitary officers had great difficulty in obtaining knowledge of the principles of sanitation, whereupon the Institute established courses of instruction suitable for these officers; and the large attendance at the first course thus instituted showed how much this development of teaching work was appreciated. Other courses of popular lectures were also established with advantage, as on Domestic Hygiene, for the purpose of instructing ladies in matters relating to household sanitation and on the Sanitation of Industries and Occupations, for the purpose of giving information to those responsible for the management of factories and instructing those likely to become factory inspectors. One of the most interesting sanitary exhibits in the first issue of the *Journal of the Institute* is the list of the lectures delivered during the past year as part of the educational work accomplished. Among the list of lecturers we find many well-known names: A. WINTER BLYTH, SIR DOUGLAS GALTON, FRANCIS VACHER, W. H. CORFIELD, SIR CHARLES A. CAMERON, and others.

We commend this first issue of the *Journal of the Institute* to the consideration of the Executive Committee of the American Public Health Association, as showing how a voluntary organization educates and graduates the sanitary officers of a country having a central health board which might have been charged with this duty. We have no health board, nor have we any provision for the education of our inspectors. Our sanitary officers have to gather up their learning as they go along, and for the furtherance of all good sanitary work the columns of this JOURNAL are always open. *We favor the creation of a Department of Public Health!*

VARICELLA IN ADULT LIFE.

The occurrence of chickenpox in adults is so rare an occurrence, that there are many practitioners who have never seen a case of that nature beyond the age of puberty. The *Lancet*, of March 10, contains a reported case, contributed by DR. MALCOLM MARGAVE, together with some editorial comments. The case is given as follows:

"I recently attended a family in which three children had well-marked chickenpox infection conveyed by the mother, who had visited a friend whose child was convalescent from the same complaint. The mother, aged 31, had a slight rise of temperature, 100 degrees F., and vesicles appeared on the chest, back and abdomen, with a few on the face. Subsequently they came out in a succession of crops and quickly scabbed over. Beyond the slight rise of temperature and headache there were no other constitutional symptoms. My excuse for troubling you is that I read in FAGGE the following: Most writers say they have never seen it in grown up patients; but HEBERDEN relates one case in which a mother caught it from her children, and another instance of it in an adult female was observed by GREGORY. I should be glad to know if this is so."

The editor's remarks point to his belief that a single attack of varicella effects an almost complete exemption from a second attack. He says:

"Chickenpox is no doubt a rare disease in adults in this country, probably because children seldom escape attack by it. We know, however, of cases of the occurrence of this disease in a number of African coal trimmers in a homeward-bound vessel from India, who were infected by an English child suffering from chickenpox. This child, for the purpose of isolation from other children, had been placed in the surgeon's cabin overlooking the engine-room, through which these men passed."

We favor the creation of a Department of Public Health!

"BOY BANE"—OR THE CIGARETTE.

A member of the Board of Education of New York City, MR. CHARLES B. HUBBELL, has interested himself in the prevention of cigarette-smoking by school-boys. He has inaugurated leagues, in the various schools, having an exclusive membership among those boys who are willing to take a pledge to abstain

from the use of the deadly cigarette until they have attained the age of 21 years. He expects to have an enrollment of 75,000 young leaguers, on or before the first of May. This plan of organization has spread to other cities, and it will not be at all surprising if we hear later of a National League and witness an anti-cigarette Congress. MR. HUBBELL uses a variety of arguments to enlist the coöperation of ambitious and thoughtful youth. For example, he adduces the fact that the medical examiner of one of the larger life insurance companies said recently that he would not accept as a risk the life of an applicant who had steadily smoked cigarettes between the ages of 8 and 18. He also calls attention to the fact that professional men and shopkeepers will no longer take boys known to be cigarette-smokers into their employ, so immediately does the habit interfere with their usefulness. These facts are to the point, although no evidence is needed to convince intelligent people of the perniciousness of cigarette-smoking by boys.

We favor the creation of a Department of Public Health!

SAMPLES FROM THE "MEDICAL" ARCHIVES OF THE PENSION OFFICE.

A reporter of the *Washington Capital* has been permitted to look over some of the affidavits and reports of the Pension Bureau, and copies the following letter said to have been given by the "family physician" of one of the claimants for pension:

"In anser to yur inkiry i wos ekquanted with Martin White Before Went in armery and also his famerly physician. He was rase in a mile of me. He was sond when he went in the servise, he complain offen times, his fingers hand is drod crucked he cant do manly labor to a grate extent I was passen by where he was making rales last sumer two years ago i took notis he could not work as abel body he had to rest as long as he worked, he complains of his nerves been stiff I sene him every two months or so an cant do nothing to cure him. I give him almost every thing they is for stiff nerves, but they is still stiff. I don't think he can do nothing much. You have my examination of him in your office. P S You are given some two much pensions i no some by me that drod 8 per month which was a plenty now dros 12 talkin of laing in for increase I say they don't reserve it."

The certifier of the above is said to be a member of the local board of pension examiners. Inasmuch as no name is given it is not possible to confirm the statement.

A claimant is said to have made the following answer:

"My age is 70; I can not say precisely when and where I contracted senile debility. It has come on quite gradually. I seemed free from it at my birth; yet if I had been born so far back as I was, I am sure I would not be suffering with it so seriously as now. The most eminent authorities are agreed that old age is of a permanent character and I begin to feel certain that my chances of becoming younger are exceed-

ingly slim. In my case senile debility is not due to vicious habits; yet I have a habit of getting older each day. I have been infirm for the last ten years."

Among the affidavits of examiners are these:

"We find dulness in this man's heart and the general symptoms that the book of instructions calls for."

"In the center was also seen a large red mass as large as a small hen's egg, or rather a small egg, be the hen herself of dimensions stately or otherwise."

"I find a scar on this man's foot at the junction of the sole with the upper."

"Please give voice test for deafness." Answer of board:

"Claimant's voice not characteristic of deafness in this case."

"The claimant alleges loss of memory, but as we could not take it out and examine it we have nothing to say, only his statement, which we rate nil."

"Claimant can't read without glasses very much. He never could much. He never learned."

Office letter:

"The claimant above named is required to file his sworn statement showing when, where and how he contracted senile debility; the cause of disability not alleged in his declaration filed under act of June 27, 1890, and that such disability is not due to vicious habits, and is, to the best of his knowledge and belief of a permanent character."

It is quite possible that the various bureaus at Washington have some curiosities of composition, but we hope that there are none that reflect more seriously than the above upon the profession of medicine. The whole shows that the system of appointments of medical examiners for the pension service needs revision. It has always needed it.

TESTIMONY AS TO PROBABLE RESULTS.

The volume of personal injury litigation at the present time is something appalling. Almost every case, too, has to have its expert witnesses. This makes the rules stated by the Supreme Court of Missouri, in the case of *BARR v. City of Kansas*, decided March 5, 1894, of considerable interest and value. It says that the plaintiff, in these personal injury cases, may recover damages suffered up to the date of the verdict, and also such damages as will be suffered in the future; but no allowance for future damages should be made, except for such as it is reasonably certain will result from the original injury. Physicians may testify as to the probable result of personal injuries upon the health and life of the plaintiff. The question whether future damages will, with reasonable certainty, flow from the injury is, however, one for the jury. But it does not follow that the witnesses must be interrogated in language which would be proper and appropriate in an instruction. The object of the examination is to get the opinions of persons competent to express an opinion on the subject, and the different shades of opinion which the physicians may entertain, leaving

it to the jury to say whether future damages are reasonably certain. To illustrate: Here there was evidence that the plaintiff received severe and permanent injuries to the spine and womb. In such a case, the court holds, the most that any physician can say as to the effect of the injuries on the life of the injured person, however expert or learned in his profession, is to give his opinion as to the probable consequences. An opinion being expressed, it becomes a proper subject for cross-examination, and in the end it is for the jury to determine the question as to the degree of certainty.

A TERRIBLE SANITARY MISTAKE.

The Washington correspondent of this JOURNAL telegraphed us in time for this edition as follows:

WASHINGTON, D. C., May 1, 1894.

"Coxey's army," 437 men and 30 horses, fatigued and improperly and scantily fed, without shelter, camping in enclosure 60,000 square feet, recently drained, containing five decomposing manure dumps, and abutting James Creek. Foul smelling, open sewers and many filthy gutters, no shade, temperature about 90 at 10 o'clock P.M. The health of "army" and city is threatened. Several cases of diarrhea are reported. The location is said to have been approved by district authorities after inspection.

We entirely disapprove of Mr. Coxey's misguided mission, but his deluded followers are human beings, and it would seem that with the noble hills all about Washington, some better place might have been found as a camping ground for these poor creatures than the most insalubrious spot in the District. The animals at the Rock Creek Zoo are better cared for.

CORRESPONDENCE.

Report on the Revision of the Code of Ethics.

DETROIT, MICH., April, 1894.

To the Editor:—Through the JOURNAL of the ASSOCIATION this report has been laid before the profession. Already it has been repudiated in several quarters. The cry is raised "Vote it down! Vote it down!"

From the language of Dr. N. S. Davis in the JOURNAL OF THE ASSOCIATION and the *Occidental Medical Journal*; of the "Conservative Member;" of Dr. Gould in the *Medical News*, the reader would infer that the authors of the proposed revision were denizens of the infernal regions and had made a special trip to the world for the purpose of working injury to the medical profession. Satire, invective, ridicule, suspicion, etc., are variously combined in these several communications, but in no one of them is a single reason given to support the belief that the adoption of the Committee's report would fail to benefit the profession.

It is interesting to inquire the occasion of such an ebullition. The report is a simple scientific statement of those lines of conduct which the Committee believed would best promote the harmonious activity of the entire medical profession. This statement differs from the one now in authority, mainly by giving greater liberty of action to the individual physician; only this and nothing more. The report shows that the Committee believed that with the changes incident to the last forty years, especially the better general and technical education prevailing among both profession and people, it would be wise to provide for an increase of the personal liberty accorded to the individual physician. In

its study of the subject the Committee apparently could find no reasons for longer withholding such liberty. Nor do any of the criticisms thus far published show that scientific medicine, the honor of the profession or of the AMERICAN MEDICAL ASSOCIATION would suffer any damage from the adoption of the report. The points of objection to the revision are: 1, the granting of increased liberty of professional association; 2, increased liberty in profiting by mechanical inventions; 3, an increased liberty of promoting professional acquaintance.

Concerning the first, the report says that doctors should choose their professional associates from among those who are well educated in all respects; who have a legal right to practice medicine in the place where they live and finally sustain a good reputation in their own community. The report ventures to suggest that any doctor should have the liberty to select from those having the above qualifications such as he pleases for his professional associates. It does not dictate whom he shall select from this group of educated, reputable, law-obeying physicians but affords him the liberty of making his own choice. In this respect the report recognizes the right of each physician. We are fully aware that the granting of this right would probably not alter in any respect the practical action of most physicians, but it is natural to suppose that all would feel better to be trusted more fully in the selection of their associates. The report places the copyrighting of medical books and the patenting of mechanical appliances used in medicine and surgery upon the same basis. As authors now receive remuneration by the copyrighting of their books, so inventors are permitted to patent their inventions, if they are so disposed. In each case natural talent and industry are permitted to claim a suitable reward by availing themselves of legal protection. It is inconceivable that any medical gentleman would harm the profession by this liberty. At any rate the harm from patenting of inventions would be of the same character as that from the copyrighting of books. It is strange that such distinguished gentlemen as Dr. D., Dr. G. and Dr. G. 2d, who have made lots of money out of the profession by securing copyrights on the excellent books they have written, should kick against permitting the doctor who can not write a book, but is able to invent a valuable instrument, from trying to make some money by his special talent. We are unable to see that the Committee has made any mistake here, and we believe the change proposed would result in the acceleration of professional development along the best lines. If not, why not? Simple negation will not do. The profession wants the evidence on which to decide that the report is bad and should be rejected. Why should it not have the increase of liberty proposed?

Concerning the increase of liberty given by the report to physicians in making known to their professional brethren their special qualifications, physicians outside of hospitals, dispensaries and medical colleges are permitted to follow the example of those inside of these institutions. It simply puts the entire profession upon the same plane in advertising itself. Dr. D., Dr. G. and Dr. G. 2d are connected with medical institutions and so are advertised over the entire medical world by the reports, circulars, announcements, etc., of these institutions, as experts in genito-urinary diseases, general medical cases, or eye and ear diseases, and yet they object because John Jones, M.D., who can not get a place in medical college or hospital or dispensary, is permitted to tell his professional friends that he regards himself competent to treat diseases of the chest or spleen, etc. It is very natural that those who have the cream of advertising should want to prevent others from getting a little of the same. It seems to us that this additional liberty in matters of professional advertising will remove a feeling of

envy and jealousy, that unbidden, sometimes steals over the mind of the humble practitioner as he sees the staring advertisements of the great hospital physician, or the college professor, heralded with pictures of the same persons, printed in the great dailies of the city in which the AMERICAN MEDICAL ASSOCIATION meets; when he reads the interviews of these distinguished gentlemen published in the daily papers; or the notices of big operations done by professors; in short, he will feel that as an humble individual in the profession, he will have the right to do exactly as his more fortunate and distinguished brother does on a larger scale.

The report gives every member exactly the same liberties in advertising himself. Naturally those who have exclusive privileges will cry, "vote it down!"

Is the AMERICAN MEDICAL ASSOCIATION prepared to "vote down" this cry for an increase of personal liberty on the part of the great mass of the thinking medical profession? If so, what are the reasons by which it will support its vote? It claims to desire the affiliation and cooperation of all fully educated, reputable, law-abiding physicians, and if so will it refuse to adopt the amendment to this end proposed by the Committee? It claims to treat all physicians with equal justice. If so, can it refuse to do that justice to the mechanical inventor which it has ever accorded to the writer of medical books? Or will it longer refuse to common doctors the rights of advertisement which it has granted to the college professor, the hospital or the dispensary physician?

The report is notable in that no mention is made of sectarian medicine or of its adherents. It takes for granted that the persons who may adopt this Code as expressing their ideas of professional conduct, are doctors, first, last and all the time. In this respect it fairly exhibits the best thought and feeling of our profession during all ages, as well as in the present. Those in the profession who believe in the largest personal liberty of the individual physician, in equal opportunities for all, in professional association with the learned, reputable and law-abiding, and in one profession unmarred by even the name of sect, in one National Medical Association commensurate in extent and breadth with the North American continent, will find on careful personal study of the report, abundant reasons for laboring to secure its adoption.

On the other hand, those who admit of no change in our knowledge of professional relations during the past two generations; those who are too indolent to think about the measures for uplifting the profession; those who follow the voice of another to whom they have committed their power to think about the AMERICAN MEDICAL ASSOCIATION; those who are dominated by interests mercantile which are furthered more by the existing than the proposed state of things; all these will oppose the adoption of the report. All these will join in "voting it down."

Certain we are that if the matter could be fairly brought to the candid thought of every physician in the land, the report would be adopted with a majority of at least seventy-five thousand.

LEARTUS CONNOR, M.D.

Code Revision.

SAN JOSE, CAL, April, 1894.

To the Editor:—It will be remembered that the writer hereof had something to say last year on the question of revision of the Code of Ethics, viz.: In the JOURNAL of April 22 and May 27, 1893. I then urged what I considered strong and cogent reasons why the Code should be revised, and have seen no reason to change that opinion since.

There had been, up to those dates, an individual writing over the signature of "A Conservative Member," who had occupied many columns in the JOURNAL for many months, to convince the profession of the beauties and perfections of our present Code. I have wondered what has befallen "Conservative" that he has kept silent in the face of the still threatening change in the dear old document. Is it barely possible that in the year of grace, 1894, he has the full courage of his convictions and now signs his real name? Be this as it may, the proposed amendments to the Code are now before us and several champions are in the field against any alteration.

There is no one who has a better right to speak on the Code question than Dr. N. S. Davis, of Chicago, whose re-

marks in opposition to revision or alteration in any particular, appear in the JOURNAL for April 14.

Dr. Davis is frequently called "the Father of the AMERICAN MEDICAL ASSOCIATION," and was present at the organization of that body, and more than likely he was a member of the committee who boiled down the original Percival Code of 20,000 words to 5,240 words. The Percival Code has been spoken of by some of the individuals discussing the question of revision, with as much reverence as would be shown almost any sacred writing on earth. I have never had the pleasure of reading this grand specimen of inspired composition, except in the form of the mutilated and concentrated extracts, known as the Code of our ASSOCIATION.

But if the 15,000 words that were expunged were of like tenor with a large portion of what has been preserved to us by the original Committee as our Code, then I am thankful that the Committee had the good judgment to boil the thing down and spare us of this generation the necessity of perusing the mass of meaningless verbiage. And if that original Committee had the right to set aside three-fourths of the original document, is it not possible, after the lapse of forty-seven years, that it may seem wise to expunge a little more of Father Percival's nonsense?

I have read the proposed new Code or revision, and according to my humble judgment it is superior in almost every particular to the original document.

It is much more brief, although in this particular there is opportunity for improvement. The new language wherever introduced is superior and more dignified than the language of the original. It does not bear so much the stamp of being addressed to fledglings. It has left out that entire article of ten sections addressed to the abyss of empty space, under the title, "Obligations of Patients to their Physicians." It has left out, as a rational committee should have done, the clause relating to the holding of patents by members of the profession.

I am happy to say that all these improvements are in exact accord with the arguments I made last year. I do not say that they have been made on account of those arguments, but it simply shows an agreement of thought on the subject.

The Committee has wisely recognized the existence of specialties in the profession and made some happy suggestions and regulations in that particular; all of which must be disagreeable to the champions of the old Code, as they want not one word added to or taken from the document. They seem not to conceive that new conditions have arisen since 1847.

But pardon me if I shall presume to reply more specifically to two or three of Dr. Davis' arguments. He complains that the Committee "has dropped whole sections here, and lines and words there, introduced new sections, and has placed their revised Code on a radically different basis." Certainly, that is the object of revision; to make some changes.

As regards the question as to whom one may consult with, I did not enter into it last year only incidentally, neither do I care to do so now, except by way of a general remark or two.

This feature of the old Code was adopted for the purpose of killing off homeopathy and other pathies and isms. In the face of history let us ask ourselves the question to what extent has that Section of the Code limited the growth of homeopathy since 1847? If it has limited, I am thankful.

There can be no consultation between a *genuine* homeopath and a regular physician so far as therapeutics is concerned, but only in regard to diagnosis and surgery. The writer has helped to kill off homeopathy by observing the law of the old Code for twenty-nine years in regard to consultations!

The next objection by Dr. Davis is in regard to the elimination of the entire article in relation to the "Obligations

of Patients to their Physicians," and he sets up the new doctrine that this part of the Code is for the purpose of informing the *physician* as to the duties of patients toward him. I observe nothing in the ten sections devoted to this subject that is not addressed directly to patients. If it was written for the profession it makes the matter still more ridiculous.

Dr. Davis says: "It is no excuse for these omissions to say that the Code was not intended for the perusal of patients or the public, for it was really intended for both; and if physicians were more diligent in placing copies of the Code in the hands of their more intelligent patrons it would greatly benefit all parties." I wonder how many copies of the Code have been distributed to the public since its adoption! Forty-seven years ought to be time enough to get a start in that line. If not, the case is hopeless!

It is objected that the revision allows physicians, devoting attention to special departments of our art, the privilege of so stating on their sign or private card.

If memory serves me rightly it was when Dr. Davis was editor of the JOURNAL, he was pressed to answer the question: "How shall a specialist call attention to his business?" and the answer was that "he may state that his practice is limited to the treatment of certain diseases."

Where is the authority in the Code for Dr. Davis' statement and interpretation in this particular? There is not one word or suggestion authorizing it. It was a new law conceived by himself. Did not that forced interpretation indicate that something had changed since 1847?

But the new law given by the editor of the JOURNAL was so worded as to prevent general practitioners from using the expression, "Special attention devoted to certain diseases, etc."

Now what are the practical facts all over the United States? Specialists for years have called attention to their business in newspapers, private cards and signs; and further, every general practitioner states, whenever he feels like so doing, that he treats a special class of diseases. If only a simple statement is made it is considered honorable by probably every county society in the United States. Therefore that part of the revision which pretends to prohibit in this particular is a dead letter already and why have it there? Let every practitioner state, if he cares to, that he treats a special class of diseases.

I wish to call attention to one other point, and that refers to the question of patents: "Equally derogatory to professional character is it for a physician to hold a patent for a surgical instrument, etc."

Dr. Davis is so wedded to the old Code and so determined that not one syllable shall be changed, that his zeal leads him to contend for this, the most inconsistent of all the inconsistencies in the Code. Why should not the ingenuity of the surgical profession be stimulated by the hope of reward in patenting new inventions, the same as in any other department or industry? The great inconsistency manifests itself in the fact that all physicians use patented instruments and appliances. It is then perfectly honorable to use a patented instrument, but not honorable to hold a patent for an instrument! Therefore if a physician wishes to profit by an invention, all he has to do is to step out of the AMERICAN MEDICAL ASSOCIATION, patent his instrument, then exhibit it at the meetings of the ASSOCIATION and all the doctors will buy. "Consistency thou art a jewel!"

No man can fairly make an argument against a member of the AMERICAN MEDICAL ASSOCIATION holding a patent for an instrument, unless he can conscientiously stand up and say he would let his patient die before he would use a patented apparatus of any kind. Otherwise than this, it behooves every one in the interests of consistency to keep silent on the patent question.

It would be interesting if some champion of the Code would define the difference, so far as honor is concerned, between holding a patent for a surgical instrument or a copyright for a medical book. Is it not a distinction without any difference? All medical books are copyrighted. Why is the writer of a medical book any more entitled to remuneration for his time and talent than the inventor? Echo answers, why?

I beg to call attention to my two former articles on the subject of revision in the JOURNALS of April 22 and May 27, 1893.

In conclusion, allow me to say that I consider the revised or new Code superior in almost every particular to the old Code, and I hope with very little modification, if any, it will be adopted at the San Francisco meeting of the ASSOCIATION.

Most respectfully,

A. C. SIMONTON, M.D.

The Code Revision.—An Open Letter.

Boston, April 26, 1894.

To H. D. Holton, M. D., Chairman of the Majority Committee of the Revision of the Code of Medical Ethics:

Dear Sir:—Perhaps I have been remiss in my duty, as also in privilege, in permitting so long a period to elapse before replying to your thoughtful letter. However, I have felt that I would prefer to examine your work as completed before writing, knowing that it is not too late for your Committee to accept modifications which meet their approval.

It is so much easier to play the rôle of critic, than to formulate, that I would in advance thank you for your earnest efforts in the behalf of the profession.

If you will note that section of my address of two years ago which prompted the appointment of your Committee, you will see that I view the mission and scope of the AMERICAN MEDICAL ASSOCIATION from quite a different standpoint than that of the majority report of your Committee. First, that it should be a representative body of the whole profession, at present consisting of quite one hundred thousand in number, doubtless to be doubled in the next century. Each and every member of our profession should be so co-related to the ASSOCIATION, that he is an integral part of it, as for example, the voter in the most obscure town has the assurance that he is an active participant in the affairs of the commonwealth, with a no less just pride that he is a citizen of the general government, and may become a sharer in its highest honors and emoluments.

In the actuality of bodily presence, as a participant in the affairs of our great annual meetings, the number must be limited, and in the limitation of the number, it should be representative. This delegated power must necessarily mean something and that something must find its expression as a sharer in the governmental affairs of the ASSOCIATION. This is felt in the power to select their own officers and, under codified rules of action to govern their own affairs. The more important object, however, sought thereby should be clearly scientific improvement. To keep these dual objects equally in mind is not always easy. I have long felt that the possibilities of membership in the ASSOCIATION were sufficiently liberal. On the one hand, it should be considered an honor and a privilege worthy of attainment, while on the other, the restriction should not be so great as to exclude any earnest, ambitious professional man from becoming a member. In making active membership representative, this delegated authority from necessity acts for a more or less large constituency who are debarred the privileges of attendance and *who* shall be thus represented, your governmental rules must determine. Here lies your first fundamental difficulty, which I recognize as much as any member of your Committee.

Had we uniformity of State Examining Boards which would determine the status of a properly educated doctor, this work would be comparatively simple. A proper amount of scientific attainment would be our criterion. But hard as we all have labored to elevate the standard of medical education, I confess reluctantly to the feeling that, as yet we have not differentiated sufficiently to define readily the standard of our educated physician, and fear that, for the present at least, we shall have to fall back upon the unsatisfactory cognomen of the "regularly educated." Otherwise the political bias of the Examining Boards of the different States will give no end of practical difficulties, as instanced in your attempted answer to the query: "With whom may we properly consult?" States like Massachusetts which have no statutory limitations as to who may practice medicine, would fail entirely of qualification.

I have given my hearty approval to the efforts inaugurated under the leadership of Dr. Connor, of Detroit, for the im-

provement of the Section work. In these subdivisions, it is easy to find place for the proper presentation of original research, and the thoughtful consideration of every contribution for the advance of the science and art of our profession, and these subdivisions must be the great corner-stones upon which to erect the temple of medical science. However, as viewed independently, they lack cohesion, and our great National meetings, to reach a higher plane of success, must have something in common for all. To this end, fortunately our science blends in the discussions of public questions, upon which great masters are ever ready to consider it a high honor to address the entire assembly. For this reason it seems to me that beside the oration of the President, the annual addresses are of importance.

Will it not be well that we content ourselves in the present limitations ascribed to our Business Committee for the better scientific development of the Sectional work, and grant to the active members present that privilege, so dear to the American citizen, of exercising his delegated power in the choice of officers? This indeed may be stigmatized as political, nevertheless it enters into the very existence and makeup of the American boy before he differentiates into a doctor. Experience proves that no matter how select the committee, this quality does not depart from the members of the organization. Your Business Committee could hardly expect to be devoid of this attribute and with a certain show of justice might be criticised as "a close corporation, political ring, etc."

May we not, at least for the present, be content with your definition for the requirements of the graduate of medicine that he be carefully and thoroughly trained before he can be considered a general practitioner, and "that specialists must be this and something more?" Has not our ASSOCIATION long since recognized the special subdivisions of practice as "proper and legitimate" fields of labor, and that specialists shall be governed by the same rules of etiquette as has been laid down by general practitioners? Is not this quite sufficient?

There are many minor subjects upon which I can well understand there will be, and I think ought to be, differences of opinion. Under this head in our present Code comes a long chapter on the duties of patients to physicians. I am often asked in what does the obligation consist? Certainly the relation in many ways is a mutual one, and how can the physician give instruction, unless he is himself taught, or governed by certain rules of action!

As to the question of patenting of instruments, many justly claim hardship and loss by being denied this privilege, while others assert that the honor attached to the presentation of some new device should be ample compensation. If this be true, it is certainly aggravating, as has happened several times to me, that some other man with more effrontery than honesty, claims, and is accredited with the honor. In the patenting of medicines, the field where modern chemistry is doing so much for our profession, this question is still open to discussion. However, I can not help thinking that the subject of patents is such a prominent source of abuse and a covert means of swindling, that the individual better suffer personal loss than risk the injury that may accrue to the general public.

To me it has always been a matter of surprise that so much acrimony of feeling should be aroused in the discussion of codes and by-laws, but this pertains alike to all societies. Upon fundamental principles all should be agreed, in the matter of detail much latitude of action must be permitted. This is necessary when honest and able men disagree and will occur when designing men of doubtful honor would take advantage. When President of the ASSOCIATION I made an earnest effort to reconcile the differences between

the great wings of the New York State medical profession. It seemed to me that the resolution which was unanimously adopted by the Association in 1885 as a conciliatory measure to meet the objections raised by the New York State Medical Society was ample:

"Resolved, That Clause 1, Article IV in the national Code of Ethics is not to be interpreted as excluding from professional fellowship on the ground of differences of doctrine or belief, those who in other respects are entitled to be members of the regular medical profession. Neither is there any article or clause in the said Code of Ethics that interferes with the exercise of the most perfect liberty of individual opinions or practice."

Reluctantly I was forced to believe that the time was not yet ripe for the harmonious adjustment of difficulties which pertained far less to the assumed faults of the Code, than to bitter dissensions on the part of individual members.

It was with this thought, without consultation with any, that I selected your honorable committee and imposed upon them the serious task of the consideration of the revision of the Code of Ethics. The gentlemen composing the committee were all known to me personally as men distinguished, not only for their learning and ability, but judging from their previous labors in the advancement of medical science, I deemed the Association peculiarly fortunate in being able to secure their services. It was a surprise to many that the first year of your efforts should be confined to a revision of the Constitution and By-laws, when you were appointed to consider only the revision of the Code of Ethics, doubtless, however, with the thought of securing an harmonic whole. To very many your revision seems extreme and I would suggest a marked modification somewhat as here outlined, preserving all there is of value in our really very excellent old Code, modifying only along the lines of advancing science, since if compelled to choose between the old and the new, as you have formulated it, I must support the former, an opinion which I can not doubt the large majority of our members will give approval.

HENRY O. MARCY.

On Revision of the Code.

NEW YORK, April 24, 1894.

To the Editor:—The venerable father of the Association in the issue of April 4, 1894, in his disapproval of the revision of the Code of Ethics asks the question: "In what direction this progress?—that of science and honor, or that of mammon and dishonor?" Now, as he has asked, it is discourteous not to reply. Also, this is the time for members to speak out their sentiments, as a matter of history and material for action. Dr. Davis says the Committee has *emasculated* the section on patents and proprietary medicines, making it prohibit only patents "for secret nostrums" (*i.e.*, ours, from *nos—we*); "a medicine the ingredients of which are kept secret to restrict profits to proprietor or inventor."—Webster; in other words, for "mammon and dishonor."

I have no doubt that the majority of the members have used antipyrin, phenacetin and sulfonal, out of which the German owners have reaped millions of dollars; yet they are practically secret nostrums patented, and I doubt if they can be made from the formulæ.

The ethics of these chemicals say that Association members can swallow their Code for Germans and not for Americans; this is free trade with a vengeance. There is a good deal of progress towards "mammon and dishonor" in the above use of such chemicals.

Further, the old Code shows the profession in a bad, if not dishonorable condition for themselves as book-makers. The father of the Association has copyrighted his books; *i.e.*, his medical ideas in paper and ink; it is the same as a patent or proprietary nostrum (ours). Now, suppose he had produced ideas in hard rubber, metal, wood or even paper

without ink; to patent such would be considered mammon and dishonorable, but protection for paper and ink is honor.

In eternal common sense and fact, medical ideas, whether printed or not, are entitled to protection or no protection alike.

I know a medical man who got up medical ideas in hard and soft rubber, linen, iron and silk; these ideas he freely gave away to the profession; in England they were said to be the best for 6,000 years; English medical students could not graduate unless they knew about them. One day, when he thought he had thus done well he was much taken down by an AMERICAN MEDICAL ASSOCIATION member, one of the most eminent in the world in the line of such ideas, by the query: "Did you make any money by those ideas?" "No," was the reply. "You ought to have made \$100,000. Why did you not get them patented? How foolish!!!!" Not much honor, then, in giving the world those ideas, according to one of the very supporters of that Code that prohibited patents! Tell a member he shall not patent his ideas, and then blow him up because he did not and followed the Code! Is this honorable, consistent with truth, morality, the Ten Commandments, the Golden Rule? How does the Code of Ethics work as to nostrum (ours—proprietary) advertisements in the JOURNAL? Take I——G——, advertised by the JOURNAL, notwithstanding that the Connecticut State Agricultural Experiment Station after examination reported that it was common flour heated, bought at from 2½ cents to 5 cents and sold at \$1 per pound. Is it science to call common flour an extract made by chemistry when it is a powder chemically made? And the "greatest food for invalids?" Is this science and honor? And yet the old Code believers allow this, and the Association makes money publishing untruths.

If a member should advertise a proprietary medicine in the JOURNAL or elsewhere, he would be subject to discipline. An outsider has greater privileges. I approve of the Committee's report as to this section also because it is a dead letter. Members are getting patents in spite of the Code, as they get copyrights. There is often more science in instruments than in books. The instrument represents new ideas; medical books are too often made by threshing out old straw and somebody's ideas because they sell best.

Another consideration: The late Dr. Louis Elsberg, a member, invented after years of study an admirable forceps for topical applications to the larynx, throat, posterior nares and nares. It took much study and time to get the right angle, 120 degrees, for the bend. It went on the market unprotected. The makers, who generally think they know more than the inventor (try it, if you do not think so), changed the angle variously—so that the forceps were a failure; I well remember how badly Dr. Elsberg felt when he knew that his instrument did not do the good it was capable of and thus relieve suffering, simply because he did not protect it from changes. I have known of like cases with other medical men; one gentleman of great eminence in his specialty in surgery has the pleasure of knowing the Government has ordered thousands of dollars worth of his instruments on which he has no protection, and hence no profit. Would it not have been better for this man, as well as others, to have made some money out of his brain children and thus conserved energy and perhaps brought forth more ideas of value? So long as our present system of economics is based on every man inheriting or earning money for his support, so long should his property be protected. We seem to forget that the competition will break down unjust monopolies and that only valuable things will stand. The greatness of our country has been made possible by inventions; the science of medicine would be nowhere but for patented inventions in locomotion, manufactures

and arts. They have made it possible to hold our annual meetings, and even in San Francisco. I deliberately say that the old Code, as to the ethics of medical ideas outside of books, is a poor arrangement; when any new ideas (save as above) come, we are to close ourselves up like the box turtle and let them blow over us—we are not to encourage inventions that will benefit humanity (Elsberg's forceps)—we are to wait until public opinion comes and kicks open our shell; and yet we can use antipyrin *et id omne genus*, swallowing our Code and all; we can blow up inventors for not patenting medical ideas when we have told them not to; we can as a medical association, advertise nostrums by the dozen to the world in the very number of the JOURNAL in which good Father Davis asks the question I am trying to answer. Is not this "mammon and dishonor?" For one, I am grateful to the Committee for what they have done so fearlessly and deftly; I admire our venerable father's energy, point and force, and what I have written here is simply on my own responsibility, declarative of my ideas in answer to the question frankly, plainly and honestly. I wish others would speak out their sentiments, pro or con, and then this vexatious matter could be settled and the ASSOCIATION attend to work of which there is dying need and members are dying in need of, to-wit: The "new gospel of Materia Alimentaria."—(Joseph Jones, M.D., LL.D., New Orleans.)

I look forward to the time when any person qualified to practice medicine, and who calls himself simply a physician and surgeon with no sectarian title, can walk into the AMERICAN MEDICAL ASSOCIATION to full-hearted membership and "not to doubtful disputations," and the Code will consist of the law of the eternal fitness of things which needs not man's arbitrary measurements, but does things rightly because complemented by the law of compensation, the executive of Justice.

E. CUTTER, M.D.

Medical Institutions of San Francisco.

SAN FRANCISCO, April 26, 1894.

To the Editor:—The AMERICAN MEDICAL ASSOCIATION will meet in San Francisco June 5 to 8. During the meeting the members will be cordially invited to visit the following institutions:

City and County Hospital, Potrero Avenue and 22d Street, contains 450 beds. Superintendent, F. H. Titus; visiting surgeons, R. A. McLean, C. N. Ellinwood and G. F. Shiels; visiting physicians, W. W. Kerr and J. O. Hirschfelder; oculists and aurists, W. E. Hopkins and Geo. Merritt; visiting gynecologists, H. Kreutzmann and C. A. von Hoffmann.

St. Mary's Hospital, First and Bryant Streets, is conducted by the Sisters of Mercy. Visiting surgeon, A. T. Leonard; gynecologist, Luke Robinson; physicians, W. S. Thorne and M. J. Fottrell; oculists, G. H. Powers and W. E. Hopkins.

German Hospital, 14th and Noe Streets, contains 200 beds. Visiting surgeon, J. F. Morse; ophthalmologist, A. Barkan; gynecologist, H. Kreutzmann; physician, Rudolph Baum.

French Hospital, Bryant Street near Sixth. Visiting surgeon, Dr. Bazan; physicians, J. D. de Chantreau and G. Gross; oculist, K. Pischl.

St. Luke's Hospital, Valencia Street near 27th, contains 75 beds. Visiting surgeon, C. G. Kenyon; physicians, Washington Dodge, F. W. D'Evelyn and C. J. Burnham; oculists, G. H. Powers and A. H. Voorhies; gynecologist, W. H. Mays.

Children's Hospital, 3700 California Street, contains 100 beds including the Maternity. Visiting physicians, Lucy M. F. Wanzer, Emma S. Merritt, Edna R. Field, Mrs. C. B. Brown, Charles von Hoffmann, A. P. Woodward; oculist and aurist, W. E. Hopkins; orthopedic surgeon, Harry M. Sherman.

California Woman's Hospital, 3118 Sacramento Street,

contains 50 beds. Visiting surgeons, C. B. Brigham, O. O. Burgess, W. Winterberg, C. Max Richter, Dudley Tait, L. L. Dorr; surgeon in charge, F. W. Vowinkel.

United States Marine-Hospital is situated in the Presidio Reservation on the banks of Mountain Lake, and is accessible by the Sacramento Street cars.

Another hospital is on the eve of completion, viz.: Lane Hospital, which will contain over one hundred beds; this has been erected by the writer at a cost of \$150,000 and has been presented by him to Cooper Medical College, thus giving this institution unsurpassed facilities for the work of medical education.

This pile of buildings, which is in conspicuous view to the traveler who enters the Golden Gate, together with the lands accompanying the gift, equals in value a half million of dollars, and has been presented as an offering to the Healing Art in its merciful service to suffering humanity.

The members of the ASSOCIATION will also have an opportunity of visiting the medical college erected and presented to the University of California by the late Dr. H. H. Toland. Some of the members will remember their visit to this institution during their sojourn here, twenty years ago, when they were given a reception there by the distinguished founder. The heart of Dr. Toland would have beat less exultantly on that occasion could he have foreseen that in less than twenty years there would be a movement on foot to sell and abandon the edifice which he had planned as an enduring monument to the name of Toland. And should history repeat itself, and the un pitying hand of ingratitude pull down the monument which otherwise will perpetuate the names of Lane and Cooper, then would the scene in heaven as painted by a modern Greek poet be realized, viz.: Benefaction and Gratitude as strangers did not recognize each other in Heaven, since they had never met on earth.

L. C. LANE, M.D.

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Rio Grande Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville, Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland, thence east by way of the Northern Pacific R. R. to St. Paul. C. M. & St. P. R. St. Paul to Chicago. A stop over at Yellowstone National Park for those who desire it has been arranged, and it has been understood that at several places on the journey there will be short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentrating on this train should be effected at Chicago and St. Louis. For all information relating to this train, fares, etc., address J. M. Connell, 212 Clark st., Chicago, or any agent of Santa Fe line in other cities. Rates promised are the lowest excursion rates at time of departure.

This is the only route on which arrangements have been perfected by the Trustees.

Circular from Committee of Arrangements.—The AMERICAN MEDICAL ASSOCIATION will meet in San Francisco, June 5, 1894.

The transcontinental railroads have made favorable rates, viz: \$65.50 for round trip from all Missouri River points, which is one and one-twelfth fare. The Southern Pacific Company's rates from Portland, Ogden and El Paso are one fare.

All tickets sold at these points carry five coupons of admittance to the Mid-Winter Fair.

The roads beyond Missouri River points are still charging about one and a half fares.

Can not our brethren east of the Rocky Mountains yet induce the Central Traffic Associations and Trunk Lines to equalize these rates? Several agents in response to our circulars asking for a single fare, replied favorably, but stated that it required united action of the several Associations. An extensive itinerary for those who come from the Northern and Middle States is published in the *JOURNAL OF THE ASSOCIATION*. In the April number of the *Occidental Medical Times* Dr. Parkinson has published an extensive itinerary of excursions and entertainments in this State for members and their families during and after the meeting. Those who come from the Southern States will probably come over the Santa Fé and Sunset routes. It will be well for them to come early and "do" the southern part of the State on the way up, and then depart via the Ogden or Shasta route. This will afford the greatest possible opportunity to note the varied resources of the Pacific Coast, and the variety of scenery and climates within our borders. The Colorado Desert through which the road passes, is 312 feet below the sea-level, with a dry hot atmosphere.

Going out over the Denver & Rio Grande, one reaches an altitude of 10,500 feet; while on the Shasta route the road passes Castle Crag Tavern, winding around the base of Mount Shasta, whose summit is 14,444 feet high and clad in eternal snows.

Colton and Riverside, the first important points reached on the Sunset route, are already far-famed for their delicious fruits and extensive orange groves which line the streets and highways for many miles.

Drs. M. F. Price and K. D. Shugart of the local committee on reception will take delight in showing them to visitors.

From here to San Diego and Coronado it is only four hours' ride. They are located upon the bay in the extreme southwestern part of the State only four miles from the Mexican border. This is now a fashionable all-the-year-round resort with one of the largest and best equipped hotels in the world, its main dining room having a capacity for a thousand guests.

Facilities for bathing and boating in the sheltered waters of the bay are unexcelled. Drs. C. M. Fenn, W. A. Edwards and C. C. Valle, of the local committee will extend every courtesy to visiting members.

Los Angeles, the chief city in the south, too well-known to need any description here, is only five hours distant on the way north. Here Drs. H. Bert Ellis, H. S. Orme, Walter Lindley, Jos. Kurtz, J. P. Widney and W. L. Wells, of the committee on reception will be delighted to show visitors the city and its suburbs, Pasadena, Santa Monica and other points of interest.

Santa Barbara, another charming resort by the sea, famous for its adjacent olive groves in which it rivals Palestine, is only three hours' ride from Los Angeles. Here Drs. S. B. P. Knox, J. M. McNulty and R. J. Hall, of the local committee will do the honors of the occasion.

Leaving Santa Barbara by rail, the next point of interest will be Bakersfield where an extensive system of irrigation has transformed a desert into a veritable garden of Eden.

Then comes Fresno, the largest and most successful vineyard district in the State, where Drs. Chester Rowell and A. J. Pedlar, of the local committee will pay every attention to visitors.

It is only seven hours' ride from here to San Francisco, where the members of the reception committee will meet the visitors and escort them to their respective hotels. Those who come in over the northern routes, via Mount Shasta, Castle Crag Tavern, Soda Springs, Chico and the State capital at Sacramento, may desire to depart by the Santa Fé or Sunset routes. R. H. PLUMMER, Chairman.

San Francisco, April 25, 1894.

Program for Section on Laryngology and Otology.—"Electro-Vibratory Reduction of Turbinate Tissue," Dr. J. Mount Bleyer, New York City.

"Tubage as Accessory Treatment in Cases of Septal Deformity," Dr. Price Brown, Toronto, Canada.

"Diseases of the Accessory Cavities," Dr. Frederick C. Cobb, Boston, Mass.

"Epithelioma of the Larynx with a Case," Dr. Cheatham, Louisville, Ky.

"The Causative relation of Nasal Obstruction to Lung Disease, with New Mechanical Devices for Treatment," Dr. O. Denison, Denver, Col.

"The Dangers of the Use of Cocain in Treatment of Diseases of the Upper-Air Passages," Dr. D. B. Delavan, New York City.

"The Removal of Exostosis and Deflections of the Nasal Septum," Dr. A. De Vilbiss, Toledo, Ohio.

"Pseudo-hysterical Aphonia," also "A Case of Retention Cyst of the Frontal Sinus," Dr. F. B. Eaton, Portland, Ore.

"The Treatment of Hypertrophy of the Tonsils in Young Children," Dr. George Z. Goodell, Salem, Mass.

"Hypertrophy of Luschka's Tonsil—Etiology and Clinical History Based on an Analysis of Two Hundred Private Cases," Dr. E. Fletcher Ingals, Chicago, Ill.

"Cigarettes," Dr. J. C. Mulhall, St. Louis, Mo.

"The Relation between Nasal, Laryngeal and Thoracic Disease," Dr. S. E. Solly, Colorado Springs, Col.

"Deflection of the Nasal Septum and its Surgical Treatment," Dr. E. A. Spilsbury, Toronto, Canada.

"Report of Cases. a—Intra-nasal Fibroid Tumors. b—Total Adherent Soft Palate. c—Septal Abscesses," Dr. J. E. Schadle, St. Paul, Minn.

"Laryngeal Tubercle Cured by Tuberculin," Dr. A. J. Erwin, Mansfield, Ohio.

"Carcinoma Laryngis; with Report of Case of Total Extirpation," Dr. Norval H. Pierce, Chicago, Ill.

"Hygienic Cures of Laryngeal Diseases," Dr. Marion Thrasher, San Francisco, Cal.

"Relation of Diseases of Upper Air Passages to Diseases of Eye and other Organs," Dr. J. G. Carpenter, Stanford, Ky.

"The Treatment of Hay Fever," Dr. A. C. Wolfe, Columbus, Ohio.

"How and Where to Drain the Antrum in Empyema," Dr. Eugene S. Talbot, Chicago, Ill.

"Diphtheria, Its Etiology, Clinical Pathology and Treatment," Dr. Marcus M. Johnson, Hartford, Conn.

"Abuse of the Galvano-Cautery in Rhinology," Dr. W. H. Daly, Pittsburg, Pa.

"Laryngeal Lupus," Dr. J. D. Arnold, San Francisco, Cal.

"The Value of Antroscopy (Endoscopy of the Antrum of Highmore)," Dr. Henry L. Wagner, San Francisco, Cal.

"Report of a Case of Laryngeal Neoplasm Simulating the Everted Nostril," Dr. S. K. Merrick, Baltimore, Md.

"Syphilis of the Upper Air Passages," Dr. Ramon Guiteras, New York City.

"The Easiest Adenoid Operation with New Instruments," Dr. Arthur G. Hobbs, Atlanta, Ga.

"Pseudo-Membranous Laryngitis," Dr. Wm. H. Parke, New York.

"Retro-Pharyngeal Lymphad Enetis," Dr. W. E. Casselberry, Chicago, Ill.

"Intra-Laryngeal Growths," Dr. J. E. Sinclair, Nashville, Tenn.

"Naso-Pharyngeal Tumors," Dr. R. P. Lincoln, New York City.

"The Middle Turbinate Bone," Dr. Arthur Levy, Denver, Col.

"Fibro-lipoma of Pharynx—Report of Case," Dr. John O. Roe, Rochester, N. Y.

"Surgical Treatment of Chronic Otorrhea and of Chronic Catarrhal Otitis Media," Dr. C. H. Burnett, Philadelphia, Pa.

"Internal Massage and Vapors in the Treatment of Chronic Aural Catarrh," Dr. H. V. Würdemann, Milwaukee, Wis.

"Some Experimental Research in Electro-Mechanical Contrivances for Relief of Middle-Ear Deafness," Dr. Geo. Wilkinson, Omaha, Neb.

"The Eustachian Openings in the Pharynx," Dr. E. Cutler, New York.

"Demonstration of New Instruments," Dr. S. S. Bishop, Chicago, Ill.

"Experiments on the Eustachian Tube by means of the Tongue thrust into the Naso-Pharynx," Dr. H. Stillman, Seattle, Wash.

The following have promised to send papers but have not given titles:

Dr. C. H. Guibor, Topeka, Kan.; Dr. E. Shurley, Detroit, Mich.

E. FLETCHER INGALS, M.D., President, Chicago,
JOHN F. FULTON, M.D., Secretary, St. Paul.

SOCIETY NEWS.

Central Illinois District Medical Society.—The following resolutions were adopted at the meeting of the District Medical Society of Central Illinois, held at Pana, April 22, 1894, relative to the prevention of blindness:

WHEREAS, Laws have been enacted by the Legislatures of

several States relative to the prevention of blindness due to ophthalmia neonatorum; and

WHEREAS, Efforts are being made by the Illinois State Board of Charities to influence the passage of a similar law by the Illinois State Legislature of 1894-5; be it

Resolved, That the District Medical Society of Central Illinois convened at Pana, April 22, 1894, hereby indorses and commends the efforts being made by the Illinois State Board of Charities to secure appropriate legislation relative to the prevention of blindness due to ophthalmia of the newborn.

DR. RAUCH.—In memory of the late Dr. J. H. Rauch, be it

Resolved, That the District Medical Society of Central Illinois hereby expresses its appreciation of his inestimable services which have raised the standard of medical education, the influence of which is felt in every State in our Union; of his unceasing zeal in the suppression of quackery in our own State, and of his persistent energy and superior knowledge, the influence of which has secured for him deserved distinction among the eminent sanitarians of the nineteenth century.

Resolved, That this Society expresses a deep regret that the death of him who is to be regarded a benefactor to the medical profession has robbed us of a friend and co-laborer.

Resolved, That the Secretary be instructed to inscribe these resolutions in the minutes, and send a copy of the same to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

W. J. EDDY, M.D., President.
J. N. NELMS, M.D., Secretary.

The American Pediatric Society will hold its sixth annual meeting at Washington, D. C., May 29, 30 and 31, and June 1, 1894. The sessions will be held at the Arlington. The following is the preliminary program:

Address by the First Vice-President, "A Eulogy on Drs. John M. Keating and Charles Warrington Earle," by F. Forchheimer, M.D., Cincinnati, Ohio.

"Eulogy on Dr. T. F. Sherman," by T. M. Rotch, M.D., Boston, Mass.

"The Influence of Blood-Supply on the Irritability of the Spinal Motor Centers," by B. K. Rachford, M.D., Newport, Ky.

"The Early Diagnosis of Potts' Disease of the Spine in Children," by Dillon Brown, M.D., New York City.

"A Case," by William B. Northrup, M.D., New York City.

"Tonsillotomy, followed by Diphtheria and 'Croup,'" by Augustus Caille, M.D., New York City.

"Discussion on the Etiology and Prevention of Rickets; a, influence of race (especially in Italians), Irving M. Snow, M.D., Buffalo, N. Y.; b, influence of race (in Negroes)," by George N. Acker, M.D., Washington, D. C.

"A Case of Congenital Rickets," by C. W. Townsend, M.D., Boston, Mass.

"Infantile Scurvy, especially its Differential Diagnosis," by J. Henry Fruitnight, M.D., New York City.

"An Aid to the Sterilization of Milk in Artificial Infant Feeding," by A. Seibert, M.D., New York City.

Report of the Committee on the Nomenclature of Diseases of the Gastro-Enteric Tract, T. M. Rotch, M.D., Chairman, Boston, Mass.

Report of the Committee on the Nomenclature of Diseases of the Mouth.

Business Meeting (for members only).

"Acute Pyelitis in Infancy," by L. Emmett Holt, M.D., New York City.

"Infantile Myxœdema," by William P. Northrup, M.D., New York City.

"The Hemorrhagic Disease of the Newborn," by C. W. Townsend, M.D., Boston, Mass.

SAMUEL S. ADAMS, M.D., Secretary.

American Dermatological Association.—Program of the eighteenth annual meeting to be held at the Arlington Hotel, Washington, D. C., May 29, 30, 31 and June 1, 1894.

Officers for 1894: President, Dr. R. B. Morison, of Baltimore; Vice-President, Dr. G. T. Jackson, of New York; Secretary and Treasurer, Dr. C. W. Allen, of New York.

The meetings will be held in the new reception room of the hotel.

Tuesday, May 29, Business Meeting (with closed doors) at 9:30 A.M.; Report of Council; Nomination of officers for the ensuing year; Appointment of Auditing Committee; Proposals for Active and Honorary membership; Miscellaneous business.

Address by the President, Dr. R. B. Morison; Dr. G. T. Jackson, "Thyroid Feeding in Diseases of the Skin;" Dr. G. H. Fox, "The Rare Forms of Alopecia;" Drs. J. A. Cantrell and E. J. Stout, "A Case of Favus of the Head and Body."

Wednesday, Business Meeting (with closed doors) 9:30 A.M.; Report of Treasurer and Auditing Committee; Election of officers; Election of Active and Honorary members; Selection of time and place of next meeting; Miscellaneous business.

Report of Committee on Statistics; Dr. J. A. Fordyce, "The Pathological Anatomy of Pearly Epithelioma of the Face;" Dr. H. W. Stellwagon, "The Question of Contagiousness of Molluscum Contagiosum;" Dr. C. W. Cutler, "The Therapeutic Value of Urea in the treatment of Skin Diseases;" Dr. S. Sherwell, "Ichthyosis Congenita (so-called Harlequin Fetus). History of a case still living."

A general session of the Congress will be held Wednesday afternoon at corner 12th and F Streets to discuss "The Distribution and Control of Leprosy in North America."

First Paper, "Distribution," Dr. J. N. Hyde. Discussion, J. E. Graham.

Second Paper, "Diagnostic Features and Treatment," Dr. P. A. Morrow. Discussion, Dr. A. Van Harlingen.

Third Paper, "Contagiousness, Prophylaxis and Control," Dr. J. C. White. Discussion, Drs. G. H. Fox, J. D. Bryant and Gen'l W. C. Wyman, U. S. M. H.

Thursday, 9:30 A.M., Dr. J. C. White, "Angioma Serpiginosum and some other Dermatoses;" Dr. M. B. Hartzell, "The Protozoa-like bodies of Herpes Zoster; a contribution to the study of Psorospermosis;" Dr. W. T. Corlett, "Cold as an Etiological Factor in Diseases of the Skin, with Report of Cases;" Dr. C. W. Allen, "Acquired Idiosyncrasy for Quinin, showing peculiar Cutaneous Manifestations."

Friday, 9:30 A.M. Open discussion upon "Dermatitis Exfoliativa;" a, Its Clinical Forms; b, Its Etiology; c, Its Treatment.

Dr. E. B. Bronson, title to be announced; Dr. J. Zeisler, "The Relation of Impetigo Herpetiformis to Pemphigus Vegetans;" Dr. J. A. Fordyce, "Notes on Drug Eruptions."

PUBLIC HEALTH.

Smallpox.—Only six new infected points have been reported since the date of the last smallpox summary, April 21, to-wit: at Worcester, Mass., origin traced to Boston; at Manchester, Conn., supposed to have originated in a paper mill from infected rags; at Fort Wayne and at Kewauna, Ind., origin of the Fort Wayne cases attributed to Cleveland, Ohio, of the Kewauna case, unknown; at Jackson, Mich., origin traced to Chicago; at Roodhouse, Ill., origin supposed to be from a tramp. Appeals have been made to Governor Matthews and to the State health authorities of Indiana, urging that the Chicago division of the "commonweal army" be prohibited from entering Indiana and marching across the State. An order of the Indiana State Board forbids the introduction and sale of ready-made clothing from Chicago, unless accompanied by a certificate from the proper authority that the clothing has been disinfected in accordance with the rules of the American Public Health Association, the Board claiming that every recent outbreak of smallpox in Indiana "has had its origin in contact with Chicago tramps or goods made in that city."

Up to the close of April there had been 1,210 cases of smallpox reported in Chicago since January 1, and the disease showed no signs of abatement. There were 544 cases reported during the month of April—an increase of 78 per cent. over the previous month, and the rapid growth of the epidemic is shown in the following figures: January, 128 cases; February, 233 cases; March, 305 cases; April, 544 cases—total, 1,210. During the corresponding period of the first year of the epidemic of 1881-83, there was a total of 412 cases, and the great increase was then, as now, in the month of April—133 cases in April as against 99 in March. The parallel is not reassuring, and unless efficient suppressive and preventive measures are vigorously enforced during the next four months there is reason to apprehend another serious increase and spread next autumn. With the wise expenditure of the recent appropriation of \$100,000, now at the disposal of Health Commissioner Reynolds, much may be done, and there is promise in the wholesale vaccination work still being carried on. Nearly 10,000 vaccine points are being used daily by the department. The general and

continuous enforcement of vaccination is the most efficient and the most economical protection against a smallpox epidemic.

Asiatic Cholera.—Advices from the cholera centers are characteristically meager. The epidemic at Lisbon continues to spread and the disease is reported to have extended to the left bank of the Tagus, cases having appeared in the province of Beira near the Spanish frontier. A cable dispatch from Madrid announces 225 new cases developed at Lisbon, April 25, and on the 29th ult. there were 284 cases under treatment. A medical commission has been organized by royal decree of the Portuguese Government to advise the civil authority in regard to measures to be taken to check the farther spread of the disease.

BOOK NOTICES.

Tables and Notes on Human Osteology for the Use of Students of Medicine. By SEBASTIAN J. WIMMER, M.A.M.M.D. With a preface by WILLIAM F. WAUGH, A.M., M.D. Philadelphia: Medical Publishing Company. 1894. Price \$1.50.

This little book is one of the best brief compilations on the subject of osteology, and is in every way commendable, as an aid to the student in the study of osteology.

A Manual of Nursing in Pelvic Surgery. By LEWIS S. McMURTRY, A.M., M.D. Louisville. 1894. Cl. pp. 92.

This book is a practical guide for nurses engaged in the surgical treatment of the diseases peculiar to women. The extensive experience of the author in this class of cases, has enabled him to place at the disposal of the profession, a very useful book. The method of preparation of the instruments and the patient; the details of the various duties of the nurse, during and after operations, are given with minuteness, and care. The work is destined to be one of the most popular of its class. The style is pleasant and clear and the little volume is attractively printed.

Hydatid Disease, Vol. II. By the late JOHN DAVIES THOMAS, M.D. (Lond.) F.R.C.S. (Eng.) A Collection of Papers on Hydatid Disease. Edited and arranged by ALFRED AUSTIN LENDON, M.D. (London), Sydney and London. 1894. Bds., pp. 166.

This volume has been prepared by Dr. Lendon from MS. notes and papers left by Dr. Thomas at his death. It opens with an appreciative biographic sketch of the author, and then discusses hydatid diseases as affecting the abdominal organs in Part I. This Section includes the liver, the spleen, the kidney, the peritoneum, the male pelvis, the female pelvis, and the testicle. Part II gives the hydatid disease of the thoracic viscera, *i. e.*, the lungs and pleura, the heart, the great blood vessels. Part III is devoted to the hydatids of the nervous system, principally a discussion of hydatid disease of the brain and its membranes and the spinal cord. This is stated to be essentially a reprint of Dr. Thomas' paper on this subject in the Transactions of the Inter-Colonial Medical Congress of Australasia. Part IV, hydatid disease affecting the bones, muscles and superficial structures, *viz.*: The bones and joints, the muscles and fasciæ and the breast. Part V concludes the work with a discussion of the operative treatment of hydatid disease. *a*, operations which destroy without removing the parasite; *b*, radical operations; *c*, operations involving the removal of the fibrous sac as well as of the hydatid cyst. There is no index. The book is very far from being exhaustive but is very useful and instructive as far as it extends.

The Etiology of Osseous Deformities of the Head, Face, Jaws and Teeth, by EUGENE S. O. TALBOT, M.D., D.D.S. Third Edition, with 461 illustrations. Chicago: The W. T. Keener Co. Cl., pp. 487.

In this edition of the book, the author states that he has extended the scope of his original inquiries into the "departments of oral and nasal medicine, and surgery of the eye, ear and face, so intimately related to dental medicine through the causation originally assigned for irregularities of the teeth and jaws. The alleged causative factors in

the case of the nose and mouth were themselves often found to be of constitutional origin. The scope of the researches presented in this edition, therefore, while seemingly extended, are practically confined to the limits of the original inquiry."

The present volume adds to the current rogues' gallery a portrait of the assassin, Prendergast, with the cranial measurements.

Those who believe that the perpetration of some outrage upon society is *prima facie* evidence of insanity on the part of the criminal, will find much to sustain their views in this book. The neurologist and the sociologist will be entertained and instructed by much of the material in this volume, which is carefully written, well illustrated and handsomely printed. The work shows great research and patient industry, and the fact that it has passed to the third edition is evidence of its favorable reception by the profession.

MISCELLANY.

Change of Address.—Dr. Edward C. Mann from Brooklyn to Madison Avenue, between 67th and 68th Streets, to which point he has also removed his sanitarium.

A New Jersey Centenarian.—On April 20, Mrs. Hannah Chard, of Glassboro, N. J., attained her one hundred and fifth birthday. The fact that she was born of Pennsylvania Dutch stock, at Brandywine, in the year 1789, is said to be well authenticated. She is said to have gone over the battlefield at Brandywine when six years of age, picking up bullets and other mementoes of the contest. Her health and perceptive faculties are exceptionally good, and she is still able to go to church on Sundays, when the weather is suitable. She has over one hundred and eighty surviving grandchildren and great-grandchildren.

World's Columbian Commission; Award to Medical Department, U. S. A.—The Executive Committee of Awards of the World's Columbian Commission, through its Chairman John Boyd Thacher, has notified the Medical Department, U. S. Army of an award on account of its exhibit of hospital, laboratory and medical supplies as follows: For excellent equipment of a military hospital including furniture, medicines, instruments and dressings. For a clinical laboratory of approved design, well supplied with all the apparatus necessary to facilitate the study of clinical microscopy. For an interesting and important collection of sections, photo-micrographs and bullet effects, all showing a high grade of efficiency in this branch of the Army service.

"Christian Science."—The Supreme Court of Nebraska, in the case of State of Nebraska vs. Buswell, has at last dealt a too long deferred blow at the so-called "Christian Scientists." One of these irreverent charlatans was prosecuted in a lower court for practicing medicine contrary to the statutes of Nebraska, but was acquitted by the jury. On an appeal to the Supreme Court it was held that the act to establish a State Board of Health, to regulate the practice of medicine in Nebraska, etc., is as much directed against any unauthorized person who shall operate on, profess to heal, or prescribe for or otherwise treat any physical or mental ailment of another, as against one who practices medicine, surgery and obstetrics as those terms are usually and generally understood.

In its decision the Court said: "The object of the statute establishing a State Board of Health, etc., is to prevent imposition upon the afflicted by ignorant and unqualified pretenders to healing power, and any person not within the exceptions prescribed in said act, and not having complied with its requirements as to a certificate, who shall under any pretense operate on, profess to heal, or prescribe for or otherwise treat any physical or mental ailment of another, thereby renders himself liable to its penalties."

Philadelphia Notes.

PHILADELPHIA COUNTY MEDICAL SOCIETY.—The election for second Vice-President (which had been postponed from the January to the April meeting) of the Philadelphia County Medical Society was held April 18, when two candidates' names were presented; the regular nominee was Dr.

Clara Marshall, and Dr. John C. Da Costa was named by the opposition. The general interest in the contest was shown by a large attendance of members. The Society was ungalant enough to reject the representative of the Woman's Medical College, and Dr. John C. Da Costa was declared elected. At the same meeting Dr. John R. Kerr, of Canton, China, was elected to honorary membership in the Society.

ORTHOPEDIC SECTION, COLLEGE OF PHYSICIANS.—At the meeting of the Orthopedic Section of the College of Physicians on April 27, a boy aged 12 years was exhibited, who five years ago had been operated upon for double club-foot by Dr. Thomas G. Morton, who removed the astragalus from each foot. The patient could walk or run naturally, the feet were in good position, and he could stand on heels or toes, there was good ankle motion. Dr. Morton presented this case because some one had expressed a desire to examine the patient five years after the operation. The result was pronounced excellent. It is claimed by the operator that cases of club-foot, with reference to the tarsus, may be divided into simple and complicated. Those of the first class can be restored to normal position by manipulation and division of tendons. Those of the second class are complicated by a dislocation and malformation of the astragalus, which prevents ankle flexion by blocking the joint. In the latter class, excision of the astragalus gives satisfactory results.

THE CHINESE LEPER, WING, who had been an inmate of the Philadelphia Hospital for several years, died recently; his savings in bank notes, amounting to \$130, which constituted his entire estate, were sent to Washington and there cremated, as it was not deemed proper to allow these notes to go into general circulation.

PHILADELPHIA is again to have a Botanic Garden. After more than a year's delay, councils have passed the ordinance opening to public use, with the University of Pennsylvania as Trustee, the tract of thirty-five acres on the west side of the Schuylkill, located between West Fairmount Park and the grounds which were recently acquired by the city by the purchase of Bartram's Garden. The University will proceed to erect a museum building on this site to accommodate the rapidly growing collection of objects illustrating archaeology, ethnology, natural history and the arts, among which is the very valuable Babylonian and Egyptian remains, and the Maxville Somerville collection of engraved gems, etc.

Medical College Notes.

APPOINTMENTS.—Dr. Solon Marks has been elected Professor of Military Surgery; Dr. Walter Kempster, Professor of Mental Diseases and Dr. E. T. Phillips of Menominee, Mich., Professor of Surgical Anatomy and Operative Surgery on the Cadaver, in the Wisconsin College of Physicians and Surgeons.

COLUMBIAN UNIVERSITY.—The Medical Department of the Columbian University, Washington, D. C., held its annual commencement April 24. There were twenty-seven graduates.

THE ILLINOIS STATE BOARD OF HEALTH.—At its recent regular meeting, April 24-28, the Illinois State Board of Health added the following named colleges to its list of those recognized as "in good standing": St. Louis College of Physicians and Surgeons, Barnes Medical College, Beaumont Hospital Medical College, Marion-Sims Medical College, all of St. Louis, Mo.; Hering Medical (homeopathic) College, National Homeopathic Medical College, both of Chicago. The American Medical (eclectic) College of St. Louis was stricken from the list and refused further recognition.

The following tribute to the memory of Dr. Rauch was adopted by the Board:

"The Illinois State Board of Health, realizing that the causes of State medicine and medical education have sustained a great loss in the death of Dr. John H. Rauch, former President and Secretary of the Illinois State Board of Health, wishes to express to the profession at large, and to the family of the deceased, its high appreciation of the services rendered by Dr. Rauch, not only to the State of Illinois, but to our entire country.

"He was the first man in our midst to place the subject of public health upon a scientific basis, treating the vital questions of drainage and water supply with the intelligence and

energy necessary to bring about results and projecting plans in sanitary science that will long remain models worthy the study of the student of public health.

"Dr. Rauch should be held in reverence by the medical profession for his zeal in the direction of advance of medical education. He was among the earliest and one of the most constant advocates of a more liberal education, and his schedule of "Minimum Requirements" is as widely known in this country as is medical education itself.

"Beside the recognition of Dr. Rauch's great knowledge of the subject he had made his own, this Board wishes to record its enthusiasm for and appreciation of his devotion to his work; likewise of his many virtues as a friend and physician."

THE PUBLIC SERVICE.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from April 21, 1894, to April 27, 1894.

Capt. WILLIAM L. KNEEDLER, Asst. Surgeon, will, in addition to his present duties as post surgeon at Ft. Mason, Cal., perform that of attending surgeon at San Francisco, Cal., until further orders.

Capt. JAMES D. GLENNAN, Asst. Surgeon, is granted leave of absence for one month, to take effect on or about April 24, 1894.

Major VALERY HAVARD, Surgeon, is relieved from duty at Ft. D. A. Russell, Wyo., and ordered to David's Island, N. Y., for duty, relieving Major JOSEPH R. GIBSON, Surgeon. Major GIBSON, on being relieved by Major HAVARD, is ordered to Ft. Snelling, Minn., for duty at that station, relieving Major CHARLES K. WINNE, Surgeon. Major CHARLES K. WINNE, on being relieved by Major GIBSON, is ordered to duty at Ft. McHenry, Md., relieving Capt. CHARLES B. EWING, Asst. Surgeon. Capt. EWING, on being relieved by Major WINNE, will report for duty at Jefferson Bks. Mo.

Capt. NATHAN S. JARVIS, Asst. Surgeon, will be relieved from duty at David's Island, N. Y., upon the arrival of Capt. SAMUEL Q. ROBINSON, Asst. Surgeon, and will report in person to the commanding officer, Willets Point, N. Y., for duty, relieving Capt. WILLIAM P. KENDALL, Asst. Surgeon. Capt. KENDALL, upon being so relieved, will report in person for duty at Ft. Columbus, N. Y.

ORIGINAL ARTICLES.

THE FIRST SUCCESSFUL CASE OF CÆSAREAN SECTION IN PLACENTA PRÆVIA, AND REMARKS ON THE METHOD OF OPERATION.

BY PROF. AUGUSTUS CHARLES BERNAYS, M.D.
MARION-SIMS COLLEGE OF MEDICINE, ST. LOUIS, MO.

History of the Case and Literature.—On Nov. 19, 1893, at 2 P.M. I was called to see Mrs. A. M., by her physicians, Drs. R. J. O'Reilly and W. W. Graves. The message calling me stated that I was wanted in order to perform the Cæsarean section and that the case was one of placenta prævia centralis. The patient is a healthy woman, 42 years of age, mother of four living children, the youngest a boy 10 years old. Dr. O'Reilly had been engaged to attend her in confinement which he had calculated would take place about the middle of December. He had been called by the husband at 1:30 A.M. on account of an alarming hemorrhage and arriving a few minutes later found the patient excited and frightened by the unexpected hemorrhage, sitting in a chair and a large bundle of cloths under her saturated with blood. The os was closed but the finger could be introduced and the placenta felt, as well as the blood streaming from the uterus. The vagina was tamponed and the patient put to bed, pelvis elevated and perfect rest enforced. Dr. W. W. Graves was sent for to assist and he arrived at 2:30 A.M. Patient's condition being good and the bleeding having ceased, the physicians determined to watch the course of events. As there had been no labor pains, it was thought that possibly the pregnancy might go on to its normal end, if the patient was kept quiet, and indeed there was no labor and no further hemorrhage occurred until 1:30 P.M., just twelve hours afterwards, when I was called. Dr. Thos. O'Reilly and Dr. Geo. F. Hulbert were also called and I brought my assistants, Dr. Ben Shanklin and Dr. Roux. After a consultation in which very conflicting views were expressed and carefully weighed, we concluded to perform the Cæsarean section, knowing full well that the operation had never been successfully performed under similar circumstances. All the physicians present concurred in the opinion that it was the best thing to be done for the mother and child under the existing circumstances.¹

Under this head I may say that the credit for suggesting the operation in this case belongs to Drs.

Graves and O'Reilly. Both of these gentlemen are experienced practitioners and obstetricians, both knew exactly what placenta prævia is, and fully understood the difficulties confronting them and the dangers to the two lives which were intrusted to them.

In a paper published in the *American Gynecological Journal* in September, 1892, by Dr. W. Hutson Ford, I find the only complete and logical discussion of this subject. In a learned and scientific manner the author arrives at definite conclusions upon purely theoretical grounds. This paper will always form the basis for the future discussions of the subject and the case here recorded will go far towards supporting the author's very positive conclusions.

The reasoning which led us to perform the Cæsarean section in this case was based on the brilliant results of this operation in the hands of expert operators in recent years. I myself had performed the Cæsarean section successfully at the Protestant Hospital in St. Louis upon a hunchback with narrow pelvis, saving both mother and child. I reported the case at the time to Dr. Robt. P. Harris and was informed by him that it was the first successful case in the State of Missouri. The statistics of the mortality of placenta prævia, when treated by the Braxton Hicks method in the hands of experts are not as favorable as those of the Cæsarean section under the same conditions. I am personally of the opinion that in this country, at least, expert obstetricians who are thoroughly well grounded in bacteriology and practical asepsis are not as frequent as similarly qualified surgeons.

The Operation.—The patient resided in a newly-built house, the external surroundings were favorable and one of the rooms was quickly prepared for the operation, while the patient herself was thoroughly cleansed after the usual methods now practiced in all cases where the abdominal cavity and the vagina are both involved.

After the patient was chloroformed, she was placed upon the operating table and again scrubbed with a 1-500 bichlorid solution, and the vagina again douched and swabbed through a speculum by the assistants. The os uteri was found closed at this examination. I am a thorough believer in rapidity in abdominal work and in a typical operation like the Cæsarean section I think that everything should be prepared beforehand with a view to performing the work in the quickest possible time, if for no other reason than to shorten the time of the narcosis. In this case which was an ideal one, so far as the condition of the patient was concerned, I stated before making the incision that I would try to break the time record and requested Dr. Thomas O'Reilly to carefully time the different steps of the operation.

The first incision extending from the umbilicus to the pubes, opened the abdominal cavity and cut the

¹ I wrote to Dr. Robt. P. Harris, of Philadelphia, and to Dr. Howard Kelly, of Johns Hopkins, as well as to the largest maternity hospitals in Europe and have found no record of Cæsarean section performed in a case of placenta prævia. Since then, I have found that the operation has been done twice before, but under the most unfavorable circumstances, once in the city of St. Louis by Drs. Hypes and Hulbert, and once in the mountains of Montana by Dr. J. M. Sligh, of Granite City. (*American Journal of Obstetrics*, February, 1892). The result in both cases was fatal because the operation was done upon patients who were much exhausted and weakened by loss of blood.

peritoneal covering of the uterus to the extent of one-half of an inch, but not being long enough to roll the uterus out of the cavity was extended about two inches above the umbilicus. All bleeding was checked and the incision washed with warm Crystal water.² The uterus was now rolled forward out of the cavity and an assistant standing between the patient's legs grasped the organ with both hands and compressed it against the horizontal ramus of the pubes.

The uterine cavity was next opened by an incision and while the water was escaping, the incision was lengthened upward and downward by a blunt-ended large pair of scissors. The living child was lifted out and handed to Dr. Hulbert for further care. Umbilical cord clamped and cut off. At this moment Dr. O'Reilly stated that a few seconds less than three minutes had been consumed in the operation.

The membranes were now stripped off and the placenta readily peeled off while the uterus was contracting down nicely. There was some oozing from the seat of the placenta and the uterine cavity was douched with the sterilized water in order to remove the clots. Some intestines had rolled out and after being washed were replaced.

The uterus was stitched with twelve deep silk sutures which embraced all of the layers of its walls. I aimed to embrace only the serous and muscular layers, but many of the sutures embraced the decidua as well. There is no good reason for not including the decidua and therefore, as long as the sutures only include the very edge of this inner coat, if at all, the healing by primary union can not be interfered with. Four superficial or perhaps "half deep" silk sutures as Dr. Kelly would call them, were placed between the twelve deep ones at those intersutural spaces where there was gaping or pointing enough to warrant their use. I have never been able to see an essential or important innovation in Slinger's sero-serous suture, and if the deep sutures are properly placed no others are necessary. It must be understood that by "properly placed," we mean that they are so arranged as to leave no pointing or gaping between the lips of the wound, that perfect approximation is achieved by one row of deep sutures. There can be no doubt that a perfect approximation by one row of sutures is better and more to be desired than by two or more rows—this part of the operation required eight minutes. The omentum was next brought down over the uterine sutures, and the closure of the abdominal incision by about twenty sutures embracing all the layers finished the operation, the entire procedure having taken exactly twenty-four minutes and forty-five seconds.

The external wound was treated by dusting it with Sennine and covering it with dry gauze and the ordinary abdominal bandage over all. The uterine cavity was now sponged out, per vaginam with iodoform gauze, the os was found easily dilatable and that part of the uterus to which the placenta was attached formed a ring about two and one-half inches wide reaching from the cervix upwards. I had prepared

a very large gum hose seven-eighths of an inch in diameter, almost as large as a garden hose, which was passed into the uterine cavity and allowed to pass through the vagina ending in a large bunch of gauze in front of the vulva. Through this hose, injections and irrigations of the cavity could be made, if there should be any necessity at any time during the puerperium.

The patient was now put to bed and the after treatment was conducted by Drs. Graves and O'Reilly who were assisted by trained nurses. There was at no time during the convalescence any serious complication, except perhaps a slight tympanitis which disappeared after a purge. Patient sat up on December 3, and the nurses were discharged on December 12. Mother made a perfect recovery and has been well ever since.

The child did well for a few hours, but became asphyxiated, as the physicians suppose, on account of non-closure of the foramen ovale and died after about ten hours. The child was probably not much over eight months' gestation.

In conclusion, I may be permitted to express some epicritical opinions. The most important question which confronts me is: Would you advise the performance of the Cæsarean section in all cases of placenta prævia where the Braxton Hicks method or some similar operation is the only alternative? I would answer as follows: If an expert operator can be had who has done or assisted at more than two hundred abdominal sections of all kinds in which the total mortality was less than 7½ per cent. by all means let him do the Cæsarean section. If no such surgeon is at hand, select a physician to deliver the child who has frequently turned and extracted, one who knows how to clean his hands and who knows that it is a very difficult and tedious task to properly shave and cleanse the vulva and the vagina.

THE DIAGNOSIS AND TREATMENT OF "FLOATING KIDNEY."

A paper read by special invitation before the Sixth Annual Meeting of the Shelby County Medical Society, Shelbyville, Ind., April 9, 1894.

BY HARVEY REED, M.D. (UNIVERSITY OF PENN.)

PROFESSOR OF THEORY AND PRACTICE OF SURGERY AND CLINICAL SURGERY
OHIO MEDICAL UNIVERSITY; SURGEON PROTESTANT HOSPITAL;
CONSULTING SURGEON B. & O. AND BIG FOUR RAILWAYS,
COLUMBUS, OHIO.

The frequency of "floating kidney" associated with its varied complications, together with the errors in diagnosis, certainly warrant our taking up this subject, and considering it for a few moments before this ASSOCIATION.

The experience of the writer both as a general practitioner and consultant, has led him to believe that the existence of a floating kidney is more likely to be misunderstood and taken for something else than any other one disease of the abdominal cavity.

I have seen floating kidney treated for "lumbago," also for so-called "sciatic rheumatism." In another case I saw an able practitioner tap it for "ascites," and still another case where it was mistaken for an enlarged ovary.

On the other hand, I have seen an enlarged and pendant "gall bladder" filled with gall stones, mistaken for a movable kidney, and the mistake was not discovered until revealed by an operation. With these few examples, which we have given, as having come under our own observation and occurring in the

² In the city of St. Louis we are very fortunately situated for doing surgical operations in private houses, since the introduction into commerce of the sterilized and filtered water known as Crystal water. The price is so low and the package so convenient, that I now use it exclusively for irrigation of wounds and flushing cavities. By using it directly out of the bottles it need not come in contact with the hands of assistants or vessels of any kind, which I feel is a most important safeguard against its infection.

experience of able practitioners, it is quite evident that the diagnosis of a floating kidney is not always an easy task. In fact, it has been my experience that the early diagnosis of a floating kidney is seldom made, unless the patient is so fortunate as to fall into the hands of an experienced diagnostician early in this class of infirmities.

As a rule, you are called upon by some practitioner who has treated the patient for months or even years without success until one or both have become dissatisfied and seek relief either through council or a change in physicians.

By this time you may have had torsion of the renal vessels and nerves, and consequently find the patient suffering from lumbar pains, sciatica or both. On the other hand, the patient may be perfectly free from pain except more or less frequent paroxysms, during which it may be likened to that of a case of renal colic. Not unfrequently the patient, and especially if the abdominal walls are thin, will observe a tumor in the peritoneal cavity, which excites attention, although when first discovered it may not cause any special pain.

It is not uncommon to find that hydro- or even pyonephrosis may have set in; if the latter, it is not unusual to find it associated with secondary infection in the form of tuberculosis.

The clinical facts have forced us to the conclusion that the symptoms of a floating kidney vary, in accordance with the conditions which may be associated with it, and which are largely modified by the changes and complications which, as a rule, sooner or later, accompany this malady.

It may be considered presumptuous on my part to even attempt a definite diagnosis of floating kidney when such a noted authority as Agnew in his "Surgery," and even Pepper, in the "American Text-Book of Theory and Practice of Medicine," fail to give it, saying nothing of its omission in the "American Text-Book of Surgery;" and yet our little cycle of experience has led us to the belief that it fills a position which is sufficiently important in the diagnosis and treatment of abdominal diseases as to justify us in contributing our mite to the study of this distressing malady. I now imagine I hear some of my collaborators ask: What difference does it make? If you are satisfied there is a tumor in the abdominal cavity, make an incision and find out what it is. It will be time enough then to remove it if you can, or relieve it if you can not do any better, or let it alone if you must.

While we are ready to accede this point to those who are experienced and practical operators, yet the point I wish to make is that in the majority of cases movable kidney presents itself to the average practitioner, who is not experienced in abdominal surgery or in the diagnosis of abdominal tumors, who dare not open the abdominal cavity and look at its contents in order that he may make a diagnosis but who must resort to text-books for his information; and when, as I have already said, these text-books fail to give him this instruction it is our duty, although our experience may be limited, to give him what assistance we can from our accumulated storehouse of practical knowledge and aid him, if possible, to make an early diagnosis in this class of diseases.

On making an early diagnosis, I believe, hangs the importance of successful treatment of floating kidney. A failure to make an early diagnosis, simply

means that your patient will take nine chances out of ten of contracting complications which are liable to be so grave as to require nephrotomy or even nephrectomy to relieve them. It is these neglected cases of floating kidney where you find long-continued severe neuralgias, due to torsion and subacute neuritis.

It is usually in the neglected cases of floating kidney that you find hydro-nephrosis, due to stenosis of the ureter, which, however, may last for weeks and even months without serious destruction to the substance of the kidney, as has been demonstrated by the author of this paper, by repeated experimental research but which, sooner or later, unless relieved is nearly certain to be followed with either cystic degeneration or pyonephrosis, tuberculosis or all, either one of which, if allowed to continue for any length of time, not only endangers the patient's life but will require a nephrectomy or to say at least, nephrotomy to relieve.

DIAGNOSIS.

In making a diagnosis of a movable kidney we should first consider the predisposition. This is largely governed by sex; women who have borne children, and especially if they belong to the laboring class, are particularly prone to this disease; poorly nourished females contribute their share, while age and occupation are important factors in contributing to this disease.

In reference to sex, floating kidney occurs much more frequently in females than in males, although I have seen several cases in males and one case in a young man who was unusually strong and muscular.

Notwithstanding our text-books inform us that floating kidney usually occurs between the age of 25 and 40 years, yet I have seen it occur in a young man under 18, and have found it in women who were past 70.

Occupation unquestionably has a great deal to do with causing floating kidney. The young man I have just referred to, was a member of a baseball club and addicted to violent exercise, which finally resulted in producing a floating kidney.

Again, washer-women who expose themselves to heavy strains, are frequently found suffering from this malady, while puny females, who lie around the house studying "how to do nothing," not infrequently become victims of this disease, often by suddenly changing their habits, during the presence of a friend by jumping out of a buggy or over a fence, which is followed by a displacement of the kidney. The same holds true of poorly nourished females, who may be suffering from some constitutional disease or marasmus, which has reduced them to such an extent that the least exertion will force the kidney out of its place. Pressure on the kidney during pregnancy has a tendency to cause displacement, and is not unusually followed by a floating kidney.

It is quite evident in attempting to arrive at a correct diagnosis that it is of the greatest importance that we carefully study all the predispositions which may lead to the production of a floating kidney and, if possible, ferret out the cause or causes which may have been the factor or factors in producing it. Having accomplished this, which is comparatively easy as compared with the differential diagnosis, we are then ready to undertake to distinguish it from other abdominal maladies, which, I am sure, we are willing to admit is not always such an easy task.

If the functions of the kidney have been interfered with by the displacement, the use of the urethral catheter will be of great service in making a correct differential diagnosis, especially if the congestion has been so great as to produce hematuria; where this occurs the use of the urethral catheter will very greatly assist us in arriving at the correct diagnosis.

In making the differential diagnosis between an enlarged and elongated gall bladder and a floating kidney, we must remember that traction upon the tumor, in the case of the gall bladder, will reveal that it is attached to the liver instead of the lumbar region, while traction upon the kidney will demonstrate that it is attached to the lumbar region instead of the liver. As a rule, the difference in texture where the abdominal walls are not too thick will enable you to diagnose between them; yet, when the gall bladder has very thick walls and is very much distended with semi-liquid bile and where the kidney is somewhat flabby, it becomes very difficult to differentiate between the two by the touch; but as a rule, with the history and the predisposition to guide you, this feature of the diagnosis can be decided.

If it happens to be the left kidney, that is affected (which is quite unusual), the complications of diagnosis are at once relieved.

Where the gall bladder is involved, it is not unusual to have it associated with jaundice and all its accompanying symptoms and complications. On the other hand, we would not expect, except in anomalous cases, to find jaundice occurring in the case of a floating kidney. In many cases digital examination will enable you to distinguish the kidney in its natural position on the well side, and its notable absence on the other side; at the same time it is often an easy matter to replace the floating kidney which, on pressure, will readily slip from under your finger and either ascend under the margin of the liver, or descend even to the brim of the pelvis; or it may be, in some cases, pushed over to the median line and assume a position on the abdominal aorta so that the pulsations of the latter may be distinctly felt underneath the displaced kidney, which may be outlined very distinctly by the aid of these pulsations. Under these circumstances, pressure will frequently shut off the circulation to such an extent that the femoral artery on each extremity can not be distinguished. It would be difficult to accomplish this with a distended gall bladder. In fact, I have never succeeded in doing so in cases of this class that have come under my observation.

As a rule, a displaced kidney is much more sensitive than an enlarged and elongated gall bladder, and while the shape may not always enable us to form a correct diagnosis, yet the difference in the outline of the tumor is such that we are guided with considerable accuracy in the line of a correct differential diagnosis. The elongation of the right lobe of the liver may complicate the differential diagnosis in this class of cases.

It is only a few days since I was consulted in a case of this kind in which a lady came to me from Northern Ohio, with the history of having suffered from a floating kidney for the last seven years. In addition to that, she had a very elongated and "hour-glass" shaped right lobe of the liver. The rest of the liver was apparently normal, but on careful digital examination we were enabled to shoot the kidney up under the elongated lobe of the liver and down below

it, and by pressing the liver outward and upward we could readily distinguish the kidney which was also elongated beside being flattened, evidently the result of pressure from the liver.

As a rule, a patient who has floating kidney is relieved when in the prone position, but in this case the pain was increased, owing to the fact that the prone position caused the liver to press upon the kidney and thus increased the pain, and no doubt, was largely the cause of the displacement.

The patient was admitted to the Protestant Hospital, and assisted by Dr. Baldwin I made the radical operation, when this condition was demonstrated and the movable kidney sutured fast to the muscles of the back; the patient is now making a rapid recovery. In this case, however, I am inclined to believe we can hardly expect to secure permanent relief, for the reason that the liver will continue to make pressure on the kidney which may sooner or later have to be removed.

The differential diagnosis between a movable kidney and that of a spleen is much more readily accomplished. The location of the spleen being on the left side is less frequently called into question, owing to the fact that the left kidney is less frequently displaced. But when it is displaced, it is seldom the spleen assumes a shape that in any respect corresponds to that of the kidney and very seldom drops down as low in the abdominal cavity as a floating kidney. Again, the kidney may be pushed up under the pendent portion of the spleen which will enable you to readily feel both organs at one time. If, however, the spleen extends down over the kidney, it will be readily distinguished from it by a digital examination, and the kidney will be felt underneath that portion of the spleen which extends in front of it.

The increased mobility of a floating kidney, as compared with that of the spleen, is a ready guide in making a differential diagnosis, so much so that we can scarcely imagine how it is possible under ordinary circumstances to misconstrue what we are almost warranted in calling positive symptoms pointing to a correct differential diagnosis. Cancer of the pylorus might possibly be mistaken for a movable kidney especially when the mesentery is very long, and where the cancer assumes the shape and size of a kidney and drops down below the normal position of the kidney, as I have seen it in several cases.

Only a few days ago, assisted by Dr. Means, I operated on a case of this kind which had been admitted to the Protestant Hospital of Columbus, in which the cancerous mass was so movable that it could be pushed beyond the median line on the left side, and down as far as the kidney on the right side; and on the other hand, could be pushed up under the margin of the liver or over the large curvature of the stomach. But on careful examination it was found entirely distinct from the kidney which remained stationary, no matter what position the tumor was placed in, saying nothing of the gastric disturbances which enabled us to make a clear differential diagnosis. On making a laparotomy it was clearly demonstrated that our diagnosis was correct. A gastroenterostomy was made with the Senn bone plates and the patient, although sixty years of age, made a rapid recovery without a bad symptom. In these cases you always have the history of stomach disturbances which do not exist, as a rule, in displaced kidney. You have no interference with the urinary

secretions, no lumbar pains, no tenderness on pressure of the kidney, while you have, as a rule, tenderness on pressure over the cancerous mass. The principal points which might lead us astray in a case of this kind are the size, shape and location of the tumor together with its mobility.

Omental tumors which are quite frequent, might possibly be mistaken for a movable kidney, but as a rule are seldom painful except as they may produce mechanical pressure, and likewise they seldom interfere with the functions of the kidney unless it is by mechanical pressure on the ureters, producing hydro-nephrosis. This, however, seldom occurs. Where an omental tumor is movable, it is readily distinguished from the kidney by digital examination and palpation, as the latter will be found in its normal position, while the other may be moved around through the different parts of the abdominal cavity, seldom if ever invaded by the kidney.

The differential diagnosis between a small ovarian tumor with a long pedicle might possibly be mistaken for a movable kidney. Comparison between the two would, however, on the one hand, enable us to raise the kidney far above a point which would be at all probable in the case of an ovarian tumor, while the latter would be found to be anchored to the pelvic region instead of in the lumbar, as in the case of the former. A vaginal examination would aid in determining the presence of an ovarian tumor, while in the case of a floating kidney it would be quite out of the question to force it down to a point where it could be touched with the finger in the vagina.

We must also remember that a movable kidney in the early stage is extra-peritoneal, while an ovarian tumor is practically intra-peritoneal, the latter usually having a broad pedicle, which, as we have already said, is anchored in the pelvis, while the former has a long narrow meso-nephron anchored near the median line of the lumbar region.

TREATMENT.

We have little confidence in the palliative treatment of a floating kidney, as we believe it is the exception and not the rule that such treatment results in any permanent relief. Experience has taught us, as well as thousands of patients, that the lesions which result from neglect of these cases in the vain effort of securing relief from palliative treatment were worse than useless. Blisters, lineaments, bandages and compressors, we look upon, and especially the latter, as actually injurious, which only submit the patient to additional torture with little or no prospect of permanent relief, and is almost certain to be followed, sooner or later, with organic disease necessitating nephrotomy and often nephrectomy.

It is our firm belief that the only safe and successful treatment of a movable kidney is a radical operation by which the kidney is replaced and firmly anchored by a number of sutures, which should not only pass through the capsule, but should include a portion of the parenchyma as well as the fascia and muscles underneath.

For accuracy and rapidity of the operation in making the radical treatment for a movable kidney, we would suggest the use of a suture of either chromatinized catgut or silkworm gut, both ends of which should be armed with a long, slim needle varying from six to seven inches in length, according to the patient, the points of which should be triangular, and when

used it should be passed through the capsule and the parenchyma of the kidney and directly through the muscles of the back, making its exit through the skin. The second needle should also be passed through the kidney from one-half inch to an inch distant from the entrance of the former, and pass directly through the muscles of the back, making its exit through the skin the same as its mate.

If you desire to have the suture remain, an incision should be made through the skin and the suture tied and the skin stitched over it. If, on the other hand, you desire to remove the suture subsequently, all that is necessary is to tie your sutures on the skin and allow them to remain until you are ready to remove them. This procedure will very greatly simplify the operation which will require a much smaller opening than when you use a curved needle and attempt to fasten by suture the kidney and its capsule to the fascia and muscles of the back in the ordinary manner. With the use of the long needle the suture can be put in very quickly and as many as are necessary to hold the kidney to place, tying them on the patient's back and the abdominal incision closed, all of which can be done in a very few minutes, and we believe it to be equally as efficient and much easier performed than the old method generally in use.

If the patient submits to this line of treatment in the early stages of this malady, before serious complications arise, there is little or no doubt of her permanent recovery and practically little danger in the operation.

On the other hand, where the radical treatment is not resorted to, there is always danger of serious organic disease of the kidney, which may sooner or later prove fatal, and if not, the patient becomes a nervous, suffering miserable creature, of little benefit to herself or those around her.

RESPONSIBILITIES OF THE ABDOMINAL SURGEON.

Presidential Address delivered before the Tri-State Medical Society.

BY RICHARD DOUGLAS, M.D.

PROFESSOR OF GYNECOLOGY IN THE VANDERBILT UNIVERSITY, NASHVILLE, TENN.

I take this, the first opportunity since my elevation to the honored position as President of the Tri-State Medical Society, to thank you for the undeserved and unsolicited expression of your confidence and regard. Conflicting emotions of pride and dismay possess me in entering upon the duties of the office.

The magnificent program we have presented for your entertainment and instruction, is convincing evidence that within the compass of this organization there are men alive to every recent issue that has created a ripple on the waters of the vast professional sea, and that these contributions, many of which you have enjoyed, attest the thoroughness and excellence of their work. Impressed with our competency to present to the world transactions of the highest order, I feel impelled to take this occasion to urge the immediate necessity of systematizing our work. As a Society and individuals, we are prone to dissipate our energies. Concentrated and united effort would yield absolute results, and my word for it, a principle or conclusion emanating from this Society would become authoritative. "In all depart-

ments of science the largest results are to be obtained by division of labor and combination of effort." Therefore, it is to be hoped, and if I may presume to exercise the rights, with which you have vested me, I would suggest that such necessary legislative action be taken for the creation of a new committee to be known as the Committee on Essays and Discussions, and that the President and Secretary be *ex officio* members. The duties of this Committee shall be the selection of a limited number of subjects, divided under several headings, and that two or more members, as may be necessary, be appointed at this meeting to present papers at the next annual meeting upon the several branches of the subject. The essays thus prepared and presented will be accepted as a careful and complete study of the subject. Manifestly, work pursued after this plan would yield a volume of transactions of inestimable worth. Far be it from me to depreciate the value of voluntary papers and accurate clinical reports, for oftentimes they are gems of originality and indisputable facts, garnered in the harvest of experience. Furthermore, the impromptu discussions following these contributions are a fair test of the ready wit and depth of wisdom of our members.

Believing the Fellows will tolerate another recommendation which is humbly submitted, I would remind you that in holding the annual meetings in Chattanooga, this body has departed somewhat from the precept born of experience, that governs all medical organizations, National and State, *i.e.*, if you desire a medical association to flourish, then you must rejuvenate it yearly by the acquisition of new members. These you can more readily acquire by going into their midst, and attracting them by the character and excellence of your work. I would recommend that our place of meeting be changed annually. Chattanooga, gentlemen of the Tri-State Society, is our mother. We, like wandering children return to cast ourselves at her feet and receive her blessing and do her reverence. Proud we should be of our natal soil. We stand upon hallowed ground. Every feature of its varied and beautiful landscape is sacred with historic significance. Nature, with sublime architectural conception, has builded here about an amphitheater, and from the terraced seats and galleries high, spectators have witnessed for more than a century, the most appalling tragedies of our nation's history. Here dwelt the fierce and implacable Chickamaugas, a tribe of the Cherokees, notorious above all for their treachery, daring and hatred of the pale face. "The eagle in his eerie, the panther in his lair," could not be safer than the wily savage was, secreted in the mountain gorges, inaccessible except through a labyrinth of narrow passes, cul-de-sacs and steep ascents. Yet, the combined courage and sagacity of Sevier, Montgomery, Robertson and Jackson annihilated him from Nickajack to Running-Water, and the brave old Cumberland settler began a life of peace and prosperity not to be interrupted until the tragic days of September, 1863, when in quick succession were fought the battles of Chickamauga and Mission Ridge—the Marengo and the Waterloo of the Confederacy. Upon the faults of Bragg and the fortunes of Grant the fate of a nation hung, yet let the dead past bury its dead, and here under the shadows of Lookout let memory be forgot.

It is yet too early in the life history of this organization to hope to interest you with a review of the

work accomplished at previous meetings. Believing a brief discussion of some specific subject will prove more acceptable than a rambling essay in generalities, it is most natural that I should give expression to those feelings which, in the hours of reflection, oppress me. The responsibilities of the abdominal surgeon is the theme of my brief discourse. In the awkward expression of my thoughts I may appear dogmatic and, perhaps, unintentionally wound the feelings of some of my hearers. Permit, me, then, to preface what I have to say with a disavowal of any such purpose. If I can rouse the slumbering conscience of a single would-be laparotomist, I may blight in embryo a glorious and *gory career*, but I will also save one, perhaps many human lives, and the object of this paper will be accomplished.

For fear my position may be misunderstood, and that I may be ranked with those, who, under the title of a plea for conservatism, are consuming valuable space in our journals with lengthy communications, mere expositions of their own ignorance and a contemptuous attempt to reflect upon some rival, I wish at the outset to declare myself opposed in principle and practice to those so-called conservative methods which permit bags of pus to remain for weeks or months in the pelvis, while the tinkering gynecologist douches, paints, poultices and stuffs the woman. Nor can I comprehend the process of reasoning that induces some of our ablest men to tease an ectopic gestation sac into the suppuration with electricity, when a properly executed section offers absolute recovery at the minimum risk to life. How pathetic it is to see one of these conservatists, from fear and selfishness only, patiently waiting for a renal or hepatic suppuration to mature. Can any one question for a moment, that the abdominal section with its perfected technique, is the crowning glory of modern surgery? The great responsibility of abdominal surgery rests with and upon the operator. Is he, as you know and hear of him, up to the full measure of the requirements? Has he a conscientious understanding of the vastness, of the seriousness of the undertaking? Does he appreciate the fact that abdominal work is above, apart and beyond all other surgery, that in its execution he is confronted with problems peculiar to this field of labor? Upon his thorough knowledge of all things within, his boldness, his comprehension and application of every principle of surgery, even to its most minute details, depends the issue of the case—the life of an individual. Furthermore has he the training in this special line of surgery, for in the language of Dr. Potter, "unless he has the abdominal experience he has no right to enter its domains except under urgent necessity." It is incomprehensible, yet a fact, that men without previous training or special work of any kind of surgery, men who would tremble to amputate a thigh, or quail if confronted with an aneurism, hail with delight the finding of a condition that gives them a flimsy excuse for opening the peritoneum. Skilled workmen have found this membrane remarkably tolerant when handled intelligently. This fact has been emphasized of late. The eager and inexperienced have interpreted it to imply that the peritoneum is insensible to any degree of heat or cold, resists violence like a prize-fighter, can digest, absorb and remove anything from a few square inches of a suppurating cyst to a pair of forceps or an occasional sponge, will entertain with cordial hospitality all manner of filth,

and in the end, by noble self-sacrifice, permit the patient to recover. "Certainly the peritoneum has overlooked more insult and withstood more foolishness than most parts of the body." Surely this wonderful structure with its great powers of absorption, is not altogether protective in its functions. Does the careless, the inexperienced, the filthy operator take into account the possibilities of danger to the patient through this membrane alone?

The italicized and oft-quoted paragraph from Mr. Tait which reads as follows: "In every case of disease in the abdomen or pelvis in which the health is destroyed or life threatened, an exploration of the cavity should be made," is an established principle for government, but does that say that you, or I, any or every one shall operate? It is not so expressed. Yet this clear cut rhetorical sentence is perverted and used as an admission ticket to the cavity of the abdomen. The amazement of many aspiring laparotomists when they first see the hitherto unknown beauties of the vasa-intestini tenuis or the Fallopian fimbriæ, or the crystal cyst of Morgagni, may be likened to the bewilderment of a country bumpkin at a village fair. Must you not confess you have seen the cavity invaded by men whose anatomic knowledge could not assign the viscera to their proper regions? Whose full knowledge of pathology might be expressed in "poultice a bile 'till its ripe, then split it." Have these would-be surgeons the knowledge of hemostasis at their command? Can they comprehend Péan or Grigg-Smith's preference for forceps pressure? Do they understand why catgut is both unreliable and dangerous? Do they know how and when to employ elastic ligature? These are common questions; a thousand more would confront them in detail work.

After years of study in general surgery, bacteriology and asepsis, it will take an average hospital interne six months to learn how to be moderately clean, and even with this education only about one in fifty become practically aseptic. Divert his mind for ever so short a time from the routine preparation necessary for aseptic work, and some fatal blunder will be committed, sepsis will creep in, and infection will follow. (I appeal to those of you who are constantly engaged in surgery, if by some chance you have not occasion to operate for several days, do you not find it necessary to keep a careful watch upon yourself to avoid violation of some rule for the exclusion of infection?) This is not the place to raise the question of the value of antiseptics, but it is meet now, and at all times to proclaim our faith in aseptic or clean surgery, and as I have above attempted to show, its practice involves not only a theoretical knowledge, but a practical training. Pray answer me, then, by what right or privilege have men without either of them to enter the domain of abdominal surgery? Upon the other hand, it may be well argued and successfully maintained, that conscientious and ambitious men are not to be restrained because they have not enjoyed the advantages of education and training. A man with bent of purpose may educate himself. Until that knowledge is acquired, it matters not how, he should keep his hands out of the abdomen. I regret to say that there is another class of men attracted to this field of surgery—men wholly incompetent and unscrupulous, that we now and then hear of throughout the country, doing a needless section simply for the glory of the thing. Happily

there are few such men, yet if reports be true, they exist. Further mention of them is degrading to our subject. Enthusiasm, an honest desire for heroic and radical measures, the temptation of sudden glory, of quick fame may lead a young ambitious man to operate without due preparation and perhaps needlessly. This doubtless is done too often and some-luckless patients suffer the consequences. Science is not altogether without some compensatory advantages. One neophyte receives an impressive lesson—pathology perhaps an interesting specimen, and our science a more devoted savant. Hawkins Ambler, in an address before the British Gynecological Society on "Abdominal Surgery," said many things that merit reflection. Every one engaged in this work should carefully study his conclusions, one of the most striking of which is thus expressed: "I believe many disasters are the result of too careless speech, by men whose experienced hands can do safely what another could not attempt with safety to his patient."

In line with this thought, it is not at all unusual to hear some of our ablest teachers and most successful operators depreciate the value of differential diagnosis in abdominal disease. With eagerness akin to cruelty, a quick conclusion is reached that the life, perhaps only the comfort, of the patient is in jeopardy and therefore a section must be made. You all are familiar with the stereotyped expression of one of our most distinguished Southern gynecologists who, indifferent as to diagnosis, remarks to his assistant as he is about to open the abdomen: "We will see what we will find ——." One more word, and you could charge me with dealing in personalities. It is my honest conviction that this careless disregard of the importance of a discriminating diagnosis is responsible for rash, needless and most unfortunate surgery. The responsibility of these errors rests not alone upon the operator committing them; the fault is reflected to those of authority who have encouraged this looseness and indifference in diagnosis. A diagnosis is the capstone of the edifice whose foundation is pathology, with a superstructure of well braced symptomatology. I grant you, a diagnosis can not always be attained; no one is more impressed with this fact than I am while writing these lines, for it occurred to me only a day or two ago to open the abdomen, believing I had to deal with a large uterine fibroid, when the true condition was a sarcoma of the kidney, which when removed weighed thirteen pounds. The surgeon who applies with painstaking patience, all recognized points of differentiation, escapes much embarrassment during and after operation, achieves better results and places himself and science on a much higher plane than one of these "trust-to-luck fellows," indifferent to pathology, only concerned with the apparent indications for surgical interference. I, therefore, maintain that a long training in the laborious study of pathology and symptomatology and practical familiarity with the methods of physical examination are prerequisite qualifications for one contemplating abdominal work. Without these, to what extent he may bring opprobrium upon our art and render himself legally responsible, is as yet *sub judice*. The necessity for operation and your fitness for undertaking it, appeals to your judgment and conscience. The propriety having been determined, your real responsibilities are now assumed. It is not the pur-

pose of this paper to enter into a detailed description of the mode of preparation, time of operation, order of room, presence of visitors, choice of anesthetics, assistants, etc.; everything should be done by the direction, every one engaged should be upon the selection of the operator. Your associates and consultants may express their willingness to indorse your action and divide responsibility, for which magnanimous expression of confidence I have more than once felt profoundly grateful, yet this is only sentiment; the patient and friends hold the operator alone accountable. The law places the burden of responsibility upon the surgeon, the science of surgery intrusts to him alone the protection of her honor, and, lastly, if he be a man made of the right kind of stuff, his own conscience accepts, without effort to shrink or shift, the weight of the occasion. When discord and indecision threatened the integrity of our government, General Jackson, he whom we love to speak of as "Old Hickory," with characteristic courage upon that memorable occasion said: "I will take the responsibility." Every abdominal surgeon should have the courage of Jackson to assume the responsibility and act in accordance with the dictates of an enlightened conscience. The frequent practice of abdominal section has eliminated more false theories, shattered more chimerical pathology, exploded more so-called established principles, resulted in more substantial scientific progress and saved more lives than any agent, method or device employed in the noble domain of medicine. All honor, everlasting and immortal honor to those who have developed this high art; from McDowell the originator, to Price its greatest exponent! A few reckless and incompetent men actuated, we fear by anything but the best of motives, have misunderstood and misapplied this great agent. Too many men fancy themselves naturally endowed with the qualifications for abdominal work, therefore the operation of celiotomy has fallen somewhat into disrepute, but this is only in obedience to the natural law of reaction. It is an established procedure—all that carping conservatists can say will not detract from the good it has done, nor lessen its future importance. All that I would say is to incite in the minds of those contemplating this work, a thorough appreciation of the requirements, difficulties and dangers that attend opening the abdominal cavity. One possessed of a thorough fitness and knowledge of these things will not abuse the procedure, but glorify our science!

PIGMENTATIONS OF THE SKIN.

Clinical Lecture delivered at the Medico-Chirurgical Hospital of Philadelphia.

BY JOHN V. SHOEMAKER, A.M., M.D.

PROFESSOR OF SKIN AND VENEREAL DISEASES IN THE MEDICO-CHIRURGICAL COLLEGE AND HOSPITAL OF PHILADELPHIA.

A smooth, pure skin, mantled with the glow of health, is an important element of comeliness. The beauty of this tissue is, however, peculiarly liable to be marred by the operation of causes arising from within or without the organism. Many constitutional ailments impair the complexion; many excite actual structural alterations of the integument. Habitual indigestion, malaria, chlorosis and other maladies exert a deleterious influence upon the nutrition of the skin. Addison's disease produces a more or less complete bronzing of the surface. A brown line extending from the umbilicus to the pubes is one of

the signs of pregnancy though it is also occasionally seen accompanying chronic uterine disease. Irregular brown patches scattered here and there upon various regions of the body may also occur during pregnancy.

I desire to call your attention to a class of pigmentations often observed, which sometimes co-exist with excellent general health, but which in other cases are associated with definite physical failures and which are always a disfigurement. I have, in the first place, three patients to show you as examples of that very common affliction known in popular language as freckles, and classified in our dermatological treatises as lentigo.

Lentigo, freckle.—The first subject is a young man of 22 years, rather tall and of a vigorous build. His hair, you will notice is of a slightly reddish cast, his eyes gray and his complexion is naturally fair. He informs me, as I should judge from his appearance, that his general health is excellent, his appetite and digestion good. I look at his tongue and find it clean. I feel his arms and I find that his muscles are well developed. Until he came to the city, a few months ago, he had been used to an active out-door life in a country village. His face is plentifully sprinkled with freckles. The spots are all small, not much larger than the head of good-sized pin. They are of a yellowish brown color and, although numerous, do not coalesce. The freckles exist also upon the back of his neck, upon the dorsal surfaces of his hands and upon his forearms. He tells me that the remainder of his body is free from the little discolorations.

The second case occurs in the person of a youth, 17 years of age. He is of average height and strength but is not of so robust a type as the preceding individual. His tongue is somewhat coated, his appetite is not very good and he has a tendency to constipation. He is employed by a tailor as an errand boy and a helper about the shop. This lad has a dark complexion. His hair and eyes are of a brown hue, verging upon reddish, the color which is generally described as bronze. He would not be an ill-looking boy if his skin was free from freckles. His face is almost entirely covered with brown spots, of various sizes and shapes. The smaller ones are round and the larger are generally oval, but in some places the confluence of neighboring lesions has produced a figure of irregular contour. The hands of this lad, also, are freckled.

Our third patient is a young girl, aged 19 years. She is distinctly blonde, with a fair skin, light brown hair and blue eyes. Her skin is, unfortunately, to a certain extent disfigured by the presence of freckles. The number of the spots is not as large as in the other two cases, but they are sufficiently abundant to detract from an otherwise comely appearance. She is in good general health.

Freckles consist of an increased deposit of the normal pigment of the skin. This coloring matter, you are aware, is contained in the cells of the deepest layer of the epidermis, the rete mucosum or Malpighii. Persons of fair skin, and especially those having red hair, are the most frequent subjects of freckles. Brunettes, however, are by no means exempt, as is shown by the second case. In those of dark complexion a copious development of freckles often gives an unsightly and dirty appearance to the skin. They are not uncommon in mulattoes, partic-

ularly in those unwholesome looking specimens with but a slight shade of color, light hair and light gray eyes.

I need consume no time in describing the gross appearance of freckles. They are so common as to be familiar to every one. Their general variation as regards size is from a pin's head to a small pea. Those which adjoin each other will often coalesce to form a larger spot. They are most frequent upon the face, but often enough occur upon the back of the hands and may even affect those portions of the body which are habitually covered. Freckles are seen in persons of nearly every period of life, but do not often develop prior to the third year of age. As a rule, they make their first appearance during warm weather and are more conspicuous in summer. In some cases the spots pale during winter or even disappear, returning with the approach of the succeeding summer. Interrogating the patients now before us, I learn that none has observed any decline in the spots during the colder portion of the year. Freckles are apt to disappear entirely and permanently as the subjects reach or pass beyond middle life.

Freckles are not dependent upon any constitutional disorder, though their development may be favored by a slight disturbance of the peripheral nerves. They may occur in association with other diseases of the skin. The direct exciting cause is heat, especially the heat of the sun, in conjunction with the high winds of the spring and autumn. A certain predisposition on the part of the skin would seem to exist.

Treatment.—It is the subject of treatment which is the most important in regard to freckles. They are so common, they seem to cursory inspection such an integral portion of the skin that many individuals simply accept them as an undesirable blemish, without seeking to have them removed. In private practice, however, you will often be consulted, especially by young ladies, as to the possibility of removing freckles. It is evident that, in order to get rid of the spots, we must either stimulate the absorbent system to carry off the excess of pigment or must remove the affected patches of epidermis *en masse*. The chief objection to the latter procedure is upon the formation of a new epidermis the freckles will be reproduced by the same causes which occasioned them in the first place. The drugs which are most serviceably employed are such as possess a stimulant or slightly cauterant action when applied to the skin. They may be used in the form of ointment or solution. Alcohol is one of the remedies which may cause retrocession of freckles and it is therefore expedient to use as a menstruum for any other article upon which our choice or preference may fall. The application of strong carbohc acid to each spot will cause the cuticle to be detached in the course of a few days. The surface will then be red but clear, and the redness will then fade away leaving an unblemished skin. Corrosive sublimate, used in guarded strength, has been very widely employed in treatment of freckles. Salicylic acid is also effective in causing the epidermis to scale. Ammoniated mercury, or white precipitate, the chlorid of ammonium, sulpho-carbolate of zinc, are other substances which we may call into use. The root of Solomon's seal or polygonatum giganteum and other species of polygonati indigenous plants may likewise be employed, in the form of fluid extract or decoction, for

the same purpose. The tincture of benzoin, the tincture of myrrh and the fluid extract of hamamelis are substances which may prove efficacious. One of the most beneficial medicaments to apply in this condition is the copper oleate, made into an ointment with lanolin, lard or cold cream, each ounce of the preparation containing from five to sixty grains, according to the circumstances of the case. The ointment of corrosive sublimate is made of the strength of from two to five grains to the ounce of excipient. Solutions of the same salt may contain from four to eight grains to the ounce.

The agents of which I have made mention may be combined in the following formulæ :

R.	Hydrarg. chlorid corros . . .	gr. iv-xvj	24-96
	Aquæ hamamelidis dest . . .	fʒjss	16
	Glycerin	fʒjss	16
	Spir. vini rectificat	fʒiij	96
℞	Hydrarg. chlorid corros . . .	gr. iv-xvj	24-96
	Tinct. benzoin	fʒij	8
	Spir. odorat	q. s. ad. fʒiv	128
℞	Acidi borici	ʒij	8
	Cocain hydrochlorat	gr. x	60
	Sp. vini rectificat	fʒiv	128

Chloasma.—The two cases which I shall now show you present a more prominent and extensive discoloration; one which, moreover, though not at all uncommon is of much less frequent occurrence than freckles. I allude to chloasma.

The first of the two patients is a young girl, 20 years of age, who, two months ago, suffered from an attack of measles. Soon after recovery her face, which had previously been fair and fresh colored, became mottled by brownish spots of an oval shape, and varying in size. They are scattered and do not coalesce. They do not itch, smart, tingle or pain. They exhibit no desquamation. The spots annoy only by their presence. The body is entirely free. The general health is entirely unaffected. Her appetite and digestion are good.

The next patient is also a girl and is 18 years old. She has several large and rather dark brown spots upon the face but has none upon the body or limbs. There is a large brown patch of irregular outline upon each cheek. The spots occasion no discomfort and the patient considers herself healthy. She is, however, somewhat anemic. Her lips and tongue are pale and her finger nails lack their normal rosy hue.

The pigmented patches of chloasma vary considerably in size. The coloring matter, like that of freckles, is deposited in the rete mucosum. The only difference between the two affections, therefore, is that the patches of chloasma are considerably larger than the freckle spots. The surface is entirely smooth to the touch. The tint varies in different cases from light yellow to dark brown or even black. The deepest shades are sometimes designated as melasma or melanoderma.

Chloasma, as well as freckles, may be occasioned by exposure to heat or wind. Other external sources of irritation may also lead to the deposit of pigment. Thus, the friction of clothing, the pressure of belts, trusses, etc., the action of mustard plasters and fly blisters, the constant scratching excited by chronic skin diseases attended by itching, determine an increased formation of coloring matter. The spots brought about by such causes are known as idiopathic chloasma.

Unlike freckles, however, chloasma may depend upon the existence of serious internal disease. It may, as in one of the cases before us, follow an infectious malady, as measles. It may occur as a result of malarial intoxication. It sometimes co-exists with malaria, tuberculosis or cancer. Chloasma may develop in consequence of mental excitement. Certain affections of the skin also give rise to chloasma. Among these I may mention senile atrophy, morphea and scleroderma. Popular opinion has long associated chloasma with hepatic derangement, and a common name for the affection is liver spot. The most usual internal cause of the anomalous pigmentation is disorder of the uterus or ovaries. When due to this cause, the affection is known as chloasma uterinum. This form locates itself particularly upon the forehead and temples. In some instances the discoloration is very deep. It is apt to be especially dark in brunettes. Sometimes there are a number of small brown patches. In other cases the pigmentation extends almost without a break from ear to ear. Chloasma of utero-ovarian origin, forms an exception to the rule that only the face is involved. A deepening of the normal color may be seen around the nipples. In some cases the discoloration is not of long duration. In others it continues for an indefinite period. The surface is smooth, unless complicated with some other cutaneous malady. In pregnancy we sometimes meet with cases in which the discolored patches are very large and, indeed, involve almost the entire surface.

Chloasma uterinum may occur either in the single or married, either as a result of disease or of pregnancy. It does not often occur after the grand climacteric has been reached. Not infrequently it is associated with hysteria. When the underlying cause has been cured the chloasma generally disappears.

It is not possible to mistake freckles for any other affection. Any one is perfectly competent to make the diagnosis. There is one disease, however, which bears some resemblance to chloasma, and that is tinea versicolor. The patches of the latter malady usually appear upon the body, those of chloasma upon the face. In tinea there are a number of spots; in chloasma, there are but few. Tinea versicolor is accompanied by a fine scaling. The surface is perfectly smooth in chloasma and there is no desquamation. The patches of tinea enlarge rapidly and itch. Chloasma spreads slowly and gives rise to no itching. Finally, the microscope furnishes us with a test. Tinea versicolor is caused by the growth of a specific vegetable organism, the presence of which can be readily recognized.

Treatment.—The treatment of chloasma depends upon the same principles as that of freckles. The list of drugs which we may employ locally is much the same in both affections. In chloasma, however, we may be obliged to take measures for the improvement of the general health or for the relief of visceral disorders. Chloasma uterinum demands a therapy addressed to the genital system. Again, we must be cautious in the use of external remedies, remembering that certain caustics, when used too freely, invite a deposit of pigment. This is especially true of mustard, Spanish fly and croton oil. The mineral acids are also open to the same objection. Carbolic acid may be mopped lightly upon the surface of the discolored patch with advantage. Acetic acid may be likewise used in the same way. The

local application of the tincture of iodine will sometimes prove beneficial. Caustic potash, potash and soda soaps may also be of avail. Veratrin ointment, the ointment of the nitrate of mercury or of ammoniated mercury, or mercurial ointment are other preparations which have their advocates. I have generally derived more satisfaction, however, from the employment of the ointment of copper oleate, the mercuric or the mercurous oleate. The corrosive sublimate was a favorite with Hebra, who used it dissolved in distilled water, alcohol or collodion, in the proportion of five grains to the ounce. A compress moistened in the solution is kept applied to the affected surface for a period of four hours. This produces a blister and the discolored epiderm is replaced by one free from pigment, though the color may subsequently reappear. Brushing the patch with peroxid of hydrogen will sometimes answer a good purpose. The tincture of benzoin and borax are also of service in chloasma. These various agents may be combined as in the manner indicated for freckles. A prescription which I have often used is thus composed:

R.	Hydrarg. chlorid corros.	gr. x.	60
	Ammon. chlorid.	ʒj.	4
	Sp. vini rectificat.	fʒij	cc 32
	Aq. hamamelid dest.	fʒiij	100

℞.

Better than all the medicinal applications named, in both freckles and chloasma, is the use of the galvanic current. I am constantly in the habit of making use of this treatment and can testify, from an extended experience, to its advantage. Galvanism stimulates absorption of the pigment and is, for that reason, far preferable to the use of drugs, after which the pigment is often reproduced in the new cuticle. The results from galvanism are more uniformly permanent.

THE IMPORTANCE OF EARLY RECOGNITION AND TREATMENT OF OBSTRUCTIVE DIS- EASES OF THE UPPER RESPIRATORY TRACT.

Read before the Philadelphia County Medical Society, March 14, 1894.

BY JOSEPH S. GIBB, M.D.

INSTRUCTOR IN LARYNGOLOGY IN THE PHILADELPHIA POLYCLINIC; SURGEON-IN-CHARGE OF THE EAR, NOSE, AND THROAT DEPARTMENT OF THE EPISCOPAL HOSPITAL, PHILADELPHIA.

The introduction of a subject so time-worn and stale might require an apology were it not that notwithstanding there is a plethora of literature there still remains a singular indifference and lack of appreciation of the merits of the matter in the mind of the general practitioner. Doubtless much of this is due to the very voluminous character of the literature, which tends rather to interest those for whom the subject has an especial attraction. We read much of the histologic structure of the various hypertrophies, and numerous are the instruments introduced for their destruction. We read less of the best means of demonstrating their existence, the etiologic factors concerned in their production, and the prophylactic measures which may be adopted to prevent their development.

Perhaps no single abnormal condition is productive of more marked alterations in physical beauty and healthy functions than diseases producing obstruction in the upper respiratory tract. The anxious

and watchful mother views with sorrow the freckling or tanning of her child's face. How much more disagreeable than these are alterations in the facial lines to such degree as to cause a face to be expressionless; and when to this is added partial deafness, with all its unpleasant effects, we have a picture which any careful mother should strive to avoid. Were as much care bestowed on the important functions of the nasal chambers as is generally given to the skin or other tissues more directly under the eye, we would have fewer of these unpleasant pictures. Nor is this marring of physical beauty the sole deleterious result of these conditions; it can be proven that serious and perhaps grave interference with important functions follow in its wake.

In order to have a proper appreciation of the importance of the subject we will review for a moment, and in a cursory manner, the anatomic structure and physiologic purposes of the nasal chambers and their contiguous structures.

In the bony nasal chambers are three scroll-like bodies, the turbinate bones, two of which, the middle and inferior, are accessible in the living subject, which form the sides of the chamber; a septum, separating the nasal chambers, which is reinforced by a plate of cartilage in the recent state. These turbinated bones divide the nasal chambers into three meatuses—superior, middle, and inferior—into which open the various sinuses or foramina which communicate with the accessory cavities—namely, the frontal sinus, the ethmoid and sphenoid cells, the antrum of Highmore, and also the lachrymal duct. All these structures in the living subject are covered with mucous membrane well endowed with blood vessels and nerves, whilst over the turbinate bones the tissue is erectile or cavernous.

The situation of these chambers, the peculiar construction of the bones, the unusually large surface of mucous membrane for so small a cavity, and the very generous blood supply, bespeak important functions. Bosworth claims three; 1 the first and very important function in respiration; 2, an aid in phonation by acting as a resonant chamber; 3, as an olfactory organ.

The atmospheric air as it passes through the nasal chambers is brought in contact with a comparatively large surface of mucous membrane which is rendered warm by the free blood supply and moist from the secretion of the numerous mucous glands therein contained. The effect of this contact is first to abstract from the air, dust and other foreign bodies, and secondly to add to the inspired air warmth and moisture. This latter function is most important. It has been computed that over 7,000 grains of water are expired from the lungs in twenty-four hours; and Aschenbrandt has demonstrated by a series of carefully conducted experiments that the source of this moisture is in the nasal chambers.

From this brief and very imperfect glance at the anatomical position and functional purposes of the nasal chambers we may draw a few important lessons. Interference with the proper and easy inspiration of air through the nasal chambers is productive of diseased conditions, not alone of those organs themselves but of the more important respiratory structures within the chest.

It can not be doubted that inspiration of air into the air vesicles imperfectly warmed, deprived of the moisture which Nature intended it should have,

must exercise a deleterious influence on the delicate mucous membrane lining these cells. I am not ready with statistics to prove the relationship between pulmonary and bronchial affection and obstructive diseases of the upper air tract, nor do I deem it necessary, for it is a matter of common experience and observation that those children whose nasal chambers are obstructed either directly by hypertrophies, polyps, etc., or indirectly by hypertrophied pharyngeal or faucial tonsils, are sunken-chested, prone to attacks of acute bronchitis and coryza, and in many respects are less healthy than other children. I am well aware that these conditions are often the result of a constitutional vice which in itself renders the subject less robust, still I am more than ever convinced that removal of the local effects of this diathetic condition results more effectually in a return to a normal condition than any plan of treatment directed solely to the condition itself. Nor is it alone the respiratory tract that suffers from these abnormal states. I have before remarked that children so afflicted are apt to be in a condition of poor health generally, and it has occurred to me that perhaps this may be not entirely due to the diathetic condition which is so frequent a concomitant, but rather that the lungs, being supplied constantly with a vitiated air, *i. e.*, air insufficiently warmed and moistened, failed to supply the blood with a healthy, proper pabulum and hence the tissues suffer. By the explanation what it may, we must not lose sight of the fact that a condition of ill health frequently does exist, and we should bend our energies to ascertain the cause and seek its remedy.

It is not the object of this paper to elaborate on the various methods of treatment, but rather to inquire into the causation and to endeavor to point out, means which may be taken to ameliorate the conditions existing and to prevent the development of more serious ones. Especially is it desired to inquire into the causative influences of obstructive diseases of the upper air passages in young children.

Eliminating all those effects of imperfect or perverse fetal development such as occlusion of anterior or posterior nares, cleft palate, etc., we have conspicuously prominent in the category of obstructive lesions in the upper respiratory tract—hypertrophic conditions of the turbinate bodies, of the pharyngeal, faucial, and to a lesser degree the lingual tonsil.

A glance at the records of any of our large throat and nose clinics will convince one that these abnormal conditions are far from rare; nor does even this showing give us a thoroughly accurate conception of their frequency. Too common is it to ignore or carelessly treat the various catarrhal symptoms presented to us, and this indifference on the part of the profession has led to a corresponding indifference on the part of the laity, so that only those cases of pronounced obstruction are brought to the notice of the general practitioner. Were the nasal speculum used as freely as the stethoscope or clinical thermometer we would be astonished at the result. Again, certain hypertrophic conditions have but comparatively recently received any measure of attention from the profession. Though faucial hypertrophies have been observed and studied from remote times, it was not until a very recent date that Meyer gave to the profession a clear idea of the significance of hypertrophic conditions of that collection of adenoid tissue

at the vault of the pharynx known as the pharyngeal tonsil; nor is the importance of the subject to-day appreciated by the rank and file of the profession, notwithstanding that much has been written about it and many instruments devised for its removal. Situated as it is in a somewhat inaccessible or rather unobservable portion of the upper pharynx, it is only by the use of the rhinoscopic mirror that its presence can be clearly demonstrated; this being the case, it is patent that it must be frequently overlooked.

With these facts before us it is clear that, whereas our clinics show us that these states are common, they give us no adequate conception of their prevalence.

At the clinic of the Episcopal Hospital it is the custom to carefully examine the nasal cavity, the pharynx, and post-nasal surfaces in every case that applies for treatment, irrespective of the fact that the subjective symptoms point to lesions in this or that locality; and in children of tender age, where a rhinoscopic examination is not feasible, if there is any suggestion of disease in this locality a finger is introduced back of the soft palate and over the vault of the pharynx to demonstrate by tactile sense the presence or absence of any abnormality. It is surprising as a result of this procedure to note the number of cases in which there are lesions of the upper pharynx in which the symptoms have been overlooked by the parents.

In considering the etiology of these hypertrophies it is as well to treat of them collectively, for whereas they are often separate and distinct lesions and exist independently, they are often associated and their etiology, so far as our knowledge goes, is in many respects similar.

In the case of the glandular tissue there can be no doubt that in a few instances these hypertrophies are congenital, doubtless the effects of an inherited vice—syphilis or scrofula—carrying out the well-known tendency of these dyscrasias to affect lymphatic and glandular tissue. Though this view is combated by no less an authority than Meyer, who leans to the view that it is always an inflammatory process in a tissue which normally is largely developed in infancy and childhood, at the same time it is difficult to explain the presence of this state in very young infants unless we presume this inflammatory process to have taken place during its pre-natal existence. Those cases developing subsequent to birth doubtless have as a starting-point an inflammatory or catarrhal origin.

We have demonstrated the frequency of hypertrophies of the glandular tissues and turbinates in children, and have admitted a few cases may be congenital, which leaves the vast majority to have its development subsequent to birth; and, as it is our belief that its causation lies in some condition outside of the child, at least in part, it is now our endeavor to seek out those causes and, if possible, lay down certain laws looking to their eradication or, at least, amelioration. Here, as with many other diseases of insidious approach, an early recognition is productive of much good.

Among the general causative agencies which it is not entirely within our power to relieve, may be mentioned atmospheric conditions incident to residence in temperate climes, and especially near the seaboard; the method of heating houses in cities by dry air frequently derived from an unsanitary source;

carelessness in the dressing of infants and trusting them too much to the care of servants who unnecessarily expose them. All these and others exercise an influence in the production of the disease, but only in a general way. The prophylactic remedies are obvious and suggest themselves.

The various catarrhal conditions which the above enumerated disturbing influences of our environment occasion, are of much importance from an etiologic standpoint. There can be no doubt that it is here we have the starting-point of the hypertrophic process. A simple coryza is neglected; the child is not even protected from the causes which produced it—the result, one coryza succeeding another the entire season. The effect of a long-continued inflammatory process is precisely the same in the nasal and pharyngeal tissues as in the other tissues of the body—namely, increase in the connective-tissue growth, increase in the cellular growth. And it is just here by a knowledge of the effects that the family physician's advice and council can be of so much value and save so much misery and suffering to the child—so much mental anxiety and mortification to the parents. I believe that parents should be taught that a coryza is by no means so simple or harmless an affair as is commonly believed. It is better to err on the right side—better by far to give some attention (possibly needless) to a few attacks of coryza than to sit quietly by doing nothing, and permitting the production of obstructive masses in the upper air-passages that may alter the child's expression and possibly injure the health.

Parents should further be taught that repeated coryzas indicate a diseased condition of the nasal or pharyngeal mucous membrane demanding prompt and thorough treatment. The physician should himself insist on making a careful examination aided by the nasal speculum and rhinoscopic mirror, and should lay down a plan of treatment which his ingenuity will suggest, and persevere with it until the conditions yield; and I believe in this way, and in this way alone can we hope to have any measure of success.

Conspicuous in the category of special causative agencies may be mentioned the eruptive diseases of childhood, and especially those in which the fauces and nasal chambers are involved in the diseased process. Foremost among these may be mentioned diphtheria. The well-known tendency of diphtheritic processes to attack glandular tissue is well exemplified in the post-nasal spaces. We are familiar with the appearance of the diphtheritic membrane on the tonsils, but usually the examination of the other mucous surfaces is not made, and we remain in ignorance as to the extent of this process into the nasal chambers and vault of pharynx. Doubtless if careful examination was carried out in every case we would find the proportion in which these structures are involved to be very large. I have no doubt that many of the cases of so-called re-infection are in reality those in which there has been an involvement of the pharyngeal tonsil in the diphtheritic process. When an examination of the tonsils reveals an absence of the familiar membrane and a subsidence of the inflammatory condition, we are lulled into a sense of security and perhaps relax in our vigilance, unmindful of the fact that the disease is perhaps making insidious inroads at a spot beyond our unaided view. However, we are not concerned with this at

present; sufficient is it for us to know the extreme susceptibility of the mucous surfaces in this disease.

After the subsidence of the diphtheritic process it is very common to have a catarrhal condition continuing for a considerable period; this is especially noticeable in cases in which the nasal mucous membrane has been implicated; though it frequently occurs where there has been no perceptible involvement of the nasal chambers, and I believe it is just in these cases that there has been a diseased process going on at the vault of the pharynx. The explanation of this mucus discharge and other evidences of a catarrhal condition is doubtless due to alterations in the nutrition of the part, in consequence of the high grade of inflammatory action, and also to septic absorption. Were an examination made at this time we would likely find a hypertrophic condition either in the nasal turbinates or the pharyngeal and faucial tonsil. Though doubtless the majority of these cases do well without any special treatment directed to the part, yet in a certain number the catarrhal condition persists, and especially is this likely to occur in those children who seem prone to catarrhal states, and the foundation is laid for the formation of masses of hypertrophied tissue.

The beneficent offices of the family physician can be here admirably employed. It is not wise to pass over lightly the persistence of a catarrhal state after the subsidence of the inflammatory symptoms. Treatment employed at this time and persisted in until an amelioration takes place, can be productive only of good.

Scarlatina, as is well-known, expends at least a part of its energy on the mucous membrane of the fauces; though, unlike diphtheria, it rarely involves the nasal chambers. Here, as in the foregoing, the inflammatory action is so high, often to the production of false membrane, as to exercise a baneful influence upon the nutrition of the tissue and aid in the production of hypertrophies. We are all familiar with the fact that hypertrophies of the faucial tonsils are a frequent sequela of this disease. The same process that gives rise to hypertrophies in this tissue is at the same time exerting its influence on the tissues of the vault.

It is needless to dwell on this; the too familiar sight of catarrhal conditions as sequela of scarlatina precludes any argument to the contrary as to its position as a causative agent in the conditions under consideration. Nor is it hardly necessary to refer to the necessity for prompt treatment—one word, however, on this point. It seems to me an imperative duty on the part of the medical attendant to insist on an examination and, if necessary, subsequent treatment in every case where a catarrhal condition evidenced by a mucous or muco-purulent discharge from the nose, a thick voice, and mouth-breathing persists, after all evidences of the exanthemata have passed away.

Measles, though commonly regarded as a light and insignificant disease, is exceedingly apt to leave some trace of its existence. The explanation of this is evident. Not commonly menacing life, it is, however, very active in its attack, and this activity is exerted on the mucous surfaces in the entire respiratory tract. Mothers should be informed of the fact that with care the course of the disease will be benign, but without it there is extreme probability of a catarrhal affection with all its unpleasant conse-

quences being left as a sequela. And here, as with others, active treatment should be insisted upon if the catarrhal symptoms persist after the subsidence of other evidences of the exanthemata.

The other exanthemata and febrile diseases, such as röheln, variola, varicella, typhoid fever, etc., exert a certain amount of influence as causative agents, but only in a general way, as any alteration in health will do. The diseases mentioned, viz., diphtheria, scarlatina and measles, exert a special influence because the diseased condition seems to expend itself on the mucous surfaces, producing alterations and perversion of function.

The clinical picture presented by sufferers from obstructive diseases of the upper respiratory tract is absolutely characteristic, and especially is this true as regards the alteration of facial lines and changes in expression. Naturally this obstruction to the entrance of the air by the normal route, viz., through the nose, necessitates its seeking some other mode of ingress to reach the lungs; the only other way is through the mouth, and hence we have the condition of mouth-breathing with all the discomfort and unpleasant effects which such a condition entails. Long-continued mouth-breathing brings into play muscles about this orifice not usually called upon for excessive work, and at the same time nominally puts at rest muscles about the nose whose functions are not called into play; the result is an alteration of facial expression to such a degree in well-marked cases as to give to the child a stupid, almost idiotic appearance. The obstruction in the case of the pharyngeal tonsil may become so excessive as to encroach on the pharyngeal orifice of the Eustachian tube, interfering with the proper supply of air to the tympanic cavity, thus inducing catarrhal or inflammatory conditions of the mucous lining of this tube and also of the tympanic chamber. The result of this is dullness of hearing or even complete deafness.

The normal course of the secretion from the numerous mucous glands in the nasal chambers is obstructed and hence flows back into the naso-pharynx; added to this we have a greatly increased secretion from the adenoid vegetations at the vault. During sleep this mucus collects in the pharynx, and as the child is obliged to breathe through the mouth, we have associated loud snoring with rattling and gurgling of air through the mucus secretion; hence the child is restless and fitful and the annoyance to other members of the household excessive.

We have then as the salient features of a case we are attempting to portray: Mouth-breathing, snoring, rattling of mucus in the fauces, and disturbed sleep; a dull, listless expression of countenance; hardness of hearing, and in many cases impairment of general health, causing the child to be anemic, sunken-chested, prone to catarrhal attacks, and of stunted growth.

Much has been written and various are the opinions as to the treatment of these distressing conditions. We are not concerned in this article whether it is the proper method to remove adenoid growths by forceps, curette, or finger; to diminish hypertrophied turbinates by means of galvano-cautery, snare or escharotics, but a few words in conclusion as to the management of cases in their incipiency may not be amiss.

Mothers should be urged not to neglect a persistent snuffle in a child, not to regard as trivial the con-

tinuance of a mucus discharge after diphtheria or the exanthemata. Physicians, on the other hand, should not pass these complaints lightly by ignoring them, or directing in an indifferent manner some simple and likely inefficient remedy.

The management of hypertrophies at this early stage is as simple as the results are happy. After a careful examination the nares and upper pharynx should be cleansed of mucus by an antiseptic and detergent spray, *e. g.*, Dobell's solution, Seiler's tablet, Listerin in diluted solution, etc., and then applications made to the affected mucous membrane of an astringent or alterant, depending on the condition of the parts. Should we find simply an increased secretion with no appreciable alteration in the turbinates, tonsils, and surrounding tissues, it is likely we will accomplish all that could be desired by directing spraying of the nares thoroughly by one or other of the solutions mentioned twice daily and continued faithfully until the membrane presents a normal appearance and the secretion ceases.

In cases still farther advanced in which we find the turbinates quite red and somewhat swollen; the pharyngeal tonsil secreting more mucus than normal, and rather large; the faucial tonsil red and somewhat hypertrophied, we will find it advantageous to use some application to diminish the inflammatory condition. These applications may be made quite painless by spraying the parts with a 5 per cent. solution of cocain or introducing a cotton tampon saturated in the same solution. In the nares a solution which has gained favor in the various clinics devoted to these diseases is that of iodin. The strength of the solution may be graded by the severity or obstinacy of the case. It is well to begin with a weak solution, increasing the strength as the necessities of the case demand. In some cases which resist this plan of treatment a touch of the fused bead of chromic acid along the turbinates will often accomplish the desired object; this latter plan should be immediately followed by the antiseptic spray to dilute and limit the destructive power of the escharotic. It is merely necessary in these early cases to touch the mucous membrane lightly to produce a superficial eschar; the resulting slough and subsequent contraction will so squeeze the blood vessels as to bring about the desired diminution in the size of the tissues.

The pharyngeal tonsil also in many cases will respond satisfactorily to applications of iodin on a pledget of cotton carried by an applicator so curved as to pass readily behind the soft palate and up to the vault. Glycerole of tannin has been found to act very happily, though perhaps a little more unpleasant in its effects. The application of chromic acid (fused) to a pharyngeal tonsil should not be advised, though undoubtedly as useful as in the nose, unless the operator is steady and familiar with making applications by the aid of the rhinoscopic mirror.

It would be hardly necessary to refer to the treatment of catarrhal and slight hypertrophic conditions of the faucial tonsils the result of the causes named, were it not that here, in spite of the ready accessibility of the part, they are subject to neglect. The same process of cleansing is as necessary as in the other hypertrophies, after which an application of a solution of 60 gr. to the drachm of nitrate of silver, glycerole of tannin, or in stubborn cases producing a superficial slough by fused chromic acid, will probably answer every purpose.

In the more advanced cases or in those which fail to respond to the above-outlined plan of treatment and a steady increase of the hypertrophied tissues occurs, there is but one plan which should be carried out at as early a date as possible, namely a destruction of the hypertrophied tissue. The various plans to accomplish this object will not be touched upon, but can be readily learned by consulting any of the modern treatises devoted to the treatment of diseases of the nose and throat.

In recapitulation the object of this paper has been to call attention to the following points:

1. The importance and desirability of early attention to diseases of the upper respiratory tract consisting of the nose and naso-pharynx.

2. The production of alteration in nutrition and possibly pulmonary and bronchial troubles by hypertrophic conditions of the upper respiratory tract.

3. The etiology of these states referring to the influence of environment and especial mention of diphtheria and the exanthemata as prominent factors in this category.

4. The prevalence of these conditions.

5. Carelessness and indifference in both physician and patient as to the various catarrhal states which are believed to be the precursors of the diseases under consideration.

6. The necessity of early treatment and the power for good exercised by the family physician in these troublesome conditions.

7. The clinical picture presented by these unfortunates, laying especial stress on the alteration in facial expression and the distressing and annoying condition of the child during sleep.

TREATMENT OF DIPHTHERIA.

Read before the Wayne County Medical Society, 1894.

BY OSCAR S. ARMSTRONG, M.D.

DETROIT, MICH.

There is no disease with which we have to contend that requires better surroundings or greater care in its treatment to insure a successful outcome, than diphtheria. It is rightly dreaded as one of the most deadly foes of childhood, and even adults do not escape its attacks. It is a treacherous disease, and one or two members of a family may have it in a mild form, while in the remaining children it may present its most malignant characteristics. Nor does its treacherous character end here, for often when our patient seems to be doing nicely, with membrane entirely gone, pulse and temperature normal and everything progressing favorably, some of its dangerous sequelæ make their appearance.

The first record we have of diphtheria in America was the epidemic in Boston in the sixteenth century, since which time it has become completely domiciled. Originally the disease appeared in epidemic form only, but at the present time it has become essentially endemic in nearly all our large centers of population. Its ravages are not confined to the homes of the poor in overcrowded and filthy tenement houses, but extend to those of the wealthy in country and city. Until the last few years little was understood of its true nature, but pathologists by careful and patient investigation have discovered its cause. Klebs was the first to demonstrate the existence of a specific bacillus of diphtheria, and his conclusions were afterwards confirmed by Löffler. Experiments have proven that

the bacillus of Klebs-Löffler, when brought in contact with the mucous membrane or inoculated therein, will produce a true diphtheritic membrane with its accompanying constitutional symptoms. We are thus prepared at the present time to treat diphtheria from a more intelligent standpoint than ever before. Yet notwithstanding this fact, from statistics which I have been able to collect, the mortality is simply frightful, and if an epidemic prevailed in any of our cities in which the death rate was correspondingly so great, it would, I venture to assert, create consternation not only among the laity but the profession as well. It seems to me that we have become so accustomed to its pestilential presence that we accept its frightful mortality as something unavoidable, and it has ceased to alarm us.

To quote from an interesting paper in the last JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, by Dr. E. L. B. Godfrey, of Camden, N. J., on the "Treatment of Diphtheria," there were 2,624 cases of diphtheria reported to the Board of Health of Philadelphia from January 1 to October 28, 1893, with 750 deaths, making a death rate of 28.5 per cent. During the same period in Camden 250 cases were reported with 56 deaths, making a death rate of 25 per cent. During the year of 1892 there were reported to the Board of Health of Detroit 1,156 cases, with a death rate of about 26.5 per cent. For the present year I have been unable to secure the statistics, but Dr. McLeod, the Health Officer, assures me that the number of cases has decreased about 40 per cent. as compared with 1892.

It would seem apparent from the diverse opinions and methods of treatment that no specific has yet been discovered. The symptoms in the early stages are so closely allied to those following the contraction of a severe cold that many times parents are misled, and do not call their physician until the disease is thoroughly entrenched. Every family physician ought to instruct father and mother how to examine their child's throat, and whenever he (or she) complains of sore throat or gives evidence of it by symptoms such as languor, headache, fever, etc., it ought to be inspected and if inflamed or white spots show, the physician summoned at once to make a diagnosis and care for the case. In the autumn of 1891 I had under my care three cases of diphtheria in a family of five children all making favorable progress. One day when making my morning call I was asked by the mother to see a fourth child, a little girl 3 years of age, whom she said was not well. On examining the child's throat I found it literally full of diphtheritic deposits of a purple hue. Fauces, tonsils, uvula and soft palate were covered and the tissues necrosed, the offensive odor being almost unbearable. The countenance was suffused, eyes dull, stupor manifest, temperature 106 degrees F. and pulse so rapid it could not be counted. It was a case of diphtheria of the most malignant type. I gave a very unfavorable prognosis and asked for a consultation. During the afternoon I saw her again with my friend, Dr. Mulheron, a gentleman of experience in this class of cases. All we could do for our little patient availed nothing and she died the same evening, about twelve hours after I first saw her. Since that time I make it an invariable rule to see every child in the house in which I am treating a case of diphtheria, at each visit.

The period of incubation in diphtheria varies from

two or three days to a week. If the attack is mild the symptoms are at first hardly perceptible. There is usually slight chilliness followed by fever, thirst, headache, anorexia, furred tongue, more or less muscular soreness and a certain amount of rigidity of the muscles of the neck and throat. There are undoubtedly cases of the disease so mild that they are not recognized, and the little one associates with his playmates and conveys to them the virulent germ. In this manner many children acquire diphtheria, leaving us ignorant of its method of introduction. If the attack is malignant in character its advent will be marked by correspondingly severe symptoms. It does not follow, however, even in the worst forms that the patients will complain of sore throat. This one diagnostic point will often enable us to differentiate between it and tonsillitis, for in the latter the pain on deglutition is generally much greater.

A large and well-ventilated room should be chosen, and the carpet or rugs, upholstered furniture and curtains removed. The most favorable temperature for my patients has been 68 degrees F. The disease being at first local and afterwards constitutional requires both forms of treatment. During the past two years I have adopted a plan of treatment that has given me excellent results in *every case*. The first and most important thing for the physician to do is to get the good will and confidence of his little patient. When this is done half the battle is already won. When the little one is willing and anxious to do as you direct, you are enabled to conduct a case as satisfactorily with a child of 4 or 5 years of age as though he were an adult. On the contrary, if a spray or gargle has to be forced on the unwilling patient with nerves wrought up to the highest tension, medication, no matter how well considered, is of no benefit, and I believe is positively harmful. The patient should be put to bed and made to understand that the recumbent position is a necessity and that this rule must not be violated by any exertion of his own. When it is necessary to use the spray, gargle or swab, he should be supported in a half reclining position by the nurse. The rule applies with equal force when nourishment or medicine is given.

As a local application I have found nothing that approaches in value the peroxid of hydrogen. It may be used as a gargle or spray or held for a few moments in contact with the membranous deposit by means of a swab. I use it varying from 30 per cent to full strength, the latter only when it is applied directly to the exudate. Children use a 30 to 50 per cent. solution as a gargle or spray, without any discomfort or objection. When the tonsils are enlarged and painful, the throat is covered by a piece of soft flannel moistened with a hot mixture of equal parts of lard and turpentine, enveloped by a thick fold of wool cotton held in place by a bandage. If the throat is not painful the turpentine and lard are omitted.

The medicines most in vogue in past years for internal administration have been the tincture of the chlorid of iron, sulphate of quinin and chlorate of potassium, all of which are more or less disagreeable to the taste and require a great deal of persuasion to get the little sufferer to take them. During the past two years I have used the bichlorid of mercury internally, in all my cases of diphtheria, as a routine plan of treatment and with unvarying good results. I combine it with alcohol, glycerin, eucalyptol and

minute doses of arsenic, in a strength varying according to the age of the patient. It may be given in doses of one-fiftieth to one-sixtieth of a grain to a child of 3 years, every two hours. For the past year I have been using it as prepared by the Detroit Chemical Company, containing one-sixtieth of a grain to the drachm. The preparation is known as diphtherol, and is combined with pleasant aromatics so that children take it without the slightest difficulty. Due credit must be given to the alcohol which this remedy contains, for in a disease so depressing to the vital centers and in which the toxemic symptoms are so pronounced, supporting and stimulating treatment ought to be pursued from its commencement. The effect of the treatment with the bichlorid is truly remarkable, and I have seen cases that I, at my first visit, deemed hopeless, improve so rapidly that in twenty-four hours the crisis was passed. It ought to be given freely until its constitutional symptoms appear, when the frequency of administration should be lessened. In very bad cases I have given 1 drachm of the diphtherol every hour for the first day, or until the constitutional effects in the way of uneasiness and pain in the abdomen were manifest. When the nasal passages are affected, I use the spray of peroxid of hydrogen solution with great comfort and relief to the patient. It ought to be used as often as every two hours.

Complications may arise requiring the use of quinin, digitalis, strychnin, etc., but they can in the majority of cases be administered in the form of a suppository. Since I have been using the plan of treatment here outlined, I have been fortunate in having laryngeal invasion in but one case. A possible intubation or tracheotomy was averted by forming a tent under which was introduced hot steam medicated with eucalyptol and the application of the hot pack to the neck.

I have thus briefly sought to direct your attention to the use of a remedy that as nearly approaches a specific for the disease as possible. Hoping and believing that you will find as much satisfaction in its use as I have done, I commend it to your favorable consideration.

A NEW APPARATUS FOR NEBULIZING NON-VOLATILE MEDICAMENTS

AND FOR ADMINISTERING THE SAME THROUGH IMPACTED AIR, AS A MEDIUM, BY THE PROCESS OF FORCED DILATATION, INSTEAD OF BY INHALATION, SPRAY, OR DOUCHE.

BY GEORGE F. HAWLEY, M.D.

Formerly House Surgeon at the Throat and Chest Hospital, Golden Square, London; Assistant Surgeon to the Ear Department of the London Hospital; late Assistant Surgeon to the Illinois Eye and Ear Infirmary, Chicago; Attending Physician Railway Brotherhood Hospital; Member Chicago Medical Society; Professor of the Hygiene and Anatomy of the Throat, Chicago College of Vocal and Instrumental Art.

The object of this paper is to describe an apparatus for preparing and administering nebulous medicaments by a process of forced dilatation, the basis of which is the discovery that the lips will act as a safety valve, and that, into any tube, cavity or air cell into which air can be forced by a high pressure, the nebulous medicament prepared by this apparatus can be forced with absolute safety, thereby enabling the physician to use agents that are capable of preventing or controlling diseases.

My attention was first called to this apparatus and process by an expert in the chemical and mechanical phenomena of pneumatics. I am using the apparatus as auxiliary to the regular medical and surgical treatment of the ears, nose, throat, and chest, with decided advantage to myself, and with most gratifying results to my patients.

The apparatus as shown in the illustration consists of a number of strong flint glass bottles, one for each medicament; adapted to be used in connection with any compressed air receiver. The valve located at the top of each bottle is provided with inlet and outlet ports in multiple, both ports being simultaneously opened or closed by turning the faucet. The inlet port of each bottle is connected with the same source of supply, namely, a compressed air receiver, and also with the vulcanite tube that descends into the medicated solution in the bottle. On turning the faucet the impacted air passes from the receiver through the inlet port down the vulcanite tube, through an ingeniously constructed device, and by eduction draws the medicated solution up into the tube and forces it out against the interior wall of the bottle, thus producing an impacted, nebulous medi-

cament. To the outlet port is attached a silk covered, flexible tube, the free end of which terminates in a vulcanite mouthpiece adapted to become sealed when the lips are tightly compressed around it, also an adjustable nozzle which becomes sealed when pressed into the nostril. Through these tubes the impacted-medicinal-nebula is forced into all the air passages, cavities and cells through and from the bottle selected; by a process of forcible dilatation,—a process that is rational, and capable of producing results that can not be effected by the use of any apparatus adapted to administer by inhalation, spray or douche.

The process of administering consists of: 1, compressing the air or gas into a suitable receiver to a pressure of from 20 to 100 pounds to the square inch or to a density sufficiently great to rapidly fill and forcibly dilate the air cells, the bronchi, the nasal cavities and the Eustachian canals by the expansive force of its own elasticity; 2, forming a communication through suitable tubing to be placed in the mouth or nose in such a manner as to allow the excess of pressure to escape from the mouth. The bottles containing the medicated solutions, being located intermediate and through which the compressed air passes at a uniform pressure with that in

the receiver, or nearly so, and conveys the medicinal nebula to all the air passages, cavities and cells.

To dilate the Eustachian tubes and to medicate the middle ear. The usual method of using the apparatus is as follows: Having adjusted the nozzle to the delivery tube, press it snugly into one nostril, the other being closed by the patient's finger, the mouth being open and the tongue thrust out as shown in Fig. 1. Turn the faucet and allow the impacted nebula to flow freely. The soft palate being pressed forcibly against the posterior wall of the pharynx will cause an undulation in the current of nebula by a valvular action of the uvula velum and appendages, which will be thrown into rapid vibration. The undulations of the impacted nebula will render the mouth of the Eustachian tube more patent and act as a massage on the diseased tissues of the middle ear, equalizing the circulation and tending to break up adhesion of the ossicles by causing them also to vibrate. To produce these vibrations it will be necessary in rare cases, especially where there is marked obstruction in the Eustachian tube to have a pressure in the receiver as high as 70 to 100 pounds to the square inch. With this shunt current, the mouth being open, no matter how high the pressure, it is impossible to rupture the drumhead, or to injure the ears.

A pressure, however, of from twenty to forty pounds will be sufficient for a large majority of cases.

Stimulation by appropriate medicaments in connection with mechanical manipulation, by increasing nutrition restores elasticity and vitality to the atrophied and paralyzed tissue. This process of administering impacted medicinal nebula by a shunt current, offers a rational means by which such stimulation, manipulation, and massage can be accomplished without any liability to unfavorable consequences.

In my practice, however, in massaging the diseased, paralyzed, atrophied or hypertrophied tissue and in dilating the Eustachian tubes and in medicating and breaking up adhesions in the middle ear, the best results have been obtained by using a pressure of from thirty to fifty pounds. The lips of the patient being tightly compressed, the nozzle is adjusted snugly into one nostril, the other being open as shown in Fig. 2. The soft palate being pressed against the posterior wall of the pharynx, turn the faucet and allow the nebulous medicament to flow, the opposite nostril being closed and opened rapidly by alternately pressing and relieving pressure on the opposite nares by

the finger of the patient. This should be continued for from one to five minutes, or long enough to cause from 20 to 100 impulses. Each impulse should dilate the Eustachian tubes and convey the medicament to the middle ear. It will also manipulate and massage the ossicles and the adjacent and surrounding diseased tissues thoroughly.

The rapid opening and closing of the nostril gives distinct impulses to the current of impacted nebula as it is forced through the Eustachian tubes, and causes it to act upon the diseased middle ear in the manner as before described. The medication of the middle ear by this method is perfect, as into any tube or cavity into which air can be forced, the medicament from this apparatus will enter in the form of impacted nebula. Not being restricted to the volatiles we can use any soluble medicament and in any strength desired. We therefore have the means of demonstrating the value of medicating the middle ear, in properly selected cases.

Impaired hearing due to congestion, inflammation, or hypertrophy of the mucous membrane, paresis, or occlusion of the Eustachian canals is a prevalent affliction. Improvement generally follows regular treatment, but the number of relapses are out of proportion to the number of recoveries. Why? There surely must be something radically wrong with either the means used or with the methods of using them, or else the results would be more permanent and satisfactory. After repeated failures to obtain satisfactory results many specialists have ceased attempting to medicate the middle ear, except with volatile vapors. The failures are due not so much to the medicament employed as to the manner in which they are administered. Liquid sprays or vaselin oils can not be forced into the middle ear by any ordinary atomizer, used either with compressed air or by hand. The spray is too coarse to enter far into the Eustachian tubes, and the injection of liquids by means of the catheter is more apt to aggravate than lessen the trouble. Vapors from volatile medicaments can be advantageously used in a few well selected cases. But nebula, impacted from non-volatile medicaments and administered by forced dilatation with gentle but rapid vibration, offers the only safe and efficient method for medicating and massaging the middle ear.

In this connection it may also be noted that in the most carefully selected cases for dilatation with the Pulitzer air bag or for dilatation and massage by the usual methods of using a compressed air apparatus, an almost immediate amelioration is often immediately or remotely followed by an aggravation of symptoms. This is evidently caused by the violence of the impulse which suddenly dilates the Eustachian tubes and inflates the middle ear. A shock is produced by the violence of the assault that prostrates the weakened and impoverished tissues. Instead of simply breaking up the adhesions and promoting the physiologic vibrations of the ossicles, the pressure on the contents of the labyrinth is abnormally increased, thereby causing pain, vertigo, and sometimes hemorrhage, and even, occasionally rupture of the drumhead. As an agent for massage, the assaults are too severe. In many cases, instead of equalizing the circulation it causes increased nervous irritation, congestion or inflammation.

The specialist in aural surgery may by the skillful use of an apparatus and process for forced dila-

tation and mild but rapid vibrations, more frequently avoid the annoyance of such accidents, as even its routine use with proper medicaments can never result in an injury to the ears, nor aggravate the symptoms.

To dilate and medicate the nasal and post-nasal cavities: Press the nozzle into one nostril, the other being open, the lips being closed as in Fig. 3. Turn the faucet, no matter how much the passages may be plugged, closed or obstructed by secretion, polypi or hypertrophied membrane, the impacted nebula will be forced through and the nasal and post-nasal cavities will be thoroughly medicated.

To medicate the mucous membrane of the pharynx, tonsils, follicles and post-nasal cavities: Insert the tube well into the mouth, the lips being compressed around it, the nostrils being left open as in Fig. 4; turn the faucet, exhale through the nose, and the impacted nebula will thoroughly medicate all the surfaces. I deem it almost useless to say that this can not be so satisfactorily accomplished by the usual methods.

The throat, the smaller bronchi, and the air cells of the lungs can be dilated and thoroughly medicated, either through the nose or mouth. If it be desirable to administer through the nose, press the nozzle into

FIG. 3

FIG. 4

FIG. 5

FIG. 6

one nostril, close the opposite nostril and compress the lips as in Fig. 5, or if it be desirable to administer through the mouth, having removed the nozzle, place the tube in the mouth, the patient compressing the lips tightly around the vulcanite; the nose being closed by the thumb and fingers as in Fig. 6. In either case having first expelled the air from the lungs by a forced expiration, turn the faucet, and allow the impacted nebula to flow, the patient co-operating by a passive inspiratory effort as in the act of taking a long, full, or deep breath, allowing the chest to expand until the internal pressure becomes great enough to force the lips apart and the impacted air to escape explosively.

The explosive escape of the compressed air is an evidence of a thorough dilatation. It also assists to detach, dislodge and expel from the air cells, the bronchi, the throat and nose, such deposits as result from excessive secretion or other morbid processes, together with a per cent. of the residual air.

It should be borne in mind that this is not inhalation but dilatation. The difference between inhalation and dilatation is, that inhalation like breathing, is the act of the respiratory organs requiring, however, a more active inspiratory effort, while

dilatation is carried out by the operation of the apparatus, together with a mild or passive inspiratory coöperation, and the mechanical force of impacted air. Consequently, a reliable automatic safety valve is necessary to insure the patient against any liability to injury from an excess of pressure. For this purpose no other device than the lips of the patient is required. The lips will act in any condition of health or disease as a safety valve, as it is impossible to retain a pressure sufficiently high by compressing the lips to cause an injury to the most delicate or the most robust person. It is equally impossible to rupture vessels, to lacerate or to injure the most delicate lung tissue because the pressure is equal on all surfaces. As an evidence of absolute safety, clinical experience has shown that forced dilatations will check passive hemorrhage; the pressure forcing the blood back, the medicament astringing and healing the surfaces. Also that forced dilatation is well borne by the very feeble, to whom it is an exhilarating tonic, affording all the benefits derived from the most labored respiratory efforts and lung gymnastics without fatiguing exertion.

Believing it necessary to emphasize the importance of thoroughly dilating the lung, I therefore repeat

that the patient must coöperate by tightly compressing the lips, expanding the chest and allowing the impacted nebula to flow into the lungs until the internal pressure forces the lips apart, allowing the impacted air to escape explosively.

The discovery that the compressed lips will act as a reliable automatic safety valve, rendering it absolutely safe to dilate to their utmost capacity the smaller bronchi and air cells of the lungs by the expansive force of highly condensed elastic fluid; and that non-volatile medicaments in appreciable quantities can thus be conveyed and deposited by impacted nebula into any tube, cell or cavity, into which air can be forced, does as an experimental basis open a new field and marks a new era in the treatment of the respiratory organs. This may engage the attention of clinical investigators and observers in the medical profession at an early date, and lead to the cure or control of tubercular consumption. This is the more probable in view of the well-known fact that highly condensed air by rapid expansion lowers the temperature and desiccates the surrounding tissue, absorbing therefrom heat and moisture; conditions necessary for the vigorous activity and rapid propagation of the bacilli and other mi-

croörganisms, without which they become inert and sterile through attenuation.

By comparing this with other apparatuses and methods, its value will become more apparent. Dr. Waldenberg's apparatus, with improvements and modifications by Prof. Solis-Cohen, and others, is used to moderately condense or rarefy the air preparatory to inhaling it. The expansion of the chest is brought about by labored respiratory effort and lung gymnastics. Forced dilatation is not an element or part of the method. The only claim is an imitation by mechanical means, of the atmospheric condition met with in a change of residence from valley to mountain, or from mountain top to valley. In the published descriptions of the apparatus and the method of using, no reference is made to forced dilatation nor to the explosive expulsion from the bronchi or air cells of the accumulation and deposits from morbid processes, and of the residual air; nor of the absorption of excessive heat or moisture, nor of medication beyond that accomplished with any good inhaler.

The pneumatic cabinet offers the only other means for dilating the smaller bronchi and the air cells of the lungs. This is accomplished by the use of the cabinet but not by the Waldenberg or any similar apparatus. Although dilatation by the cabinet may be complete, the medication is not complete, from the fact that exhalation is but partial, due to the inability of the patient to thoroughly exhale against the pressure. Nor do we obtain by its use the benefits derived from the absorption of heat and moisture, and the explosive expulsion of morbid deposits and a percentage of the residual air. Consequently, the bacilli are not so thoroughly attenuated and the capacity of the lungs is not so greatly increased by the use of the cabinet as by forced dilatation with impacted air; nor is the physiologic function in the processes of osmose so effectively promoted.

The advantages of forced dilatation with impacted air in the treatment of the respiratory organs is patent, for the reasons that the physician after selecting the medicament, either according to the law of natural selection, or for its remedial or physiologic action, can dispatch it in the form of impacted nebula along lines, the obstructions of which would offer an impassable barrier to inhalation. At the same time the benefits resulting from the absorption of heat and moisture, the attenuation of the bacilli, the checking of passive hemorrhage, the expulsion of morbid product and a moiety of the residual air, together with an increase in the breathing capacity, the restoration of the physiologic function in osmose and a more perfect oxidation in the processes of nutrition and assimilation, can be obtained through the mechanical elasticity of the impacted nebula.

The process of preparing and administering nebulous medicaments from this apparatus into the air passages, cells and cavities by forced dilatation is rational. The mucous membrane throughout being upon the stretch with all its convolutions unfolded, as a result of the expansive force of the impacted air, is in the most favorable condition for the reception and absorption of the infinitesimal particles of medicament that are conveyed and deposited by the impacted nebula. Thus maximum effects result from a minimum of medicament.

Among the many advantages may be mentioned the fact, that an increased amount of air is breathed

after forced dilatation, and that, too, without conscious effort, which must result in increased oxidation, and therefore must aid in the chemical and physiologic processes of assimilation and nutrition. The improvements in the general health of those treated is an evidence of this, the improvements being so marked as to be apparent to even a casual observer. Hence the claim put forth to the effect that it is equally well adapted to the treatment of other diseases as well as the ears, nose, throat and chest, seems to have a foundation in fact. The capabilities of the apparatus and process of administering are therefore, to say the least, worthy of candid consideration by specialists who limit their practice to other distinct branches as well as by the general practitioner.

My apparatus was manufactured by the Owens Brass and Copper Works of this city, but apparatus can be procured through any dealer in surgical instruments and physicians' supplies.

It was my intention to report the results from the use of this apparatus, but the length of this paper has already far exceeded the usual limit. Therefore the reports of cases must be deferred.

Columbus Memorial Building.

SOCIETY PROCEEDINGS.

The Medical Society of the State of Tennessee.

Held at Memphis, Tenn., April 10 and 11, 1894.

FIRST DAY—MORNING SESSION.

After the Address of Welcome, the reports of the Secretary, Treasurer and Publication Committee were received, and the Committee on Corporation was continued.

Dr. G. C. Savage, of Nashville, asked the indorsement by the Society of a bill to be presented before the State Legislature, looking to the prevention of blindness by the early recognition and treatment of ophthalmia neonatorum. This was unanimously granted after a thorough discussion.

In reference to the proposed change in the Code of Ethics, it was

Resolved, That it is the sense of this Society that the Code of Ethics is good enough for us.

FIRST DAY—AFTERNOON SESSION.

Upon motion the privileges of the floor were granted Drs. Weisynger and McNeal, of Mississippi.

DR. D. E. NELSON, of Chattanooga, read a paper on "Longevity." (See JOURNAL, April 28, 1894.)

DISCUSSION.

DR. D. D. SAUNDERS, Memphis, thought a man should live one hundred and five years, which is five times twenty-one years, the length of his maturity. The people in the Arctic regions wash their children in urine, and there are old people among them, notwithstanding their hardships and bad hygiene. It is also true that some hard drinkers live to an old age. An acquaintance, "Uncle Billy," aged 90 years, a massive picture of health, strength and power, was an old toper. When asked how many were living who commenced drinking with him twenty years ago, he replied: "Not one." There is the lesson, temperance; temperance in all things is the secret of health, strength, success, and the secret of longevity.

DR. WATERFIELD, Memphis, suggested that physicians should, as far as possible, make object lessons of themselves, as had the previous speaker. There is no controversy in regard to the importance of temperance, but would it not be well to go a little farther and ask why it is that a temperate life in diet, drink, exercise, in psychological action, in everything, is conducive to longevity, and why intemperance in these things is deteriorating? If we would let nothing enter the economy that is not constructive, and will not create force, and if we, as physicians, would teach

the people that whatever else passes the lips is destructive, life would be very greatly prolonged.

Dr. I. W. PERKINS, of Henderson read a paper on

FECAL IMPACTION WITH TYPHLITIS.

The paper was the report of a case he had been called to treat for what was supposed to be colic. The patient had been given the usual routine of purgatives, which had been retained but a short time. Upon examination the tenderest spot was found over the ilio-cecal valve. The patient had vomited for twelve or thirteen hours; temperature and pulse high. In ten hours he was again seen, and he had vomited everything taken on his stomach in the meantime. Various things were tried to quiet his stomach and relieve the pain, but all to no purpose. Finally, after a hypodermic injection of morphia, he was given a rectal injection, and after one hour the trouble was all over. The principal point is the position of the last injection and the manner of giving it, using the morphin hypodermatically five minutes before the rectal injection.

(Discussion postponed.)

Dr. W. S. SCOTT, Dickson, read a paper on

CHRONIC ENDO-CORPOREAL METRITIS.

The author is of the opinion that chronic endo-corporeal metritis is found as a distinct disease, and explains why we have so many cases of rebellious leucorrhœa, dysmenorrhœa and sterility. The uterus is seldom found in its normal position between the bladder and the rectum. Normally it is anteflexed. The cause or causes of endo-corporeal metritis are numerous. In the multipara it is most frequently caused by subinvolution. Strumous diathesis, imperfect general nutrition, overtaxation of the system, tuberculosis, frequent parturition, prolonged nervous depression, displacement of the uterus, are some of the predisposing causes. Some of the exciting causes are cervical endometritis, chronic or acute general metritis, pelvic peritonitis, especially from chronic abuse of sexual intercourse, abortion, retained menstrual flow, exposure during and checking the menstrual flow, etc. The symptoms naturally are of two kinds, local and constitutional. The constitutional symptoms are made manifest by the nervous system and the digestive organs. While the latter may be wanting, the former never is. The local symptoms are to be relied upon mostly in making a diagnosis. We almost invariably find pain on pressure over the body of the uterus, enlargement of the organ and leucorrhœa. While the disease is not incurable, and we find very few cases of death from it, yet it is a troublesome malady and hard to overcome. If we can succeed in removing all the causes, we can expect a favorable prognosis, but in cases of gonorrhœal origin or of purulent catarrh, in which the general health is bad, the prognosis is unfavorable. It is best to use intrauterine treatment freely but cautiously. The therapeutics employed range from the blandest anodynes to the actual cautery. We should be governed by the indication of each case. Sodium chlorid should be preferred in most cases as a vaginal douche as it is purifying in character, convenient and safe. We can not expect improvement until we have depleted the pelvic circulation, and nothing serves so well as a gallon of water at 80 or 125 degrees F. Pessaries are but little help. To deplete the engorged uterus, the local application of glycerin is valuable.

Case 1.—Miss C. M. developed endo-corporeal metritis when 14 years of age. When first seen she had not walked alone for three years. She was a nervous wreck, no appetite, poor in flesh, no desire for company, and had suffered pain almost incessantly for two years. By digital examination the external labias were found to be ulcerated and tender, and the vaginal canal was so much ulcerated that it was not practicable to examine the uterus for three weeks. When examined the uterus was lacerated, dilated and undulated, and from it passed a very offensive muco-purulent discharge. It was curetted with a dull instrument, washed out with a hot carbolized solution, Churchill's iodine freely applied to the entire uterine cavity, and pinus canadenses applied to the external os, and left for twelve hours, and then for three days the sodium chlorid douche was used three times a day. As a tonic she was given the tincture of the chlorid of iron, tincture of nux vomica, fluid extract of ergot, and the fluid extract of black haw. For the first ten days ammonia was administered at bedtime. After two months she could walk with little inconvenience unsupported across the room, and at the expiration of the fourth month she claimed to be well. After two years she had suffered no relapse. Six months later she married, and twelve months later was confined, and died of puerperal septicemia.

Case 2.—Mrs. M. C. D., multipara, age 34, had suffered

from endo-corporeal metritis for three years, during which time she was unable to attend to her domestic affairs. Examination showed cephalalgia of the crown, constant pain in the loins and pelvis, vaginal tenesmus, bowels constipated, menstrual flux irregular, painful and profuse, appetite poor, and but little assimilation of food, general relaxed muscular system and inability to sleep. The os was dilated and undulated, and from it poured a profuse leucorrhœa, tenacious and tinged with blood. The uterus was enlarged, retroflexed and tender. With the sound the trouble was found to involve almost the whole endometrium. After an intrauterine injection of carbolic acid solution she was curetted and Churchill's iodine applied to the entire uterine cavity. Glycerin and pinus canadenses on lint were applied to the external os, and allowed to remain twelve hours, when it was removed and a sodium chlorid douche used three times a day for three days. Then iodine and carbolic acid were applied thoroughly to the endometrium, and glycerin and pinus canadenses were used as before, the same being repeated every three days. The constitutional treatment included strychnia, ferrum, lactucarium, ergot, phosphorus and black haw. As she had become somewhat of an opium eater, the fluid extract of cocoa was given to overcome it. After three weeks the intrauterine treatment was discontinued, but the local applications to the os, and the douches were continued three weeks, then the douches and a constitutional treatment for two months, when all catarrhal discharge had ceased, the appetite had returned, and there was a general constitutional improvement. The prognosis in the case as to a complete cure was negative, but as to permanent relief positive, and after eighteen months she conceived and passed through confinement without unusual trouble.

DISCUSSION.

Dr. RICHARD DOUGLAS.—The endometrium, being destitute of any claims to mucous membrane, is peculiarly susceptible to parenchymatous inflammation, and there is likely more or less metritis in all these cases. That this disease occurs separate and apart from cervical inflammation we must admit, but it usually occurs associated with cervical inflammation. There is sepsis in all these cases, caused by some accident during parturition, some lesion or some remains of placenta or blood clot, incomplete absorption, and last but not least the tinkering gynecologist. We can not treat it without constitutional methods, but we ought to get along with fewer drugs than the essayist mentioned, although they are all useful. Rest is essential, and a life of continence is absolutely necessary. The use of hot water does not more than clean the vagina. The topical application of coagulants to the body of the uterus favors sepsis and extends the disease. The disease resides in the glands, and until the mouths of these are opened, until the endometrium is removed, we can not accomplish much. We must look upon it as a foul stinking sac, and clean it as best we can. We should dilate the uterus, curette with a sharp instrument, irrigate well and pack with gauze, remove the packing in from one to five days, repack, and treat the surface of the uterus as if it were an ulcer. The cavity of the uterus should be treated upon surgical principles. It is a question if the first case ever recovered from the endometritis. The other was a beautiful recovery.

Dr. J. S. CAIN, Nashville.—Septic and specific troubles probably cause the majority of cases, but many of them grow out of general causes. In those cases in which we find degenerated fungosities, the sharp curette should be used. The aseptic and antiseptic part of the treatment was carefully carried out. The dull curette should be considered less dangerous than the sharp one, because it does not go so deep.

Dr. T. J. HAPPEL, Trenton, read a paper on

APPENDICITIS.

Until lately it has been agreed by the surgical world that the knife was the only resort, when there were reasonable grounds upon which to make a diagnosis of appendicitis. Now the surgical world is at sea, and the general practitioner begins to realize that this disease has not entirely departed from his domain.

The Doctor then reported eight cases of typhlitis and appendicitis. In one case death followed within thirty-six hours after the onset of the attack, being apparently due to shock from perforation of the appendix and the development of general peritonitis. In three of the cases pus developed, and was discovered in two of them with the hypodermic needle; but was discharged per rectum in all three of the cases, with rapid recovery in each. In one case only was abdominal section made, and in this case at least one gallon

of pus was discharged. Three of the cases were males, five females; six were white, and two colored. The report served to show that not all cases belong to the domain of surgery, and in none of the six cases that recovered could better results have been gotten with the knife than were obtained by the expectant plan of treatment. However, the knife should be used in proper cases, and where the presence of pus can be proven beyond question, it is not safe to delay operation, although as shown in my own cases, spontaneous cure may even then take place. If pus is present, and the patient refuses to allow the knife to be used, the pus should be removed and the cavity washed out by means of a large sized aspirator needle. It is surprising how much relief often follows the use of the aspirator, even when only a small amount of pus, or even exudate is removed, and how often resolution follows this treatment.

A patient with appendicitis is in a dangerous condition, but before the formation of pus, before ulceration or perforation has taken place, or the appendix has become gangrenous, or has sloughed; the danger lies in the future. During this period we are warranted in resorting to medicinal measures alone, and these measures should be active vigorous ones. I would advise the use of morphin hypodermatically, in such quantities as may be necessary for the relief of pain; a mustard plaster should be applied over the seat of the pain, and this should be followed by hot turpentine stupes, and these by the hot water bottle. Although ice is recommended as a local application, I prefer the hot ones. Sulphate of magnesia should be given, half ounce doses, repeated every three hours until free and full evacuations are obtained and the bowel is completely emptied. In cases of catarrhal appendicitis these measures will usually succeed and resolution will speedily take place. The sulphate of magnesia acts not only as a purgative but also as a local depletant. By its action the blood vessels of the cecum and adjacent parts are unloaded, and resolution much aided. Should these measures fail to give prompt relief, the aid of the surgeon's knife is to be invoked. Should the attack be due to an enterolith or any other body dropping into the appendix, the probabilities are very strongly in favor of the knife.

DISCUSSION.

DR. CAIN believed the great majority of cases originate from fecal obstructions in the colon. These impactions occur more frequently in the ascending colon, where the matter has to overcome the force of gravitation to a certain extent. After dropping into the cecum, the matter remains there for awhile as a fluid, when it is forced out, and it then takes the direction of least resistance, and sometimes part of it is forced into the small opening of the appendix.

DR. DOUGLAS—It is impossible to draw the line when all cases of appendicitis come entirely under the domain of surgery. We have different varieties of appendicitis, as catarrhal or recurring appendicitis, suppurative appendicitis, adhesive in character, slow in progress and oftentimes terminating favorably, and we have acute perforative appendicitis, that causes death before you can do ought to save your patient. In the first variety the pain is diffused over the abdomen, and the patient is frequently relieved by purgatives. The symptoms are only concealed by morphin hypodermatically. In the second variety, delay is dangerous. The mythical grape seed does not enter into the cause so much as people generally believe, and in a number of operations only once have I found a seed, although I have frequently found impaction. Feces will always be found in the appendix upon postmortem examination of these cases. I have seen a number of cases with no tumor, and they are the dangerous cases. We should not rely on the temperature. I have removed ounces of pus with a temperature of 99 degrees. If ice applications for twenty-four hours do not cause the temperature to yield or show symptoms of improvement we should operate. The operation is simple if undertaken early, and delay is dangerous.

DR. EVE, Nashville, thought the essayist very fortunate, and agreed with Dr. Douglas. While believing in conservative surgery, conservatism must not be pushed too far, for there is a point where the physicians should stop and the surgeons begin. These cases are frequently allowed to go too far, and an operation is not a success because of shock.

DR. SAUNDERS—Conservatism here means overwaiting. I do not think any man is justified in waiting more than forty-eight hours. I have never had a case upon which I operated too soon. There is comparatively no risk in the operation, and if you wait you take the life of the patient in your own hands. When you operate, remove the appendix, if it is not already removed.

DR. ROBERT PILLOW, Columbia.—I believe there is a happy medium. I have operated on six cases at home without a failure. One of them had probably fifteen recurring attacks previous to operation. It is true in some cases it does go away without operation, and does not return. This seems to have been the case in my own person. Nearly eight years ago I had an attack which has not recurred. I treated it with saline purgatives.

DR. S. S. CROCKETT, Nashville, was pleased with the remarks of the last speaker. The medical fraternity is made up of two classes; one is chasing the victim with the knife, and the other is letting them die of neglect. Dr. Pillow and Dr. Douglas have both had it and have both gotten well without operation, and there are a number of similar cases, but some of them do die. In the perforative and suppurative varieties an operation is imperative. But, because a patient has an appendicitis, we should not subject him to an operation without a trial. It is remarkable how easily these patients recover from an early operation. We should operate when we are driven to it.

DR. B. L. BRANCH, Rossville, had seen four cases recover after conservative treatment. From one of them a gallon and a half of pus had been aspirated.

DR. WILLIAM KRAUSS, Memphis, had operated successfully on two cases of supposed appendicitis, and in both cases the appendix was perfectly healthy. In one, the cecum was ulcerated through, and both had general peritonitis. He raised the question, whether those who do a great deal of operating for appendicitis, always find appendicitis.

DR. T. J. CROFFORD, Memphis, believed the appendix a murderous sort of thing that should be cut out whenever it gets to cutting up any of its gyrations. If the patient is not comfortable after administration of salts, I advise an operation, and I have never seen a case die when operated upon early. You do not know whether they are perforative or not until you wait. He reported several cases cured by operation.

DR. T. R. MOSS, Dyersburg, thought an operation usually demanded. With regard to the simplicity of the operation, if he had appendicitis he would go to the best surgeon he could get.

DR. ERSKINE had never operated, but had successfully treated a good many cases, and related a number of them. Several got well after the formation and breaking of an abscess. He did not believe in never operating, but is in favor of a very wise conservative line of treatment.

DR. A. J. SWANEY, Gallatin, said the great mistake in this operation is the delay. Besides, it is said that the man who gets well without an operation has just time to make his will. It would be interesting to know how many cases have been lost by conservatism and how many by too early operation.

DR. GASSELL reported a fatal case, which had been treated on the expectant plan.

DR. HAPPEL, in closing, remarked that some have said there will be recurrence of those cases not operated upon, and that they do not get well. One patient I reported has never experienced any relapse in fifteen years. If one-half of these cases will get well without operation, we should give them an opportunity to do so. We should keep them under medicinal treatment a reasonable length of time, and I would fix this at sixty hours.

FIRST DAY—EVENING SESSION.

DR. N. T. DULANEY, the President, delivered an address on "Then and Now, or Forty Years in the Field." The paper was a review of the advances and changes in the science of medicine during the forty years he had been in practice.

DR. RICHARD DOUGLAS, of Nashville, gave as his subject

EXTRA-UTERINE PREGNANCY.

A report of three cases, in each of which operation was followed by recovery. These were supplemented with six others, five of which were operated upon, with one death. The unfortunate case was an extra-peritoneal rupture of some three weeks standing, and the operation was undertaken under most adverse circumstances. The patient died the third day from exhaustion. The sixth case in the series was a postmortem. The patient was taken suddenly while shopping, and died before an operation could be performed. In seven out of nine cases reported, the left tube was the seat of the vicarious growth. In eight cases there was a history of antecedent pelvic inflammation, and in four cases there was reason to believe that gonorrhoea was the cause. Pain was a conspicuous symptom. The cases that abound in literature show that primary intraperitoneal ruptures are comparatively infrequent, compared with intraligamentous rupture.

However, three of these cases were intraperitoneal rupture, and six of the downward variety. In cases of intraperitoneal rupture, we should without delay open the abdomen and grasp the proximal side of the tube. This arrests hemorrhage. Then transfuse the patient with a saline solution, bring up the blood pressure and complete the operation by removal of the tube. In cases of extra-peritoneal rupture, prudence recommends waiting twenty-four to thirty-six hours and preparing the patient in the usual way for section. The changes that take place in the tube under the influence of ectopic gestation leave it as a dangerous and useless appendage, and its removal is required.

THE MANAGEMENT OF ECTOPIC GESTATION DURING THE LATTER HALF OF PREGNANCY.

Was given by Dr. R. B. MAURY, Memphis. In connection with a report, he presented two specimens. The first specimen had been pronounced an extrauterine pregnancy by Dr. Allen J. Smith, and had been published. The second specimen was presented because of the circumstances connected with it. The rupture took place at the sixth week, and the operation was performed the eighth week, two weeks after the rupture. The gestation sac had been completely detached from the side of the uterus, and was lifted out of the abdominal cavity with the coagulum. An interesting question is what the peritoneum could have done with the detached gestation sac if an operation had not been performed. The coagulæ with the gestation sac were completely cut off from the general peritoneal cavity by intestinal adhesions. From the statistics it is evident these cases can not be wisely left to nature, and we should operate for ectopic gestation as soon as the condition is recognized.

DISCUSSION.

Dr. T. J. CROFFORD, Memphis, presented a gestation sac, still in the tube, successfully removed from a case of ruptured pregnancy. The operation lasted twenty minutes. The omentum reached down over one of the largest torn places in the tube, beautifully illustrating the efforts of nature to control the hemorrhage. The history of the case was interesting in that the patient was a young woman, married little over a year; there was a temperature of 100.5 at the time of the operation, and in the abdomen there were about two gallons of blood and fluid. He considered the papers very commendable, but did not think the patient ought to be kept on the operating table too long. Dr. Maury's statistics run back ten or fifteen years, whereas the best results have been obtained in the last few years.

Dr. W. W. TAYLOR, Memphis, claimed to be the first person in Tennessee to diagnose ectopic gestation previous to rupture. The case occurred in 1887.

Dr. J. S. CAIN remarked that these cases first come under the care of the general practitioner, who should be able to diagnose them, and he asked how the previous speaker made a diagnosis before rupture.

Dr. TAYLOR—There was no sign characteristic of tubal pregnancy, but the patient was sterile for ten years. She had missed her periods in December and January, showed the morning sickness; paroxysmal pains; there was a slight bloody discharge from the uterus, a tumor to one side of the uterus, and some early breast changes.

Dr. CAIN claimed there is no crucial test for ectopic gestation at this period. However, he believed the casting off of the decidua membranes is sure evidence of ectopic pregnancy.

Dr. DOUGLAS had never diagnosed a case of ectopic gestation before rupture.

Dr. MAURY had been called to see the case, and said that Dr. Taylor was correct. He had been slow in recognizing the nature of the case and apologized for it.

(To be continued.)

Association of the Military Surgeons of the United States.

Fourth Annual Meeting—Report of Proceedings.

The Association of Military Surgeons of the United States held its fourth annual meeting May 1-4, 1894, in Washington, D. C. The meeting was opened by President Cleveland at 10 A. M., in the National Theater. The interior was brilliantly illuminated, the Committee of Arrangements having made a free use of the National colors for this purpose. Almost 250 members were present, all in uniform—in accordance with the requirements of the program. The house was well filled with interested spectators, many no doubt

having been induced to enter by the unusual military display. It may safely be asserted that never before in this country has the opening meeting of a medical association presented so brilliant an appearance. Washington's famous Marine Band added to the military character of the scene.

Surgeon-General George Henderson, of the District of Columbia National Guard, Chairman of the Committee of Arrangements, called the meeting to order, and after prayer by the Rev. T. S. Hamlin, of the Church of the Covenant, President Cleveland opened the proceedings with a few appropriate remarks. He said that as Governor of the State of New York he had taken an interest in its National Guard, and since then he had kept up and extended this interest, as it is upon the Guard that the country must depend in a time of need. He referred to the necessity for coöperation between the National Guards of the different States, and between them and the Army of the United States.

District Commissioner Ross, in an address of welcome, referred to the benefits derived from organization and the advantage to be had by annual meetings for the comparing of professional observations among those having similar responsibilities, similar hopes of honorable preferment, and the same ambition to serve well and loyally the Government established by the fathers of the Republic. He then touched on the natural relation of Washington to the meetings of National associations; and the Coxey Good Roads Association coming into his mind, inasmuch as its members were then marching into the city along Fourteenth Street, he remarked that while citizens may peaceably and reasonably assemble at the National Capital, no man who comprehends our system of government needs to be convinced that any attempt to compel action on the part of any of the three great coördinate branches of the Government by menace or threat, or show of physical force, would be not only unlawful, substituting the rule of the mob for that of the people, but would be an insult to the people of the United States in so menacing or threatening its agents. Dr. S. C. Busey, President of the Medical Society of the District of Columbia, and General Ordway, commanding the National Guard of the District, followed with words of welcome.

The President of the Association, Dr. SENN, of Chicago, Colonel and Surgeon-General Illinois National Guard, devoted his address to the consideration of

ABDOMINAL SURGERY ON THE BATTLE FIELD.

He referred to the probable influence of the new small caliber and long range rifles on the character of wounds, which would be more numerous and dangerous than with the old projectiles; but to do justice to this address a full report would have to be penned.

As the members crossed Pennsylvania Avenue to reach the office of the Registrar, they had an opportunity of viewing the long-heralded march of the Coxey army on the Capitol. Quite a number, attracted by curiosity, reviewed the "army," and no doubt created in Mr. Coxey's mind the idea that the military of the United States was out in strong force.

The working sessions of the Association were held in the lecture hall of the National Museum, Smithsonian Institute grounds. The afternoon of the first day was devoted to a "Symposium" on the Transportation of Sick and Wounded, which was opened by Major Charles Smart, U. S. Army, with an admirable review of the history and extent of the subject, which was published in the JOURNAL of May 5. Major Havard, U. S. Army, then described the requirements of a good litter: 1, it must be one and the same for all purposes, that is, the stretcher on which the wounded man is carried from the field must be such that it will fit into the ambulance wagon; 2, it must admit of quick and easy opening and closing. The traverses of our regulation stretcher are not yet perfect; 3, the handles must be fixed and immovable, that is, they must be simply the ends of the poles and in no way jointed or detachable; 4, it should have legs—short so as not to be in the way when the stretcher is closed or strapped, and fixed, as folding legs are a constant source of trouble to the bearers and danger to the patient besides complicating the manual and interfering with the loading of the ambulance wagon; 5, it should be light, strong and simple in construction. Its weight, should, if possible, be reduced to sixteen pounds. Aluminum may hereafter give good results. Major Havard condemned all attempts at procuring lightness at the expense of other essential qualities; 6, the sling should be a part of the bearer's equipment, not of the stretcher. Our regulation

stretcher is satisfactory in most respects except weight; it weighs, with its slings, twenty-four pounds. It is seven and one-half feet long, six feet of canvas for the patient, and one and one-half feet of pole (nine inches at each end) for the handles. Its fixed feet raise it four inches from the ground.

Captain Myles Standish then exhibited the light and easily carried stretcher in use during the past nine years by the Massachusetts troops, and illustrated the ability of the men of the Hospital Corps by photographs of arms and legs bound up in all kinds of extemporized splints. Captain Ives, U. S. Army, Fort Sheridan, Illinois, and Captain Glennan, of Fort Sill, Oklahoma, also submitted papers on the litter and ambulance wagon. That of the latter officer, read in his absence by Colonel Alden, was mainly devoted to pointing out the faults of the present Army ambulance wagon as developed by its use in campaigning in the West.

Major J. Van R. Hoff, U. S. Army, described the travois as used in the Northwest for the transportation of sick and wounded and presented an improved specimen, claiming for it a sphere of usefulness in the future, if long-range bullets are found to necessitate the carriage of wounded men for long distances from the fighting line to the first aid stations or the field hospitals. It is so made that the regulation stretcher fits neatly and securely between its trailing poles. Colonel Louis W. Read, Surgeon-General, Pennsylvania, devoted attention in his paper to transportation by rail and the best methods of fitting up cars for hospital purposes; and Medical Director A. L. Gihon, U. S. Navy, described the methods of handling the sick and wounded on shipboard, pointing out their faults and showing an ambulance cot of his own invention by which they could be remedied. A paper on a field hospital kitchen wagon for sterilizing dressings at dressing stations and on the march, by Captain H. O. Perley, U. S. Army, was read by title in the absence of the author; after which there was some discussion on the best form of stretcher and a committee, consisting of Drs. Hoff, Gihon and Standish was appointed to consider the subject.

A reception and collation in the evening, at the Ebbitt House, the headquarters of the Association, closed the proceedings of the day in a most enjoyable way.

Promptly at 9 A.M., May 2, the meeting was called to order by Dr. Senn. Some committee reports, including that of the Secretary, were presented; after which, to facilitate the selection of officers for the next year, a Nominating Committee was appointed consisting of one member from each State and service represented. The first paper on the program, that of Colonel B. J. D. Irwin, U. S. Army, "Notes on the Introduction of Tent Field Hospitals in War," was read by Colonel Alden. Lieut.-Colonel L. B. Almy, Medical Director Connecticut National Guard, then took up the history of the Red Cross Society, in the course of which he urged that some action be taken to protect the emblem of the Society from desecration by use as a trade-mark for patent medicines, soap, cigars, etc. The Association took immediate action, and Drs. Gihon, Almy and Smart were appointed a Committee to carry out its views. This Committee lost no time in its work, for next day it reported a memorial to Congress, which was adopted by the Association, praying that the Red Cross be not permitted to be used for advertising purposes.

"The Medical Officer at Summer Encampments," by Lieut.-Colonel Chas. R. Greenleaf, U. S. Army, was read by Colonel Alden. According to the author of this paper, there are at these encampments no systematic drilling of the attendants in the handling of stretchers or helpless men, or in the loading of ambulance wagons, no instruction in routine or battle field administrative methods, a too general ignoring of the administrative duties of an Army medical officer and an absence of the discipline on which the successful performance of this duty is founded. The faults, he considers, the result of a failure to appreciate the necessity and importance of such duties; and he describes what he saw at the maneuvers of the Medical Department of the French Army in October last in the field at Puntin, a village near Paris, where nothing was lacking save bullets and blood to complete the realism of the battle field. It may be said that such perfection of high-class field drill is impossible with the small number of troops mustered by us in our summer camps, but the same earnestness and interest put into the work with small detachments would be productive of satisfactory results.

Assistant Surgeon C. W. Galloupe, Battery A. M. V. M., Boston, Mass., in a paper entitled: "The Diet of the National Guard in Summer Encampments," discussed the causes which bring men on sick report,—as many as 10 per cent.—

on the first or second morning of the camp. Unusual fatigue of drills or guard duty in men of sedentary occupations; loss of sleep from novelty of surroundings and occupation, unusual noises, the glare of the morning sun on tents and the inopportune visits of uninvited comrades were instanced; but the chief cause was averred to be the change from simple and regular meals to a mixed and injudicious bill of fare, soft drinks and sometimes those of a harder character. In Massachusetts each company caters for itself, paying for meals out of the company fund at the rate of \$1.50 daily per man; but the food is never inspected. As showing the advantage of regimental messes by which good cooks are procured and a uniform bill of fare for all the companies, Lieutenant Galloupe gave a description of the method as carried out by his advice in the 8th Mass., in July, 1892, with the bills of fare for fifteen meals (Monday to Saturday) at the rate of 50 cents each. Instead of the usual 30 or 40 at sick call every morning from this command of 600 men, only a few reported sick and after the first two days none at all.

Surgeon J. C. Wise, U. S. Navy, in a paper on "The Naval Medical Officer on Expeditionary Boat Duty," referred to the apathy in providing surgical aid to those injured in these duties, instancing the Battle of the Barges in 1782, in the Chesapeake, where by the explosion of an ammunition chest on the Virginia barge *Protector*, twenty-nine men were killed and as many wounded, many of the deaths having resulted from preventable hemorrhage. During the Civil War, boat expeditions, although of frequent occurrence, were not specially dangerous to life. Boat patrols are common in foreign waters. In cutting out expeditions the gig carrying five men and a medical officer is the hospital boat. This boat is long and narrow and in so far inconvenient, but she is the best because the swiftest. The assignment of a stanch and swift steam cutter is hoped for as one of the advances of the medical service afloat. The paper then touched on the equipment of the boat and its position under certain conditions of service and duty, and concluded with the management of emergencies likely to occur in such service. Sylvester's method was considered the best in cases of drowning.

Captain Jas. E. Pilcher, U. S. Army, read a paper on "The Place of Physical Training in the Military Service." In this he commented on the attention given by the medical department to the prevention of disease by the removal of threatening conditions, and the almost total neglect of prophylaxis by increasing the powers of the soldier to resist disease; and again, weapons are developed and perfected but not men. The perfect man is an ideal. No one man is an embodiment of perfect health. A physical examination of the most vigorous individual would reveal some lesion of actual disease or some predisposing weakness. The object of training is to take cognizance of these physical deficiencies and correct them by movements adapted to that end. Hard labor is not equivalent to physical training. Laborers develop strength in localized groups of muscles; but at the expense of others. Candidates for entrance at West Point, all passed as physically sound by experienced medical officers, are nearly all awkward, unsymmetrical and unevenly developed, and, as they march to the mess hall form a particularly instructive contrast with the third classmen who have enjoyed the benefits of a year's drill in physical training. Dr. Pilcher divided training into: 1, preparatory, by which unequal development is corrected and a proper equilibrium of the system secured; 2, conservative, by which this equilibrium is afterwards maintained. The first specially demands medical supervision. Accurate examination of the recruit exposes his deviation from the normal type and the rectifying exercises may thence be easily deduced. Muscular development depends on the frequency of muscular action. A man with undeveloped calves would be given foot and ankle exercises, and one with a slender forearm the wrist and finger movements. Military drill fails to maintain bodily efficiency; it tends to accentuate asymmetry. Hence the necessity for physical training. Athletic sports should be encouraged because they develop an interest in training.

Captain G. C. Clark, Assistant-Surgeon, member of the National Guard, discussed the relation of the National Guard surgeon to the medical profession and to the community. In the recent great advance in military sanitation and surgery, the medical officers of the Army have taken a leading part; and a high degree of efficiency has been attained by the National Guard surgeons in many of the States in the development of their hospital corps and ambulance organizations. The medical officers of the Guard are by no

means men attracted to the service by bright uniforms and the pomp and panoply of dress parades. The roster of the Association shows the names of many gentlemen eminent not only in the profession but in the special domain of military surgery. Captain Clark suggested that each State should send one medical officer to the Army Medical School, the expense to be borne by the State represented. A surgeon so educated would be of inestimable value to the community in which he lives. His special acquirements would make him of value as an executive health officer, and he would be one of the best qualified railway surgeons.

A paper by Medical Director C. J. Cleborne, U. S. Navy, entitled "Brief Notes on Ships, Hospital, Barrack and Camp Furniture, and on Electric Heating and Cooking" covered a large expanse of ground. Its author considered the modern army ambulance well suited for its purpose but the civic and naval wagons he regarded as too heavy. The ideal ward bedstead should be entirely of metal, light and strong, easily and quickly set up and taken apart, and devoid of ornament, free from cracks, crevices or anything that would give lodgment to dust or vermin. The requirements are, in the main, met by the pipe iron bedstead, weighing with its wire mattress from 120 to 140 pounds, which can be taken apart in from three to seven minutes by the aid of a bed wrench or screw driver; but a new bedstead of similar character weighing only seventy-five pounds has been introduced which can be set up in a few seconds and used as a field stretcher, the legs becoming utilized as handles. Various materials for mattresses are suggested by this officer; among them, for summer use, on a woven wire mattress, one or more layers of thick Japan sponge paper quilted between layers of felt and bound along the edges. Every ship, hospital and barrack should be provided with a crematory for the immediate destruction of animal and vegetable matter, ward sweepings, soiled bandages, etc., and also with a hot air or steam chamber large enough to disinfect iron bedsteads, wire mattresses, bedding and clothing. Aluminum dishes are recommended. In well constructed electric cooking utensils and ovens the heat is dry and concentrated, and unless properly regulated, joints may not be evenly cooked in their interior—a difficulty which may be overcome by gauze or asbestos screens or aluminum wire grills. Loss of weight in roasting, which in the ordinary process amounts to from 20 to 40 per cent., is only 18 to 20, and may be reduced to 10 by an asbestos screen.

Among the papers read by title, on account of the absence of their authors, were: "Notes on the Late Civil War," by Colonel R. F. Michel, Surgeon-General Alabama State Troops; "Camp Hospitals," by Major Lawrence C. Carr, Surgeon Ohio National Guard; and "The Progress of Medico-Military Science in the National Guard of New Jersey," by Surgeon-General John D. McGill.

The afternoon session was opened by Lieut.-Colonel W. H. Forwood, Deputy Surgeon-General U. S. Army and Professor of Military Surgery in the Army Medical School. His subject was: "Weapons of War," and he illustrated these by samples of modern small arms, projectiles and smokeless gunpowder. Among the projectiles were shells as beautifully finished as if they had been intended for parlor ornaments. He had also exposed on the wall of the lecture hall a chart showing the name and caliber, weight and other details of the principal small arms in use by the various nations. His lecture following up the history of small arms to the present small-bore, long-range rifle was interesting and instructive, and as such highly appreciated by the members and the many strangers attracted from the Museum to the Lecture Hall by the proceedings of the Association. Dr. Robert Reyburn, late Surgeon and Brevet Lieut.-Colonel U. S. Vols., followed with a paper in which he showed how the principles of aseptic surgery could be carried out by means of ordinary household utensils. Major W. Reed, U. S. Army, Director of the Bacteriological Laboratory of the Army Medical School, then spoke of the virtues of certain germicides, and particularly of those of trikresol. At the close of this paper the President having observed Miss Clara Barton in the audience, turned the chair over to the Vice-President, Surgeon-General Read, of Pennsylvania, and descended from the platform to greet the President of the American branch of the International Red Cross Society. Miss Barton was presented to the Association and led by Dr. Senn to a seat on the platform, the members rising as the lady was escorted along the aisle.

After a short paper on the action of rattlesnake venom on the serum of the blood, by Captain C. B. Ewing, U. S. Army, the meeting adjourned to enable its members to be present at the reception given by the President and Mrs. Cleveland,

at the White House. In the evening the Corcoran Art Gallery was brilliantly illuminated, but very few of the members took advantage of the opportunity to enjoy the pictures and statuary. The interest of the evening centered in the executive session at the Ebbitt House, where after a long close session the Nominating Committee reported the results of its labors to the Association, and the Secretary cast the ballot electing officers as follows:

President, Brigadier-General Geo. M. Sternberg, Surgeon-General U. S. Army. First Vice-President, Colonel Louis W. Read, Pennsylvania National Guard. Second Vice-President, Medical Director Albert L. Gibson, U. S. Navy. Secretary, Lieut.-Colonel Eustathius Chancellor, Medical Director Missouri National Guard. Treasurer, Major Lawrence C. Carr, Surgeon Ohio National Guard. Chairman Committee of Arrangements for the ensuing year, Major Albert H. Briggs, Surgeon New York National Guard, Buffalo, N. Y.

A committee was appointed to inform Surgeon-General Sternberg of his selection by the Association as its President. Drs. Grant, Foster and Hoff were appointed a committee to decide upon a special badge to be worn by members of the Association, and several other business matters pertaining to the domestic economy were attended to. The President was authorized to appoint a committee to consider the relations of the Red Cross Society to the Association of Military Surgeons and the Medical Department of the Army. A resolution was adopted having in view to secure for the Surgeons of the National Guard and the Naval Reserve all the privileges of the Army and Navy Medical Schools now accorded to the medical officers of the army and navy.

The Association was called to order next morning, May 3, at 9:30 when some discussion took place on the advisability of establishing a journal. Captain Pilcher, U. S. Army, and Secretary Chancellor were strongly in favor of this project believing that it would help the Association out by its success financially. Major Carr, the treasurer, was opposed to the undertaking; as the Association was over \$400 in debt, he thought it would be wise for it to be sure of floating before it began to swim. Lieutenant R. A. Foster also urged caution and spoke of the risks attending an attempt of this kind. This judicious advice prevailed and the subject was laid over until next meeting.

General H. L. Burrell, Massachusetts Volunteer Militia, then discussed the subject of the special education of military medical officers. He spoke in high terms of the advantages derived by the service from the schools of the soldier and officer, and believed that schools of instruction for the officers of the medical department of the National Guard would not only prove of great value to the Guard but to the regular Army, the medical profession and to the country at large. Lieut.-Colonel E. J. Forster, Medical Director, Massachusetts, exhibited copies of the various records and blank forms in use by the Medical Department of the Massachusetts Volunteer Militia and pointed out their advantages. A number of the delegates commended these forms, but others advised the adoption of those of the regular Army as the best way of securing uniformity. Major Hoff, U. S. Army, then gave a brief *resumé* of his paper on "The Military Sanitary Organizations of some of the Great Armies of the World," after which Major Havard demonstrated the equipment of the United States sanitary soldier on the person of a member of the Hospital Corps who was present for that purpose. Colonel Aiden, U. S. Army followed with some notes on the course of instruction at Army Medical Schools at home and abroad, with special reference to the training of the medical officer. "The Remote Effects of Gunshot Wounds of the Extremities" was the title of the paper read by Lieut.-Colonel C. M. Woodward, ex-Surgeon-General Michigan State Troops, and "First Aid on the Battlefield," that of Surgeon H. G. Beyer, U. S. Navy.

The last-named paper contained an excellent presentation of the duties and responsibilities of medical officers on the field of battle, the positions to be taken for rendering first aid and those to be selected for the establishment of field hospitals. Naval surgeons, apparently, do not forget that crews may be landed and that they may have to deal with wounded men under the same conditions as their Army brethren. Major William H. Egle, Surgeon Pennsylvania National Guard, occupied some time in following up the history of the troops of his State to the present time. The first encampment of the Guard, at the Centennial, was considered a failure; but it has seen much active service since then, and is now in most efficient condition. During the course of the day several papers were read by title in the absence of their authors and for want of time.

At 3:30 p.m. the Association met in the Hospital grounds at Washington Barracks, where Captain J. M. Cabell, U. S. Army, superintended a litter and ambulance drill, with illustrations of first aid by a detachment of the Hospital Corps company on duty with the garrison. At 4:30 the meeting embarked on the steamer *Macalester*, for Marshall Hall, a summer landing a little below Mount Vernon, where the Committee of Arrangements had a planked shad dinner in preparation. The party returned to Washington about 10:30 p.m. Next day many of the delegates crossed the Potomac to inspect Fort Myer, Virginia, and be present at a drill of the cavalry companies stationed at this post. Only a few followed out the original program, by making the special excursion to the field of Bull Run.

An excellent exhibit of surgical instruments, dressings and first aid cases, etc., was held in the Armory of the Washington Light Infantry Corps in connection with the meeting.

The fifth annual meeting will be held in Buffalo, N. Y., in May, 1895.

Texas State Medical Society.

The Society Indorses the Public Health Bill of the American Medical Association.

AUSTIN, TEX.—The State Medical Association met, for the third day, April 26, at 9 o'clock.

The Section on Medical Jurisprudence being called by President Sears, Chairman B. F. Brittain, of Arlington, read his report, which, on motion, was referred to the Publishing Committee without debate.

An invitation was received and accepted to visit St. Mary's Academy.

Dr. D. R. Wallace, of Waco, read a paper on the "Increase of Mental Unsoundness," at the conclusion of which a recess was taken for the purpose of selecting members of the Nominating Committee, with the following result:

W. R. Blaylock, McLennan County; G. W. Abney, Robertson; L. Ashton, Dallas; J. M. Frazier, Bosque; G. W. McCaleb, Gonzalez; J. H. Barham, Nacogdoches; J. M. Strayhorn, Williamson; W. P. Powell, Montgomery; J. D. Osborn, Johnson; J. P. Oliver, Burleson; W. M. Cunningham, Bastrop; J. S. Price, Jefferson; S. N. Sholars, Orange; J. H. Reuss, DeWitt; William Caston, Navarro; A. B. Gardner, Austin; W. T. Evans, Leon; E. D. Capps, Tarrant; J. S. Morris, Madison; W. B. Newland, Coryell; J. H. Blackburn, Palo Pinto; S. Bowers, Washington; J. T. Carter, Fayette; F. R. Martin, Hays; C. M. Alexander, Coleman; David Cerna, Galveston; R. C. Nettle, Falls; E. L. Menefee, Hood; R. E. Moody, Nolan; A. S. McDaniel, Bexar; J. E. Thomas, Limestone; George D. Bond, Hill; J. A. Davis, Travis; J. E. Gilchrist, Cooke; W. J. Bever, Houston; J. W. Carhart, Lampasas; E. W. Lenk, Anderson; J. M. Inge, Denton; R. Rutherford, Harris; R. S. Lewis, Wichita; T. J. Bell, Smith; F. A. Fuller, Cherokee; J. L. Autrey, Freestone; B. F. Church, Terrell; Z. T. Bundy, Ellis; J. D. Law, Bell.

At the conclusion of the selection of delegates, Dr. Cunningham discussed Dr. Wallace's paper, and reported some of his experiences with cases of insanity, and the paper was referred to the Publication Committee.

Dr. E. D. Capps, of Fort Worth, followed with a paper entitled: "Morphin Suicides—Prevention—Treatment of Opium Poisoning." Dr. Kennedy, of Galveston, discussed the paper and agreed with Dr. Capps in the main. Dr. Cerna, of Galveston, also made some remarks on the subject and Dr. Wooten, of Austin, followed and related some of his experiences with morphin cases. Dr. Warfield, of Galveston, and Dr. Osborne closed the discussion, and the paper was referred to the Publishing Company with a vote of thanks to Dr. Capps for his paper.

The remaining papers in this Section were referred to the Publishing Company by caption.

A report was received from the Judicial Committee finding the credentials of the following persons regular and recommending their admission to membership: F. A. Fuller, J. E. Brown, William Gammon and L. D. Hill.

Dr. Denton offered a resolution denouncing a secret nostrum manufacturing company. Referred to committee.

The report of the Johnson County Medical Association was read. Dr. Yates, of Plainview, made the report and presented a short paper on guaiacol.

Reports were also received from the Galveston County

Association, the Williamson-Bell-Milam Society, the Collin County Association, and the Hill County Association, indicating strong organization and manifest interest therein.

The Section on State Medicine was called and Dr. Bennett, of Austin, read a paper on "The Progress of Preventive Medicine," which was referred to the Publishing Committee with instructions to publish. On motion it was decided to send a copy of Dr. Bennett's paper to the Texas delegation in Congress as the official expression of the Association on sanitary legislation.

Dr. J. W. Carhart, of Lampasas, offered the following resolution, which was adopted:

Recognizing the necessity for additional and advised legislation by the National Government for the protection of the public health against diseases other than cholera, smallpox and yellow fever, which diseases science has demonstrated to be preventable by proper attention to sanitation, the Texas State Medical Association hereby indorses the action of the AMERICAN MEDICAL ASSOCIATION in its petition to Congress to create a Department of Public Health, with an executive officer at its head with equal power and dignity with that of the executive of the other departments of the Government.

Resolved, That the neglect to make laws for the protection of the public health against preventable diseases, in accordance with the revelations of sanitary science, is attributable to the want of definite information on the part of Congress as to the requirements, and not to indifference or disregard of the rights of the public to such protection, and that in the absence of a head of the public health interest, the action of the AMERICAN MEDICAL ASSOCIATION should be taken as an expression of medical opinion on this subject.

Dr. Carhart read a paper on "How to Prevent Typhoid Fever," which was referred to the Publishing Committee without discussion.

He was followed by Dr. Clarence Marfield, of Galveston who read clinical notes on typhus fever in northern Mexico, based upon personal experience, he having but recently recovered from an attack of the fever contracted while practicing in Durango. His paper was largely descriptive, and he asserted that with the mode of living of the lower classes in Mexico it was a wonder that they lived at all, and attributed to the utter disregard of all laws of sanitation the spread of contagion in that country. He remarked that the suggestion of a bath to a Mexican patient was equal to suggesting the swallowing of a dose of poison, and that in consequence layer upon layer of dirt accumulated upon the bodies of these people, ending in disease, poisoning the very air they breathe, and neutralizing the natural salubrity of the climate. According to the Doctor, the native Mexican looks stoically upon the approach of death and resists the aid of science to prevent its attack.

The completion of the reading of the paper was prevented by the entrance of the Nominating Committee, and its reading was continued until to-morrow.

The Committee reported the following officers selected for the Association for the ensuing year: President, J. W. McLaughlin, of Austin; First Vice-President, W. L. York, of Decatur; Second Vice-President, W. R. Blaylock, of McGregor; Secretary, H. A. West, of Galveston; Treasurer, Dr. Laurendon, of Dallas.

The Committee also announced the selection of Dallas as the place for holding the next annual meeting, and the meeting adjourned until 8 p.m.

This afternoon the doctors went up the lake on the *Ben Hur*.

A short night session was held and officers installed.

The banquet at the Driskill was largely attended and speeches were made.

AUSTIN, TEX., April 27.—The State Medical Association met again this morning at 9 o'clock and disposed of the unfinished section work.

Resolutions condemning the custom of bidding for the practice of communities, jails, poor farms, and also denouncing as contrary to the ethics of the profession the giving of certificates to secret formula medicines and deprecating the advertising of such medicines in medical journals were introduced, discussed and passed.

An unsuccessful attempt was made by resolution to abolish the annual banquet.

All unread papers were referred to the Publication Committee by caption.

An invitation was received and accepted from the Mississippi Valley Medical Association to attend its next annual meeting, after which the session adjourned till the fourth Tuesday in April, 1895, when it will convene again in Dallas, Texas.

Blank Applications for membership in the ASSOCIATION, at the JOURNAL office.

BOOK NOTICES.

Report of Typhoid Fever. Baltimore: The John Hopkins Hospital Press. 1894. Volume IV. Number 1.

The broad and enduring basis on which this hospital was founded, and the careful manner in which the provisions of the trust have been carried out, are year by year bringing forth fruit of scientific value. The present report is one on typhoid fever by Prof. Osler. It is divided into eight chapters, as follows: 1, "General Analysis and Summary of the Cases"; 2, "Treatment"; 3, "A Study of the Fatal Cases"; 4, "Notes of Special Features, Symptoms and Complications"; 5, "Neurosis Following Enteric Fever known as the Typhoid Spine"; 6, "Report of Two Cases of Post-Typhoid Anemia with Remarks on the Value of Examination of the Blood in Typhoid Fever," by Dr. W. S. Thayer; 7, "The Urine and the Occurrence of Renal Complications in Typhoid Fever," by Dr. John Hewettson.

The volume concludes with a chapter on typhoid fever in Baltimore.

The work is illustrated by charts and diagrams. It is printed on good paper and has broad margins, and is altogether creditable.

An examination of the report shows that there were 229 cases of typhoid fever treated in the wards. Of these, 22 died, making an average rate of mortality 9.6 per cent. Under the cold bath system, which has been adopted for most cases, the mortality has been reduced to 7.1 per cent.; but a "large proportion of cases, 75 per cent. at least," says Prof. Osler, recover under any and all forms of treatment; even without the good nursing and regulated diet, upon which we lay so much stress. "Medicines are not, as a rule, indicated. No known drug shortens by a day the course of the fever; no method of specific treatment, or of antiseptics of the bowel has yet passed beyond the stage of primary laudation." This somewhat pessimistic view will not, we think, be adopted without protest by our distinguished friend from Youngstown, Dr. Woodbridge, nor by Trouessart or Bouchard. The latter insists on the four indications: General antiseptics, intestinal antiseptics, antipyretic medication, and regimen, and Trouessart states: "There are few diseases in which rigorous intestinal antiseptics is more plainly suggested." Certainly, there would seem to be reason for further experimentation with antiseptics, when it is seen that under the best form of treatment, as recommended by Prof. Osler, there is no such thing as cutting short the usual duration of the disease.

In regard to typhoid fever in Baltimore, Prof. Osler refers to the well-known unsanitary conditions in that city, and states that "while it has a well arranged water supply, still with unprotected sources and constant liability to contamination, it has nothing else—no sewage system, no system of isolation of the sick, no hospital for infectious diseases, no compulsory notification of such a disease as typhoid fever, no disinfecting station, no system of street watering, no inspection of dairies, no inspection of meat. The streets are cleaned, but usually so carelessly that for a large part of the year the citizens breathe a mixture of air, horse dung, and filth of all sorts"

Prof. Osler shows from the health reports of Baltimore that there has been since the year 1888 a yearly average of 229 cases of deaths from typhoid fever, but the morbidity of that disease, namely, those taken sick, can not be ascertained, owing to lack of registration. These facts, which Prof. Osler so forcibly sets forth in this volume, are not new to sanitarians generally of this country, nor indeed to the Board of Health of Maryland; but even at the expense of what some of our literary friends might term "damnable

iteration," it is well to keep them before the public. Perhaps coming from an institution of the high professional standing of the Johns Hopkins Hospital, and from the pen of so distinguished a scientist as Prof. Osler, the legal gentleman holding the purse strings of the city exchequer may relax them sufficiently to cause the necessary sanitary work to be instituted.

Pain in its Neuro-Pathological, Diagnostic, Medico-Legal, and Neuro-Therapeutic Relations. By J. LEONARD CORNING, A.M., M.D. Illustrated. Philadelphia: J. B. Lippincott & Co. 1894. Cl., pp. 328. Price \$1.75.

This book is divided in two parts of which Part I discusses the physiology, pathology and clinical characteristics of pain, its diagnostic value, and medico-legal relations. Part II is wholly devoted to the special therapeutics of pain. The last chapter discusses "torture or the infliction of pain as a judicial punishment or for the purpose of extorting a confession of guilt."

The book, as a whole, is scientific, well written and interesting. The author has elaborated his well-known views on the therapeutic effects of the application of compressed air, and expresses a belief that many cases of spastic hemiplegia may be permanently cured by the administration of antipyrin internally and jugular compression while the patient is placed for a few moments in the compressed air chamber. Many cases are cited, and while the dangers of the induction of the caisson disease are probably not overestimated, yet the author seems to have established the fact that it has a potent value in many hitherto intractable cases. In disseminated sclerosis, in spastic spinal paralysis, and in polio myelitis, the result was negative and it is contra-indicated in cerebral-hemiplegia and articular rheumatism. He asserts that the compressed air treatment is "absolutely unapproachable" in all "cerebral and cerebro-spinal difficulties of a functional character, in which pain, exhaustion, insomnia or depression are prominent features." The book should find a place in the library of every neurologist, or general practitioner giving attention to this class of cases.

First Aid in Illness and Injury. By JAMES E. PILCHER, Captain Medical Department U. S. Army. New and revised edition.

In this little work is successfully accomplished the difficult task of presenting in a clear way important medical points to the non-medical mind. This work finds its largest field of usefulness in the instruction of soldiers, sailors, policemen, firemen, railroad men, etc., the classes most frequently called upon to meet a medical emergency. To avoid the criticism that "a little knowledge is a dangerous thing," instruction of this kind should be under the direction of a competent medical man and such a book as this used as a text-book. To the ordinary layman the book, without such personal instruction, would be of little value. Knowledge of how to meet a medical emergency should be more general; dissemination of such knowledge should be, "especially among the classes referred to," encouraged in America as it is in Great Britain and on the Continent. The new edition of Dr. Pilcher's work presents a number of changes. The entire eighteenth chapter has been re-written. It will maintain the place earned by the former edition as a standard work of its class.

Transactions of the New York State Medical Association for the Year 1893. Vol. X. Edited for the Association by E. D. FERGUSON, M.D. New York City. Published by the Association.

This handsome volume, printed in the same style as the preceding volumes, contains also a general index which includes the preceding volumes as well.

The printed papers with the discussions are those of the last regular meeting, held in New York City Oct. 9 to 12, 1893, all of which have been elsewhere printed. In addition, the volume contains memoirs of deceased Fellows, and the minutes of the sessions, and of the Council. That the Association is flourishing is manifest from the long list of members who attend its meetings and subscribe to its tenets. A large proportion of its Fellows are members of the AMERICAN MEDICAL ASSOCIATION and among its staunchest supporters.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, MAY 12, 1894.

THE RATIONAL TREATMENT OF DIPHTHERIA.

Diphtheria, more than any other disease, has taught physicians how little can be accomplished by any treatment not fully based on a clear understanding of the causes and determining conditions concerned in the production of the disturbances. All speculative reasoning has not yet given us a single remedial measure which can be relied upon to influence the outcome of that disease. Fortunately, however, recent studies have now opened the definite prospect of combating successfully diphtheritic infection by employment of the very same means by which the system protects itself during spontaneous recovery.

One of the most fundamental recent discoveries in pathology was the demonstration—less than four years ago—by BEHRING (in conjunction with KITASATO) of the antitoxic properties of the blood of immune animals. It was shown that in diphtheria (as well as in tetanus) the recovery from infection or from poisoning with the toxins of the specific bacteria, was accompanied by the formation of a certain substance capable of neutralizing the poisonous effects of the bacterial products. This "antitoxin" is found in the serum of the blood of recovered animals. It was later on shown by EHRLICH that it also passes into the milk of nursing females in considerable quantity. The antitoxic blood serum when mixed with a proportionate amount of a culture of the bacteria of that disease renders the injection of that mixture harmless to fresh animals. It is as yet undecided whether this result is due to a chemical interaction between the poison and its antidote, or, what is more probable, whether it depends on an effect upon the animal system whereby the latter is made insusceptible to a proportionate dose of the bacterial poison.

But greater interest even, centers in the fact that

antitoxic serum will neutralize the poison, not only when not mixed with it in the flask, but also when the two are injected separately and at different times. If the antitoxin be introduced first, it remains in the animal system without appreciable loss for some days, and even weeks will elapse before it is entirely eliminated. If, however, the infection or the poisoning with the bacterial products precedes the injection of the immunizing serum, then too, the latter will protect the animal as long as the effects of the poison have not yet become manifest. After the symptoms have begun to appear, the injection of antitoxic serum can no longer be expected to exert a preventive influence. But it can now combat the bacterial poisoning directly, and thus prove *curative* in the most absolute sense of the word, provided the dose of serum is increased to several hundred times the amount necessary for mere prevention.

The most varied experiments by BEHRING and others, have shown beyond doubt that animals infallibly doomed by diphtheritic infection or diphtheritic intoxication can be saved with certainty, if a *sufficiently active serum be employed in sufficient quantity and at not too late a period after the infection.*

The activity of the serum of an immunized animal, that is to say the amount of the antitoxic substance formed, depends on the amount of diphtheria-culture which the animal has withstood. The most active serum is obtained by poisoning animals at first cautiously with sterile cultures, and later on with increasing quantities of the most virulent diphtheria bacilli grown in broth. By thus increasing the tolerance of an animal to the diphtheria toxins by successive inoculation during several months, serum of marvelous power can be obtained.

While BEHRING's experiments on animals had warranted a trial in man since some time, a delay occurred on account of difficulty of getting active serum in sufficient quantity for systematic clinical use.

Finally, a report appeared one year, by KOSSEL, of a trial of the serum treatment on eleven children with diphtheria in KOCH's institute. Of this number two died. Although both the low mortality, as well as the tangible improvement in the individual cases spoke in favor of the method, the trial was not extensive enough to decide the utility of the method.

At the International Congress at Rome, HEUBNER related his experience with the injection of diphtheria-antitoxin furnished by BEHRING. He had used it on seventy-nine children. It does not appear from the short report as yet published, what death rate existed amongst these cases. But in summing up the mortality of ninety-six consecutive cases which entered the hospital during the time he was supplied with serum, he records 38.5 per cent of deaths, while of these ninety-six cases but seventy-

nine—and these the selected severest type—were really treated with serum. In comparison, he gives the mortality of the previous ninety-six children not so treated, as 62.5 per cent, and of the next series, likewise not specifically treated, as 49 per cent.

While his conclusions are in favor of the efficacy of immunizing serum, the abstract of his paper does not permit the reader to weigh the evidence fully.

A report of a much more positive and satisfactory character, and one destined to introduce the universal clinical use of diphtheria antitoxin, has finally appeared from KOCH's laboratory over the signatures of EHRLICH, KOSSEL and WASSERMANN (*Deutsche Med. Wochenschrift*, April 19, 1894). The serum was obtained from highly immunized goats. Its activity was measured by testing the quantity requisite to neutralize the fatal dose of (sterile) diphtheria culture for 1,000 grams animal weight (guinea pig). The amount of antitoxin which can save an animal from ten times the minimal dose the authors call the immunizing unit (I. U). The serum employed was of such strength that one cubic centimeter contains sixty I. U.

Injections of this serum were made on 220 diphtheritic children in various hospitals of Berlin. The dose employed was 130 to 200 I. U. (2.15—3.5 ccm.), and in a few of the more severe cases the injections were repeated every day. Of the 220 cases, 168 cases recovered, *i. e.*, 76.4 per cent.—an exceptionally favorable figure in German hospital experience. Of the cases requiring tracheotomy, sixty-seven gave a mortality of 44.9 per cent, while those not requiring operation had but 14.3 per cent. of deaths.

A better way of showing the efficacy of the treatment is obtained by classifying the cases according to the day of the disease on which the treatment was begun (the figures in brackets giving the number of tracheotomies):

Beginning of the treatment on the	Total number.	Recoveries.	Per cent. of recoveries.	Deaths.
First day	6	6	100	6
Second day	66 (9)	64 (7)	97	2 (2)
Third day	29 (8)	25 (7)	86	4 (1)
Fourth day	39 (14)	30 (10)	77	9 (4)
Fifth day	23 (10)	13 (4)	56.5	10 (6)

The total shows the remarkable influence of the treatment on the disease, as long as it is yet uncomplicated. For the streptococcus invasion, so frequently secondary in diphtheria, is not controlled by the specific treatment. Indeed, a further analysis shows that the deaths were generally due to complications, since of fifty-two deaths, twelve were due to sepsis, thirty to pneumonia, two to miliary tuberculosis and eight to subsequent affections (nephritis and cardiac failure). The authors state it as their opinion that a more liberal use of the serum would help to prevent these late accidents, even to a greater extent. They further show that their death rate is largely due to delay in sending the patients to the

hospitals, since one-half of the fatal cases died before the end of the second day of treatment.

While KOCH's laboratory has not yet offered to supply the public with the immunizing serum, the "Chemische Fabrik auf Actien (vorm E. Schering)" has sent out a circular advertising a diphtheria antitoxin solution made from the serum of immune animals, under the supervision of DR. ARONSON, who has done work on the same subject. It is claimed that its activity has been tested and found equal to twenty I. U. per cubic centimeter according to the nomenclature of the authors quoted. It is recommended to use one ccm. for the prevention of diphtheria after exposure. While the circular also speaks of curative effects to be obtained with the antitoxin, no actual therapeutic experience with it is mentioned. A note, however, has just been published by BEHRING, according to which the advertised antitoxin does not possess the full degree of activity claimed for it.

"THE GREAT WHITE PLAGUE."

DR. BRYCE's contribution¹ to the study of the extinction of the tuberculosis is, on the whole, a rather depressing document—chiefly because it deals so largely with the agency of tuberculous cattle in the propagation of the disease in man. It is only within the past year or two—that is to say, since KOCH discovered his tuberculin test in 1891—that the extent of bovine tuberculosis has been fairly comprehended; and already we are confronted with data upon which may be based statistics whose enormous totals make the figures of an ordinary sanitary problem insignificant in comparison.

Prior to 1891 the examination of cattle for suspected tuberculosis consisted, in the main, of such examination of the glandular system as might be made by the eye, by palpation and by auscultation, while the crucial diagnostic test was that of the famous French pathologist for enteric fever—the *post-mortem*. Now, all this is changed and by the use of tuberculin—a means for proving the presence of tuberculosis, "so delicate and yet so accurate that the most unbelieving among veterinarians are to-day confessing to its marvelous diagnostic value and significance"—it has been demonstrated that from 2 to 3 per cent. of the cattle in the State of New York are afflicted with the disease.

If only the lower percentage holds good for all the cattle in the United States, then there are over 1,200,000 head, with an aggregate value of nearly \$14,000,000, which should be killed forthwith, since their destruction is the only certain method of preventing the further infection, not only of other ani-

¹ Report on tuberculosis. By P. H. BRYCE, M.A., M.D., Secretary Provincial Board of Health, Toronto. Presented to the Provincial Board of Health, Feb. 15, 1894, and adopted with recommendations therein contained.

mals but of man himself from their flesh and milk.

It is possible, indeed, that even these stupendous aggregates are below the mark. DR. BRYCE, in his report, cites figures to illustrate the relative prevalence of tuberculosis in cattle in different countries, from which it is learned that 4.5 per cent. of the cattle slaughtered in Berlin were tuberculous, 9.5 per cent. of those in Upper Sileria and 12.22 per cent. of 12,000 head slaughtered in England under the Pleuropneumonia Act of 1890. Computation halts before applying these percentages to the sixty-odd million head of cattle on farms and ranges in the United States, with their aggregate value of nearly \$700,000,000. The \$100,000 which a recent Washington dispatch tells us the Department of Agriculture is preparing to expend "in eradicating tuberculosis among cattle," seems pitifully inadequate in comparison.

Still, as DR. BRYCE says in speaking of PROF. Kocu's discovery, "some light has come which has served in some slight degree to make the cloud hanging over this all-important subject less dark and to cause, perhaps, even some rifts in it to appear." The prominence recently given to the success of measures of prophylaxis against "the great white plague," with its annual tale of 163,500 victims in this country alone, is, of itself, full of promise. The indisputable fact that its death rate has been reduced to one-fifth of its former proportions by the rigid enforcement of the simple and practicable measure of disinfection of the excretions and discharges of every tubercular patient, and of every material thing liable to be contaminated by such excretions and discharges, is a rift in the cloud through which may be discerned the time when tuberculosis, "like leprosy and the black death, shall be of interest merely to the historian of human progress."²

LIABILITY FOR TAKING AWAY MEDICINE.

A very singular case was decided by the Supreme Court of North Carolina March 6, 1894, (State v. DANIEL). The defendant apparently a physician, was indicted for and convicted of obtaining goods by false pretenses. The indictment was as follows: "The jurors for the State upon their oaths present that J. H. DANIEL, late of the County of Wake, wickedly devising and intending to cheat and defraud, on the 27th day of August, 1893, with force and arms, at, and in the county aforesaid, unlawfully, knowingly, designedly, and feloniously did, unto one MARK BARKER, falsely pretend that certain medicine, to-wit, one ounce thereof, in the possession of the said MARK BARKER, was too strong to be applied to a sore on the face of the said MARK BARKER, whereas in truth and in fact the said medicine was not too strong to be applied to the sore aforesaid; by means of which said false pretense, he, the said J. H. DANIEL, feloniously,

knowingly, and designedly did then and there unlawfully obtain from the said MARK BARKER the following goods and things of value, the property of said MARK BARKER, to-wit, one ounce of medicine, with intent then and there to defraud, against the form of the statute," etc. After a verdict of guilty, the defendant moved in arrest of judgment, because the bill did not charge an indictable offense, but merely the expression of an opinion as to the strength of the medicine. The lower court overruled the motion, and pronounced judgment, from which judgment an appeal was taken to the Supreme Court, which has granted the motion denied by the lower court. It says that the representation being that the medicine was too strong for further use, and the inference being that it was the intention to temper or weaken it, it might well have been held that the judgment ought to have been arrested. But there was the stronger ground that in no case, which could be found had it ever been held that a false expression of opinion, alone, is indictable. The only question left, then, was whether the representation alleged to have been falsely made was a mere opinion or a statement of a fact. It would seem that it could only be construed to be the expression of a judgment of the effect of the medicine upon the sore for the healing of which it had been applied. Too strong for what? For the sore it was intended to heal? This was a matter of professional judgment, and necessarily an opinion. It was impossible to be stated as an abstract fact. And it would be too harsh a rule, the court further says, to hold the physician or the lawyer to criminal account for a statement upon a professional question when it turned out that his judgment was at fault, and by reason thereof his patient or his client had been injured. Especially so, when it has been so often held that such expressions by non-professional persons as to conditions and qualities of goods or animals are only their opinions, and not indictable.

GRADUATION IMPLIES A DIPLOMA.

The fact that a man is a graduate from a medical school carries with it a presumption that he has received a diploma. By the fact of graduation, he becomes entitled to a diploma. So says the Supreme Court of Wisconsin in the case of RIDER v. Ashland County, (decided Feb. 23, 1894,) which was an action brought by a physician to recover a balance claimed to be due him for medical services.

He had testified that he was a practicing physician, and a graduate from an incorporated school of medicine—the Albany Medical College—but was not a member of any medical society in Wisconsin. It was objected that this evidence did not show that he was a qualified physician, within the meaning of the Wisconsin statute providing that no person prac-

²The Extinction of Tuberculosis. By GEORGE H. ROHE, M.D., JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. May 5, 1894. p. 659.

ting physic or surgery, or both, shall have the right to collect, in any action, in any court, fees or compensation for the performance of any medical or surgical service, unless he shall have received a diploma from some incorporated medical society or college, or shall be a member of the State or some county society legally organized in the State.

But the Supreme Court declares that it would be a very narrow construction which should hold that one who had acquired the learning and received the training of such a school—was in fact a graduate of such a school—comes under the ban of this statute, if by reason of some accident or oversight, his diploma has not been physically received by him.

The object to be secured by the statute was, the court continues, not so much that the physician should have the diploma, as it was that he should have the learning and training of such a school. The statute was enacted to furnish a remedy for an evil which was supposed to exist. The people were imposed upon by the ignorance and quackery of medical pretenders. The statute is to be fairly construed to advance the remedy intended. For that purpose it was intended to provide that only men who had been educated and trained in medicine should collect pay for medical services. The most convenient—perhaps the most natural—way of expressing the qualification was as in the words of the statute—that he should have received a diploma. The diploma is a certificate evidencing the fact of graduation.

INDIVIDUAL COMMUNION SERVICE FOR SANITARY REASONS.

DR. FORBES, of Rochester, N. Y., has been instrumental in causing the adoption of one of the long-looked-for innovations in the Central Presbyterian Church of that city, in respect to the manner in which the rite of communion is therein celebrated. He has caused the ordering of two thousand small cups for the communicants of the church. At the May service of the church, each communicant will be handed his or her own cup or glass, instead of, as formerly, only six to ten cups for some 1,600 participants. DR. FORBES makes the statement that twenty-two diseases may be communicated from mouth to mouth by means of drinking vessels. In this number he includes tuberculosis and catarrh. He has already obtained some backing, in his notions, from the Pathological Society of his city, and he purposes to urge the Board of Health, as well as the Legislature of 1894-5, to pass ordinances and laws that will prohibit the use of mutual drinking cups by religious bodies.

CORRESPONDENCE.

EUROPEAN LETTER.

[From the Berlin correspondent of the JOURNAL.]

THE GERMAN CHIRURGICAL SOCIETY.—TWENTY-THIRD CONGRESS.

BERLIN W., April 18, 1894.

The first session of this Congress, held annually at Berlin, was opened to-day in the Langenbeck House by Prof. Es-march, of Kiel. Having touched in his opening speech some interests of the Society, he held a necrologue on Theodor Billroth, who died at Abbazia February 6. He had been one of the founders of the Society. His renowned inquisitions on bacteria and wound-healing, his part in promoting surgical proceedings on the stomach, his labors in surgery of the ear, his attention to the hospital service for the sick, his humanity, his universality, his interest for art and sciences of all kinds found a warm-hearted commentator in the necrologist. In the year 1893 out of the members of the Society, Prof. Luecke, of Strasburg, and Dr. Passavant, of Frankfurt a. M., were dead, in remembrance of which the Society arose.

The introductory paper, "On the Final Results of Tuberculous Inflammation of Hip-joint treated in the Conservative Way," was read by Bruns, of Tübingen. He mentioned first the researches of Billroth in the same direction, and then gave his own results, going backward to statistics of forty years. His hospital, being situated in Wurtemberg, a State belonging to the German federation, and giving the possibility of a perfect and sure inquiry, his figures may claim an extraordinary worth. He reports 600 cases of cured tuberculous disease of the hip-joint. Cases in observation less than one and one-half to two years were omitted. The disease for the most part appears in young individuals up to about twenty years of age. Fifty per cent. were cured after having been sick four years in the average. When older persons fall sick of tuberculous hip-joint, the hope to be cured is diminished. Often when the coxitis is cured, tuberculosis of other organs sets in and leads to a fatal end. Those who are cured can avail themselves pretty well of the leg and hip-joint, which remain totally fixed in two-thirds of the cases. Then he went over to the remaining deformities, especially the ankylosis in different angles and the shortenings of bone. Bruns is not at all a friend of the excision of tuberculous hip-joints; however, he will wait with a definitive decision on this point till the modern methods of wound-dressing have had their full work in this disease.

DISCUSSION.

Dr. Schede, of Hamburg. Of 229 cases of coxitis since the year 1880 he has treated 112 in the conservative way, with extensions, dressings, injections, etc. Of these, seventy-six have been cured, 68 per cent. Those treated with injections of iodoform gave a result of 82 per cent. cured. Resections, 60 per cent. cured.

Prof. Helferich, of Griefswald. The conservative method will be the method of the future. The children must be extremely well nourished, and sent to the country or seacoast, as is done in England already.

Prof. Gussenbauer, of Prague, saw a case of tuberculous coxitis cured without any treatment at all, only by good outward conditions of air, residence, food, etc., on which, as it is, the hope of curing tuberculosis is founded. If there is no reaction of tissue in a person sick of tuberculosis, every way of treatment will fail.

Prof. v. Bergmann found a rapid recovery of the general health after operation of tuberculous hip-joint. His indications for resection were: formation of large masses of pus; of fistulæ, and necrosis of bone. Some cases should never suppurate during all the time of the disease.

Prof. Hoffa, of Wurzburg, read a paper on "Anatomo-Pathological Demonstrations concerning Congenital Luxation of Hip-joint." By histological researches he found that on the place of resection in the acetabulum new built chondral (hyaline) substance was produced. In some cases the ligamentum teres is absent. In these cases there is crepitus when the leg is moved. They can be improved without operation. Where the ligamentum teres is preserved it slips between the margin of the acetabulum and the femur, and any orthopedic measures will by necessity part it. Operations should be done when children are three to six years of age. Then prognosis is best.

In the discussion Schede rejected operations in adult persons. Lauenstein sees the danger of the operation in the circumstance that the little patients let urine into the dressings. This he prevents by putting them on the wounded hip, by elevating the dressed leg and by a sort of wire mask which holds the dressing on the wound. Its ends are fastened up and down by cambric rolls, so that the perineum is let free. Then the dressings remain clean.

The German medical schools in the different universities during the last winter mustered 7,876 students, of which 1,279 studied at Berlin, 1,114 at Munchen and 788 at Leipzig.

Prof. Heubner, of Leipzig, has been nominated successor of Prof. Hensch in the Chair of Pediatrics in Berlin. Prof. Dr. Escherich at Graz, Austria, will replace Heubner as director of the infirmary for the diseases of children, and docent in the University.

Prof. Dr. Disse, of Göttingen, has been nominated Professor of Anatomy at Halle.

April 19, 1894.

We are obliged to add to our former report, that Prof. Bruns had collected 600 cases of tuberculous inflammation of hip-joint. Of 200 of these cases he was able to get data, and it is these 200 cases to which his percentage of cures, deaths, etc., refer.

Dr. Habs, of Madgeburg, presented to the Congress "Eighteen Cases of Exarticulation of Knee-joint after the Method of Hagedorn." The operations were done, for the greatest part, some years ago. All those presented go on their stilts in a very clever manner and with great tenacity. A girl, operated upon fourteen years ago, dances whole nights on her wooden leg without letting out any. Others can bear bags of 200 pounds weight without more help than a staff, for better directing his march. The patella in this method is fixed backwards, the surface of the femur being in this manner protected from getting injured.

Prof. Küster, of Marburg, read a paper on "Rhinoplastics" from the skin of the arm. The nose in the case had been destroyed by lupus. If we take the skin of the glabella, [Indian method] the face of the patient is deformed by the scar. The proceeding, as used by Küster, had already been used by Antonio Branca in the middle of the fourteenth century, and afterward neglected. The operation was finished in seven different sessions. The skin newly implanted was fixed at the wound within seven days. The position of the arm was borne well during the first days, but afterwards the operator was obliged to resort to morphia to get over difficulties. The result is now a very good one, but there is a danger that the new implanted skin will shrink. Therefore this is best employed when there are only small defects of the nose. However, rhinoplasty gives but small glory to surgery. The newly built noses soon shrink and take a very unpleasant aspect.

Prof. Heidenham, of Griefswald, showed some cases of "Resection of Foot with Dorsal Position of the Incision."

Dr. Peterson, of Kiel, spoke on the "Treatment of the Colles Fracture of Radius" (fractura radii typica). There

are many proceedings of dressings. The best is: After careful re-position of the fragments, the arm is fixed by a simple sling formed by a blanket. The hand hangs flapping downward. Prof. Bardeleben approved this view, stating that for the good result of this method very intelligent patients were wanted.

SECOND DAY.

Prof. Küster, of Marburg, read a paper "On Early Operation in Osteomyelitis." The germs of the disease may be implanted by scratch-wounds. As for treatment, he thinks best to lay open the medulla ossium by broadly chiseling the diseased bones and evacuating the pus. Twenty-four cases were seen, of which fourteen were operated upon in the second week of the disease; nine recoveries. Of three patients operated upon in the third week, two died. In the following weeks, results were better. Therefore he gives counsel to operate as early as possible. Some doubts may be felt about diagnosis, but this will soon be cleared up, the symptoms of the swollen and aching bones being unmistakable. Only when the development of symptoms is slow, the diagnosis may become difficult.

DISCUSSION.

Dr. Karewski, of Berlin, was of the same opinion concerning early operation of osteomyelitis. He calls it even an abortive treatment. Fourteen cases were operated upon, of which six had no suppuration; in the remainder, pus had developed. He operated in the two first weeks of the disease. The operation is not so dangerous for children, great loss of blood being avoided. No deaths in consequence of operation or immediately by the disease. A man of thirty years died after being operated upon for osteomyelitis after he had recovered from an attack of influenza.

Dr. Koerte, of Berlin, has made twenty operations in children up to ten years of age, of which six died; the rest recovered.

Dr. Schede, of Hamburg, had formerly the opinion that osteomyelitis was a benign disease. After he had seen 150 cases in Hamburg his opinion was changed. Osteomyelitis was extremely dangerous if the pelvis or lower mandibles were attacked. After all, osteomyelitis was a part of septicopyemia, with localization in the bones. The acute cases were hopeless.

Dr. Gusenbauer had seen four hundred or five hundred cases of osteomyelitis. It is an endemic-epidemic disease. Its causation is founded on the presence of the same bacteria as other purulent diseases of swift progress. Even in desperate cases, operation could sometimes save life.

Dr. Sonnenburg says that it is impossible to give general rules; the gravity of the disease is dependent on bacteria of different quality and virulence. To the degree of the disease the treatment should be adapted. Light cases could be treated as a localized disease.

Dr. Helferich, of Griefswald, reported a case of operation of ankylosis of the joint of the lower mandibles in a child, with good function of the joint.

The Revision of the Code.

To the Editor:—Please allow a member to refute a misstatement which seems to have been purposely made by your voluminous, vituperative and dogmatic correspondent, "A Conservative Member," in his last—the tirade against the committee on revision of the Association's Constitution and Code (April 21 issue). He asserts, "they were not authorized to transmogrify the Code," and that they have "greatly exceeded their instructions," etc. Now, one who attended the Detroit meeting, should know that this committee was doubly instructed to do just what it has done. The committee's announcement of their instructions and plan of work, in the Nov. 19, 1892 JOURNAL contains an

imperfectly condensed statement of the two sets of resolutions which were unanimously passed by the ASSOCIATION at two different days' sessions. Both of these sets of resolutions were offered in sympathy and harmony with President Marcy's wise and liberal recommendations contained in his admirable address, and there was not a voice raised to question the unanimity of their adoption. The first related to needed changes in the ASSOCIATION'S Constitution and By-Laws, while the second set, that which was unanimously reported from the Committee on Nominations, had more special reference to the needed revision of the Code. In this latter, this committee, already appointed, was distinctly instructed to report *for the adoption by the Association at its next annual meeting*, such changes in the Code and Constitution "as in their judgment will properly liberalize the relations of this ASSOCIATION to the great body of the medical profession."

The committee appointed was composed of honorable representative medical men. They have conscientiously and faithfully performed the work assigned them. In this arduous task they sought the opinions and advice of their fellow-members in the ASSOCIATION (see November, 1892 issue of the JOURNAL, page 605). The re-arrangement of our rules of conduct, and of professional relations to suit these changing and broadening times is no easy task when the changing of faulty rules and customs must seem like the abandonment of orthodoxy to a certain number, until their minds shall have broadened to a full appreciation of the present needs of a successful medical profession. However, the Committee's work has been well done. While the writer would have preferred to have seen the Code still further simplified, say by another 30 to 40 per cent. reduction in space occupied compared with the old Code, yet he recognizes such objection as trivial compared with the incorporation of the fundamental and vital changes needed, as marked out by the Majority Committee's preliminary statement at the Milwaukee meeting. In the presentation of these needed amendments, which, as they stated, required the re-writing of the Code, they have not exceeded, but simply executed what they were told to do. The three vital points attended to are:

1. The omission of superfluous and useless portions.
2. Non-interference with the personal rights of members to protect, by patent, surgical or mechanical appliances, and the divorcing of such worthy invention—the same as the copyrighting of books—from "secret nostrum" making and similar frauds.
3. And particularly, the lessening of the friction and frequent misunderstanding between physicians of different scientific attainments and of various professional purpose, by a more liberal construction of the vexed "consultation" problem.

It does not appear to have occurred to the biased and headstrong mind of "A Conservative Member" that the present anomalous condition of the medical profession in the United States is largely due to these impolitic and unwise or unjust sections of the old Code. He does not seem to see that a considerable school of pronounced irregularity has been "boomed" so to speak into popularity, and the possession of the cream of family practice in many large cities gained through the exclusiveism engendered by the old Code. There is no more potent way to promote a weak cause than to make martyrs of its adherents. And homeopathy would be no more to-day in this country than it is in the others over the sea, had it been let entirely alone, *i. e.*, were it not for the unwise opposition of the over-conservative controllers of the AMERICAN MEDICAL ASSOCIATION.

What is the result in the United States up to date? A factional, disjointed, overcrowded medical profession—roughly

estimated at over one hundred thousand physicians, about one-eighth of whom are openly arrayed against regular medicine; and about one-fourth of the regular profession in greater sympathy with and in stronger allegiance to special societies or associations than to the would-be parent society of the country. These latter are not in open opposition to the AMERICAN MEDICAL ASSOCIATION, but their representative men, of highest professional repute in commercial centers, are gradually being weaned from the not overfond embrace of a cranky mother.

Evidently for very many of this class, professional respectability—is no longer an outgrowth of or dependent upon what they consider the effete rules of the old dogmatic Code. Of the remainder of the members of the AMERICAN MEDICAL ASSOCIATION, there are probably more than half who stand practically where the writer hereof does, always faithful to the old society, because it is the recognized source of authority for medical men in this country, yet always hoping for the time when broader principles and policy will dominate, so that a unification of the best elements in the medical profession of the United States may be accomplished under the fostering care and control of the AMERICAN MEDICAL ASSOCIATION.

This spirit of unification, mutual concession and harmony which actuates a very large portion of the members of the ASSOCIATION is in no way represented by the dogmatic and uncompromising *conservatism* of the correspondent previously referred to.

From the frequency with which the "learned, honorable and faithful physicians" are lauded in these epistles for writing a code "for all time" and "not susceptible of betterment," one may naturally assume that "A Conservative Member" had had the writing of it himself, and that in his dotage, with a "ruling passion strong in death" for his own individual glory he could not bear to see his own pet phrases changed in any way.

The question remaining unsolved is, Which shall be permitted to die first—"A Conservative Member" or the AMERICAN MEDICAL ASSOCIATION?

HARMONY.

Proposed Amendments of the Constitution and Code of Ethics of the American Medical Association.—Some of the Parliamentary Questions Involved.

CHICAGO, May 4, 1894.

To the Editor:—When the report of the Committee on Revision of the Constitution and By-Laws, was made in the meeting of the ASSOCIATION last year, and the President ruled that said report must lie on the table one year and be acted upon at the next annual meeting, several members contended that the ruling was wrong. They claimed that inasmuch as the proposed amendments or revised instrument had been prepared by a committee appointed for that purpose the preceding year, it was equivalent to one year's notice, and consequently was eligible for final action at once. They were quickly silenced, however, by simply reading the present constitutional provision for its amendment, as follows: "VII.—No amendment or alteration shall be made in any of these Articles, except at the annual meeting next subsequent to that at which such amendment or alteration may have been proposed; and then only by the voice of three-fourths of all the delegates in attendance." This language admits of but one meaning, namely, that every proposed amendment or alteration of the Constitution must be presented at an annual meeting and remain on the table for consideration until the next annual meeting before action can be taken thereon. It makes no difference whether the amendments are proposed by a committee previously appointed or by an individual member.

This was fully tested at the annual meeting in 1887. At the preceding annual meeting, 1886, a special committee had been appointed to consider and report upon the practicability of certain alterations in the Constitution and plan of organization of the ASSOCIATION. At the next annual meeting, 1887, the committee made a full report recommending in due form three important amendments to the Constitution. A motion was made to accept the report and adopt the proposed amendments, which was seconded, and at once adopted by the required majority. The small minority immediately claimed that the action had been contrary to the requirements of the Constitution, while others insisted that the special topics under consideration having been in the hands of a committee during the year was sufficient, and at first the President ruled in their favor; but at a later stage of the meeting the action was set aside and the three proposed amendments were laid on the table until the next annual meeting. (See JOURNAL AMERICAN MEDICAL ASSOCIATION, pp. 716-717, Vol. viii, 1887.) At the next annual meeting, 1888, two of the proposed amendments were adopted and the consideration of the third was again postponed another year. (See JOURNAL AMERICAN MEDICAL ASSOCIATION, pp. 694-698, Vol. x, 1888.) At the next annual meeting, 1889, it was fully discussed and rejected by a decisive vote. (See *ibid.* p. 98, Vol. xiii, 1889.) As the revised or amended constitution proposed by a majority of the Committee on Revision was duly presented at the last annual meeting it will be ready for final action at the next meeting. And as the revised constitution since proposed by the *minority* of the same Committee is strictly *germane* to the topics embraced in that reported by the majority; a motion to substitute the minority report for that of the majority, would be in harmony with both the present Constitution and parliamentary rules.

During all the past history of the ASSOCIATION, its Code of Ethics has been regarded as a part of its organic law; and all attempts to alter or amend it have been subjected to the same rules as govern proposed alterations of the Constitution. The only important amendment that has been made to the Code since its original adoption, in 1847, is the addition of Section, or paragraph 2, Article I, under the head of "Duties for the Support of Professional Character." Its history is as follows: In 1877 a controversy had taken place between the Michigan State Medical Society, or its members, and the Medical Department of the University of Michigan, in which the Faculty of that Department was charged with violation of the Code of Ethics by teaching and recommending for graduation students known to be intending to practice some exclusive or irregular system of medicine. The charges had been referred for adjudication to the Judicial Council of the ASSOCIATION, and it reported that there was no clause in the Code of Ethics bearing with sufficient directness on the subject to constitute a basis for judicial action. It was immediately voted that the Judicial Council, as a special committee, prepare and report at the next annual meeting such an amendment of the Code in the form of an additional Section, as would cover the questions in controversy.

The next annual meeting, 1878, the Committee reported an additional Section of the Code, in accordance with the instructions given the previous year. The President, the late T. G. Richardson, decided that the amendment proposed by the Committee must lie upon the table until the next annual meeting, as the Code was a part of the organic laws, and the decision was fully sustained by the ASSOCIATION, (See Transactions, p. 44, Vol. xix.) The next year, with Theophilus Parvin as President, the proposed amendment was taken up for consideration near the close of the session, when, on account of the small number present, it was post-

poned until the next annual meeting. At the next meeting, 1880, it again escaped attention until near the close of the session, when it was taken from the table and made a special order for consideration at 10:30 A.M. on the second day of the next annual meeting. (See Transactions, p. 65, Vol. xxxi.) Accordingly, at the next meeting, which was at Richmond, Va., 1881, with J. T. Hodgen presiding, the proposed amendment was fully discussed, somewhat modified in phraseology, and adopted by the voice of three-fourths of the delegates present. (See Transactions, p. 39, Vol. xxxii.)

It is thus seen that in both theory or principle and in practice, the ASSOCIATION has regarded the Code of Ethics as a part of its fundamental law, to be amended or altered only on the same conditions and in accordance with the same rules of procedure as are prescribed for amendments of the Constitution. If this eminently wise and judicious policy is to be adhered to, when the *revised* Code of Ethics is proposed by the majority of the committee on revision at the next annual meeting, it will be subject to only two parliamentary motions; one to lay it on the table for action at the next annual meeting; the other to postpone its consideration *indefinitely* and discharge the Committee. Neither of these motions would be debatable, and the adoption of the latter would save much valuable time of the ASSOCIATION and greatly promote the best interests of the whole profession.

Yours truly, N. S. DAVIS.

The Golden Opportunity of a Great National Medical Association.

DETROIT, MICH., May, 1894.

To the Editor:—They only gain the largest success who improve every opportunity. The medical profession of the United States has presented for its acceptance or rejection, the opportunity of a generation. This opportunity is the report of the Committee on Revision of the Constitution, By-Laws and Code of Ethics of the AMERICAN MEDICAL ASSOCIATION. The adoption or rejection of the main features of the majority report, will profoundly influence the activities of the medical profession of the United States far into the future. To a few of these features we desire to direct attention.

As to membership: At present, most members of the ASSOCIATION are dummies, viz: They can pay their dues and talk, but can not vote. Yet in the management of the affairs of the ASSOCIATION, votes are the only things which count. It matters not that a member has attended and worked in the interests of the ASSOCIATION for forty years, except he have a delegate's certificate, secured during the present year he can not exercise any final influence upon the management of the ASSOCIATION.

The revised law gives every member the right to vote on all occasions, and so long as he continues his membership. Thus when at a meeting he will not be compelled to stand by as a wooden person while the delegate members vote away his convictions and rights.

This change in membership offers inducements for all to become members, and stay members, in that the old have the same rights as the new members. In this it is a marked contrast to the existing plan, which has no active members, except during the time of meeting, and these must be appointed yearly. The proposed plan is likely to keep, as active members of the ASSOCIATION, most of those who join, because they can retain their rights of membership continually. We do not hesitate in affirming that had this new rule always existed, the increase in membership of the AMERICAN MEDICAL ASSOCIATION would have kept pace with the development of the country, and have been thousands where now it is but hundreds. Those who desire this ASSOCIATION to number seventy-five thousand actual members

will do well not to neglect the present opportunity in securing the adoption of the revised Constitution, By-Laws, etc.

2. The proposed changes afford the ASSOCIATION an opportunity to conduct its meetings entirely in accord with the views of the scientific workers—those who attend the meetings for the purpose of increasing their ability to cope with disease. Such conduct is absolutely essential for the best growth of the ASSOCIATION. Only such conduct will compensate for the loss of practice necessitated by absence from home, and for the expense and fatigue incident to a long journey.

By the present method, more than half the time is consumed in a general session, the principal features of which are disputes over parliamentary laws, personal wrangles, unprofitable and disgusting to all but the participants, and long-winded papers which interest only a few. The proposed changes provide for a general session of the shortest possible length; not more than one or two hours daily; limits all addresses to twenty minutes; takes from the floor of the house all debatable questions and has them first considered by a representative business committee before they are offered for final adoption. It is believed that the proposed changes will render the general sessions profitable to all, and still leave practically the entire day open for effective work in the sections. It is believed that this plan would augment greatly the number of workers in the Sections and multiply largely the membership of the ASSOCIATION.

Will the ASSOCIATION neglect this opportunity?

3. The proposed changes offer the ASSOCIATION a chance to systematically and habitually secure as its advisers the best men in the Sections. Already these exist in an organized body known as the Central Business Committee. The proposed plan makes them the advisers of the ASSOCIATION in selecting its place of meeting and officers. It would seem as if this were better than the present haphazard method.

Will the ASSOCIATION select the better way?

4. In the matter of professional fellowship, an opportunity is presented for the ASSOCIATION to take a position which it can successfully defend, not only in its own ranks, but before any intelligent person. The Revision Committee proposes that all reference to pathy or sect be eliminated from the Code of Ethics, and that every physician select his professional fellows as he chooses, if only the selection be made from those well educated having an honorable reputation and a legal right to practice medicine.

Will the ASSOCIATION improve its opportunity?

5. The Revision Committee advises that equity be established between members of the profession by placing the copyrighting of books and the patenting of mechanical appliances upon the same basis; and by permitting special workers outside of medical colleges, hospitals, dispensaries, etc., to have the same rights of advertisement as have been accorded to those inside. Let the "outs" be placed on the same footing as the "ins," is suggested.

Will the ASSOCIATION heed the suggestion?

After nearly half a century of marvelous advances, both within and without the medical profession, it would seem possible to effect such changes in the organic laws of the AMERICAN MEDICAL ASSOCIATION as would bring it into closer contact with the great forces moving the medical profession, and so attract a membership of vastly greater proportions. The Committee on Revision, acting under instructions from the ASSOCIATION, has studied the situation as best it was able, and has presented its conclusions through the JOURNAL for consideration. It is quite in order to revise the revision so that it may still more accurately represent the medical profession in this country.

The writer has always cheerfully obeyed both the spirit and letter of the old organic laws, and the adoption of the revision would make no difference with his actions. But he also believes that the adoption of the revision would render it possible for the ASSOCIATION to gather within its ranks tens of thousands of physicians who otherwise would stand aloof; that the revision is quite in accord with the spirit of the old Code; in accord with the best spirit of the medical profession from the earliest historic ages; and with the spirit of the best portion of the modern medical profession of all countries. He believes that the increase of individual responsibility given, harmonizes with the larger education, the better morals and general spirit of the age, and so is imperatively demanded of an organization which must stand or fall as it is able to gather to itself the elements of physical, intellectual, professional and moral power which dominate the medical profession of the United States.

Will the ASSOCIATION grasp its golden opportunity ere it passes?
LEARTUS CONNOR, M.D.

Revision of the Code of Ethics.

To the Editor:—A few additional notes on the "revised" Code seem necessary to particularize some of the many defects of the extraordinarily unphilosophical and disorderly production of which the proem is the type. Therefore this second series of notes relate principally to the proem, only a few of them being directed to the letter and spirit of the "revised" Code.

1. Recusancy has characterized the acts of the Majority Committee throughout its work. Had it performed its duties as ordered by the ASSOCIATION, and confined its labors within the prescribed limits, it would not have exposed itself to general censure. But the revisers' condemnation of the original Code and their suggestion that it be re-written "in phraseology so plain as to make it a practical common sense document" implied that they were competent to give a prodigiously well-arranged and admirably well-composed substitute for what they substantially alleged to be obscure, unpractical and senseless. That they have made a sad failure in their attempt to improve upon the original is well shown by their inaccurate, illogical, ill-arranged and ridiculous "revision." Their pretentious but meaningless proem is worthy of tyros of a college society, trying their prentice minds in composing a burlesque; and it is difficult to believe that such a marionettal exhibition of ethics and literature could have been made by men of mature years. It is pitiful that this "Revising" Committee, after angling in vain for arguments in the turbid stream of charlatanism, should endeavor to thrust upon the profession a production whose perusal affronts the eyes, distresses the minds, and assaults the moral sense of loyal physicians. Parts of the "revised" Code are so speciously stated that younger members of the profession will do well to compare them with the original; the fraud will then be apparent, and they will not be likely to accept this counterfeit. Let them remember that when bad morals, sustained by self-interest, are inadvertently indorsed by thoughtless men of good character, the eradication of these evils is next to impossible. Let them remember, also, that the repeal is often much more difficult than the passage of an act. And may they join the older loyal members of the profession in a vigorous defense of its honor against the nefarious attack upon its grand and glorious code of morals!

2. Since the first sentence of the proem—"a code may be either penal or ideal"—seems intended to be aphoristic and is supplemented by characteristically witless definitions of a penal and an ideal code, it is proper to say that a brief analysis of the "aphorism" and "definitions" proves the one to be fallacious and the others to be worse than inaccurate, and that a little reflection has led to the following annota-

tions: 1, that penal is not logically opposed to ideal, and can not be used in contra-distinction; 2, that all the laws, all the works of men, are first ideal and become real only when expressed, when performed—the idea coming first is elaborated in the mind, afterward it is expressed, perhaps in words, or is executed by the hand; then and then only it is real; 3, that a penal code and all legal maxims were ideal when conceived in the mind, and became real, authentic, as soon as expressed; 4, that a code of medical ethics and all moral maxims were ideal when conceived in the mind, and became real, authentic, as soon as expressed; 5, that the adjective, ideal, is applicable to qualify all unexpressed maxims, codified or not codified, and can not be used exclusively to qualify any particular code of ethics; 6, that all ideal codes of laws and morals, when expressed, become real, authoritative and penal; 7, that some penalty is necessarily attached to the violation of every law whatsoever; 8, that all laws command or imply thou shalt or thou shalt not; 9, that the penalty is generally proportionate to the kind and degree of violation; 10, that the penalty may be imposed by a judge, by the violator himself in his own conscience, or by nature; 11, that the penalties for some crimes are defined by statute, but the degree of violation is often determinable by the court; 12, that violations of laws governing the reciprocal relations of men, not criminal violations, are punished by damages awarded to the injured "party;" 13, that for violations known to the violator only, the penalty is sting of conscience; and 14, that when fire is applied to his body by a man, the penalty for this violation of a natural law is pain and a more or less severe burn—even in this case the penalty is proportionate to the degree of violation. Hence criminal, civil, moral and natural laws—all ideal when conceived in the mind, then, when expressed, all real, authoritative and penal. This exposition may give an idea of the legal, ethical and logical lore of the committee of men who allege that a great masterpiece of literature and of moral laws is ill arranged, impractical, obscure and senseless!

3. The "revisers" announce the startling discovery that an ideal code is a "crystallization of thought and sentiment." It is, however, proper to record, for the purpose of "exact definition," they qualify the announcement by saying that the thought and sentiment of only a "considerable body of men who, for long periods have been associated with a common purpose" are crystallizable. Therefore only long association of men with a common purpose can bring forth crystals of thought and crystals of sentiment which, commingling, give birth to an ideal code. The committee, representing as it seems a kind of progress, the leaders in which decry the works of the past and many of the present, will not be likely to accept some of the definitions of "ideal," nevertheless two definitions by reputable scholars are here given. "The ideal is that which the mind contemplates as a representative of excellence." "The ideal is the prototype of all things . . . though it is impossible that they can ever attain its perfection." An ancient philosopher, whom the "revisers" may characterize as a fossil, said: "The image is the work; the idea is before the work."

4. Used in any sense, "ideal standard" is a forced expression. Criterion—that rule of judgment—would have better expressed the thought, while standard relates to material things. Standard is too frequently used in a figurative sense. The too free and indiscriminate use of figures of rhetoric in the language of science is often evidence of poverty of diction and even of ideas. A striking example of needless figures is found in the third paragraph of the proem: "A lamp to the feet of the young" . . . "A mirror. . . for the more mature. . ." the "revisers" leaving the less mature in total darkness, with neither lamp nor mirror. Such figures of speech might have served to relieve the

tedium of a lay sermon, but in the proem to a code of medical ethics they are surely out of place. But to give illustrations of the thought-and-idea-saving figures of rhetoric, and thus pay them in their own base coin, the "revisers" may be said greatly to need a mirror in which to see themselves, in their present position, as others see them, and a lamp to guide their tottering steps through the mazes of ethics, rhetoric, law and logic which they have so recklessly entered. There is nothing so easy, space-filling, and time-saving as to borrow figures of speech. These borrowed figures are, however, among the best parts of the "revision," for they are so quaint as to excite mirth, and have even served to rouse a sleepy listener to whom the "revised" Code was read soon after its publication. In the fourth paragraph of the proem it is written—"a code of ethics . . . takes cognizance of, and formulates rules of action . . ." The "revisers," but not any code of ethics, might, could, would or should take cognizance of, and formulate rules of action. Had they taken cognizance of this fact, perhaps they would have made fewer blunders in their "revision," and would have been likely to say in plain and simple words that a code of ethics is a suitably arranged collection of maxims for the guidance of men in their reciprocal relations. A good code of ethics with well formulated rules of action does not contain "non-essential details" and therefore can never require changes—such is the American Code of Medical Ethics.

5. Verily the "revising" body must have been at a loss what next to say when it gravely reduced to writing that which it probably regarded as mere bombast, with the hope, however, that it might pass as an assertion of professional dignity. "Obviously the code adopted by a learned profession must be ideal rather than penal, as it would be beneath the dignity of its members to bind themselves by penal restrictions." This is little more than a repetition of the idea of the ideal code which is still festering in the ponderous collective mind of the "obnoxious" committee beneath whose dignity are all penalties, including stings of conscience, and which might, with profit, devote more time to the study of ethics in general and medical ethics in particular, together with a sprinkling of rhetoric and logic, and the art, not of "conducting a career," but of self-conduct throughout their career—their course in life. All of which is suggestive of a few years' devotion to "the humanities." The section on etiquette in this proem is written in the same loose, inaccurate and unscholarly manner as the preceding paragraphs. Much is still left unsaid against this proem, composed by men who regard the National Code as senseless and inferior in arrangement and in language!

6. What induced the "revisers" to perpetrate the egregious blunder of composing Article I, of Chapter I, Part I, of their ever-to-be-censured "revision," is past human understanding. This Article, which is even worse than the proem, begins with Bunsbyan platitudes; then it "hangs" issues of life and death, and does not seem certain whether it be the issues, or life and death, that perform duties; to responsibilities it gives consciences which "adjudge penalties for ignorance or neglect," although the oracular "revisers" say in their "ideal" proem that "the Code adopted by a learned profession must be ideal rather than penal, as it would be beneath the dignity of its members to bind themselves by penal restrictions;" for good effect, it solemnly interposes some borrowed figurative language, and finally exhorts those assuming responsibilities to abjure ignorance and improve their minds. This is followed by a travesty on some introductory lecture on preliminary and medical education, such as those delivered a little less than two score years ago by each professor, at every successive annual session, in the schools of medicine. The fashion has long since passed

away. Its revival may be due to the genius of the Majority Committee. Not one sentence in this first Article has a legitimate place in any code of ethics. So much for the Committee's method of "revising" the American Code of Ethics!

7. Xs, these two letters, long ago united in good literary faith, were finally discovered to be incompatible and were divorced by an act of literature. They are now recoupled for the sole purpose of symbolizing the unknown quantity and superfluity in concubinage. Xs would be an appropriate device for the signet of the Code "revising" committee which was an unknown quantity and a superfluity from the beginning. The methods of this Committee long remained unknown, its views were uncertain and often shifting, and the time for publication of the "revision" delayed for unknown reasons. Its appointment was made through intrigue and was not necessary; its "revision" is full of superfluities; it is a superfluous committee which should be discharged without delay, lest it introduce many superfluities likely to be injurious to the ASSOCIATION, through its sophistication of the Code, as exemplified in the second article of the first chapter which begins in true Polonian manner, with a flourish of empty words followed by the shrewd interposition of "sanction of government." This is one of the minor illustrations of the craftiness of the "revisers." The other sections of this article are perversions of the original. The third article consists of two sections worse than perversions of the original, from which have been expunged sections relating to the obligations of patients to their physicians. Such is the manner in which the National Code has been treated by the committee instructed to report if changes be necessary. The first article of the second chapter is another example of the perversion and mutilation of the original with the insertion of a clause which, if adopted, would be an entering wedge for many kinds of irregularities. The second article, "of consultations," is the crowning work of their craftiness, the objective point of the disorganizers. If ever accepted it will lead to the admission of every charlatan in the land within the fold of the regular profession. This is the way in which the Committee is guarding the honor of a respectable medical association!

8. Year after year, ever since their voluntary disfranchisement, the disorganizers have labored constantly and shrewdly to induce some members of the ASSOCIATION to demand a revision of the Code, and have at last succeeded. Their wish is realized but they have no reason to be satisfied with the maxims, arrangement and literary character of the long desired "revision" of the Code. They would probably have preferred its total abolition, but such abolition would surely be injurious to them. Although the codification of ethical maxims does not necessarily change the moral nature of followers of Belial, it warns others to avoid evil and evildoers and points out the right path, which is not always easily found by those who seek it and are in doubt as to its course. The "revisers" have omitted much that is necessary for the guidance of those in search of the right path, and have introduced much that is foreign to an ethical code and much that is unnecessary, notably the chapter on special departments in medical practice, which is one of the blots on the "revision," an addition to their many blunders and superfluities. Then comes the silly divorce of the ethical maxims and rules of etiquette, to which are added the numerous absurdities that the committee chose to prescribe. It is needless to carry this examination farther, and it suffices to say that there are few properly constructed sentences in the whole composition of the "revisers." What is correct in the published "revision" belongs to the original Code. And the ambition of these "revisers" was to reform medical morals!

9. Zealous in their advocacy of the disorganizers' infamous cause, the "revisers" despite their "depreciation," have done all they could to "abolish, belittle, distort and ridicule" the Code and "otherwise lessen its hold upon the profession." They offer, for the grand original, a substitute which is not likely to do them honor or credit, for it is shown that this work of four minds in labor during nearly two years, this much heralded "revision," begins with fallacy, is characterized throughout by sophistry, and ends in absurdity!

A CONSERVATIVE MEMBER.

The Code Revision.—An Appeal to Men of Good Sense.

NEW YORK, May, 1894.

To the Editor:—Will you be so kind as to insert in your esteemed JOURNAL, this short appeal to those members who sincerely have at heart the welfare of the ASSOCIATION?

I am one of the many who believe that our excellent code of morals requires no alterations whatsoever. Therefore I exhort all members to waste no more thought and time in considering the question of revision, but to devote their best energies to carry out the real objects of the ASSOCIATION, which are: To cultivate and advance medical knowledge; to raise the standard of medical education; to promote the usefulness, honor and interests of the medical profession; to protect public health; to enlighten the people concerning the duties, responsibilities, and requirements of medical men; to encourage emulation among members of the profession; to further concert of action in the profession; and to establish friendly relations among members of the profession.

I earnestly appeal to all loyal members of the ASSOCIATION, to exert their utmost influence against propositions which do not pertain to these wise and lofty objects, or which are not in harmony with the Code, and to endeavor to put an end to the disgraceful agitation begun by self-seeking malcontents whose motto seems to be "rule or ruin." It is high time for the men of good sense to assert themselves and rescue the ASSOCIATION from the grasp of those who seek its destruction. Let the revision question be speedily dismissed, and the ASSOCIATION will prosper and its grand mission will be fulfilled.

JOHN G. TRUAX, M.D.

PUBLIC HEALTH.

Tuberculosis Prevention.—The Health Department of New York has inaugurated its preliminary measures for the prevention of tuberculosis in that city. A circular is issued requesting all physicians to furnish the Department the name, address, etc., of each tuberculous patient coming under their care. The information thus obtained will be registered by the Department, but in no case will it interfere with the patient or premises, unless the attending physician so request or unless the patient be an inmate of a tenement house, boarding house or hotel—nor even then if the physician will deliver the circulars of the Department or furnish such equivalent information as is required to prevent the communication of the disease to others. In other cases in these places, inspectors will visit the premises and furnish necessary instructions and the circulars of information and advice.

Where it comes to the knowledge of the Department that premises which have been occupied by a consumptive have been vacated by death or removal, an inspector will visit the premises and direct the removal of infected articles, such as carpets, rugs, bedding, etc., for disinfection, and will make such written recommendations to the Board as to the cleansing and renovation of the apartments as may be required. An order embodying these recommendations will then be issued to the owner of the premises, and compliance with the order enforced. No other persons than those there residing at the time will be allowed to occupy such apartments until the order of the Board has been complied with. Infected articles, such as carpets, rugs, etc., will be removed by the Department, disinfected and returned, without charge to the owner.

In order to secure a prompt and positive diagnosis in a suspected case of tuberculous disease, the Department will make the necessary bacteriologic examination and furnish a report thereof to the attending physician free of charge. The authorities of all public institutions, hospitals, dispensaries, asylums, prisons, homes, etc., within the jurisdiction of the Board are required to furnish to the Department the name, sex, age, occupation and last previous ad-

dress of every consumptive coming under observation within seven days of such time, and the Board earnestly requests the cooperation of all practicing physicians in its efforts "to restrict the ravages of the most prevalent and formidable disease with which we have to deal."

"Cholera" and Cholera.—Our old acquaintance, "cholera," the official euphemism for Asiatic cholera, has strutted his brief hour and disappeared from the bulletins, at least for the present and in the localities where it is no longer possible to conceal the truth. The full truth is, however, not yet known as to the extent of the Portuguese epidemic. A rigid censorship is exercised over all information on the subject, but from such information as has transpired it may be estimated that there have already been over 3,500 cases with a high rate of mortality in Lisbon and vicinity. Senor Montaldo, the Chief Medical Director of the Spanish Government, who visited Lisbon last month to investigate the epidemic, reports that the disease was imported by a merchant vessel from the Cape Verde Islands, off the western coast of Africa. A cable dispatch of May 3, however, says that the Board of Health of Lisbon declares the port in a healthy condition. Other recent dispatches confirm the reports of the epidemic prevalence of Asiatic cholera in Western Russia and in the Austrian province of Galicia, of its appearance in Western France in the Department of Finisterre and of its continuance in Constantinople.

Revised regulations to be observed at foreign ports as to vessels destined for the United States, at our own maritime quarantines and on the Canadian and Mexican borders were recently signed by the Secretary of the Treasury.

Smallpox.—The unchecked spread of smallpox in Chicago and its increasing menace to the country at large has caused the health officers of several States and the Dominion of Canada to call another conference on the situation. Drs. Bryce, of the Provincial Board of Ontario; Probst, of Ohio; McCormack, of Kentucky; Baker, of Michigan; Metcalf, of Indiana; Scott, of Illinois; Reeve, of Wisconsin; Hewitt, of Minnesota; Kennedy, of Iowa; and King, of Missouri, are among the signers to the call and the conference was held in Chicago on the 9th and 10th inst.

Notwithstanding the milder weather and the increased energy and multiplied resources of the Health Department, the first week of the present month shows an increase of 27.7 per cent. in the number of cases of smallpox in Chicago as compared with the daily average of cases in the previous month. During April there were 544 cases reported—a daily average of 18; from May 1 to May 7 there were 162 cases reported—a daily average of 23. It is possible that as is claimed, this increase is due, in some measure, to the more thorough work of the inspectors and that a larger proportion of existing cases are now being reported than heretofore. There is scant comfort, however, in this view of the case; it suggests at once the question, What, then, is the actual number of cases of smallpox in Chicago at the present time?

Attention has been called to the fact that clothing is being manufactured in and shipped from infected workshops and tenements, and the factory and tenement inspectors have asked for instructions as to their duties, responsibilities and authority in the premises under the law. It is understood that they have been advised that their authority is plenary, and that their duty is clearly defined to be not only the protection of the health of the inmates of tenements and factories, but of the public health in so far as this may be affected by such establishments, their inmates and employes.

In Illinois, outside of Chicago, the situation shares in the general improvement noted in the country at large and the disease is rapidly losing its importance as an epidemic. There are only seven infected points remaining out of the total twenty-seven reported since January 1, namely, Bloomington, Freeport, Harvey, Lockport, Madison, Rockford and Rock Island. Up to May 7, there had been a total of eighty-three cases with fifteen deaths at twenty-seven points; in sixteen of these points the origin of the outbreak was traced directly to Chicago, in one to Joliet and in ten the origin is reported "unknown."

Infected points are still reported remaining in Massachusetts, Connecticut, New York, Pennsylvania, Tennessee, Texas, Arkansas, Missouri, Michigan, Indiana, Illinois, Wisconsin and Iowa.

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Rio Grande Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville, Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland, thence east by way of the Northern Pacific R. R. to St. Paul. C. M. & St. P. R. St. Paul to Chicago. A stop over at Yellowstone National Park for those who desire it has been arranged, and it has been understood that at several places on the journey there will be short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentrating on this train should be effected at Chicago and St. Louis. For all information relating to this train, fares, etc., address J. M. Connell, 212 Clark st., Chicago, or any agent of Santa Fe line in other cities. Rates promised are the lowest excursion rates at time of departure.

This is the only route on which arrangements have been perfected by the Trustees.

SOCIETY NEWS.

Susquehanna County, Pa., Medical Society.—At the annual meeting of the Susquehanna County Medical Society held at Montrose Pa., May 1, 1894, the question of revision of the Code of Ethics was considered and freely discussed by the large number of members present. It was resolved, with one dissenting vote, that this Society does now renew its allegiance to the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION, and the Secretary was directed to report this action to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.
CALVIN C. HALSEY, Secretary.

Ohio State Medical Society.—The forty-ninth annual meeting will be held at Zanesville, May 16, 17, 18, 1894, when the following program will be presented:

- The Physician, Dr. Samuel Hart, Marietta.
- The University and Medical Education, Dr. D. S. Kellcott.
- The Prevention of Consumption, Dr. C. O. Probst, Columbus.
- Infection in Tuberculosis. Food Products, Dr. H. H. Spiers, Ravenna.
- Is Consumption Curable? Dr. R. E. Chambers, Chandlersville.
- La Grippe in the Differential Diagnosis of Scarlet Fever, Measles and Rötheln, Dr. James L. Tracy, Toledo.
- Scarlatina, Dr. Amelia J. Prior, Cincinnati.
- Diphtheria, Dr. J. S. Haldeman, Zanesville.
- The Prevention of Pertussis, Dr. George M. Clouse, Columbus.
- Studies in the Etiology of Smallpox, Dr. J. C. Graham, Columbus.
- The Value of Recent Therapeutic Literature, Dr. W. C. Chapman, Toledo.
- Certain Entozoa of the Dog and Sheep, Prof. D. S. Kellicott, Columbus.
- On Imparting Rudimentary Knowledge to Lawyers, Dr. Dan. Millikin, Hamilton.
- Unjust Malpractice Suits; Causes and Prevention, Dr. Wm. Estep, Loydsville.
- A Year's Operations for Appendicitis, Dr. Dudley P. Allen, Cleveland.
- A Case of Cirroid Aneurism, Dr. W. D. Hamilton, Columbus, and Dr. L. S. Holcomb, Pennsville.
- A Case of Aneurism by Anastomosis, Dr. J. C. Crossland, Zanesville.
- Splenectomy, with the Report of a Successful Case, Dr. W. J. Conklin, Dayton.
- Nephrectomy for Tuberculosis, Dr. R. Harvey Reed, Columbus.
- Gastrostomy; A New Method, Dr. M. Stamm, Fremont.
- The Radical Cure of Hernia, Dr. F. C. Larimore, Mt. Vernon.
- The Treatment of Uterine Fibroids as Indicated by their Natural History, Dr. C. A. L. Reed, Cincinnati.

Some Remarks on the Total Extirpation of the Fibroid Uterus, with Illustrative Specimens, Dr. Rufus B. Hall, Cincinnati.

Total Extirpation of a Pregnant Myomatous Uterus, with Specimen, Dr. C. N. Smith, Toledo.

Hysterorrhaphy, The Cure for Retro-deviation of the Uterus, Dr. F. D. Brandenburg, Cleveland.

Practical Application of the Principles of Sterilization, Dr. Hunter Robb, Baltimore, Johns Hopkins University.

Obstetrical Operations Involving Mutilation and Death of the Fetus, Dr. E. Gustav Zinke, Cincinnati.

The Treatment of Fractures in the Light of Advanced Histology and Pathology, Dr. Donald MacLean, Detroit.

Studies in Immunity and Treatment of a Specific Fever, *i. e.*, Hog Cholera, Dr. D. N. Kinsman, Columbus.

Is There a Better Remedy in Cholera? Dr. E. B. Fullerton, Columbus.

The Rationale of Systematic Elimination in the Treatment of Typhoid Fever, Dr. Robert Peter, Canal Dover.

Typhoid Fever, Dr. John E. Woodbridge, Youngstown.

The Modern Treatment of Typhoid Fever, Dr. Howard Jones, Circleville.

Syphilitic Spinal Paralysis, Dr. C. J. Aldrich, Cleveland.

Multiple Neuritis, Dr. Jos. Eichberg, Cincinnati.

The Symptomatology of Hereditary Syphilis, Dr. R. C. Longfellow, Cincinnati.

Acute and Chronic Diseases, Dr. J. R. Black, Newark.

Pneumonia, Dr. A. E. Bell, Zanesville.

The Phenomena of Fertilization and their Bearing on Heredity, Dr. J. Playfair McMurrich, Prof. Biol. Univ. Cincinnati.

Diseases of a Reflex Nature arising from Pathological Conditions of the Uterus and Appendages, Dr. Wm. H. Humiston, Cleveland.

The Importance of Determining Reflex Irritation in Catarrhal Processes, Dr. Jno. P. Sawyer, Cleveland.

The Effect of Obstructive Disease in the Upper Air Passages on the General Health, Dr. J. A. Thompson, Cincinnati.

Headache, Its Relation to Optical and Muscular Defects of the Eyes, Dr. S. C. Ayres, Cincinnati.

Sympathetic Ophthalmia, Dr. B. F. Templeton, Zanesville.

Diseases of the Cornea in Childhood, Dr. C. W. Tangeman, Cincinnati.

The Use of Plaster in Joint Diseases, Dr. T. C. Hoover, Columbus.

Subcutaneous Osteotomy with Cases. A New Osteotome, Dr. Willis W. Hall, Springfield.

Subluxation of the Knee, with Treatment, Dr. S. L. McCurdy, Dennison.

Fractures of the External Condyle of the Humerus, Dr. F. E. Bunts, Cleveland.

Practical Points in Ether Anesthesia, Dr. W. D. Porter, Cincinnati.

Rectal Abscess, Dr. Auguste Rhu, Marion.

Trephining, with Report of Cases, Dr. Leonard Freeman, Cincinnati.

Middle Florida as a Winter Resort for Invalids, Dr. F. D. Case, Ashtabula.

Tonsillitis, Dr. H. J. Noyes, McConnellsville.

A Case of Myxœdema, Dr. E. M. Fitton, Hamilton.

Valvular Disease and Chronic Rheumatism, Dr. W. W. Pennell, Frederickstown.

The Local Treatment of Cystitis, Dr. G. W. Morehouse, Sparta.

Cremation as a Means of Practical Sanitary Reform, Dr. Chas. P. King, Newark.

THOMAS HUBBARD, M.D., Secretary.

The Illinois State Medical Society.—The forty-fourth annual meeting will be held at Decatur, Illinois, May 15, 16 and 17, at Powers' Opera House.

Section One.—Chairman, Dr. T. J. Pitner, Jacksonville. Secretary, Dr. H. McKennan, Paris.

The Practice of Medicine, J. T. Stewart, Peoria.

Fashions in Medicine, G. W. Nesbitt, Sycamore.

The British Institute of Public Health.—Preliminary program. Congress in London from July 25 to July 31, 1894.

Honorary President: The Right Hon., the Lord Mayor of London.

President: Prof. William R. Smith, M.D., D.Sc., F.R.S. Edin., Barrister-at-Law; Professor of Forensic Medicine and Director of the Laboratories of State Medicine in King's College, London; Medical Officer of the School Board for London.

Vice-Presidents: His Grace the Archbishop of Canterbury; His Eminence the Cardinal Archbishop of Westminster; His Grace the Duke of Westminster, K.G., Lord Lieutenant of the County of London; the Right Hon. and Right Rev. the Lord Bishop of London; the Right Hon. the Lord Mayor of Dublin; the Right Hon. the Lord Mayor of Belfast; the Right Hon. the Lord Provost of Edinburgh; the Right Hon. the Lord Provost of Glasgow; the Right Hon. the Lord Provost of Aberdeen; the Right Hon. the Lord Provost of Dundee; Sir Stuart Knill, Bart., LL.D., Master of the Worshipful Company of Plumbers; Sir Richard Webster, G.C.M.G., M.P., Q.C., Prime Warden of the Worshipful Company of Goldsmiths; Sir John Simon, K.C.B., LL.D., D.C.L., F.R.S.; Sir Joseph Fayer, K.C.S.I., M.D., LL.D., F.R.S.; Sir George Buchanan, M.D., LL.D., F.R.S.; Sir Charles A. Cameron, ex-Pres. R.C.S., Ireland; Sir T. H. Johnson, Master of the Worshipful Company of Drapers; Sir A. K. Rollit, Chairman of the Council of the Association of Municipal Corporations and President of the Chamber of Commerce, London; Professor Sir Douglas MacLagan, M.D., Pres. R.S. Edin.; Sir Benjamin Ward Richardson, M.A., M.D., LL.D., F.R.S.; Henry Duncan Littlejohn, Esq., M.D., LL.D., Medical Officer to the Board of Supervision for Scotland, Medical Officer of Health to the City of Edinburgh; Edward Frankland, Esq., Ph.D., D.C.L., F.R.S.; Alderman J. Voce Moore, Sheriff of the City of London.

Honorable Treasurer: J. C. Dimsdale, Esq., Alderman and Sheriff of the City of London.

Honorable Secretary: Henry C. Jones, Esq., Clerk to the Board of Works for the St. Giles District; Hon. Solicitor to the Incorporated Society of Medical Officers of Health.

The following is a list of the Sections of the Congress, with the Honorary Secretaries:

A.—PREVENTIVE MEDICINE.

Sectional Discussions have been arranged on the following subjects:

Diphtheria, its Mode of Spread, and Methods of Prevention; the Alleged Aerial Diffusion of Smallpox; the Dissemination of Disease by River Water; the Prevention of Phthisis; the Microorganisms in Sewer Air.

Honorable Secretaries, F. J. Allan, Esq., M.D., F.R.S., Ed., Medical Officer of Health for the Strand District, London, W.C.; J. W. Mason, Esq., M.D., Medical Officer of Health for Hull; Phineas Abraham, Esq., M.A., M.D., Hon. Sec. National Leprosy Fund, 2 Henrietta Street, Cavendish Square, London, W.

B.—CHEMISTRY AND CLIMATOLOGY.

Sectional discussions have been arranged on the following subjects:

Air Pollution; Chemical Treatment of Sewage; The Examination of Potable Waters; Working of the Food and Drugs Act.

Honorable Secretaries, B. Dyer, Esq., D.Sc., Hon. Sec. to the Society of Public Analysts, 17 Great Tower Street, London, E.C.; G. N. Huntley, Esq., Assoc. R.C.Sc. Lond., Demonstrator of Public Health, King's College, London.

C.—NAVAL AND MILITARY HYGIENE.

Sectional discussions have been arranged on the following subjects:

Ambulance Organization; Exhibition of Various Forms of Ambulance with Demonstrations; Meeting of Volunteer Medical Officers Association.

Honorable Secretaries, Surgeon Lieut.-Col. J. M. Beamish, M.D., D.P.H., Medical Officer in Charge of Royal Arsenal, Woolwich; A. H. Cheate, Esq., F.R.C.S. Eng., Assist. Surgeon, King's College Hospital, London, Surg.-Lieut. Third Vol. Batt. The Queen's Own (Royal West Kent Regiment).

D.—MUNICIPAL AND PARLIAMENTARY.

Sectional discussions have been arranged on the following subjects:

Public Abattoirs and the Inspection of our Meat Supplies; The Utilization of Towns' Refuse for the Reclamation of Land by Aid of the Unemployed; The Registration of Plumbers; The Training and Qualifications of Sanitary Inspectors; Cholera and Port Sanitary Authorities, a Question of National Expenditure.

Honorable Secretaries, A. MacMorran, Esq., Barrister-at-Law, 2 Elm Court, Temple, London, E.C.; J. M. Robinson, LL.D., Solicitor and Clerk to the Shoreditch Vestry, London.

The meetings of the Congress will take place by the kind permission of the Council, in King's College, London.

Members of the Congress will attend in their official or academical robes, meeting at King's College at 9:45 A.M.

Membership of the Congress is free, as follows: Members or Associates of the Institute; to others \$2.50 (10s. 6d.).

MISCELLANY.

St. Louis is to have a hospital exclusively for colored people.

First Pan-American Medical Congress.—The reports in full of the transactions of the first Pan-American Medical Congress are in the hands of the public printer.

University of Buffalo.—The Medical Department of the University of Buffalo, held its annual commencement May 1. There were sixty graduates.

A Fee of Five Figures.—According to a statement in the *New York Sun*, Dr. E. L. Keyes received \$60,000 for his four months trip on the yacht, *Valiant*, while attending its owner, Mr. Vanderbilt.

Female Athletes Oppose Vaccination.—Miss Robusta M. Strong was asked why it was that she and so many other physically cultured young ladies declined to be vaccinated. Her reply was: "I do not see how I can give up my Indian clubs—and then, you know, I can't possibly spare my bicycle."

Central Dispensary and Emergency Hospital.—At the annual meeting of the contributing members of the Central Dispensary and Emergency Hospital, at Washington, D. C., held Friday the 27th inst., the following were elected as members of the Board of Directors to serve for three years: Dr. G. L. Magruder, W. W. Johnston, E. L. Tompkins, James Kerr Mason, Henry F. Blount, H. L. West, E. Kurtz Johnson and Miss Waite. The annual statement of the work of the Hospital was presented.

The Appointment of Charcot's Successor.—The *Lancet* letter from Paris states that Dr. F. Raymond will, without doubt be given the chair of the late Professor Charcot. He is the first choice of the Committee of the Faculty, Dr. Dejerine standing second, and Prof. Brissaud third, although the latter has had the opportunity of filling the professorate *ad interim*. Dr. Raymond is in his fiftieth year. He is known as a clinician at La Charité and as the author of a text-book on diseases of the nervous system, muscular atrophies and amyotrophic diseases. He has also made a report to the Ministry of Public Instruction regarding the diseases of the nervous system among the Russians.

An Origination of Rural Malaria found in Potable Waters.—Dr. Richard H. Lewis, of the North Carolina State Board of Health, has prepared a circular letter for the medical men of his State, regarding the influence of well water in the production of fever and ague. He gives a homely illustration in the recited history of two families who resided as next-door neighbors, in one of the eastern towns of his State. The two families each contained two adults—father and mother—and seven children. The two families were friendly but their homes were sufficiently separated to require inde-

pendent water supplies for each. One family drank from what was regarded with pride as "the best well in town;" the other of rain-water caught in wooden tanks. The members of the first family were constantly sick with malarial disease of one kind or another. Those of the second never had even a chill.

It is the wish to build up a line of testimony, of a like character, if such can be obtained through the medical men of North Carolina. To this end, he has written the appended letter giving an invitation to a coöperative study of the well water origin of malarial diseases:

Dear Doctor:—The evidence that malarial diseases are introduced into the system in many, if not most instances, through the medium of the drinking water is, to my mind, conclusive. The water containing the germs or plasmodia in surface or superficial soil water. Those living in malarial districts who confine themselves to water from cisterns or wells driven or bored beneath the stratum of marl or impervious clay—in other words, beyond the water which soaks down from the surface—are to a large extent free from attacks. If the people of our eastern counties could be generally convinced of this fact and thereby induced to act upon it, the health conditions of that really fine section would be revolutionized for the better. To bring this about is the object of the Board of Health. In order to do this, facts must be presented to them in the concrete—not by illustrations from "Asia and Spasia and t'other side 'o Hillsborough," so to speak, but by instances from among their own neighbors. I write to ask you if you know any facts bearing on this subject and, if so, that you will write them to me in detail at your earliest convenience. Give me the name and postoffice of the head of the family having the experience. If not personally familiar with the facts send me the name and address, that I may write to him direct.

The Maryland State Medical Faculty.—The *Baltimore Medical Journal* congratulates the faculty on the fact that its efforts on behalf of legislation to reduce the dangers of blindness among the newborn have met with success. Maryland is now the fifth State that has adopted this form of preventive legislation, the other States in their order of historical precedence being New York, Rhode Island, Maine and Ohio. The members of the Maryland Faculty who have acted as a committee to promote legislation, were Drs. Woods, Rohé, Friedenwald and Michael. Senator L. C. Carrico, M.D., was sponsor for the bill, before the last legislative session, by which it is made the duty of midwives and nurses to report to a medical man, if there be none in attendance upon the infant whose eyes become swollen and discharge "matter." The age of infant is specified as under two weeks to which this Act is made to apply. The object of paramount importance is to compel non-medical persons to report ophthalmia cases without delay; also to induce them to pay a closer attention to cleanliness, and guard the eyes of the newborn for whose well-being they may chance to be responsible. In the second place the Act accentuates to a certain proportion of our profession the need that devolves on it to instruct the midwife and others as to the perils to vision that attend upon delay and neglect. Another question that, according to the *Maryland Medical Journal*, has arisen more than once in the current discussion, is: "Can all physicians treat the trouble properly? A little self-examination is in order. We think ophthalmia neonatorum is a disease whose treatment no medical man has a right not to know. Exceptionally a case may be incurable; but such a case is very exceptional. Of eyes lost, neglect or bad treatment can be found in a large majority. A disease so serious as to receive special legislation in five States demands attention from every practitioner."

We have reason to believe that this rather slowly moving reform will not stop where it is, but will advance more rapidly in the next two or three years. The profession at large should take it up and encourage it.

Barnes Medical College.—At a meeting of the Faculty the following resolutions were passed:

WHEREAS, It is the desire and purpose of the Faculty of the Barnes Medical College to aid in advancing the standard of medical education in every prudent and proper way; and,

WHEREAS, It is desirable, from an educational and humanitarian point of view, to fully qualify those who offer to take charge of so delicate a structure as the human body, and of so valuable a thing as human life; and,

WHEREAS, The extensive departments of Medical Biology, Chemistry, Toxicology, Microscopy, etc., now parts of all well equipped modern medical institutions, require so much more of time and labor to master than has been hitherto devoted to them in our medical colleges; therefore be it

Resolved, That, in order to afford to the teacher and student alike, such time as is necessary to complete a proper curriculum in each department of medicine, "of all regular

medical students who intend graduating at the Barnes Medical College at the close of the session of 1899 and 1900, and in all subsequent classes, four years medical study and attendance upon four regular courses of medical and clinical lectures of not less than five months each, shall be required." Provided, that graduates of literary colleges, who have taken a course of scientific study, graduates of schools of pharmacy, and graduates of schools of dental surgery, may be admitted to the second year's work and course of lectures without examination.

Resolved, That we instruct the delegate of the Barnes Medical College to the meeting of the Association of American Medical Colleges, to be held at San Francisco, Cal., on June 5, 1894, to vote upon all questions arising before that body, in accordance with the above resolution, and to use all honorable means to secure the unanimous adoption (by all colleges), of requirements for graduation of students, of four regular courses of lectures of not less than five months each in different years.

THE PUBLIC SERVICE.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from April 28, 1894, to May 4, 1894.

Major PETER J. A. CLEARY, Surgeon, so much of par. 13, S. O. 79, A. G. O., April 3, 1894, as assigns him to duty at Ft. Wingate, N. M., is revoked. Major CALVIN DE WITT, Surgeon, is granted leave of absence for two months, to take effect on or about May 1, 1894, with permission to go beyond sea.

Capt. EDWARD EVERTS, Asst. Surgeon, is granted leave of absence for two months, on surgeon's certificate of disability, to take effect when his services can be spared, with permission to leave the Department of the Colorado.

Capt. C. N. BERKELEY MACAULEY, Asst. Surgeon, is relieved from duty at the U. S. Military Academy, West Point, N. Y., and ordered to duty at Ft. Wingate, N. M., relieving Major WASHINGTON MATTHEWS, Surgeon, who, on being thus relieved, will repair to Washington, D. C., and report in person to the Surgeon-General, for temporary duty in his office.

ADDRESSES.

ORGANIZATION A NECESSITY FOR PROFESSIONAL PROGRESS.

President's address, delivered before the Michigan State Medical Society at its annual meeting, held in Lansing, Mich., May 3-4, 1894.

BY EUGENE BOISE, M.D.

GRAND RAPIDS, MICH.

That professional progress, or the advancement of the interests and reputation of the science of medicine is to be desired, we all admit, but how it shall be attained is a problem that has not yet met with a satisfactory solution. It is evident that it must be along certain lines, prominent in which are a higher standard of education, and a higher standard of professional morals, as well as advancement in therapeutic resources.

At present the title, "Doctor in Medicine," in this country does not indicate any degree of literary or scientific excellence in the holder. It does not necessarily mean that he is one whose fitness to care for the physical trials and sufferings of his fellowman has been passed upon and established by a body of competent examiners, but that he is one who has either assumed to himself the title, or one to whom it has been given by a corporation legally chartered by some State Legislature.

In either case there is none to say him nay. In many States, after laborious effort, an imperfect law has been enacted, purporting to protect their citizens from the dangers consequent on the predatory instincts of him to whom the practice of medicine is merely a road to wealth. But so open is the network of these laws, and so indifferent are they whose duty it should be to enforce them, that many slip through and prey upon the public upon whose fitness no corporate college has passed judgment. The facility also with which charters are granted by our unstable Legislatures to any body of men for any or every conceivable purpose, without inquiry as to necessity or even expediency, enables any unprincipled individual whose fancy has pictured to him the enormous revenue to be obtained by "practicing medicine," to acquire legal status among physicians with the slightest appreciable outlay of time, money and industry. The possession of any degree of preliminary education, of the acquirement of any appreciable amount of medical knowledge, is only of importance as a means to an end; and that end the legal right to call himself doctor, and to collect fees from the credulous but innocent public.

Such is the condition in nearly all of these United States, and such will it remain till the honest and honorable members of this profession of medicine unite, all over the country, to establish some method by which there shall be some distinction between the man who practices medicine for revenue only, and him who holds the welfare of his patient and the

honor of his profession as his highest earthly ambition.

We, the State Society, profess to stand between the public and fraud. Let us make the profession reality. Let us establish a standard entirely apart from that recognized by law or by any chartered medical college. A standard that embraces more than the possession of a certain amount of medical and surgical lore. One that shall stand to the public as a warrant that the physician who holds a certificate of membership in this body is in all respects entitled to its confidence.

The first and highest qualification of him who is to hold the lives and physical welfare of others in his care should be thorough professional education and training. To the attainment of this, a *habit* of study is necessary; therefore a grade of preliminary education should be demanded which shall be a warrant that habits of study have been formed; that the power to grasp and hold ideas has been cultivated; that a certain amount of trained analytical power has been acquired, so that logical inferences and conclusions can be drawn from existing facts. The young man who steps forth from his college into the world's arena may be called upon at once to grapple with the most serious surgical emergencies, or to wrest human lives from the threatening death consequent on a placenta prævia, and this without time to call upon the older experience of others. It is not enough for him, or for his patient at that time, that his diploma narrates the fact that he has consumed three years in getting his education. Happy is he and thrice fortunate is his patient if his habits of study and his professional pride and ambition have been such as to have enabled him to master the teachings of his professors and to have the knowledge within call of his mind at such time. Nor will the man who is by ability and character fitted to be a member of this body, be content with the knowledge gained while within his college walls.

The true physician will be an inquirer during life. He will, by the force of his own aspirations and impulses, be a searcher after knowledge. He will study the experiences of others as embodied in the weekly or monthly journals, will reason from their reports to his own experience, and as the science advances will put aside views formerly held and grasp that which has been proven. No physician can be progressive who does not, by the reading of medical journals, keep in touch with the thought and experience of the great body of the profession. No conscientious practitioner can feel that he is living up to the highest possibilities of his profession, and doing his full duty to those who intrust their lives to his keeping, who contents himself with the lessons of his own experience and the teachings of former text-books. Professional progress demands constant study.

But for those who by education and industry are fitted to hold the responsible and honorable degree of "Doctor in Medicine," other qualifications should be required to enable them to hold membership in this State organization.

One of the most difficult and yet most vitally desirable virtues for a physician to acquire, if he is so unfortunate as not to possess it, is a recognition of what should be his deportment toward his professional brethren.

If we will place our profession on the heights originally destined for it; if we will make the name of physician honorable and its bearers honored, professional courtesy must stand on a plane but little, if any, lower than professional education.

We must demand that he who will become a member of this organization shall so conduct himself toward his brethren as to add dignity to the profession of medicine, instead of degrading it to the level of low trickery and dishonesty. While there are many who know no other way to rise than by pulling down those above them, many who by openly expressed jealousies and calumnies of their professional brethren have rendered just the remark that was made to me not long ago by a Jewish merchant: "You doctors are worse than Chatham Street Jews;" (let your minds dwell for a moment on the full significance of that remark), I say, while there many who, by their conduct toward their fellow workers, have justified this public opinion, there are a great many, aye, a great majority whose impulses are honorable, whose desire it is to live in harmony or in a spirit of friendly rivalry with their fellows. These by organized effort could so elevate the standard of professional dignity as to implant in the thoughts and hearts of the most dishonorable and mercenary practitioners, a feeble spirit of emulation.

"Harmony and a proper *esprit du corps* may uphold the dignity of even an inferior profession; but the public rarely respects any class of men, the members of which have no respect for each other."

Nothing is to be gained by slanders and calumnies of those in the same profession. There only results (unless the slanderer is lost to all sense of honor and professional pride) a loss of self-respect, a loss of respect on the part of others, and a public degradation of the profession of which he is, unhappily, a member.

Again, by such organization as I have in mind, a stronger stand against the inroads of irregular practitioners would be possible. I doubt very much whether we do not sometimes injure our cause with the public by showing too great sensitiveness as to the tolerance shown such men and by injudicious efforts at their suppression.

"A certain portion of mankind are so constituted that they require to be ridden by others; and if you succeed in unhorsing a particular impostor, it is only to prepare the saddle for a fresh and more unflinching equestrian." By throwing the gauntlet at an insignificant man we at once raise him to the dignity of a competitor.¹

But apart from our conduct toward pretentious impostors, whom we should utterly ignore as something beneath notice, our conduct toward each other should be marked with dignity and honesty. The professional intercourse of men qualified to bear the title, "Doctor in Medicine," should be characterized

by a spirit of friendly emulation and honorable support.

"Medicine, cultivated as a science, aims by innumerable influences to unite its members in a universal brotherhood, and that fraternity should be one of perfect equality. There can be no class privilege, no aristocracy, and no distrust among medical men who properly estimate the honorable character of their calling.

"They will accord to each new member that generous confidence and fraternal regard which are due to brethren bound together by a common sympathy. Nor will that bond be broken, nor that confidence destroyed except by the most absolute proof of professional delinquencies."²

But no man can respect his professional brethren in whose breast is not implanted a feeling of reverence and love for his profession. It is his duty to maintain in his individual character a high moral rectitude, a just and honorable conduct, a devotedness to the welfare of his patients, and an unceasing effort to improve himself and his science.

Our profession demands from us respect and honor. It demands the best service of our lives. To live worthy of the profession we have chosen should be next to our religion. That its name shall not be dragged in the dust and trampled upon by all men, it is incumbent upon us, its disciples, to dignify it by lives of professional purity and honor; and by untiring effort to plant its standard still higher.

Hippocrates said (and his remark may unhappily apply to our own times): "Medicine is of all the arts the most noble; but owing to the ignorance of those who practice it, and of those who inconsiderately form a judgment of these, it is at present far behind all other arts." But in our own times it is not merely ignorance on the part of the doctor and the public that has degraded the profession; many other factors have combined to that end. One of the most potent of these is the degeneration of the doctor himself, by reason of his having placed the acquisition of wealth far higher in his desires than the acquisition of knowledge. Cupidity is one great obstacle to professional progress. It stands in the way of the search for more advanced truths. The physician who falls under its power is led into evil practices and unprofessional associations by which his profession, which he should honor with his every power, is degraded to the level of the merest trade.

The spectacle of a man who bears before the public the honorable title of Doctor in Medicine, selling his honor and reputation to the highest bidder and giving testimony in a court of justice which dishonors his profession and degrades its followers is one that merits universal condemnation. An undue desire for wealth blunts a man's professional conscience and lowers his standard of life. Just remuneration for skilled service is right and honorable, but it should not blunt the sense of professional honor; nor displace the desire for professional eminence.

The science of medicine has a right to the first place in the love and devotion of its followers. The struggle for "success" as represented by the largest income or the most fashionable *clientelé* often leads to a forgetfulness of or a disregard for "success" according to the standard of educated men.

¹ Bigelow, "The Medical Profession and Quackery."

² Dr. Stephen Smith, "Our Status Abroad."

There is a moral in the remark made by a distinguished Parisian surgeon to an American friend who was speaking of the great reputation of his preceptor: "What has he done?" asked the Parisian; "I do not remember to have read of any of his writings." The American responded in a puzzled way: "It is true he has never written anything, but he has a very large business." "And is that the standard by which you estimate professional excellence?" retorted the Parisian.

A man may by his ability and by his professional traits rise to the highest pinnacle of local public esteem. His reputation as an able successful practitioner may be merited, but his profession demands something more from him. He is not living up to his professional duty if he does not endeavor to enrich the field of professional knowledge by the ripe results of his own investigations and experiences. If he, by writings and contributions to professional journals, gives to his fellow physicians the valuable knowledge which he is continually gathering, his reputation is imperishable. But if he lives content with the wealth he can acquire, his name and his fame die with him.

Every man, if he would have the respect of the public, must respect his profession. He must honor it if he would be honored by it. He must remember that it depends on how he bears himself whether he is the peer of the highest or the barely tolerated servant of the public. As Dr. Oliver Wendell Holmes puts it,—

"If Sir Astley Cooper was ever called to let off the impure ichor from the bloated limbs of George the Fourth, it was the king who was honored by the visit and not the surgeon. If you do not feel, as you cross the millionaire's threshold, that your art is nobler than his palace, the footman who lets you in is your fitting companion, and not his master."

But it is not merely that the relations of physicians to each other would be raised to a higher standard by such thorough organization of the best elements in the profession as I am advocating; nor that thereby our respect for, and attitude towards our profession would be advanced, but that the relations between the public and the medical profession would be gradually changed.

We should enter upon an era when to this organization and its individual members the people would naturally look for advice as to matters pertaining to the public health.

The physical training of our youth, and the relation of the physical to the mental well-being would be placed under the supervision of those who by reason of their membership in this Society would be esteemed and accepted as qualified censors in such matters.

It is the duty of rational medicine to enlighten the public, as well as the profession, in regard to the true powers of the healing art.

The people deserve to be undeceived and re-educated that they may know what is true and trustworthy from what is unfounded and fallacious.

The profession themselves will proceed with greater confidence and self-approval in proportion as they shall have informed mankind on these important subjects. Honesty toward ourselves and the public will encourage trust and confidence in return. The physician who can forget, for the time, his own pride and professional ambition in his desire to deal

honestly with his patient, will ultimately win from his patients and the community at large such reputation as shall afford more satisfaction to his professional instincts and aspirations than a lifetime of selfish effort will attain. Mistakes are made, reputations are injured, and the profession itself brought into disrepute by the habit of promising more than we know we can perform. Our profession is often brought into disrepute and made unpopular with a large and sagacious part of the community because so many members, by unfulfilled promises, have disappointed expectations which they have allowed themselves to raise. We may safely undertake and promise to cure diseases which we know to be curable, and to perform what art and science can do towards conducting doubtful and dangerous cases to a happy issue, and we will thus cultivate confidence and elevate our profession.

It should be every man's ambition to elevate the standard of his profession among his brethren and in the estimation of the public; and to gain such eminence as he may by upright conduct toward his fellows, by honesty to the public and by literary and professional industry. No man can permanently sustain his status among gentlemen if he do not first secure to himself the sympathy and respect of his fellow laborers. This being attained, he can by laborious effort and persevering industry rise to eminence in his profession and acquire the honest regard and respect of his fellow citizens. He can live an honored and envied life and build to himself that grandest of monuments, a name that will live forever in the annals of his profession and in the hearts of its disciples.

If, on the contrary, his ambition is confined to himself, and his conduct to his fellows and the public regulated only by his estimation as to how everything may be made to serve selfish aims, and to rebound to his own personal aggrandizement, he alienates his fellows, he dishonors his profession and he defrauds the people who trust him. His practices become corrupt, and driven by the scourge of his own outraged personal self-respect, he descends continually to lower levels. Pitiably, indeed is the condition of that man who is shunned by his *confrères*, whose name provokes only contempt, and who is dismissed from the thought as one fallen from the high estate of a Christian gentleman and an honorable man.

And yet such there are in our profession. Such there are whose names are enrolled as members of this Society, and who thereby, to the great mass of the citizens of this State, are indorsed as the peers of those whose names are endeared to us by long lives of honest and honorable professional effort.

Such things should not be. Our profession demands of us that we should countenance only that which is honorable. That we should never forget its claims and our duties. The public have a right to demand of us that we shall point out to them those who are worthy of confidence; those to whom they can intrust the lives of their children. And finally, an honorable and proper pride demands of us that we shall do what we may to purify the name, "Doctor in Medicine." This is possible, but only possible by means of re-organization on the lines that I have pointed out. Do not imagine that I am dreaming of a professional Utopia "where every prospect pleases," and even man's not vile. There will

be in every Eden a serpent. There must needs be men who, with the outward semblance of honesty, cover dishonorable characters; but we can make the manifestation of such dishonesty unpopular. We can educate the public to a belief in the reality of our profession and the nobility of our art. There are enough physicians in this State, to whom their profession is dear, to rehabilitate the name, "Doctor in Medicine," if they will act together. This can only be done through organization; not merely into societies, but in such a way and according to such plan as shall unite the profession of the entire country in one bond, under one government, and designated by such title as shall be distinctive.

It is true that we have a national organization, and that we have State organizations, and innumerable minor or local societies, but there is no concert of action, no community of interests, except that the members of all legally bear the title, "Doctor in Medicine," and all agree to conform to the Code of Ethics of this national organization. There is need that we re-organize so that all may be under one central government and act as one body. It must be with any member of any county society as it is with the private soldier in the United States Army. By enlisting as a private soldier, he becomes a member of a company, and at the same time and by the same act, a member of a regiment, a brigade, a corps, etc., so that he is directly under the control of the Commander in Chief of the Army of the United States. After some such plan might the medical profession of this country be organized. We may not be able to remove at once from our societies those members who through dishonorable practices degrade their profession, but we can protect our domain from further incursions.

Such organization as I shall suggest will enable the AMERICAN MEDICAL ASSOCIATION to erect such defences as it chooses, and to dictate authoritatively who may and who shall not be admitted to its highest privileges. It can not control the acts of legalized medical colleges as to what preliminary education they shall demand of their students, nor can it dictate to them how long and of what character their course of study shall be, but it can say what qualifications of education and conduct shall be necessary to enable an applicant to join its membership. At present each State has its own State society, and in this, our State of Michigan, there are some twenty-five local societies. But there is no mutual interdependence. Each organization is independent of every other. There can be no concert of action throughout the nation or even throughout the State, because there is no central universal government.

I have said we might organize in some respects according to the plan of our Army. It would be well that every local society should be a part of our State society, and not merely in name but actively, and under its government. And that every State society should be a living constituent of the National organization, and that no local or county society should be represented in the national society, except through its State organization. It would be well also that every man, by joining a local society should by that same act become at once a member of the State and national societies, and that no man can become a member of either of these societies except through joining a society in the county or district where he resides. Thus would these local organiza-

tions stand guard at all the avenues of entrance, first to the State society and, second to the AMERICAN MEDICAL ASSOCIATION, and fewer unworthy men would find entrance.

To the annual dues demanded by and payable to the local society, would be added \$3 for the State and \$5 for the National organization, and every member would not only be a member in name of these organizations, but he would be entitled to, and receive their Annual Transactions. He would also bear the title of "Fellow of the AMERICAN MEDICAL ASSOCIATION," which could thus be made to stand to the public and to the profession of the world as a title of honor and a guarantee of professional worth; on a plane as high as, or higher than, the F.R.C.S. of the British profession.

It might be well also, in this plan of re-organization, that the presidents of the local societies in the State, which are in affiliation with the State society, should constitute an Advisory Board of the State Society, to which all matters pertaining to the admission of members and the government of these local societies should be referred. This Board might also be the executive organization of the State society, through which many matters of routine which now take up the time of the entire society, could be transacted. Thus more time could be devoted to literary and professional work, and not only the number of papers, but the standard of excellence increased.

It would also follow, if the profession of all the States should organize on the same general plan, that the presidents of the various State societies would constitute an Advisory Board (if I may so term it) of the National organization, which should have general supervision over matters pertaining to the government of the State societies, and which should formulate rules controlling the admission of members to these smaller county and district societies. In this way would uniform rules in all the States be secured, and the standard could be placed as high as seemed desirable. It is probable, also, that such rules and regulations would be respected by the local societies to which they would be directed, because formed by a Board of State officers, elected through delegates from these various local organizations.

By such a plan as I have outlined, the qualifications of education and character necessary to become a "Fellow of the AMERICAN MEDICAL ASSOCIATION" would be uniform throughout the country, and could be placed high enough to stand to the public as a guarantee of the fitness of such men to practice the profession of medicine. The membership of the State societies might be doubled, and instead of five thousand members of the AMERICAN MEDICAL ASSOCIATION the number might easily be twenty thousand.

The financial condition of these societies would be sufficient to enable them to carry on all desirable lines of professional work. The desirability of being able to write himself a "Fellow of the AMERICAN MEDICAL ASSOCIATION" and thus stand before the public indorsed by the best elements of the profession throughout the entire country, would be sufficient inducement to make most physicians live up to the requirements of their societies and promptly pay their annual dues.

The standard of medical education would necessarily be raised to conform to the requirements of

the national society, because, while we could not legislate against or indorse any college or set of colleges, we could require each applicant for membership to be a graduate of a college that required a four years' course, or to conform to some similar standard. If laws were needed to regulate the practice of medicine, we should be in a position to secure uniformity throughout the entire country.

It would not be long before the public would understand that to be a "Fellow of the AMERICAN MEDICAL ASSOCIATION" was a certificate of such professional ability as would enable its possessor to grapple with any disease, however intricate, or to meet any emergency, however sudden. That its holder was a gentleman in his professional life, and one who would be a reliable guide in all matters pertaining to the physical well-being of his patients.

Thus would the science of medicine be continually advanced, not only in the estimation of the public, but, what is far more important, in the estimation of the members of the profession. There would be an incentive to honest effort toward professional growth and toward honorable professional intercourse.

The acquisition of wealth would not be placed far above all other motives. Honor and honesty would co-exist with a desire for an advancing reputation in the professional world and the science of medicine would attain the position to which it is entitled.

THE NATION'S SIN OF OMISSION.

Read before the Texas State Medical Association at Austin, April, 1894.

BY T. J. BENNETT, M.D.

AUSTIN, TEXAS.

CHAIRMAN SECTION ON STATE MEDICINE AND PUBLIC HYGIENE.

The Constitution of the United States guarantees to every citizen life, liberty and the pursuit of happiness. The laws of the country have been framed by wise men, after careful study and observation, looking to these ends; and, in a sense, every enlightened government is "paternal." It is jealous of any infringement of these rights, and the humblest citizen can claim, and through the courts receive, protection in his life, liberty and property; and any trespasser upon either is swiftly punished. The arbitrary arrest, in a foreign country, of the humblest person claiming protection of the stars and stripes, is resented, his liberty secured, and restitution demanded, and the demand is backed, if need be, by the whole military and naval power of the country.

The laws in respect to life and liberty, and in regard to peaceful possession of one's own, and the enjoyment of the fruits of his labor, have been amended and made better, as time and experience have revealed defects, and as changed conditions have made necessary.

The laws with regard to special privileges are framed with an eye to the protection of the life, liberty and property of others, and of society generally. No man is permitted to conduct a business the nature of which threatens society with danger; such, for instance, as the running of railroad trains and steamboats, and the operation of factories, mills and shops; and such conditions are attached to the privilege, when granted, as to reduce the danger to others to the minimum.

In return for this protection and paternal guardianship, the citizen is taxed to carry on the operations of the machinery of government, and certain duties are

required of him, all of which are duly specified, and made compulsory, under a penalty for neglect, failure or refusal to perform them. He shall serve on the jury, do certain road work and, in time of war, shall bear arms in defense of the country; or he may be impressed by any sheriff to put down any local lawlessness. He is taxed, moreover, for the support of the defectives, and for schools and poorhouses.

As civilization has advanced, and experience demonstrated the necessity, laws have been enacted which throw every protection around one's live stock. His cattle are protected from infectious diseases by expensive quarantine, if need be; and, especially in Texas, the theft of cattle, a horse, more particularly, is a most heinous crime.

But with regard to the *health of the citizen*, there is, in Texas and some other States, a woeful lack of either solicitude or legislation. The most ignorant man is permitted the dangerous privilege of practicing medicine, without a restricting clause in the law. He is licensed by the possession of a diploma alone (it may be stolen or purchased) which, according to Webster, is only a certificate, or "evidence of a degree having been conferred," and "conveys no rights or privileges whatever," to enter the community, to invade the family of his confiding dupes, and take in hand the life of any member; to prescribe the most deadly drugs—of the properties of which he may be entirely ignorant—and, by his ignorance, kill with impunity. He can set aside the law in regard to the sale of liquor on certain days and, by a prescription, can accommodate any old toper with the stuff he craves. Moreover, by virtue of his calling, he is exempt from certain duties to the State or county which other citizens have to perform. In short, the quack doctor (with or without a diploma) is one of the many and grave dangers that threaten society; and in this State protection has, so far, been prayed for in vain; the bugaboo of "personal rights" is pleaded, and the individual's alleged "rights" to practice medicine are respected, often to the great detriment of society. The citizen *has a right* to protection against this, as all other dangers—purchased by his taxes—and his support of the government and his obedience to the law.

Enlightened governments become enlightened through observation and experience; and, as we have shown, our laws are amended, and jurisprudence, in every respect (except medicine), has developed *pari passu* with the progress made in the many relations of life and business.

The existence of a soul in man is said to be evidenced by the possession of the faculty of reason, and this faculty alone distinguishes man from the lower animals; the power to reason, philosophers say, is evidenced by the ability *to profit by experience*; and no race or people is thought to be capable of self-government who do not so profit. Estimated by that test our boasted civilization is a myth, and our government unreasoning and unreasonable; for it is evident to the most casual observer that it has failed to profit by past experience in dealing with one of the most vital and essential elements of danger, to-wit: Disease. True, quarantine has been improved year after year, as experience has revealed defects and the necessity for additional requirements or changes, until it is now reduced to a rational system, and is almost perfect. But, while we would not be thought to underestimate the value and im-

portance of quarantine as against the invasion of foreign disease, we will aim to show that by attention to this feature of protection alone, to the neglect of internal sanitation, the Government, to use a homely expression, is "saving at the spigot and losing at the bung." The lives lost, the time lost, and the property values destroyed in time of the most destructive epidemic, are as a drop in the bucket to the lives, labor and property being destroyed every day, all over the country, by diseases *easily preventable*; and it is not, by any means, through ignorance of their nature and cause and the mode of prevention that this loss occurs, but by the apathy, indifference, neglect, failure—call it what you will—of the general and State governments to take hold of the subject, and, profiting by the experience and wisdom of the medical profession, apply the law to the eradication and prevention of the local and internal diseases, to amend the laws in accordance with the discoveries and recommendations of the medical profession; in short, to avail of the benefits and apply the principles of State medicine.

Society has the right to protection from typhoid fever, consumption and diphtheria, as well as from yellow fever and cholera, or other danger of whatever kind; and it is clearly the duty of the Government to secure it.

Recognizing, then, the fact that thousands of lives are annually lost through the agency of preventable diseases; recognizing that the general Government has failed so far, to secure to society the protection to which every citizen is entitled, it is pertinent to inquire as to this grave omission.

In view of our civilization, the intelligent zeal with which laws have been framed for all other requirements of the citizen, whenever experience has shown what was best; the solicitude manifested for the safety of the poorest citizen, if in trouble abroad, it can hardly be said that it is either ignorance or indifference, on the part of the lawmakers, that causes this sad lack of legislation, and the consequent great danger that threatens the public health. Our Congressmen, beyond doubt, have an intelligent appreciation of the maxim, "Public Health is Public Wealth," and of the importance of health to the happiness and prosperity of our country. What, then, is the reason that in so many States no safeguard is thrown around that which is so essential to all other rights of the citizen—the possession of health? Why has not the general government profited by the experience of sanitarians everywhere; utilized their observations and researches in the bacteriological laboratory and at the bedside, and the results of experiments shown in abating disease by cutting off a vitiated water supply, for instance?

The question is easily answered: It is because there is no *organization* in the medical ranks—no coöperation between medicine and law; because there is no *head* to direct the vast energy of sanitarians and laboratory investigators, which, being expended spasmodically and individually accomplishes nothing; no one to direct how the accumulated knowledge of medical and sanitary science may be utilized; no department devoted to this paramount interest, whence such information can be procured as will enable Congress to frame laws which shall constitute an intelligent application of means to ends—the adaptation of the principles of State Medicine.

Individual effort counts for nothing. We have, all over the land, the most intelligent and indefatigable workers in biological research, and in every field of medical and sanitary investigation. They find that certain deadly diseases are caused by the presence of a bacillus or its products, and they discover also its antidote. The knowledge that hydrophobia is caused by a poison in the salivary gland of a dog or other animal; the knowledge that, to date, no antidote has been revealed to science—that she has no remedy even to palliate the dreadful sufferings of one inoculated with this poison—had as well never been acquired, so far as any protection is afforded by law against this great danger. The same may be said with regard to many other sources of danger; no protection is afforded by law against polluted water, nor against diseased meat, or decaying fruit and vegetables on sale at every stall in most cities. The medical profession is like an army of brave and capable men without a leader; each man is waging war upon his own hook against the invisible hosts of earth, air and water, and each cries out singly for help from the strong arm of the law.

Were the statistics compiled by the State Boards of Health, showing the fearful mortality from preventable diseases, and the results that have followed even spasmodic efforts at sanitary reform, brought to the attention of Congress by the united medical profession, it is not to be doubted that they would be convinced, and speedily enact such laws as would enforce sanitary reform everywhere. But, unfortunately, the profession is divided; and each section represents to Congress a different course with reference to meeting the trouble. And Congress, for want of intelligent advice, really does not know what is best to be done.

As the AMERICAN MEDICAL ASSOCIATION comes nearer being a representative organization, reflecting the concensus of medical opinion, than any other in this country, the bill formulated by their committee and now before Congress should be regarded as being the first step in the sanitary reform needed.

In this connection the movement is of vast importance. Indeed, it is the most important matter now engaging the attention of the medical profession. In that bill the many sources of danger are pointed out, and suggestions are made for compilation of such statistics and the gathering of such information generally, into one office, as will enable the Secretary to give to Congress the exact data upon which to frame laws to meet every requirement.

Certain States have been pioneers in this great work, and, listening to the suggestions of their sanitarians, they have enacted laws which, in a short time, have reduced the mortality of certain diseases 50 to 100 per cent. Illinois, Ohio, Michigan, Massachusetts, and other States, may be mentioned as setting a praiseworthy example. In Illinois, Dr. John H. Rauch,—the Farr of America, peace to his ashes,—did more for sanitation and the advancement of preventive medicine than any man living or dead. That State should erect to his memory a monument that will pierce the clouds, and in letters of living light inscribe upon it, "*Benefactor*." The condition of affairs sanitary in Illinois before and after Rauch's measures of reform were inaugurated, will serve as an illustration of what may be done by legislation based upon sanitary and medical knowledge.

The saving to the State by the wisdom of that one man, and the energetic and younger men who succeeded him and still further carried out the inspirations of his genius, if estimated in money would pay the national debt, or the expenses of his Government ten years, and yet—that is only one State. We will confine ourselves to Chicago, and briefly point out the results in the city alone, since the inauguration of the World's Fair. For the purpose, we avail ourselves of an admirable paper in the *Independent*, entitled,

SOME SANITARY GAINS.

"In 1891, in Chicago, there was an average daily mortality from typhoid fever of 5.4, chiefly young lives. There was a betterment in 1892, as a result of some sanitary attempts as to water supply and sewerage.

" At one time in 1891 the percentage of typhoid fever deaths was 16.6 in 10,000, making a total of 1,997; only three short of 2,000, and each death is justly presumed to represent ten cases which recover.

" Nobody doubted that the cause of the trouble was a polluted water supply. . . . Matters had considerably mended in 1892, but then the mortality was equal to that of Philadelphia in the Centennial year.

"It will perhaps present a more striking picture if we say that in January, 1892, there were 311 deaths from typhoid fever in Chicago, while in the much more compact city of Brooklyn there were only 8. In May, 1891, half as many people died as in the whole of Massachusetts during the entire year. Such was the condition before the beginning of the World's Fair project, and people were afraid to go there. Sanitary measures were inaugurated. To be brief, a canal four miles in length was cut, which disposed of the sewage, and pure water was conducted to the city from a distance of twenty-five miles. Crematories for the disposal of garbage were introduced, and from being a city of naturally unhygienic surroundings, situated on the borders of a great marsh and lake, where sanitary engineering was not only difficult but very expensive, and having consequently a heavy death rate, Chicago has become, while not a sanitary model, a standard for comparison with older and less densely and more favorably located cities, like Baltimore and Philadelphia, the mortality from typhoid fever having fallen from 311 deaths in January to 47 in December. And this was accomplished by laws in accordance with suggestions of the State Board of Health, based upon statistics compiled by the Board, and other sanitary knowledge, the result of individual experiment and research; an example of how medical knowledge can be applied by the State for the protection of the public health.

Should Congress create a Department of Public Health in accordance with the petition of the AMERICAN MEDICAL ASSOCIATION, it will be the first and most important step in the direction of remedying the great evil complained of,—the unnecessary deaths of so many thousand people. In the Committee's memorial to Congress, the duties of the Secretary of the Department are suggested, and they cover every phase of sanitation, comprehend every subject that has a bearing upon the public health. When a head shall have been created and the department organized, all the discoveries of individual workers, all the statistics collected by State and local boards of health

will be focused there, collected and classified, and thus will be made evident what laws are necessary. The results of such compilation would be most astounding.

To give an illustration, even on a small scale, of the immense losses being sustained, we will take the deaths from preventable diseases in only one or two cities, and estimate in dollars and cents the value of the lives and time lost.

In the *Scientific American* is published, under the head of "Sanitary Negligence," a table showing the mortality of a number of cities in America and Europe (prepared by the Secretary of the Maryland Board of Health). From this table we take the following as illustrating the difference in mortality of the principal American cities.

The annual death rate per 1,000 inhabitants is as follows:

New York	26.47
Brooklyn	21.84
Chicago	18.95
Boston	23.88
Philadelphia	21.95
St. Louis	18.47
Baltimore	21.10
San Francisco	18.21
Cincinnati	19.67
Cleveland	18.19
Buffalo	16.28
New Orleans	28.72
Milwaukee	16.00
Minneapolis	9.60
St. Paul	9.61

The writer of the article says: "There is no more accurate gauge of civilization actually attained by cities than their comparative mortality tables. It is the object not only of medicine to save and lengthen human life, but it is (ought to be, but apparently it is not,) also the supreme object of the entire governmental and social mechanism." "In a general way, the higher the death rate, the greater the indifference to hygienic conditions of life." "There is no reason, except a disgraceful reason, why New York should allow a death rate of 7.36 higher than that of London, (19.11). This means that New York permits the unnecessary death of 6,630 of her citizens every year." "With a difference of death rate between New York and Brooklyn, just across the river, of 4.63, New York is criminally chargeable with 4,171 additional and unnecessary deaths every year. As compared with Philadelphia there are 4,071 more deaths to her debit. And as compared with Chicago, the appalling number of 6,774. There is certainly no good reason why the mortality of Philadelphia and of Boston should be higher than that of Chicago; but the table shows that Philadelphia kills, proportionately, 1,673, and Boston 1,200 more of her citizens each year than the city that is accredited with drinking her own diluted sewage. It is plain that something is radically wrong."

And these comparisons were made, it seems, even before the great source of typhoid fever,—the polluted water of Lake Michigan,—was abandoned and the introduction of pure water from a distance; the disparity in mortality as compared with these same cities must be still greater in future.

The excess of deaths in five cities over the deaths in Chicago foots up as follows:

Boston as compared with Chicago	1,200
Philadelphia	1,673
New York	6,774
Brooklyn	1,413
Baltimore	490
Total	11,550

"This," says the writer quoted, "is the cost of criminal negligence of known laws of health in only five of our cities. If London cared as little for the lives of her citizens as New York seems to care for hers, there would die in that city every year 21,556 people more than at present die." The money value of the lives lost in those five cities alone, as figured by the statistician quoted, is over forty-six millions of dollars; while the time lost by others sick, *i.e.*, according to Farr, there are two years of sickness to every annual death, or in this instance (11,556 deaths) 23,110 years of needless sickness, which, estimated in money values means, for lost time alone, \$6,930,000 besides bills for the doctors, nurses, druggists and all other expenses. "And yet," says the writer, "when the city fathers are asked for a few thousand dollars for meat inspection, for new and necessary sewers, for an unpolluted water supply, or for any other measures of preventive medicine, the request is refused, or acceded to with such cringing stinginess as to be ludicrously inadequate." "In only five cities, and estimated in crude financial losses, we have seen there is a squandering of some fifty-three millions of dollars. Extend the calculation,—easily made,—to the whole country, and it is recognized that we are wasting several hundred million dollars worth of human lives each year, by our recklessness and our stupidity. The medical profession heroically works to save a few thousand sick, while the community goes on blunderingly and savagely killing and making sick by the million."

Our writer is wrong,—as we have attempted to show—to attribute this fearful mortality to either ignorance, or stupidity, or parsimony, so far as the Government is concerned. It is a national sin not to lower the death rate all over the United States; but it is a sin of omission in the failure to apply the vast concrete knowledge obtained by medical and sanitary science to the prevention of disease,—in accordance with the clearest dictates of humanity, reason, justice and common sense. But this the general government can not do, or be made to see the necessity for doing, until provision has been made for collecting, compiling and classifying this knowledge, and there is brought to its attention the cost in dollars and cents, of sanitary neglect; till the deaths all over the United States from preventable disease are consolidated, and it can be shown how much in money can be saved to the Government by the passage of laws to apply the remedy pointed out by sanitary science. Until the Government recognizes the great necessity here attempted to be shown for the creation of a Department of Public Health, and creates it, and puts it into operation, it must stand chargeable with criminal neglect, and held responsible for this fearful waste of human life.

The annual meeting of the New York State Board of Health was held May 3. Dr. Florence O'Donohue was re-elected President, and Dr. J. T. Barnes, of Albany, was elected Secretary of the Board, *vice* Dr. M. Barnes resigned.

ORIGINAL ARTICLES.

A NEW METHOD OF VALVULAR GASTROSTOMY WITH A MUCOUS MEMBRANE LINING.

BY EDMUND ANDREWS, M.D., LL.D. AND
E. WYLLYS ANDREWS, M.D.

PROFESSORS OF CLINICAL SURGERY IN THE MEDICAL SCHOOL OF THE
NORTHWESTERN UNIVERSITY, AND SURGEONS IN THE
MERCY HOSPITAL, CHICAGO.

The older methods of making a stomach fistula for feeding, in case of impassable stricture of the esophagus, seldom proves satisfactory. Food is easily introduced and digested, but can not be forced through the pylorus into the intestine, because at every contraction of the stomach for that purpose most of the contents are forced out through the fistula. Thus the food is lost, and many of the patients die of starvation. A mechanical rubber valve which we invented in one case partly overcame the difficulty, but did not permanently save the patient.

Wetzel devised the following method: A small opening being made into the stomach, a rubber tube was inserted, and the outer portion of the tube laid along the external surface of the viscus, the stomach wall was folded over it for one and one-half inches and fastened with Lembert stitches, taking up only the peritoneal and muscular coats. The outer end of the new canal was stitched to the skin. The fistula thus formed resembled the ureter where it enters the bladder, and being thus valvular prevented leakage. A difficulty, however, arose. The new canal was lined with peritoneum and not with mucous membrane. It threw out granulations, and could only be kept from closing up by constantly wearing the tube.

Kocher, of Berne, modifying a plan of Alberti's, proceeds as follows: He draws about four inches of the stomach out of the abdominal wound, and stitches up the latter except about two inches. Then the surface of the protruded stomach-pouch is stitched to the wound. Next, he begins at the upper end of the wound and forcibly makes a channel between the superficial fascia and the muscle, etc., carrying the channel up outside the cartilage of the seventh rib, and onward to the sixth rib. Here he cuts an orifice through the skin. He then seizes the projecting stomach-pouch, forces it up through the new channel, and brings the tip out at the orifice on the sixth rib. Here it is opened and stitched to the wound in the integument. The bulging cartilage of the seventh rib acts to compress the pouch, and is said to prevent leakage. It seems like rough treatment of a delicate organ, but there has not yet been enough experience to decide the question of its usefulness.

In a recent case of esophageal stenosis we first tried the plan of opening the stomach with retrograde dilatation of the stricture of the esophagus, closing the stomach wound and returning the viscus. This restored the power of swallowing for a time, but the stricture again contracted, and shut off nutrition. Next we tried Wetzel's plan with perfect success, but for reasons above stated, the tube must be constantly worn.

After considerable experiment on cadavers and animals, we find the following operation feasible, and as it furnishes a valvular orifice lined with mucous membrane, a tube will only need to be used occasionally to prevent possible contraction at the orifices:

The mucous membrane of the stomach is connected with the muscular coat by a layer of exceedingly loose connective tissue, so that any spot on the mucous coat can be made to glide some three-quarters of an inch on the parts beneath. As an experiment, we injected melted lard forcibly into this loose submucous tissue, raising up the membrane three-quarters of an inch, in places. The specimen was then dried to render it rigid, cut into thin sections and the fat dissolved out in ether. Fig. 1 shows a section of this sort, the outer and inner walls being connected only with delicate reticulated fibers.

Fig. 1.

When the muscular walls of the living stomach contract, the mucous membrane is thrown up into high ridges, presenting to the eye of the surgeon curious quadrangular patterns, very different from the appearances in a dead stomach. Fig. 2 is a diagram to represent the folds in cross section.

Fig. 2.

P—Peritoneal coat. M—Muscular coat. C—Connective tissue coat.
Mc—Mucous membrane thrown into folds. FF—The folds.

This exceeding looseness of the membrane greatly facilitates raising flaps from it, to construct the valvular mucous canal.

The operation is made as follows: External anti-sepsis is obtained as usual, but the preliminary washing out of the stomach can not be performed on account of the stricture of the esophagus. The external incision is made in the usual way, and the stomach exposed and identified. It is then drawn out through the wound far enough to give freedom in handling. An incision is then made from near the upper border directly downward about two inches. Before this is done, however, provision must be made to prevent its fluids from getting into the peritoneal cavity by the careful placing of large sponges. As the patient has been prevented by the stricture from taking food, the contents will be found to be only the secreted fluids. The cavity is now washed out with warm boric acid solution, and the edges of the incision secured against slipping back into the abdomen. Now the lower part of the anterior wall is raised, turned out through the incision, and spread out flat. From the lower end of the cut, two incisions are made through the loose mucous membrane, one to the right, and the other to the left, each extending about three-quarters of an inch laterally from the lower end of the main incision. From the end of each of these two mucous membrane incisions, another cut is made downward through mucous membrane, parallel to the axis of the body and to each other for a distance of about one inch and one-half. At the lower ends the two incisions are turned at a right angle toward each other, but not meeting, a separation of one-third of an inch being left between them.

In Fig. 3, the quadrangular incision is shown by the letters A A, and the mucous membrane flaps by F F.

Fig. 3.

A A—The angular incisions through the mucous membrane, exposing the muscular coat. FF—The loose mucous membrane flaps. T—The tube. I—The dotted line shows the position of the incision into the stomach when the parts are replaced.

The next step is to place in position a smooth rubber tube of about the size No. 10 of the English catheter scale. There is nothing better for the purpose than a piece of well sterilized "velvet-eyed" soft rubber catheter. This is laid along the middle of the quadrangle of mucous membrane, and projects an inch below it. Now turn up the flaps *FF* over the tube and close them together with Lembert stitches, placed so as to turn the mucous surfaces in, and bring the connective tissue surfaces in contact. The extreme looseness of the submucous tissue allows the membrane to close over the tube without force.

Fig. 4.

T—The tube. *F*—The flaps of mucous membrane closed over it. *M M*—The mucous membrane adjacent to the incision.

This stage of the operation is represented by Fig. 4. Now take hold of the edges *M M* of the mucous membrane with toothed forceps, and they can be folded without difficulty over the membranous tube *F*, and stitched together. In closing these flaps, the edges should be laid with the connective tissue surfaces against each other, and the needle passed to and fro, or through and through, something like a reversed Appolito's suture. At least, we prefer this method, though it is not absolutely necessary. The three following cross sections will make the operation more fully understood:

Fig. 5.

T—The tube. *II*—The incision through the mucous membrane. *Me*—The mucous membrane. *M*—The muscular coat. *P*—The peritoneal coat.

Fig. 5 shows the tube laid in position ready to have the mucous flaps *II* folded over it.

Fig. 6.

T—The tube. *S*—The mucous flaps folded over the tube. It is well to loosen one flap more than the other, so as to bring the suture, *S*, a little on one side of the center.

Fig. 6 shows the cross section after the first flaps are in position.

Fig. 7.

S—The suture of the first flap on one side of the tube. *Si*—The second flap lapping over the first suture, so as to come somewhat on the opposite side.

Fig. 7 shows both flaps in position, arranged so as to "break joints," which can be accomplished by pulling the edge of the second [flap past suture *S*, and securing it by letting part of the stitches of the seam *Si* go deep enough to take hold on the surface of the first flap beneath it.

Fig. 8.

Diagram showing the relations of the tube to the parts.

T—The tube. *O O*—The outer wall of the stomach. *M M M*—The mucous membrane.

Fig. 8 is a diagram showing the tube in position and enveloped in its double mucous flaps.

Fig. 9 is an outline sketch showing the tube in position, and the incision above it closed by a Czerny-Lémbert seam. The dotted lines indicate the portion of the tube inside the stomach.

Fig. 9.

Sketch of the stomach with the tube in position.

The flaps having been carefully closed, the prolapsed portion of the stomach is returned to the interior, with the upper end of the tube projecting out of the incision. The stomach wound is then closed with a Czerny-Lembert suture, and the edge of the orifice, from which the tube projects, stitched to the skin. Finally, the wound in the abdominal wall is closed, except the point occupied by the tube. A small plug is inserted into the end of the tube, and the whole dressed antiseptically. I think it well to begin almost at once to put in a little milk with a syringe, so as to keep up general nutrition enough to favor union by first intention.

A female dog weighing forty-five pounds was subjected to this operation April 5, 1894. There was no leakage of the contents of the stomach whatever. At the end of a month she was in robust health, and on being killed May 4, the valve in the stomach was found in good working order, and readily pervious to tubes. We think that there might be a liability in some cases to a contraction of the external or internal orifice of the channel, and hence after the tube is withdrawn, it should be occasionally re-inserted to test the size of the channel, and if necessary to dilate it.

65 Randolph Street, Chicago.

INSANITY; SYMPTOMS AND TREATMENT.

BY FREDERICK HORNER, M.D.

P. A. SURGEON, RETIRED, U. S. NAVY.

Dr. Carpenter's "Principles of Human Physiology," tersely defines insanity to be "in its highest degree a complete disturbance of the intellectual faculties; the thoughts are not inactive, but rather far more active than in health; they are uncontrolled and wander from one subject to another with extraordinary rapidity; they twist and turn a single subject in every way; the faculties seem to have escaped from all restraint, thought after thought succeeding with such velocity that all power of perception is destroyed and the mind ceases to perceive impressions made upon the senses. The patient raves, unconscious of what occurs around him; he fancies that he hears voices, while ocular spectra excite further rhapsodies and a condition of delirium. The intellectual powers are disordered, depending upon structural disorder of the cerebrum. Disordered emotional excitement constitutes impulsive moral insanity or monomania, destructive in tendency and presenting examples, sometimes of homicide or suicide, without any apparent motive." Such cases, it may be added, can not always be attributable to perversions of the reasoning process; but arise out

of a perverted emotional state—the victims or subjects of which do not belong to the criminal class, though they may imitate their evil example, since it is well known that the consciousness of the performance of a certain act by one individual gives rise to a tendency to its performance by another.

Of other forms of insanity, there are mania—due to excessive cerebral action—and dementia, enfeebled action. Alcoholism, the puerperal state, fevers, chronic meningitis, or certain forms of inflammation, nervous shock due to wounds, loss of property, etc., all predispose to insanity, especially where heredity exists. The man whose insanity is often not so much as suspected, until he breaks out in a terrible and shocking crime, is the most dangerous person in the community. And here the opinion may be advanced that riots, murder and suicide would occur, perhaps, less often in some portions of our country if the people were more enlightened as to the origin and etiology of insanity. It may be asserted as a fact that the mass of the profession do not make the subject of insanity a specialty, but rather ignore it. The medical journals contain few publications on this theme. The *American Journal of the Medical Sciences* at one time contained a synopsis of the reports of superintendents of hospitals for the insane, prepared annually by the late Dr. Pliny Earle. Among the pioneers and co-workers in behalf of the insane in this country during the present century are Kirkbride, of Pennsylvania; Stribling, of Virginia; Nichols, of Massachusetts; Grey, of New York; J. Preston Jones, W. W. Godding and Miss Dix, first to suggest the founding of the Government Hospital for the Insane of the U. S. Navy and Army, and who also subsequently prevailed upon the governments of Europe to institute hospitals on the principle of those in America, which have contributed to rescue from a state of misery hundreds of the human race who would otherwise have died hopeless and forlorn. It is to be deplored that neither the State medical magazines or the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION take any special interest in the subject of insanity, though the regular practitioner in town or country may occasionally receive the annual reports of such hospitals. Few medical colleges give instruction on the subject. Neither at the Universities of Virginia or New York is it embraced in the curriculum of study.

Happily, within the scope of the proposed Department of Public Health, recommended by the Committee of the AMERICAN MEDICAL ASSOCIATION, there is a clause to ascertain the extent, the origin and classification of insanity in the several States and territories of the country. In connection with the origin of insanity, it may be added that the Bible is not silent on the subject. In the Old Testament, when the Jews, the chosen people of God, incurred His displeasure, among other judgments inflicted was insanity; an example of which was presented in the person of the haughty King of Babylon. At the period of the New Testament times, when the Great Physician, the Savior, was on earth, mankind were submitting the insane to a most cruel and pitiable condition; cast out from human society and counted as possessed of devils as was the raving maniac of the tombs; no worse spectacle of misery in human guise could be presented when, by the magic presence and word of Christ all was changed, and the miserable victim afterward was found clothed and in his

right mind. From that era to the present century, Christian men and women have sought in every way to ameliorate the condition of this class. The so-called bedlams of England and the jails and reformatories where such were confined, have given place to the more rational methods of hospital treatment, carried out by enlightened physicians. Among hospitals abroad and here, which the writer was privileged to visit and inspect, were some of those in France, England and Canada. The Salpêtrière in Paris at the time had M. Charcot as superintendent. His patients were healthy in appearance, well clad and many usefully occupied. Recreation and amusement were prime factors which this eminent alienist employed to recover his patients. To the Quakers belong the credit of establishing the first building in America—a wing of the Pennsylvania Hospital being appropriated for the care of insane patients—thereby antedating by a half century a like provision in Great Britain. Among the institutions of the kind in England may be especially named the Royal Naval Hospital at Great Yarmouth, where according to the tables prepared by Dr. J. D. Gatewood, Surgeon U. S. Navy, the mortality averages 10 per cent. Since the late Dr. Seguin inaugurated a work in behalf of imbeciles, fifteen States of the Union have made provision for this class, aggregating 4,000 unfortunates. In 1879 the first hospital for the colored insane of Virginia was located at Petersburg, Va.

The late Report for 1893, of the Superintendent of the State Hospital for the Insane at Staunton, Va., gives the following statistics, viz.:

Male inmates, 338; females, 326; total, 659.

Admissions for 1892-3: Males, 76; females, 61; total, 137. Of these, 41 were re-admitted.

Per cent. of recoveries, 56; of deaths, 0.6. Since founded, 1827 to 1893, total number admitted, 4,666.

Phthisis pulmonalis caused the largest number of deaths. The report emphasizes the value of employment and amusements, always followed by gratifying results. Of 936 patients of the Pennsylvania Hospital 454 are classed under mania; 333 under melancholia; 142 under dementia. At the Salpêtrière Hospital, already referred to, of the 2,005 cases considered curable, 604 were cured in the first year, 497 in the second; 71 in the third, and 46 in the seven years following; in all 1,218 in ten years.

The report of the Surgeon-General, Dr. James K. Tryon, U. S. Navy for 1893, under the head of insane of the Navy, the Government Hospital for the Insane gives the number remaining in the Hospital Sept. 30, 1892:

Remaining Sept. 30, 1892	75
Number admitted to June 30, 1893	10
Total number	85
Total number discharged to June 30, 1893:	
Recovered	3
Improved	1
Died	9
Total number	13
Remaining June 30, 1893:	
Officers	6
Enlisted men and marines	66
Total	72
Force afloat: Cases of insanity, 1892:	
Dementia	1
Mania	6
Melancholia	5
Total	12
Navy Yards and Stations, 1892:	
Dementia	4
Mania	3

Melancholia	2
Total	9
Naval Hospitals:	
Dementia	2
Hypochondriasis	1
Mania	3
Melancholia	11
Total	17

Thus allowing, according to the Report, 10,000 or more officers and seamen of the Navy, one-tenth of this number to be admitted in one year for treatment for insanity, as already stated for 1892-93, the proportion is relatively small, considering the exposure to disease, accidents and injuries common to the naval service. In this connection it may be added that as a case of an inebriate officer of the U. S. Army was committed to the Government Hospital for the Insane for treatment, the fact is suggestive that Army and Navy authorities may properly recommend the founding of a hospital for inebriates.

THE TREATMENT OF INSANITY.

Every enlightened physician concedes the importance of an early recognition of a case of insanity, and the commitment of the patient to hospital *regimé*. Unluckily as yet, public sentiment is against such decision, and too often the family physician yields through fear that he may offend, knowing that by some to be insane is deemed a disgrace and certain to be followed by loss of reputation. Hence the golden opportunity for proper treatment is lost, diseased action is allowed to proceed unchecked until diseased organization has taken place and the patient has become incurable. Dr. Forbes Winslow on "Obscure Diseases of the Brain," says: "It is a fact that 70, if not 80 per cent. of cases of insanity admit of easy and speedy cure, if treated in the early stage with proper remedies, and there be no strong constitutional tendency to cerebral affections or cranial malformation." The acceptance of the doctrine of modern times, that insanity is a disease of the brain and should be treated as a physical illness is vitally important, because of the large increase of insanity. For example, in 1844 there were 20,000 insane people in England, about 1 in 800; in 1871 there were 56,000, or 1 in 400 of the population of that country. Its occurrence may be looked for where heredity exists after an acute illness of typhoid, puerperal or other fevers, meningitis and shock incident to severe injuries of the head—especially if the patient be intemperate or a brain worker. The regular physician of such cases should not lose sight of them, since disastrous consequences may follow such neglect. The writer recalls in his practice the case of a bright youth, 17 years of age, whose malady was hypochondriasis with neurasthenia; he committed suicide by taking laudanum. His mother, the widow of a Virginia judge, had often been advised to commit him to a hospital, but in vain.

With the help of modern pharotherapy, the physician can dispense with the crude, if not harsh, remedies and appliances formerly resorted to in the treatment of the insane, especially when carried out by the gentle, intelligent and trained nurse, whose services are now to be commanded even in private practice. The locked doors, the barred windows and padded chamber walls of the asylum are still necessary, but the skilful use of the hypodermic syringe charged with the needed duodyne, whether to insure sleep, to avert a paroxysm or to induce an alvine motion, now well-nigh supersede the resort to coer-

cion, oral medication or the straight jacket, which tended to excite cerebral exacerbation and delayed recovery. The use of the hot bath, as hot as can be borne, for its anesthetic effects can not be too urgently recommended, when aided in acute cases by the free use of sulfonal and phenacetin; the latter combined with caffeine promptly relieves insomnia and suffering—without the after effects of the opium salts.

Where urotoxemia exists in chronic forms of insanity with symptoms of parenchymatous nephritis, accompanied by debility and loss of appetite, the free use of bicarb. potass., the mercurials, cod liver oil, Fellows' hypophosphites or the compressed tablets of the Hypophos Company, prepared by H. K. Mulford, chemist, Philadelphia, are invaluable as a tonic and restorative of the enfeebled nerve action of the digestive organs, as well as of the brain. As an article of diet, the fluid beef, such as is prepared by Libby, McNeil & Co., of Chicago, can not be excelled. During the stage of convalescence the system of furloughs may be practiced with advantage; the patient being always commended to the care of some medical friend, and the time for his return to the hospital should be distinctly stated by the authorities.

LEGISLATION FOR THE PREVENTION OF BLINDNESS.

Read before the Chicago Medical Society, April 15, 1894.

BY BOERNE BETTMAN, M.D.

Professor of Ophthalmology in the Chicago Post-Graduate Medical School; Oculist and Aurist to the Michael Reese and German Hospitals; Attending Surgeon to the Illinois Charity Eye and Ear Infirmary; Professor of Ophthalmology and Otology in the College of Physicians and Surgeons, Chicago.

The object of this paper is to call the attention of the Society to the need of legislation for the prevention of blindness. The necessity for adopting such a measure can only then be advocated when sufficient data have been collected, indicating the cause and increase of blindness, and then demonstrating that legal restrictions would decrease to a large percentage this awful calamity. A thorough elucidation of these facts would tend towards elaboration. I will content myself, therefore, by bringing to your attention in a concise form, the main features only. If we consult the United States census from the year 1850 to date, we learn that the number of blind enumerated during the various decades is as follows: 1850, 9,794; 1860, 12,658; 1870, 20,320; 1880, 48,928; 1890, 50,411.

If compared with the population, which increased from 23,191,876 in 1850 to 62,622,250 in 1890, we obtain the following ratios:

Number of blind to 1,000,000 of population: 1850, 422; 1860, 403; 1870, 527; 1880, 976; 1890, 805.

As we are especially concerned about our own State of Illinois it will be interesting to ascertain the number of blind allotted to us in the records quoted. The following table comprises both the total number of blind for each period and their ratio to 1,000,000 of the population:

Number of blind in the State of Illinois: 1850, 264; 1860, 476; 1870, 1,042; 1880, 2,615; 1890, 2,834.

Number of blind to 1,000,000 inhabitants: 1850, 310; 1860, 278; 1870, 410; 1880, 850; 1890, 741.

It will be observed that the proportion of these sadly afflicted has greatly increased, notably so in

1880, and again decreased in 1890. These apparent inaccuracies are due to the methods of enumeration adopted, and are fully explained in the following words of Dr. Wines, quoted from the Report of the Board of Public Charities of Illinois, 1892: "With regard to the so-called 'defective' classes, it should be known that Dr. Wines, in 1880, supplemented the enumerators' returns by correspondence with physicians, who added many names to the lists. This correspondence was not renewed in 1890, which accounts, at least in a large degree, for the seeming slight falling off in the ratio in 1890."

The above figures will suffice to prove the existence of a large class in our community whose infirmity makes them dependent upon others. Deprived of, perhaps, the most important sense, their mode of education and subsequent training demand the existence of schools and workshops equipped with all the requirements of a model blind asylum and industrial school. The large outlay of money this entails can only be undertaken by the State. The total amount appropriated for the blind asylum in Jacksonville from 1849 to 1891 was \$1,156,690.50. Dr. Howe states that the blind of the State of New York costs directly and indirectly over one million and a half of dollars yearly. If computed for the entire civilized world, the sum would reach an enormous amount.

If we regard the question from a philanthropic standpoint, we become so thoroughly alive to the helpless condition of our crippled brethren that our hearts go out to them in sympathy, and every human sentiment is aroused not only to better their state, but to improve the condition of affairs which in a large measure is responsible for their affliction. Physicians can not deal much with sentiment. Our skeptic science calls first for research, and then for the practical application of our investigations. We will therefore, next inquire into the causes of blindness and later on its preventive measures.

Valuable statistics have been compiled, both in this country and in Europe, with reference to those questions which are the results of much labor and patient searching inquiries. Magnus¹ collected 2,528 cases of bilateral blindness which, when grouped under four heads, attribute 3.77 per cent. to congenital blindness, 66.50 per cent. to idiopathic diseases of the eye, 10.73 per cent. to injuries, and the remaining 19 per cent. to diseases of the body which affect the eyes secondarily.

I could multiply these statistics by referring to those collected by Cohn, Krückow, Skrebisky and others. Those I have quoted will suffice for illustration. The above figures clearly indicate that in order to prevent loss of sight in a great proportion of cases, our efforts must be concentrated in one direction. Congenital defects of the eye and ocular lesions due to bodily ailments are comparatively few. They necessarily are not so amenable to preventive measures as are those caused by idiopathic diseases of the eyeball and injuries of that organ. The latter can frequently be ascribed to carelessness and defy intervention. The second category of cases, those resulting from primary diseases of the organ of vision demand our special attention, for they comprise the largest percentage and come directly within our sphere of action. An analysis of this group will demonstrate that blennorrhœa neonatorum must be responsible for the largest quota, almost 11 per cent.

¹ Die Blindheit, ihre Entstehung und ihre Verhütung, Breslau, 1888.

If statistics of the youthful blind, such as are found in our blind asylums, are tabulated, the percentage of blindness due to infectious infantile disease rapidly increases. Thus Reinhardt² found 30.39 per cent. in a material of 2,165 individuals, inmates of twenty-two blind asylums. Claisse, of Paris, 46 per cent.; Katz, of Berlin, 41 per cent., and Magnus, of Breslau, 34 per cent.

Having shown that blennorrhœa neonatorum is responsible to a great extent for blindness in the young, the question will naturally arise: Can this disease be prevented, and if so how? We all know that it can, and every intelligent physician has heard of and should conscientiously carry out the prophylactic measures known as Credé's and Hausmann's methods. Hausmann aims at cleanliness and strives to render the tract through which the newborn child must pass, aseptic, and thereby prevent infection of the conjunctiva. Credé, on the other hand, aims at innocuousness of the germs which may have lodged in the conjunctival sac. Since it is impossible to determine at birth of the child whether infection has occurred or not, all eyes are subjected to the same prophylactic treatment. A single drop of 2 per cent. solution of nitrate of silver is dropped between the lids of every newborn child. The proof of the efficacy of this procedure is presented in the following figures borrowed from Fuch's work, page 129.

Author.	Before Introduction of Prophylaxis.		Prophylactic method.	After introduction of Prophylaxis.	
	Total number of newborn.	Cases of blennorrhœa. In per cent.		Total number of newborn.	Cases of blennorrhœa. In per cent.
Abe ³			Cleansing with water		3
Schirmer ⁴			Dry cleaning	50	0
Blschoff ⁵		5.6	Salicylic acid		2.6
Olshauson ⁶	550	69	12.52 per cent. carbolic acid after tying cord	137	12
Olshauson			2 per cent. carbolic acid sol. before ligating cord	166	6
Kruckenber ⁷	1266	92	7.32 per cent. carbolic acid sol. before ligating cord	82	11
Konigstein ⁸	1092	51	4.81 per cent. carbolic acid sol. before ligating cord	1541	21
Credé ⁹	2897	314	10.82 per cent. argentic nitricum solution	1160	1-20
Konigstein			2 per cent. argentic nitricum solution	1250	9
Kruchenber ⁹			2 per cent. argentic nitricum solution	730	1
Felsenreich ¹⁰	1887	82	4.32 per cent. argentic nitricum solution. (First period of time in use)	3000	58
Felsenreich			2 per cent. argentic nitricum solution. (Second period of time in use)	2100	21
Ressel ¹¹			2 per cent. argentic nitricum solution		5.0
Simpson		11.76			
Bayer ¹²	1106	136	12.32 per cent. argentic nitricum solution	361	0

Should this disease make its appearance, notwithstanding the introduction of preventive measures, or owing to a lack of their enforcement, it can be treated and vision saved in the great majority of cases, provided the physician's attention is called to it at an early date. This disease calls for prompt interference. Delay of a few hours is often dangerous. Ulceration of the cornea and loss of sight can in most instances be avoided, provided the proper rem-

edies are applied at the very onset of the inflammation. That this is not done and that the dictates of Credé are not complied with in many, often too many instances, is a fact known to every physician and especially to oculists of some experience. In large cities and in the country, midwives lawfully attend to confinements and, unfortunately, also, to the inflamed eyes of the babes. The last "Official Register of Midwives" for the State of Illinois contains a list of 1,152. Of these, 700 are located in the city of Chicago. Of the 28,742 births recorded in Cook County last year, over one-half, I have been assured by the registrar of births, were reported by midwives. We all have come in contact with the results of their ministrations. The usual popular remedies, such as instillation of breast milk, camomile tea and other noxious agencies are applied to the swollen, suppurating lids, and only after the loss of precious time when complications have arisen, the physician is at last, and unfortunately too late, consulted. Such sad examples of ignorance and criminal negligence have come under my notice dozens of times. Very often the charge of carelessness must be laid at the door of the parents. Either ignorance or penury induce them to listen to the advice of foolish counselors. It can not be said with a shrug of the shoulders that they themselves reap the harvest of their sowing. The innocent child whose future life is blighted is thrown upon the care of society at large and becomes a burden to the State. It might be said that midwives should be taught to carry out the safeguards referred to. But they are not, and furthermore, persons who are not acquainted with the first principles of medicine can not possess the requisite knowledge and should not be permitted, except for unavoidable reasons, to assume charge of so dangerous a disease. Many otherwise well-qualified practitioners are not capable of coping with it; surely a midwife can not be intrusted with its care. In such communities, where the population is sparse and medical men few, the treatment must be intrusted to the midwife, over whom the State Board of Health should exercise vigorous control by refusing a license, unless exact knowledge of this branch of their duties is shown. These detailed reasons prompted the authorities of Switzerland in 1868, of Prussia in 1878, Austria in 1882, and America in 1891, to force midwives and nurses to report inflammation of newborn babes' eyes at an early date, to call in the aid of a physician and thus prevent, to a large extent, blindness.

This brings us now to the essential feature of this paper, or as Dr. Howe in his address, read at the forty-fourth annual meeting of the AMERICAN MEDICAL ASSOCIATION, says: "What means can be adopted to bring these children as soon as possible to the notice of a competent physician? Education of the laity is useless, urging the nurses, professional or others, is equally insufficient. It remains only to place the responsibility at once where it belongs, by imposing upon such persons a severe penalty. The surest and best means of accomplishing this is undoubtedly by legislation."

New York was the first State in the Union to take up this subject, and through the untiring efforts of Dr. Lucien Howe and his colleagues, both Houses of the Legislature of 1890 passed, without a dissenting vote, the following Act known as Chapter 41 of the Laws of 1890.

AN ACT FOR THE PREVENTION OF BLINDNESS.

SECTION 1.—Should any midwife or nurse having charge of an infant in this State, notice that one or both eyes of such infant are inflamed or reddened at any time within two weeks after its birth, it shall be the duty of such midwife or nurse so having charge of such infant, to report the fact in writing, within six hours, to the Health Officer or some legally qualified practitioner of medicine of the city, town or district, in which the parents of the infant reside.

SEC. 2.—Any failure to comply with the provisions of this Act, shall be punishable by a fine not to exceed one hundred dollars, or imprisonment not to exceed six months, or both.

SEC. 3.—This Act shall take effect on the first of September, Eighteen Hundred and Ninety.

The word *notice*, in the first sentence was omitted in a similar law enacted in Maine in 1891, and known as 97 of the Senate.

This law reads as follows :

SECTION 1.—Should one or both eyes of an infant become reddened or inflamed at any time after birth it shall be the duty of the midwife, nurse or person having charge of said infant, to report the condition of the eyes at once to some legally qualified practitioner of medicine of the city, town or district, in which the parents of the infant reside.

SEC. 2.—Any failure to comply with the provisions of this Act shall be punishable by a fine not to exceed one hundred dollars or imprisonment not to exceed six months, or both.

SEC. 3.—This Act shall take effect on the first day of June, 1891.

Rhode Island only lately, in 1893, followed the good example of her big sisters by an enactment practically similar to theirs. I will again quote Dr. Howe to answer a question which has been repeatedly put to me and to which he so pertinently and concisely replies. He says :

"A question might arise as to what advantage it is to oblige nurses and midwives to report a disease of which a certain class of so-called doctors are almost as ignorant as the nurses themselves. The answer to this is three-fold: 1, the nurse is made to appreciate her responsibility, not only in that case but in others, and to know that the condition indicated by redness and discharge is not anything to be trifled with; 2, the parents also become alarmed when they know the disease is sufficiently serious to be the subject of special legislation, so that in choosing a practitioner they select with rather more than ordinary care. Finally, as for the physician himself. If he accepts the case he feels that he must understand it thoroughly, and he will be apt to look it up with considerable care in text-books and treat it intelligently. Above all, if he fails to do that, the parents have a responsible individual against whom they can, with perfect justice, enter a suit for malpractice, and if he has proved himself incompetent, he not only suffers the penalty which a law has provided for him, but one such case would be an example to him and to other practitioners in the community in which it occurred."

And now we are confronted with the momentous question, Whether the great State of Illinois which has shown itself so willing and prompt to champion the cause of all worthy enterprises will be behindhand in this deserving undertaking. I think not. It remains only for us, the physicians of this commonwealth, to show by united action and unanimous indorsement, that we favor the immediate enforcement of such legislation. The representatives will then be convinced of the need of such a measure, and no doubt will readily make it a law. At the March meeting of the Chicago Society of Ophthalmology and Otology, my paper on "Legislation for

the Prevention of Blindness" called forth an animated discussion, which resulted in the adoption of the following resolutions :

WHEREAS, Statistics compiled in this country and in Europe demonstrate that fully 25 per cent. of our blind owe their affliction to an inflammation of the eyes appearing a few days after birth; and

WHEREAS, Experience has proved that the inflammation can be cured and the eyesight saved in the majority of cases if treatment is instituted at an early stage of the disease; and

WHEREAS, The destruction of the eye and blindness are usually the result of delay in treatment; be it

Resolved, That we heartily recommend that the people of the State of Illinois represented in Senate and Assembly, do enact as follows :

SECTION 1.—Should one or both eyes of an infant become inflamed, swollen, or reddened at any time within two weeks after its birth, it shall be the duty of the midwife or nurse having charge of such infant, to report in writing, within six hours to the Health Officer or some legally qualified practitioner of the city, town or district, in which the parents of the infant reside, the fact that such inflammation or swelling or redness of the eyes exists.

SEC. 2.—Any failure to comply with the provisions of this Act shall be punishable by a fine not to exceed two hundred dollars, or imprisonment not to exceed six months, or both.

Committee: { F. C. HOTZ, M.D.,
LYMAN WARE, M.D.,
BOERNE BETTMAN, M.D.

I think this Society should put itself on record and aid the cause by passing resolutions to the same effect. We thus not only indicate to the world our approbation of preventive medicine, but give a moral support to the instigators of this movement.

RUPTURE OF THE UTERUS DURING LABOR.

Read before the Cambridge Society for Medical Improvement,
April 23, 1894.

BY EDMUND SCOTT DOW, M.D.

ALLSTON, MASS.

I wish to call your attention to this subject tonight, owing to a case which I saw recently in consultation with a physician who gave me the following history :

"Mrs. X., age 33, 4-para, her youngest child being 7 years old. Her previous labors had been normal, never needing even the use of forceps. At different times during the last few years she has been in a hospital for some uterine disease, but has never had an operation, although one was advised for a laceration of the cervix. Her term of pregnancy has been uneventful, except she was said to be subject to faint spells but was able to attend to her family cares and to take out-of-door exercise. The membranes ruptured on a Wednesday night, but labor pains did not start until eight days later at about 7 in the morning. During this past week the waters had continued to drain away. The labor continued uneventful until nearly noon, when the os was fully dilated and, as the labor pains seemed to diminish, I thought best to deliver by forceps and so asked for counsel."

When I saw her about 12:20 P.M. she was in a very critical condition from loss of blood, which bleeding must be internal, as there was very slight hemorrhage externally. She was pulseless, cyanosed, with sighing respiration, limbs cold, and covered with clammy sweat.

On examining per vaginam the head was found low down, the os fully dilated and the cervix wholly taken up. The patient was given hypodermic injections of brandy and ether; a slight amount of ether was given her and a stillborn male child of ten pounds was

easily delivered by forceps. The placenta was not easily expressed and so the doctor tried to take it manually. Meanwhile I was busy with hypodermic stimulations, to which the patient did not respond, and I was asked to try for the placenta. On examination the hand passed readily into the abdominal cavity through a rent in the side of the uterus, and the intestines could be easily felt. Here, then, was the cause of the collapse. The placenta was readily removed from the uterus and the uterus pressed down and contracted, but the patient expired a few minutes later.

The postmortem examination was made twenty hours after death; *rigor mortis* still present. The abdomen only was examined. The abdominal cavity was found to contain a large amount of fluid and the uterus was fairly well contracted. The uterus and its appendages were removed and found to contain a tear on the left side, extending from the mouth to the Fallopian tube, but not involving it; a tear fully five inches in length.

Rupture of the uterus during labor may be one of two kinds; either spontaneous, or that due to manual or instrumental force. As to the cause of rupture, in a general way, it may be said that uterine contraction causes it. Of course the effect of uterine contractions in normal cases is the expulsion of the fetus; but if the child meets an obstacle such as a contracted pelvis in the mother, or from abnormal size of the child itself, then continued hard contractions end in rupture of the uterine walls. Again, the improper use of ergot, as in the first stage, has been known to be followed by rupture.

The frequency with which cases of rupture occur seems to vary much according to different authorities. Ramsbotham puts the proportion as 1-4,887, Bandl 1-1,200, and Dr. Jolly, of Paris, says 1-3,403. In 1880 Dr. Harris, of Philadelphia, made a careful study of the subject, especially as regards the frequency in the United States, and he says that many physicians see several thousand cases of labor without meeting a single case of rupture, and he concludes the proportion is 1-4,000. There is no doubt that many cases occur which are not reported, even if recognized at the time, for the symptoms of rupture are not the same in each case. In the one case the tear may occur in one pain and be so extensive that the fetus would go into the abdominal cavity, when acute pain followed by collapse and recession of the presenting part would occur; while in another case the rupture would take place by degrees, the tear would not be so extensive and the pain of tearing would be so masked by the pain of labor that the condition would not be recognized until too late. Thus it will be seen that the accident, fortunately rare, may be much more frequent than these figures would show.

That the accident happens much more frequently in multiparæ, admitted by all writers, is partly on account of the thinning and weakening of the walls in successive pregnancies and on account of the increase in size of later children. One writer speaks of the greater number of shoulder presentations in multiparæ as a cause of rupture.

The extent of the tear may vary from one or two inches, to such size that the entire fetus escapes into the abdominal cavity. As to degree, the rupture may be complete or incomplete; complete if the tear extends through the walls to the abdominal cavity, and

incomplete if it involves the muscular layer only, the peritoneal coat remaining intact, in which case there is no hemorrhage into the abdominal cavity, but may be very grave hemorrhage into the surrounding tissue.

Rupture of the uterus is one of the gravest accidents of labor. Occurring, as it does, at a time when all seems going well, and when the family and friends are expecting a speedy cessation of the labor and the advent of a new life to the home, the blow seems doubly severe. The child is almost invariably still-born, and the mother is put in jeopardy of her life through shock and hemorrhage, and if she survive these she is in great danger of septic infection.

As to treatment two factors are to be considered: 1, how shall we extract the child? 2, how treat the tear?

As to the first question, most authors now agree that if the rupture is complete and the entire child has passed into the abdominal cavity, then do laparotomy; the same treatment is indicated if part of the child has passed through and the rest is so high up that the presenting part can not be readily reached. If the presenting part is low down and easily reached, then deliver through the natural channel. If the head is low down, use forceps; if not successful with forceps, perforate and use cranioclast. If transverse presentation, do embryotomy; if arm is down, do decapitation. Version is not permissible, for the tear, if small, is increased by so doing, and if subperitoneal it is made perforating and hemorrhage is thereby increased. The placenta should be removed manually and not expressed. If the placenta has passed through the tear and is not found, then do laparotomy.

How are we to treat the tear? Different views are held by different observers. If laparotomy has been done and child removed from the abdominal cavity, some prefer to sew up the tear; others to remove the uterus entire and drain through the abdominal wound or through Douglas' pouch. If delivered through the natural channels many authors believe in laparotomy in cases of complete rupture, in order to secure drainage. Others prefer to treat these cases by tampon and drain through vagina. Statistics show better results by the latter than by the former method.

In cases of incomplete rupture almost all authors prefer the tampon, although many prefer laparotomy, as they claim that otherwise you can not control hemorrhage. In case of rupture, should laparotomy be done immediately with danger of adding the shock of an operation to that of the rupture, or is it better to tampon the vagina to control hemorrhage and wait until the patient rallies from the shock? Mortality is much greater by the immediate plan.

I bring that subject to your notice this evening, that there may be free expression of opinion as to the proper course for us to pursue in a case which may occur at any time in a family where we have not all the facilities for doing a grave operation. The saying is that "grave emergencies demand bold measures," and the physician will have to bear some blame in a case of this sort, no matter how careful he may be.

DISCUSSION.

DR. NORRIS had one case of rupture of the uterus in a young woman 25 years of age, in a twin pregnancy, at full term. Labor had been delayed all day and at evening assistance was called and an attempt made to deliver. A child with presenting head was taken with forceps, when the mother apparently became exhausted. The second child was delivered by turning, after which the woman went

rapidly into a state of collapse and died. An examination showed a rupture of the uterus, which the doctor attributes to a long delay in the delivery and the act of turning the child.

Dr. TAYLOR asked in what per cent. of cases of ruptured uterus has laparotomy been performed and how many have recovered?

Answer. The per cent. of cases operated upon is unknown; about 50 per cent. of the cases operated upon have recovered. A case in the practice of Dr. Ed. Reynolds recently was treated expectantly and recovered.

Dr. HORACE MARION saw a case in consultation some time ago which proved fatal.

Dr. M. BROWN, seventeen years ago, had a young Irish patient, primipara, in labor, where there was a great obliquity of the uterus and owing to which he expected trouble. The woman had a severe pain while in a standing position and shortly afterward went into a state of collapse. Examination showed a rent in the uterus and the child in the abdominal cavity. The child was delivered and then the placenta, but the bowels protruded and the woman died the next day. This was a case which might have recovered had an early laparotomy been performed. A very remarkable case of repeated rupture of the uterus has been reported by Dr. Row, of W. Lyndonville, N. Y., where in four consecutive pregnancies the uterus has ruptured during labor, and yet the child has been successfully delivered. The great obliquity of the uterus is emphasized by Dr. Brown as a cause of rupture.

Dr. A. P. CLARKE had one case, twenty years ago, in a 4-para. He was called in the afternoon and found the patient in the first stage of labor, with some pain, and the os undilated; in the evening there was some dilatation of the os and the head was found presenting. The patient got out of bed, was seized with a pain which was very hard, and then became collapsed and bloodless. Dr. Wellington was called in, but the patient died before he arrived. The hand passed into the abdominal cavity through the uterus, felt the head of the child. There did not seem to be much hemorrhage present; the woman apparently died from shock. In his case, laparotomy would have been of no avail.

Dr. DRIVER was called to see a woman who had been in labor all day. On the right the uterus appeared to be very thin, and on the left there was a hard mass. He passed his hand up the vagina and found the uterus was ruptured and the child lay in the abdominal cavity. The woman did not appear to be suffering much from shock or hemorrhage. The child was delivered through the T-shaped rent in the uterus and the placenta expressed. There seemed to be no tendency for the tear to close by uterine contraction, and the patient died twenty-four hours after the accident. As he looks back on the case, it seems to have been one where the life of the patient might have been saved by opening up the abdomen, cleaning it out and closing the wound in the uterus.

Dr. MARCY said the blood supply of the uterus during pregnancy is very great and the hemorrhage must be greatly increased, as well as the size of the rent, by dragging the child through this avenue into the world. A rapid laparotomy should be performed. Dr. Marcy was called to a case of pregnancy where the labor was complicated by a large fibroid, weighing seven pounds; the physician in charge had turned the child and attempted delivery by the feet, and in doing so had torn the head from the body and let it remain at the fundus above the tumor. As it could not be removed by the usual channel there was only one thing to do, a laparotomy. The abdomen was opened and the head delivered by an incision in the uterus, but the patient died.

PROLAPSE OF THE IRIS. (HERNIA IRIDIS).— A CASE OF SUCCESSFUL REDUCTION.

Read before the Tri-State Medical Society of Alabama, Georgia and Tennessee.

BY FRANK TRESTER SMITH, A.M., M.D.
CHATTANOOGA, TENN.

The case before you, David Lucas, of Chattanooga, came to my office September 20 with a history of having been struck in the right eye half an hour previously with a piece of steel. Inspection showed a pear-shaped pupil with the point downward and inward, with the iris prolapsing through a linear wound at the margin of the clear cornea. A solu-

tion of sulphate of eserin was instilled into the eye and the patient sent home. Two hours later the prolapse was pushed inside the eye with blunt point of a small squint hook. The iris was freed from the wound except a small part which was adherent to its inner side and it was thought that further use of eserin would reduce this more safely than further manipulation. The pupil was almost circular but was still drawn to a point. Eserin was used for several days, the eye was kept bandaged and quiet enjoined on the patient. The eserin gradually drew the iris from the cornea but in so doing its anterior layers were torn loose and remain incarcerated in the wound. This can be readily seen by direct inspection. In the dark room a red reflex can be seen through this rent, nearly as bright as through the pupil. This interferes with the function of the eye in no way. The vision is 20-15, the same as the other eye. The pupil is now circular. You will notice that at the periphery of the iris the striations are absent, the black pigment can be seen, and by looking obliquely part of the iris is observed adherent to the cornea.

In the diagnosis of hernia iridis, the distortion and displacement of the pupil are important points. The prolapse can not always be distinguished from a foreign body especially if covered with exudation. Attempts at reduction, as a rule, do not succeed, because the surgeon is not consulted at an early period after the injury. This is the only successful case I have ever seen reported. Within a short time an exudate is poured out which prevents the return of the iris effectually. In such cases practice differs, many oculists advising excision; others advocating that it is better to let it alone. The use of eserin is contra-indicated if there is any tendency to iritis.

Prognosis is doubtful, generally, most cases recovering with good or fair vision; others result in an inflammation which destroys the interior structures of the eye. All cases of this kind should have the best expert attention available.

CHROMICIZED CATGUT AS A MEANS OF DIRECT FIXATION IN THE TREATMENT OF FRACTURES AND OSTEOTOMIES, WITH A REPORT OF A CASE.

BY F. W. JAY, M.D.

COLUMBUS MEMORIAL BUILDING, CHICAGO.

Without attempting to depreciate the mechanical value of unabsorbable material as a means of direct fixation of the bone fragments in operations performed for the cure of fracture, the writer believes that bone repair is accomplished more rapidly and satisfactorily in the absence of foreign bodies from the bone. He is further convinced that in many cases in which some form of direct fixation of the fractured ends is required, a comparatively readily absorbable material will suffice. Consequently this case, an ununited fracture of the femur of one year's standing, in which some immediate mechanical support was required to retain the bone ends in apposition, and in which sutures of chromicized catgut met the requirements perfectly, is reported.

From the conditions found at the operation, and the methods adopted to secure fixation and union, some points of practical value may be gathered.

Histological research has demonstrated facts in

regard to bone growth and bone repair, that should indicate to surgeons operating for the cure of fractures the value of details in the operative procedures which will greatly aid the *vis medicatrix naturæ*, and in the use of material of but temporary mechanical value we must carefully carry out all procedures that will aid nature's resources, in the accomplishment of bone repair. The case also demonstrates the operative procedures necessary to faithfully carry out operations with absorbable material, which will enable the temporary fixation to serve its purpose, and without which it is valueless.

Each detail of an operation performed for the cure of an ununited fracture, may prove of decisive value in obtaining union; and it was by the minor steps in the operation, as they are by some regarded, that union was effected in this case. As Senn says: "Brilliant operators are not always the best surgeons. The best results in surgery follow the one who is the most painstaking in following out the minutest details."

Considering the periosteum, or its inner layer, the cambium, and the endosteum as the two principal regions of bone, in which are found myeloid tissue with its bone-producing cells, or osteoblasts, the proliferation of which is to accomplish definitive union of fractured bones, (Virchow, C. O. Weber, Gurlt, Billroth, Volkman, Senn), we have in this case some points of interest and value demonstrated.

While definitive union between fractured bone ends is accomplished by proliferation of the osteoblasts of the compacta, as well as of the periosteum and marrow, the latter are regions in which are found bone-producing cells that are in a condition to respond more quickly to the requirements of repair by the early production of callus. These regions are the seat of osteoblasts in a constant and physiologic state of proliferation at the time the fracture occurs, and lose no time in initiating the process of repair. Kraft asserts that karyokinetic figures can be seen in the nuclei of the bone-producing cells of the periosteum twenty to thirty hours after the occurrence of fracture. Hence it is in these regions that we look for that early callus production that will allow of the use of such temporary fixation material as catgut. That such a process can take place promptly only under aseptic conditions is positive, as the method of repair of bone wounds is subject to the same division as the healing of any other tissue, *e.g.*, healing by primary and secondary intention, considering healing by secondary intention where the proliferating cells are compelled to combat infected and suppurating surroundings.

As this was the second operation performed for the cure of this fracture and a buried wire suture had been used in the first operation, which had been performed six months previous to the one reported, the condition of the bone in which this wire suture was found may demonstrate the tendency of *aseptic*, unabsorbable foreign substances in bone to expedite or retard the process of repair.

The word *aseptic* is italicized because, in regarding the action of unabsorbable material in bone, we shall consider the material used as being absolutely aseptic in aseptic tissue and not influenced in any way by the action of bacteria.

I consider the most thorough antiseptic precautions necessary when catgut is to be used for the direct fixation of bone fragments, although should sup-

uration occur at the seat of fracture it is a question if an unabsorbable foreign body when infected has not disadvantages that may overtop its mechanical virtues. In this paper we shall consider materials from their influence when aseptic. I believe in the ability of a conscientious and painstaking surgeon to prevent infection, and consider catgut in these cases a blessing to humanity made possible by antiseptic surgery. The possibilities of even aseptic foreign bodies in bone to determine subsequently the localization of bacteria floating in the circulation is worthy of serious consideration from the influence which such bodies possess to vitiate the surrounding parts, and thus establish a *locus minoris resistentiæ*.

The fact that chromicized catgut was used for the direct fixation of the bone ends, and the more permanent fixation accomplished by the external dressing, and not by more decided means of direct fixation; such as bone or ivory pegs or wire sutures, etc., and less substantial external support, as extension, is, I think, suggestive.

What served to retain the fractured ends in this case until union was accomplished will not establish any surgical rules, yet the fact that such means did serve, and serve perfectly, must be of some value and indicates a rather ideal method to adopt in suitable cases.

HISTORY OF CASE.

A maiden lady, 28 years of age, of good previous health, sustained Oct. 14, 1892, a fracture of the right femur, at the juncture of the upper and middle thirds. She was taken to her home and treated by Buck's extension and long-side splints for eight weeks. As there was no union at this time, her physician advised the forcible rubbing of the bone ends together, as a means of expediting union. She, however, desired to obtain hospital care, and was admitted to one of the large hospitals of the city Dec. 6, 1892. Here extension was applied and retained until April 24, 1893, during a portion of which time she was subjected to a thorough administration of iodid of potassium. As union had not been accomplished at this time, more radical treatment by means of an open operation was advised and consented to. The operation was performed April 24, 1893. The ends of the fragments were denuded and freshened, and one wire suture was introduced through the fragments, the ends of the wire buried, and wound of soft parts sutured. Buck's extension was applied. Primary healing of wound of soft parts. Patient stated that she felt motion at the seat of fracture on the third day following the operation. The use of extension and long-side splint was continued until her discharge from the hospital July 31, 1893. She returned to her home with very great and free mobility at the seat of fracture, completely bedridden. No further treatment was employed until October, 1893, at which time Dr. Milton Jay, by whose kindness I report the case, being called to see the patient, advised another radical attempt to secure union by open operation.

The operation was performed at her home, Oct. 2, 1893. After a thorough preparation of the surroundings of the patient, and the site of the operation, an incision eight inches in length was made in the line of cicatrix, present as a result of the first operation, and the seat of fracture exposed. There had evidently been no attempt at callus formation, as the ends of the bones were conical in shape. They were considerably separated, freely movable, and covered

by cicatricial tissue. The upper fragment was abducted and firmly ankylosed at the hip joint. No attempt was made to produce motion at the hip joint, as the immobility of the upper fragment would prove a strong factor in aiding fixation; and if the upper fragment was brought to its proper axis, a recurrence of the abduction would in all probability occur. It was better treatment to bring the entire limb into a line with the upper fragment and restore the motion at the hip joint after union of the fracture. A wire suture was found in the exposed end of the upper fragment in a perfectly aseptic condition, it having pulled through the lower fragment. It was easily removed, as the bone surrounding it was extremely osteoporotic. In denuding the ends of the fragments, the tissue in immediate contact with the bone was stripped back from the ends of the bone but not removed. It was found that the cicatricial tissue covering the lower end of the upper fragment was but loosely attached to the exterior of the bone, and its separation caused no hemorrhage from the bone; in fact, the bone appeared avascular, and a fear was expressed as to the viability of the upper fragment, or, at least, its lower two inches. This fear was intensified when the medullary cavity was exposed. The marrow was found pale, granular and avascular, as no hemorrhage was excited by removing fragments of it. The tissue surrounding the lower two inches of the upper fragment presented no appearance of active healthy periosteum, but resembled this membrane converted into cicatricial tissue, and its capacity to produce callus by proliferation of the osteoblasts of its inner layer was doubtful. On sawing through the upper fragment, the vessels of the bone were found pervious, as hemorrhage was excited and the bone was therefore viable; but with the little prospect of active cell proliferation from either periosteum or endosteum of the upper fragment, the accomplishment of bone repair and union of the fracture appeared hardly possible. It was believed that the proliferating capacity of the structures in the interior of the upper fragment, in the condition in which they were found, would not be sufficient to produce new bone; but that by curetting the medullary tissue from the cavity, until more active tissue was exposed, a growth of granulation tissue would occur, and that this new tissue would contain active proliferating osteoblasts. By the growth of this granulation tissue into the medullary cavity of the lower fragment and its union with the apparently healthy medullary tissue in this part of the bone, with the subsequent laying down of new bone, union would be greatly facilitated. The medullary cavity of the upper fragment was therefore curetted for a distance of three inches from the exposed end until healthy and vascular tissue was exposed. With the loss of bone from two operations permitting of the greatest mobility and the small surface of bone in apposition, inactivity-atrophy having greatly diminished the diameter of the bone, it would have been impossible to have retained the fragments in apposition without some means of direct fixation.

The bone sutures in this case, were of chromicized catgut, carefully prepared and reliable, of moderate size and used double.

The bone was drilled and sutures passed through a drill-hole into the medullary canal, out at a corresponding drill-hole in the other fragment and tied.

There were four of these circumferential sutures

applied. The end of the lower fragment was made slightly convex from above downward to fit into a corresponding concavity made in the lower end of the upper fragment, and when the sutures were tied, the bone ends were found to come perfectly into apposition with the limb abducted, into a line with the upper fragment.

The bone ends were in the apposition produced by a Fenwick's curvilinear osteotomy, which has been found efficient in preventing displacement, as well as having the advantage of sacrificing but a slight amount of tissue.

The atrophic and cicatricial periosteum of the upper fragment was stitched to the periosteum of the lower fragment, covering as completely as possible the break in the continuity of the bone. A most important detail in the operation is to provide a covering of periosteum for the line of fracture by suturing this structure carefully around the bone, thus incasing the space between the bone ends with an osteogenetic structure capable of filling the gap with new bone, as well as preventing the interposition of surrounding soft parts.

The slipping of the bone ends into a ferrule of decalcified bone, as advised by Dr. N. Senn, (*Annals of Surgery*, August, 1893) would prove a valuable aid to the reparative process, especially where it is found impossible to suture the periosteum over the line of fracture.

The wound of the soft parts was sutured from the bottom with several layers of buried catgut. This was done as carefully and thoroughly as could be, in order to obtain as early definite healing of the wounds of the soft parts as possible, especially in the immediate vicinity of the bone; the skin was sutured with catgut and a capillary drain of catgut applied in each end of the wound.

It will be evident that the incision in the soft parts was not only made ample, but that the bone ends were brought clearly into the wound and subjected to radical and thorough treatment. In operating for the relief of ununited fractures, the procedure must be most thorough and radical, being conservative only to a rational degree. The treatment of the bone ends, in such a case as the one here reported should consist in an absolute subperiosteal resection and the bringing together of bone capable of initiating and completing the reparative process. If the bone is subjected to such treatment as this, the aseptic cases of ununited fracture in which union will not be accomplished are rare.

Jacobson—Ununited fractures of the femur: "The large number of failures after operations for this condition are well known. The difficulties which may be present during and after these operations are very considerable; among them, sufficient exposure of the fragments and keeping the wound aseptic are most prominent." He recommends the use of wire sutures, either temporary or permanent, and to treat the wound open to allow of perfect drainage.

Treves—As regards wiring the fragments, says: "So far as the long bones of the extremities are concerned, I think that this measure may very well be dispensed with." It is said that this wire excites the growth of new bone, but if it does it appears to effect its end at a great cost.

"As a practical measure, the wire is a delusion and a snare, so far, certainly, as the long bones are concerned."

Treves does not make use of any direct fixation of the fragments, but makes a subperiosteal resection of the bone ends, and the careful application of an efficient external dressing. This, I am sure, in many cases, providing the treatment of the bone ends is radical, and Treves certainly accomplishes this, will make the use of unabsorbable material unnecessary; but I believe that by the use of bone sutures of chromicized catgut, or some other resisting absorbable material, with the additional procedure of suturing the periosteum over the line of fracture, we have greatly aided the process of repair.

If the presence of permanent buried aseptic, unabsorbable foreign material, used for the direct fixation of fractured bone ends, has a tendency, aside from the mechanical fixation, to expedite the reparative process in the bone, and the definitive union of the fracture, it must be due to the fact that the presence of such material in bone excites and retains a reparative process, and not a destructive one.

The presence of aseptic foreign bodies in bone must excite an osteosclerosis, and not an osteoporosis of the bone in order to complete the process of bone repair. All wounds of bone must heal by the formation of a bone cicatrix, of greater or less extent, and a bone cicatrix is formed of sclerosed bone. "But as soon as the fragments are fixed this union occurs, and ossification, running on to sclerosis follows."—*Green*.

Osteoporosis is an early step in the reparative process. "A rarefying osteitis begins probably immediately after the injury and results in a round-cell growth, which slowly eats away the walls of, and enlarges the Haversian canals."—*Green*. The value of this rarefying process in the early steps of bone repair is well demonstrated in the production of callus as a result of Brainard's drill operation.

The use of temporary ivory nails to expedite union of fractures, as recommended by Dieffenbach, is a valuable procedure, from the fact that their presence in the bone excites an osteoporosis at the seat of fracture, increasing the vascularity of the part and initiating the reparative process. After they have served this purpose they are a hindrance to repair. The continuation of this rarefying process is, if not actually destructive, at least inhibitory to repair, and will prevent the laying down of new bone in the immediate vicinity of the foreign body. To obtain union, requires the perfect completion of the reparative process; not the simple production of osteoporosis, but the subsequent proliferation of osteoblasts, with the final deposit of lime salts around the new cells. "Prompt bone union does not imply that the osteoblasts at the seat of fracture should undergo karyokinetic changes and multiply, but that the new tissue must be placed under the influences of favorable chemical conditions, which will enable it to be transformed into bone."—*Senn*.

In the case here reported, the wire suture has been present in the bone six months, in a perfectly aseptic condition, and the surrounding bone for a considerable distance was in an extremely osteoporotic condition, while the upper end of the lower fragment in which there was no wire suture was of almost normal density; the slight osteoporosis present in this fragment was simply that due to inactivity.

This suture should have been imbedded in bone scar, or osteosclerotic tissue, after six months influence, if such influence has a tendency to produce this condition in bone.

As far as the conditions found in this case are concerned they demonstrate what is true, that the presence of aseptic unabsorbable material placed in the bone to serve as direct fixation, when allowed to remain beyond a certain limit of time tends to prevent union by retaining in its immediate vicinity a condition of osteoporosis.

"The ends of the fragments are variously affected in accordance with the extent of the rarefying and productive processes which follow the injury; according as one or the other predominates the ends are diminished in size, sometimes to slender conical points or enlarged by the formation of irregular masses of bone on them.

"In a very few cases the rarefying process has gone so far that a large portion or even the whole of the shaft has gradually disappeared.

This tendency to excessive rarefaction, when present is a serious obstacle to the success of the operation undertaken to secure union, and it has seemed to some writers to be increased by the presence of metallic sutures binding the fragments together."—*American Text-book of Surgery*.

The osteoclasts, excited into activity by the presence of any foreign body in bone, produce the osteoporosis, although in any case where the material and its site remains aseptic the osteoclasts are sure to be conquered finally, and the material become encysted by the action of the osteoblasts, the battle has delayed union to a greater or less extent, depending upon the relation of the amount of the foreign body to the size of the bone. I believe this rather theoretical assertion to be of real practical value, although I realize that many surgeons at the present time use telegraph wire to retain the fragments of a fractured ulna in apposition.

While the ability of bone to encyst aseptic foreign bodies has been proven by clinical and experimental demonstration, I believe that these foreign bodies retain a condition of osteoporosis at their site for a longer time than is compatible with early, prompt definitive union, and although this is probably never sufficient in itself to cause non-union, it is at least an indication to use as fine a wire as possible, and as small an amount of it as will meet the mechanical requirements.

"The use of metallic suture and similar devices to maintain the fragments in contact with each other is rarely desirable, since sufficient support can usually be given by the external apparatus; the presence of the foreign body appears somewhat to retard bony union."—*American Text-book of Surgery*.

Now, if by any method we can make a readily absorbable material serve the mechanical requirements in any of these cases, such a method should be adopted. Although among the cases requiring direct fixation, we may find at the present time but few in which the surgeon believes such temporary means will suffice, I predict that the number will constantly increase. In describing the repair of recent fractures, *Green* says: "The ends of the fragments are actively granulating at the end of three days; on the tenth day the periosteum has united and covers the spiral-shaped enlargement of the external callus." And while in ununited fractures the history of the case has already proven that there are factors present that have prevented this rapid and satisfactory callous formation, it is believed by the writer that these factors are local in practically every case,

and that if the operation is made thorough, as regards the resection of the bone ends, and the careful suturing of the periosteum, such a process as Green described will follow in the great majority of cases of ununited fracture.

In regard to the etiology of delayed union and ununited fractures, I will insert here the classification as found in the syllabus of Surgery by N. Senn, after the "American Text-Book of Surgery:"

Defective production of callus.	{	Suppuration.
		Scanty covering of soft parts.
		In joints.
		Defective local and general nutrition.
		Lateral displacements.
General causes.	{	Longitudinal displacements.
		Rachitis.
		Syphilis.
		Pregnancy.
		Lactation.
Delayed union and pseudarthrosis.	{	Marasmus.
		Acute disease.
		Displacements.
Local causes.	{	Interposition of soft parts or foreign body.
		Defect in innervation.
		Defective blood supply.
		Inflammation of surface of limb.
		Loss of substance.
Faulty treatment.	{	Application of cold.
		Imperfect reduction.
		Imperfect immobilization.
		Circular compression.
		Early passive motion.
		Early use of limb.

According to Lewis A. Stimson, "the causes of ununited fracture may be general or local. Among the former, are included general conditions and diseases which give rise to notable deterioration of the health, such as severe acute diseases, anemia, pregnancy and syphilis. Cases have been reported in which these affections have appeared to be the efficient causes, but they are so few that it must be admitted that the influence upon the healing of a fracture in general is very slight. Local causes are classified as follows: 1, unfavorable relations or conditions of the fractured part; 2, interposition of a foreign body; 3, defective innervation; 4, defective blood supply; 5, disease of the bone; 6, inflammation of the surface; 7, defective treatment."

Without commenting upon the causes of ununited fracture, I will make the assertion that the cases in which the essential factor is a constitutional one are very rare.

White and Wood report an interesting group of cases of ununited fractures in the *American Journal of the Medical Sciences* for January, 1893, and illustrate the use of an ingenious mechanical device for the direct temporary fixation of the bone ends, which should serve a most valuable purpose, especially in cases in which an open treatment of the wound was necessary on account of suppuration. They state that Hennequin, in a report of a series of unsuccessful cases of osteotomy and wiring for ununited fractures which he had published, attributed his failures to some constitutional condition interfering with

repair. White and Wood state that Hennequin's report certainly illustrates the need of some more reliable and satisfactory method of fixation than the wire suture. This, they believe, will be found in the use of their apparatus.

I would say that in many cases absorbable material can not rationally take the place of unabsorbable and more decided mechanical fixation, and that the apparatus figured by White and Wood is ingenious and valuable from its mechanical virtues and the fact that it is of a temporary character, but I should attribute a certain number of Hennequin's failures, or any other series of failures, not to a constitutional factor interfering with repair, or to imperfect mechanical fixation of the bone ends, but to local conditions retarding or preventing union, conditions which he had not been able to overcome with even decided direct mechanical fixation, the use of which had perhaps led him to make use of insufficient external support. I believe that in selected cases the use of absorbable material for the direct fixation after a subperiosteal resection of the bone ends, with careful attention to the suturing of the periosteum, less reliance being placed upon decided means of direct fixation of the fragment, but extraordinary care in the external dressing, will be productive of better results.

Extension is out of the question when using absorbable material in a fracture of the femur, and in this case as the fracture was transverse, at the time of operation, and there was considerable loss of bone with very little inclination of the fragments to overlap there were no indications for its use. A plaster-of-paris cast was applied, encasing the entire limb, and the body to the armpits, and while hardening, the limb was abducted into a line with the upper fragment.

The catgut sutures in the bone would hold the bone ends in apposition until the cast hardened; they would be of effect until the periosteum and entire wound of the soft parts had united, and the drilling of the holes for the suture and the presence of the suture material itself would tend to excite a reparative process in the bone ends and would allow of such a process accomplishing early union of the fracture. The recovery in the case was uneventful. A fenestrum was made in the cast opposite the seat of fracture at the end of the third week, and the progress noted. There was not at any time much external callus. Rotation of the foot was communicated to the pelvis at the end of ten weeks. The cast was removed at the termination of eleven weeks, at which time there was very little external callus perceptible. Another cast was applied, and allowed to remain five weeks, at the end of which time passive motion was begun at the hip and knee joints.

The fact that absorbable material answered so perfectly in this case may suggest the possibilities of such material as a means of direct fixation of the bone ends in operations of recent and ununited fracture, and the writer believes that the near future will find catgut more frequently used for the direct fixation of fractured bone ends, while the use of unabsorbable material will be less frequently adopted.

As regards direct fixation in osteotomies, we can best introduce what we have to say by quoting from an article by Dr. Wilson which appeared in the *American Journal of the Medical Sciences* for March, 1893, on "Fixation After Excision of the Knee Joint:"

"There is abundant evidence to prove that in many cases, notably those in which there was tubercular osteitis, primary bony union is rarely obtained until after months or years have elapsed, and often when it has apparently been accomplished it yields, resulting in subsequent deformity.

"This would indicate that temporary methods of fixation are inadequate and tend to the abandonment of catgut, which can exert retaining force for a comparatively short time only.

"Steel nails are of doubtful efficiency, because of the short time in which they are employed. They are usually removed at or about the fourth week, and are generally found to be loose, and therefore easily removed. (Italics my own.)

"These facts show that they could not have exerted any force. The same statements would apply to screws, gimlets, drills, dowels, or other methods which are removed during the course of the first treatment.

"In four cases in which I have used steel nails four inches long, I have found that *there was absolutely no resistance to their easy removal, and that they were simply loosely imbedded principally in the cancellous matter.* (Italics my own.)

"In experiments on the cadaver, screws or dowels did not prevent motion, but upon lifting the leg by the thigh the weight of the leg produced great separation.

"Rotation of the leg broke loose the attempted fixation, and they appeared to be perfectly useless without efficient external support, and the employment of the latter appeared to be just as efficacious.

In the same cadaver, I employed stout wire at four points, through holes drilled in the compact tissue, and found that the objectionable movements were entirely absent although great force was exerted.

"If the wire suture is efficiently used, it would appear to be the method promising the best ultimate results, but its success depends upon its long-continued use.

"I can not agree with Treves, that primary union is apt to be hindered by the use of the metallic suture, and that their presence excites carious action.

"I have seen cases where the wire sutures were in two years after an incision, and Bryant says that he has not removed the wires in any case, unless trouble was caused by them and this rarely occurred.

"The accurate approximation of the tibia and femur, secured by metallic sutures, *naturally permits of less dependence being placed upon the external fixation apparatus, but should not tend to its disuse.*" (Italics my own.)

I quote from Dr. Wilson's paper at some length because I take exceptions to his conclusions.

I do agree with Treves that the primary union is apt to be hindered by the use of metallic sutures.

I would never allow decided means of direct fixation of the fragments to take the place of decided external support, but always place my reliance on the nature of the external dressing, and make use of such means of direct fixation of the fractured ends as would be productive of the earliest possible bony union.

The only guarantee against later deformity is the absolute and perfect repair and complete ossification of the bone ends, which is accomplished best in the absence of foreign bodies, and if this is not accomplished, wire sutures will never prevent such deformity taking place.

Dr. Wilson reports in his paper a case of excision of the knee, in which he used internal fixation of chromicized catgut, and applied an efficient external dressing of plaster-of-paris including leg, thigh and pelvis, which was allowed to remain five weeks.

At this time, as apparently bony union had occurred, the patient was allowed to walk about, using a light posterior apparatus of plaster. Six months from the time of resection there was found a backward displacement of the tibia.

Dr. Wilson doubts the value of catgut as a means of internal fixation in these cases, and he suggests the use of wire sutures. I attribute the occurrence of post-operative deformity in the case he reports, to the fact that the apparent bony union present at the time the primary cast was removed was not yet complete. I must defend the manner in which this operation was performed, and attribute the latter deformity to some other cause than the use of catgut. I believe with Dr. Wilson that an important point in preventing such an occurrence is the prolonged use of an external support; but I do not believe as Dr. Wilson does, that wire sutures will prevent such late displacement taking place. I attribute the late deformities in these cases to the too early removal of substantial external support. In the case reported by Dr. Wilson, five weeks was too early a date to discontinue the plaster cast. Some of the late displacements take place as a result of an epiphyseolysis, or continuation of the osteoporosis from incomplete removal of the tubercular foci.

"The use of direct means of fixation of the resected ends in resection of the knee joint is being gradually abandoned. If the hip is well supported by a circular plaster-of-paris splint, or a posterior suspension splint, accurate apposition of the sawn surfaces and perfect immobilization of the limb are maintained almost to perfection, rendering the use of fixation nails or sutures unnecessary. The use of proper mechanical support should not be dispensed with until the resected ends have been united by an osseous callus, which will require, according to the age and general condition of the patient, from six weeks to three months.—*Senn's Tuberculosis of Bones and Joints.*

In arthrectomies and joint resections for tubercular affections in which Tilings' most valuable suggestions can be carried out, *e. g.*, temporary resections of those portions of the bone extremities to which important muscles and joint structures are attached; which can after the completion of the removal of the diseased tissue be replaced and fastened to the bone, catgut will serve a most excellent purpose. In the knee joints the patella is cut across transversely and later united with catgut sutures; at the elbow joint the olecranon is sawed with the insertion of the triceps and at the ankle joint temporary resection of the malleoli; at the hip joint the trochanter is temporarily resected and after the completion of the resection of the head of the femur the trochanter is united to the end of the bone, thus saving the attachment of important muscles, as well as securing a center of bone growth for the upper extremity of the femur; an important factor in the prevention of the shortening that follows removal of the epiphysis during the period of bone growth. In all these operations chromicized catgut will meet the fixation requirements.

EPIDEMIC INFLUENZA; COMMONLY CALLED "THE GRIP."

BY EDWARD ANDERSON, M.D.
ROCKVILLE, MD.

This disease has been commented upon by some of our ablest men, but it has not received the consideration it deserves, for it extends throughout the habitable world and has destroyed more lives than the cholera and yellow fever put together, attacking alike the centenarian and the child within its mother's womb.

Statistics show that railroad employes on freight trains are in more danger than men engaged in battle, yet there is much less dread of enlisting in the railroad service than the military. So also is there less dread of the grip than of cholera or yellow fever, for there are not so many lives lost at one time and in one place.

When the Colorado beetle, (the potato bug) first made its appearance among us it was thought that one year would end its ravages, but twenty years have now passed and still it is as great a pest as ever. At first the farmers undertook to pick the insects from the potato vines and burn them, but when they appeared year after year the task became Herculean and some other means had to be resorted to. Arsenite of copper is now employed so that the young beetles may feed on the plants and the poison at the same time.

After tormenting the human race for four years and four months, the grip is as prevalent as ever. As we can not destroy all the microbes that produce this disease, we must saturate the system with some germicide so that they may feed upon the human organism and the poison at the same time and die. Influenza is not only a disease *per se*, but it has entered into and complicated all the diseases and added to their fatality. When called to the bedside of a patient now I wonder at nothing I find present: Temperature ranging from 95 to 106.2 degrees F.; apoplexy in persons formerly supposed to be too young for it; intermittent pulse in those whose heart action was perfect the day before; inflammation of the mucous membranes everywhere, sometimes confined to that of the external ear accompanied by intense pain which is never relieved except after free suppuration. Sometimes it is confined to the membrane lining the air passages, the alimentary canal, the urinary organs or all of these together. Hemorrhages from any of these surfaces may occur at any time and do occur. An uncomplicated case of typhoid fever may be converted into a hemorrhagic case probably ending in death. A hearty meal or even a small amount of solid food may cause sufficient indigestion to produce heart failure or apoplexy, or both. Whole families of children have been swept off by tubercular consumption whose parents were perfectly healthy.

The phases that this disease assumes are too numerous to mention, and those advanced in life, rarely, if ever, thoroughly recover from it. Until last fall I had not lost a white typhoid patient for six years, when out of thirteen adults, six had profuse hemorrhage from the bowels, with four deaths; three directly from loss of blood. I have within the last two months had four such cases from the grip alone, three of which have recovered by the use of turpentine or blue mass and opium. The fourth is now in progress

but is nearly cured after the use of salicylate of sodium, everything else having failed,—lead and opium, ergot, aromatic sulphuric acid and all. This patient had a hemorrhage four years ago and has been more or less demented ever since.

I am firmly convinced that the loss of blood in my typhoid cases was due to the grip and that, had their stomachs been in a condition to receive salicylate of sodium, they would still be alive, for all those to whom I could give it recovered.

Dec. 12, 1890, a young man was found wandering on one of our public roads. He did not know his own name or where he came from. I had him under observation only twenty-four hours before his friends took him away, and during that time was unable to find anything amiss with him. After his departure I discovered that he had passed only one ounce of urine mixed with mucus, showing inflammation of the bladder. Two weeks later when influenza became epidemic I would have had no difficulty in diagnosing this case but at the time was sorely puzzled. Three years ago I had under my care a gentleman between seventy and eighty years of age whose digestion was so much impaired by this disease that a mouthful of solid food would throw him into a high fever and would bring about such feeble heart action that I, three times, had to sit by his bedside for ten hours at a time in order to administer whisky and digitalis when needed. This state of affairs continued from the middle of May until the middle of October. One of the patient's legs was swollen and four degrees warmer than the other, as was also the leg of another patient affected with the same disease. As in typhoid fever, as much calomel should be used as can be employed without danger of salivation or undue purgation. In other words, where it is not contra-indicated calomel acts as a specific. Many authorities affirm that benzoate of soda is a specific in the disease under consideration, but I prefer the salicylate of sodium to any other drug where the stomach will bear it, for there is almost always more or less rheumatism or neuralgia present, calling for its employment. The fact is, that any preparation of soda is beneficial, the carbonate often being all that is required. Rochelle salts has acted better in some cases than anything else on account of its laxative properties, and probably also on account of the soda it contains.

I do not condemn the coal tar preparations altogether, as some do, for if not curative they mitigate the symptoms in this disease, and are perfectly safe in the treatment of the young and the aged too, if stimulants are at hand to counteract their depressing effects.

Nine-tenths of the sudden deaths that occur are due, I believe, directly or indirectly to indigestion, and the timely use of the carbonate or some other preparation of soda would avert most of them; and especially has this been the case since epidemic influenza first made its appearance among us. Hence the importance of confining our patients strictly to a liquid diet. Rest in bed should always be enjoined in the acute form of this disease, and often in the chronic form also, particularly if accompanied by hemorrhage.

**Report of the Committee on Medical Education
Appointed by the Illinois State Med-
ical Society.**

Presented at the meeting held at Decatur, Ill., May 15, 16, 17, 1894.

It will be quite readily conceded by any one who examines into the subject that there is a conspicuous lack of uniformity in the quality of the medical diplomas of this country. That this lack of uniformity has been recognized by other countries is well known, and evidence of the fact is furnished when it is stated that no American degree entitles its possessor to legally practice his profession in the countries of Europe, while nearly all their degrees are recognized here, as entitling their holders to practice under the protection of the law.

It does not follow that the present very unsatisfactory and uncertain status of the American diploma implies either a want of ability, perception or honesty on the part of the American doctor; it came about naturally in the course of rapid national development, and indeed, in view of all the facts I think we should rather feel proud than apologetic of our medical schools. But many of the causes which in the past furnished sufficient excuse or perhaps created a necessity for the medical schools throughout the land to pursue the course and adopt the methods which they did pursue and adopt, no longer exist, and the time having arrived when national development has become so general, when there is no longer any frontier or back settlements, according to the former meaning of those terms, it is likewise time that the frontier and back settlement in medicine should disappear.

Though I am always in favor of a high grade of medical education, I wish to take this occasion to say that it is not my present purpose to in any way discuss the height of the standard of medical education. My sole purpose is to argue for uniformity, to place the American degree upon a firm foundation, so that wherever it is met with its value may be known. Manifestly this can only be accomplished by making it uniform. The problem, then, is to provide some practical means of securing uniformity. Probably there will be first uniform qualification in each State and finally a uniform national qualification.

It would doubtless prove profitable and interesting to investigate the methods long and satisfactorily in vogue in the various countries of the old world, but the conditions here are so very different from those which obtain there that it is hardly to be expected their methods could be transferred to our country. We should, however, always be willing to learn from our neighbors, and we happen in this instance to have a neighbor, the Province of Ontario, which has for the last twenty years had a plan in operation which has given great satisfaction and which I think we would, with certain necessary modifications do well to imitate.

Three cardinal principles form the basis of the proposed measure:

1. Each candidate must have submitted to him exactly the same set of questions.
2. The identity of the candidate must not be known to the examiner.
3. The examining body must be distinct from the teaching body.

The following is offered as a practical suggestion for the improvement of the existing state of affairs:

An Act to establish a State College of Examiners in Medicine and Surgery for the State of Illinois, for the purpose of securing Uniformity in the Qualifications of Practitioners of Medicine and Surgery in the State of Illinois.

SECTION 1.—A State College of Examiners in Medicine and Surgery for the State of Illinois is hereby established and may be known as, and called, "The Illinois College of Examiners in Medicine and Surgery of the State of Illinois." The membership of said College shall be made up as follows: The Governor of the State shall appoint seven members from each of the regularly established medical colleges of the State, and nine physicians who are not connected with any medical college in a teaching capacity, these latter to be known as members at large, as follows: Three members from each college and three of the members at large for a period of two years, the remainder for a period of four years. All subsequent appointments to fill vacancies caused by expiration of term of service shall be for a period of four years. Vacancies of unexpired terms made by death, resignation or other cause may be filled by appointment by the Governor.

The members appointed in the manner as above provided, may elect by ballot a number not to exceed fifty associate members, to hold office not to exceed four years, to assist in conducting the examinations or perform such other duties as the College of Examiners may assign to them. These associate members, however, shall not be entitled to vote at the meetings of the College of Examiners. No person shall be eligible for appointment as member, or to election as an associate member, who is not a regular graduate of medicine in good standing and a member of the Illinois State Medical Society.

SEC. 2.—The College may prepare and adopt by-laws for its government, elect its own officers, collect a fee of not to exceed \$25 from each candidate for a license to practice, and a fee of not to exceed \$10 each for preliminary or intermediate examinations. The College is hereby authorized to disburse all money received by it, and to make such contracts as are calculated to promote the interests of the organization.

The annual meeting shall be held on the day when, and at the place where, the annual meeting of the Illinois State Medical Society meets.

SEC. 3.—It shall be the duty of the College of Examiners to decide upon and fix the requirements of study and graduation, and to notify the faculties of the various medical colleges within the State definitely, in writing, of these requirements, at least six months prior to the commencement of the fall term succeeding the adoption of such requirements. To hold examinations, not less frequently than once a year at such times and places as it may fix upon, giving at least six months printed notice thereof to each of the medical colleges within the State, and cause a notice of such examinations to be published in the official journal of the Legislature not more than six weeks nor less than four weeks prior to the time said examinations are to be held.

To prepare and cause to be printed for the benefit of students, or prospective students of medicine, a definite statement regarding the course of study and requirements for graduation, together with such other information as might, in the opinion of the College of Examiners, prove helpful to said students.

To present such students as shall at said examinations display a satisfactory knowledge of the several subjects therein contained, a certificate duly signed and to the effect that said student has successfully passed such examination.

To issue a license to practice medicine and surgery in the State of Illinois to such students as pass the final examination, furnish satisfactory evidence of good moral character, and fulfil all other requirements in conformity with the law.

To provide means in conducting the examinations for concealing the identity of students by examiners, and otherwise securing a uniform, fair and impartial examination.

SEC. 4.—All examinations shall be written, each student having presented to him the same printed questions at the same time, excepting that the College may in addition, when it deems proper, call upon any or all students to submit to an oral or practical examination, or both, after the written examination shall have been completed.

No candidate shall put his name, initials or any mark or marks of identification upon his papers of written answers except the number or character assigned to him after he has sealed himself for the purpose of writing.

SEC. 5.—Graduates of medical colleges outside of the State of Illinois, and all other persons excepting such as are here-

inbefore provided for, desiring to practice medicine and surgery within the State of Illinois, shall notify the Secretary of the College in writing of such desire, and submit a certificate of their qualifications if they have such certificate, whereupon the College may take such measures as it deems expedient to determine the fitness of such persons to practice medicine and surgery, and grant or withhold a license in accordance with its findings.

SEC. 6.—All other laws regarding the licensing of persons to practice medicine and surgery in the State of Illinois are hereby repealed.

SEC. 7.—The license to practice medicine and surgery granted by the College of Examiners in Medicine and Surgery for the State of Illinois, as hereinbefore provided, shall be the only legal authority to practice medicine and surgery in the State of Illinois.

SEC. 8.—Students of medicine who were registered at a medical college within the State of Illinois prior to the enactment of this law shall be exempt from its provisions.

SEC. 9.—This Act shall only apply to the profession of regular medicine.

NOTE.—The writer is personally in favor of having a joint board providing for homeopaths and eclectics, but for the sake of clearness omitted to provide for it in the above suggestion.

SANGER BROWN, M.D., Chairman.

SOCIETY PROCEEDINGS.

The Medical Society of the State of Tennessee.

Held at Memphis, Tenn., April 10 and 11, 1894.

(Concluded from page 708).

SECOND DAY—MORNING SESSION.

DR. B. B. CATES, Knoxville, read an article on
SOME EXPERIMENTS UPON THE PRIMÆ VIÆ, WITH REPORT OF A
NEW METHOD OF ENTERORRHAPHY; ITS TECHNIQUE
AND RESULTS.

For the purpose of familiarizing myself with the technique of intestinal surgery, and of testing the efficacy of hydrogen gas in locating perforations of the primæ viæ, I instituted some observations upon animals. As far as the technique is concerned, these operations were done with strict antiseptic treatment of the wounds, instruments, sponges, utensils, hands of operator and assistants, but there was no preparation regarding the condition of the animal before or after the operation. Nevertheless, after the abdomen was entered I was very careful to prevent any extravasation into the abdominal cavity, by drawing only that portion of the primæ viæ intended for operation into the external wound, and packing bichlorid gauze around the gut at the margin of the wound. I then displaced the fecal matter from the field of operation by pressing on either side of the gut with my fingers, and tying elastic ligatures around the gut above and below the point of incision in the bowel. These ligatures prevented fecal regurgitation contaminating the wound and embarrassing the operation. No attention was paid to the toilet after closing the external wound, the animal being allowed to run about and eat what it wished. These experiments, eighteen in number, lead me to the following conclusions:

1. Perforations occurring at the site of operation when making invagination, are more liable to be near the mesenteric attachment.

2. Nothnagle's test corroborated three times.

3. When using hydrogen gas in locating perforation and obstruction in primæ viæ, we should be sure there is no occlusion in the rectum, as ordinary feces, etc.

4. In excision of the cecum, when ligatures are applied to the mesentery to stop hemorrhage, there is liability of including the arterial supply of the bowel not in the area of the cut-off gut.

5. That it is not absolutely necessary to apply a ligature to the mesenteric arteries in the cut-off gut, simple compression with hemostatic forceps and carrying the mesentery from its attachment to the cut-off gut being sufficient.

6. In making lateral anastomosis, or end-to-end union of bowel wall, a slight scarification of the serosæ, would, as first pointed out by Davis, of Birmingham, hasten the adhesion and consequent healing of the coapted parts. This may be ignored where the adherent surfaces are backed up by sutures.

7. Where the coapted parts are re-inforced by sutures such as catgut, it serves as a framework for the plastic exudate which is quickly thrown out, thereby shutting off any avenue for the intestinal secretions to escape into the abdominal cavity.

8. Whatever sutures are applied to serosæ, they will be covered with plastic exudate within twelve to forty-eight hours.

9. Buttons offer many advantages as sutures over plates in making approximation of bowels by later anastomosis: 1, time, which is such an important factor in these operations, is greatly reduced; 2, they do not slip about and thus annoy and vex the surgeon; 3, the approximate surfaces can be increased or reduced at the surgeon's will; 4, they act as splints to the bowel and bring the coapted parts into closer union, and the ectropium is easily controlled. Lastly, the button, when it frees itself by pressure atrophy will, on account of its small size, easily pass through the ilio-cecal fissure.

10. Wherever the fistulous communication between the bowel is over an inch in length, a button should be inserted every three-fourths of an inch to prevent ectropium, and bring the bowel into closer union.

11. Lateral anastomosis as a surgical procedure offers better ulterior results in restoring the fecal circulation than end-to-end union of bowels. In the former method, when the opening is not long enough, it is not followed up by so great traumatic stenosis as in end-to-end union.

12. In making this anastomosis, my button is superior to plates, and therefore I offer it to the surgeons of America, (in lieu of plates), into whose hands its future usefulness as a surgical process is resigned.

13. Whatever procedure is adopted, it is safer to back up or enhance the circumference of the fistulous communication in coapted bowels with sutures of fine aseptic silk, which will encapsulate itself, or catgut, which will be ultimately absorbed, the Dupuytren or the Dieffenbach suture being the quickest and easiest applied.

The button used in my experiments consists of a male and a female portion. The female portion of the button is made of brass, though for obvious reasons aluminum or silver would be better, and has a base seven-sixteenths of an inch in diameter, with a small cylinder projecting from it about three-sixteenths of an inch long, hollow from end to end, and with a slit on either side of the cylinder reaching nearly to the base. The male portion of the button, which is solid, consists of a base five-sixteenths of an inch in diameter and a neck one-fourth of an inch long. This fits into and may penetrate beyond the base of the female button. To make the buttons easier of introduction, the female is accompanied by a sharp point about an inch long, which has a neck guarded by a shoulder, and this neck fits into the apex of the cylinder of the female button. The male button is also accompanied by a sharp point, a cap, an inch long, hollow at its base. This fits over the neck of the male button. The technique of the operation, when using the button, is the same as when using the plates until after the incision is made into the intestine, when an assistant arms the female portion with the steel point, which you quickly thrust through the entire thickness of the bowel wall from within outward, commencing on the lower side of the fissure. Then fitting the sharp spike or cap over the male button, it is passed through a corresponding point in the opposite cut edge of the bowel, from within outward. The male is then fitted in the female button and pushed home from within the lumen of the bowel. In like manner the angles of the fissure are approximated, leaving the upper sides of the opening to be closed last. Here the surgeon, after inserting the buttons, is to grasp the base of the male and female buttons separately with tissue forceps, and after inverting the cut edges of the wounds with buttons *in situ*, so as bring the serosæ *vis-a-vis*, he engages the male button in the female and pushes it home from without through the bowel wall.

(This button is smaller than the Murphy button).

DR. J. I. MINOR, Memphis, presented the subject

THE EAR AS A FACTOR IN CAUSING CEREBRAL DISTURBANCES IN INTESTINAL AND OTHER DISORDERS OF INFANCY.

These cases usually first come under the observation of the general practitioner, and he ought to be able to recognize them. Inflammation of the middle ear is the most common cause of these disturbances, when they are due to ear trouble, and for its positive detection only a mirror and ear spectrum is necessary, with an ability to see the drum of the ear. This will be found red and injected when inflamed. The treatment is simple, medicinal applications usually sufficing, ex-

cept in a few cases where pus is present, where paracentesis may be necessary.

DISCUSSION.

DR. SAVAGE.—Attention is often directed to the ear by spasmodic nursing. Excluding nasal obstruction and capillary bronchitis, the only cause for spasmodic nursing is an inflammation of the middle ear. The child will not hold its head still. Besides, there is a peculiar outcry that is readily recognized after having been once heard. He had obtained excellent results with chloroform in olive oil. This ought never to be warmed, as heat drives off the chloroform.

DR. SMITH mentioned the fact that the general practitioner must not neglect the ear.

DR. GRADY.—Olive oil alone will accomplish as much as the chloroform and olive oil, and warm goose grease or lard will do the same thing. The action is purely mechanical. When applied locally, chloroform is not an anesthetic.

DR. NEAL thought chloroform valuable.

DR. HERRON had used morphia, atropia, olive oil, glycerin, and chloroform, and considered them all valuable. He had never performed paracentesis.

THE PRESIDENT had heard from a non-professional source, that "possum grease and onion juice" is excellent.

DR. CAIN.—Goose grease is excellent, and warm water is good, as are also hot applications. Dr. Savage failed to mention acute stomatitis as a cause of spasmodic nursing. This is much more frequent than disease of the middle ear.

DR. THOMAS W. GALLION formerly used olive oil and tincture of opium, but now prefers glycerin and tincture of opium, which acts admirably. After congestion of the drum membrane is relieved, he employs warm water douches.

DR. SAVAGE stated that chloroform has other virtues than those of an anesthetic, and is excellent to keep things sweet. For instance, it will preserve urine almost indefinitely.

DR. MINOR, in closing, said olive oil was excellent. When combined with chloroform, the latter seems to act as a counter-irritant and draws the soreness out.

DR. T. J. CROFFORD, of Memphis, gave a

REPORT OF CASES.

This was a report of an operation for epilepsy. The reasons given for the operation were as follows:

1. The epilepsy began with, or soon after, and was always associated with menstruation for the first four or five years.
2. The attacks were increased by pregnancy and parturition.
3. There was a uterine flow at the time of the attack. Even in the interval between the menstrual periods, four or five years after the inception of the epilepsy, she would invariably have a slight show.
4. Sexual intercourse invariably produced it within twenty-four hours.
5. Examination proved there was a disease in the pelvis.
6. Neither she nor her husband desired a progeny, because statistics show that epilepsy is likely to be transmitted.
7. She claimed a right to be rid of it, a right to enjoy life, and a right to make her life as useful as possible. Both ovaries and tubes were removed to stop menstruation, and she is now much improved.

DISCUSSION.

DR. DOUGLAS.—It is not a determined fact that the ovaries have anything to do with menstruation, although he (Dr. Douglas) thought it influenced more or less by ovulation. In reference to the sixth reason; if the husband did not desire a progeny why should not he have submitted to an operation? When there is nervous disease and local pelvic disease, demonstrating the presence of disease in the ovaries, we should always operate, and epilepsy is no contra-indication. The results show an operation was required.

DR. GILLESPIE thought the operation justified, and spoke of a similar case cured by removal of the clitoris.

DR. HAPPEL did not think the last two reasons would justify an operation. He agreed with Dr. Douglas in reference to the sixth reason.

DR. SAVAGE referred to the condition being a reflex trouble. If a center in the brain is continuously irritated it will undergo molecular change and the trouble will then continue after the cause is removed. If the general practitioner does not understand the case, he should call a specialist, for these cases can be absolutely cured if the cause is removed early.

DR. CROFFORD, in closing, said the trouble is primarily of peripheral origin, and the central nervous system becomes secondarily involved. Although the moral reasons alone would not have justified an operation, I doubt if I should have operated without them.

DR. GEO. H. PRICE, Nashville, presented a paper on

CAUSES OF EYE-STRAIN.

Beginning with the least and ascending in the scale, according to the gravity of the symptoms which they as a rule present, the causes we would consider factors of eye-strain are as follows:

1. Myopia, uncomplicated.
2. Myopic astigmatism, with the rule.
3. Myopic astigmatism, against the rule.
4. Hypermetropia, uncomplicated.
5. Hypermetropic astigmatism, with the rule.
6. Hypermetropic astigmatism, against the rule.
7. Myopic astigmatism, oblique.
8. Hypermetropic astigmatism, oblique.
9. Myopia, any form combined with esophoria.
10. Hypermetropia, any form combined with exphoria.
11. Myopia, with esophoria and hyperphoria.
12. Hypermetropia, with exophoria and hyperphoria.
13. Myopia, esophoria, hyperphoria and cyclophoria.
14. Myopia combined with insufficiency of interni and externi, insufficiency of externi predominating.
15. Hypermetropia combined with same conditions, insufficiency of interni predominating.
16. Mixed astigmatism, with muscular complications.
17. Muscular conditions alone.

Defective focus is in many cases the least important condition demanding our attention, but at the same time I am not to be understood as disposed to place these entirely in the background, for in some instances they are the only cause of complaint.

A patient comes to you complaining of being annoyed by a sensation of something in the eyes, a gritty feeling, which soon causes the eyes to water and burn when any near work is attempted. If they discontinue the near work, the symptoms subside, to return again when they resume the work. If the work is compulsory, they soon show some conjunctival irritation with hypersecretion of tears and some mucus, which causes a blurring of vision. Later they complain of a tired feeling about the eyes, a running of the letters together, a constricted condition of the brow or head, a pain localized anywhere from the temple to the back of the head, sometimes extending down the back of the neck and about the shoulders, an inability to keep the eyes open or to read for any length of time without growing drowsy, photophobia, a twitching about the lids, later a blepharospasm, choreic condition of muscles of face and extending beyond, or most violent attacks of pain ordinarily called neuralgia, to say nothing of even graver disorders, such as epileptic seizures.

After reporting several cases as examples, the essayist presented a set of prisms he had recently devised, which consists of two prisms in each cell of the frame, resembling in construction the Franklin bifocal lenses, but quite different in their action. The bases of the prisms in each cell of the frame are placed in opposite directions. Their use exercises both the externi and interni. In closing the paper he presented the following statistics, compiled from five hundred cases refracted from March 1890 to March 23, 1891:

- Myopia, five cases or 1 per cent.
 - Myopic astigmatism, sixty-six cases, or 13 1-5 per cent.
 - Mixed astigmatism, nineteen cases, or 3 4-5 per cent.
 - Hypermetropia, seventy-one cases, or 14 1-5 per cent.
 - Hypermetropic astigmatism, 339 cases, or 67 4-5 per cent.
 - 500 cases, or 100 per cent.
- (Discussed with Dr. Graddy's paper).

SECOND DAY—AFTERNOON SESSION.

DR. L. B. GRADY, of Nashville, gave a paper on the subject of

THE MECHANISM AND THE PRESENT STATUS OF THE TREATMENT OF ASTHENOPIA.

The paper was an explanation of the mechanism of astigmatism. The essayist claimed that through innervation of the ciliary muscle the other muscles become tonically contracted and exhausted.

DISCUSSION.

DR. F. G. SMITH, Chattanooga.—In young persons with hypermetropia, where there is a good supply of energy and the eyes are strong, glasses may not be indicated, but usually they are indicated. The principle is that a greater or less amount of hypermetropia will be corrected by the glasses. In myopia the indication is for a dim distant vision. The majority of patients may be advised that they need not employ glasses.

Dr. GRADY was impressed with Dr. Price's paper, in that it dealt with very small degrees of hypermetropia.

Dr. SAVAGE.—Since the ciliary muscle can influence only the internal and external recti muscles, he could not agree with the author of the paper that that muscle is a veritable Pandora's box, out of which escape all the ills that come to human flesh as a result of eye-strain. There is an intrinsic muscle error and there is a pseudo muscle error, the one very different from the other in nature; and the treatment of the one must be different also from the other. The intrinsic muscle error may depend on the size of the muscle, on its attachment to the globe, and possibly on the fact that it may be too abundantly supplied with nerve fibers. The intrinsic error may affect any one of the six muscles concerned in the movements of the eyeball. The pseudo muscle error is dependent on the now well-known relationship between the centers of accommodation and the centers controlling the internal recti muscles. The intrinsic or inherent muscle errors must be treated by means of operations or by exercise; and it is an easy matter to determine whether the one is to be resorted to or the other. Sometimes it is necessary to resort to both operations and exercise before a case of this kind is cured. The cure of the pseudo muscle errors must be effected either by the correction of focal error or by exercise of either the internal or external recti. Sometimes these cures must be effected by a combination of these two means.

Dr. PRICE.—In some cases the amount of myopia, hypermetropia, or any combination of myopic astigmatism, or mixed condition, is to be totally disregarded. The most important cases are those in which there is no indication for muscular correction.

Dr. GRADY.—If we simply apply tests for exophoria and esophoria, and depend on them, we may say all cases are due to that. When the muscle has lost capacity for strength, the only thing is to operate. Weak prisms, while they do innervate the muscles, may not unjustly be compared with the principles of homeopathy: The little doses may cure; the big doses are certain to cure.

The election of officers followed.

On motion it was voted to pay the expenses of the Treasurer to and from the Society, and to increase the salary of the Secretary \$50.

Dr. F. L. SIM, Memphis, read

ASEXUALIZATION FOR THE PREVENTION OF CRIME AND THE CURTAILMENT OF THE PROPAGATION OF CRIMINALS.

Capital punishment is a curse to our nation, as it has been to every government on earth that has practiced it. Judicial homicide or legalized murder, are names that place the hanging of criminals in line of proper nomenclature. Even the *methods* of execution are now becoming repugnant to the people, and it is sought to glide the criminal, on "flowery beds of ease" over the Jordan, with the aid of electricity or anesthesia.

The desideratum of the hour is a substitute for capital punishment, now almost a farce with the American people, that will give the greatest protection to the community and avert the degrading horrors of the retreating custom. Tennessee makes rape punishable with death, but this is too good for such a class of men, and the tortures of former times too demoralizing upon the community for their rehabilitation. Castration and the penitentiary are their just dues. Sterilize criminals, confine them in the penitentiary for a term of years, and no ill effects from a moral point of view will follow, while it fully protects from further crime originating in sexual disease, and shields society from their like forever. When the question of insanity is urged in justification of crime, and such mental condition is due to sexual excess, sexual sterilization, whether the criminal be male or female, should undoubtedly be a part of the remedial agency punishment prescribed. Would castration be a grave punishment to man? This question opens a wide field for thought. Castration among the moral, for disease, is grave enough, but with him who devotes his entire thought to sexual gratification, death is secondary to sterility.

In the scientific handling of all criminals, whose crimes are associated with or dependent on sexual depravity, such persons would keenly feel the awful justice of the remedial agency, and would appreciate a life of rectitude, should they regain their freedom. The history of the eunuch of former times shows that he not only lost his licentiousness, but all feeling of manhood and equality as well, and grew fat from an easy conscience and a tranquil nervous system. Sexual sterilization undoubtedly robs the subject of all hope in this world, but it leaves intact his prospects for a life of

virtue and happiness in the great beyond. It is to the prevention of such crimes that we must bend our energies if we would save the community.

One has only to look over the current literature of the day, North and South, for assurance that the black people are rapidly coming to the front as criminals. The frequency of the crime of rape perpetrated upon the white female is becoming paralyzing to the country, and yet provisions of our law, making such attacks felony punishable with death, coupled with the terrors of the mob, have not only failed to check but have actually permitted an increase of the crime. A prominent attorney of the law recently informed the writer that certainly not more than one-fifth of the rapes committed by negroes with their own color ever come to light. A free dispensary physician states that application for remedial agents to relieve the suffering following rape or attempt thereof are by no means uncommon.

If the law provided sterilization for all such rascals, the colored man would soon know that rape is a crime of no small magnitude, even with his own color. Then, too, it would place an object lesson, a prideless and demure eunuch, within every negro community in the Southern States.

In former times, in Oriental countries, it was no uncommon habit to castrate males for the purpose of making suitable domestics. Many of them, however, subsequently gained high and honorable rank among the citizens.

In the opinion of the writer, the method of scientific inquiry into the causes leading on to the committal of crime, and the adaptation of remedial agents that render such causes subsequently inoperative, either with or without additional punishment, is the proper method for the immediate and permanent protection of society, the punishment of criminals and the arrest of their propagation.

DISCUSSION.

Dr. J. B. LINDSLEY, Nashville.—As to capital punishment one-tenth of the little code, constituting that wonderful system of law published by the great law-giver, Moses, said: "Thou shalt not kill;" to this day there has not been any revocation of that code, and you can not find the authority in any government to commit murder under any name whatever, whether in war or peace. Of course it follows that we must have some other mode of punishing criminals. We want to save society from all criminals, and hence the idea of asexualization has been propagated throughout the country. This will eventually be practiced for the prevention of propagation of not only criminals, but of idiots and all people we do not want to live. Questions such as these depend more on medical men than on any other persons.

Dr. RODGEAS reported two cases of asexualization of the male. In the first, appetite was diminished directly, though the sexual act could be performed. In this case there may have been some of the secretory part of the testicle left. In the second case, performed about five years ago, there was none left. Several months after the operation this patient claimed there was no particular change, but the appetite has since diminished.

Dr. NEIL regarded the subject as not in the province of medicine, thinking it a legal and legislative question.

COL. HOLT, of the Memphis bar.—This is a living and real question, and one which must be solved by the medical profession rather than the legal profession. The actions of the human mind are as regular in their operations as any of the laws of nature. Scientific men are beginning to consider crime due to a mental aberration or to an abnormal mind. The legal profession can never handle a question of that sort. We regard capital punishment a fallacy. It certainly has not succeeded heretofore; what it may do in the future we do not know.

Dr. HAPPEL has been an advocate of the whipping post. If you apply the lash freely, the little crimes and petty offences will not be committed. Under the present form of punishment, the same criminals are brought back to jail, year after year. The prison punishment is a fallacy. There is an old principle that like begets like. There are exceptions to all rules, but as a rule a criminal will beget a criminal.

Dr. SIM, in closing the discussion, referred to excessive indulgence as a great factor of producing diseases, which are handed down as such. A man suffering the pathological change of chronic alcoholism or excessive indulgence in venery, will hand down his disease in the form of epilepsy, chorea, catalepsy, excessive nervous debility, etc.

Dr. C. R. ATCHISON, Nashville, presented the

LOCAL TREATMENT OF CUTANEOUS MALIGNANT EPITHELIOMATA.

No matter what the cause of cancer may be, the offending

agent is merely a morbid epithelium, and anything which will remove or destroy this epithelium will cure the disease. A cancer enlarges by peripheral extension, not by centric, the surrounding tissues are infiltrated, though perhaps only to the extent that they can not be recognized by touch or unaided sight. Indeed, these diseased cells are sometimes so slow and insinuating in their growth that they can not be found even with the microscope, yet they prove their presence by a so-called recurrence after operation. These epithelia traverse the lymph channels and pursue their only way in no regular order. It can easily be seen how difficult it is to decide with any certainty how far from the lesion the incision should be made, especially about exposed surfaces where minimum disfiguration is of importance. The way to remove a cancer is to remove the epithelial cells to which it is tributary, and the method of removing them should be employed that is most likely to remove all the offending epithelia, even if the operation be followed by more pain and deformity. Other things being equal, we should select that method which gives the least deformity.

Among other means of treating cancer should be mentioned electricity. Though temporary improvement seems to have resulted from the use of the current, no permanent improvement has occurred. As a caustic it is as efficient as other caustics, the disadvantage being that it attacks sound tissue as well as that which is diseased. It is advantageous in some localities where the use of strong caustics is impracticable, as upon the roof of the mouth.

Where there are flat surfaces or where there is a good deal of loose tissue which can be removed without much deformity, the knife had perhaps best be used. Early cancer of the mammary glands is to be removed by this method. No other method can accomplish as good results with as much certainty. Old and advanced cancers upon the extremities are often best relieved by amputation.

In selecting the caustic to be used, it is a *sine qua non* that only those should be chosen that can destroy the epitheliomatous tissue rapidly and effectively; nitric, sulphuric, carbolic and arsenious acids, caustic potash and chlorid of zinc. The use of caustics which are not strong enough to destroy sufficient area immediately, really does more harm than good. The strong mineral acids are sometimes useful, especially when the cancer is small and superficial; but when large and deep seated we had best rely upon the celebrated trio, with which all physicians are familiar, viz.: Caustic potash, chlorid of zinc, and arsenious acid.

Pyoktannin, fuchsin, pyrogallic acid, resorcin and salicin have all been used, but they are slower in action and not so sure as the trio just mentioned, which will do all the others will and do it quicker and better. Cancer, so often pronounced incurable, will become less dangerous when we come to realize the absolute necessity of promptness and the value of caustics.

DISCUSSION.

DR. CAIN mentioned the lymph channels as a method of extension, and for this reason did not indorse the treatment recommended by the essayist; caustics and escharotics. In some cases these are to be used, but usually the knife is the ideal treatment. The remedies mentioned, and all cauteries except actual cautery, would stimulate the spread of the disease through the lymph channels and drive it farther through the tissues. This the knife does not do.

DR. LOUISE DRUILLARD reported a case of a child, probably 6 years old, living in a small town in Texas, who had cancer under the ear. It was subjected to operation twice unsuccessfully, and was finally cured permanently upon the application of a paste by a traveling "doctor."

DR. CROCKETT reported a case of epithelioma of the cheek, in a patient with heart disease, which was treated like the case reported by Dr. Druillard, and the patient died of heart disease about ten years afterward.

DR. JONES reported a case of epithelioma within half an inch of the eye, and the same distance from the nose, the growth being the size of a nickel, in which a previous operation with the knife was unsuccessful, and asked if the use of caustics would produce a scar which would be more likely to evert the lid than the use of the knife.

DR. HILLSMAN replied that in a case under his observation the lid was everted after the application of a paste by a quack doctor. A great many people will not permit the use of the knife at all, and consequently they fall into the hands of charlatans. We discard this method of treatment too much. There is a tendency of the remedies mentioned to destroy the diseased tissue.

DR. HAPPEL reported a case operated upon with the knife

last June, after caustics had failed. The eyeball, lid and all the tissues from the principal portion of the eye were removed, and so far it has proved a success.

DR. DOUGLAS.—One reason why the general profession has discarded the various pastes is just because the charlatans have taken them up, and no doubt there is some good in them, but in carcinoma of the breast and uterus, the knife is the only thorough method.

DR. CAIN thought the magical cures, seemingly, were usually not cases of cancer, and if epithelioma is cured at all it is very rare. Dr. Waterfield's case could not have been a case of malignant disease. The diagnosis can only be made with the microscope. In Dr. Jones' case he thought the knife should be used and a plastic operation made to fill up the space. He had known such cases to heal after a plastic operation, but they are very likely to return.

DR. ARCHISON, in closing, said the results of the caustics will extend as far as the surgeon would go with his knife, and even farther. We may say there are three circles: The first indicates where the caustic is applied; the second, where the cells had infiltrated; and the third, healthy tissue. Under ordinary circumstances the incision would never be made as far as the second ring, and the cells remaining will then cause another outbreak.

Upon report of the Judicial Council, the following members were dropped from the membership of the Society: Dr. E. E. Jones, Nashville; Dr. B. P. Keys, of Chattanooga; and Dr. E. E. Kerr, Chattanooga.

Under the title, "The Treatment of Inebriates," DR. HEBER JONES, of Memphis, presented a resolution to be offered at the next meeting of the State Legislature, providing for the admission of alcoholic patients to the pay wards of the public institutions. The following resolution was passed:

Resolved, That it is the sense of this Society that the medical profession in this State should unite in an effort to lessen as far as possible the evil effects of intemperance.

Resolved, That in the opinion of this Society this cause can be materially advanced by suitable legislation to this end. It is our belief that many otherwise hopeless inebriates may be permanently cured, if the physician is enabled to exercise proper control over them. We think this can best be secured in our public asylums. We therefore desire to ask the Tennessee Society to use every effort to secure at the next session of the Legislature the enactment of a law permitting any citizen of the State to enter any of our asylums for the treatment of confirmed inebriety. Provided, however, that this shall apply only to the pay department of these institutions.

On motion by Dr. Crockett, a committee was appointed to place the matter before the next session of the Legislature.

Adjourned until the second Tuesday in April, 1895, to meet in Nashville.

The Journal on Top.—Instead of there being an unanimous desire among the profession to do everything in its power to make the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION the leading periodical of its kind in this country, and, if here, in the whole world, there seems to be a desire on the part of some to annoy, hamper and criticise with a view of lessening its growth and power. We are pleased with a recent editorial note under the head of "Captious Critics," in which the editor says in plain language to his adversaries, "mind your own business." The JOURNAL never won a more complete victory than it has recently. A few weeks ago it published an article on "The Abortion of Typhoid Fever." The author of the article claimed he could abort all cases of typhoid fever, and gave a number of cases to illustrate his statement. But he did not give any reference to his methods of treatment, neither did he intimate in any way what that treatment was. This gave another large journal the opportunity to express itself in most forcible terms. The editor says the author of the paper "refuses to divulge his remedy, and it is surprising that any respectable medical journal should give publicity to his claims." But the laugh comes in just here, when the subscribers to each of these journals received their number of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION which contained the second article, giving the author's treatment in full, nearly a week before the editorial of the second journal arrived. In other words, before the criticism had reached the subscribers, the cause of the criticism had been removed, and the JOURNAL came out on top, as usual. The moral of this little tale is, it is best to look before you leap.—From the May number of *Food*.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
F. J. REBMAN, LONDON AGENT, 11 Adam Street, STRAND, LONDON.
W. H. LOWDERMILK & CO., WASHINGTON, AGENTS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, MAY 19, 1894.

PERMANGANATE OF POTASSIUM AS AN ANTIDOTE
TO MORPHIN.

The recent advocacy of permanganate of potassium as an antidote to morphin, in cases of poisoning, recalls the treatment of snake bite and other similar applications of this therapeutic agent, and invites to the study of the chemic and physiologic considerations upon which its employment is based.

About 1885 CONDY introduced permanganate of potassium into medical practice as an agent having special power in infectious conditions. He presented it in the form of a solution, which also contained aluminum sulphate, the latter being added to increase the oxidizing effect of the permanganic acid. He asserted that he had found by experiment, that in this form and combination all the available oxygen of the permanganic acid is utilized, whereas only about 60 per cent. of this amount is obtained when the simple alkaline permanganate is used, as in the ordinary solution, which is generally called CONDY'S Fluid, and which was official in the "United States Pharmacopœia," edition of 1870.

It has been demonstrated by clinical observation as well as laboratory experiment, that permanganate of potassium is antidotal to infectious disease, because it is destructive to the lower forms of life. It is especially applicable where it can be brought directly in contact with the microorganisms, as in diphtheria, gonorrhœa, local infective processes, suppurating wounds, etc. By its great oxidizing powers, it is able to destroy the infectious quality of septic matter, and in virtue of this it is a true disinfectant. The chief objection to its use is that in strong solutions it is caustic; even weak solutions if too freely used, excite irritation and, occasionally, inflammation of the skin and mucous membranes. Thus, in treating diseases of the middle ear, solutions stronger than 1 grain to the ounce should not be used; for the

nose and mouth 3 to 5 grain solutions may be employed; and for applications to the skin ordinarily, it is not advisable to order solutions much stronger than this. From 15 grains to a drachm to the pint of warm water, is the ordinary limit for the treatment of foul ulcers, bromidrosis, etc. Twenty-four grains to the ounce is considered a saturated solution, but this is only exceptionally used, applied locally to counteract infection. That the permanganate of potassium is a germicide has been fully established by the experiments of STERNBERG. As an antiseptic, it has the great advantage over corrosive sublimate of being comparatively non-toxic and of being a prompt deodorizer.

To DR. S. WEIR MITCHELL is due the credit of suggesting the use of permanganate of potassium in snake bite, in which it has proved to be a valuable resource. In order to obtain the antidotal action, the solution is to be injected as quickly as possible after the accident, directly into the punctures made by the fangs of the snake and also in the immediate neighborhood, so as to secure the contact of the remedy with the yet unabsorbed poison. This treatment was indorsed by LACERDA, and many instances of its successful application have been reported. To cite a single communication out of many, we may refer to the paper¹ of DR. A. W. BARBER, of Cheyenne, based upon the successful treatment of nine cases of rattle-snake poisoning by means of permanganate of potassium. The method he employed is the following: A 15 per cent. solution is kneaded into free incisions made to the bottom of the wounds; it is also injected hypodermically in the vicinity, and the dressings wet with the same solution applied. Alcohol and carbonate of ammonium are also given in amounts regulated by the state of the pulse; laxatives, diuretics and diaphoretics are subsequently utilized in eliminating the poison. An important point in DR. BARBER'S method is the intermitting application of the tourniquet, by means of which only a little of the poison is permitted to enter the circulation at a time. Here the permanganate is used locally as a chemic antidote and the well-established physiologic antidotes, alcohol and ammonia, are relied upon to overcome the poison as it gradually enters the circulation, in what might be termed broken doses.

The oxidizing effect of this agent has also been utilized in the condition of phosphorus poisoning. Last year, BOKAI recommended the internal administration of a solution of one-third of 1 per cent. strength, where phosphorus in substance had been taken into the stomach. It acts by coming in contact with the poison in the stomach and converting it into ortho-phosphoric acid, which is harmless. Here again it acts only upon the excess of poison remaining in the stomach, and does not follow the toxic agent into

¹ Therapeutic Gazette for January, 1892.

the circulation. Indeed, the statement of RINGER that "the permanganate itself can not pass into the blood undecomposed," is in full harmony with the teaching of other authorities. Moreover, on account of its attraction for organic matter, the permanganate is decomposed in the stomach in a very few minutes after being swallowed.

We now come to the most recent application of permanganate of potassium, as an antidote in the treatment of morphin poisoning. Its claims rest upon the experiments and clinical trials of DR. WM. MOOR, published in the *Medical Record* of February 17 of this year. According to this observer, morphin is rapidly oxidized by the permanganate, even in the presence of peptones and albumen. By clinical experiment it was ascertained that if comparatively large doses, of from 3 to 5 grains of sulphate of morphin, are quickly followed by a solution of permanganate of potassium, no narcotic influence will result. In other words, the permanganate, by oxidizing the morphin prevents the toxic effects from being manifested. As the result of several trials, which corroborated his first experience, DR. MOOR pronounces the permanganate of potassium a reliable antidote for morphin, if given immediately after the poison has been swallowed. He gives from 10 to 15 grains, dissolved in half a pint of water, repeated at intervals of thirty minutes. It may be assumed as proven, then, that in a case of morphin poisoning the permanganate, as in the former instances cited, acts as a chemic antidote and renders inert the poison yet unabsorbed, with which it must be brought in contact. There is absolutely nothing to warrant the view that this agent can act as a systemic or physiologic antidote to morphin or any other toxic agent. Nevertheless, cases are reported, occurring in different parts of the country, in which the permanganate is employed hypodermically, the poison having been administered by the stomach. The widespread newspaper notoriety given to this new treatment, according to its prominence immensely beyond its importance, can only be accounted for on the ground that it originated in New York city, and first appeared in the daily papers which are always eager for the sensational and the marvelous, but are poor authorities in matters of science. The most recent communication on the subject appears in the *Medical News* of May 5. It is a clinical report emanating from the Homeopathic Hospital of Pittsburg, and is entitled: "Practical Applications of Potassium Permanganate as an Antidote to Laudanum."

In this communication a case is reported, in some detail, in which it is stated that about eighty cubic centimeters two and one-half fluid ounces of laudanum, of unknown strength, had been swallowed some three hours before the patient was brought to the hospital. He was then comatose with respirations only

four to the minute. In addition to the usual treatment, including coffee by mouth and rectum, and hypodermic injections of atropin, artificial respiration and so on, and when the case seemed hopeless, repeated injections of a half-saturated solution of permanganate, in doses of 2 drachms, were administered at intervals of half an hour. After the third injection, improvement was first observed, and after the fifth injection the patient became conscious and tried to articulate. With the fact that recovery was delayed by abscesses of both arms, we are not immediately concerned; the main fact is that the patient recovered, as did also two other cases, which were not so marked, and in which the same treatment by hypodermic injection of permanganate was resorted to.

From what is known of the chemic nature and physiologic effect of permanganate of potassium, we must admit that the successful use of this agent administered hypodermically, in cases of laudanum poisoning is something we were not prepared for. We can understand that when morphin which is a powerful reducing agent, is brought in contact with the permanganate, which is a vigorous oxidizer, a mutually destructive reaction would ensue. But when the morphin enters the blood where the permanganate can not possibly follow, the antagonism ceases to be available. It is possible that when hypodermically administered, although decomposed in the tissues, the nerve centers may be influenced by some of its products, but even if so, it would not be permanganate *per se*, but something else which does the work. What the active agent may be in such case, it ought not to be a very difficult matter to determine. In the meantime the distinction between a chemic and physiologic antidote must be kept in view and, above all things, we should not require of a chemic antidote that it shall be also a physiologic one.

A new antidote to morphin was not urgently demanded and it could not in fact be truthfully denominated as a "long-felt want," since the treatment already in general use is very efficient and, as a rule, is successful. But even allowing some usefulness to potassium permanganate as an antidote, when swallowed immediately after morphin has been taken into the stomach, this will not warrant the assumption that in such cases its hypodermic administration will have any beneficial effect. Certainly, we are not warranted at this stage of the investigation, in abandoning our well-known physiologic antagonists in the treatment of poisoning either by morphin or by opium or its preparations. When a human life is trembling in the balance and fatal coma is threatening, it would be criminal to lose time by experimenting with therapeutic novelties, to the exclusion of the established treatment and the "rejection of the accumulated experience of the profession." Some

might be led to do so, however, were no word of protest raised against the implication that the suggested treatment is a safe and efficient substitute for the approved methods already in use.

THE STATE SOCIETIES.

By the time this number reaches the readers of the JOURNAL, nearly all the State societies will have held their annual meetings—meetings which, judging from the proceedings, seem to have been marked by great harmony, unanimity of sentiment and fraternal feeling. The chronic growler was there as usual, but either his voice was husky, or there was something in the atmosphere which prevented its resonance, for very little of him appears in the reports of the proceedings.

The time is ripe for professional organization, and the profession at last seems to have realized it in a largely increased attendance of most of the societies, notwithstanding the financial stringency of the times, which has reduced professional incomes very materially and made collection of earned bills extremely difficult. The attendance has been fully the average in most cases, and several of the societies have increased it. We have printed abstracts of the proceedings of some of them; others are to come, and it may fairly be said that at no time in the history of American medicine has the standard been higher, nor have the papers presented shown higher scientific value. With this awakening of the profession to a sense of its duty, there is little question that the local, State and national associations will steadily grow in usefulness for the profession, and exert a commanding influence on all public questions in which the profession as a whole are interested.

THE MEDICAL DEPARTMENT OF THE NATIONAL GUARD AND OF THE ARMY.

In the *Congressional Record* of Tuesday, May 8, 1894, we find the following: *Senate Proceedings*: The Vice-President presented a memorial of members of the Medical Department of the National Guard, remonstrating against the passage of House Bill 6373, relating to the reduction of the Medical Department of the Army, which was referred to the Committee on Military Affairs. *House Proceedings*: By the Speaker (by request): Memorial of delegates from the Medical Department of the National Guard of the States to the fourth annual meeting of the United States Military Surgeons, against reducing the Medical Department of the Army, as proposed in House Bill 6373,—to the Committee on Military Affairs.

Our National Guard brethren did well in taking prompt action in a matter of such vital importance to the efficiency of the Army Medical Department, and we trust that their protest will meet with the consideration which it merits. The surgeons of the

National Guard can recognize better than most medical men the importance of having, in time of war, a thoroughly educated and disciplined medical staff. The memorialists held that to keep the Army Medical Department up to its present point of efficiency, young men must be elected from time to time, educated in practical sanitation and familiarized with military methods and discipline to take the place of those who drop out by disability, age or death. A gap of eight years in the recruiting of the Department, which would be the result of the proposed legislation, would be felt harmfully for a generation to come. We trust this will not be.

MUTUAL CONSULTATIONS ARE NOT CONFIDENTIAL.

In a murder trial where the defense is insanity and the court, upon motion of the accused, with the consent of the district attorney, appoints a physician to make an examination, and to testify on the trial, as the mental condition of the accused, the Supreme Court of Colorado holds, in the case of Nesbit v. People, decided March 7, 1894, that an examination and consultation between the accused and the physician, under such circumstances, are not confidential, and that the physician can be called by the State to testify in rebuttal, even though he has not been called by the accused. It can not be, it is said, that an accused can seek and obtain such an examination at the hands of the court, and with the consent of the prosecution, with the privilege of introducing the testimony if the result of the examination shall be favorable to him, and yet reserve to himself the power of excluding the testimony if it shall be unfavorable.

DUTY AND POWER OF THE WISCONSIN COUNTY BOARD.

The Supreme Court of Wisconsin holds, in *Rider v. Ashland County*, that it is, in that State, without doubt, the duty of the county board to procure and furnish all needful medical aid and attendance to persons confined in its jail, and to such poor persons as are a county charge. It may be more convenient and cheaper to engage one physician by the year than to employ one or several by the visit, and without previous engagement. Whether the employment shall be by the year or by the visit is in the discretion of the county board. It is not a question of power, but of detail, merely.

ASSUMPTIONS PERMITTED IN HYPOTHETICAL QUESTIONS.

Counsel are not confined to facts admitted or absolutely proved in propounding their hypothetical questions to experts. So declares the Supreme Court of Colorado in the case of *Jordan v. People*, decided March 7, 1894. They may assume, the court holds,

for the purposes of the questions, any statement of facts which the evidence tends to establish. It is the province of the jury to determine the truth or falsity of the assumed facts.

CORRESPONDENCE.

Revision of Constitution and Code.

TROY, N. Y., May 4, 1894.

To the Editor:—The adoption of the amendments to our Constitution, By-laws and Code of Ethics, as proposed by the special committee and printed in the JOURNAL for April 7, might induce results in some directions not apparent from a cursory examination of the subject—effects it is to be hoped not intended by the gentlemen making the majority report.

The changes are in some directions so radical it would seem that probable danger of evil would be appreciated at once, even from a cursory reading of the report, but finding on inquiry that some of my friends failed to notice the trend of the amendments, I concluded that the length of the document, the variety and number of subjects necessarily considered, and the separation of provisions so as not to fully disclose the extent of their relations, might confuse one not on the alert, or not familiar with such subjects.

Though the proposed amendments have received able and careful consideration at the hands of several revisers in the columns of the JOURNAL, notably by Dr. N. S. Davis, I feel that there is occasion to emphasize some of the objections which have been presented.

The title of our ASSOCIATION would imply an intention to have an organization on principles consonant with the governmental and social features of the nation, *i.e.*, it should be an *American* association.

The first radical and fundamental change provided for, consists in the abolishing of delegates—who at present are the voters at the meetings—and the introduction of a provision for a *general active and voting membership*. This would place the affairs of the ASSOCIATION in the hands of the members of the profession residing in the vicinity of the place of meeting. This amounts to an endeavor to apply the methods of the town-meeting, (invaluable in their proper spheres) to affairs having a national importance. It is consequently undemocratic, in that it would allow a small and sectional portion to act for the whole and to cite the British Association as an instance of the successful application of the proposed methods is specific and misleading, as a moment's reflection on the relative territorial extent and density of population would show.

The importance of the questions to be decided at the approaching meeting should be ample illustration of the danger which might arise in leaving the ASSOCIATION in the hands of the voters of a certain locality, which locality may by wily methods be selected for certain but concealed purposes, for language is said, at times, to conceal thoughts.

This radical change in the legislative methods of the ASSOCIATION should be considered in connection with certain other proposed amendments which are not found in direct relationship or order of verbal sequence, but are found by adding together detached but related items. Some of these disarticulated provisions give the following results:

1. It is provided that the chairman of each Section shall appoint a Nominating Committee, ("consisting, if practicable, of ex-chairmen of the Section") to nominate Section officers.

2. The Executive Committee of each Section shall consist of the chairman of the Section, and his predecessors in that office for the two years just passed.

3. The Executive Committees of the several Sections shall meet together and constitute a General Business Committee.

4. Much of the business of the ASSOCIATION is to be referred to this General Business Committee without debate.

5. This same Business (should we say *Busy*) Committee is to be the Nominating Committee.

If the revisers of the Constitution intended to offer provisions whereby the wishes of the whole profession, in all parts of the country, could find expression in the proceedings and acts, in the management of the affairs, and in the official *personnel* of the ASSOCIATION, their schemes must prove a signal failure, for a better plan for a close corporation could hardly be conceived. These provisions are in every way anachronisms, unless governmental methods are to evolve backward.

I shall not accuse the Committee of an intention to place the control of the ASSOCIATION in the hands of a few men, nor will I press my objections closer by urging that in this scheme the general practitioners, who still constitute the large majority of the profession, will find that they can have only a very limited share in the official work of the ASSOCIATION. As a matter of fact, the present organization, when contrasted with this new scheme, would illustrate a republican and representative liberty in contrast with a probable oligarchy. And all this, we were told at Milwaukee, is to be done for the interests of the ASSOCIATION and for the advancement of scientific medicine. *Is it true that words are means for concealing thoughts?* Let any one weigh carefully the natural tendency of the provisions for the government of the ASSOCIATION to which I have called attention and then consider, if it can be truthfully claimed that log-rolling has existed under our present plan of organization, what should be the estimate as to the probable evils in that direction under the new *regimé* (which would be a heptarchy, more or less).

These objections do not exhaust the subject as to the proposed Constitution, but they seem broad enough and deep enough to suffice.

And now a few words concerning the Code: I will take as my text an extract from the Milwaukee "Proem," in which they say: "The Committee deprecates all efforts to abolish, belittle, distort, ridicule, or otherwise lessen its hold upon the profession." As a matter of fact, the adoption of this *newest* Code would do each and every one of those five things, only it would come in the reverse order of their statement. It took ten years to go through a similar process in the State of New York. *Facile decensus.*

The dignified and pure English of our present Code has been the subject of frequent comment; and while wishing to avoid any mere verbal criticism of the Code reported by the Committee, I feel it is but right to state that its principal claims for credit as a composition lie in the large extracts it has received from the old Code. But, without stopping to specify such points of comparison, which though important are not of first interest, we may briefly consider a few of the radical changes from the provisions of our present Code.

In their preliminary report at Milwaukee, the Committee were at considerable pains to show that a specialist and general practitioner are not fit parties to a consultation, and the inference is that the average physician is only the guide-board to the office of the specialist, or the quasi usher for that individual.

It is submitted that no provision in a Code is necessary to show *how* a physician may relinquish the care of a patient, when the motive is purely personal, but it is proper that specialists should be kept in mind of the fact that general practitioners exist who are competent to discuss with them

questions relating to their special fields, and it should be freely conceded that there are specialists who are competent to discuss cases from the standpoint of the general physician. As a matter of common courtesy, the physician is entitled to a full consultation if he desires it, and no presumption to the contrary should be created. I believe that all well qualified and well disposed physicians and specialists will accept that proposition.

We should remember in this part of the question that the *sedilia* of infallibility abides neither with the physicians nor with the specialists, and that "honors are easy" so far as errors are concerned.

Personally, I shall insist on my right to a consultation where I am to have any professional interest in a case, though I may waive my privilege for personal reasons.

As to the provision which allows consultations with "legally qualified practitioners," the object is so apparent as to require no comment, for without the limitations made by the old Code, in most of the States it would virtually allow consultations with all the varieties of charlatans, for the *respectability* of the *licensing board* would be a matter of taste.

One word concerning patent rights and proprietary medicines. Justice is always to be honored and sought; but justice is not always to be found, particularly by a superficial consideration of a case. No honorable means for pecuniary advancement should be closed to members of the profession, but if our surgeons are to furnish a quota of itinerant venders of the latest modifications of forceps, scissors and *snares*, and specialists with stethoscopes, ophthalmoscopes, etc., or ingenious physicians with a turn for chemistry and the "main chance," should conclude to patent the latest "extract," and all be added to the hordes of non-professional representatives of business firms who now invade our offices, who is to protect the general practitioner who seems to be the natural prey of such schemes and schemers. He would need some additions to the litany of defense and deliverance.

As a matter of fact, how many instances of invention of surgical appliances can be adduced where notable pecuniary profit would naturally follow a patent, at least sufficient to justify the sorry spectacle of a scramble for success in the sale of rival inventions. There is our solution of the question, and it seems the only one, *i. e.*, if the invention is likely to be more profitable than the honors and rewards connected with strictly professional work, then let the inventor cease to practice medicine and surgery, patent his "machine," and enter upon the strictly business methods belonging to its manufacture and sale.

If we are to remain a *liberal* profession we must avoid the methods of pure commerce.

This new Code, we should remember, is practically a twentieth century code, and yet let us pause a moment, only a moment, to consider its provision relative to advertising. After following the language of the old Code so as to condemn and prohibit advertising *by the general physician*, the revisers add: "It shall not be considered a violation of the spirit of this section, however, for physicians engaged in the work of medical education, either singly or associated in colleges, or for *physicians practicing in hospitals, whether public or private, general or special, to announce the fact or allow it to be announced to the profession in the advertising pages of strictly medical journals, or for physicians devoting special attention to one of the recognized special departments of medical practice, to note the fact on their signs or private cards.*"

Who is to decide on the list of "strictly medical journals?" Let us pause and think of the deluge of that kind of literature which the postman brings almost daily. Is it not another notice to the family physician to hide his diminished and still diminishing head? Pah! The thing is offen-

sive. The proper limitations have been fixed by long usage interpreted by the present Code, and this new provision would prove to be the thin edge of a very large wedge which would split off all that has been retained of good from the old Code in relation to the subject.

One point more and I will stop, though not for want of material for criticism—it is sadly abundant.

The Committee has stricken out all those parts of the old Code which relate to "the obligations of patients to their physicians and the public to physicians," as useless and "superfluous," according to their Milwaukee announcement. It has been the opinion of many, and the writer shares that opinion, that much good has been done, and much more might be done, by placing the Code in the hands of intelligent laymen, but the "logic of events" pursues our revisers even here, for they have devoted an Article (Article III, in Part I) to "circumstances under which physicians may properly decline to render their services," in which they refer to "reciprocal obligations of patients to their physicians." Where is the scheme or standard for their "reciprocal obligations?"

Gentlemen of the Committee: You took ample time, nearly two years, to formulate your revision of the Code, which you yourselves said should be couched "in phraseology so plain as to make it a practical, common-sense document for daily guidance in the performance of our various duties." Have you *accomplished* your work? Is your instrument philologically the equal of the one you seek to abolish? Is true liberty as loyally upheld? Have you thought that the adoption of your scheme would result in class distinctions and provide a means for class oppression? Is it possible that you contemplated a failure in the adoption of your proposed Code, but made provisions in your new Constitution which would facilitate such ethical changes in the near future? These questions are too serious for other than the most careful consideration. My own judgment is that your efforts have been misdirected and that it would have been well "had you stopped before you began."

Your obedient servant, E. D. FERGUSON, M.D.

Electricity for Salpingitis.

CHICAGO, ILL., May 12, 1894.

To the Editor:—I always find it interesting reading the report of the proceedings of the American Electro-Therapeutic Association, and in the *JOURNAL* of April 7 an article appeared read before that body by Dr. W. B. Sprague, of Detroit, on "A Contribution to the Electro-Therapeutics of Salpingitis." As this subject is of great interest, and as I have found it especially interesting, you will pardon me if I review his article.

The pathology of tubal troubles has been so recently evolved that the therapeutics is still in the embryonic stage. Many of our leading lights declare that there can be no rational therapeutics—that there can be no remedy but extirpation—as if decapitation were a cure for cephalalgia! Yet many men have a firmer faith in nature's economy, and are seeking to aid her efforts at repair by, at least so far as possible, removing the cause. Nearly all cases are accompanied by, and most of them caused by endometritis, either acute or chronic, specific or non-specific. Since this has been established, our first duty is plainly to relieve the endometritis. To this end, many forms of treatment have been advised, but Polk's revival of Sim's conception of depletion and drainage seems to be the only one which has brought satisfactory results, and the relation of parts is such that the application of this principle to the womb produces a direct as well as an indirect influence upon the tubes—it removes the cause and relieves the

chronic congestion in those cases which bear the treatment well.

Now the severity of the measure by which it is accomplished, as taught by its author and the profession at large, has limited its applicability in the hands of even its warmest advocates. Divulsion, and curetting of an inflamed womb with inflamed adnexæ has often aggravated the inflammation, making extirpation necessary. This has seemed to the surgeon good ground for the argument that extirpation should be the first and only resort.

But Apostoli has taught us that the same results may be attained by a milder and more rational means; the intra-uterine application of the negative pole of the constant current of electricity is the most reliable method we have for treating endometritis to-day, the *rationale* of which is this same principle of depletion and drainage, by the cataphoretic action of the current, aided by the trophic influence and by its constriction. Goelet has shown that the influence extends to salpingitis and, if carefully and judiciously used, is the safest and best treatment yet advocated for this affection. He says that many cases of simple inflammation of the lining membrane of the tubes will subside with the endometritis, if free drainage through the uterine canal is established and maintained, and if protection is afforded against such influences as would tend to irritate the sexual organs.

My experience leads me to indorse the foregoing most heartily, but the object of this contribution is to call attention to a modification of Goelet's treatment which has been quite successful, in a few cases in my hands. At the meeting of the Michigan State Medical Society held at Grand Rapids in 1890, I reported a case as follows:

"Mrs. H., aged 32, has had one miscarriage, but for several years previously she had suffered from pain in the right iliac region, at frequent intervals. A year ago last April she began to suffer more than ever before, and she came to me for relief. She told me, in describing her symptoms, that she had an enlargement in the side, with pain. I found this enlargement to be considerable, but the abdominal muscles were strong and I could not distinctly outline it. I diagnosed an ovarian tumor, and felt that my diagnosis was confirmed as I watched its growth in after days. But one day she came to tell me that she had had a free discharge of yellow matter after a sensation as of something giving way the night before, and the swelling was subsiding. An examination proved the correctness of her statement, and I changed my diagnosis to pyosalpinx. My treatment up to this time had been merely palliative, principally faradism, to relieve the pain. She was now comfortable, and I suspended treatment a few weeks, when the tube began to fill again. I resumed the faradism, and soon after added galvanism. On June 15 I gave twenty-five milliampères, intrauterine, negative. After three intrauterine applications, the last one sixty-five milliampères, I changed to the vaginal electrode, placed against the tube, and gave sixty-five milliampères June 29. Soon after this, there was a second discharge of pus, and relief from pain. I gave twenty-one more applications similar to the last described, before March 29, 1890, when the tube had again filled and was giving considerable trouble. I now determined to try to effect an entrance. I therefore converted my graduated uterine sound into an electrode, insulating it with small rubber tubing, and passed it into the womb. I then connected it with the negative pole of the battery and turned on ten milliampères. Turning the end of my sound toward the right cornu, I exerted gentle pressure against the point that I thought to be the proximal end of the tube. Suddenly, within five minutes, my sound slipped onward about an inch. I was startled, and thought of perforation of the uterine wall, but perceiv-

ing my patient undisturbed I decided that I had really been more fortunate than I had expected, and accomplished my purpose. So I passed the electrode still further in and raised the current to twenty-five milliampères for seven minutes. There was free discharge of pus for several days following, and renewed relief from all the symptoms. I have since introduced the sound into the tube on May 12 and 25, and on June 12, the last time in the presence of Dr. Manton, who kindly came in to confirm my diagnosis. The tube seemed quite empty of pus at the last sitting. The sound has passed more readily at each subsequent sitting, and enters to a depth of more than five inches. The patient, who is a seamstress, has not lost an hour's work from treatment and her general health is much better than a year ago." (Trans. Michigan State Medical Society, 1890).

The subsequent history shows that the patient was completely cured. The author of the above paper also gives the history of several other cases that are very interesting. Further on in his valuable paper he says: "I am aware that the possibility of entering the tubes in these cases is discredited, and I have found many cases in which I have been balked in my efforts, but I have good reason to believe that I have succeeded in several cases besides these that I have reported, and have had no untoward results following my efforts in any instance."

The author ends his paper by describing the method by means of which he effects an entrance into the tubes:

"I use an insulated Simpson sound, with the normal curve a little accentuated at the extremity. As soon as I have passed the internal os uteri, I turn the point of the instrument to the side which I wish to enter and gently follow along the bottom of the fossa until I reach the os uterinum of the tube, which is indicated by the points sliding into a slight depression. I then attach the negative conductor, turning on slowly, ten to thirty milliampères, according to the nature of the case. I exert just sufficient leverage to hold the bulbous point in firm contact with the ostium. I usually notice evidence of the cataphoretic action by the oozing of fluid from the os uteri. In those cases where I have succeeded in entering the tube I have felt the point of the electrode suddenly advance, and have immediately found it fixed, as if in a narrow canal. In some instances I have then been able to advance it from one to three inches farther, and then have felt the point in the ovarian region, with the other hand, through the abdominal wall, in several instances. After the first one or more treatments the point does not always stop at the fornx, but enters the tube readily, as was the case in the instance where Dr. Manton verified my observations. I have always exercised great care to avoid force, simply guiding the electrode, with my hand supported at the forearm. With this precaution, and the low current used, I do not think the danger of perforation is as great as is sometimes represented."

In the discussion which followed, Dr. A. Laphorn Smith said that if this paper had been read before the Philadelphia Obstetrical Society the author would be glad to escape from the room with his life. At the same time he quite agreed with the author in his statements. He felt quite sure that the tubes can be catheterized. Dr. Wallace showed him in his Liverpool hospital six cases at one time in which he had introduced a uterine sound into the tubes. Again, he had himself frequently had cases in which fluid accumulations in the tubes were discharged spontaneously. The source of the discharge had been proven by the use of clean, dry, cotton tampons. In view of these facts, why can not we empty the tubes in the natural way through the uterus?

Dr. N. W. Weber, of Detroit, also spoke in favor of the method.

Dr. Massey said that while appreciating this conservative

surgery, it should not be forgotten that this work is for experts only. In 1888 he had himself brought the subject of treating such conditions by intrauterine negative galvanism up before the Philadelphia Obstetrical Society. He succeeded at that time in emptying a number of tubes. Dr. Sarah A. Stevenson, of Chicago, said that notwithstanding the law which has been laid down that electricity is contra-indicated whenever there is pus present, she had for a long time employed it in such conditions. Dr. Sehrung remarked that as electricity is known to cause dilatation of various apertures, it would seem that this agent would greatly facilitate the catheterization of the tubes.

Now I was tempted to review considerable of the author's paper because it is of unusual interest, and because the article might be entirely overlooked, especially by those who do not use electricity, or by those gynecologists who are of opinion that the only treatment for pyosalpinx is extirpation of the tubes.

The great law of surgery—drainage—holds good here as in other conditions, and that drainage through the uterus can be effected is, according to the above testimony and to my mind, beyond a doubt. (Though there may be some exceptions where entrance into the utero-Fallopian opening can for some reason not be effected, and which would be cases for the surgeon.) I have myself treated cases of pyosalpinx, and have seen the pus ooze out of the uterus; the last case is still in my charge but is completely recovered from that trouble.

That a sound can be passed into the Fallopian tubes in the healthy state is also, I assume, an accepted fact. Dr. E. C. Dudley, Professor of Gynecology at the Chicago Medical College, several years ago, in one of his lectures remarked: "Gentlemen, having passed a sound into the uterus a number of times and having determined positively that it is—say three and one-half inches deep, and you subsequently by turning your sound a little to one side or the other, find it suddenly slips in an inch farther without force, you can conclude that you have entered the Fallopian orifice."

Now then, as pyosalpinx is a retention of pus within the Fallopian tube, and as this pus is retained because the utero-Fallopian orifice is closed, undoubtedly by an inflammatory adhesion, from the above testimony, the experiments of Bozeman and Newman with the use of negative galvanization of fibrous strictures of the urethra, and from the well-known dissolving qualities of the negative galvanic current, we are justified in giving this treatment a fair trial. We may thereby save many tubes, and keep many women from undergoing the terrible ordeal of a laparotomy.

JOHN KERCHER, M.D.

American Medical College of St. Louis.

To the Editor:—My attention has been called to an article in your JOURNAL, headed "Stirring up the Colleges," published in the issue of April 7. Will you do me the honor of correcting that which seems to me a great injustice to the American Medical College of St. Louis? Your informant, in speaking of the act of the Missouri State Board of Health, says, among other things, that the Dean of the American Medical College has been notified that this College does not conform to the requirements of the Board, and therefore its diplomas will not be recognized as entitling their possessors to practice in Missouri. I desire to say, that no such notice has ever been received, and that your article was the first information I had read on that subject. My attention was called to it by a private letter of inquiry from New York. This College has been in good standing for the last twenty years, and if an action of the kind has been taken by the Board, justice would demand that due notice

be given that the College might have an opportunity to answer to the charges.

I imagine that this damage inflicted, has served as a precedent for abrupt action of other State Boards, hence the great injustice there is in it; among these the State Board of Health of Illinois, a notice of which is given in your JOURNAL of May 5. Had your correspondent in this case given the reason for their action, it would have shown more fairness. Want of proper equipment and apparatus seems to have been the basis of action with the Illinois Board. It is true that some carelessness in this regard had crept in, and when the Illinois committee visited us they came abruptly and gave us no opportunity to supply what might seem to them a deficiency. This College has been taught a lesson and has now undergone a thorough change and has equipped itself. When Boards of Health will give us their standard in these matters they will find the American Medical College perfectly willing to conform to their wishes.

Respectfully,

C. YOUNKIN, Dean.

Reply to Dr. Worcester.

RICHMOND, VA. April 25, 1894.

To the Editor:—Allow me a few lines in reply to the "open" and "sweet-spirited letter" of your fair correspondent, O. E. Worcester, M.D., of Florida, in your issue of April 21:

1. The age of legal consent in Virginia is 14 years.
2. Twenty years ago I organized a Magdalen Home and have been its President ever since. Your account of "a domestic chloroformed in a physician's office" must be taken with a "grain of allowance." I have learned to have little faith in the excuses for women's fall told by themselves. It is the old story.
3. The dishonorable doctor spoken of was not worthy of belief. Bad men always believe others as bad as themselves. This man is a slanderer of his brethren. But as I have sent your correspondent my pamphlet on "Woman's Place," where woman's power of self-protection is fully discussed, I need say no more on this subject here. My advice to young girls going out from the Magdalen Home is to hold their persons sacred and let no man put his hand upon them. If lynching followed lying and betrayal or assault, it might be better.

4. Nine-tenths of the doctors in this city will not disobey the law you refer to. There are always "men of the baser sort," as Paul says, in every city. But I can not discuss this subject with a lady. Though an M.D. married thirty years, with ten children, yet there are some questions I would not think of discussing with my wife, from respect to her finer feelings. I claim and have proven that women are "four times" better and purer than men. The shrinking, instinctive modesty in woman which causes her to shun man's gaze and veil her eyes, I hope never to see removed. It is the golden shield that God has given her. No union do I want to see between the sexes, but that of holy matrimony. Familiarity is dangerous. The women at the North who expect and demand that men shall be as pure as women, don't know what they are talking about. There is no excuse for the unfaithfulness of married men. But I did not expect to say so much.

Respectfully,

W. W. PARKER, M.D.

Colorado State Medical Society.

DENVER, COLO., May 11, 1894.

To the Editor:—As notice has, by some misunderstanding, appeared in the JOURNAL, that the Colorado State Medical Society would entertain the delegates to the AMERICAN MEDICAL ASSOCIATION on their way to San Francisco on May 30,

it is to be regretted that, the State Society not being in session at that time, and no committee having power to take any such action, the Society will be unable to give any such entertainment.

Members and officers of the Society residing in Denver will, however, be glad to meet members of the AMERICAN MEDICAL ASSOCIATION as they pass through Colorado, and the latter are again cordially invited to become the guests of the Colorado State Society during its session, June 19 to 21, on their return from the Coast.

Yours very truly,

J. N. HALL, Chairman Executive Committee,
Colorado State Medical Society.

ASSOCIATION NEWS.

The Association Train will leave Chicago Monday, May 28, via Santa Fe R. R., Rio Grande Western, and Southern Pacific, for San Francisco via Denver, Colorado Springs, Leadville, Manitou, Glenwood Springs, Salt Lake, Ogden, Truckee and Sacramento. Returning, after the meeting, the train will pass through Sacramento and Northern California to Portland; thence east by way of the Northern Pacific R. R. to St. Paul. C. M. & St. P. R. St. Paul to Chicago. A stop over at Yellowstone National Park for those who desire it has been arranged, and it has been understood that at several places on the journey there will be short stops. President Hibberd's party in a special car join the train at Chicago, and the St. Louis party are expected to join at Kansas City. From all points east and south, concentrating on this train should be effected at Chicago and St. Louis. For all information relating to this train, fares, etc., address J. M. Connell, 212 Clark st., Chicago, or any agent of Santa Fe line in other cities. Rates promised are the lowest excursion rates at time of departure.

This is the only route on which arrangements have been perfected by the Trustees.

Program for Section on State Medicine.—The Prevention of Diphtheria, from the standpoint of the Health Officer, U. O. B. Wingate, Milwaukee, Wis.

Diphtheria, Andrew W. Imrie, Detroit, Mich.

On the Principles of Sanitary Science, the Chief Obstacles to their Practical Application, and the most Efficient Means for the Removal of such Obstacles, N. S. Davis, Chicago, Ill.

A Study of Impure Air in the Causation of Inebriety, T. D. Crothers, Hartford, Conn.

State Medicine in the United States, What is it? P. C. Remondino, San Diego, Cal.

State Medicine, its Relation to Patent Medicine, Sam'l. P. Duffield, Detroit, Mich.

The Physician and State, Chas. E. Winslow, Albuquerque, N. M.

Leprosy, H. S. Orme, Los Angeles, Cal.

Restriction of Tuberculosis, J. H. Davison, Los Angeles, Cal.

Consumption and its Prevention, Winslow Anderson, San Francisco, Cal.

Cleanliness as the Chief Antiseptic, C. F. Ulrich, Wheeling, W. Va.

The Bath in Modern Medicine, Chas. H. Shepard, Brooklyn, N. Y.

Drinking Water, Hal C. Wyman, Detroit, Mich.

Transportation Companies as Disseminators of Contagion, S. S. Herrick, San Francisco, Cal.

Vaccination and Re-Vaccination, Ezra M. Hunt, Trenton, N. J.

To be announced, Walter Wyman, Surg.-Gen. M.H.S.

To be announced, J. H. Kellogg, Battle Creek, Mich.

To be announced, Lawrence Flick, Philadelphia, Pa.

To be announced, Jas. A. Steuart, Baltimore, Md.

To be announced, F. H. De Vaux, Valley City, N. D.

Section on Obstetrics and Diseases of Women.—Dr. Joseph Eastman, Chairman of the Section, will deliver the Annual Address. The following papers will be presented:

Treatment of Fibroid Tumors of the Uterus, Franklin H. Martin, Chicago, Ill.

The Pedicle in Abdominal Hysterectomy, A. H. Cordier, Kansas City, Mo.

Removal of Fibroid Tumors through the Abdomen, E. E. Montgomery, Philadelphia, Pa.

Placenta Prævia, Llewellyn Eliot, Washington, D. C.

The Influence of Gestation upon Chronic Diseases of the Kidney, T. Ridgeway Barker, Philadelphia, Pa.

Tetanus Puerperarum, Allison Maxwell, Indianapolis, Ind.

Some of the Uses of Strychnia in Obstetric Practice, John Milton Duff, Pittsburg, Pa.

Status of the Means to Banish the Pain in Parturition, William B. Dewees, Salina, Kan.

Symphiseotomy, with Case, W. Winterberg, San Francisco, Cal.

Recto-Vaginal Fistula, its Etiology and Surgical Treatment, Augustus P. Clarke, Cambridge, Mass.

Suspension of the Uterus in Extreme Anterior Displacements, H. R. Holmes, Portland, Oregon.

A Plea for Thorough Training in Obstetrics and General Medicine on Part of the Gynecologist, Henry Parker Newman, Chicago, Ill.

A Case of Didelphic Uterus, Unilateral Hematometra, Hemasalpinx and Hematocolpos, X. O. Werder, Pittsburg, Pa.

A Case of Gangrene of the Mammary Glands, J. Schneck, Mt. Carmel, Ill.

Emmett's Inside Operation, Joseph Price, Philadelphia, Pa.

What Causes Relate to the Unsatisfactory Results following the Removal of Diseased Uterine Appendages, Hugo O. Pantzer, Indianapolis, Ind.

Ovarian Pain, O. B. Will, Peoria, Ill.

SOCIETY NEWS.

New York State Medical Association.—The Fifth District Branch of the New York State Medical Association will hold its tenth annual meeting in Wurzler's Building, 315 Washington Street (near City Hall Square), Brooklyn, on Tuesday, May 22, 1894.

The morning session will be called to order at 11 A.M., and will be devoted to the President's Address, On the Prevention of the Disagreeable and Dangerous Symptoms produced by Ether as a General Anesthetic.

Biographical sketches of the late Dr. W. T. White, by John Shradly; Dr. John Young, by C. M. Kittredge; Dr. Wm. Govan, by I. D. LeRoy; Dr. M. K. Hogan, by Wm. O'Meagher; Dr. A. L. Carroll, by E. S. F. Arnold, J. W. S. Gouley, G. T. Harrison, C. A. Leale, A. Lukens, Stephen Smith, J. G. Truax, W. C. Walser.

A scientific paper on the Dietetic Treatment of Consumption, will be read by Dr. T. J. McGillicuddy.

The afternoon session will be called to order at 2 P.M., and will be devoted to the remaining scientific papers:

The Treatment of Chronic Oophoritis by Electricity, Edward Sanders. Discussion opened by L. G. Baldwin, of Brooklyn.

Report of a Case of Chronic Peritonitis with Intestinal Fistula. Celiotomy. Enterorrhaphy. Recovery, Frederick Holme Wiggin.

General Discussion of Vaccination. Opened by F. A. Jewett, S. E. Jelliffe and H. H. Morton, of Brooklyn.

The Nominating Committee will then make its report on members of the Executive Committee for the ensuing year.

Association of American Physicians.—The ninth annual meeting of the Association of American Physicians will be held in connection with the third Congress of American Physicians and Surgeons, at Washington, D. C., May 29, 30 and 31, and June 1.

President's Address, Reginald H. Fitz, Boston.

The Treatment of Certain Symptoms of Croupous Pneumonia, particularly in Adults, Beverly Robinson, New York.

A Treatment of Typhoid Fever, Samuel A. Fisk, Denver.

Six Cases of Traumatic Headache, C. F. Folsom, Boston.

Clinical Report of Two Cases of Raynaud's Disease, Frederick P. Henry, Philadelphia.

Dr. S. C. Martin's Researches on the Bacteria of Vaccinia, Harold C. Ernst, Boston

Morphology as a Factor in the Study of Disease, Opened with a paper by Harrison Allen, Professor of Compar-

tive Anatomy in the University of Pennsylvania, and discussed by Thomas Dwight, Professor of Anatomy in the Harvard Medical School, Dr. Frederic H. Gerrish, Professor of Anatomy in Bowdoin College, Dr. Frank Baker, Professor of Anatomy in the University of Georgetown, and Burt C. Wilder, Professor of Physiology, Comparative Anatomy and Zoölogy in Cornell University.

Modification, Temporary and Permanent, of Physiological Characters of Bacteria in Mixed Cultures, Theobald Smith, Washington.

The Effect of Various Metals on the Growth of Pathogenic Bacteria, Meade Bolton, Baltimore.

Note on the Observation of Malarial Organisms in Connection with Typhoid Fever, W. Gilman Thompson, New York.

Experiments in Artificial Melanosis, George Dock, Ann Arbor.

Stomatitis Neurotica, A. Jacobi, New York.

Tetány in America, J. P. Crozer Griffith, Philadelphia.

Sewer Gas, The Bacteriology, by Alexander C. Abbott, First Assistant in the Laboratory of Hygiene, University of Pennsylvania; As a Cause of Disease, by Abraham Jacobi, Professor of Diseases of Children in the College of Physicians and Surgeons in New York City.

The Distribution and Control of Leprosy in the United States: The Distribution. Opened with a paper by J. Nevins Hyde, Chicago, and discussed by Wm. C. Haraway, St. Louis, and James E. Graham, Toronto. The Prophylaxis and Treatment, opened with a paper by Jas. C. White, and discussed by George H. Fox, New York City, W. C. Wyman, U. S. M. H. Service, and Joseph D. Bryant, New York City.

Lead Palsy in Children, Wharton Sinkler, Philadelphia.

A Study of the Temperature in Cerebral Apoplexy, Charles L. Dana, New York.

The Mild Character and Diminished Prevalence of Syphilis and the Infrequency of Visceral Syphilis, John H. Musser, Philadelphia.

Some Remarks on the Significance of Albumin and Casts, especially in those past Middle Life, Frederick C. Shattuck, Boston.

Experimental Phthisis in the Rabbit with Formation of Cavities: A Demonstration, T. M. Prudden, New York.

A Report of the Ultimate Results obtained on Experimental Eye Tuberculosis by Tuberculin Treatment and Anti-Tubercular Inoculation, E. L. Trudeau, Saranac Lake.

Nephritis in its Surgical Aspects: Opened by a paper by Edward L. Keyes, of New York City, followed by a paper from George M. Sternberg, Surgeon-General U. S. Army, on the Bacteriology of Nephritis, and discussed by George Chismore, of San Francisco, Cal., L. Bolton Bangs, New York City, Francis S. Watson, Boston, Mass., and W. N. Wishard, of Indianapolis, Ind.

The Conservative Surgery of the Female Pelvic Organs. Papers will be read by Wm. M. Polk, of New York, and Wm. Goodell, of Philadelphia.

Address by the President of the Congress, Alfred L. Loomis, on the Influence of Animal Experimentation on Medical Science.

Some of the Chemical and Bacteriological Characteristics of Milk, Thomas M. Rotch, Boston.

The Chemical Products of the Anaerobic Putrefaction of Pancreatic and Hepatic Tissues, and their Effects upon the Tests for Morphia, Victor C. Vaughan, Ann Arbor

Gastro-Enteric Rheumatism, H. M. Lyman, Chicago.

A Case of Osteomalacia, George Dock, Ann Arbor.

A Case of Calculus Pyelitis with Invasion by the Bacillus Lactis Erogenes, J. H. Musser, Philadelphia.

The Surgery of the Accessory Sinuses of the Nose: To be discussed by J. Solis-Cohen, Philadelphia. F. I. Knight, Harvard, George M. Leferts, New York City, F. H. Bosworth, Dr. William C. Glasgow, of St. Louis, and E. Fletcher Ingals, of Chicago.

The Influence of Infectious Processes on the Nervous System: Pathology and Etiology, Jas. J. Putnam. The Relation to General Nervous Diseases, E. C. Seguin, of New York; the Relation to Mental Disease, by Charles K. Mills; the Therapeutics, by F. X. Dercum, of Philadelphia.

military reservation at Fort Pike for a hospital for lepers and contagious disease patients.

Quarantine on the Great Lakes.—Ohio, Indiana, Michigan, Wisconsin and Illinois, through the executive officers of their respective State Boards of Health, have adopted the following:

Resolved, That no vessel plying on the lakes should be allowed to enter any port within the boundaries of our respective States without having on board, subject to inspection, a bill of health, duly signed by an officer of the United States Marine-Hospital Service.

Yellow Fever Precautions.—A State disinfecting station has been ordered by the Florida State Board of Health to be established at Fernandina, Fla., similar to that at Mullet Key. Port physicians are on duty at Fernandina, Mayport, Key West, Punta Rossa, Punta Gordo, Port Tampa, Apalachicola and Pensacola, and strict inspection of all vessels is enforced. The Jacksonville Sanitary Association reports a balance of yellow fever funds in its treasury amounting to \$26,545.33, drawing 4 per cent. interest. It contributed \$2,000 to the relief funds of Brunswick, Ga., and other places last year.

"Membranous Croup" vs. Diphtheria. — Dr. H. M. Biggs, the bacteriologist of the New York City Board of Health, has been led, as a result of his recent examinations, to recommend that so-called membranous croup be included in the list of contagious diseases. In the bacteriologic examinations of 286 cases reported as "membranous croup," 229—or about 80 per cent—were proved to be true diphtheria by the existence of the Klebs-Löffler bacillus. Of the remaining 57 cases, 40, or only 14 per cent. of the total number, were clearly not true diphtheria, and 17, or 6 per cent., were doubtful.

Cholera in Europe.—It is not even "choleric" now in Lisbon, according to late cable dispatches; what was so reported at first and subsequently was pronounced by Medical Director Montaldo of Madrid, after a personal investigation, to be Asiatic cholera, it is now asserted, on the authority of the Austrian Consul-General at Lisbon and the Portuguese Minister at Washington, is only diarrhea and "absolutely dangerless." Meanwhile, from time to time, there continues to be received more or less definite reports of the westward extension of the disease from Russia and Turkey through Austria to the Iberian peninsula and to France.

Smallpox in Chicago.—Chicago continues to be the center of interest with respect to smallpox. Contrary to expectation the milder weather has caused no diminution in the number of new cases reported daily; there was an increase of 17.3 per cent. in the second, as compared with the first, week of May, and of 37.5 per cent. in these two weeks as compared with the month of April. The total number of cases reported between January 1 and May 14 is 1,559. The growth of the epidemic during this period is shown in the following figures—to which are added, for purposes of comparison, the figures for the corresponding period in the epidemic of 1881-83.

	1894.	1881.
Daily average of new cases in January	4.1	2.6
“ “ “ “ February	8.3	3.5
“ “ “ “ March	9.8	3.2
“ “ “ “ April	18.1	4.4
“ “ “ “ May	24.9	2.7

Percentage of increase or decrease:			
	1894.	1881.	
	Increase.	Increase.	Decrease.
February as to January	102.6	34.6	
March as to February	18.		8.5
April as to March	82.6	37.5	
May as to April	37.5		38.6

Increase of May over January, 1894, 507.3 per cent.
“ “ “ “ “ “ “ “ 1881, 4.6 “ “

As heretofore remarked, the result of this comparison is

PUBLIC HEALTH.

A Leper Hospital.—At the request of the Senators and Representatives from Louisiana, the Secretary of War has given New Orleans and the State the right to use the Government

not reassuring—especially in view of the fact that the epidemic of 1881-83 did not reach its height until January, 1882, when there were 1,038 cases, and did not finally die out until September, 1883, with a tale of 6,786 cases, 2,518 deaths, an actual money cost of \$940,948.80, reported and a constructive cost of \$5,528,122.66, exclusive of the aggregate of misery, suffering and loss of life. Chicago is now three times larger than then and can well afford to spend whatever sum is necessary to prevent a repetition of that experience. The municipal authorities have at last awakened to a comprehension of the gravity of the situation and have given the Health Commissioner, Dr. A. R. Reynolds, plenary authority and resources, hitherto wanting. On the 13th a proclamation was issued ordering the vaccination of "all persons within ten days from this date;" there has been a large increase of the vaccinating corps and of the quarantine police force; hospital accommodations have been enlarged, so that every case of smallpox may be removed at once; the "sweat shop" district has been put under the direct supervision of the State Board of Health; and the U. S. Marine-Hospital Service of the port, under charge of Dr. Hamilton, inspects every vessel before it leaves the harbor.

The following is the form of the bill of health furnished:

BILL OF HEALTH.—Marine-Hospital Service, District of the Great Lakes, Surgeon's Office, Port of Chicago, Illinois.—189.

To Whom it May Concern: This is to certify that I have this day carefully inspected the _____ of _____ whereof Captain _____ is Master, and have inspected the passengers and crew. The crew have been vaccinated.

I further certify that the vessel and its cargo are in good sanitary condition, and that none of the passengers or crew are suffering from any contagious disease.

JOHN B. HAMILTON, Surgeon U. S. M.-H. S.

By _____ Surgeon U. S. M.-H. S., Inspector

No. of crew _____ No. of passengers _____ No. of officers _____

BOOK NOTICES.

Essentials of Practice of Pharmacy. Arranged in the form of questions and answers, prepared specially for pharmaceutical students. Second edition, revised by Lucy C. Sayre, Ph.G., Professor of Pharmacy and Materia Medica, University of Kansas. Philadelphia: W. P. Saunders, 1894. Price \$1.00. An excellent book of its class.

Manual of Practical Obstetrics. By EDWARD P. DAVIS, A.M. M.D., Professor of Obstetrics and Diseases of Infancy in the Philadelphia Polyclinic, etc. Second edition, revised and enlarged with 134 illustrations. Philadelphia: P. Blakiston, Son & Company, 1894. Chicago: E. H. Colgrove & Co. Price \$2.50.

When the first edition of this book appeared we commended it as being a concise summary of obstetrical knowledge. The illustrations are good and the teachings fully abreast of the time. We note that the author lays less stress on antiseptic treatment of the cord than modern teachings would seem to indicate. With the exception of this slight omission there is nothing to criticize.

An Aid to Materia Medica. By ROBERT H. M. DAWBARN, M.D. Professor of Operative Surgery and Surgical Anatomy, New York Polyclinic. Third edition, revised and enlarged by Woolsey Hopkins, M.D. New York: G. P. Putnam & Sons, 1894.

The preface to this book states that "this revision of the book was made necessary by the changes in the last United States Pharmacopœia. The book aims to present in a brief space in tabular form all the drugs and preparations recognized by the Pharmacopœia. It is interleaved for the convenience of the physician. It contains the doses and the decimal system, as well as the old English form, with samples of prescription writing in the metric system. The little book will be found extremely useful.

Seventh Annual Report of the State Board of Health and Vital Statistics of the Commonwealth of Pennsylvania, 1891. Harrisburg. Paper, pp. 1,044. The same, 1892, pp. 785.

The work of our State Boards of Health is an index of the general intelligence of the community. Great praise is due to the manifest zeal and wisdom in action of this Board, yet we can but feel that the thousands of intelligent citizens of the great State of Pennsylvania, and especially the members of the medical profession, have failed in their duty to the State by not insisting upon an appropriation that would have a moderate relation to the needs of the community. As it is, any emergency finds the Board wellnigh helpless.

We find much of present interest and of permanent value in these pages. Every practitioner should regard himself as an assistant of the Board of Health, and nowhere so well as in these records can he read the lessons taught by loss of life due to lack of cleanliness and of care for infectious disease.

The reports of proceedings of the American Public Health Association, of the Section on State Medicine of the AMERICAN MEDICAL ASSOCIATION, and of the Pennsylvania State Sanitary Convention, and a Compendium of the laws of Pennsylvania relating to Public Health and Safety find a place in these volumes, and enhance their permanent value.

The first volume contains the report of the Secretary of the Board and minutes of meetings, and twelve appendices comprising reports of standing committees, of inspections, annual reports of cities, reports of conferences and conventions, articles on quarantine, disinfection, epidemics and special sources of disease, circulars issued by the Board, a compendium of laws relating to public health and safety, etc.

The second volume contains the report of the Secretary for 1892, minutes of meetings and appendices including reports of committees, of inspections, articles on quarantine, disinfection, epidemics and special sources of disease, reports of conferences and conventions, circulars issued by the Board, annual reports of cities, etc.

NECROLOGY.

BEN. DAVIS, M.D., New Holland, Washington, April 25.—M. G. Osborn, M.D., Delmar, Iowa, April 23.—T. T. Dorwin, M.D., Decatur, Ind. He had been retired from practice for some time and for the last ten years had been President of the Decatur National Bank.—M. L. Malory, M.D., of Rochester, N. Y., April 28.—W. H. Carruthers, M.D., of Northfield, Minn., May 1.

WM. V. KEATING, M.D., died suddenly at St. Joseph's Hospital, Philadelphia, immediately after making a brief address to the graduating class of trained nurses. At a special meeting of the Hospital Staff, April 20, the following action was taken:

It was with peculiarly painful, tender and reverent feeling that the Medical Staff of St. Joseph's Hospital assembled to pass resolutions in memory of their most distinguished colleague and beloved President, Dr. William V. Keating, who for nearly fifty years has faithfully served the Hospital, with no recompense except the approval of his own conscience and the gratitude of those whose hearts were in the service of the same Divine Master.

Dr. Keating was interested in the Hospital even prior to its foundation, securing funds by personal effort and his own generosity, and since by his professional eminence aiding, and always giving unsparingly of his time, effort and wisdom.

To him the Sisters of the Hospital went freely, always sure of wise counsel in perplexity and sympathetic assistance in every effort to advance the Hospital in the efficiency of its charitable work. He was alive to every professional advance, and in singleness of heart he labored to place those institutions with which he was connected always abreast of the times.

That his ripe wisdom and his last strength and hour should be expended in the service of that institution to which he gave freely his youthful vigor, has in it an impressive example of duty performed to the end.

Dr. Keating died shortly after addressing a few encouraging words to the class of nurses in training, making his remarks brief because of the illness he felt suddenly overwhelming him.

To the gentle Sisters was given the opportunity to render the last services to their old friend and benefactor of years—moments pitifully brief, yet not without their consolation.

The Staff passed the following resolutions:

Resolved, That in the death of Dr. William V. Keating the medical profession has lost a man of most distinguished ability, who has reflected honor upon the profession alike by his attainments, his spotless integrity and loftiness of character.

Resolved, That St. Joseph's Hospital has lost a friend whose labor and far reaching influence will long be felt.

Resolved, That we, as a Staff, have lost a true friend, whose example of professional culture, high bred and delightful courtesy, untiring devotion to duty, kindness and purity of heart we will hold in reverent memory.

Resolved, That the Sisters of Charity and all friends of the sick poor have lost an efficient and sympathizing helper.

Resolved, That we publish and communicate to the family of the deceased the sentiment and resolutions of this meeting.

MISCELLANY.

Change of Address.—DR. W. L. SCIENCK, of Kansas, to New Castle, Colo. Dr. E. J. Doering to Hotel Metropole, Chicago.

Gladstonian Nerve.—The anecdotes regarding the Grand Old Man are beginning to pile up, now, in suitable commemoration of his marvelous public career that is now drawing to a close. Mr. Smalley, the well-known correspondent of the *New York Tribune*, stands sponsor for the following medical narrative of a man who never knew what fear meant:

"Mr. Gladstone is now staying at Biarritz. The day before he left he called on Dr. Granger, who has succeeded Sir Andrew Clark as the Premier's physician, and who is also an oculist. He told Mr. Gladstone that a cataract had obliterated the sight of one eye and that another cataract had begun to form on the other. The Prime Minister reflected a moment, and said: 'I wish you to remove the cataract at once.' The physician replied that it was not yet far enough advanced for an operation. 'You do not understand me,' answered the Premier; 'it is the old cataract I wish removed. If that is out of the way, I shall still have one good eye when the new cataract impairs the sight of the other.' As the physician still hesitated, Mr. Gladstone continued: 'You still seem not to understand me. I want you to perform the operation here and now, while I am sitting in this chair.' 'But it might not be successful,' said Dr. Granger. 'That is a risk I accept,' was the instant reply."

Ambroise Paré Accused of Poisoning his King.—Lately there has appeared in Paris an admirable medico-historical sketch of the diseases and death of Francis II, of France, by Dr. Albert Potiquet. The King was sickly from infancy, but he was sufficiently robust to pass successfully through an attack of variola when four or five years of age. His death was probably caused by the extension of mid-ear trouble to the brain. Among his surgical attendants was Ambroise Paré, who was present when a consultation was held for the purpose of determining the question of trephining the King's cranium. The operation was adjudged to be unnecessary.

Very soon after the King's demise certain partisans began to insinuate that that event had been brought about by poison. A writer in the *Lancet-Clinic* gives the following statement of the way in which the name of the great Paré came to be brought into the matter:

"Writers more inspired by passion than by love of truth sought to accredit the death to poisoning. They went so far as to affirm that Ambroise Paré, the illustrious and irreproachable surgeon, was the principal factor in the monstrous crime. But it was not necessary to seek so far for an explanation when we read Dr. Potiquet's work, for we find that Francis II not only died poisoned but lived poisoned; he had septic fever, and the pus, finding no exit without, naturally went in. The death was only the epilogue of this suppuration, left to itself, and not let out. As if he feared a doubt might remain in some minds, Dr. Potiquet asked if any other diagnosis than that of *adenoid vegetations* can be found. Had it been from syphilis or fetid rhinitis these affections would have been revealed by symptoms that could not have passed unperceived. Could the malady have arisen from nasal polypi? A polypus of the nose is apt to project and be perceptible at the exterior, and is, besides, a

rare thing in an infant. Adenoid vegetations, on the contrary, are more frequent in the first childhood than even later. It is, then, highly probable that at this distance we can affirm with certainty that Francis II died of meningo-encephalitis, consecutive to a suppurating inflammation of the left ear connected with adenoid vegetations. This diagnosis, disengaged from all contiguities, reposes on a rigorous scientific basis. Moreover, in deficiency of the truth, it presents all the attributes of likelihood. We should, then, be easily dissatisfied were we not to agree with Dr. Potiquet."

An Epileptic Colony for New York.—The Legislature of New York has passed, and the Governor signed the bill establishing a colony for epileptics in that State. The colony is named after the late Oscar Craig, President for some years of the State Board of Charities. The bill provides for the purchase of a tract of 1,875 acres of beautiful land in the Genesee Valley, near Mount Morris, in Livingston County. This tract is all in one piece, well watered by brooks, and consisting of fine fields, woodland and orchards, and already provided with picturesquely-grouped buildings to the number of thirty-five. It has been a colony of the Christian Believers for twenty or thirty years, and is, therefore, perfectly adapted to its new use.

The law requires that all of the buildings put up should be on the village plan. A board of five managers is provided for, and these have already been appointed.

The Governor appointed as the Board of Managers: Dr. Frederick Peterson, of New York; Mrs. C. F. Wadsworth, of Genesee; Geo. M. Shull, of Mount Morris; Dr. Chas. E. Jones, of Albany, and W. H. Cuddeback, of Buffalo.

An important provision in the bill is that the Managers may accept any bequests of persons interested in the welfare of epileptics, and it is believed that many charitable wealthy people will build cottages upon the splendid sites on the tract to bear their names and exist as lasting memorials to their desire to serve humanity in this wise.

A medical superintendent, steward, matron, pathologist, nurses, school-teachers, teachers of various industries and arts, and so on, are to be appointed as needed; but the colony will not be ready probably to receive patients before the autumn of 1895.

It is thought that the colony will ultimately number 1,500 to 2,000 members. As soon as possible the 600 epileptics in the county almshouses will be taken in charge. Later, private patients will be received at prices corresponding to the accommodations asked for. It is sure to become self-supporting in the course of time, and to grow into an industrial and agricultural village that will more than rival the similar and famous colony at Bielefeld, Germany, upon which this is, to a certain extent, modeled.

At their organization, in Albany, on May 3, the Board of Managers made Dr. Frederick Peterson, of New York, President, and George M. Shull, of Mount Morris, N. Y., Secretary of the Board.

Washington Notes.

MISS ROBERTA M. WEST, Superintendent of the Emergency Hospital, formerly of the Philadelphia Hospital, has been appointed editor of the "American Text-book of Nursing."

THE NEW LAW in the District of Columbia requires druggists to sell whisky or other liquors only on physicians' prescriptions. Forgeries for obtaining drinks are becoming very frequent.

COLUMBIA MEDICAL COLLEGE.—The commencement exercises of the Columbia Medical College followed by Faculty dinner took place May 3. General prize of \$50 awarded to Gottlieb Werhle; clinical medicine to W. S. Washburn; clinical surgery, Miss C. Kiefe.

ASSOCIATION OF MILITARY SURGEONS.—The fourth annual meeting of the Association of Military Surgeons of the United States was held May 3 (proceedings published in last week's JOURNAL), and was a grand success. To Dr. George Henderson, of Washington, Chairman of Committee of Arrangements, and Dr. Henry A. Robbins, of Washington, Chairman Committee of Finance, is due this grand success. Transactions are to be printed and sent to members. The addresses by President Cleveland, Commissioner Ross and Dr. Senn were the features of the first day's session.

THE COXEY CAMP still appears to be exempt from the sanitary laws here in vogue. The manure is being turned up and removed and the underlying ground saturated therefrom is being covered with ashes. No disinfectives have been used so far. Neighboring vacant houses and the ground in the camp enclosure will not be much longer used for privy purposes as a permit has been taken out to make sewer connections. Alternations of rain and hot sun have the usual effect upon the health of the men, who wear the same clothing day and night and sleep on straw, wet and soiled, on the ground. There is no water in the enclosure and the supply, depending on the manual labor of the men, is naturally very limited. The bath is unknown. The burning and scalding of clothes together with incessant scratching of the body is very suggestive. The men are very quiet and well disposed, being of a very low intellectual capacity, and appear to be entirely satisfied with their lot (wet straw bedding, bad food and bad emanations). Speeches at night by the officers of the army serve to attract a large number of persons to the unhealthy enclosure and surroundings. There is also a constant throng of visitors during the day. The valuable horses have been removed to healthy quarters though the work horses still remain. The men were entirely wet by the severe rain last night and had to stand or walk about until this morning. The hardships from this pest hole can not be imagined, and ordinary charity should suggest their removal to some healthy place. Many of the men are sick and complaining, and there is every indication of an epidemic which may extend, through the visitors, to the entire city.

Philadelphia Notes.

DR. WM. H. PARISH has been appointed Medical Director of St. Agnes Hospital, in place of Dr. Wm. Keating recently deceased.

THE CITY BOARD OF HEALTH has begun a house-to-house inspection in order to prepare in time for a possible invasion of cholera next summer. Circulars of information regarding tuberculosis have been printed for free distribution, in which especial attention is directed to the infectious character of the disease, and the importance of destroying or disinfecting the sputa. Although there are only four or five cases of smallpox in the whole city, the Board has ordered all the school children to be vaccinated.

THE SEMI-ANNUAL CONVERSATIONAL MEETING of the Philadelphia Pathological Society was held on the 26th ult., when Dr. Simon Flexner, Associate in Pathology in Johns Hopkins University, delivered an address entitled: "An Experimental Study of the Nature and Action of certain so-called Tox-albumins," which was most interesting and instructive. After the meeting a reception was tendered Dr. Flexner at the University Club.

THE SECTION ON GENERAL SURGERY of the College of Physicians had a very interesting program at its meeting on the 11th inst. Dr. J. Wm. White read a paper on "Appendicitis," the surgical discussion being opened by Dr. Robert F. Weir, of New York, the medical side being opened by Dr. William Pepper. A general debate followed. Dr. Joseph Leidy reported two cases of appendicitis complicated by glycosuria, and Dr. Thomas G. Morton also reported a case of appendicitis with glycosuria. "Gunshot Wounds of the Brain" was presented by Dr. Jos. Hearn and two cases reported, illustrating treatment. Dr. Thomas G. Morton presented an improved aseptic ward carriage, for hospital use.

THE ATTENTION of the Board of Education having been directed to the possible spread of contagious diseases among the younger school children from the clay used in modeling in kindergarten work, the subject was referred to the Committee on Hygiene, of the Board. This Committee has just reported that they had been unable to discover an instance of the communication of skin diseases or infection in the schools of this district; that clay itself is antiseptic, and that with ordinary care the same clay can be used over and over again, almost indefinitely, without any risk of communicating infectious disease. They insist, however, as a matter of cleanliness, that children shall be forbidden to put the clay to their mouths or use spittle to moisten it; freshly boiled water only should be used for this purpose.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from May 5, 1894, to May 11, 1894.

Major William E. WATERS, Surgeon U. S. A., is granted leave of absence for two months, to take effect on or about July 1, 1894.
 Capt. WILLIAM G. SPENCER, Asst. Surgeon, will report in person to the President of the Army Retiring Board at Omaha, Neb., at such time as he may designate, for examination by the Board.
 First Lieut. JOHN S. KULP, Asst. Surgeon, is relieved from duty at Ft. Sheridan, Ill., and ordered to Ft. Spokane, Washington, for duty.
 First Lieut. GEORGE M. WELLS, Asst. Surgeon, will proceed to Ft. Bowie, A. T., and report for temporary duty, not later than the 15th instant, during the absence on leave of Capt. JEFFERSON D. POINDEXTER, Asst. Surgeon.
 Major JOSEPH R. GIBSON, Surgeon, is granted leave of absence for twenty days, to take effect on being relieved from duty at David's Island, N. Y.
 First Lieut. BENJAMIN L. TEN EYCK, now on temporary duty at Ft. Clark, Texas, is assigned to duty at that post.
 First Lieut. WILLIAM F. LIPPITT, JR., Asst. Surgeon, is relieved from duty at Camp Eagle Pass, Texas, and ordered to Ft. Leavenworth, Kan., for duty.
 Captains GEORGE H. TORNEY and LOUIS W. CRAMPTON, Asst. Surgeons, will report in person to Col. CHARLES H. ALDEN, Asst. Surgeon-General, President of the examining board appointed to meet at the office of the Surgeon-General U. S. A., on Tuesday, May 8, 1894, at such time as they may be required by the board, for examination as to their fitness for promotion.
 First Lieut. HARLAN E. MC VAY, Asst. Surgeon, par. 2, S. O. 86, A. G. O., April 12, 1894, assigning him to station at Angel Island, Cal., is revoked. He will be relieved from duty at Ft. Huachuca, Ariz., and will report for duty at the Presidio of San Francisco, Cal., relieving First Lieut. CHARLES WILCOX, Asst. Surgeon, who, on being thus relieved, will report for duty at Angel Island, Cal.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending May 12, 1894.

Surgeon R. A. MARMON, hold himself to relieve Medical Inspector G. A. BRIGHT, on the U. S. S. "Newark."
 Surgeon G. E. H. HARMON, to the U. S. S. "Monongahela," June 15, 1894.
 Asst. Surgeon W. M. BARNUM, to the U. S. S. "Monongahela," June 1, 1894.
 Surgeon J. M. STEELE, from the U. S. S. "St. Louis," and to League Island Navy Yard.
 Surgeon H. G. BEYER, from Naval Academy, and to the "Bancroft."
 P. A. Surgeon CLEMENT BIDDLE, from League Island Navy Yard, and to Marine Rendezvous, Philadelphia, Pa.
 Asst. Surgeon J. F. LEYS, granted one month's leave, with permission to go abroad.

LETTERS RECEIVED.

ORIGINAL ARTICLES.

PNEUMONIC FEVER—ITS SYMPTOMATOLOGY.

BY EDWARD F. WELLS, M.D.

CHICAGO.

SKIN.

The skin, in ordinary cases, is dry and hot—often pungently so—until the exudative stage is completed, whereupon a gentle perspiration appears. When sweating occurs it is usually first noticeable upon the head and parts of the body which are warmly covered, and is most abundant at night.¹ In weakly and anemic patients the perspiration usually comes on earlier than in others.² The appearance of moderate sweating after the height of the fever has been attained is generally followed by considerable relief to some of the most distressing symptoms and is of good import.³

Sturges⁴ has never been able to satisfy himself that sweating was either of good or evil augury. Dietl⁵ was of the opinion that no relief was afforded by early perspiration or by those induced by sudorifics, but in this view I can not coincide.

It is true that some of the most severe cases pass on to recovery with no indication of moisture of the skin, and that most of the fatal cases have sweated profusely, yet I think that the almost universal experience of the profession confirms the opinion that moderate perspiration is welcomed by both patient and physician. Some cases are remarkable for the excessive diaphoresis attending them. This usually denotes a dangerous case, and may be in itself an element of peril.

A very common picture of the latter end of a fatal case is as follows: There is dyspnea, cough without expectoration, tracheal râles, profound prostration, a weak and rapid pulse, coldness of the surface and extremities, blueness of the nails and a cyanosed skin from which a cold and clammy sweat is literally streaming. Such perspirations were noticed in the Plymouth⁶ and other epidemics.

Sudamina may appear⁷ in connection with profuse sweating. They are scattered over the entire surface, but are most abundant on the trunk. They are not peculiar to pneumonic fever.⁸

Other exceptions, *e. g.*, erythema,⁹ vibices,¹⁰ petechia,¹¹ purpura,¹² pustules, abscesses,¹³ erysipelas,¹⁴ etc., have also been observed.¹⁵ Rose spots resembling those of typhoid fever are occasionally encountered.¹⁶

In Andral's thirty-seventh case¹⁷ there was "an eruption of small military, transparent vesicles, surmounting a very small red patch, which was succeeded in three days by desquamation. The eruption covered the chest and abdomen and appeared on the twelfth day." In the Cincinnati epidemic of 1874 an eruption resembling lichen—with papules of a dull red color but without pruritis—was observed in many cases.¹⁸

Petechia are harbingers of death.¹⁹

When pneumonic fever complicates any of the acute exanthemata, the cutaneous eruption some-

times disappears upon the advent of the pulmonary symptoms.²⁰

An herpetic eruption frequently appears upon the lips and borders of the nostrils, and occasionally upon the chin, about the eyes,²¹ ears, anus, genitalia²² and other parts of the surface. The vesicles²³ may, rarely, be seen in the prodromal stage,²⁴ but usually in from two to five days after the beginning of the attack. It has been stated²⁵ that the eruption is invariably preceded by rigor, but this has not been my experience, although in one of my cases successive crops of vesicles followed recurrent chills. In the case referred to there was no indication of a malarial taint, although I believe herpes is oftener encountered in pneumonic patients who are the subjects of malarial infection. It has been supposed that herpes was due to a disordered state of the blood,²⁶ but I think it quite clear that the nervous system is primarily at fault.²⁷

Herpes was present in 43 per cent. of Bleuler's²⁸ cases; in 40 per cent. of Drasch's²⁹ cases; in 13 per cent. of Folkmann's³⁰ cases; in 43 per cent. of Geisler's³¹ 421 cases; in 36 of 220 cases reported by Hawkins^{31x}; in 20 per cent. of Hermann's³² 40 cases; in 34 per cent. of Rall's³³ cases; in all of Kissel's³⁴ cases in the Oberlahnstein epidemic of 1847; in 13 per cent. of Lebert's³⁵ cases; in 20 per cent. of Scheef's³⁶ 44 cases; in 18 per cent. of Speck's³⁷ 50 cases; in 29 per cent. of Schapira's³⁸ 173 cases; in 20 per cent. of Stort's³⁹ 286 cases; in 7 per cent. of Townsend's⁴⁰ cases; in 47 per cent. of Waller's⁴¹ 81 cases; in 50 per cent. of Wunderlich's⁴² 50 cases; in 50 per cent. of Ziemssen's⁴³ cases, and in 26 per cent. of my 498 cases.

The appearance of herpes is of good import,⁴⁴ although some consider it of little or no prognostic value.⁴⁵

Herpes zoster occasionally occurs in connection with pneumonic fever.⁴⁶

This occurred in three of my cases. One of these presents some unusual features: A farmer, aged 74, the subject of subacute rheumatism and chronic bronchitis, suffered for a long time, in 1881, with lassitude and widely distributed pains in the muscles, bones, joints, stomach, etc., terminating in an abundant eruption of herpetic vesicles at the base of the chest on the left side, with relief to all his other symptoms. The eruption disappeared after a few weeks, leaving whitish spots of the size of a split pea and resembling scars following a superficial burn. A year later there was a recurrence of the herpes zoster in the same locality, with similar but less severe prodromata. In this instance instead of obtaining relief upon the appearance of the eruption, he suffered an attack of pneumonic fever, locally affecting the base of the left lung. There was severe pain, elevation of temperature, an acceleration of pulse and respiration, cough, expectoration of characteristic sputa, etc. There was dullness on percussion and auscultation revealed fine crackling, tubular breathing and moist râles. There was also present considerable cardiac irritability due to a moderate amount of aortic stenosis. Recovery ensued in due time, but similar attacks occurred in December, 1883, and February and August, 1884.

Bedsore on the sacrum may form in this disease,⁴⁷ but they must be very rare. They appeared in none of my cases.

A male, aged 24 was admitted into the U. S. Marine-Hospital, Cincinnati, March 6, 1889, with well-marked pneumonic

fever, and died five days later. Patient stated that he had felt perfectly well until the day before admission, when he had a severe chill. This was followed by nausea, headache, pain in the chest and limbs and cough. The day preceding death a large bedsores developed over the sacrum. Necropsy revealed hepatization of entire right lung.

Furunculosis has been noticed in isolated cases⁴⁹ and as a feature of some epidemics.⁵⁰

In pneumonic fever the odor exhaled by the patient presents nothing peculiar except in typhoid⁵¹ or fatal cases. So long ago as 1850, Skoda⁵² was wont to point out a peculiar odor—an *odor mortis*—as a sure precursor of death in his pneumonic patients. If this smell of death is of the same character as that referred to by Isham⁵³ as having been frequently noticed by himself since 1863, it is of a moschiferous nature, very peculiar, and having been once experienced is ever afterwards easily recognizable.⁵⁴ An odor of this kind I have encountered in a number of cases.

The peculiar and disagreeable odor noticed by Copland⁵⁵ in disease of the suprarenal capsules, the ammoniacal odor noticed by Badgley⁵⁶ and Drake⁵⁷ as emanating from emigrant fever patients, and that observed by Thompson⁵⁸ in phthisical patients are probably of different natures.

The color of the skin varies with the stage and character of the disease and constitutional peculiarities of the patient. In the early stages, in the plethoric, well nourished and thin-skinned it will be brightly flushed,⁵⁹ while in the pale, cachectic, thick and dark-skinned, and at a later stage of the disease, it will be pale and sallow.⁶⁰ At a late stage of the disease in grave and fatal cases the color of the skin often resembles the pale-yellowishness of carcinoma.⁶¹ An ashen⁶² or leaden hue is of very bad augury, patients usually surviving its appearance only a few hours, or at most one or two days.

A flushing or circumscribed redness of one or both cheeks is a very marked and a very common symptom.⁶³ The redness is usually of a brighter hue than that of the dusky cheeks of typhoid fever, although this distinction may not apply to the very worst forms of pneumonic fever. It is not so bright as the hectic flush of phthisis. Its margins are generally—not always—more sharply defined than are those of the typhoidal duskiness. It was formerly supposed that this redness of the cheeks, as well as that of the hand sometimes noticed in this disease, was always of the same side as the affected lung.⁶⁴ This is, however, by no means always the case. In a considerable number of cases in which I particularly observed this symptom it was noted that the flushed cheek was usually the one most applied to the pillow, and I believe that local pressure often locates the redness. The flushing is often migratory,⁶⁵ passing from one cheek to the other, and often appearing on the chin. It usually comes on early and may even precede the other symptoms.

Jaccoud⁶⁶ in his own person experienced a local flush on one cheek—which happened to be on the side opposite the ensuing pneumonic inflammation—twenty-four hours before the initial chill and whilst in apparent health. He has noticed the same phenomenon in five other cases.

The redness of the cheeks is due to a localized dilatation of the capillaries.

Mann⁶⁷ noticed as a common symptom in the New England epidemic of 1815 "a remarkable pink-colored suffusion over the whole face, distinct from the usual febrile redness of the cheeks—the face becoming, at the same time, puffed and bloated." This appearance was most conspicuous in individuals of a light complexion, and in some instances it was also extended to the body.

During an attack of pneumonic fever, nutrition is interfered with and the measure of this is very graphically portrayed in the depression in the nails and constriction in the hairs grown during the febrile period. Owing to the short duration of this period the phenomena referred to are less marked than in typhoid fever, yet they are distinctly noticeable. The depression in the nails is most marked in those of the thumbs. It is from one-twentieth to one-tenth of an inch broad, with an abrupt declivity at the distal margin, but rising gradually out of the depression to the full thickness of the nail on the proximal side. It becomes visible in about a month after the beginning of the illness, is thrust gradually forward as the nail grows and disappears in about five months.⁶⁸ The constriction of the hairs can only be thoroughly appreciated by a microscopic examination.

NUTRITION.

From the inception of the disease to the close of the attack there is a constant preponderance of waste over repair, with, consequently a steady loss of weight until about the end of the first week of convalescence. The loss of weight ranges from three to twenty-four ounces daily, on an average, according to the age and size of the patient.⁶⁹ The ordinary weight is rapidly regained during convalescence and it not infrequently increases to much above the former standard of health.⁷⁰

PROSTRATION.

The degree of prostration is variable but it is always considerable and often great. The patient is almost always confined to his bed, although in some cases he may only be compelled to keep his room, and in yet other and rarer cases he may even walk about. Although usually confined to his bed, yet the patient can as a rule, arise to evacuate his bowels and bladder, and can sit up in bed to eat and drink. In some exceptional cases, however, he may be so weak as to be unable to raise his hand from the bed or to speak aloud, while in other, and even graver cases, prostration may be so slight as to attract but little notice. The degree of prostration is usually a correct measure of the gravity of the general disease, but bears no relation to the extent and character of the local lesions.

As an illustration of the slight weakness which occasionally attends severe or even fatal cases I may instance the case of a farmer, aged 33, whom I saw March 28, 1877. He had already been ill nine days, and the entire left lung was consolidated. The pulse was 140, respirations 60, temperature 106, face dusky, lips and tongue dry, teeth covered with sordes, urine retained and skin streaming with perspiration. His mind was perfectly clear. He was evidently moribund, yet, upon my entering his chamber he arose from the chair upon which he was sitting and, without aid, walked across the room—showing no indication of any great muscular weakness or that he was to die within a few hours, as was his fate.

The same fact was very forcibly impressed upon my mind by the case of an Irish ditcher who came to my office in 1874, complaining of an oppression of the chest and an inability to continue his work because of shortness of breath. His entire right lung was hepatized, yet he was not confined to his bed, had come to town a distance of three miles and had even essayed to work. He recovered promptly.⁷¹

On the contrary, the muscular weakness may be of the most pronounced character, with but a mild fever and slight local affection.

In the winter of 1878 I was called to see a large and very powerful man, 30 years of age, sick with pneumonic fever. He was most profoundly prostrated and barely escaped with his life, yet the fever was insignificant and a most searching

examination revealed the presence of only a trifling consolidation at the base of the left lung.

With convalescence, prostration usually gives place to rapidly returning strength, although the patient usually remains weak and easily exhausted for a long time.⁷²

Muscular tremor sometimes occurs irrespective of previous addiction of the patient to the excessive use of alcohol, and when it appears it should be viewed with grave apprehensions. Incontinence of feces and retention of urine are not infrequently associated with profound prostration.

Subsultus tendinum is occasionally,⁷³ but rarely,⁷⁴ met with in this disease. I have encountered it in three fatal cases.⁷⁵ In these it was not so clearly marked as is usual in typhoid fever, yet it was perfectly distinct.

PHYSIOGNOMY.

Pneumonic fever is sometimes quite clearly portrayed in the patient's features and attitude, although not so frequently or unequivocally as in typhoid fever, obstructive heart disease, chronic Bright's disease, etc. Nevertheless in a certain proportion of cases the aspect is sufficiently characteristic to be of diagnostic importance.⁷⁶

The face is flushed,⁷⁷ the lips dry and parched and the expression fixed and anxious.⁷⁸ Respiration is quick, catching and restrained and the patient speaks in short and broken sentences.⁷⁹ At the first view the beholder is impressed with the fact that he is in the presence of one who is laboring under a very grave disease which affects every fiber of his body.

As convalescence approaches the expression becomes suddenly and wonderfully changed. The patient breathes easier, his complaints cease, his mind and actions are quickened, the anxious expression vanishes and becomes restful, he experiences a sensation of relief which is mirrored in his face, he rejoices in a new lease of life and congratulates himself upon his escape from a great and imminent danger.

The positions assumed by the patient while lying in bed are so various as to defy description. Very often he can not lie upon the affected side because of the pain produced by the pressure, yet he as often lies upon this side⁸⁰ in order that the dyspnea may be relieved by free expansion of the sound side. Again, and this is most common, he is unable to lie upon either side and must maintain the dorsal position. He often lies upon the back, inclined to one or the other side. Some evince a propensity for slipping toward the foot of the bed, and when replaced are soon found to be again slipping down. This symptom is of evil import. As first pointed out by Aretæus,⁸¹ some patients can not assume the recumbent position,⁸² and must be propped up in bed or sit in a chair.⁸³ When the malady has nearly pursued its course an ability to lie upon either side, or a realization of a slipping down in bed, or from off the pillow, is an indication—often one of the earliest—of improvement.

Children sometimes assume a "gun-hammer" position,⁸⁴ with the face turned from the light or persons about the couch,⁸⁵ and evince a strong desire to be let alone.

TERMINATIONS.

Pneumonic fever ends in either recovery, invalidism or death. When the issue is successful the acute manifestations of the disease are either sud-

denly or gradually ended—termination by *crisis* or by *lysis*.

CRISIS.

Ordinarily pneumonic fever terminates by crisis, as has been the observation of physicians from the earliest days of medicine.⁸⁶ Whether or no crisis will be the termination may depend upon a variety of circumstances, *e. g.*, the extent and nature of the local lesions, amount and consistence of the pleuritic effusion, the recuperative powers of the patient and the character of the epidemic influences. If the local morbid action does not spread after the first brunt of the attack, all portions of the exudate will be ready for softening and removal at about the same time and crisis will be the most probable termination.

The physical signs of beginning resolution and crisis do not always run parallel. The former generally first appear in from twenty-four to forty-eight hours after crisis.⁸⁷

Of 192 cases analyzed by Grisolle,⁸⁸ crisis antedated the stethoscopic signs by one or several days in 72; in 92 they were coeval and in 26 the auscultatory changes first appeared.

The shorter the duration of the attack the more certain it is that crisis will be the termination. Crisis is rare in cases continuing longer than nine days⁸⁹ and is uncommon after seven days.

Crisis may be marked by the occurrence of peculiar phenomena, *e. g.*, profuse perspiration, diarrhea, copious discharge of urine, epistaxis, collapse, hepatic eruptions, profound and prolonged sleep, etc.⁹⁰ The duration of crisis varies from one to several hours, as shown in the following table:⁹¹

TABLE VII.—SHOWING DURATION OF CRISIS.

	Bleuler.	Thomas.	Kocher.	Author.
0 to 6 hours	25.3%	1.9%	14.2%	7.8%
6 to 12 "	21.6%	13.7%	34.6%	25.2%
12 to 24 "	29.4%	37.2%	30.3%	35.0%
24 to 36 "	23.3%	21.5%	8.1%	18.5%
Over 36 "		25.4%	12.2%	10.5%

LYSIS.

A gradual defervescence—termination by lysis, occurs oftener than is supposed by many. Termination by lysis occurred oftener than by crisis in the 1,030 cases analyzed by the Collective Investigating Committee of the British Medical Association.⁹² It is the usual ending of cases with a duration of more than eight or nine days. With such a termination it is often difficult to say precisely, where disease ends and convalescence begins.

DURATION.

Pneumonic fever is a disease having a pretty definite duration. Dating the commencement of the attack from the initial chill or other marked first symptom, and the beginning of convalescence at the time of permanent defervescence, the duration is usually from five to ten days, with an average of about one week.

Chomel⁹³ gives the duration of the disease as from seven to twenty-one days. Pasadski⁹⁴ analyzed forty-eight cases with an average duration of 7.6 days. Barthez⁹⁵ states that the duration is from four to eight days, and Lebert⁹⁶ five to seven days. Huss⁹⁷ found the duration usually from five to nine—often seven—days, and Lépine⁹⁸ six to nine days. The average duration of Folkmann's⁹⁹ 125 cases was twenty-two days. Auenbrugger¹⁰⁰ says that it is generally four days, rarely earlier, but often later. Tanner¹⁰¹ places it at ten days, as do also Andral,¹⁰² Bouillaud,¹⁰³ Watson,¹⁰⁴ Gerhardt,¹⁰⁵ and others. Doubleday,¹⁰⁶ in 252 cases, found the average duration 12.5 days. Of thirty-two cases analyzed by Scheef¹⁰⁷

the average duration was 5.5 days. In ninety cases reported in the U. S. Naval Reports¹⁰⁸ the average was 17.8 days, and of 366 cases analyzed by Hermann¹⁰⁹ it was thirty-two days.¹¹⁰ It was 7.8 days in thirty cases analyzed by Satterthwaite.¹¹¹ Swett¹¹² says the duration is about two weeks, counting to the time the patient is able to sit up most of the time. Schuyler¹¹³ says that the duration is from five to nine days, but it may be much longer.¹¹⁴ Dietl¹¹⁵ places the duration as follows: In a very few cases, three days; in many, five or six days; in most, seven to nine days; and in a few⁷ eleven to thirteen days. Flint¹¹⁶ makes it eleven days. A number of observers have given the exact duration of their cases as shown in the following table:

TABLE VIII.—SHOWING DURATION OF PNEUMONIC FEVER.

Various circumstances may tend to materially contract or widen the bounds as above mentioned, yet the vast majority of cases will be found to fall within these limits. Thus, in certain states of the system, or from innocuity of the disease, or from the action of appropriate remedies, convalescence may begin at any time.¹³⁴

Very rapid recoveries are denied by some,¹³⁵ but I am not only prepared to admit their occurrence, but several such are recorded in my case book.

On the contrary, unfavorable conditions of the patient, severity of the morbid processes or various complications may cause the attack to be protracted far beyond the extreme limits mentioned. Thus, cases are by no means rare in which convalescence is delayed for several weeks. The duration is increased if the patient is cachectic, dissipated, aged or of the female sex.¹³⁶ Also in apical and double cases.¹³⁷

It has been thought that convalescence began oftener on odd than on even days, but I know of no facts to support the view.¹³⁸

RESOLUTION.

Resolution of the local inflammation usually begins immediately, or soon after the decline of the fever, and proceeds with more or less rapidity until the exudate is completely removed. This may proceed with such rapidity that the physical signs may disappear in a few hours¹³⁹ or it may be greatly retarded.

In twenty-four cases analyzed by Stokes¹⁴⁰ the physical signs disappeared in one week in nine; in from one to two weeks in nine; in from two to three weeks in five, and in from three to four weeks in one. In twenty-six cases reported by Fox¹⁴¹ they disappeared in two days in one; two to three days in three; on the fourth, fifth, and sixth days in one each; on the seventh day in three; on the ninth day in one; in from ten to fifteen days in nine; in from twenty to twenty-five days in five, and in from twenty-five to thirty days in one. In 150 cases analyzed by Bleuler¹⁴² they disappeared on the first day in five; on the second day in two; on the third day in four; on the fourth day in two; on the fifth day in twenty-one; on the sixth day in thirty; on the seventh day in thirteen; on the eighth day in eleven; on the ninth day in five; in from ten to fifteen days in nine-

teen; in from fifteen to twenty days in six, and beyond twenty days in seven. In my own cases it was practicable to obtain information on the point in only 151 cases, and in these the physical signs were no longer recognizable after the first day in two; second day in two; third day in five; fourth day in nineteen; fifth day in twenty-four; sixth day in thirty-one; seventh day in fourteen; eighth day in ten; ninth day in seven; tenth to fifteenth day in sixteen; fifteenth to twentieth day in six, and after the twentieth day in seventeen.

In a certain small proportion of cases the local morbid action is of a fleeting nature and the inflammatory products are removed with remarkable rapidity. In this evanescent form the disease is not infrequently aborted¹⁴³—the local inflammation being checked in any part of its course, with a precipitous disappearance of the physical signs. This may be due to the impress made upon the local morbid action or upon the general constitution by the rheumatic, gouty, scorbutic, typhus, typhoid or other poisons circulating in the blood, or by epidemic or medicinal influence.

In the epidemic of typhus fever which raged in Ireland in 1854-55, pulmonary complications were very common. The symptoms and signs of the first stage of pneumonic inflammation were suddenly developed, continued but a short time and subsided again with singular rapidity. Silently, rapidly and spontaneously was the disease developed, and equally as silently, rapidly and spontaneously did it disappear—flitting like a shadow across the path of the original disease, and leaving as little evidence of its presence.¹⁴⁴

In some instances there may be a rapid and complete removal of the inflammation in a portion of the affected lung, while in the remainder it pursues an ordinary course.

A farmer, aged 37, twenty-two days ill with typhoid fever, was taken, Nov. 30, 1880, with pneumonic engorgement of the entire right lung. He had a frequent cough, moderate pain and distressing dyspnea. There was comparative dullness over the entire right side of the chest, and in this region the crepitation rale was everywhere heard. There was, in addition, active delirium, a dry and furred tongue, sordes, tympanitis, iliac gurgling, ochre diarrhea, subsultus tendinum, and a moist skin. He passed his urine in bed and was continually picking at the bed clothes. His pulse was 100, respirations 30 and temperature 101.5 degrees. After thirty hours the respiratory murmur and percussion note over the upper and lower lobes of the affected lung were almost, if not quite normal, while the middle lobe was completely hepatized—with dullness and tubular breathing. He expectorated characteristic pneumonic sputa. Recovery ensued.¹⁴⁵

This case illustrates the occurrence in the deeper organs of the body of conditions which are frequently seen upon the exterior.

Thus a patient presents himself with all the signs and symptoms of acute inflammation of the integument and subcutaneous areolar tissue of the entire fore-arm. There is pain, heat, redness, swelling and disordered function. On the morrow there is a decided change. In the central parts all the symptoms are present in increased severity and an elevated spot indicates the place where the abscess will point, while elsewhere the symptoms have almost disappeared. On the next day the abscess will have pointed, and will be surrounded by an areola of inflammation, while all the other parts have regained their normal condition. Such pictures have, no doubt, been often seen by every practitioner of medicine, but only too generally passed by as being a morbid process of too commonplace a nature to be worthy of a second thought. To the thoughtful student of nature, however, such phenomena illustrate in a graphic manner one of the most interesting and important problems in pathology with which the physician has to deal.

If inflammatory action may be aborted and inflammatory effusions be dispersed, as if by magic, in the superficial parts of the body, is it not reasonable to conclude that the same may take place in the deeper seated structures as well?

The "wandering" form of the disease, in which the morbid

action leaps from point to point is a curious feature which may be mentioned in this connection.¹⁴⁶

Pneumonic fever as it is sometimes associated with rheumatism¹⁴⁷ is often of a very fugitive nature.

Trousseau¹⁴⁸ records two interesting cases of this form of the disease. The first was a young man who was admitted into the Hotel Dieu with all the symptoms of pneumonic fever. By the following day all traces of the malady had disappeared and there was developed rheumatism of the left foot. The second was that of a young woman with fever, redness and swelling of the left leg and foot, and severe pain in the entire left side of the body. The left side of the chest was especially painful, but no abnormal respiratory sounds were audible. During the night cough came on, and on the following day the signs of pneumonic inflammation were manifest and two or three pneumonic sputa were expelled. On the next day the pulmonary symptoms had vanished.¹⁴⁹

One of my cases is as follows: A girl, 6 years of age, was taken with rheumatism, locally affecting in turn almost every organ of the body. After the first fortnight, hemorrhage from various organs, as *e.g.*, the nose, mouth, eyes, stomach, intestines, kidneys, vagina, etc., and purpuric patches in the skin, together with spongy gums, gave the case a scorbutic character. On the eighth day pneumonic inflammation of the right lung set in, with the most distressing symptoms, which disappeared completely in thirty-six hours. Recovery eventually ensued.

In some cases convalescence is protracted over a prolonged period, because of delayed resolution of the pneumonic exudate.¹⁵⁰ This event is neither so rare nor so frequent as has been supposed by many writers. These cases vary infinitely in their severity, course and termination. In the mildest cases the acute symptoms subside almost entirely at the usual time, but, from some peculiarity of the exudation material, or of the local circulatory or absorbent systems, or from some unfavorable state of the general system, the products of inflammation remain for a longer or shorter time quiescent, to be finally removed in the ordinary manner. In other cases absorption begins promptly and proceeds continuously but because of the above conditions the process is very slow and an unusual length of time is required before the lung regains its normal state. The duration of these cases varies from a few weeks to several years.¹⁵¹ They terminate in complete and permanent recovery.

A large, fleshy woman, aged 54, was taken Dec. 20, 1880, with an eighth attack of pneumonic fever. There was a severe rigor at night, followed by accelerated respiration, considerable dyspnea, incessant coughing, dark expectoration, fever, sleeplessness, delirium, diarrhea and involuntary passage of feces and urine, together with an assemblage of other symptoms usually recognized as indicating a very severe case. The local manifestations began at the base of the right lung and gradually advanced upward until the entire lung was involved. After the ninth day the acute symptoms gradually declined, yet frequent breathing, dyspnea upon slightest exertion, cough, scanty expectoration and weakness persisted. Resolution began promptly in the upper and middle lobes and was here soon completed, but at the base the evidence of consolidation remained unaltered for six weeks, after which the exudation was slowly, but gradually and completely removed in the course of a month. The entire duration of the attack was three months, with recovery. During the entire course of the disease, subsequent to the decline of the acute symptoms, the temperature was normal, and, after the first three weeks the appetite was good and the patient progressively gained in strength. The pulse, however, was always about 90, and would leap to 120 upon slight exertion or excitement. The respirations usually numbered 30, but ascending a flight of stairs would cause them to be 45 or 50, with marked oppression. Cough would appear upon awakening from sleep, after eating, deep breathing, changing position or exertion, was severe and convulsive and was accompanied by slight expectoration.

Even in childhood, resolution may be long delayed. A little girl, aged 6, was taken Dec. 1, 1886, with pneumo-

nic fever, locally affecting the lower two-thirds of the right lung. There was fever, pain referred to the epigastrium, cough, earache, epistaxis, restlessness, delirium, etc. After a week she improved somewhat, but three weeks later there was still slight fever, prostration, a troublesome cough, etc. The right side was almost motionless during respiration, with dullness as high as the third rib, bronchophony, tubular breathing and moist râles. She gradually improved but resolution was not completed until in March, 1887.

In the severer cases the picture must be cast quite differently. In these, as the stage approaches in which convalescence is usually declared, a decided improvement may take place, but the fever never entirely ceases. The cough continues and the pulse and respiration remain accelerated. The patient has no appetite, his digestion is impaired and he becomes progressively more and more cachectic, emaciated and prostrated. The fever takes on a hectic form, with diarrhea, night-sweats and perhaps dropsy, and the patient, worn out by the persistent cough, copious expectoration and terrible oppression, after a gradual decline, dies, or rarely, after passing fearfully near the brink of the grave, a change for the better takes place and he lapses into a condition of chronic invalidism, or astonishes every one by recovering.

A young man aged 21, was taken March 20, 1880, with pneumonic fever, locally affecting the base of the right lung. The case ran an ordinary, although severe course until the fourth day when the entire left lung became involved. On the tenth day he was much improved, almost free from fever, but his cough and expectoration continued. Subsequently he quit his bed and walked about, but continued weak and the pneumonic deposit was not absorbed. He emaciated so rapidly that his weight declined in four months from 160 to 115 pounds. In August he had complete obstruction of the bowels for twelve days, followed by alternating attacks of diarrhea and constipation, with a decline in weight to 108 pounds, but by December he weighed 120 pounds. During the following summer and winter his cough continued, the respirations increased to 60 or 80 per minute and he gradually lost weight, strength and hope, and only awaited death. There was extraordinary contraction of the thoracic walls, causing considerable lengthening of the chest. Over its greatest extent there was dullness, tubular breathing, bronchophony and increased vocal fremitus. At various places the resonance was tympanitic and the respiratory sounds loud and harsh. For three weeks before death, which occurred March 4, 1882, he suffered terribly from want of sleep, not being able to obtain more than a very few minutes at a time, when he would be awakened with a start and the most distressing dyspnea. At the autopsy both lungs were found very much contracted and universally adherent to the chest walls. In both apices the air vesicles and bronchi were dilated, while in the lower parts the lung tissue was light colored, hard, condensed and gristly, bearing but slight resemblance to healthy pulmonary tissue.¹⁵²

A seaman, aged 40, exposed to cold winds while overheated, was attacked with pneumonic fever, locally affecting the whole of the right lung. On the tenth day a violent and uncontrollable diarrhea set in which continued for ten days. During this time there was a profuse perspiration which was greasy to the touch and offensive to the smell. The pulse was weak, temperature about 102 degrees, respirations 40 and noisy, tongue dry and coated with a thick dark fur and the teeth covered with sordes. The cough was frequent and there was expectorated without much effort an abundance of thick, dark and tenacious matter. He became very weak and the muscles were tremulous. After eight weeks the lung, which had changed in condition but little, began to gradually clear up, the cough moderated, the expectoration diminished, the hectic disappeared and he finally completely recovered.¹⁵³

Occasionally this tendency toward a protracted course is a feature of entire epidemics. Not only this, but the type of the disease may be peculiar, both clinically and anatomically.¹⁵⁴

Subsequent attacks of pneumonic fever may occur in a patient suffering from a cirrhotic condition of the lung due to a former attack.¹⁵⁵

Bouillaud¹⁵⁵ relates a case in which a patient, after a second attack of pneumonic fever, remained dyspneic, with dullness on percussion, until he was again attacked five years later. During the last attack there was much dyspnea, the respirations were 52, the *alæ nasi* dilated with each inspiration and there was a jerking resonance of the voice.

If the apex is the portion of lung affected it is often difficult, clinically, with an imperfect history of the course previously pursued by the malady, to decide whether the case be one of chronic pneumonic consolidation or phthisis, into which many of these cases eventuate.¹⁵⁷

With the normal progress of resolution, cough and expectoration gradually decline and cease with the removal of the offending materials from the lungs.¹⁵⁸

When the patient is at rest respiration is easy and regular and but slightly if at all accelerated; but if active exercise is attempted there is noticeable oppression and a hurried, panting breathing. This gradually diminishes until it quite disappears.¹⁵⁹ The appetite gradually returns and all the digestive functions are properly performed, and with a preponderance of assimilation over waste, the heart rapidly regains its tone.

At the beginning of convalescence the patient is very weak, although as he lies in bed in moderate comfort he does not realize or appreciate the fact. It is only when he attempts any unusual exertion that he realizes the extent of his weakness. After a few days, however, his strength rapidly returns and in the majority of instances he will have fully regained his lost ground in from a fortnight to a month.

The patient sleeps much and his repose is quiet, restful and exhilarating. His mind is at ease and after a few days becomes remarkably clear and penetrating. He is not given to day dreaming or aerial castle building, but he perceives new possibilities all along the old lines of thought and effort, and, with complete recovery he proposes to again wage battle upon his chosen field of labor with renewed courage, energy and vigor.

While an extension of the local inflammation in pneumonic fever is of comparatively frequent occurrence a relapse¹⁶⁰—recurrence of acute local and general symptoms during convalescence is a rare event.

Baginsky¹⁶¹ never saw a case of relapse in this malady, although in two patients second attacks occurred very soon after convalescence was completed. Bourman¹⁶² has reported a single case. Briquet¹⁶³ saw relapses in one-fifth of his cases. Binz¹⁶⁴ reports one case. Clark¹⁶⁵ and Carroll¹⁶⁶ each report cases as does also Edbohls.¹⁶⁷ Fisser¹⁶⁸ saw one case. Flint¹⁶⁹ never saw a case, while Fox¹⁷⁰ and Grimshaw¹⁷¹ do not consider them very infrequent. Grisolle¹⁷² met with relapses in 35 per cent. of his cases and Jacobi¹⁷³ considers them frequent in children. Köttnitz¹⁷⁴ saw one case. Lépine,¹⁷⁵ Monthius,¹⁷⁶ Neumann¹⁷⁷ and Onlmont¹⁷⁸ report cases while Orton¹⁷⁹ never saw one and does not believe in their occurrence. Schuyler¹⁸⁰ says they are rare. Strong¹⁸¹ reports a case. Walshe¹⁸² thinks relapses rare, while Ziemssen¹⁸³ considers them not infrequent.¹⁸⁴ Relapses occurred in five—1 per cent.—of my cases.¹⁸⁵

⁷² Dakeman—*N. Y. Med. Rec.*, Aug. 3, 1889, p. 122, reports the case of a young man who worked at street paving during the first six days of an attack of pneumonic fever and did not subsequently take his bed. He recovered, although the entire right lung was consolidated.

⁷³ For further information see Fox, *op. cit.*, p. 163;—Kühn, *Arch. f. k. Med.*, Bd. xvi;—Juergensen, *London Lancet*, 1884, Vol. II, p. 27.

CEREBRAL SIGNS AND SIMULATIONS IN PNEUMONIA.

Read before the Forty-eighth Annual Session Wisconsin State Medical Society.

BY J. R. BARNETT, M.D.
NEENAH, WIS.

It is probable that the various papers on the different inflammatory diseases of the lungs, to be presented by this Committee, will take into account the cerebral complications and counterfeits often present, as well as other more frequent, if less serious, complications; and perhaps so fully that anything more would be superfluous. Still, the relative frequency and importance of these cerebral manifestations, grown more frequent and more important since the Russian influenza added its baleful quota to the list of human ills, gives good reason for something of repetition. Indeed, when different writers discuss the subdivisions of lung inflammations practically, that is from the standpoint of bedside observation, there will be much of repetition all through, for at the bedside we find few of those distinct entities which the text-books delight to photograph and catalogue, but instead, a mixture of conditions which baffle rather than invite either delineation or classification.

Again, contrary to what was first confidently expected from the disclosures of bacteriology, the discovery of the specific germ of pneumonia, far from conferring upon that disease well-defined and easily known boundaries, actually added to their vagueness and uncertainty, so that what the culture tube and microscope might determine to be a pneumonia might nevertheless be proven by the stethoscope and percussion hammer to be a pleuritis or a pericarditis or, perhaps, all three.

The co-existence of these or other lesions as the result of pneumonic infection is always of great clinical interest, but its discovery is not always of vital importance, judged by its practical application to treatment. When, however, this infection invades cerebral or meningeal structures, or, originating there, invades later the lung, the case is different, for now it is of vital concern to make out the graver condition, to the end that appropriate changes in treatment may be made, and in time.

What determines this invasion of regions anatomically so remote and dissimilar? So far the question does not seem to have been definitely answered. Fränkel, Weichselbaum and others have found the diplococcus of pneumonia within the membranes and ventricles of the brain coincidently with an attack of pneumonia, and also when that disease was not present. Similarly the influenza bacillus of Pfeiffer and the pneumococcus of Friedlander have been found in those situations, and, to further illustrate the neighborly relations in misfortune of the brain and lungs, cerebro-spinal meningitis is often followed by pneumonitis, the specific germ of the former being found in the lungs.

Perhaps, however, it should be said that the common germ of both is found in the lungs after the previous invasion of the membranes of the brain or spinal cord, since it looks the same, whether found in one inflammation or the other. So, also, the same mixed infections may be present when these inflammations coexist, as by any of the pyococci.

Bacteriology has thus thrown a flood of light upon what was formerly looked upon as the strangest co-

incidence of distinct diseases, and reduced to law the most erratic vagaries of morbid processes. Now we expect that with every epidemic of cerebro-spinal fever, some—few or many—cases of lung complications will occur, and, *vice versa*, that a generally prevalent pneumonic fever will have its quota of brain cases, and that each, in epidemic or endemic form, will be haunted by the independent presence of the other.

The existence, then, of these mutual relations being known, it would be naturally inferred that they could be promptly recognized when present, but actual experience shows that this is not always easy to do. With young children especially, some of the most striking symptoms are common to both, nor are they necessarily different in character or degree. This is particularly true of fever, headache, vomiting and delirium, and it will often be true of the pulse, respiration and certain nervous signs, like the contracted or dilated pupil, regional hyperesthesias, and the like. As for temperature, while it would be expected to run higher in meningeal inflammations, it is not uncommon for it to remain relatively low throughout. Thus, the temperature of uncomplicated pneumonia often reaches 105 degrees or higher, while a case complicated by meningitis may show no higher range than 102 or 103. Nor will sudden variations make the discrimination any easier, for a rapid rise from 102 to 105 degrees may, and usually does, come from those still mysterious factors in the production and dissipation of heat supplied by the specific toxinaemia of the pneumonic inflammation, or, again, from the septic effects of pyogenic bacteria. Since the same chronic causes are operative in cerebral complications it follows that a feeble toxinaemia would be attended by a moderate temperature, always excepting the direct irritating effects of an inflammation involving heat centers, or pressure effects of large effusions upon the medulla.

Headache is often a prominent symptom in pneumonia with or without complication, but I have seen no case where it afforded help in making a discriminating diagnosis. Sometimes the restlessness and violence of the patient will be attributed to intense headache, but it is very rarely that he complains specifically of this, as is often done in cerebro spinal fever. It has seemed to me that other regional neuralgias and hyperesthesias have more diagnostic value than this, but they also have their perplexities, for, occurring in the chest, they may be explained by the presence of the existing inflammation, and it is only when this last is deep-seated in the insensitive region of the interior of the lung, that it can be eliminated as a cause of pain. Occurring in the extremities they are far more significant, and when is superadded tonic or clonic spasm it is made tolerably certain that the membranes of the cord, at least, are involved in the morbid process, although it must not be forgotten that these, too, are sometimes present when, at most, a meningitis can be only suspected.

As an early symptom in pneumonia, vomiting is present in from 30 to 60 per cent. of cases, according to the experience of different observers. Exceptionally it continues throughout the disease. By itself, therefore, it is only in such cases that it could justly arouse the suspicion of meningeal complications. There is a peculiar explosive vomiting, or a

passive regurgitation, without previous or attendant nausea, which is believed to come from a central irritation through the vagus; but this, too, may be seen when the cerebral structures are intact, so far as can be judged by attending symptoms. Correspondingly, the nausea and vomiting characteristic of gastric irritation as commonly observed may be the stomach symptom of a well-marked meningitis.

Certain forms of delirium, particularly the violent kind occurring before the last days of the disease, or the half-stupor which seems to observe without taking cognizance of the sights and sounds of the sick-room, afford a strong presumption of brain trouble, but they are not proof of this, since they occur fairly often without it. But with it the delirium may be quiet and unalarming till it verges to stupor and unconsciousness.

By itself, the pulse does not afford a criterion by which to judge, unless extreme rapidity be replaced by abnormal slowness. This would be fairly pathognomonic of intracranial pressure, unless it could be explained by some cardiac depressant administered in treatment. But it goes without saying that the significance of all symptoms present should be read in full remembrance of remedies employed and their natural results.

A rapid, more or less cordy pulse, characteristic of serous inflammations is apt to be present, but the pulse of resistance that goes with parenchymatous inflammations may not always be easily known from it. In general, it may be said that, with the exception noted, the pulse gives but little aid in making a discriminating diagnosis.

Usually the respiration has greater significance than the signs and symptoms already mentioned. It may be alike rapid and fairly even in both simple and complicated pneumonia, but irregularity, particularly of the Cheyne-Stokes character, and abnormal slowness, or both, point strongly to a crippled medulla, and a sudden cessation of breathing, from a basal pressure, may all too late give the first positive evidence of a brain complication.

For me the pupillary signs are the most positive, excepting, possibly, the muscular, afforded in the whole history of the case. Exceptionally, without cerebral lesion the little patient's eyes may be bright and glistening, intolerant of light, irregular of pupil—which may be contracted or widely dilated, and as some affirm, the eyes may be distinctly squinted; but such an array of signs should point to the brain, and if the pupils be of unequal size, or insensitive to light, or momentarily contracting to dilate widely in the presence of strong light, then, in my opinion, the evidence should be considered as well-nigh complete.

Reverting to muscular signs, it should be stated that clonic spasms early in the sickness are usually not indicative of nervous lesions. They are regarded by the older writers as having a like significance to the chill in older patients. Now, however, it would be more rational to attribute them to the irritating effects of microbic toxins upon the appropriate motor centers. When we remember how mixed the pulmonary infection may be, how Pfeiffer's bacillus of influenza may reinforce Fränkel's or Friedlander's pneumococcus, or both, and how one or more of the pyococci may join this coalition against the health and life of the little patient, it is not strange that this mixed intoxication should have varied and

alarming effects upon the sensitive brain and cord, nor is it strange that they should not always be easy of analysis. Tonic rigidity of the nuchal muscles and those of the back and extremities has long been regarded as significant of meningeal inflammation, and it would be well to regard it as a positive sign. But if to this be added the eye symptoms already spoken of, or the characteristic vomiting without nausea, the diagnosis would admit of no doubt whatever.

Auditory symptoms will sometimes be available when others are absent or few. There may be a hypersensitive hearing, or impairment or loss of this sense. In the few cases I have seen where either of these has been present it has been the former. It should probably have the lesser diagnostic meaning, as it may doubtless occur when neither the center of hearing nor the auditory nerve in any portion of its course is affected.

The middle ear, as an *atrium infectionis*, should not be lost sight of. Especially in the broncho-pneumonia of influenza, though other forms do not always leave the tube and middle ear inviolate, the danger of tympanic inflammation is very great; and, once present, it involves all the risks to adjacent structures which are known to attend such diseases from commoner causes. A resulting thrombo-plebitis and following abscess might show focal signs according to its location and the extent of pressure.

Focal symptoms might also supervene upon the occurrence of embolism, depending upon the region made anemic by the arterial plug. Remembering the hyperinosis usually present in croupous pneumonia, and that clot is not an infrequent incident, should a local paralysis suddenly occur it would be safe to assume that the corresponding cerebral circulation had been occluded by clot. This is all the more certain if, as usual, it happens before the decline of the inflammation, for the brain sequels of middle ear diseases are of later origin.

In my experience, meningitis is more apt to recur as a complication in endemic than in epidemic or sporadic pneumonia; but this is limited, being based upon only two instances. In the first, of three cases occurring in one family two died of meningitis, well-marked symptoms presenting after more or less extensive lobar exudation. In another family, living but a few rods away, out of two cases, one died of meningitis. All of these, and some dozen more of simple pneumonia in the same neighborhood, were nearly cotemporaneous. Neighboring towns had few or no cases.

Four or five years ago, also, Neenah had a visitation of mild pneumonia, and out of the cases I saw two had most of the signs characteristic of meningitis, and two or three others many of them. No deaths occurred, but in the two I could not avoid a diagnosis of brain complication.

This experience is much too limited to generalize from, but it will lead me to look for like coincidences in future epidemics, and, if nothing more, to greater alertness in the discovery and comprehension of early cerebral signs.

From what has been said, a further point of practical interest might be inferred, but it will not be amiss to speak of it. Not only the simulations, but the signs likewise, of pneumonic fever, will sometimes mislead; for as it happens not seldom that a distinct limited exudation may be positively made out

one day to be positively and forever lost the next, so it may happen that slight pulmonary sounds may be attended by alarming cerebral signs, and all replaced in a day or two by evidences of the most extensive lobar exudation. In such cases it is well for the attending physician if the consultant see them before the miraculous transformation, if at all, for he will thereby be saved some mortification of spirit, although the latter will miss the glory of finding out, or seeming to find out, what his colleague had blindly overlooked.

IS MEMBRANOUS CROUP DIPHTHERIA?

Read before the Indiana State Medical Society at Indianapolis, May 17, 1894.

By FREDERICK C. WOODBURN, M.D.

CONSULTING PHYSICIAN ON DISEASES OF THE CHEST, INDIANAPOLIS CITY DISPENSARY.

Notwithstanding the investigations which this question has provoked during the last decade, there is still quite a diversity of opinion concerning the identity of these two affections, and considerable time must yet elapse ere a positive answer may be given to the query which forms the title of this paper.

The desire of the writer is to stimulate an interest upon this subject in the Society, and to bring about a thorough discussion upon it, believing, as he does, that a free interchange of ideas and experiences is one method by which an elucidation of the problem may be brought about.

In the past few years the bacteriologist and microscopist have stepped prominently to the foreground, and to their indefatigable labors and their valuable investigations and experimentation are we indebted for the marvelously rapid strides forward which medical science has taken. Our ideas of the etiology of disease have radically changed, and in consequence of our increased knowledge in this direction our methods of preventing and treating disease have become much more effective.

Through these bacteriologic investigations the discussion has arisen concerning the identity of membranous croup and diphtheria, and although the investigations in this matter may be said to be yet in their infancy, they have proceeded sufficiently far to convince many of the workers that the two diseases are one and the same, viewed from an etiologic standpoint.

As I stated, however, these investigations have but recently been commenced, and in this controversy I fear that we have depended too largely upon the statements of our friends, the bacteriologists, and paid insufficient attention to those men who see disease at the bedside as well as in the laboratory. The opinions of intelligent men who are daily in contact with the clinical manifestations of disease are certainly of great importance.

In treating this subject, I shall commence with the consideration of the etiology of diphtheria, as it is generally accepted at the present time. Without burdening you with a discussion of the predisposing causes, with which you are all familiar, I will proceed at once to the exciting cause which is contagion.

The disease is now known to be transmitted by a specific organism, and this is known as the Klebs-Löffler bacillus, which was first described by Klebs and afterwards more extensively studied by Löffler. The production of the false membrane is the primary

or local result, while the secondary or constitutional symptoms are due to the absorption of the poison generated by the Klebs-Löffler bacillus.

In the examination of the diphtheritic membrane, however, it has not uncommonly occurred that the characteristic bacillus was absent, and only streptococci, staphylococci, and at times other cocci were present.

The streptococcus, staphylococcus, etc., were also found in those cases, wherein the Klebs-Löffler bacillus existed, and in these cases the attacks were almost invariably more severe than when these cocci were absent. This fact has been accounted for by the supposition that these cocci penetrated parts that the Klebs-Löffler bacillus did not reach, it being confined entirely to the membrane.

Baginsky, in a paper recently read before the Berlin Medical Society gave the following statistics: Out of 154 cases of diphtheria he obtained cultures of the Klebs-Löffler bacillus in 118 instances. In the remaining thirty-six cases the streptococcus and staphylococcus alone were found; of this latter class, thirty-two of the cases terminated in complete recovery, unhindered by any complications.

From these observations, Baginsky is strongly inclined to the opinion that there occur two separate and distinct forms of diphtheria; a true diphtheria having for its cause the Klebs-Löffler bacillus; and a pseudo-diphtheria, in which streptococci and other cocci are the etiologic factors. Dr. T. M. Prudden, of New York, publishes an account of his investigations, which comprises twenty-four cases. A vast majority of these cases occurred as a complication or sequel to scarlatina, and in none was he able to demonstrate the presence of the Klebs-Löffler bacillus. Martin publishes an account of the examination of 200 cases, in 79 of which the characteristic bacillus was absent, and in this latter class the mortality was very markedly lower than in those cases characterized by the presence of this bacillus.

Dr. Wm. H. Park, of New York, states that in 127 cases in which the Klebs-Löffler bacillus was found to be present, the mortality was 34.2 per cent. while in 79 cases in which it was absent, the mortality was but 4.3 per cent. Park also says: "The inflammation caused by the streptococci and to a less extent by other cocci, differ greatly. They may be conveniently divided into:

1. Pseudo-membranous angina.
2. Pseudo-membranous laryngitis.
3. Croupous tonsillitis.
4. Follicular tonsillitis.
5. Acute pharyngitis and tonsillitis without exudate.
6. Cases similar to all the preceding, but complicating infectious diseases."

From the above facts I would glean the following points, the correctness of which is accepted by many.

1. That those cases which we have heretofore diagnosed as diphtheria are divided into two classes, one of which constitutes true diphtheria, the etiologic factor of which is the Klebs-Löffler bacillus, while the other class consists of cases of exudative tonsillitis or pharyngitis, caused by the presence of streptococci, staphylococci, etc.

2. That true diphtheria is a disease attended with a very high death rate, the severity of the affection

being caused by the absorption of a toxalbumin, which is generated by the Klebs-Löffler bacillus, and which produces septicemia, paralysis, albuminuria, ganglionic engorgements, etc.

3. That uncomplicated exudative pharyngitis or tonsillitis (so-called pseudo-diphtheria) is followed in a vast majority of cases by complete recovery.

4. That only the true diphtheria is contagious.

I will next briefly consider the etiology of that affection known as membranous croup. The exciting causes of this affection were until recently supposed to be exposure to cold and moisture, and the infectious diseases, contagion having no etiologic importance.

It is now claimed by many writers of authority that the disease is produced by the Klebs-Löffler bacillus, and is in consequence diphtheria.

Frankel records four cases of idiopathic membranous laryngitis, in none of which was there any membrane found in the fauces either before or after death; but in all four of these cases pure cultures of the Klebs-Löffler bacillus were obtained; and he concludes as a result of his investigations that idiopathic membranous laryngitis and diphtheria are etiologically identical.

Other investigators whose opinions are also worthy of respect and consideration have arrived at practically the same conclusion.

It should be remembered, however, that the examinations of the membrane of croup have been comparatively few, and, although we have proof positive that many cases of croup are in reality true diphtheria, the investigations have not as yet proceeded sufficiently far to admit of the opinion that all cases are produced by the characteristic diphtheria bacillus, or to make such opinions of any great value.

If, however, this is the case, then membranous croup must of necessity be a highly contagious disease, and right here is the stumbling block in the pathway of the advocates of this theory.

In studying the literature of the subject I have been unable to obtain any tangible evidence of the contagiousness of this affection. On the contrary, I find abundant testimony to the effect that the possibility of communication from one to another does not exist.

Osler, in his recent work on the "Practice of Medicine," states that he has twice observed cases of membranous croup in the Infants' Home in Baltimore where the conditions favorable to the spread of the disease existed, yet no other cases occurred. Other authorities agree with this opinion.

It has been my own misfortune to have had in my charge, at various times, four cases which I believed to be idiopathic membranous laryngitis, the last one occurring about one year ago.

At the time of my attendance upon these cases I gave little or no thought to the possibility of contagion, especially as there was no exudate visible on the fauces. Consequently no precautionary measures whatsoever were taken. The patients were not isolated, other children being allowed the freedom of the sick chamber.

In each of these cases there were other children in the family, of an age rendering them susceptible to contagion. In one other family there were four other children under the age of twelve years. Neighbor children were also allowed by the family in and out of the room and were frequently in close contact to

patient. This occurred in two cases. In not one of these four families did there develop a case of diphtheria, neither was there an appearance of the disease in any of these neighborhoods. It seems to me that these cases would have formed excellent nuclei for an epidemic had the trouble been true diphtheria.

Such experiences have occurred, I have no doubt, to nearly every one within the sound of my voice. What would be the result if we were to handle a case of diphtheria in this fashion? We would undoubtedly have a nest of diphtheria to pay for our negligence. It may be said in answer to this, that in the majority of cases we have but one patient in the family, the disease not extending to other members. This is true, but the precaution every physician takes to prevent the spread of the disease is the reason for it. How many physicians five years ago took these same precautionary measures in membranous croup?

In further support of the view that many cases of membranous laryngitis are due to causes other than diphtheria, permit me to briefly present some statistical facts.² From 1775 to 1850, diphtheria was almost or quite unknown in this country and in Great Britain, but many cases of non-contagious membranous laryngitis occurred during this period.

In Philadelphia from 1846 to 1849 the annual mortality from croup was from 111 to 312. No deaths from diphtheria are recorded during this period. From 1860 to 1879 the annual mortality from croup ranged from 185 to 455, while from diphtheria it was from 110 to 708.

Previous to 1859, when diphtheria made its appearance in Philadelphia, there had occurred altogether 3,078 deaths from croup, during which period no diphtheria was encountered so far as is known.

In New York City previous to 1858, but three deaths from diphtheria occurred during the present century, while croup had been more or less prevalent.

From 1858 to 1875 the annual death rate from croup ranged from 338 to 758, while that from diphtheria was from 5 to 2, 329. Dr. Lewis Smith, in this connection makes the following observation: "It is evident that most of the cases of croup occurring in New York prior to 1858 were due to other causes than diphtheria. It seems hardly probable that so many cases occurring in the hands of hundreds of skilled practitioners should have presented none of those symptoms which we now recognize as characteristic of diphtheria, especially septicemia. It is probably an acute, non-contagious, non-infectious inflammation of the larynx, local in character. But there is also a true diphtheria (laryngeal), and this is the more common form at the present time."

The two diseases present some differences in their clinical aspects. In diphtheria the initial symptoms are slight chilliness, fever, aching in back and limbs, etc. In croup the first symptoms are slight hoarseness accompanied by a rough cough, while there is little or no elevation of temperature.

In diphtheria, the temperature gradually rises, generally reaching 108 or higher, while in croup the temperature is ordinarily much lower than this and not infrequently it remains normal. In diphtheria the first indication of local trouble is slight redness of the fauces and more or less difficulty in deglutition. In croup we have in addition to the cough and hoarseness, which gradually increase in severity,

²Reference, Handbook of Medical Sciences.

dyspnea, which gradually becomes more and more intense.

In diphtheria, the exudate in the vast majority of cases makes its initial appearance upon the tonsils, later extending to the pillars of the fauces, the uvula and even to the posterior pharyngeal wall; later, in some cases extending into the posterior nares or downward into the larynx, trachea and bronchi. In croup, the membrane invariably first appears in the larynx, from this point extending upward or downward or both. In diphtheria, we generally have a characteristic glandular swelling, which is absent in croup. Constitutional symptoms are prominent in the former disease and absent in the latter. In croup, all the symptoms are rapidly increased in severity, the dyspnea becoming intense. Cyanosis soon appears, and death generally closes the scene.

Should the diphtheria be laryngeal in character, there would not be such a wide divergence in the symptoms. Still the fever would be higher than in croup, glandular swelling would occur and the constitutional symptoms be marked.

Two of the cases of croup in my own practice, to which I referred, had absolutely no rise of temperature at any time, and in all four of the cases no glandular swelling existed and no symptoms characteristic of diphtheria were present.

In the earlier portion of this paper we have seen that there occurs a true diphtheria, highly contagious and very fatal; and a so-called pseudo diphtheria not contagious and much less fatal than the former affection. We have seen that the etiology of these two diseases is very different.

Is it not possible, nay, even probable, that these same conditions prevail with reference to the laryngeal mucous membrane? I would answer the question affirmatively, and would further strengthen this opinion by studying the history of diphtheria and croup as they occurred in this country during the present century, and to a certain extent by the study of the clinical manifestations of the two affections.

The conclusions, then, which I have reached are as follows:

1. That there are two forms of membranous laryngitis; one a true diphtheria, produced by the Klebs-Löffler bacillus and the other non-contagious membranous laryngitis, produced, if you please, by streptococci, staphylococci, etc.; and that both of these types are very fatal.

2. That membranous croup as we have heretofore understood it, is a disease of much less frequency than was formerly supposed.

3. That it being impracticable to make a bacteriologic examination of the membrane in many cases, and as this is the only method by which we may be absolutely positive of our diagnosis, the same precautionary measures should be taken to prevent a possible spread of the disease as would be adopted in a case known to be diphtheria.

Those who believe that a non-contagious membranous croup does not exist will hardly be favorably impressed with the idea of carding the house, isolating the child, and causing any other children who may be members of the family, to remain from school for several weeks, but in the light of our present knowledge upon the subject it is the only safe method to pursue, unless a careful microscopic examination by a competent bacteriologist has demonstrated the absence of the Klebs-Löffler bacillus.

ON LOCAL ANESTHESIA PRODUCED BY INTRACUTANEOUS INJECTIONS.

BY DR. CHOLEWA.

BERLIN, GERMANY.

[The following paper was sent to me by the writer, my old friend, the well-known aurist of Berlin, Germany, with the request that I look it over and have it published here. He was induced to write the essay, not only because he found the method described of great value in the practice of his own specialty, but out of gratitude to Dr. Schleich (the originator of it), who performed an operation upon him that under ordinary circumstances would have required a general anesthetic. This otherwise very painful surgical procedure was carried out with perfect comfort to the patient, by employing the local "infiltration-anesthesia" method, which he describes.—CASEY A. WOOD.]

In the winter of 1891, a young surgeon gave a discourse on infiltration-anesthesia before the Berlin Medical Society which excited great interest. That is saying a great deal, since this Society, the greatest and most famous in Germany, consists mostly of professors in the University as well as the heads of the great hospitals in almost equal numbers. He who aspires to address this scientific body must be very sure of his subject, for he will have to suffer a most merciless criticism.

Prof. Virchow is the President of this Society, and who does not know the sharp tongue and the caustic wit of this gentleman, who has so often promoted as well as humiliated scientific efforts? But this young physician was master of his subject. A numerous array of cured patients surrounded him and were introduced to the audience by him, in order that his colleagues might with their own eyes see, and with their own ears hear, and investigate. He did not discuss the ability to operate without pain in the various branches of minor surgery only, but asserted that capital operations could be done by his method. For example, he exhibited one case in which an ovarian tumor weighing many pounds was removed and the woman did not faint once during the long operation. An old man showed scars on his thigh which were left by a carbuncle extending from the trochanter of the femur to the bend of the knee, and yet this old man had in this case undergone a very severe operation without the use of one single drop of chloroform! The applause, the enthusiasm, especially among the younger members of our profession, was general; it rose to rapture when a young colleague showed the assembly his finger, to which a short time previously this method had been applied by the author, after which a deep but painless incision was made into a well developed whitlow.

How many since this never-to-be-forgotten evening have been treated with this method; how many have been freed from the danger of chloroform and from their own dread of employing it! Over and over again this method of infiltration-anesthesia has been employed in hundreds of cases, simply because surgeons prefer infiltration-anesthesia to the anxiety of a chloroform-narcosis, the dangers of which stand in no proportion to the importance of the operation.

In what respect does this method differ from other local anesthetics?

Inasmuch as the description of the first reception of this method by the medical world was witnessed by myself, in explaining it I beg permission to use the words of the master who discovered it. In the spring of 1892, Dr. Schleich took the opportunity, at the annual meeting of the Head Surgeons at the Laugen-

beck Haus, to lay before the assembled colleagues the management of his method in the following words:

INFILTRATION-ANESTHESIA AND ITS RELATION TO
GENERAL ANESTHESIA.

The efforts hitherto made to perform painless operations by means of local anesthesia have not been very successful. To all the methods of local anesthesia hitherto employed, was opposed a danger in one or another direction. Anesthesia produced by vaporization of ether, or mixtures of ether, brought with it the danger of gangrene of the frozen tissues, to which was added great pain, especially of the inflamed parts during the freezing, thus considerably diminishing the advantages of the process. The dangers of poison were opposed to the general use of cocain, that most excellent of all local anesthetics. To this must be added that the pricking with the Pravaz needle and the act of injection itself, especially into the inflamed parts, was so painful that the procedure was considerably robbed of its value. By the employment of the ether-spray as a preliminary to anesthesia by means of cocain injections, I succeeded to some degree in avoiding this evil. The surface of the skin above the part to be made anesthetic became sufficiently insensible by the ether-vaporization to render painless the introduction of the needle. The contents of the syringe entered first into the skin (intracutaneous), and not under the skin (subcutaneous). If I am not mistaken, it was our colleague, H. Schmidt (of Stettin), who first suggested the necessity of these primary intracutaneous injections. I have for many years very frequently performed operations by this species of cocain anesthesia, and have reported several cases. Nevertheless, after the application of solutions from 1 to 5 per cent., as soon as a maximum dose of 0.005 cocain had been reached, frequently even below this point, the most serious symptoms of intoxication have taken place. This occurred even after the application of from two to five small syringe-fuls, and even when, by previous compression with Es-march's bandage, the circulation was stopped as long as the narcosis lasted. Medical periodicals are full of reports of cocain intoxication, a large percentage of which have had a fatal issue. Owing to this state of things, it was impossible that local anesthesia could successfully compete with "general" narcosis.

I have, therefore, undertaken the task, in a series of trials on myself, on my assistants and the attendants of my clinic, to settle where precisely lay the limit of the efficacy of cocain. These and the experiments following, the results of which I had the honor of laying before the Medical Society of Berlin last November (1891), were all performed in such a manner that the real question, whether a given fluid be an anesthetic one or not, was decided within the intracutaneous limits of the skin. We made the punctures as parallel as possible to the surface of the skin immediately under the papillæ, until a white and slightly elevated blotch rose, resembling the sting of a gnat. The reason that the investigations of this subject, so carefully made by Liebreich and his pupils, as well as by Levin and Kanewsky, did not immediately lead to the discovery of any new facts, was that the aforesaid authors applied the fluid under examination *subcutaneously*.

We tried these experiments first on ourselves; those authors experimented chiefly on the skin or the mucous membrane of animals. During these "intracutaneous" trials of the various solutions of cocain, first appeared the surprising fact that solutions of 1-5000 in water were able, within the limits of the infiltration, to produce a complete anesthesia, so that punctures, cutting, scratching and scraping could be done absolutely without pain. Henceforth this fact may be justly considered as indisputable, after my having proved it in several hundreds of operations. After the discovery of this fact it was a natural inference that the cocain could be altogether left out of the fluid, and the same results were obtainable with pure water and solutions of salt. We found, indeed, that pure distilled water is able to produce perfectly anesthetic blotches. But here an essential difference appeared, namely, the process of injecting water into the substance of the skin itself with the formation of water blotches is painful, and that to no slight degree. Not until from a half to a minute after the injection does pure anesthesia take place, and then is quite as perfect as after the injection of cocain of from 1-5000, or in stronger solutions. The result was that distilled water, according to the meaning of Liebreich, is an "anesthesia dolorosa;" that is, the commencement of anesthesia (the paralysis of the nervous substance), is preceded by a stage of pain, a hyperesthesia of the nerves. This hyperesthesia was an obstacle to the use of pure water for operating purposes, although the refrigerating of the water to zero (Cels.), as well as the use of the ether-spray, employed in the above-mentioned way, reduced this stage of irritation to a minimum, so that I was several times enabled to perform with pure distilled water, such operations as opening furuncles or carbuncles, removal of small ganglia, etc.

Further experiments revealed that a number of substances were practically available as anesthetics without producing irritation. First, as strong a solution of common salt as 0.6 per cent. produces no anesthetic effects worth mentioning. On the contrary, it was found that a further diluted solution of common salt, namely, a 0.2 per cent. solution, by itself, especially in lower degrees of temperature, produces a perfectly prompt anesthesia in the region of the infiltration. I may here, perhaps, remark that what is true of the skin also refers to other tissues of the body; for instance to the subcutaneous layers, the muscular layers and the periosteum. The 0.2 per cent. solution of common salt produces not only anesthesia, an effect which it possesses in common with water, but the process of injection is painless. This proves that it is the infiltration itself that produces the anesthesia.

The anesthetizing fluid need not be itself anesthetic. The proportion of common salt in a solution is important, as witness the following experiment: The smallest effective dose of cocain—weaker injections caused pain—was 0.2-100, or 1-5000. This watery solution of cocain produces anesthesia and makes other injections painless. The same dose of cocain containing 0.6 per cent of common salt is painful and is not able to produce anesthesia, while the same solution wherein the amount of common salt is not greater than 0.2 per cent. again affords perfect anesthesia; indeed one gram of cocain in ten liters of a 0.2 per cent. solution of common salt is capable of producing complete anesthesia, or in other words,

I may use half a liter of my anesthetic solution before the maximum dose of 0.05 cocain is reached.

Now, when you consider that for most operations, as for example the amputation of the breast, about fifty to eighty grams of the solution are employed, you will agree with me, that there can be absolutely no question of danger of poisoning from this method of anesthesia, especially as the dose is never administered all at once, but is extended over the time occupied by the whole operation. If I may be permitted to suggest a theory to explain the incontestable fact of anesthesia by the thoroughly penetrating infiltration of "indifferent" fluids, I must not omit to say that cocain, common salt and water are not the only materials that are able in this way to produce anesthesia. You will obtain as complete a state of anesthesia by using a solution of 3 per cent. sugar or of 0.1 per cent morphia or of 3 per cent. potassic bromid, or of 1 per cent. methyl-violet, or of 2 per cent. caffein, and so on. I may mention that the efficacy of all of these materials, to which may certainly be added a great many others, will be increased by dissolving them, not in water, but in a 0.2 per cent. solution of common salt.

How is this fact to be explained? I assume that the physiologic solution of common salt of 0.6 per cent. on account of its similarity with the composition of blood serum is highly irritating when presented in excess to the sensitive nervous tissues.

Water, on the other hand, is sufficiently different with respect to the lining tissues and its normal fluid to modify the nervous substance; it first produces irritation, and afterwards paralysis of the nerves and anesthesia. I surmised that between these two effects, the indifferent one of the 0.6 per cent. solution of common salt and of the distilled water (differing from the composition of the fluid of the lining tissues) there must be a territory within which a weaker solution of common salt would be able to produce anesthesia without the irritation to nervous tissues resulting from the use of both stronger and weaker solutions. This border land was found in a 0.2 per cent solution of common salt in distilled water. This is the very anesthetic fluid which I employ in my operations; the addition of 1 gram of cocain to 10,000 or 5,000 grams of this solution facilitates the practical application of the solution without entailing even a shadow of danger. One gram of this solution contains only 0.0001, that is a tenth of a milligram, of cocain. The maximum dose of cocain is not reached till 500 grams of the solution have been used. It must be remembered, also, that during the operation more than half of the fluid employed runs out again or is wiped off.

In minor operations I make use of a solution of 1-5000 grams, and for dressings recommend the employment of a solution from 1-1000 grams.

I advise two "stock" solutions: One of 1 gram of cocain to a 1000 grams of water (Solution A) and the second of 2 grams of common salt to a 1000 of water (Solution B). Parts of solution A are mixed for use with five or ten times as much of fluid B. Both fluids are easily sterilized.

The cause of anesthesia by infiltration is not a simple one; several factors are at work; first the pressure of the injected fluid and the removal of the blood from the infiltrated tissues. After a properly performed injection, they appear perfectly white. That is, instead of the tissue juices the foreign mix-

ture is incorporated in all the lymph vessels and the areolar spaces, while the blood is gradually forced into the neighboring vessels. But besides this pressure and anemia of the tissues, temperature plays a prominent part. The proof of this is very simple. All my solutions of common salt of from 1-1000 to 10,000 have the best effect at zero, Celsius.

Every edema of the skin would produce anesthesia of the parts, every swollen limb would become insensible, did not the injected fluid, which causes this pathologic edema, contain the same amount of common salt (0.6 per cent.) as the serum of the nervous fluid. If one produces an artificial edema with other fluids—with or without a little common salt—the whole region of the artificial swelling will become insensible and will enable one to operate without causing pain. This is briefly the principle of infiltration-anesthesia, which in practice has gained such a widespread application. This proceeding is, in the first place, beneficent to the patient, for whom the danger of the operation is diminished in the same degree as we are able to spare him the general narcosis.

The danger of an operation, in so far as loss of blood is concerned, scarcely exists, thanks to the advanced progress of our operative technique, for which we are indebted chiefly to our great masters of the pre-antiseptic era, and not the least to him whose immortal name has been given to this house. Lister has enabled us to make the dangers of infection depend upon our sense of duty and our carefulness; the danger of poisoning by the use of antiseptics we have banished by our efforts to reveal the laws of asepsis. What remains, then, to be done? To diminish the dangers of narcosis. What is wanted is sufficiently shown by the ever recurring recommendation of new and improved inhalation-anesthetics, such as ether, ethyl-bromid, pental, etc. Among these, local anesthesia claims the first rank.

For operations of medium importance, in which I include simple uncomplicated laparotomy without extensive adhesions, amputations of the breast, and removal of large tumors from other situations, there can now be no question of the efficacy of infiltration-anesthesia. It will be the task of the future to render this matter of proceeding, in principle unassailable, practical for surgical purposes in still more serious and extensive operations. I have so far operated upon 521 patients painlessly and without a sign of danger. Among these I might mention such operations as nephrotomy, herniotomy, removal of sequestra, amputations of the mammae, removing glands from axilla, and laparotomies. It must never be forgotten that chloroform narcosis increases the danger of the operation. This danger is incalculable. Even the most circumstantial statistics can not tell us anything definite as to whether the danger be great or small for the individual. But how many dangerous cases of asphyxia of this or that kind, even of the deaths happening hours or days after the use of chloroform come to our knowledge, but are never in our statistics!

"General narcosis" is not the ideal method for the patient or for the physician; if I operate upon one part, why should I deprive the individual wholly of his consciousness and force him to give himself helplessly into my hands? especially if, as frequently happens, I am obliged to deprive him of consciousness not in the form of a quiet, delightful sleep, but too

often only after a struggle followed by anxiety about the eventual danger of the narcosis.

Of 537 operations, I have used chloroform in only 16 instances, and then in cases where an especial exigency demanded it as, for instance, insurmountable fear, hysteria, the personally expressed wish of the patient and failure of local anesthesia.

I now consider myself no longer justified in making use of general narcosis in my operations, unless the method of infiltration-anesthesia has been previously tried. To perform operations under chloroform or other narcosis, when they are certainly practicable with one or other form of local anesthesia, I must, from the standpoint of humanity, denounce as absolutely unjustifiable.

Königgrätzer Strasse. 47.

ARTIFICIAL HYPEREMIA IN THE TREATMENT OF DELAYED UNION.

Read before the Mahoning County Medical Society, April 9, 1894.

BY W. H. BUECHNER, M.D.

CONSULTING SURGEON TO ST. ALEXIS HOSPITAL, CLEVELAND.
YOUNGSTOWN, OHIO.

In 1875, Nicoladoni¹ published an article upon Dumreicher's method of treating threatened pseudarthrosis. The underlying principle of the method was the production of hyperemia at the seat of fracture by means of compression above and below that point. The method demanded the use of graduated compresses, extra splints, etc., and was quite complicated. It does not seem to have come into general use, as Bruns² says he only knows of five cases where it was successfully employed. H. O. Thomas,³ of Liverpool, recommends a similar method, combining with it, percussion. He endeavors to produce severe irritation at the seat of fracture by vigorous percussion—sometimes in anesthesia. After this he seeks to retain the congestion by elastic constriction above and below the part percussed.

In a paper read before the German Surgical Society in 1887, Helferich⁴ proposed to employ artificial hyperemia, produced by elastic constriction, in the treatment not only of delayed union, but in that of bone cavities produced by operative procedures, and in cases of infantile paralysis, congenital dislocation of the hip, and other conditions in children where an increased growth in the length of the bone is desired. I have had no experience with this method in other cases than those of delayed union. The object of this paper is to once more bring this comparatively unknown but very efficient method before the profession, and to report my experience with it in a limited number of cases.

Helferich proves, by citing cases where an increased blood supply, caused by some pathologic condition produces a thickening of bone in adults, and a lengthening, or thickening or both in children, that hyperemia plays a prominent part in the formation of new bone. He gives warning, however, that it will not cause the production of callus but will only increase it when started by some other natural or artificial means.

To illustrate the technique of his method, Helferich takes a fracture of the humerus for an example. He first applies a flannel bandage from the fingers to a point about an inch and a half below the fracture; at the same distance (an inch and a half) above the fracture he applies a piece of rubber bandage or tubing tightly enough to retard the return of the

venous blood but not to interfere with the arterial circulation. This produces a marked congestion in the parts surrounding the fracture and left uncovered by the bandages. At first the constriction is only allowed to remain a short time, but the duration of its application is rapidly increased until it is soon left on day and night. I have found its almost continuous application for a period of ten days sufficient in the cases in which it has effected a cure.

During the use of this method, the fracture should be properly immobilized. In the case of the upper extremity, this is easily accomplished by the use of splints. In fractures of the leg, a plaster-of-paris dressing is employed and the constrictor applied at its upper margin. To admit of the swelling and congestion at the desired point the plaster dressing is applied quite snugly, the part where the congestion is desired being either heavily padded with cotton or large fenestræ being cut in the dressing. In fractures of the femur the Buck extension is used, the flannel bandage and constrictor being applied *à*s in the case of the humerus.

This method may be employed alone in cases of delayed union, but is only of use in the treatment of pseudarthrosis subsequent to some operative procedure. The time of its application after an operation depends upon the condition of the wound. As a rule it should not be applied until union of the soft parts has taken place, still small granulating spots offer no contra-indication for its use.

This method should not be used where there is any tendency to a varicose condition of the veins. Helferich says it will not produce this condition in normal vessels.

Helferich reports eight cases "in which at the time a fracture is usually healed there was very little or no callus." Six were fractures of the leg and two of the thigh. By the use of this method alone he accomplished a cure in each case in a few weeks. He also reports four cases—three of the leg and one of the forearm—in which it was employed subsequent to the nailing together of the fragments. All resulted in cures.

Six cases which were treated by this method have come under my observation. Four of these occurred in Volkmann's clinic at Halle, Germany, during my connection with that institution, and two in my own practice. Of the four hospital cases three were of the humerus and one of the radius. The fractures of the humerus were all healed, that of the radius was not benefited. One of the cases of fracture of the humerus was of particular interest in showing the utility of the method. The patient, a man about 40 years of age, had two years before sustained a compound fracture of the humerus which resulted in pseudarthrosis. Six months subsequently the ends of the fragments were resected and the bones wired together. His condition was not improved and in another six months the operation was repeated. He derived no benefit from the second operation, and at the end of a year returned to the hospital where, for the third time, the resection and wiring was done. As soon as the incision had healed the elastic constriction, as described here, was applied. In ten days a marked callus could be felt and a few weeks later he was discharged with the fracture firmly united.

A subsequent operation upon the case of fracture of the radius, mentioned above, revealed the fact

that there was a loss of substance of the radius and an interposition of muscle between the fragments. My own two cases were fractures of the upper third of the humerus. In the first, a young lady of 25, the constriction was applied four weeks after the injury. It resulted in no benefit. The case then drifted into other hands and I am unable to state the present condition of the arm. My second case was a youth of 20. Four weeks after the accident no callus could be felt. After a week of the above described treatment an abundant callus had formed and a month later he was discharged, cured.

These cases, together with those reported by Nicoladoni, Thomas and Jones,⁵ where methods involving the same principle were used, indicate that in constriction and the resulting hyperemia we have a valuable adjunct to the better known methods of treatment in delayed union and pseudarthrosis.

LOCAL TREATMENT OF PSORIASIS.

Read in the Section on Dermatology at the Forty-fourth Annual Meeting of the American Medical Association.

BY R. C. LONGFELLOW, M.D.

CINCINNATI.

Psoriasis stands in the front rank of those skin diseases whose course and duration is often chronic, accompanied by frequent relapses. This disease is one that often exhausts the medical man's storehouse of remedies, as well as his ability to keep the patient satisfied with his condition and treatment prescribed. One of the obstacles to proper local treatment is the usual objection of the patient to the remedies employed, their odor, staining qualities or ointment consistence. The essayist has no lauded specifics to offer, whose perfume or color charm the patient's nose or eyes, but desires to call out discussion on the few remedies which have been of any special value. Can these few remedies, whose objectionable features have been a vexed question, be dressed in new clothes that will give a less objectionable treatment to the patient? Can we use more agreeable remedies than the ones referred to, and hope to secure any favorable results or permanent cure? While this question is of lesser importance in hospital practice, to treat this disease successfully in private patients and yet not render them obnoxious to themselves or friends, is an important question. Some patients can bear with the scales, and keep from their friends the knowledge of their infirmity, yet the remedies prescribed by their medical adviser render them an object of inquiry. The object of local treatment is to macerate the scales, produce desquamation, and thus bring to the surface the hyperemic and diseased skin. In simple cases this can be done by hot baths—plain or medicated,—gentle friction, bland oils, or ointments rubbed in daily. These applications are allowed to remain for a few days, and then the skin is washed in a hot bath, with very mild friction by a cloth or brush. If the scales and patches are not large or extensive, they will yield to simple treatment, with free use of diaphoretics, covering the patches with oiled paper, and the maceration and desquamation will be sufficient. In the simple cases, the essayist

has had excellent results with the daily use of a hot bath—a toilet soap composed of green soap, 75 parts; washed sulphur, 25 parts; oil rosemary, 1 part. It lathers freely, and gives a very cleansing and refreshing bath, exerting the desired effect on the scales. One of the obstacles to satisfactory local treatment is to get the patient to remain the proper length of time in the hot bath, which is invaluable in softening and removing the scales. The vaunted springs that have been supposed to be specific in psoriasis can exert no special effect on the disease itself, but the regulation of diet, beverages, food, exercise, long baths, copious drinking of the water produces the improvement ascribed to the springs. If the patient at home would follow his physician's orders as faithfully and willingly as he does the printed rules of the springs, his reward would be greater improvement and more permanent results. No better method of removing the scales in chronic or severe cases exists than green soap thoroughly rubbed on each infected patch, and allowed to remain and dry. Such applications should be made every morning for a week; if possible, keep the patient well covered in bed during these applications, and give diaphoretics. In three to five days considerable desquamation will occur; after a week the patient should receive a hot bath, gentle friction being used; the remaining scales will be removed, exposing the hyperemic skin beneath. When the patient will not submit to going to bed, or is compelled to be at daily duties, and we can not use green soap as indicated, a 10 per cent. solution of green soap in collodion can be painted on the patches twice daily. Such a solution can be made by first rendering the green soap anhydrous, dissolving in smallest quantity of absolute alcohol, then adding the collodion. This method is more agreeable to patients, being a trifle less active than when soap alone is used, but the same result is accomplished. This method of using green soap prevents it from being rubbed off or soiling the linen, as the patient engages in his daily occupation. The collodion gives relief from itching, nor does the crust produce itching when several layers have been painted on and hardened. The irritation that green soap produces on some tender skins is overcome by the collodion. These applications are made twice daily for a week; then the loose, dry crusts are removed, the remaining ones loosening and coming off by the hot soap bath, gentle friction being used by cloth or hands. When the scales have been removed, the hyperemic skin must be treated by a remedy that will have a curative effect. Many remedies have been suggested and used without any special degree of satisfaction. During the few minutes allotted to this subject, only the three remedies will be mentioned which have been of real service and most used at the present time namely, *pix liquida*, *chrysarobin*, and *acidum pyrogallicum*. These are disagreeable agents in the matter of odor, staining qualities and ointment consistence when prescribed in the usual way. In some patients the use of tar produces a febrile condition, the skin is irritated and looks as though a dermatitis would supervene. The method of using tar which is least objectionable the essayist has found, is to make a 15 per cent. solution in collodion. Each patch is painted every other day until four or five applications have been made, then the layers of collodion being removed, the patient is given a hot bath, after which the tar is painted on as before. The odor of tar is greatly re-

duced in the collodion, and has the advantage over other methods in not being rubbed off or soiling the linen, yet loses none of its therapeutic effects. The irritation that tar sometimes produces is overcome by the local anesthetic effect of the collodion. Chrysarobin should be applied with caution and not allowed to extend beyond the area of the infected patch. It stains both skin and linen a yellowish color; frequently, even with caution, it will produce considerable irritation, or may have to be suspended. Applied once daily with care, the patches desquamate, the skin becomes of normal thickness and color, contrasting with the brownish color at the limit of the former patch. The method of Fox, to use chrysarobin combined with collodion, is the safest and least objectionable of the present modes of application. Infected patches should be painted once daily, or every two days, care being taken to limit its application only to the patch, as even when used most carefully troublesome irritation occurs in not a few cases. These applications, made for a week, should always be followed by a prolonged hot soap bath, while the general baths of non-infected parts should not be neglected. Pyrogallic acid, less active than chrysarobin, does not produce as much irritation of the skin as the latter remedy. In psoriasis of the head and face, pyrogallic acid is much better adapted for local treatment than chrysarobin, but if allowed to come in contact with the hair will stain. Too extensive or careless application of this agent has caused it to be absorbed, resulting in strangury, vertigo and vomiting. The safest and least objectionable of local applications to the head and face are salicylic acid in plaster or collodion, resorcin or aristol in ointment of roses.

DISCUSSION.

DR. OHMANN-DUMESNIL remarked that treatment of psoriasis of the scalp, especially in women, can not be effectuated by the means recommended by the speaker, and therefore he uses oil of cajeput, which he finds very useful and of easy application.

DR. BULKLEY recommended the use of white precipitate and bismuth in form of an ointment. He does not advise to wash the scalp too often, but he anoints it twice a day with this ointment, in the following formula:

R. White precipit., } aa ʒss.
 Bismuth sub. carb., }
 Acid carbolic, gtt. x.
 Unguent. ammon. roset., ʒij.

M. F. Unguent.

He believes, however, that 25 per cent. of the patients can be better cured by internal and hygienic means than with local treatment.

DR. FRANK is satisfied with the use of chrysarobin and pyrogallic acid, and with a salve consisting of ichthyol and vaselin.

PHYSIOTHERAPY FIRST: NATURE'S MEDICAMENTS BEFORE DRUG REMEDIES;
 PARTICULARLY RELATING TO
 HYDROTHERAPY.

Read at the last Semi-annual Meeting, in Ottawa, of the Rideau and Bathurst Medical Association.

BY EDWARD PLAYTER, M.D.

EDITOR CANADA HEALTH JOURNAL.
 OTTAWA, CANADA.

All through the records of the history of medicine—in the early Assyrian and Egyptian period, five or six thousand years ago, in the time of Æsculapius and of Hippocrates and down, as we find in modern uncivilized tribes, we have clear evidence that in the first or early steps in the science of medicine the

practice of the art consisted for the most part in the employment of magical incantations, the laying on of hands, etc., and was apparently somewhat of the nature of modern hypnotism, acting through the mind, as if the chief reliance in the healing of disease was upon the natural living forces within the body. We are here reminded of the old saying that "God made man upright, but he hath sought out many inventions." Although Æsculapius in his practice, we are told, enjoined first of all a hygienic regimen, attention to the diet, strict temperance and absolute cleanliness by frequent ablutions, and although the temples that were afterwards erected in his honor were built in the healthiest localities and the patients in them treated upon like hygienic principles, including rest and pleasing impressions, yet so far as we know it was Hippocrates who, practicing in a similar way, first drew special attention to the inherent natural curative force within the body, which he termed *phusis* (*φύσις*) nature, the *vis medicatrix nature*, of late Roman writers; while he also recognized subordinate forces which he termed *dynamis* (*δύναμις*), relating more particularly to the various organs of the body. Moreover, in practice this father of medicine allowed these forces to pursue unmolested and uninterrupted their benign course; and he was in practice it appears remarkably successful. Coming down through the obscurity of the Dark Ages, to two or three centuries ago, we find the discerning Van Helmont advancing the theory of a more specific healing force or power within the body, different from that belonging to inanimate matter, and which he personified as the "Archæus," or "Grand Regulator," a sentient principle seemingly distinct from the corporeal frame, whose throne was the stomach; Wepfer designating a like power as the "president of the nervous system;" and the bold Stahl attributing such an influence "directly and entirely to the rational soul, diffused over the whole body." And while we still continue to pour in drug remedies as our sheet anchor in the treatment of disease, the schools especially wave before us, perhaps not now so much as a few years ago, the endless and ever increasing drug formulæ of the Pharmacopœia as the Alpha and Omega of resource in therapeutics, leaving us to find out for ourselves in practice, through years of most bitter, most destructive experience, the futility and danger of most drug remedies.

A Metchnikoff now rises up and displays before our wondering eyes, as it were, the *vis medicatrix nature* actually personified—certain living cells in actual combat with disease germs; while other investigators teach us that there is generated in the body and found in the blood serum, itself, a germicide more powerful than corrosive sublimate.

It is not my intention to make a tirade against drug remedies. Some of them are of undoubted value in certain diseases, although as Prof. Erb, of Heidelberg, says, of "chemical or internal remedies:" "Here we enter upon a very obscure field which needs thorough cultivation. We know almost nothing of it; the little which therapeutic experience has taught us is neither securely established nor in any way scientifically or intelligibly founded." But I would like to deliver a vigorous tirade against the practice of the text-book makers and of the schools giving these remedies first place, usually, instead of the last, in the *Materia Medica*.

Many years ago I suggested at more than one meet-

ing of the Canadian Medical Association that the profession in Canada take the initiative and appoint a committee with the view of inducing the profession elsewhere to join and cut out about nine-tenths of the Pharmacopœia—and to separate the few grains of gold in it from the enormous amount of what is practically dross.

I will just mention here a few points relative to some of the dangers which may arise from drug remedies. On the 13th of the present month the *British Medical Journal* gives the report of "An inquiry regarding the importance of ill effects following the use of antipyrin, antifebrin and phenacetin, by the Therapeutic Committee of the British Medical Association." I can only give two or three lines of the ten to eleven close columns of the report, as follows: "The list of ill effects noted with antifebrin is not only a very formidable one in itself, but it loses none of this character when we consider the frequency of their occurrence." True it is that, as regards the freedom from ill effects of the three drugs, antifebrin is third and last; phenacetin being first.

We must admit, furthermore, that ill effects from the administration of almost any drug may be considerable, even serious, and not be manifested even on close observation for a long period of time; just as we know is the case with certain kinds of food consumed. And when we think for a moment of the complex and intricate nature of the physiologic and vital processes going on within the human organism, or of the susceptible nature of the digestive ferments, for example, we can readily understand, theoretically, that the introduction into the body in any way of but a mere trace of some chemical product, even one regarded as mild in its action, may interfere with or disturb, little or much, the processes of nutrition, as well as other functions. The same may be said in respect to disturbing in like manner the natural healing processes,—to interfering with the formation of nature's germicide, for example, or with the vigorous action of the army of phagocytes. For do as we will or may, nature ever reserves for herself the maximum of power in the direction of the processes of healing. In the words of a paper by Dr. Von Dunhoff, in the *New York Medical Journal*, of a few months ago: "I submit that, however efficient as germicides certain chemical agencies may prove to be in the laboratory, the same impracticability attends them in their adaptation to clinical issues, and renders the effect of their use here either *nil* or mischievous, as is the case with respect to the effects of many of the so-called chemical preparations, presumably prepared with the nicest precision as supplemented ingesta, intended for the correction of certain qualitatively defective conditions of the blood and tissues; and unless the inherent residual *vis resistentiæ naturalis* vouchsafes recovery, no man has yet attained the means of compelling such an issue artificially.

Experiments have shown that mice under the influence of chloral contract infections more readily than mice not under such influence; the chloral probably depressing or embarrassing the action of the phagocytes.

The millionth part of a drop of blood from a rabbit affected with anthrax may communicate this malignant disease to a healthy rabbit. Possibly a much smaller quantity than the millionth part of a drop, say the four-millionth part, would not communicate

the disease to the animal when it is in a natural vigorous physical condition. But who can measure the infinitesimal quantity of chloral for example or other drug which, having been first given to the healthy animal, might so depress the phagocytes in its blood as to enable the bacilli of the disease in the four-millionth part of a drop of the infected blood to come off conqueror, establish their colonies and the disease and destroy the life of the rabbit? Or who could weigh the mere trace of some of the depressing or soothing drug remedies commonly given in infectious pneumonia, or in the earlier or sthenic stage of some of the infectious fevers, which might possibly so interfere with the formation or action of the natural germicides in the body of the patient as to lessen the chances of recovery, or possibly to favor auto-infection?

Nor must we, moreover, meddle too far with benign nature even with our more natural remedies. No physician dare interfere with compensating hypertrophy of the heart in valvular disease. So in certain cases of epilepsy. In the works of Dr. Lyman, Professor of the Principles and Practice of Medicine, in the Rush Medical College, Chicago, in a recent address delivered before the Michigan State Medical Society on the "Limitations of Therapeutics;" "Though the paroxysms of the disease may have been suppressed and the patient apparently cured, or if not absolutely cured, greatly relieved for a long period of time, the patient will sometimes tell you that after all he would prefer not to continue treatment any longer. Not because dissatisfied with your methods or measures, but because he felt so much better when the disease was allowed to run its natural course, and because an explosion or convulsion at certain stated intervals seemed to give absolute relief, showing that the wisest and best therapeutic methods (or what appears to us to be the wisest and best) may nevertheless absolutely fail in giving to the patient that degree of comfort and satisfaction which we desire, but which nature knew how to bestow." So that it is sometimes better to bear the ills that we have than fly to others we know not of. True, if the cause or causes of the diseased state which gives rise to these explosive convulsions as a means of relief were first removed instead of the mere symptoms being treated, the result would be quite different.

Permit me, then, to mention in this connection, as a reminder, and we all need frequent reminders, the fact that, in the treatment of disease, there are two most important points to bear in mind: 1, to ascertain, if possible, by the most careful and thorough examination the cause or causes of the diseased condition or symptoms we are called upon to treat; and 2, to remove the cause or causes or prevent the recurrence of the same. Then, in very many cases, if we provide the ordinary essentials of health and life—pure air, water and sunlight, securing the utilization, through the respiratory organs of abundance of oxygen, with suitable food, clothing and rest, or it may be exercise, probably partial passive exercise, as in passive movements by another person or in massage, with the means of absolute cleanliness—abundance of water, dirt being so common a cause of disease,—then, usually, benign nature "will do the rest." Hence a very much larger proportion of the time given to the study of medicine should be devoted to the study of pathologic conditions and especially to the causes of these conditions.

The application of these natural remedies, the essentials of life, as above named, may be termed natural therapeutics. Or, if I may be permitted to coin from the Greek a new term, for I have never observed it in print, a term more in accordance with medical nomenclature than the words hygienic treatment, commonly used, I would suggest the term physiotherapy. Let us notice more in detail, yet briefly, a few of these therapeutic remedies.

PURE AIR AND SUNLIGHT are recognized by everybody as being most valuable remedies and restoratives, but they are not nearly so often prescribed and administered therapeutically to patients as they might and should be, and before drugs. Were they costly remedies and not free to all they would perhaps be more commonly prescribed. Besides, many people do not know how to breathe in, and get the full benefit of pure fresh air with its life-giving oxygen. They make only partial use of their respiratory organs. I have tried the experiment of inducing patients who suffered from weak, inactive lungs and consequent general debility, to draw in more fresh cool air at each inspiration, to "eat the air," as the Hindoos have it, and from this prescription alone great improvement has followed.

THE DIET being a common cause of bodily derangement and disease, we have in modifications of it and in feeding or fasting, a potent remedy. While many patients need feeding with a more nutritious or suitable, if not more abundant diet, many on the other hand require to let the digestive, nutrient and excretory organs rest by remaining in bed for a time and eating almost nothing—fasting. Regulation of the diet in these various ways has alone in my hands proved to be a very efficacious remedy.

A COMPLETE REST for the whole organism, in this rushing age, with feeding or fasting as indicated, probably a few days of fasting and many more of feeding, is not infrequently a prescription strongly indicated and much needed, and alone is often sufficient to restore health. And the "rest cure," as it is called, is becoming, as we know, a somewhat common practice. It is to be hoped it will not become too fashionable.

MENTAL INFLUENCE: Before noticing passive exercises and hydrotherapy, I may just refer to mental influence as a remedy. To this may be attributed the "miraculous cures," "we read about" occasionally; "faith cures" and the like. What physician has not witnessed the effects of mental influence exercised through the power of hope, in many cases of disease? Or of the power of a strong will in overcoming disease? I will allude to but one practical and direct example of the power of the mind over the body; that of defecation in constipation from a sluggish state of the lower bowel. Persistent concentration of the will upon the parts accompanied, not by straining but simply by the desire of action, will alone overcome many cases of habitual constipation. Massage will usually aid in producing and hastening the desired action.

Mention may be made, too, as associated with mental influence, of hypnotism with suggestion; not yet well understood nor generally recognized as a remedy.

ELECTRICITY is apparently destined to become an important remedy, and may also be regarded as a natural one, in the treatment of disease; especially as produced by friction or induction, usually termed

static electricity. With its small volume and high degree of force in this form it has already produced highly satisfactory results. The nature of its action not being yet well understood, its use is necessarily empirical and it is a very bonanza for quacks. True it is that many of our most valuable remedies have been brought into use in this way. It has not fallen to my lot to have had much experience with electricity. Indeed with the other remedies at command I have never yet experienced the need of it; the electrical effects of massage usually sufficing.

IN KINESITHERAPY, passive local movements or exercises, as in massage and the manual or mechanical movements commonly termed Swedish, we have a most potent remedy in a large number of diseases. It is a remedy the action of which we can readily understand, regulate and control. While the practice of massage—kneading, rubbing, percussing or tapping, is rapidly coming into general use, the so-called Swedish movements, which are of equal if not greater value, seem not to be so generally practiced.

The effect of these passive exercises of the muscular tissue, by either massage or the more natural movements, while readily comprehended, are sometimes almost phenomenal. Diseased conditions are removed by substituting natural healthy action. They aid the natural forces in eliminating morbid or poisonous accumulations from the system. In all forms of dyspepsia, in dilatation of the stomach, when the muscular tissue is weak and inactive, in helpless cases of rheumatoid arthritis, even of several years standing, in curvatures of the spine and other deformities, and in paralysis of motion, no other treatment is so applicable and successful; when combined, I need hardly add, with other hygienic remedies, especially with abundance of atmospheric oxygen and proper food, and in rheumatism with the warm bath.

In relation to kinesitherapy, I will only add that, in all cases of muscular asymmetry, with the accompanying want of uniformity in action and vigor, a condition which is the forerunner or cause of many diseased conditions, especially as found in gynecologic practice, and in which ordinary exercise is not admissible, no other treatment meets the requirements so completely. As Dr. Kellogg, of the Battle Creek, Mich., Sanitarium, says in "Modern Medicine and Bacteriological World," in his "experience with several thousand cases, lack of muscular development is the cause of a great share of uterine and ovarian displacements," and a "substantial cure can not be effected by any other means." In the majority of cases the patients can not take general "exercise" themselves, and these partial exercises supply the want.

We now come to the last therapeutic agent to which I shall draw attention, and which, indeed, I regard as the most important and valuable of all—the common element, water, in its various forms of application.

When we consider the broad fact that many diseases, functional and organic, if indeed there be any distinction, are caused more or less directly by dirt, dirt outside the body or within it, we can at once comprehend the value of water as a therapeutic remedy, and in its simplest form of application—water in which to wash and be clean. I need hardly refer to its value, as confirmed by the highest authorities, in washing out, with copious water or salt and water

injections, the intestines in cases of cholera. I believe it would have an equally good effect in typhoid fever. Nor need I refer to its value when copiously swallowed in washing out the entire internal structure of the human body, to the minutest recesses among the tissues, as when the organism has become loaded with the *débris*—the dirt, practically—of the ordinary functions of life, which has accumulated in the fluids and tissues from want of proper hygienic care or habits. We know that it is now the opinion of many physicians that it is to the copious water drinking in most cases, much more than to any mineral ingredients in the water, that many of the popular "springs" owe their popularity. Persons suffering from excess of waste matters, and the poisonous substances arising from the decomposition of these, in the tissues and fluids of the body, impure blood, receive at the springs a complete wash-out—a flushing—a succession of internal baths; they are simply washed and made clean.

But water, it need hardly be said, has as a medication a much broader application than is indicated in any of these pathologic conditions. Remarkable physiologic and therapeutic effects can be produced by the application of water in various ways and, on the whole, more safely and naturally than with drugs.

The only work in the English language which is not tainted with quackery, so far as I know, if we except the valuable treatise of Winternitz in Ziemssen's "Hand-book of Therapeutics," now practically out of print, is that on the "Uses of Water in Modern Medicine," by Simon Baruch, a physician holding many high positions in New York, which was published a year or so ago by Geo. S. Davis, of Detroit. If any of you are not in possession of this practical little work, I take the liberty of saying you should get it. It consists of two volumes of the "Physician's Leisure Library" series, and is very inexpensive.

Dr. Baruch makes this happy distinction between hydrotherapy and hydropathy: "The former accepting water as one important remedial agent; the latter regarding it as a universal remedy." To my mind, it is just about as Dr. Baruch further says: "While I emphasize my belief in all those drugs whose effects have been positively demonstrated in the laboratory and at the bedside, I espouse water as perhaps the most potent of all remedial measures; and upon the historical, physiological and clinical grounds succinctly set forth in the following pages,"—*i. e.*, of his book. Again, he continues: "The history of water as a therapeutic agent is not only a most interesting chapter, but it affords the clearest demonstration of the instability of therapeutic propositions, and the manner in which prevailing ideas influence them. Although the literature of the subject is the most extensive published with regard to any remedy, recent works on therapeutics treat it with a decidedly stepmotherly regard; they dismiss it in a few beggarly lines, preferring to devote their columns to essays upon the action of remedies whose actual clinical value is, in most instances at least, problematical. The history of water teaches clearly that no other remedy has so creditably passed through vicissitudes of depression; and that despite professional and lay prejudice, it stands to-day unscathed and rendered secure against assault by the panoply obtained from physiologic and bedside results."

A few words here on the history of hydrotherapy

will be both interesting and profitable. Hippocrates laid down rules for the treatment of disease by water, which even at this day are practiced by both physicians and quacks. Two and a half centuries later, Asclepiades, though it appears not possessed of much real medical knowledge, by his great natural ability and discretion attained eminence in Rome as a practitioner, depending almost entirely for his success on a judicious diet, massage and baths; by means of which he performed "miraculous cures." So warm an advocate was he of the water treatment that he was dubbed "Psychrolutus." Through Asclepiades hydrotherapy was popularized in Rome. He formed the school whence sprang Themison, Celsus and other eminent physicians. A pupil of his, Antonius Musa, restored the Emperor Augustus to health by the vigorous use of cold water; and he had Horace too for a patient. So grateful was the Emperor that he bestowed upon him and the whole medical profession the privilege of citizenship, and had a statue erected to Musa next to that of Æsculapius. Celsus, the "Latinorum Hippocrates," prescribed water freely; so did also Aurelianus, who originated the wet sponge abdominal compress for hypochondriacs. Galen was an advocate of cold water baths and was the first, it appears, to advise cold applications to the head while the body was immersed in warm water. We know but little relating to the history or practice of medicine in the many dark centuries which followed the time of Galen. Oribasius of the fourth century, Ætius of the fifth, Trallianus of the sixth, and Paulus Ægineta of the seventh, the most noted of their time, were all zealous Galenists and followers of his practice. Ægineta was an enthusiastic advocate of the use of water, and was the first to advise the cold douche in sunstroke. All the more eminent physicians of the next few centuries, during the more dense barbarism of Europe—Serapion of Damascus, Rhazes of Irak, Avicenna of Bochara, and Avenzoar of Seville, who, it is said, lived to the age of 135, appear also to have been disciples of Galen, following in his line of practice. Chemistry made considerable progress during that period, and there were many additions to pharmacy, and possibly but little water was used in any way until the dawn of the seventeenth century. The Hippocrates of England, Sydenham, holding the more enlightened view that diseased action consists essentially in a natural effort of the system to remove morbid or noxious products, his practice was, like that of Hippocrates, to assist nature. I can not learn that he relied much upon hydrotherapy, but a few years after his death, about the close of the seventeenth century, Sir John Floyer, physician, of Litchfield, England, published a "History of Cool Bathing, Ancient and Modern," a book which created an epoch in hydrotherapy, passed through six editions within a few years, and many years later was translated into German. Blair and Cheyne, English physicians of the highest standing, recognized hydrotherapy in their practice. The illustrious German physician, pathologist and clinical teacher, Hoffmann, was the first to distinctly recognize the influence of water upon the "tone" of the bodily tissues. After his time, during the eighteenth century, the use of water in medical practice became much more popular in Germany. The surgeon of Frederick the Great, Theden, was the first to use it in fevers, smallpox and rheumatism. He improved the shower bath and warmly advocated its use.

About this time, Hahn and his son and Oertel helped much to establish the principles of modern hydrotherapy in Germany, in both acute and chronic diseases. The work of the illustrious Currie, published in 1797, first placed hydrotherapy on a scientific basis, it appears. It advocated the use of water in gout and paralysis as well as fevers, and was translated into German and other languages. Although the practice of hydrotherapy was more popular in Germany than in England at this time, it is contended that it was by reason of translations of English writers, as Floyer and Currie. The practice of the latter was adopted in the Vienna hospitals. To mention the wise philosophic Hufeland as an enthusiastic and yet judicious advocate of hydrotherapy, as Baruch says, is to "give the imprint of true medical wisdom to it, and to indicate its wide adoption among the profession. He offered a prize for the best treatise on the action of cold water in fevers, determined by scientific thermometrical study." A Vienna professor was the successful competitor, whose treatise was published in 1823.

Notwithstanding all this, and more, hydrotherapy did not become generally popular until the time of the German farmer, Vincentz Priessnitz, who at his home in Grafenberg, Silesia, first received patients, enlarging his house as occasion required. In 1840 he had treated over 1,500 persons from various parts of the world, and twelve years later had amassed an immense fortune. "His success was brilliant because he was a careful observer, a good judge of human nature, and his mechanical skill enabled him to invent various technical modifications of the water treatment, many of which have been adopted by the profession and are still in use. A copious literature sprang up in all parts of the world, and many institutions were modeled after his. The government built roads to facilitate access to his establishment; monuments and fountains were erected to his memory. Physicians from all countries, who had been attracted to the mountain home, became converts to and missionaries of his practice." A few years later, Scut-titten, a French physician, after studying hydrotherapy in Germany, reported that, "the numerous permanent cures it has wrought recommend it," and it "lies in the interest of humanity and medical science that its practice in Paris take place under the eyes of able physicians." Magendie aided in the propagation of hydrotherapy by physiologic demonstrations. Fleury introduced douches, and explained his clinical successes on physiologic principles. Fever treatment as now practiced was initiated by Brand, who in 1861 published his startling results from immersions and compresses with water at 54 degrees to 68 degrees F. The practice was soon introduced into England by Wilson Fox.

Respecting the practice of hydrotherapy, as Niemeyer in his work on practice says: "A series of cases are on record in which complete and perfect cures have been obtained" by it, "after all other methods of treatment had been applied in vain." Dujardin-Beaumetz (lectures at l'Hôpital Cochin, 1887) said: "The benefits we obtain from cold water in the cure of disease arise from its physiologic effect upon the circulation, the nervous system, the nutrition, and from its revulsive and heat lowering influence." Prof. Peter, of Paris, in his preface to the great clinical work on hydrotherapy of Duval, writes: "Hydrotherapy suffices in most cases of disease; added to other treat-

ment, it is a most powerful auxiliary." Prof. Erb, in his classical contribution to Ziemssen's *Cyclopædia*, writes: "To the most important and most active agents in the therapeutics of our field (nervous diseases) belong cool and cold baths, viz., the application of cold water in the most varied forms; that which is usually termed cold water treatment. Having been in recent times practiced more rationally and studied more exactly, it has attained remarkable prominence. Its results in all possible forms of chronic nervous diseases are extraordinarily favorable. If we add to this the heightened skin and muscular action induced by various methods of bathing, the influence of diet, etc., it becomes evident that we possess few remedies which produce an equally powerful effect upon the nervous system." Semmola, Professor of Therapeutics in Naples University (lectures, 1890), says: "Hydrotherapy stimulates cutaneous activity, and with it all functions of tissue change and organic purification, so that often real marvels of restoration in severe and desperate cases are accomplished. Unfortunately, these remarkable results are more rare to-day than they were in the time of Priessnitz, of which I was myself a witness." In all cases of retardation of tissue-metamorphosis, he says: "Hydrotherapy presents a truly rational treatment, and therefore unfailling effects, unless the local processes have reached incurable limits."

I could give many pages of such quotations from our highest authorities as to the value of water in the treatment of disease, but the above will suffice.

About a year ago, Ravighi, at a medical congress in Rome, read a paper respecting the effects upon the blood cells of the application of water, as shown by experiments he had made on men and rabbits. In March last, Prof. W. Winternitz, of Vienna, published (in *Cent. fur Klin. Med.*) a contribution on the same subject. Since that time, investigations by Dr. W. S. Thayer, of the Johns Hopkins Hospital, and more recently still, studies at the physiological laboratory at the Battle Creek Sanitarium, have verified the results of the other investigations. In "Modern Medicine" for December is a translation by Dr. J. H. Kellogg of another article, which had just been published by Winternitz (*Blat. fur Klin. Hydrother.*) on the same subject. All these show clearly that the application of water, apparently hot or cold, to the surface of the body produces an increase, sometimes large, in the red corpuscles, leucocytes and hemoglobin in the circulating blood. Winternitz reports: "The maximum increase of red blood corpuscles observed in fifty-six persons examined, was 1,860,000 per cubic mm. The maximum increase of leucocytes was to the extent of three times the ordinary number. The maximum amount of hemoglobin observed was 14 per cent."

At the late Pan-American Medical Congress in Washington, Dr. Baruch, opening the discussion relating to the value of cold water in asthenia, mentioned the astonishing effects of the cold douche. It rouses the circulation and "sets the wheels of life again in motion" in the very climax of this condition—with "thready pulse, shallow breathing, dull eye, picking at bed-clothes, subsultus, involuntary defecation,"—(*Therap. Gaz.*, January, 1894) in any febrile condition, scarlet fever, etc., which no known drug remedy, not even alcohol, will produce.

I will but mention, what some of you may not have read of (in *JOURNAL OF AMERICAN MEDICAL ASSOCIA-*

TION and *New York Medical Journal*); the Schott method of treating chronic heart disease by warm baths aided by muscular exercises. During the baths there is a reduced frequency of the pulse, with increased volume and strength and less irregularity. This effect is lasting, and a gradual amelioration of symptoms follows persistent treatment. It is said this treatment is applicable to a greater variety of cases than is Oertel's method. Schott medicates the baths by salines or carbonic acid; but their value is probably almost solely from the regulation of the circulation by the temperature of the baths. This I believe from personal experience.

Permit me in conclusion to say a very few words in respect to my own limited experience in the practice of hydrotherapy. In the latter part of my teens, having been a pretty hard working student, I was troubled a good deal with indigestion and a consequent want of good general health and vigor. In opposition to the wishes of my father, who was bitterly opposed to any semblance of quackery, and after having taken a good deal of medicine from the best physicians in the country, under pretence of visiting friends during holidays I placed myself under the care of a Mr. Brown, who had during the time of Priessnitz a popularity which it appears extended to the uttermost parts of the earth; and started a hydropathic establishment, or "Water Cure," in Newmarket, Ontario, near my home. Brown had but little medical knowledge and his failures probably outweighed his successes; but the "cold wet pack" or "sheet bath" and other forms of water application which he prescribed benefited me, and were the starting point of my faith in the value of water in literally washing away disease. During after years of laborious country practice, and many of them, although the want of available correct literature on the subject was a great drawback to me, I frequently availed myself of water as a remedy. Especially in copious draughts of it as a most certain and efficient diuretic and diaphoretic, directly unloading the cutaneous tissues and urinary organs, and through them in a large measure the entire body, of accumulated obstructing matters; as hot and cold compresses in local pathologic disturbances; as a tonic in the form of a cold sponge or shower bath; as a most soothing regulator of the entire organism in the form of a warm bath; and in other ways. Of one thing I feel certain; I never in my practice knew the free use of water to do any harm. This, neither you, I think, nor I can say of drug remedies. When weary and exhausted from riding all day and perhaps all night in the saddle or a two-wheeled chaise nothing, be assured, will rest and recuperate, soothe the irritated nerves and equalize the disturbed circulation like a warm bath, at a temperature of 93 or 94 degrees to 97 degrees F. Having spent many an hour reading in such a bath, I speak from personal experience. And now, largely as a consequence, when not very far from being 60 years "young," I feel better, more vigorous, youthful and clear headed than when at half the age. The warm bath has a high reputation, too, for warding off the effects of age. There is no other remedy so refreshing and invigorating. Thus Minerva is said to have imparted renewed vigor to the wearied limbs of Hercules. And over two thousand years ago, Hector's wife prepared warm baths that "returning from the fight," at Troy, "Hector might be refreshed."

"Not yet the fatal news had spread
To fair Andromache of Hector dead;

"Her fair-haired handmaids heat the brazen urn
The bath preparing for her lord's return."

SOME THINGS THAT SHOULD NOT BE FORGOTTEN BY THE GENERAL PRACTITIONER.

BY B. C. KEISTER, M.D.

SOUTH BOSTON, VA.

In a previous communication under this heading, I endeavored to bring out a few salient points of interest to the general practitioner. It is my present purpose to emphasize a few minor points that often escape the notice, but which should have the due consideration of the entire medical profession.

The first item of general interest that presents itself to my mind, is the patent medicine fake. It is passing strange that this great evil should be allowed to assume such wonderful proportions in this advanced age of civilization and superior education. It is no less strange that laws have not been enacted to abolish an evil whose deleterious effects upon the constitutions of its victims are so apparent to every observing mind. How preposterous the idea seems for an intelligent being to take into his stomach a mass of things that he knows nothing *under heaven* about, except through the flattering, false description that he reads in a newspaper, whose editor knows no more about it than he does about the function of the vermiform appendix. This evil is gradually assuming greater proportions every year, and I must frankly say it is a *burning disgrace* to our boasted civilization, as well as to the medical profession, that such is the case. It is *high time* for us to act in the matter. As conservators of the public health, and well-wishers of our fellow-mortals it is our duty to take the initiatory steps toward stamping out this great destroyer of human health and impoverisher of the sick poor. It is no strange sight in these times of financial depression, to go into a well-to-do household and see in some secluded corner or on the pantry shelf, a dozen or more empty bottles that bear the obnoxious titles or trade-marks of as many varieties of nostrums, such as "Dr. King's New Discovery for Consumption," "Chamberlain's Cough Remedy," "New Great South American Kidney Cure"—that cures all forms of kidney disease in six hours. These are but historic guide-posts to the physician as he enters an adjoining room and there beholds the victim of these empty nostrum bottles, lying on his sick bed nigh unto death's door. During the brief intervals of coughing and attacks of short breathing, the dying man begins his tale of woe, by telling of his neglected bad cold, and then of the newspaper accounts of "Chamberlain's Cough Remedy" that his neighbor Brown told him to get for his cough; not getting any better, he tries several bottles of "Dr. King's New Discovery for Coughs and Consumption." He next tells about his first night sweats, which occurred some weeks previous, and of their weakening effects. After trying the last named medicine some time and finding no relief, he decides that his kidneys are diseased, as his urine has become more scant and his night sweats more profuse; hence he tries several bottles of the "New South American Kidney Cure" which his druggist recommended to him through his oldest son, John,

and sent him several papers containing a full description of its magical effects in curing all kidney diseases in the short space of six hours. Ere he could finish his tale of woe, the dark shadows began to hover about his placid brow, and while his trembling lips were growing pallid, the curtain was drawn and death claimed the old man as a victim of patent medicines. This is but an illustration of what, too often, occurs under the observation of the general practitioner. Now let every physician who feels any pride in his profession, and who has a spark of genuine sympathy for the well-being of his fellow-creatures, resolve to put forth his best effort in his own community to get laws enacted, by our Legislatures, by which the human family may be spared the penalty of this popular (?) curse. Why not follow the example set by the State of Iowa? This State passed an Act recently, requiring all firms that sell patent medicines in that State to have the formula plainly printed and labeled on each bottle that is offered for sale, under a heavy penalty, in case of violation. This will enable the physician to judge as to the merits or demerits of the contents of the bottle. And, inasmuch as these preparations have no merits, it is reasonable to suppose their vendors will not submit them to this test, hence will stop their sale in the territory that requires these restrictions.

One of the fertile sources of this evil, as it now exists, is the counter-prescribing druggist, whose desire for "filthy lucre" crowds out all other considerations. It is no uncommon occurrence, in this fast age, for a druggist to assume the role of doctor, and undertake to treat private cases who are too ignorant and penurious to employ a regular physician, and as the *wise* (?) druggist indicates a willingness to undertake all such cases, the physician is thus deprived of his licensed privilege. The counter-prescribing druggist will also show his want of respect for the medical profession by advertising his "cure-alls," such as his "chill pills" (for malaria), "dinner pills for the digestion," etc.

Now, what shall we, as regular practitioners of medicine, do, in remedying such discrepancies? After mature and deliberate consideration, I have come to the conclusion, that the best and only way out of these embarrassing difficulties, is simply and plainly for every general practitioner who feels so disposed, to fill his own prescriptions at his office. This may seem to some a very ludicrous and selfish idea; but to me, it seems the only alternative by which to keep our noble profession independent and free from the blighting intrigues and contaminating influences that are making such rapid inroads upon her domain. I do not mean to reflect upon the true, gentlemanly, professional druggist, who would disdain to stoop to such low and unprofessional acts. Hence, what I have said applies only to the counter-prescribing and patent medicine-advertising druggists, and it is to the detriment of both professions that there is such a large percentage of this latter class of druggists. Like unto our own profession, there are many "crooks" and unprofessional men, who should be shown up to the profession in their true colors.

And just here let me call to mind the terrible fact that we have men in our profession who, from lack of medical knowledge, have allowed themselves to get into the habit of prescribing and indorsing patent medicines. In talking with a druggist on the hum-

buggery and imposition practiced on the ignorant public in the sale of patent medicines, I was astounded when he told me that several of my brother physicians had been prescribing some of the patent medicines he kept in stock. Just think of a physician prescribing for a sick person something that he knows nothing about!

While we are looking so carefully after the health and interests of the public we must not lose sight of our own peculiar interests, but ever be watchful of the malignant diseases, like the eating cancers, that are constantly threatening the vitals of our profession. Whenever a physician becomes too negligent and careless to prescribe well-known and tried remedies for the relief of suffering humanity, he then becomes a *nonentity* to the profession.

If you will pardon the digression, I will give you the benefit of a ridiculous yet practical, anecdote a brother practitioner related to me about his ludicrous experiment with a patient who was very fond of taking patent medicines. The Doctor stated that his patient was one of those chronic grumbling fellows who had lost faith in doctors, and as a last resort made up his mind to try patent medicines, and asked the Doctor if he knew of any *special one* that *might* suit his case. The Doctor told him to return to his office in the course of two or three days, when he would have something that would suit his case precisely. He then secured half a dozen large bottles and, after having them filled with *stale horse urine*, went to a drugstore and in a sly way secured a lot of old surplus patent medicine labels. He took the labels to his office and pasted them on the six bottles of *stale horse urine*, carefully adjusting the patent medicine wrapper, containing a glowing description of the magical effects of the medicine, etc., and set them aside for his patient. The following morning the patient called, and asked the Doctor about the expected medicine. He was given one of the bottles and told to take the medicine in tablespoonful doses three times daily, before meals (according to the printed directions on the bottle). The patient returned after taking the first bottle and told the Doctor that he thought he had struck the right medicine at last, adding that he was improving very fast, and his appetite was better than it had been for the previous six months. Suffice it to say, he paid for the six bottles and ordered a half dozen more. The Doctor informed me that his patient got entirely well under his novel treatment and paid him ten dollars for the dozen bottles of *stale horse urine*.

This is a practical illustration of the patent medicine fake of the present day.

A physician can fill his own prescriptions at his office very effectually and successfully to both himself and patients, and this will prove a means of self-defense in our warfare against counter-prescribing druggists and the patent medicine fake. Go back with me to the days of Galen, when drugstores were unheard of, and patent medicines were not dreamed of; or, if you please, to the more recent time of McDowell, when it is said that doctors made as much clear money from the sale of their medicines at their offices, as the general practitioner makes at the present day from writing prescriptions. There were but few prescription drugstores then, and these were confined to the larger cities, hence the doctors ordered their medicines in large quantities from the cities.

And just here, let me say, there were no patent medicines on the bill of drugs ordered by the medical men of that day. The medical man was honored for his worth, and the medical profession was free from the intrigues and trickery that curse it at the present day.

What is there to hinder a general practitioner from having a special apartment arranged in his office for the express purpose of keeping all the standard medicines that are in daily use, and also, have his prescription desk, printed labels, bottles, boxes, etc.; in short, all that constitutes a regular outfit for his business? Will it not more than pay? Will he not get the druggist's 50, 100, yea, 250 per cent. on his outlay? I answer, Most assuredly. Any physician, who wishes to do so, can get the very same rates on medicines from the large wholesale drug houses, that the druggist gets. I know whereof I speak, as I am experimenting along this line. Take, as an illustration, the syrup of hydriodic acid, which costs the druggist \$3.50 per gallon, or 2½ cents an ounce. He sells a four ounce bottle of this to a patient for 50 cents. Now, allow for cost of bottle, label, work and medicine, say, 15 cents. He thus clears 35 cents. Take Fowler's solution of arsenic, which costs the druggist just 20 cents a pint, or 1¼ cents an ounce. The druggist will sell an ounce to a patient at from 25 cents to 40 cents. Now, why should not the doctor have a share in this immense profit, regardless of the claims of the counter-prescribing druggist?

These are plain *hard sense* facts, and worthy the consideration of all general practitioners of medicine who wish to rid the profession of some of the obstacles and chicanery that are damaging our honor and lowering our standard.

SELECTIONS.

THE USE OF TRICHLORACETIC ACID.

BY DR. STANISLAUS V. STEIN,

PRIVATDOCENT IN THE MOSCOW UNIVERSITY, MOSCOW, RUSSIA.

Translated, and read before the Milwaukee Medical Society, May 8, 1894.

BY H. V. WÜRDEMANN, M.D.

MILWAUKEE, WIS.

Director Wisconsin General Hospital; Oculist and Aurist, Children's Hospital; Oculist and Aurist, Milwaukee County Hospital for Chronic Insane; Instructor in Eye, Ear and Throat, Elms Hospital; and to the Milwaukee County Hospital Training Schools, etc.

[Since the publication of Gleitsmann's articles¹ upon the use of trichloroacetic acid two years ago, I² have been in the habit of using this application in much the same manner as is recommended in the following translation of an article by Dr. v. Stein. In some thousands of applications I have yet to learn of re-active inflammation or erysipelas following its use. It renders potential cauterization safe even when abundant causes of infection exist, and galvano-cauterization, in conjunction with the after application of trichloroacetic acid, may be resorted to with impunity where otherwise we would dread the possibility of septic infection. In several instances where I have neglected its use I have had severe reactive inflammation and in two cases facial erysipelas after potential cauterization, but have always had uniform rapid healing where it has been applied. The same may be said of its use as indicated by the author after chromic cauterization, which I have now used with satisfactory results for over one year.—H. V. Würdemann.]

(The following is translated from Dr. v. Stein's article in the *Monatsschrift für Ohrenheilkunde*, January, 1894).³

The excellent caustic and astringent qualities of trichloroacetic acid upon mucous membranes, which I first wrote about in a previous article (1889), have since been corroborated by a number of observers. Some additional good therapeutic properties of this acid which I have had occasion to note during the last two years have been little, if at all, considered by others.

1. I showed in my first article that a solution of trichloroacetic acid of the strength of 1:500–2000 kept all suppurative processes in abeyance for a week. Therefore I recommended the same to cure acute rhinitis in the first stage, to secure disinfection of the eschar after galvano-cauterization and after bloody operative procedures.

In coryza I have noticed that a half teaspoonful of a 1 per cent. solution dropped lukewarm in either side of the nose, two to four times a day, produced an abundant secretion of mucus and improvement of the subjective symptoms. Since using this as a prophylactic method, I have seldom observed consecutive ear inflammation in those patients who usually had the same during the fall and spring of the year. I would explain this favorable result both by the anti-bacteriologic action of the acid and by the imprisonment of the microorganisms in the coagulated secretions. Accordingly, I sought for other agents more stimulating to the mucous membranes of the nose, and found a satisfactory one in uranium acetate.

R. Uranii acetici 0.05
Aquæ dest 10.00

M. S. A couple of drops lukewarm in each side of the nose two to three times a day.

2. Weak solutions of trichloroacetic acid used in the nose in simple atrophic rhinitis for a considerable time sometimes produce such a decided hypertrophy of the turbinated membranes that it may become necessary to cauterize them in order to secure free breathing. No other medicine of which I am cognizant produces such a remarkable effect, and thus this agent is particularly applicable in the treatment of ozena.

3. In true ozena I now apply much stronger solutions than I did at first; *i.e.*, ½ to 10 per cent. The odor is not so quickly nor so safely abolished by any other medicinal agent as by the acid. Here it is certainly a specific. Sometimes I combine it with iodine (glycerin-kalii-iod. pur.), especially in syphilitic cases.

For the best results it should be applied in the following manner: I begin with a weak solution, 1 to 2 per cent., and use this so long as there is improvement, and afterward using the stronger solutions. It is not proper to begin with a strong solution, as at first many patients are unable to bear them. In many cases the fetor is stopped in a couple of days.

For the application I use a probe 20 cm. long and 2½ to 2 mm. thick, which is grooved on each end. One of the ends is bent in order to get under the turbinated body better. Upon one of the grooved ends hygroscopic cotton is wound in the form of a bead. For each application a small amount of solution is *dropped* upon the probe, and in this manner the other portion of the solution is kept pure. The hardest part of the treatment lies in thoroughly but gently massaging the medicine into all parts of the

nasal passages, and to continue this method until the crusts no longer form. This procedure is done at first two or three times a day, if it causes no irritation. As soon as the fetor is removed and the crusts are softened it should be applied once a day. In a couple of visits, under the direction of the physician, the most uneducated patient learns the necessary manipulations. Hemorrhage is readily stopped by cotton wool tampons. Zinc ointment or ordinary vaselin may be used in the anterior nares of those patients with delicate skin or tendency to eczema.

By the above described treatment, the fetor is always controlled in my patients; the crusts are softened, are without odor, and are easily blown out of the nose. In many cases the procedure should be repeated once a week to guard against a relapse. In none of my cases did the odor return.

4. If a little white of egg or blood serum be precipitated by chromic acid, and another portion by trichloracetic acid, and the coagulum well washed with water to remove the excess of the acid, it will be remarked that the albumen treated by trichloracetic acid forms a tough membrane while the other is readily broken into pieces.

Upon being kept in Petri's cups, a putrid odor soon arises from the chromic albumen, while the acetic albumen becomes covered over with a moldy scum without odor. In the last case, the putrefactive germs, except when inoculated in a mass, have an unfavorable environment for their development. From this observation I was brought to use trichloracetic acid for disinfection of operations in the nose, the naso-pharynx and pharynx, in order to procure in this way assured antisepsis. I have used this method in a number of thousand of cases in private practice and the out-patient department of Prof. Osbroumoff's clinic of Moscow, Russia, and always with satisfactory results, in that the subsequent history was free from fever and that the wounds heal quickly without infection, even in those persons in whom the opposite had been previously observed. Only one very nervous student, out of all the patients, complained of chills after the cauterization. Before this, I often had consecutive tonsillitis and feeling of stoppage in the ears after galvanic or chromic acid cauterization of the posterior parts of the turbinated bodies.

Accordingly, after cutting operations, I usually put a crystal of trichloracetic acid on the edges of the wound, but use it in a different manner upon the galvano-cauterized surface. In the latter instance the burnt part is divested of its water so that the crystals do not liquefy except upon the edges of the burn. I apply here a strongly concentrated solution, (as this acid is very hygroscopic, if the cork of the bottle containing crystals be kept open for a few hours such a solution may be obtained.—*Trans.*)

The end of a silver probe one mm. thick is wound about with a little cotton, wet with the solution and applied several times to the spot. The eschar becomes snow-white and closely adherent. The course of such a galvano-cauterization is without reaction like that of ordinary trichloracetic cauterization. The slight pain resultant is of shorter duration though a little sharper than that of chromic acid or the galvano-cautery. Trichloracetic acid is given the preference indisputably by many observers for all other effects. After the scab drops off, the wound should again be disinfected.

The same satisfactory results follow chromic acid cauterization followed by application of trichloracetic acid. I must here speak of a peculiarity. If the nasal membranes are but lightly touched by a chromic acid crystal or the concentrated solution, and the superfluous acid removed by a pledget of cotton and the spot again treated by trichloracetic acid, a deep groove may be made similar to that obtained by galvano-cauterization. The reaction is also but little. The application of the two acids is to be particularly recommended in the case of young children.

Trichloracetic acid may be used alone when the hypertrophy is not great. The most satisfactory results are obtained when the areas to be cauterized are weak in elastic tissue. For this reason, turbinated hypertrophies eligible for this treatment are those which are readily contracted by cocain. For greater degrees of thickening, the results are more quickly obtained by the galvano-cautery combined with trichloracetic acid. Acetic acid alone gives less satisfaction in these catarrhs characterized by loose hanging hypertrophied membranes with very abundant flow of mucus, (several handkerchiefs a day) such as is common in children. This may be explained by the fact that the acid becomes weakened by the reaction and loses its (caustic) properties. Chromic acid gives the same result and the secretion may only be controlled by energetic galvano-cauterization, followed by the trichloracetic acid application.

I take away polyps and polypoid growths by the galvano-caustic loop and afterwards apply acetic acid. For experiment in several patients, the cauterization was done in one side of the nose, and omitted in the other. In these cases the patients complained of an unbearable pressure on the one side of the nose (not so treated) occasional pains and abundant flow of irritating mucus.

5. An important factor in the use of trichloracetic acid is that after its use no adhesive inflammation of neighboring portions follows, such as often occurs after chromic acid and galvano-cauterization. This kindly action has allowed me to use the galvano-cautery with after-application of trichloracetic acid upon growths of the nasal septum in very narrow noses without danger of adhesion, in order to pass in the Eustachian catheter, and also to blow out pus deposits from the antrum of Highmore and the frontal sinus.

The results in inflammations of the pharynx are similar to those obtained in the nose. In deep infiltration of the membranes, trichloracetic acid acts superficially and slowly. In other forms, healing is quickly obtained. In follicular tonsillitis following upon acute inflammation the swellings are reduced to their former size after two or three cauterizations. In those lacunar tonsillites in which considerable pus is contained deep in the tonsillar crypts, and in which exacerbations occur every few months or in some cases at intervals of years, I carry the trichloracetic acid crystal upon a fine bulbous-ended and cupped silver sound deep into the crypt. When the mouths of the crypts are greater, I take a fine silver canula three mm. thick in which is contained a piston-like wire with a couple of rings for the fore and middle fingers. To use this pistol-shaped instrument the wire is drawn a little way in and a couple of the crystals laid in the lumen of the canula. Then the bent end is inserted deeply but gently into the crypt and the wire pushed with the thumb on the button.

The entire manipulation, even without cocain, is painless as long as the application of the acetic acid is limited to the tonsil. The application is renewed after the disappearance of the white eschar. The healing is most happy. The submaxillary glands diminish in size and become indolent.

In an old hypertrophic tonsillitis, pharyngitis granulosa and retro-arcualis with proliferation of connective tissue, galvano-cauterization followed by application of trichloracetic acid is most applicable. The result is always recovery without fever and without reaction. Only during the same day is there difficulty in swallowing.

The application of trichloracetic acid in the ear is painful but is of use for small granulations. For these cases I recommend resorcin. Chromic acid is better for larger polypi. When its use is followed by a highly putrid discharge this may be rendered odor-

less by touching the scab accurately with a concentrated solution of trichloracetic acid. In order to protect the walls of the meatus from harm, it is necessary to smear it well with vaselin and to push in the ear speculum deeply. The excess of acid should be washed out.

(The translator has never used trichloracetic acid in the ear on account of severe neuralgic pain thereby produced. Polypi and other growths are better removed entire than to be slowly burnt out by acids.)

Dr. v. Stein here describes a set of five fenestrated nose specula of different lengths, the use of which is hardly necessary for any one skilled in exact manipulation. Gleitsmann's applicators for the crystallized acid, and the bent probe or Bosworth applicators wound on the end with a minute quantity of cotton, used under strong illumination by the forehead mirror, the nares opened by the dilating hand speculum, are all that are required in educated hands. 805 Grand Ave.

SOCIETY PROCEEDINGS.

The Illinois State Medical Society.

Abstract of the Proceedings of the Forty-fourth annual meeting held at Decatur, May 15, 16 and 17, 1894.

FIRST DAY—MORNING SESSION.

The Society convened in Powers Opera House, and was called to order by the President, Dr. O. B. Will, of Peoria, at 9:30 A.M.

Prayer was offered by the Rev. W. H. Penhalleton.

The reports of the Executive Committee, Committee of Arrangements, and Committee on Registration were read and accepted.

Section 1.—Chairman, Dr. T. J. Pitner, Jacksonville; Secretary, Dr. H. McKennan, Paris.

Dr. J. FIREBAUGH, of Robinson, read a paper entitled

MISTAKES AND SURPRISES IN GENERAL PRACTICE.

The paper consisted of a report of several instructive cases. The essayist said the errors of the physician lived on in his memory, while his patients may be covered up in the ground. It has been his observation during almost twenty years' country practice, that the cases in the management of which he had been conscious of some error, either in diagnosis, prognosis, treatment or general management, however hard it may have been on the patients, were just the ones of which he had thought the most, and

therefore just the ones which had been the most instructive to him.

Dr. N. S. DAVIS, JR., of Chicago, contributed an interesting paper on "Diabetes Mellitus—Some Statistics." He illustrated his remarks with charts.

ARTERIO-SCLEROSIS,

Was the title of a paper read by Dr. FRANK BILLINGS, of Chicago.

This is a chronic degenerative and inflammatory disease of the vascular system, with secondary changes in other organs. Gull and Sutton were the first to describe it as an independent affection. The disease may involve the arteries alone, or it may implicate the veins and capillaries as well. It may be local or general in its manifestations, be confined to the aorta or to the whole arterial system. Involvement of the pulmonary system is rare, and secondary always to lung or heart disease. Arterio-sclerosis is essentially a disease of old age, and is rarely found before the age of 40. According to Nothnagel, arterio-sclerosis occurring before the fortieth year is always due either to syphilis or nephritis.

The treatment must vary with the part of the body involved. Much may be done to retard or modify the disease before irreparable damage is done, and especially in the gouty form of the affection. A diet suitable to the case must be selected. This will consist of the nitrogenous elements chiefly, in some cases, and in others of the cereals and hydrocarbons. When the kidneys are involved a diet as free as possible from urea-forming products should be chosen. In all cases it is important that the existing malnutrition should be overcome by an abundance of proper food. Milk in generous quantities is the food par excellence for all patients. If necessary to aid its digestion, it may be

freed from the cream, even diluted with water or peptonized. Excretion should be maintained by giving a large amount of fluid. In addition to the milk a pure water should be taken when the stomach is empty. In all cases it is essential to restore nutrition, and if the diet, medication and general hygienic management are directed to that end much will be accomplished in retarding the course of the disease. Dr. Billings closed his paper with a report of four cases which illustrated some of the conditions peculiar to arteriosclerosis.

FIRST DAY—AFTERNOON SESSION.

Section called to order by the Chairman.

DR. J. T. STEWART, of Peoria, read a paper on

THE MEDICAL PROFESSION.

He said that the practice of medicine is not a science but an art founded upon many sciences. The general impression of the profession, and through it of the laity, that about all that is of value has been acquired in the last fifty years, is a mistake. His personal knowledge extends back forty-seven years, and while he grants many improvements have been made since then, the profession was then on bed rock and fully up to the condition of science at that time. The standard remedies of that day are standard remedies now. Quite a number of invaluable ones have been added since, but not one of the old remedies had been displaced to his knowledge. Practitioners should adapt themselves to the age in which they live.

DR. J. L. REAT, of Tuscola, followed with a paper on

ATROPIA IN SOME FORMS OF GENITO-URINARY DISEASE.

He said that if there is irritability of the bladder, the condition where the desire to micturate comes on suddenly and very frequently, so that a patient is compelled to pass his urine every thirty or sixty minutes, the local use of atropia relieves the urgency of the case promptly. What is known as Ludham's formula was given, and is:

R Atropia	gr. i.
Aconitin	grs. iss.
Oil Tiglii	gtts. ij.
Petrolati	ʒiv.

Apply as much as the size of a pea.

Where the urethra is the seat of the trouble, the essayist uses a forcible catheter with piston attachment, filling the eye of the instrument with the medicament, introducing it into the bladder, then as it is withdrawn, presses out the ointment.

DR. W. C. BOWERS, of La Place, reported an interesting case of aortic regurgitation with symptoms obscuring severe acute pericarditis.

THE PROVISIONAL TREATMENT OF INSANITY.

This was the title of a paper read by DR. SANGER BROWN, of Chicago, in which he said the purpose of the paper was to draw the attention of the general practitioner to the considerations which should prompt him in reaching a decision as to the course to be taken in the treatment of insanity when cases occur in his practice. Those who had studied closely the problem of treatment of insanity in hospitals, had found that quite a considerable proportion of cases under hospital treatment, with what the term usually implies, had been aggravated and the symptoms perpetuated. The associations are certainly to some extent harmful in nearly all cases, and particularly so in the earlier and more curable forms of the disease.

The ideal way of treating a case of insanity consists in having spacious quarters and grounds sufficiently isolated, plenty of experienced attendants and competent medical supervision, and only sane associates, no other insane person on the premises. All desirable forms of mental tonics should be available, including traveling and sojourns at watering places. The author had seen incurable cases taken from the best asylums of the world and treated along these lines with very satisfactory results.

DR. J. B. MAXWELL, of Mount Carmel, read a paper on

EPILEPSY AND ITS TREATMENT.

After defining the disease and dealing with the causes, the author dwelt upon the treatment. Associations of a pleasant character have a very favorable effect upon patients suffering from this disease, and he knew of cases that were much relieved by being taken away from discordant home surroundings and placed in a hospital or boarded in a private family where the environments are more agreeable.

The medicinal treatment may be confined to the bromids, and of the various bromids the salt of potassium he considers the best. The amount and time of administration must

be regulated by the age of the patient, frequency and time of the fits. In nocturnal epilepsy a dram dose at bedtime often does the best. In the diurnal form of the disease a scruple, three times daily for adults; for children proportionately less. The best and safest rule is to continue the medicine in the smallest doses that will control the disease.

The author urged the establishment of homes or retreats where these unfortunates can be taken care of and treated in order that they might be cured, if curable, and if not, their condition ameliorated and their intellectual decay prevented.

DR. CARL E. BLACK, of Jacksonville, read a paper on

PHYSICAL EXERCISE AS A THERAPEUTIC AGENT.

He said that many of the ills of humanity came from faulty physical development due to neglected or perverted physical exercise. It behooves the medical profession to become an educator in the matter of physical exercise to develop health. The field for usefulness for exercise as a therapeutic agent is a broad one, if it is properly prescribed. The statistics of Amherst College show a low sick rate where systematic exercise is carried out. Authorities differ, however, somewhat as to the amount of exercise required daily by a well developed adult. It is said that a healthy adult of five feet six inches in height, and weighing from 130 to 140 pounds, should take an amount of physical exercise which is equivalent to a walk of eight miles.

DR. C. BARLOW, of Eaton, read a paper entitled

RHEUMATIC SPINAL AFFECTIONS.

In consulting the literature on this subject, he had found reports of cases of rheumatism of almost every part of the body, but rheumatic affections of the spinal cord, its meninges and nerves had not been much written about. In all cases of rheumatism, where there is marked tenderness over the spinous processes, together with exaggerated reflexes, there is a disordered condition of the spinal cord and its nerves. He had noticed this in old soldiers who contracted rheumatism while in the service, and in sixty-four consecutive cases forty-two had tenderness of the spine, and thirty-two had disturbances of patellar tendon reflexes. Twenty-five of the number had increased knee jerk on both sides, three on one side, and in two the knee jerk was diminished. Forty-one of them had a heart murmur.

Treatment.—Hygienic management, flannel or silk under-clothing, traveling, suitable climate, warm baths, laxatives, alteratives, as an occasional dose of mercury or colchicum and the iodid of potash, or nitric acid after meals, continued for several weeks. For the relief of pain salol, phenacetin, antikamnia, etc., should be used. Electricity, tonics and codliver oil in some cases, and above all the patient should be regular in his habits and avoid unnecessary exposure.

DR. GEO. F. BUTLER, of Chicago, read an interesting paper entitled,

ELEMENTS OF UNCERTAINTY IN THERAPEUTICS.

Many of our failures in treatment can be attributed to an incorrect diagnosis. Assuming, however, that a correct diagnosis of the condition of the patient has been made, what then are the elements of uncertainty in therapeutics?

A very common and almost universal practice of prescribing ready-made preparations, which masquerade under a copyrighted name which can claim but the faintest relationship to their empirical constitution, is one of the greatest elements of uncertainty in modern therapeutics. The thousands of proprietary articles on the market are unworthy the distinction of being prescribed by the medical profession. "They are directly at variance with scientific progress, their promoters have contributed absolutely nothing of value, and had they never existed, medicine and pharmacy would have reached a higher plane in the development of science." Every physician knows this, yet there is not a single day but that thousands of these articles are prescribed and dispensed. Through the courtesy of twenty druggists in Chicago, located in widely different parts of the city, the speaker had recently looked over several thousand prescriptions with the result that 15 per cent. were for articles of this character. Several proprietary preparations were cited by the author as examples.

Another element of uncertainty is the variation in strength of many of our pharmaceutical preparations.

DR. E. B. MONTGOMERY, of Quincy, contributed a paper entitled,

SOME OBSERVATIONS CONCERNING THE DISEASES OF OLD AGE, THEIR PROPHYLAXIS AND TREATMENT,

which was read by Dr. C. W. Rook in the absence of the author.

The author summarizes his observations in the following conclusions:

1. There are no diseases that are a necessary result of mere length of life; in other words, that old age is not of necessity pathologic.

2. That diseases of a degenerative nature, occurring in the aged, most frequently, are those most distinctive of the decline of life.

3. That such diseases are either due to faulty heredity, overwork, errors in food and drink, or constitutional dyscrasia, than from any necessary wear and tear of the vital mechanism, the result of long life.

4. As a corollary of this, the prophylaxis of such diseases consists in a good heredity and a well ordered life, especially the avoidance of syphilis and alcoholism.

5. That their treatment consists largely in proper personal hygiene and the treatment of the constitutional dyscrasia, upon which such degenerations so frequently depend.

Dr. WILLIAM F. WAUGH, of Chicago, read a paper on

MANAGEMENT OF VALVULAR HEART DISEASES.

Dr. Waugh's paper called attention to the importance of the mechanical principle in the treatment of acquired valvular lesions of the heart. The progressive deficiency in the heart's power is to be met by diminishing its work: *a*, by limiting the exercise to that necessary to keep up the health; and *b*, by reducing the bulk of the blood by abstinence from liquids and from fattening foods.

The recent intravascular deposits may be removed by the iodids. By these means, comfortable and useful life may be prolonged to the full normal limit, barring accidents.

The use of digitalis and its congeners is limited to their temporary administration, to afford relief while waiting the effect of the physiologic treatment.

Dr. C. B. JOHNSON, of Champaign, read a paper entitled

STOMATITIS MATERNA,

in which he epitomized some of the more important facts pertaining to this disorder as follows:

1, it is a disease to which certain nursing or pregnant women are subject; 2, it is probably true that the disease has been comparatively infrequent of late years; 3, it is positively true that there has been nothing, or next to nothing, in medical literature of the past twenty or thirty years upon the subject; 4, in consequence of this, many medical men of ten, fifteen, or twenty years' experience are not cognizant of ever having seen a case, and would perhaps not recognize one if met; 5, of the real nature of the disease, nothing is known, even by those who have made it a special study, except that it is a peculiar cachexia to which certain pregnant or nursing women are liable; 6, the alimentary canal is the favorite seat of the disease; but should any nursing or pregnant woman suffer from obscure trouble about the lungs, nose, head or ears, the possibility of stomatitis materna acting as the underlying cause should be carefully considered; 7, when the disorder attends lactation the remedy above all others is the suppression of the secretion of milk; 8, when pregnancy is complicated by the disease, cases of such a grave character may come up as to even justify the bringing on of premature labor.

Dr. M. P. HATFIELD, of Chicago, read a paper on

MATERNAL IMPRESSIONS.

He prefaced his remarks by quoting Dewees, as follows: "Nor do we believe in the influence of the imagination upon either the form, color or future destiny of the child, however powerful this faculty may exert itself during gestation." He rejects all the reasoning as well as the appeals of facts, purporting to be illustrative of this wonderful influence. "We conscientiously declare that we have never in a single instance had reason to believe that the imagination had exerted the slightest control upon the fetus in utero—contrary to our early belief upon this subject."

Dr. Hatfield summarizes thus: 1, that such cases must have come under your personal knowledge and reported to you by some one incapable of judging; 2, whether the alleged blemish is not one well recognized in teratology as produced by other causes than maternal impressions; 3, that the possibility of atavic defects must be excluded before any given defect can be admitted to be due to maternal influences; 4, that there will occur from time to time a certain number of remarkable coincidences as yet inexplicable, except by that cast of mind which is always looking for the occult and marvelous.

Dr. RICHARD DEWEY, of Chicago, contributed a paper entitled

A COMPARATIVE STUDY OF EARLY LIFE CONDITIONS IN TWO HUNDRED CASES OF SANE AND INSANE PERSONS,

which was read by the Secretary of the Section in the absence of the author. Tables were presented in connection with the paper showing the relative ratio of various early life influences in these cases.

FIRST DAY—EVENING SESSION.

The Association met at 8 P.M., and was called to order by the President.

Introductory remarks were made by Dr. J. N. Randall, of Decatur, after which the first Vice-President, Dr. D. R. Brower, of Chicago, took the chair, and President Will delivered his annual address, his subject being

VIVISECTION IN ITS RELATION TO THE ADVANCEMENT OF MODERN MEDICINE.

The utilization of living beings for the purposes of scientific experiment and investigation was not a new practice, said the speaker. Modern surgery virtually owes its existence to the work of the vivisector, not only in the art but in the science. The very first principles upon which it rests, those of asepsis and antisepsis, have been developed under the pressure of vitality's obedience to experimental force. No more brilliant illustration of the dependence on vivisection for the art of modern surgery can be found than is exemplified in the work of some of those who have been and are honored members of this Association. Who, for instance, with a knowledge of the facts, can for a moment gainsay the value of the results of the work in that direction of an Andrews, a Parkes, or a Senn? The thousands of lives that are every year saved through the merciful instrumentality of modern surgery—especially abdominal—attest the value of that preliminary effort on the lower animals which is necessary to secure not only operative skill, but the most perfect technique. Nearly every principle of modern surgery has been wrought out by the careful study of the vital processes on the lower animals, under artificial conditions and circumstances imposed for the purpose of arriving at a most careful estimate of the correlation of forces or influences involved, and the most practical results in their guidance and application to the welfare of the human race. Upon the basis of such commanding principles as those elucidated by actual experiment on the lower animals, has been built the noble structure of our science and art as it appears to-day, which is a gem of architectural beauty grandly visible here and there, giving promise of the sublime heights and magnificence yet to be attained.

Dr. EDMUNDS ANDREWS, of Chicago, delivered the address of Section 2, taking for his subject

A NEW METHOD OF GASTROSTOMY.

The address was illustrated with diagrams. He said impermeable stricture of the esophagus necessitates making an artificial opening in the stomach, for the purpose of feeding the patient. In the old method an unexpected obstacle arose. Though the stomach received and digested the food put into it through the artificial opening, yet it was unable to propel it onward into the intestines, because whenever it contracted for that purpose, the resistance of the pylorus was greater than that of the artificial orifice, and the chyme was forced out of the wound and lost, hence the majority of the patients ultimately, though slowly, died of starvation. Several plans have been devised to overcome this difficulty, notably those of Kocher, Alberti and Wetzel. The respective methods of these gentlemen were then dealt with. Dr. Andrews said the thing needed for permanency is the formation of a valvular canal with a lining of mucous membrane. The mucous membrane of the stomach is separated from the muscular coat by an exceedingly loose stratum of connective tissue. In testing this, he found that the mucous layer could be made to glide to and fro in a remarkable manner over the muscular coat. This exceeding looseness of the membrane greatly facilitates raising flaps from it to construct the valvular mucous canal. He describes his procedure as follows: External antisepsis is obtained as usual, but the preliminary washing out of the stomach can not be performed on account of the stricture of the esophagus. The external incision is made in the usual way, and the stomach exposed and identified. It is then drawn out through the wound far enough to give freedom in handling. An incision is then made from near the upper border directly downward about two inches. Before this is done, however, provision must be made to prevent its fluids from getting into the peritoneal cavity by the careful placing of large sponges. As the patient has been prevented by the stricture from taking food, the contents will be found to be only the secreted

fluids. The cavity is now washed out with warm boric acid solution, and the edges of the incision secured against slipping back into the abdomen. Now the lower part of the anterior wall is raised, turned out through the incision and spread out flat. From the lower end of the cut, two incisions are made through the loose mucous membrane, one to the right, and the other to the left, each extending about three-quarters of an inch laterally from the lower end of the main incision. From the end of each of these two mucous membrane incisions, another cut is made downward through mucous membrane, parallel to the axis of the body and to each other for a distance of about one inch and a half. At the lower ends the two incisions are turned at a right angle toward each other, but not meeting, a separation of one-third of an inch being left between them.

A female dog weighing forty-five pounds was subjected to this operation April 5, 1894. There was no leakage of the contents of the stomach whatever. At the end of a month she was in robust health, and on being killed May 4, the valve in the stomach was found in good working order, and readily pervious to tubes. We think that there might be a liability in some cases to a contraction of the external or internal orifice of the channel, and hence after the tube is withdrawn it should be occasionally re-inserted to test the size of the channel and if necessary to dilate it.

The address of Section 3 was next in order, and was delivered by Dr. WILLIAM E. QUINE, of Chicago. Dr. Quine selected for his theme

COMPULSORY VACCINATION.

He said vaccination was introduced to the attention of the medical profession by Edward Jenner in 1798 as the result of investigations that extended over a period of twenty years. During the century preceding, according to the estimates of our most authoritative writers and statisticians, smallpox, "the most terrible of all the ministers of death," destroyed in Europe alone, 50,000,000 human lives. Think of it! Five hundred thousand deaths every year from the most loathsome pestilence known to man; thirteen hundred deaths every day, nearly a death every minute for a hundred years. If it be true, as is believed by enlightened people, that universal vaccination and revaccination, efficiently done, will put an end to all this desolation and horror from epidemics of smallpox, and finally eradicate the disease altogether, it would appear that the discoverer of vaccination is the greatest benefactor that mankind has known. Alexander was great. Cæsar was great. Hannibal was great. Napoleon was great. They were all great—as destroyers. What have they done? What have all the kings and potentates and warriors of earth done, in comparison with one member of the medical profession in the direction of adding to the sum total of human happiness and human life? Are such conceptions of the possibilities of vaccination an idle dream?

As proof of the protective influence of vaccination, many examples were cited by the speaker, and but one will suffice here. A village in Leicestershire of thirteen hundred inhabitants was visited in 1872 with smallpox. All but two of the inhabitants were vaccinated, and they escaped the disease. The two unvaccinated persons contracted the disease and died of it.

Age for Vaccination.—Children are more liable to smallpox than adults, and more liable to die when attacked. The younger the child the greater the danger; hence vaccinate during the first year of life.

The speaker then dwelt eloquently upon inefficient vaccination, susceptibility, anti-vaccination societies, vaccination laws, and finally made an eloquent and earnest plea to more thoroughly educate the profession in regard to the disease and, above all, the press and public schools.

SECOND DAY—MORNING SESSION.

After the transaction of some miscellaneous business, the Society listened to the address of Section 1, which was delivered by Dr. Victor C. Vaughan, of Ann Arbor, Michigan, who selected for his subject, "Nucleins and Nuclein Therapy."

Section 2.—Chairman, Dr. D. W. Graham, Chicago; Secretary, Dr. Ellen H. Heise, Canton.

Section called to order by the Chairman.

Under the head of

SURGICAL SHOCK,

Dr. LESTER CURTIS, of Chicago, made some remarks on its physiology and pathology. He said that Billroth states that he had never lost a case from shock within twenty-four hours after operation, which would almost preclude the possibility of shock, and still surgeons had seen patients suffer

from railroad injuries with depression and other symptoms so well known, that the fact of such a thing as surgical shock could hardly be doubted. Surgical shock is a condition of the nervous system that is produced by any sudden or violent injury without any lesion that can be demonstrated after death. The speaker then dwelt upon the different varieties of shock.

Dr. WM. BARNES, of Decatur, followed with a paper on

THE DIFFERENTIAL DIAGNOSIS AND ELEMENTS OF PROGNOSIS OF SURGICAL SHOCK.

The relation of cause and effect is usually so apparent that the question of diagnosis of shock rarely presents any difficulty, so little in fact that in most treatises on surgery there is no mention whatever made of the subject, and in practice the physician seldom gives much thought to the matter. As regards prognosis the very young and very old are especially prone to severe shock, but in the former the reaction is apt to be rapid and complete, while in the latter it is often slow and feeble. The extent, character and seat of the injury must always be considered in prognosis. The more profound the prostration, and longer the condition prevails, the greater is the danger. Increasing rapidity of the pulse with diminution of force and volume in connection with continued subnormal temperature almost always indicate a fatal termination.

TREATMENT—WHAT TO EXPECT FROM DRUGS IN SURGICAL SHOCK.

By Dr. E. W. WEISE, of Ottawa. In the absence of the author of this paper, Dr. Wm. E. Quine was called upon by the Chairman of this Section to make some remarks. Dr. Quine said that treatment in relation to the management of any morbid condition refers to the removal of the cause. If the cause of the shock be violent, accompanied with agonizing pain, the immediate or rapid control of the element of pain contributes to the prompt removal of the consequences of that suffering. The employment, therefore, of medicinal agents to control pain and relax the spasm of the cutaneous blood vessels can usually be resorted to with satisfactory results. His conception of the medical management of shock relates first of all to the immediate control of pain, and second to the restoration of the functions of circulation and metabolism which were profoundly and instantaneously interfered with by reason of the operation of the primary disturbing cause.

Dr. C. C. HUNT, of Dixon, contributed a paper entitled SOME OBSERVATIONS ON THE TREATMENT OF FRACTURES OF THE NECK OF THE FEMUR WITH ILLUSTRATIONS SHOWING A PRACTICAL AND EFFICIENT METHOD.

In the absence of the author, this paper was read by the Secretary, Dr. JOHN B. HAMILTON.

The point brought out in the paper was that union by bone of non-impacted intracapsular fractures of the neck of the femur is now accepted as proven. The principles governing the treatment of fractures within and without the capsule are the same. Then followed a statement of the conditions favorable for repair by bone. The author thought the comfort of the patient was too often overlooked by the desire on the part of the surgeon to effect fixation and equal length of the limb. A report of cases followed and photographs were exhibited illustrating the method of treatment by Hunt's modification of Dr. Verity's splint with lateral as well as longitudinal extension.

Dr. WILLIAM J. EDDY, of Shelbyville, reported a case of secondary hemorrhage in gunshot fracture. The paper dealt principally with gunshot fractures of the long bones of the leg and the manner of dealing with them in the light of to-day.

Dr. F. C. VANDERVOORT, of Bloomington, read a paper entitled,

PEROXID OF HYDROGEN AND THE RESULT OF ITS USE IN MY HANDS.

He considered the drug one of the most important additions to our list, and one that will give entire satisfaction in properly selected cases. He has used it in cases of empyema and in abscesses of all kinds, and especially in large ones with very small openings, with gratifying results.

OPERATIVE TREATMENT OF PROSTATIC OBSTRUCTION.

Dr. LEWIS L. McARTHUR, of Chicago, read a paper with this caption.

At various times, by different authors, the following plans of treatment have been more or less strongly advocated for the relief of prostatic obstruction: Electrolysis, cauterization (actual or galvanic), castration, prostatectomy (partial or complete), drainage, perineal or suprapubic.

With regard to suprapubic drainage, the technique is to be found in all of the more recent works on vesical surgery, but the essayist recalled some of the special points as follows:

1. After irrigation with an antiseptic solution, distend, but do not rupture, the bladder with your antiseptic solution, and constrict the penis.

2. Put the rectal bag in place and gently distend with water.

3. In all the dissection do not tear, but cut.

4. Gently separate the recti and pyramidales with few cuts, cut slowly through the presenting transversalis fascia with its fat, after pushing that at the upper angle forward. When muscular wall of the bladder is reached, pack the wound with gauze for twenty-four or forty-eight hours at the point where you desire to puncture.

Drainage tubes of various kinds are recommended, but the speaker had found Andrews' empyema tube to answer the purpose. The nature of the siphon and its method of working should be made clear to the attendant. Broome suggests the use of a trocar for making the perforation in the bladder wall, and then using a tube of the same dimensions. It prevents all leakage, and when siphonage is employed it insures the good action of the latter by preventing the aspiration of air into the bladder, which is likely to occur if the drain fits the wound loosely.

DR. WILLIAM E. GUTHRIE, of Bloomington, reported an interesting case of resection of the shoulder joint with especial reference to restoration of function, and exhibited the patient. The case was unique on account of the amount of bone restored and the remarkable restoration of function in a short time.

DR. A. E. HOADLEY, of Chicago, read a paper entitled,

INDICATIONS FOR MECHANICAL TREATMENT IN THE VARIOUS STAGES OF HIP JOINT DISEASE.

He said the first indication for mechanical treatment in hip joint disease is a diagnosis of the affection, and that just as soon as this can be made, mechanical treatment should be instituted. The first stage of hip joint disease was characterized by fixation and abduction, and more cases could be cured at this time than at any other. The author emphasized the importance of early treatment. Relative to traction, he favors a degree of traction that is comfortable. If three or four pounds of traction are sufficient to relieve the muscular irritability, in his opinion it is sufficient. As far as lateral traction was concerned, there were only a few cases in which it was particularly indicated or advantageous. Direct traction in a great majority of cases was ample.

SECOND DAY—AFTERNOON SESSION.

DR. FRANK H. MONTGOMERY, of Chicago, contributed a paper entitled

SOME COMMON ERRORS IN THE TREATMENT OF INFANTILE ECZEMA,

which was read by the Secretary of the Section in the absence of the author. Statistics show that more than one-third of the cases of infantile eczema originate during the first twelve months after birth. They also show that in over 80 per cent. of these cases some portions of the face and head are affected. These reports are based largely on dispensary and hospital practice where eczema of the covered parts of the body is much more common, caused by the presence of lice, dirt, by rough, coarse clothing colored with cheap dyes and by secretions and excretions retained in contact with the unwashed skin. The questions that enter into the treatment are a proper diet, and the judicious selection of local remedies, etc.

DR. E. FLETCHER INGALS, of Chicago, followed with a paper entitled

CAUTERIZATION OF THE NARES AND ACCIDENTS THAT MAY FOLLOW.

Although from time to time articles have been written to show that serious accidents often follow cauterization of the nares, the author thinks, when properly done, this operation is quite as free from discomfort or danger as any other minor surgical procedure. Serious results following these operations, he thought, were due to carelessness or inexperience upon the part of the operator which induced him to make extensive wounds, or to repeat burnings too frequently.

The essayist summarized as follows:

1. It is important that antiseptic applications be regularly employed after cauterization of the nasal mucous membrane, and that the nostril be closed by cotton for several days, whenever the patient is out of doors, to prevent taking cold.

2. As a rule, at least two weeks should intervene between operations upon opposite sides, and three or four weeks between those on the same side.

3. No serious results are at all likely to follow cauterizations made in this way.

4. Practically all cases of hypertrophic or intumescent rhinitis may be cured by this treatment, though occasionally portions of the turbinated body must be removed.

DR. NORVAL H. PIERCE, of Chicago, read a paper entitled "The Treatment of Otitis Media Purulenta Chronica."

DR. T. MELVILLE HARDIE, of Chicago, reported an interesting case of empyema of the sphenoidal sinus and posterior ethmoid cells.

If one is to judge from the great rarity with which the sphenoidal sinus is mentioned in current medical literature, it must be considered in a great measure an unknown land, so that the history of the case as presented by the essayist was very interesting. The patient was nine and a half years of age.

DR. J. ELLIOTT COLBURN, of Chicago, read a paper entitled

PROGRESSIVE MYOPIA,

in which he took up the physical side of the subject in its relation to the development of the eyes, and then especially in relation to the causes of progressive myopia. Myopia of a low degree is a serious inconvenience, but when it reaches four or five dioptics it is a calamity. It would seem from looking over the statistics of various observers that a refraction in the newly born infant is that described as hyperopic, the static refraction being too low for the length of the eye. The evolution of the eye from that time is toward the emmetropic eye. In case of arrested development the result is hyperopia of varying degrees, or if the evolution is carried beyond emmetropia, it becomes myopia of low or high degree. The author cited three cases illustrating the development of myopia from hyperopic eyes. The treatment of progressive myopia consists in correcting the error of refraction, giving general tonics, prohibiting the use of the eyes for close work, and instilling atropin.

Under the head of

FIBROID TUMORS OF THE UTERUS,

the following divisions of the subject were considered:

a, "Natural History," by Dr. L. A. Malone, of Jacksonville; b, "Their Complications," by Dr. Marie J. Mergler, of Chicago. Dr. Mergler's paper was read by the Secretary of the Section, Dr. Heise, in the absence of the author.

As we have no reliable data as to the relative frequency of fibroid tumors of the uterus, it is impossible to state even approximately, what proportion of fibroids are complicated with other morbid conditions, for there is still much diversity of opinion as to the relative frequency with which the fibroid *per se* occurs.

In a series of fifty-three consecutive cases, observed in the gynecological clinic of the Woman's Medical School, in which the presence of one or more fibroids was discovered, only three were sufficiently large to lead the patient to suspect the growth, and in every instance the patient applied for treatment of some marked symptom or complication—for example, sterility, repeated miscarriages, dysmenorrhea, menorrhagia, and irritation of the bladder. Six of these cases applied with sterility; seventeen gave a history of one or more miscarriages; twenty-eight suffered with dysmenorrhea; seventeen with menorrhagia; two with amenorrhea; thirteen with irritable bladder, and four with the symptoms of chronic nephritis.

c, "To What Extent are they Influenced by Medical Treatment?" by Dr. WALTER RYAN, of Chicago.

The author said it was essential, before attributing curative results to any medicinal agent, to exclude all *post hoc non ergo propter hoc* cases, otherwise medicines might be given more credit than they deserved. Numerous medicinal agents have been recommended from time to time for the treatment of fibroid tumors with an enthusiasm which amounts to fanaticism. These were gallic acid, cannabis indica, hydrastis, cinnamon, ergot and many others, but we had seen very few cases really cured by drugs. In the imagination of Apostoli and the many little apostles, we had seen uterine fibroids almost universally cured by electricity, but after their treatment by electricity and other medicinal means, the surgeon was called upon to remove them by surgical interference. In general, uterine fibroids are influenced by drugs only to a slight extent, but in exceptional cases apparently to a considerable extent.

d, "The Palliative Operations and their Comparative Value." This paper was read by Dr. F. HENROTIN, of Chicago.

e, "Choice of Radical Operations for the Cure of Uterine Fibroids," by Dr. HENRY T. BYFORD, of Chicago.

Polypoid fibroids should always be removed per vaginam when smaller than a child's head, and the same may be said of the submucous variety when not complicated by other tumors of good size belonging to other classes. Submucous tumors larger than a child's head usually require abdominal section. In such cases the uterus may be incised, the tumor enucleated, the bed sewed up, and the uterine cavity drained with gauze.

Intramural fibroids are usually multiple. When small they can sometimes be radically cured by ergot, electricity, oophorectomy, or vaginal ligature of the uterus, as recommended by Dr. Franklin H. Martin. When they press injuriously upon surrounding tissues or occlude the cervix and can not be enucleated, the uterus may be removed, per vaginam, with or without *morcellement*, provided the whole mass is not larger than a child's head.

Single subserous and pedunculated growths can be removed without taking out the uterus. Multiple subserous, intraligamentous tumors require supravaginal amputation or total extirpation.

f, "The Radical Operations—a Review, with Description of Technique," by Dr. N. SENN, of Chicago.

Dr. A. R. SMALL, of Chicago, read a paper entitled

SHOULD LACERATIONS OF THE CERVIX UTERI BE MORE FREQUENTLY REPAIRED?

This question the author answered in the affirmative. Few would believe, unless they had had personal experience in repairing these lesions, that even a slight tear in the cervix uteri would give rise to as many and varied symptoms, as those who had performed trachelorrhaphy many times know to be the case. He knew of no lesion, so apparently slight, which was capable of producing so many and varied symptoms as a lacerated cervix. He believes every woman should be examined within three months after confinement, and if her cervix is lacerated it should be repaired at that time.

Dr. J. F. PERCY, of Galesburg, reported a case of tubal pregnancy upon which he had operated, with recovery of the patient.

Dr. C. W. ROOK, of Quincy, reported a case of parotitis with metastatic metritis of the pregnant uterus, resulting in the miscarriage of a three months' fetus. The patient was 30 years of age. In consulting the literature he was unable to find but one recorded case in which the pregnant uterus was the seat of metastasis, and this case is recorded by Dr. F. D. HALDEMAN, in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, May 14, 1887.

All writers on parotitis refer to a possible metastasis of the testicle, mammae, ovaries, etc. Niemeyer and Constatt include the uterus, while a study of parotitis, such as can be obtained from current medical literature, shows that nearly every organ and tissue of the body have figured in the metastatic complications of parotitis.

ABORTION.

This subject was dealt with in a series of papers as follows: a, "The Prophylactic Management," by Dr. J. C. MCKINNEY, of Barry.

According to Schuhl, repeated abortions in the same woman are usually traceable to some one cause. More rarely, there is a different cause for each one.

Treatment should be begun in the intervals of pregnancy, or after the beginning of gestation. The cause is to be sought for and treated. Some diseases, such as nephritis, pulmonary tuberculosis and cardiac affections are not amenable to treatment, and are aggravated by pregnancy. Such patients should be advised to avoid pregnancy. The prophylaxis depends altogether on finding the cause and removing it if possible.

b, "Management of Inevitable Abortion," by Dr. C. W. SIBLEY, of Fairchild.

To decide just when a threatened abortion becomes inevitable is always desirable and sometimes difficult. When it is decided in a given instance that an abortion is inevitable, the case loses none of its interest, for there is no class of cases which cause more anxiety to the average medical man than abortions. Until comparatively recent years extreme conservatism was the rule of practice, this being more especially so before the prevention and treatment of sepsis were brought to their present state. Even now a practitioner may follow any course he may fancy and find some authority for his course; and yet the trend of modern practice is undoubtedly toward radical methods, and this because the two chief sources of danger in abortion are best thus avoided.

Of these two principal sources of danger, hemorrhage is the most immediate, and sepsis, while more remote, the most far-reaching and terrible in the suffering it may cause and the sequelae liable to follow it.

The tampon, hot and cold douches, ergot, quinin and aortic compression are resources likely to be efficient in the control of hemorrhage until the uterine cavity can be emptied. With the danger in this direction, when proper after-treatment has passed, as the dangers of sepsis are all augmented by delay, and as sepsis is always easier prevented than remedied, the only safe rule is to immediately evacuate the contents of the womb in all cases where it is decided that abortion is inevitable, due care being taken to avoid rupture of the membranes, which accident facilitates the escape of the ovum and the retention of the membranes.

c, "Management of Neglected Cases," by Dr. ABBE F. ROONEY, of Quincy.

The essayist said he supposed by neglected cases was meant such cases as call no doctor, and those in which the doctor does nothing when he is called. When the physician can convince himself either by the profuseness of hemorrhage or its long continuance, or by the odor of decomposition and upon bimanual touch note the loss of elasticity which accompanies an unruptured fetal envelope, then an effort should at once be made to remove thoroughly whatever may be found within the uterine cavity. Having douched the vagina with a bichlorid solution—1-4000—to avoid any external infection, Sims' speculum and a tenaculum will bring the cervix clearly under control, and slight dilatation will enable one to carry Emmett's curette forceps into the cavity and grasp whatever is loosely attached therein. Now, swab the cavity with a bichlorid solution on cotton held in the forceps before proceeding to pass a dull wire curette about in all directions to discover adherent particles of the placenta that have escaped the forceps. Hemorrhage is sometimes quite free, but it lessens after all the shreds are removed and if the cavity is swabbed with a saturated solution of iodine crystals in a 95 per cent. solution of carbolic acid, there will be provoked a contraction of muscular tissue and closure of torn vessels, so that there is no danger of subsequent hemorrhage.

d, "The Sequelae—Their Importance to the Gynecologist," by Dr. HENRY P. NEWMAN, of Chicago.

The importance of the subject of abortions in their connection with the causation of gynecic disease, can be somewhat appreciated when we consider that their frequency is placed by the most conservative writers as about one in nine normal deliveries, and the French writers so far exceed this estimate that according to Pajot and Verrier, it may be stated that abortion is more frequent than delivery.

First upon the list of unfortunate consequences of abortion is acute sepsis. This complication may occur by infection *in loco*, or by infection from without. The former is more rare, but the latter not infrequent, and this is largely owing to the neglect which prevails among women who abort, particularly those who have induced the occurrence. Infection from without, while more common, is a complication which should always be prevented, and is caused by the introduction of pus-producing bacteria through the use of various instruments, the hands, or some mechanical agents.

The author also referred to subinvolution as a complication following abortion. This may be produced by retained secundines, keeping the uterus distended, engorged, and inflamed along its inner lining, or it may be the result of a metritis proper, or inflammation of its adnexa, set up by trauma and acute infection. It is well known that a single abortion predisposes to recurrence, this in turn to a third and fourth, and hence what is termed the abortive habit is produced.

A paper on "Conduct of Natural Labor in Country Practice," contributed by Dr. JAS. E. SUTTON, of Canton, was read by the Secretary of the Section in the absence of the author.

THIRD DAY—MORNING SESSION.

Section 3.—Chairman, Dr. Geo. W. Webster, Chicago; Secretary, Dr. G. A. Zeller, Peoria.

Section called to order by the Chairman.

Dr. M. S. MARCY, of Peoria, read a paper on

WHAT IS THE PROPER MODE OF EXECUTING CRIMINALS?

The author suggested as one of the best means morphin and asphyxia. A criminal who is condemned to die should be placed in an air-tight cell, a large dose of morphin given hypodermatically, and while he peacefully sleeps the gas should be turned on in his cell and continued until he ceases to breathe.

In this way, the author said justice could be meted out,

death would be sure, and none of the horrors incidental to the customary mode of executing criminals would linger in the minds of the sheriff and his aids.

DR. ROBERT BOAL, of Lacon, followed with a paper in a similar line, which was entitled,

EMASCULATION AND OVIARTOTOMY AS A PENALTY FOR CRIME IN THE REFORMATION OF CRIMINALS,

in which he took strong and advanced ground in favor of unsexing, by law, habitual criminals as the best means of preventing or minimizing the grosser crimes. The essayist had been in active practice for more than sixteen years, and has been during that time a close observer of the efforts at the reformation of criminals, and considers that these efforts have been in a large degree failures.

DR. W. R. ALLISON, of Peoria, read a paper with the following caption:

THE CORRECTION OF CRIMINALS BY EDUCATION.

He said that while public punishment and execution may not accord with the prevailing opinion of to-day, it is a fact that punishment by burning at the stake, if secretly executed, would have no influence upon the individuals whose penalties for crime are intended. It is the result of crimes acting as an effect by education through reason or fear that will check the cause. Perverted bodily functions which stimulate immoral and criminal acts, if not amenable to an educational equilibrium, should be removed, when they can be, without shortening longevity and preventing crime. Abnormal or criminal masculine acts, for which the rapist is punished, should be emasculated, not secretly, for that would be revolting to a few.

DR. BOERNE BETTMAN, of Chicago, followed with a paper entitled

LEGISLATION FOR THE PREVENTION OF BLINDNESS,

in which he advocated and urged the adoption of legislative measures for its prevention. He offered the following resolutions which were adopted:

WHEREAS, Statistics compiled in this country and in Europe demonstrate that fully 25 per cent. of our blind owe their affliction to an inflammation of the eyes appearing a few days after the birth; and

WHEREAS, Experience has proved that the inflammation can be cured and the eyesight saved in the majority of cases if treatment is instituted at an early stage of the disease; and

WHEREAS, The destruction of the eye and blindness are usually the result of delay in treatment; be it

Resolved, That we heartily recommend that the people of the State of Illinois represented in Senate and Assembly, do enact as follows:

SECTION 1.—Should one or both eyes of an infant become inflamed, swollen or reddened at any time within two weeks after its birth, it shall be the duty of the midwife or nurse having charge of such infant, to report in writing, within six hours to the health officer or some legally qualified practitioner of the city, town or district, in which the parents of the infant reside, the fact that such inflammation or swelling or redness of the eyes exists.

SEC. 2.—Any failure to comply with the provisions of this Act shall be punishable by a fine not to exceed two hundred dollars, or imprisonment not to exceed six months, or both.

DR. D. R. BROWER, of Chicago, read a paper on

MEDICAL EXPERT TESTIMONY,

in which he said he believed every member of the Society would agree with him that the display of medical expert testimony in the Cronin and Prendergast cases of Chicago, and the Hart case of Rockford, were not creditable to the medical profession, had not promoted the cause of justice, and had not protected the interests of society by the suppression of crime. He said we had seen in these several cases medical men arrayed against medical men with precisely the same set of facts reaching diametrically opposite conclusions, as though all medicine was but empiricism, while the reputable and true physician knows that the laws upon which it is based are scientific and that two persons equally competent, with the same facts to consider, must of necessity reach the same conclusion.

At the conclusion of the paper, Dr. Brower presented the draft of a bill for an Act authorizing the judges of criminal jurisprudence in the State of Illinois to appoint persons to act as expert witnesses, which was approved by the Society. It is as follows:

Be it Enacted, By the people of the State of Illinois in the General Assembly represented, that the judges of the Circuit

and Superior Courts of the State of Illinois, be and the same are hereby authorized to appoint in the month of January of each year, persons who shall act as expert witnesses in the medical and other sciences in giving opinion upon the evidence, as presented in a hypothetical form, of criminal causes that may be on hearing in the courts presided over by the said judges. Such expert witnesses shall hold their said appointments for one year or until their successors are appointed and qualified. They shall be entered as expert witnesses upon a list of such witnesses kept by the circuit clerk, and the said clerk shall issue a certificate of appointment as such expert witness to the person appointed as above.

Such expert witnesses shall be citizens of the State of Illinois and shall be known in the communities where they reside for their professional competency and personal probity, and if physicians they shall have been at least five years in regular and active practice. When expert opinion is desired in any cause pending in a criminal court, the trial judge presiding in such cause may, at his discretion, summon for duty under this Act, such expert witnesses to the number of three. Such expert witnesses shall be paid for their services by the county in which the trial for which they are summoned is held, in such sums as may be named by the judge.

It shall be the duty of such expert witnesses to give an opinion on the evidence as presented in hypothetical form in the case in which they are called. Such experts shall be subject to cross-examination by both prosecution and defense; but such cross-examinations shall be limited entirely to the subjects embraced in their opinion.

In criminal cases previous to trial, if the State's Attorney deems it advisable to have expert opinion, he shall so state to the court having jurisdiction of the cause, and the judge receiving such statement may summons expert witnesses to serve under this Act.

DR. SANGER BROWN, of Chicago, read the

REPORT OF THE COMMITTEE ON INFORMATION,

of which Dr. E. F. Ingals is Chairman. Among other things, the report dealt with the prevention of smallpox, and the cocain habit.

Before the days of vaccination, the annual mortality from smallpox in England averaged about three thousand to each million inhabitants. In France there were 30,000 deaths per annum, and in Russia smallpox is said to have destroyed 200,000 of the inhabitants in one year. The Committee urged the necessity of re-vaccination at least once in seven years, or oftener in case of unusual danger from the disease.

Another subject of much interest to the profession was the alarming increase of the cocain habit due to the promiscuous sale of various catarrh powders containing a dangerous quantity of this drug. The Committee said they could not urge too strongly upon the profession that prescriptions containing cocain, which may be repeated, should never be given, and it should be considered criminal practice to place this drug in the hands of the laity for their unrestricted use.

The following resolutions were read and adopted:

By J. B. Maxwell, of Mount Carmel:

Resolved, That the Illinois State Medical Society give the scheme for an epileptic colony, as proposed, its emphatic and unqualified indorsement:

By A. C. Corr, of Carlinville:

Resolved, That the Secretary be hereby instructed to request Senators and Representatives in Congress from the State of Illinois to use all means in their power to secure the passage of the AMERICAN MEDICAL ASSOCIATION Bill for the establishment of a Department of Public Health, with a competent medical man at the head.

By Dr. Graham:

WHEREAS, The bill making appropriation for the support of the army for the fiscal year ending June 30, 1895, was passed by the House of Representatives with the proviso "that hereafter no appointments shall be made to the office of Assistant Surgeon until the number of Assistant Surgeons shall be reduced below ninety, and thereafter the number of officers in that grade in the Medical Department shall be fixed at ninety;" and

WHEREAS, Such a reduction in the number of medical officers would seriously impede the administration of the Army Medical Department and greatly interfere with a continuance of the high standard of proficiency that has heretofore characterized that department, therefore be it

Resolved, That this Society earnestly protest against the proposed reduction, and urge the Representatives and Senators from this State to prevent its enactment.

Adopted unanimously. The Secretary was instructed to so inform our Senators and Representatives in Congress.

By Wm. E. Quine, of Chicago:

Resolved, That the Committee on Legislation be and hereby is instructed to use its best efforts to secure the adoption of a law prohibiting the sale of proprietary and other medicines in this State except on the prescription of duly licensed physicians; and except as

Provided, That such medicines may be sold if accompanied by a certificate from the State Board of Health to the effect that said medicines contain no ingredient hurtful to the public health.

The following officers were elected:

President—Dr. D. R. Brower, of Chicago.

First Vice-President—Dr. A. C. Corr, of Carlinville.

Second Vice-President—Dr. C. B. Johnson, of Champaign.

Permanent Secretary—Dr. John B. Hamilton, of Chicago.

Assistant Secretary—Dr. E. P. Bartlett, of Springfield.

Treasurer—Dr. George N. Kreider, of Springfield.

DR. J. HOMER COULTER, of Chicago, offered resolutions thanking the retiring President for his work in behalf of the Association, and also thanking the Committee of Arrangements, the Decatur Club, and the press for their excellent reports, all of which were unanimously adopted.

The retiring President thanked the Society for courtesies extended to him during his presidency.

Dr. Brower, the President-elect, was then presented, and made a few timely and appropriate remarks. There being no further business, the Society, on motion, adjourned to meet in Springfield, the third Tuesday in May, 1895.

NOTE.—By reason of the expeditious manner in which the President and the Chairmen of the respective Sections discharged their duties, forty-six papers were read, four addresses delivered, and the regular and miscellaneous business that came before the General Sessions disposed of.

Nebraska State Medical Society Votes for Revision.

Report of Committee on President Mansfelde's Address.

LINCOLN, NEB., May 18, 1894.

To the President and Members of the Nebraska State Medical Society:

Your Committee to whom was referred the address of the President beg leave to report: That a careful consideration convinces them that the earnest attention given the Constitution, By-laws and Code of the AMERICAN MEDICAL ASSOCIATION by the profession all over the country, makes the action of the ASSOCIATION in referring the matter to the several State Societies, a timely one. We find, also, that two contending opinions exist—one that the Code is good enough as it now stands and should not be altered or amended; the other, the very opposite, that the instrument has long since outgrown its usefulness. Your Committee suggest:

That it is unjust to the labors of the past to abolish its landmarks, the old Constitution and Code of the AMERICAN MEDICAL ASSOCIATION; and, also, that the assumption of infallibility of these documents is contrary to the spirit of our times, and it is, finally, our opinion that real grievances exist, for the correction of which we beg leave to recommend: That the President and Secretary of the Nebraska State Medical Society, under the seal of the Society, submit to the AMERICAN MEDICAL ASSOCIATION, for its approval, the following:

That no one shall become a member who has not the qualification hereinafter provided in an amendment to the Code.

That the membership shall be restricted to the members of the State and Territorial Societies, the Medical Corps of the United States Army and Navy, and the Marine-Hospital Service, having subscribed to the Constitution and Code of the AMERICAN MEDICAL ASSOCIATION, and that representation by delegates be abolished. That in case local and district societies are also admitted, either as such or by delegates, then such societies or delegates shall show that they have subscribed to the Constitution and By-laws of the State or Territorial Societies in the jurisdiction of which they are located.

That the existence and duties of the Nominating Committee be left as now provided for.

As to the Code: Article I. Section I should read: No student of medicine shall be accepted by any college or school of medicine, whose graduates expect to become members of the regular profession in good standing, who do not possess as a minimum qualification a diploma from a high school, admitting the owner to the first or freshman year of the best universities of the United States.

And further, no graduate of any college, or school of medicine, which does not require a course of medical training, comprising four school years of not less than six months each, or three school years of not less than eight months each, shall be entitled to membership in any subordinate body forming a part of the AMERICAN MEDICAL ASSOCIATION. And provided further, that the course of study must comprise all the branches now embraced in the curriculum of the Association of American medical colleges, and such requirements shall never be lowered, except by and with the consent of the AMERICAN MEDICAL ASSOCIATION.

That Article IV, Section 7 be amended to read: Any physician, who is a member of this ASSOCIATION or of one of its subordinate bodies, or any physician who by his qualifications is entitled to be a member thereof, shall enjoy the benefits of consultations, and these shall be the prerogatives of such members of the profession only. *Provided*, that this shall not preclude any member, or a physician entitled to membership, from rendering services in which urgency becomes a factor to the saving of life and limb, and such services only shall constitute an emergency, which precludes the possibility of calling into the case of legitimate consultants, who, as defined in this Section, are entitled to such distinction.

A violation of this Section shall be followed by loss of membership, or be a bar to it.

Article II, entitled: "Obligations of patients to their physicians," should be abolished; because the first party to this contract never has fulfilled, and never will keep its part of the compact.

Article I, Section 5, should be amended by striking out the words, surgical instrument or;" thus the Section should read, "equally derogatory to professional character is it for a physician to hold a patent for any medicine or dispense a secret nostrum, etc."

In case the ASSOCIATION will not grant this change, then it should, as a matter of justice and equity, include in the prohibitions: "The copyrighting of any book on medical subjects; then the Section should read, equally derogatory for a physician to hold a copyright for any book on any medical subject or a patent for any surgical instrument, etc."

(Drop ordinance Vol. 20, page 28, referring to specialists.)

There should be added a Section 6 to Article I, of the chapter, "On duty of physicians to each other," to read: "The field of medical knowledge is now so vast that no one mind can compass it in all its details. Nor can any one hand obtain the dexterity essential for the successful procedures and daring operations of modern medicine and surgery. Such work has become by selection that of specialists, who have become a decided factor in the progress of the healing art, and should therefore be encouraged."

They should be permitted to give notice, in manner entirely truthful, of their special practices.

Every practitioner shall have the right to state in his card that he gives preference to any one of the specialties now or hereafter recognized by the profession.

Finally your Committee recommend that the AMERICAN MEDICAL ASSOCIATION be respectfully urged to refer all proposed changes, including our own, to the Council of the ASSOCIATION, with instructions to report such changes to Constitution, By-Laws and Code as a careful consideration of every suggestion submitted may elicit, and that final action may be taken upon such report at the San Francisco meeting.

Your committee further makes suggestion that members of the ASSOCIATION will adopt as a custom for a distinction the signing of the letters A.M.A. after the affix M.D.

And we will ever pray.

GEORGE WILKINSON,
J. M. ALDER,
E. M. WHITTEN,
D. C. BRYANT,
C. INCHES,
P. L. HALL,
A. S. VON MANSFELDE, *ex-officio*.
Committee.

Moved and seconded that the report be adopted.

Dr. Mitchell moved to adopt that part of the report of the Committee which refers to the requirements for admission to the AMERICAN MEDICAL ASSOCIATION; also including that part relating to Nominating Committee. Motion seconded and carried. He also moved that the remainder of the report referring to the Code of Ethics be referred to a committee of three, who shall report to-night.

THURSDAY EVENING.

Meeting called to order at 7:40 P.M. Vice-President Crummer presiding.

Under miscellaneous and unfinished business, on motion the rules were suspended to elect Dr. S. E. Cook, of Lincoln, whose application was filed during the meeting. The Secretary then announced that those desirous of obtaining credentials to the AMERICAN MEDICAL ASSOCIATION should make themselves known to the Society. The Secretary said further that he held in his hand the message that the Nebraska State Medical Society would send to the AMERICAN MEDICAL ASSOCIATION at San Francisco; that the Society in delivering such a message was acting cowardly. The AMERICAN MEDICAL ASSOCIATION cares little to be told to raise the standard of medical education. "It is doing this with little trouble each year. What it desires of you is to give it some idea of the feeling in the States concerning the Code. Give it some idea on this question. Tell it concerning the questions of consultation and the patenting of instruments, whether they shall remain or whether they shall go, or acknowledge frankly that the matter is too much for you. Let us say something."

Dr. Ely introduced the following resolution:

WHEREAS, This Society is pleaded with by the AMERICAN MEDICAL ASSOCIATION to assume part of the responsibility of the national question, the Code of Ethics; and

WHEREAS, It is right that we do lend ourselves to the responsibility of this issue; and

WHEREAS, It seems impossible for our Committee to point out what changes are desirable; therefore,

Resolved, That in our opinion the interests of professional honor and rectitude will be best served by the entire abrogation of all that portion of the Code which relates to consultation and the patenting of instruments.

Dr. Ely, in answer to a question that if he meant by said resolution to abolish entirely the Code, said: "No; it will only abolish that part of it which makes of the Code, a *questio vexatio*, and that which our Committee on this matter acknowledge, after a night's work, entirely unable to revise. Our vote will in no way bind this Society to anything. It is simply an expression of opinion."

Dr. Wilkinson: Mr. President, before you put this matter to a vote I should like to say a word. Remember this is a serious matter. We do not need to adopt this resolution; adopt or reject, it serves the same purpose. Are you satisfied that the members present will represent the opinion of the Society? This is the important and dominant part.

The resolution was carried.

College of Physicians and Surgeons of Philadelphia.

ORTHOPEDIC SECTION.

EXHIBITION OF APPARATUS FOR PREVENTING AND CORRECTING DEFORMITIES OCCURRING AFTER EXCISION OF THE KNEE JOINT, BY DR. G. G. DAVIS.

DR. G. G. DAVIS—In the treatment of resection of the knee, flexion often occurs. It is difficult to get firm union in a straight line, and I believe this difficulty is not recognized sufficiently, and efficient means are not taken to provide against it. This is seen not only in private practice, but still more frequently in cases on which operation has been previously done, which afterwards apply at our surgical dispensaries. I am quite of the opinion that effective apparatus of some sort is necessary. I do not know what appliances the other members have used for the treatment of this tendency, but the apparatus which I have found to be most efficacious has been as follows:

It consists of two iron sides which are joined at the ankle and have a stirrup beneath the foot; on the inner side the upright reaches to the perineum; on the outer, to above the trochanter.

The outer piece is fastened above to a metal hip band passing three-fourths around the pelvis and lying, like a truss, just below the crests of the ilia. The posterior portion of the leg is supported by the heel in the shoe below, and a piece of sole leather above going around the posterior half

of the thigh from one side iron to the other and touching the gluteo-femoral fold. Pressure is made on the front of the knee by a padded sole-leather knee cap, fastened to the inside iron by two straps, while its outer side, passing down between the limb and side iron, is depressed by one or two screws fastened to a plate on the outer side iron.

Antero-posterior displacement is met by turning the screws and thus forcing the knee backward.

Lateral displacement is met by bending the side irons in or out as required by wrenches.

Any tendency to inversion or eversion is met by twisting the outside iron just below the hip joint with wrenches.

A soft leather hip band will not do, as it will not fix the brace firmly enough in relation to the pelvis to prevent rotation. In order to avoid dropping of the toe, while the patient is going around with a high shoe and crutches, the ankle joint should be fixed by locking it with a screw which can be removed when the limb is used for walking.

I am averse to using any apparatus, like plaster-of-paris, that can not be altered, and conceals the part. I wish to see the limb every week, so that if any tendency to deformity shows itself, it can be at once met by applying a positive pressure in the proper direction.

DR. DEFOREST WILLARD—It seems to me questionable whether the plate upon the outer side will make as much pressure as the pad ordinarily placed in this position.

DR. G. G. DAVIS—It is simply a matter of taste. I prefer the screw arrangement because straps are apt to yield and become loose, while with it the parents can, by turning the screw with a key, always keep the pressure firmly applied.

DR. H. AUGUSTUS WILSON presented a cast of a leg, showing right angle flexion and rotation after excision of the knee, and said: When I first saw this patient five weeks ago at the Jefferson Hospital he said he was aged 14 years, and that nine years previously he was operated upon at St. Petersburg for what appeared to have been tubercular osteitis. The operation seems to have been excision of the knee joint, and it occurred to me it might be of interest to the Section to study the case showing such serious ultimate deformity. For six months the child walked with crutches, but on abandoning them the leg became bent, and at the end of a year the leg presented the appearance of right angle flexion.

At the time I performed secondary resection at the line of the original excision, there was an immense amount of callus. In sawing, I also found a large amount of callus thrown in the popliteal space. The curve which existed was very large in the upper end of the tibia and flexion seemed to have occurred in the callus; the case illustrating one of the unfortunate results of not using absolute fixation and crutches long enough. From the history of this case I judge that the condition of tubercular osteitis existed something like two years previous to the first operation. It is interesting also to know that at the upper end of the tibia, which was the original seat of the tubercular osteitis, there was a clearly marked cavity, and in the center a fibrous mass of cheesy consistency. I gouged this out and the patient did fairly well until the relighting of the tubercular inflammation. There has been primary union and the inflammation has subsided under the use of iodoform injections. The case is interesting in connection with a number of cases which I reported at the Academy of Surgery, in which flexion took place after excision. (*American Journal of the Medical Sciences*, March, 1893.)

DR. F. X. DERCUM—As displacement occurs from active flexion of the muscles, would it not be a good plan to excise the joint and then tenotomize the muscles?

DR. G. G. DAVIS—Tenotomy of the muscles would obviate the tendency to deformity occurring immediately after operation, but would have no influence upon deformity occurring subsequently; that is to say three months, six months, or a year afterwards, because union would already have occurred.

DR. G. G. DAVIS—I would like to say a word about the use of the apparatus of Dr. Goldthwaite which has been exhibited by Dr. Willard, because in it there is an attempt made to exert force in a manner which has not yet been alluded to. Dr. Willard spoke of posterior luxation and said that in such cases he usually used excision. Ordinarily, straightening of a joint is done by simply flexion and extension movements; not only can these movements be made with the apparatus shown to-night but there is a direct pulling forward of the head of the tibia and fibula. If this apparatus will do that satisfactorily, it will obviate the necessity of resection in some of these cases of sub-luxation and therefore I would like to hear the results of its trial.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above subscription the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, MAY 26, 1894.

ABORTION.

In its consequences, there is no accident that can befall the child-bearing woman more serious than abortion. There is no doubt that a long period of invalidism, ending perhaps in a trying and critical operation or a tedious convalescence and slow regaining of a shadow of the former health, may have a starting point in an abortion. The picture is a familiar one to the gynecologist. A recent writer¹ has declared: "In my private or dispensary practice, it is an almost daily experience to meet a new case of advanced disease of the uterus and its adnexæ which from the history elicited can be clearly traced to an abortion." If such be the case, it behooves the physician to look upon abortion in its true light and prevent the unfortunate sequelæ, as far as possible, instead of regarding it as unlucky accident which will keep the woman in bed for a few days and there end.

The treatment naturally resolves itself into that of two periods; before the abortion has become inevitable and after the fetus has been expelled. In the early stages, while the fetus is yet alive, rest and opium in full doses may quiet the contractions of the uterus, stay the hemorrhage and enable the woman to go to term. When the hemorrhage is great, ergot in small doses, either alone or combined with hydrastis, has succeeded. Quinin in 2 grain doses every hour till cinchonism occurs has had a happy effect where a malarial taint was at the bottom of the mischief. But whatever the drug employed, absolute rest must be enjoined and without this all is futile.

In spite of the best endeavors, the contractions often keep up, and it is in this crisis, when the abortion is inevitable and the womb refuses longer to hold its unwelcome tenant, that the woman has the most need of the doctor's care and skill. He may

find that the woman has been lucky enough to expel the whole product of conception—fetus, membranes and placenta—at once. Lucky indeed is the aborting woman who has nature for an accoucheur, when nature does all and leaves nothing for the doctor to do. But should this not happen, what is the attendant to do? Two courses lie open to him: He can either trust to nature that the placenta will be expelled before it becomes putrid and infects the woman, or he may take the better course and empty the uterus with his own hands. If he has true regard for his patient as a woman and a human being he will not allow her to run any risks of possible poisoning from a decomposing placenta. The operation is not a difficult one and while many special instruments have been devised for the removal of the placenta, after all the only instrument required is the hand of the operator. The one secret in the operation is that the woman be placed on a hard unyielding surface, such as a table, instead of the bed which, with its soft mattress, allows the buttocks to sink, thereby adding greatly to the difficulty of introducing the fingers within the uterus. Placing the woman in the lithotomy position, one hand is placed above the pubes to steady the uterus and bring it down on two fingers of the other placed inside. Gently the fingers go all over the cavity of the uterus, peeling off the placenta much as an orange is peeled out of its skin. When all is removed the uterus is washed out with an antiseptic and the woman returned to bed. Clean hands will have done the work and the woman should have no fever, no sequelæ of any kind.

There is little doubt that this is the proper treatment for abortion, and yet there are those who still cling to the older let-alone policy, arguing that all will be well and that nature will take care of the patient. In answer to them we say that the placenta in these cases holds the position of a foreign body and should be treated as such. There is little safety in allowing it to come away piecemeal in the course of days or weeks, and the rational treatment is that it should be removed at once. An adherent placenta would hardly be allowed to remain after natural labor, and it is false reasoning to permit it to stay after abortion.

Delay means the danger of septicemia and this danger may be averted by removing the cause by means of a curette with brains—the fingers. But, mark you, let those fingers be strictly, surgically sweet and clean, or fuel is added to the fire, and the doctor instead of a life and health-giver becomes an assassin who stabs the friend who trusted in him.

HEALTH OF LARGE CITIES.

A late bulletin, with statistics, issued by the German Imperial Health Department, claims for Berlin the credit of being the healthiest city in the world. The death rate for 1893 is given as only 16.3 per

¹ Dr. Charles H. Bushong, Virginia Medical Journal, December, 1893.

thousand. Alexandria in Egypt, despite its unvarying fine weather, its 300 fountains and its soft sea breezes, has a death rate of 52.9 per thousand and is, probably, the unhealthiest city in the world. London, with its enormous aggregate of 4,500,000 inhabitants, has a death rate of 20.3 per thousand.

These figures suggest some comparisons with the large cities of the United States. Among these Chicago ranks highest in point of salubrity. In 1893, with a population of 1,520,000, the death rate was 17.8 per thousand, or 1.5 per thousand greater than that of Berlin, with a population of 1,600,000—substantially the present population of Chicago.

Of other large American cities whose bills of mortality for 1893 are at hand, Baltimore ranks next with a population of 455,427 and a death rate of 20.54 per thousand; Brooklyn, population, 983,841, death rate 20.58; Washington, population, 250,000, death rate, 23.98; New York, population, 1,856,695, death rate 24.; Boston, population, 487,397, death rate, 24.02; Philadelphia, population, 1,115,562, death rate, 24.48.

In order of lowest death rates from zymotic diseases—including the tuberculoses—Chicago also ranks first, with a death rate of 6.8 per thousand; and the other cities named, as follows: Boston, 7 per thousand; Baltimore, 7.2; Brooklyn, 7.28; Philadelphia, 7.88; New York, 8.; Washington, 8.04. As to typhoid prevalence, as indicated by death rates, these cities rank in the following order—the rates given being per 10,000: Brooklyn, 1.83; Boston, 3.03; New York, 3.13; Philadelphia, 3.99; Chicago, 4.66; Baltimore, 4.92; Washington, 7.88.

The typhoid death rate is persistently excessive in Washington. During the six-year period ended May 31, 1890, it averaged annually 7.55 per 10,000 of population, and during the census year it rose to 8.62 per 10,000—only less than the proportions assumed in Philadelphia during the Centennial year. The reduction of typhoid in Chicago is marked. Between 1886 and 1889 the proportion of deaths from typhoid fever to deaths from all causes had fallen from 3.5 per cent. to 2.4 per cent.; but in 1890 it suddenly rose to 4.16 per cent., and in 1891 to 7.19 per cent., with the prodigious death rate for the disease of 16.64 per 10,000 of population; there were 385 more deaths from typhoid fever in the city of Chicago during 1891 than in the whole State of New York, with five times the population, and 1,400 more deaths than in London, with three and a half times the population. In 1892 this enormous rate had fallen to 10.4, and during the past year it has been still further reduced to 4.66 per 10,000 of population. Improvements in the manner of obtaining the water supply from Lake Michigan will, no doubt, still further reduce this rate, which is yet much too high.

KINGS COUNTY (N. Y.) LUNATIC ASYLUM.

The Supervisors of this County have adopted measures for placing the insane poor under the care of the State Board of Lunacy, and after that shall have been accomplished they will sell their asylum property to the State. It will probably be necessary to part with this property at the rate of about one-half million of dollars, the cost of which to the County has been about six times that sum. This sale and transfer of the insane will effect two desirable objects; first, the patients will obtain better care, by being separated from the influence of pot-house politicians; second, the County will be benefited to the extent of an annual saving of \$200,000 in the tax-levy. The reason for this latter statement is seen in the fact that the Legislature of the State, when passing the "State Care Law," ordained that each and every county that refused to accept the provisions of State Care should be taxed just the same for the care of the insane of the entire State as if they accepted the terms of the law. If the overtures of Kings County, for the transfer of the County charges to the Lunacy Commission are successful, there will then remain only New York County persisting in its separation from State Care. This separation is dictated by political motives and the retention of a large amount of patronage by the Tammany Hall party now in control, rather than by incentives on behalf of the pauper insane. If Tammany Hall shall be driven out of power next fall, as hundreds of thousands of people believe, the State Care Law will undoubtedly be given full sway over the whole of the Empire State.

PRESUMPTIONS AS TO OPINIONS OF EXPERT WITNESSES.

The fact that a person is called as an expert, the Supreme Court of California holds, in *HEALY v. VISALLA & T. R. Co.*, decided March 14, 1894, assumes that his opinion is based, not merely upon the empirical knowledge which he has gained through his own practice, but also upon that which he has acquired in the study of his profession, and from his intercourse with other members of the same profession. As an expert it is competent for him to give the grounds upon which he bases his opinion, as well as the opinion itself; and the fact that his opinion is based upon information derived from his reading does not make it incompetent for him to so state. It is entirely different for an expert witness, in making his answer to a question as to what are likely to be the results of certain injuries, to give as a reason for his opinion, "because" there are cases on record which have resulted in death, from reading medical or scientific books to the jury, or seeking to influence them by opinions or theories contained in such books. The witness being only asked to give his

own opinion, which he does under the sanction of his oath, it must be assumed to be a conclusion reached by him after a judicious comparison of all that he has read or learned upon the subject; and upon this opinion, as well as its source, he can be subjected to the most rigid cross-examination. Thus, in an English case it was held that medical books themselves can not be read, but that the witness, who was the President of the College of Physicians, could state, not only his judgment, but the grounds of it, which were in some degree founded on books, as a part of his general knowledge.

THE DEATH OF DR. ALBERT DAY.

DR. ALBERT DAY, for nearly forty years identified with the Washingtonian Home for Inebriates, Boston, as its Superintendent, died recently. He was the pioneer in the establishment of these useful institutions in our country. A scholar, a gentleman, a courteous man of the world, a true philanthropist, he will leave a vacant place very hard to supply. His modesty was in keeping with his great knowledge, and his thorough understanding of the physical conditions and psychic state of the inebriate, never led him into any species of personal advertising. He was content, in his unassuming way, to devote his life and talents to the service of the unfortunate creatures for whose benefit the Washingtonian Home was instituted. He did his work well, and we should not be stinted in praising the character of one who has done so much for suffering humanity, and so much to restore to manhood those who lost it by their own act, perhaps, but yet through defects in original constitution or acquired obliquity. May he sleep well.

LIABILITY FOR UNHEALTHFUL CONDITION OF JAILS.

The Supreme Court of Michigan holds, in the case of Webster v. Hillsdale County, decided March 6, 1894, that counties are not liable in damages for injuries to the health of prisoners in consequence of the unsafe, unsuitable, unwholesome, unventilated and unhealthful condition of their jails. The basis of this non-liability is said to be that counties are involuntarily territorial and political divisions of the State, created for the convenience of the government, and that certain public duties are imposed upon them as a part of the machinery of the State, for the performance of which no liability should attach, any more than it would to the State itself. The Legislature of Michigan, recognizing that cases might arise where prisoners would be injured in health by the unsanitary conditions of jails, enacted that when a jail should become unfit for occupation the judge of the circuit court should designate the jail of some other county for the confinement of prisoners. There would be as much good sense, the Court says, in hold-

ing the county liable for the neglect of the circuit judge as to hold it liable for the neglect of its supervisors. The duty in the one case is as imperative as in the other.

PHYSICAL EXAMINATIONS UNDER NEW YORK'S NEW LAW.

The General Term of the New York Court of Common Pleas holds, in Lyon v. Manhattan Railway Company, decided March 9, 1894, that under the new legislative enactment of 1893, an order for a physical examination of the plaintiff in personal injury litigation can not be made except in connection with, or as a part of, an order for the oral examination of the plaintiff before trial. This statute, the court says, leaves the question of ordering a physical examination in actions for personal injuries, to the discretion of the judge, unless the defendant proves "that he is ignorant of the nature and extent of the injuries complained of," in which case the court is bound to grant the order. The reason for connecting the physical examination with the oral examination is to afford the plaintiff, who is examined, as well as the defendant, who has demanded the examination, the benefit of such examination on the trial, and to that end to preserve the record of it. Where a physical examination is had, the questions put to the plaintiff, the answers thereto, and the testimony of the physicians by whom the examination is made, are (so far as required by either party) to be reduced to writing, verified, certified and filed, and may be read by either party.

CORRESPONDENCE.

Relation of the American Medical Association to the State, Interstate, and Railway and National Guard Surgeons Associations.

KANSAS CITY, Mo., May 19, 1894.

To the Editor:—The writer drew up resolutions below given to present to the Tri-State Medical Society, Iowa, Illinois and Missouri, at its Kansas City meeting, April 3 and 4, 1894, and again prepared them for presentation at the meeting of the Medical Society of Missouri at Lebanon, Mo., May 15, 16, and 17, 1894, but it so happened that he was not present when opportunity offered for bringing up such matters, and therefore they were not offered at either time. However, a number of members of these Societies have read them, and urged him to present them, even at a very late hour, at the meetings of these Societies, all expressing the opinion that the measures would be of the very greatest benefit to the Associations interested. As the carrying out of these resolutions involves many very radical changes in Constitutions and By-Laws, they are matters not to be hastily considered. I therefore send them to you to publish, if possible before the San Francisco meeting, as there can be no harm in canvassing the matter.

Resolutions offered for adoption at the thirty-seventh annual meeting of the Medical Association of the State of Missouri, May, 1894.

PREAMBLE:—Whereas, the AMERICAN MEDICAL ASSOCIATION, and the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

tion, are representative organs of the medical profession of this country, and this Association, and similar State associations are the representative societies of the States and territories; and

WHEREAS, A number of societies, representative of the general profession of two or more States, and other associations, representing large numbers of the profession engaged in special lines of professional work, have been formed throughout the country; and

WHEREAS, The interests of these State societies and associations would be advanced by a more intimate relation with the AMERICAN MEDICAL ASSOCIATION, and their proceedings would, if published in the JOURNAL, reach a much greater number of readers, and the strength and usefulness, and the higher character and efficiency of officers of the American and the State and Inter-State organizations would be reached, if these officers were, in part, chosen in common to the subordinate and national societies. Therefore be it

Resolved, That this Association respectfully petitions the AMERICAN MEDICAL ASSOCIATION to become a local branch of that body, and to have its President, and the Presidents of other societies having received a like recognition, and having a membership of over one hundred members be *ex-officio* Vice-Presidents of the AMERICAN MEDICAL ASSOCIATION, and that all such branches shall annually elect five Vice-Presidents, the first of whom shall be *ex-officio* member of the Executive and Nominating Committees of the AMERICAN MEDICAL ASSOCIATION, with the remaining Vice-Presidents in the order of succession as alternates; the Secretaries of such branch societies be *ex-officio* associate editors of the JOURNAL. That the proceedings of these subordinate bodies after reference to their own committees on publications, and the editorial staff of the JOURNAL, (as much as is not unsuitable), shall be published in the JOURNAL. The privilege of the membership of the branch society constituting also a membership in the American society, be conditional on the payment of a membership fee, which shall be agreed upon and established by the By-Laws of the two societies; a percentage of which will go to the support of the JOURNAL.

Further resolved, That a copy of these resolutions be transmitted to the AMERICAN MEDICAL ASSOCIATION, the representative State and Territorial medical societies, and the State, and Inter-State societies, and Associations of Railway Surgeons, Military and National Guard Surgeons.

Some of the advantages that it seems to the writer would come from adopting the plan above outlined, would be: First, doubling or trebling the membership of the ASSOCIATION, and the subscribers to the JOURNAL, increasing the dignity and importance of the offices of the subordinate associations, and bringing to the meetings of the AMERICAN MEDICAL ASSOCIATION a larger body of well-qualified men from which to select the President and other officers, to increase the quality of the papers prepared for the meetings of these associations, by making the feeling in those preparing papers that they were addressing the profession of the country through a widely distributed JOURNAL, rather than burying their work in a publication of Transactions seldom read by fifty members of the profession, either members of the society, or outside of the society. It would better provide for weeding out the inferior papers, by having them pass through the hands of the local committee, and then through the hands of the editors of the JOURNAL, by taking the responsibility of rejection away from home.

The Executive Nominating Committee constituted outside of the AMERICAN MEDICAL ASSOCIATION would do away with the so-called medical politics, of which the writer knows nothing excepting hearsay from his fellow-members of the ASSOCIATION, yet he has heard that frequently enough to believe that there must be some fire where there is so much smoke, and judging from the men who have represented his State in the years he has been a member of the ASSOCIATION, he is inclined to think the methods of the politician stand a good chance.

The officers selected in the subordinate societies would be of higher character, from the very fact that a position in the AMERICAN MEDICAL ASSOCIATION was assured by election to certain offices in the home society.

It seems to the writer that the interest in all of these bodies would be increased by this relation, and that there is no reason why the JOURNAL should not have 25,000 or 30,000 subscribers, instead of less than 5,000, if this arrangement was made.

There is nothing new in the suggestion, as it is very much the one in practice by the British Medical Association, the journal of which is said to have 70,000 subscribers.

JOSEPH SHARP, M.D.

ASSOCIATION NEWS.

Executive or Business Committee.—The first meeting of the Business Committee of the ASSOCIATION will be held in Parlor A, Palace Hotel, San Francisco, on Monday, June 4, at 5 o'clock.

A full attendance is requested in order that the Committee may get to work early, and be ready for business referred to it by the ASSOCIATION.

Subsequent daily meetings will be held in the same place, which has been secured for the purpose by the Committee of Arrangements. The time of subsequent meetings will be determined by the Business Committee.

L. DUNCAN BULKLEY, M.D., Secretary.

The Forty-fifth Annual Meeting.—The AMERICAN MEDICAL ASSOCIATION will meet in San Francisco June 5 to 8 inclusive.

The entire work of the ASSOCIATION will be done in Odd Fellows Building, Cor. Market and Seventh Streets.

Exhibition room for instruments, pharmaceutical preparations, etc., is also in this building.

Registration will begin in Marble Hall, Palace Hotel, on Monday, June 4, when all who arrive early enough should register to avoid the rush on Tuesday. Working hours of the Sections will be from 9 to 12 and 2 to 5—except the forenoon of the first day. The General Assembly will convene at 10 o'clock on Tuesday.

The following hotels have quoted special rates for members and their families: Palace, Grand, Lick, Russ, Occidental, California, Baldwin and Pleasanton.

There will be room for all. Visitors desiring to engage rooms in advance can do so by communicating directly with the hotels or with R. A. McLean, 305 Kearny Street, Chairman Committee on Hotels. Headquarters at Palace Hotel where there will be a concert in the Grand Court, Monday evening, June 4.

Tuesday evening a reception will be held at Pioneer Hall; Wednesday evening at Cooper Medical College; Thursday evening at the Mid-winter Fair, and Friday evening at the Hopkins Art Institute. The Ladies' Committee on Reception—Headquarters Palace Hotel—will provide entertainment for visiting ladies during the day.

Saturday will be devoted to an excursion around the Bay, starting at 9 o'clock and returning at 5, passing in view of the Irving Scott Ship-building Yards, Spreckles' Sugar Refinery, United States Military Posts—Alcatraz, Fort Mason, Presidio, Fort Winfield Scott, and out to the "Heads" for a touch of old ocean; returning pass United States Quarantine Station and land at Mare Island where an hour will be spent inspecting the Government Hospital and reconstruction works.

Railroad tickets will be good for return till July 15. Members will therefore have time to make numerous side excursions in the State, after the meeting. On the S. F. & N. P. Railway the rate for such excursions will be a single fare for a round trip.

The Southern Pacific Company's rate will be one and a fifth to one and a third fare for a round trip. Some of our

seaside and mountain resorts, mineral springs and sanitariums will well repay for time spent on a visit. Among them are Santa Cruz, Del Monte, Santa Barbara, Santa Monica and Coronado; peerless Yosemite and her giant sequoia forests, Lake Tahoe and Mount Shasta, Pass Robles, Arrowhead, Gilroy Hot, Byron, Soda, Vichy, Geysers, Harbin, Bartlett, and Highland Springs, all possessing medicinal virtues, and justly popular with our own people. Special inducements are offered at all these places. Pass Robles Hotel offers the best entertainment for members at half regular rates, and Highland Springs, in the Switzerland of America, with its lathstring on the outside, invites members to come and partake of its hospitality, free as the bubbling waters of its Springs.

June will be the height of the season for the Alaska excursion, unequaled by any other trip in the world save that to North Cape. Members who desire to secure accommodations in advance for this trip can do so by applying to the Committee of Arrangements.

Any one desiring to secure space in Exhibition Hall should apply to R. L. Rigdon, Nucleus Building, Chairman Committee on Exhibits.

If members who are getting up excursions will immediately send us approximately the number we may expect from their respective localities it will simplify our work of preparation for reception and entertainment.

We request also, that they will wire us the exact number on departure of their trains.

SOCIETY NEWS.

American Orthopedic Association.—Program of the eighth annual meeting, to be held at Washington, D. C., May 29, 30, 31 and June 1, inclusive.

The sessions will be held in the Preparatory Department, Columbian University, H. near 14th Street. The annual dinner will be omitted, and instead a breakfast will be given by the outgoing President at 2 p.m. on Wednesday at the Shoreham, to members of the Association. This will give the members an opportunity to attend the dinner of the General Congress on Wednesday evening, to which they are all invited. The President's address will be delivered on Wednesday after the Executive Session, on: Orthopedic Surgery, of the Past and Future, and the Influence of Surgical Bacteriology and Modern Pathology upon the Subject.

Officers for 1894: President, Dr. A. M. Phelps, New York; First Vice-President, Dr. Augustus Wilson, Philadelphia; Second Vice-President, Dr. Harry M. Sherman, San Francisco; Secretary, Dr. John Ridlon, Chicago; Treasurer, Dr. E. G. Brackett, Boston.

Member of the Committee on Arrangements for the Congress of American Physicians and Surgeons: Dr. DeForest Willard, Philadelphia.

Committee on Membership: Dr. L. A. Weigel, Dr. A. J. Gillett, Dr. Ansel G. Cook, Dr. J. D. Griffith, Dr. John C. Schapps.

Publication Committee: Dr. E. H. Bradford, Dr. J. E. Goldthwait, Dr. Samuel Ketch.

Member of Executive Committee, Congress of Physicians and Surgeons: Dr. Newton M. Shaffer; *Alternate*, Dr. Ap Morgan Vance.

The Treatment of Severe Forms of Club-foot, Dr. Edmon Owen, London.

Disease of the Shoulder-Joint, Dr. W. R. Townsend, New York.

Titles to be announced, Drs. W. J. Taylor, Philadelphia, and W. O. Plimpton, New York.

Fixation and Traction in the Treatment of Fractures into Joints, Dr. Ansel G. Cook, Hartford.

Title to be Announced. Dr. James Kerr, Washington, D. C.

First Discussion, first day: Flat Foot. *a*, Its Etiology and Mechanism of its Production, Dr. Newton M. Shaffer, New York; *b*, Pathology, Prognosis and Mechanical and Surgical Treatment, Dr. T. C. Morton, Philadelphia; *c*, Gymnastic Treatment, Dr. H. Augustus Wilson.

Drs. Royal Whitman, New York, Sidney Roberts, Philadelphia; J. D. Griffith, Kansas City, Roswell Park, and others will take part in the discussion.

Second Discussion, second day: Rachitic Deformities. *a*, Etiology, Clinical History and Lesions, Dr. A. Jacobi, New York; *b*, Its Various Manifestations, Diagnosis, Differential Diagnosis and Prognosis, Dr. Benj. Lee, Philadelphia; *c*, Mechanical and Constitutional Treatment, Dr. Samuel Ketch, New York; *d*, Operative Treatment, Dr. DeForest Willard, Philadelphia.

Third Discussion, third day: Paralytic Deformities. *a*, Etiology, Clinical History, and Pathological Conditions producing them, Dr. E. H. Bradford, Boston; *b*, Varieties, Diagnosis, Differential Diagnosis and Prognosis, Dr. E. G. Brackett, Boston; *c*, Mechanical Treatment, Drs. John Ridlon, Chicago, and Joel Goldthwait, Boston; *d*, Operative Treatment, Paralytic and Rachitic Deformities, Dr. DeForest Willard, Philadelphia.

The Red Cross.—The following report of the Committee of the Association of Military Surgeons of the United States on the proposed Act of Congress for the protection of the insignia and name of the Red Cross, was unanimously adopted and has been transmitted to the President of the Senate by the President of the Association, Surgeon-General George M. Sternberg, U. S. Army:

WHEREAS, In the International Convention at Geneva, Switzerland, Aug. 22, 1864, twelve nations of the world met and formulated Articles of Treaty, for the purpose of mitigating the evils inseparable from war; of suppressing the needless severity, and particularly providing that persons employed in hospitals, and affording relief to the sick and wounded, and supplies for this purpose, shall be deemed neutral and entitled to protection; and that a distinctive and uniform flag shall be adopted for hospitals and ambulances, and convoys of sick and wounded, and an arm badge for individuals neutralized; and

WHEREAS, Said treaty has been ratified by every civilized nation of the world with one or two exceptions of minor importance; and

WHEREAS, The flag adopted was the distinctive sign of the Red Cross alone, under which insignia or sign, the purposes of the treaty shall be carried into effect, the same being a red Greek cross on a white ground, and which shall constitute the military hospital flag of all the nations within the treaty and designate all persons serving under it; and

the same is adopted and used throughout the world; and

WHEREAS, The United States gave its adhesion by Act of Congress, March 1, 1882, which was ratified by the International Congress of Berne, June 9, 1882, and proclaimed by President Arthur, July 26, 1882, thus adopting by solemn compact and treaty this universal and only military hospital flag; and as the insignia is prescribed in the United States Army Regulations, they are a part of the equipment of regular armies and militia and are incorporated in the rules of the government and regulations of the land forces; and

WHEREAS, The unauthorized use of said insignia in all countries within the treaty, becoming a source of embarrassment and serious injury causing perplexing complications to arise, all of the nations under said treaty have taken vigorous action against this evil, and have passed stringent laws with heavy penalties for the protection of this special insignia; and

WHEREAS, The same great evil exists to-day in this country—the merchant prince, the manufacturing chemist, the speculator and huckster alike, seizing upon and adopting for purposes of trade and barter, this greatest of humanitarian emblems, made sacred by solemn compact and the wisest of counsel; and

WHEREAS, The fact becoming known that this country has no laws for the protection of the Red Cross, the whiskies, drugs, pills and nostrums of the world, bearing the Red Cross on their labels, are being imported; thus the laws for the protection of the sign in other countries, are working us positive and fatal injury and, unless this wrong shall be righted and this Congress protect the interests of the Government, the Red Cross will be brought into such contempt that its value as a relief sign will be gone and its usefulness utterly destroyed; and

WHEREAS, The American National Red Cross—the United States branch of the International Red Cross—has, through its honored President, Miss Clara Barton, been endeavoring for five years to secure by Act of Congress, at least a measure of the protection which is accorded this emblem in other countries; and

WHEREAS, A Bill "to protect the insignia and the name of the Red Cross" was introduced in the House of Representatives this session and, on March 23, passed unanimously without alteration or amendment, referred to the Senate, read twice and referred to the Committee on Foreign Relations; and, therefore, be it

Resolved, That we, the Association of Military Surgeons of the United States, in Congress assembled, do earnestly recommend the Bill now before the Committee on Foreign Relations for the protection of the insignia and name of the Red Cross, and urge its immediate passage.

Respectfully submitted,

ALBERT L. GIHON,
Medical Director U. S. Navy, Chairman.
LEONARD B. ALMY,
Lieut.-Col. and Medical Director Ct. N. G.
CHARLES SMART,
Major and Surgeon U. S. Army.

NECROLOGY.

MARTIN LUTHER, M.D., of Reading, Pa., died on February 23.

EDWARD F. DRAYTON, M.D., of Brooklyn, N. Y., died Saturday, May 5, in the sixty-sixth year of his age. He was a naval surgeon during the late war. After the war he settled in Brooklyn and interested himself in certain matters of public improvement, especially in street transit. He was for a time the president of one of the important companies. His death was due to lobar pneumonia.

DAVID CRARY, M.D., probably the senior medical man of Connecticut, died April 16, at Hartford, from senile asthenia. He was born in Wellingford, Vt., April 18, 1806, and had practiced medicine there and in Hartford since 1838. He had assisted at the birth of more than three thousand children. He was a member of the Hartford County Medical Society and the Connecticut Medical Society and was a noted fox hunter. He has been twice married and leaves three children. Dr. David Crary, Jr., and Edwin Crary, of Hartford, and Frank Crary, of Wisconsin.

PUBLIC HEALTH.

Physical Education.—At a recent meeting in Exeter Hall, London, Eng., the appointment of a Minister of Physical Education was suggested and seriously discussed. One of the speakers, the Marquis of Caermarthen, M.P., said that gymnasiums should receive substantial aid from the government, "the proper physical culture of the people being a matter of greatest national importance."

Compulsory Vaccination in Public Schools.—The U. S. Commissioner of Education, the Hon. W. T. Harris, in a recent interview, expresses himself as "opposed to the compulsory vaccination of public school pupils." He adds: "However, I believe that children should be refused admission to the schools when it is found that they lack evidence of having been vaccinated." It would be interesting to learn the Commissioner's definition of "compulsory vaccination." He would not compel a public school pupil to be vaccinated; but—if it didn't show evidence of having been vaccinated he would compel it to cease to be a public school pupil.

Sanitation of Mexico.—For centuries the City of Mexico has suffered from the pestilential exhalations of the bed of the lake which is the site of the city, and its growth has thereby been seriously retarded. The great sewer, intended to drain this area is now completed at a cost of nearly \$10,000,000, and is pronounced as important a work in modern engineering as the Manchester ship canal; while, as a sanitary undertaking, it is expected to benefit the Mexican capital to a greater extent even than the English city will be benefited commercially by her enterprise.

Yellow Fever.—The attention of the Treasury Department having been called to the fears of a possible recurrence of yellow fever at Brunswick, Ga., Acting Secretary Curtis has requested the Department of State to instruct United States consuls stationed in the Atlantic seaports of South America, Central America, Mexico and in all the West Indian ports, particularly those of Cuba, to notify masters of vessels leaving such ports for any port in the United States between the southern boundary of Virginia and the western extremity of the Mississippi coast, that "if yellow fever or if fever suspected of being yellow fever, appears on board any such vessel during the voyage; or if the master has reason to believe during the voyage that the vessel is infected with yellow fever, said vessel, en route to her port of destination, should repair to the United States quarantine station at Dry Tortugas, Fla., or if more convenient, to the United States quarantine station at Blackbeard Island, Sapelo Sound, Ga., for inspection or treatment."

Smallpox.—With the gradual subsidence of the smallpox epidemic, reports become more and more meager and incomplete. The following is a summary of those received during the past week:

Dr. Benjamin Lee, Secretary Pennsylvania State Board of Health, reports May 17, since April 11, a total of 61 cases at 17 different points, to-wit: Philadelphia 5 (2 traced to Danville or neighborhood), Harrisburg 2, Danville 6, Lee 16 (origin Danville), Shickshinny 7, (origin Danville), Muncy 1, Jerseytown 1 (origin Danville), Reading 4, Lewisburg 1, Blandon 4, Walnuttown 1, Lidell's 1, Hyde Park 2, West Hempfield 1, Derry Township 3, Lewistown 3 (origin Danville), Dorrancetown 1 (origin Danville). Dr. Lee also reports 3 cases of typhus, isolated in the Municipal Hospital, Philadelphia, "probably imported via New York."

Dr. J. W. Scott, Secretary Illinois State Board of Health, reports, May 22, for the State outside of Chicago, only three infected points remaining, to-wit: Havana 1, Evanston 2,

Aurora 1; origin in all cases, Chicago. In Chicago there has been a notable decrease since May 18, the daily reported cases since last summary being as follows: May 15, 37 cases; May 16, 28; May 17, 33; May 18, 14; May 19, 8; May 20, 6; May 21, 5. Total cases from January 1 to May 21, 1,690. The energetic enforcement of the measures detailed in the last smallpox summary would seem to have got the outbreak under control for the present season; and there is ground to hope for an avoidance of any recurrence next fall in the wholesale vaccination still being vigorously carried on. Between May 1 and 21 inclusive, the Health Department used 304,900 vaccine points, and this is exclusive of the vaccinations by private physicians.

Dr. C. N. Metcalf, Secretary Indiana State Board of Health reports cases in Fulton, Marshall, Pulaski and Wayne Counties. He also reports that there had been 31 cases with 10 deaths in Fulton County; that the greatest negligence had characterized the treatment of the outbreak and that the local health officer had been removed for incompetency. All State benevolent and penal institutions have been closed to visitors by order of the State Board of Health; neither patients, visitors or other persons are admitted without a permit from the Board.

No new cases reported in Minnesota—the last having been two cases at Duluth, announced May 8.

Dr. M. O'Brien, Secretary Kansas State Board of Health, reports, May 22, 30 cases in Atchison.

Dr. J. T. Reeve, Secretary Wisconsin State Board of Health reports, May 19, a case at Wausau and one at Milwaukee, "both traceable to Chicago."

Suppression of Tuberculosis.—The crusade against consumption is growing. The Massachusetts State Board of Health, in a recent exhaustive circular, recommends local boards of health to distribute widely a notice, in substance as follows:

"Consumption is the most destructive disease of New England, the number of persons dying annually from this cause in Massachusetts amounting to nearly six thousand.

"The disease is infectious and can be communicated from one person to another. The chief danger consists in the expectoration of the sick; if the expectorations be carefully destroyed little danger need be feared.

"Consumptives should be instructed not to spit upon the floors of rooms, public halls, street and railway cars and other vehicles, nor in the streets; but into pieces of cloth or receptacles made for the purpose containing water or a saturated solution of carbolic acid. Such bits of cloth should be destroyed by fire before the sputa becomes dry; and other receptacles should be cleansed with scalding water—their contents having been destroyed or otherwise carefully disposed of. Handkerchiefs, which may have been used from necessity, should be boiled half an hour before being washed.

"A healthy person should not sleep in the same room with a consumptive.

"Remember that sputa must never be allowed to become dry."

The Committee on Tuberculosis of the District Medical Association of Washington, D. C., in its report, submitted at the meeting of May 16, shows that in the District of Columbia from 1883 to 1892 8,091 persons died from tuberculosis, the percentage of deaths from that disease to all deaths being 15.87 during the ten years. In Philadelphia there were 76,272 deaths from this disease from July, 1860, to April, 1892. In New York the autopsies in hospitals show that 60 per cent. of the patients were affected with the disease, though they did not die of it, and it is estimated that one death in seven throughout the whole world is due to tuberculosis. The committee recommends:

"1. That a committee be appointed to prepare the manuscript for circulars or pamphlets, with the view of having the same distributed among the people, setting forth the facts, that each person having consumption is a constant source of danger to others not thus afflicted; that the disease is curable, and, above all, that it is easily preventable.

"2. That hospital authorities be urged to set apart certain

wards for the exclusive use of consumptives; although the committee believes that special hospitals for this purpose are preferable.

"3. That physicians be especially requested to inform their consumptive patients of the necessity of thorough disinfection of the sputa and of the methods by which this can be accomplished; and further, that they insist that the rooms once occupied by consumptives be thoroughly disinfected before they are again inhabited.

"4. That the Society take such action as will best procure the enactment of a law whereby no milk can be offered for sale until the cows from which said milk was taken have been tested and found to be free from tuberculosis. Furthermore, it is recommended that the health officer of the District of Columbia shall be requested to formulate such regulations as will insure to all persons purchasing vaccine virus in this District a guaranty that the animals whence such material has been obtained were treated with tuberculin and proved free from tuberculosis."

Epidemic Smallpox in Large Cities.—At the recent Conference on the smallpox situation, the following measures were recommended for adoption in dealing with an epidemic outbreak of smallpox in a large city:

1. The city should be divided into districts containing not more than 10,000 people.

2. Each district should be placed under the supervision of a competent medical inspector with necessary assistants: *a*, to make a house-to-house inspection; *b*, to successfully vaccinate, within the shortest possible time, all persons who have not been vaccinated during the outbreak—the first vaccination to be completed within seven days; *c*, to properly disinfect all houses and their contents where smallpox occurs.

3. Necessary means and appliances for efficient disinfection of materials, premises, etc., should be provided as the exigencies of each district may require.

4. Each case of smallpox should be immediately removed to a suitably constructed and properly equipped and officered isolation hospital.

5. Except in extreme cold weather, hospital tents, as prescribed in the United States Army Regulations, floored and warmed, are preferable to the average hospital or private dwelling, and increase the chances of recovery of the patients. Cases of smallpox necessarily retained in their own homes should, with their attendants, be rigidly isolated during the period of danger, and physicians visiting such patients professionally should be subject to such regulations as may be prescribed by the local health officer.

6. Persons exposed to smallpox contagion should be immediately vaccinated and kept under observation for not less than fourteen days from time of last exposure.

7. It is the sense of this Conference that unless such measures are enforced, it will be necessary for neighboring cities and States to exclude all persons from such city who are not protected against smallpox by recent vaccination, and to require proper disinfection of all clothing, baggage and merchandise capable of conveying smallpox infection.

Signed by

JOHN B. HAMILTON,

Surgeon U. S. Marine-Hospital Service.

ARTHUR R. REYNOLDS,

Health Commissioner of Chicago.

C. N. METCALF,

Secretary Indiana State Board of Health.

D. C. RAMSEY, and

L. L. WHITESIDE,

Members Indiana State Board of Health.

J. P. REEVE,

Secretary Wisconsin State Board of Health.

HENRY B. BAKER,

Secretary Michigan State Board of Health.

F. W. REILLY,

Ex-Secretary Illinois State Board of Health.

J. W. SCOTT,

Secretary Illinois State Board of Health, and Chairman of the Conference.

C. O. PROBST,

Secretary Ohio State Board of Health, and Secretary of the Conference.

MISCELLANY.

No Code Instructions.—The Illinois Medical Society, at its last annual meeting appointed its delegates to the AMERICAN MEDICAL ASSOCIATION without instructions on the Code revision.

Charity Hospital for Consumptives.—A number of wealthy New York women have purchased a large tract of land at the foot of the Saranac Mountains near Liberty, N. Y., and intend to erect thereon a charity hospital for consumptives.

Deep Artesian Well in Lower New York.—An artesian well, 1,056 feet deep, was completed last week at the home office of the Manhattan Life Insurance Company, on New Street, New York City. The water that will thus be obtained will be used for sanitary purposes and for the elevators.

Dr. Balch's Successor.—Dr. J. F. Barnes, of Watson, N. Y., has been elected Secretary of the New York State Board of Health, to succeed Dr. Balch, whose resignation has been accepted, to take effect June 1, prox. Dr. Florence O'Donohue was re-elected President for the ensuing term.

A New Disease.—"Mary," said a lady to her colored servant; "you said you lived with a man and his wife and one of them died?"

"Yes, mum; Dr. Blank said she had 'intejection' so long before he saw her that he could not cure her."

A Nobly Generous Doctor.—The *Congregationalist* states that Dr. W. Pepper, LL.D., after thirteen years' service has resigned as Provost of the University of Pennsylvania. A check for \$50,000 accompanied the letter. It states also that he has during each year of service given from between \$20,000 to \$30,000! Such beneficence deserves the highest approval.

New York Post-Graduate Hospital.—On May 8 the new buildings belonging to this school, at the corner of Twentieth Street and Second Avenue, were thrown open to the profession and the public. The babies' ward is the first to be occupied and is regarded as a model apartment for invalid infants. One of the new features of this ward is an ingeniously devised *couveuse*, or incubator for prematurely born and asthenic infants. This *couveuse* has an unflinching supply of fresh air drawn into its interior through a filter of antiseptic cotton, and a weighing attachment or balance whereby the weight of its inmate can be ascertained at any time; also, an improved means of effecting the uniform radiation of heat for the benefit of the child. The other wards or rooms are to be completed for occupancy during the present month.

Summer College of Biology.—The third annual session of the Cold Spring, New York, Biological Laboratory will open July 5. Lectures will begin on the following day. The regular courses of instruction include comparative embryology, bacteriology, advanced botany, elementary zoölogy and elementary botany. In addition will be given a series of fifteen illustrated lectures on popular scientific subjects. For young folks who have a liking for out-door study and natural history, the opportunities for a rational use of vacation time are scarcely to be surpassed anywhere in the wide country. Cold Spring Harbor is thirty-two miles from Brooklyn and New York on the Long Island Railroad. The Laboratory is at the head of the harbor and on the north shore of Long Island. The Laboratory fee for five weeks is \$15; for eight weeks, \$24; rooms cost from \$1.50 to \$3 per week and board about \$4.50 per week.

Washington Notes.

CENTRAL DISPENSARY AND EMERGENCY HOSPITAL.—The election of officers of the Board of Directors of the Central Dispensary and Emergency Hospital on May 11, resulted in the selection of Mr. C. J. Bell for President; Mr. Henry F. Blount, Vice-President; Mr. Wm. B. Gurley, Treasurer, and Mr. H. Randall Webb, Secretary.

DR. LEONARD BELL, of Indianapolis, Ind., who for the past year has been Second Assistant, was elected to fill the office of Resident Physician.

ASSISTANT RESIDENT PHYSICIANS.—A competitive examination for First and Second Assistant Resident Physician, will be held on the 25th instant. This is open to any graduate of any regular medical college in this country.

A **COLORED MAN** with confluent smallpox arrived in this city on the 12th instant, via railroad, and was promptly taken to the pest house. Dr. J. R. Nevit has charge of that institution and this case, and reports the patient to be in a dangerous condition. Previous to going to the hospital the patient was in close association with a number of persons on the train and in the depot. It is hoped that the powers that be will exhibit more discretion in dealing with this dreaded disease than they did in the health affairs of the Coxe camp.

MEDICAL DEPARTMENT GEORGETOWN UNIVERSITY.—The graduating exercises of the Medical Department Georgetown University were held May 8, and twenty students received their diplomas. Professor William H. Hawkes A.M., M.D., delivered the annual address to the graduates, advising them that their profession is also a business and urged them to place a proper estimate upon their medical services, and to use every honorable business means for the enforcement of their just claims.

THE **ARTICLE** in the *JOURNAL* of May 5, referring to the bad sanitary condition of the Coxe camp had a decided influence on the lay press and health authorities here. Of the former, the *Washington Post* was the first to urge the abating of the nuisance. Notwithstanding the daily accounts of the bad conditions existing, the local authorities did not declare the camp "unsanitary and a menace to the public health" until May 9. Three days later (the 12th) the army left the city, camping in Bladensburg, Md., where they have again selected an unhealthy location. It would appear to be decidedly prejudicial to public health for large numbers of men under the conditions found in this army to travel about, from more or less infected districts, and finally locate in unhealthy portions of any large city.

Philadelphia Notes.

THE **MEDICO-CHIRURGICAL COLLEGE** graduated a class of forty-four on the 11th inst.

THE **STATE MEDICAL SOCIETY** held its annual meeting in this city from the 15th to the 18th inst. The sessions were well attended.

THE **JEFFERSON MEDICAL COLLEGE COMMENCEMENT** was held on the 9th inst., when 163 students were graduated. The Trustees conferred the honorary degree of Doctor of Laws upon Prof. William Goodell, M.D.

THE **WISTAR INSTITUTE OF ANATOMY AND BIOLOGY** of the University of Pennsylvania was formally opened on May 21 in the afternoon. An introductory address was made by Prof. William Pepper, M.D., President of the Board of Managers, followed by addresses by Prof. William Osler, M.D., of Johns Hopkins, and Prof. Harrison Allen, M.D., Director of the Institute. An elaborate program has been prepared by the Alumni Committee which has in charge the exercises for Commencement Week, in which some radical changes have

been introduced in the usual routine, which will make the exercises more in accord with those of other American universities. The Baccalaureate Sermon, as the opening event of the week, will take place on Sunday evening, June 3, and will be delivered to the graduates of all departments. Monday, June 4, has been set aside as Class Day, the exercises taking place at the Chestnut Street Opera House, at 11 A.M., after which there will be a ball game, at 3 P.M., and the ivy planting on the campus at 5. In the evening the Law School will hold a banquet in the Library Building, and the Zelosophic Society will hold its annual commencement in College Hall. For Tuesday, Commencement Day, an elaborate program has been arranged. The usual exercises are to be preceded by a procession from the University grounds to the Academy of Music. The procession will be headed by Governor Pattison and his staff, Mayor Stuart and cabinet, and the City Troop, followed by the University Faculty, Trustees and students in cap and gown. The afternoon is taken up with the open track games of the Athletic Association, with several important events, and the evening by a banquet of the Alumni of the College department in the Library Building and the Philomathean Society commencement in College Hall. Wednesday has been designated as Alumni Day; Franklin's statute will be unveiled at 11 A.M., and Russell Duane, a great-grandson of Franklin, will make the address. At noon Horace Howard Furnace will make the formal transfer of a fine bust of Provost Pepper to the University. A ball game will be the attraction in the afternoon, and in the evening the Mask and Wig Club will give a benefit performance of "King Arthur," and the Veterinary department will hold a banquet. On Thursday morning the Medical School will hold its commencement exercises at the Academy of Music. The Phi Beta Kappa exercises will take place in the afternoon, the address being delivered by Hampton L. Carson. A promenade concert on the College campus is being talked of for the evening. The Sophomore Cremation has not yet been assigned a place, and it will probably have to take place on Friday evening.

Medical College Notes.

ANOTHER MISSOURI COLLEGE.—The Central Medical College of St. Joseph, Mo., has been organized to replace the Northwestern Medical College of that city—suspended because of the refusal of the Missouri State Board of Health to recognize its diplomas.

"**MUSHROOM**" COLLEGES.—Moved thereto by the apprehension that the degree of M.D. "is in danger of being greatly reduced by the organization of mushroom colleges in various parts of the State as well as in other States," the State Board of Medical Examiners of Iowa adopted the following resolution at its recent meeting:

"*Resolved*, That no medical college shall be recognized by this Board as in good standing until it has maintained a reputable existence for five years, provided this regulation shall not apply to colleges already so recognized."

A similar resolution of the Illinois Board, adopted in July, 1892, was rescinded at its January, 1894, meeting.

RUSH MEDICAL COLLEGE.—At the Class Day exercises of Rush Medical College, Chicago, portraits of Prof. DeLaskie Miller, and of Prof. Ephraim Ingals were presented to the College. Prof. Henry M. Lyman accepted the portrait of Prof. Ingals, on behalf of the Faculty, and Prof. John B. Hamilton accepted that of Prof. Miller. Dr. Hamilton said:

We accept from the original himself, at your hands, this faithful representation of an ideal teacher, an accomplished obstetrician, a scholar, a sagacious counselor and a patriotic citizen. Prof. DeLaskie Miller has been identified with Rush Medical College almost from its beginning, and although still vigorous in mind and body, he has been actively associated with every movement which step by step has

placed this College in the advance rank of American educational institutions. His early career as a medical journalist, and his Presidency of the Section on Obstetrics of the International Medical Congress at Washington extended a knowledge of his worth and ability beyond the confines of his city to other lands; for at the close of that now historic Congress, he had acquired friends and admirers almost to the ends of the earth. I need scarcely speak in this presence, of his long and faithful service as a Professor in this College; hundreds of Alumni have heard his voice, and thanks to the instruction those Alumni received, thousands of American citizens that otherwise might have blighted as mere experimental suggestions, were born to the glory of God and the increase of the population of the Republic. We need not enlarge on this topic; we need only say that in the presentation of this picture, the generous donor has added another jewel to the Rush Medical College collection. We read in Northern mythology of the Walhalla, that the building itself whose dome was so high that its summit could scarcely be seen, was as marvelous as the heroes whose virtues it was built to commemorate; that its location was in the midst of the grove "Mansur," where all the trees bore leaves of gold. In time this will become our Walhalla, although we lay no stress on architectural display as did those who designed that famous structure. In years to come Alumni visiting Rush Memorial Hall of the future may truthfully say of this picture, as of the "animated bust" and "storied urn" of song:

"Bright Fancy, hovering o'er,
Scatters from her pictured urn
Thoughts that breathe, and words that burn."

An Adult Insane Native Killed by Driver Ants in Africa.—Dr. Robert Hamill Nassau, a medical missionary stationed at Gaboon, Africa, narrates the following incident of native life in a letter recently addressed to Dr. Thomas G. Morton, of Philadelphia, who has kindly placed it at our disposal. The following extracts may interest the readers of the JOURNAL, as they solve the question whether or not human life could be destroyed by ants, as Eugene Sue described in his "Chronicles of a Family."

After mentioning the killing of two pet gorillas by the ants, and stating that human lives have also been lost in this way, Dr. Nassau explains that this occurs only when the person or animal is tied or confined so as to be unable to escape, because "the ants do not pursue but only attack what happens to lie in their way, and they conquer by their immense number and their persistence." The case he graphically describes as follows:

"An instance occurred here some six months ago. There was a crazy man who for several years had been a nuisance in the community. He had formerly been rich, but loss of his property, *i. e.*, his wives, his goods, etc., had turned his head. He belonged properly across the Gaboon estuary, but he had wandered over on this side. Most of the time he was harmless except that he annoyed women by offers of marriage. . . . Mostly, his nuisances were entering people's houses uninvited, sitting down to eat with them and appropriating pieces of clothing, etc. He was always worse at the new and full moons; then he was really dangerous. If at all crossed in his wishes he would beat the offenders with his staff or flourish his knife, and smash plates or other furniture. People did not dare defend themselves; they dreaded his threats of revenge, or were patient, not regarding him as responsible, or awed by superstitious fears of the spirits by whom some supposed him possessed. They often complained to the French magistrate asking that he might be confined; but the government here has no place in which to confine such and treated the matter lightly, bidding the complainants to endure, that he was irresponsible, etc.

"Finally, some six months ago, complaints became so numerous that the magistrate ordered his relatives across the estuary to come and remove him. They accordingly came and with the aid of the police he was bound, placed in a canoe, and taken across the estuary.

"Until they could decide among themselves just where he should stay and who should assume the burden of the care of him, they left him bound that night in a hut. He had been protesting, shouting, and swearing; but his complaints were not heeded; even when his words were not incoherent, they were not regarded as true, (and it is currently believed that the relatives did not care to believe or understand even

when they did hear, for they must have heard enough to know what was going on in the hut).

"Lying there bound in the hut and alone, a wandering army of "drivers" came across him, and attacked him. (Those ants never let go of a victim). He was helpless; his screams and calls were unresponded to. Those hundreds of thousands of ants filled his eyes, mouth, ears, and every opening of his body; and fiercely bit at every square inch of his entire naked body. What torture! If one were sane, those hours of agony would drive one mad!

"In the morning he was dead. The statement of the relatives that they had not supposed that the cries they heard were other than his usual mad ravings, was accepted by the government, though, by the public, quietly disbelieved. Neither the relatives nor the public were very sorry, even for the tragedy that relieved the latter of a constant dread and the former of a prospective burden."

[The Rev. Dr. H. C. McCook of Philadelphia, who has given such an interesting account of "The Ants of the Garden of the Gods" and is particularly devoted to the study of their habits, upon reading the above letter of Dr. Nassau's, wrote to Dr. Morton that the "incident of the killing of a native by the driver ants, was certainly an interesting one, though horribly realistic in its description," and requested that it be put upon record, as "an authentic case of the power and disposition of those insects to destroy human life."]

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from May 12, 1894, to May 18, 1894.

Major VAN BUREN HUBBARD, Surgeon, is granted leave of absence for four months, on surgeon's certificate of disability.
Capt. ALONZO R. CHAPIN, Asst. Surgeon, is granted leave of absence for three months, on account of disability, with permission to leave the Department of Texas.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending May 19, 1894.

Surgeon JOHN W. ROSS, placed on the retired list, May 11, 1894.

ADDRESS.

THE NUCLEINS AND NUCLEIN THERAPY.

Being the Annual Address of Section One of the Illinois State Medical Society, read by invitation.

BY VICTOR C. VAUGHAN, M.D.

ANN ARBOR, MICH.

Some recent investigations indicate that a knowledge of the nucleins is likely to be of service, as well as of interest, to the practitioner. These studies have already thrown some light upon certain physiologic problems and have enabled us to interpret more correctly some pathologic conditions. Moreover, some of the nucleins promise to be of value therapeutically. These facts make it desirable for us to familiarize ourselves, as far as possible, with these substances. I have therefore decided to discuss the nucleins in this address.

Physiologically, nucleins may be said to form the chief chemical constituents of the living parts of cells. Speaking broadly, we may say that the nuclein is that constituent of the cell by virtue of which this histologic unit grows, develops and reproduces itself. It is the function of the nuclein of the cell to utilize the pabulum within its reach. It must be evident that those tissues most abounding in cellular elements contain relatively the largest amounts of nuclein. It must also be seen that it is by virtue of their nuclein that the cells of various organs and organisms possess and manifest their individual peculiarities. We should therefore expect to find that the nuclein of the yeast cell is not identical with that of the bacillus tuberculosis, and that the nuclein of the spleen differs from that of the thyroid gland. The number of kinds of nuclein is limited only by the varieties of cells. Nuclein is the chemical basis of that part of the cell designated by the histologist as the nucleus, sometimes called chromatin on account of the readiness with which it absorbs and holds coloring agents. It is the nuclein of the bacterium which takes up and retains the stains, and it is on account of this fact, that the nuclein of the bacillus tuberculosis differs from that of other bacilli, that we are able to distinguish the former from the latter by its tinctorial properties. Differences in reaction with staining reagents, so plainly seen under the microscope, are only outward manifestations of less apparent and more important differences in chemical composition.

Chemically, the nucleins are complex, proteid bodies, characterized especially by the large amount of phosphorus which they contain. The phosphorus exists in the form of nucleinic acid, which is combined with a highly complex basic substance. So far as we know at present, the nucleinic acid of all nucleins is the same, yet the basic part differs in the various nucleins. This basic substance yields, as

decomposition products, one or more of the so-called xanthin bodies; adenin, guanin, sarkin and xanthin. Some nucleins yield only adenin, and these may be designated as adenylic nucleinic acids. Those which furnish xanthin most abundantly may be called xanthyl nucleinic acids. Generally speaking, the nucleins are insoluble in dilute acids and soluble in dilute alkalies. They resist peptic digestion and in this way may be separated from most other proteid bodies.

Certain substances which are histologically and functionally nucleins do not yield any xanthin base as a decomposition product. These are now called paranucleins. Some of these are the antecedents of true nucleins. Thus the yolk of the egg contains a paranuclein, which may be isolated by removing the accompanying proteids by peptic digestion. This substance does not yield any xanthin base, but during the process of incubation it develops into a true nuclein.

Some nucleins are combined with albumens, forming compounds known as nucleo-albumens. When one of these bodies is submitted to peptic digestion, the albumen is converted into a peptone and the nuclein forms an insoluble precipitate. The casein of milk is a nucleo-albumen, the albumen of which is peptonized by gastric digestion.

The literature on this subject is not very extensive and a brief epitome of it at this time may be of some interest. Braconnot (1831), Quevene (1838), Schlossberger (1844), Mitscherlich (1845) and Bechamp (1865), all studied substances which we now know belonged to the nucleins. Chemically, their work was fairly accurate as far as it went, but no physiologic importance was attached to this substance thus early in their study, and as a consequence even those facts which were discovered, could not be properly interpreted.

Miescher was the first to study the nucleins with a fair appreciation of their importance and it was he who named them. The corpuscles from pus were obtained by the addition of dilute solution of sodium sulphate, subsidence and decantation. Then they were digested with pepsin and hydrochloric acid so long as peptones were formed. This left the nuclei of the cells. These were found to be rich in phosphorus and soluble in dilute alkalies. From the alkaline solution the substance is precipitated by dilute acids.

Hoppe-Seyler prepared nucleins from yeast; Lubavin, from casein; Plösz, from the nuclei of the blood corpuscles of birds; and Miescher from the yolks of eggs.

In 1874, Miescher made his most important contribution to the knowledge of nucleins. The material with which he worked consisted of the spermatozoa of salmon. The cells were best separated by feebly acidifying the spermatic fluid with acetic acid.

A small amount of albumen was carried down at the same time, but the quantity was so small that it did not interfere with the microscopic examination of the cells. In the fresh state, the spermatozoa were found to be very resistant to chemical agents. Strange to say, however, dilute solutions (10 to 15 per cent.) of common salt were found to be more destructive to them than boiling alkali or concentrated hydrochloric acid. Microscopically it could be seen that salt solutions cause the thick membrane of the head of the spermatozoon to first swell and then become invisible. The middle portion and the tail remain unchanged and indeed are less affected than by water. These parts are soluble in dilute hydrochloric acid (0.1 per cent.) and consist of an albuminous material.

The removal of fat from the spermatozoa is best accomplished with warm alcohol. Lecithin and cholesterin are removed with the fat. The greater part of the residue, insoluble in hot alcohol, consists of an organic base very rich in nitrogen, combined with an acid-like body rich in phosphorus. This compound is nuclein. The organic base is the substance which yields the xanthin bases, and the acid-like body is now known as nucleic acid. Miescher called the complex, organic basic substance protamin. The readiness with which protamin may be split up into xanthin bases probably depends upon the period in their development which the spermatozoa have reached. Miescher found protamin a fairly stable body and obtained it in the form of a chlorid. The head of the spermatozoon is practically free from albumen and consists of nuclein with smaller quantities of lecithin, cholesterin and fat.

The wonderful lability of the nuclein molecule and its power of recuperating itself after being partially decomposed, are illustrated by the following experiment reported by Miescher: Well washed sperm, free from fat, is placed in dilute salt solution. Jelly-like lumps are formed and float in a clear fluid. The fluid portion contains protamin chlorid, but no nucleic acid. The salt solution has partially decomposed the nuclein. On the addition of successive portions of common salt, more and more of the protamin passes into solution. However, the amount passing into solution remains always a fraction of the whole. Now, if the mixture be poured into a large volume of water, the jelly-like lumps disappear, an opaque network forms and all the protamin disappears from solution. A regeneration of the nuclein takes place.

Miescher further shows that certain organic and inorganic bases may be placed within or drawn from the nuclein molecule without modifying visibly the character of the substance. However, while there is no visible change, the nature of the nuclein may be in fact markedly altered. Each new combination is a body *sui generis*, possessing its own distinctive affinities and probably its own peculiar molecular arrangement. We have seen how an apparently indifferent substance, like common salt, may markedly alter the composition of nuclein. One may say that every change in the salt content, in the concentration and in the alkalinity of the fluid surrounding the tissue forming cell, however resistant the cell itself may appear, produces chemical changes which may be of the most vital consequence. With these facts before us, we can no longer be surprised when the pathologist fails to find, either macroscopically or

microscopically, lesions commensurate with the symptoms observed during life.

Miescher failed to find any protamin in the sperm of the carp, frog or bull. Piccard found guanin and sarkin along with protamin in the sperm of salmon. Von Jaksch separated nuclein from the brain, and later this was done by Geohegan.

In 1879, Kossel published his first paper on nuclein, and since then he has made repeated and most valuable contributions, especially with reference to the derivation of the xanthin bases from the nucleins.

In 1889, Altmann prepared nucleic acid from yeast, thymus, yolk of egg and salmon sperm. Impure solutions of nuclein in dilute alkali are rendered feebly acid with acetic acid. This throws down albuminous bodies which are removed by filtration. The filtrate is treated with hydrochloric acid and alcohol. The precipitate which now forms is nucleic or nucleic acid, which is washed with alcohol and purified. Nucleic acid contains about 9.4 per cent. of phosphorus and is free from sulphur.

Liebermann has claimed that nuclein is a combination of albumen and metaphosphoric acid, and he has prepared an "artificial nuclein" by precipitating albuminous solutions with this acid. However, since the substance thus formed does not yield xanthin bases, it can not be a true nuclein, but is a paranuclein. This artificial preparation corresponds with nuclein in the following particulars: 1, it is not digested by gastric juice; 2, it reddens moist litmus paper, although aqueous extracts of it are not acid; 3, it burns with difficulty and leaves an acid residue; 4, it is insoluble in dilute acids; 5, it is soluble in dilute alkalies; 6, it takes staining reagents as the nuclei of cells do; 7, it yields, according to Malfatti, nucleic acid.

In view of these points of resemblance, it will be of great interest and of some importance to determine whether or not the artificial preparation has the germicidal properties which, as we will see later, are possessed by the natural nucleins.

Horbaczewski has made a most valuable contribution to our knowledge of the relation of uric acid to the nucleins. As has been stated, Kossel had demonstrated that the true nucleins yield one or more xanthin bases as decomposition products, but the relations of the nucleins to uric acid could only be surmised from the well-known close chemical connection between xanthin and uric acid. Horbaczewski has ascertained that uric acid is produced from the nuclein of spleen pulp, when the substance is brought in contact with certain oxidizing agents, such as fresh blood or dilute solution of the peroxid of hydrogen. Spleen nuclein does not contain ready formed uric acid, but it does contain the antecedent or mother substance of uric acid. This mother substance yields not only uric acid, but the other xanthin substances, as xanthin, sarkin, guanin and adenin. Uric acid is formed when the antecedent substance is split up in the presence of an oxidizing agent, while the other substances result when the process is carried out in the absence of such agents. This is in complete harmony with the facts which have been ascertained by the conversion of one of these xanthin bodies into other members of the same group. Certain other nucleins, as well as that of the spleen, serve as antecedents of uric acid. This discovery makes clear a hitherto most perplexing problem, which has concerned the chemist, the physiologist

and the clinician. In short, it explains the origin of uric acid in the mammalian body. The chemist had taught us to look upon uric acid as the result of an imperfect oxidation, the completed product of which is urea, but the physiologist has been unable to demonstrate this supposed relationship between urea and uric acid. The experiments of Horbaczewski show that the amount of uric acid and other xanthin bodies formed is a measure of nuclein metabolism. In other words, it indicates the number of nucleated cells which are suffering disintegration processes. Normally, the white blood corpuscles constitute the most important and probably the most numerous nucleated cells daily undergoing destructive changes. Therefore, any condition which induces an abnormal leucocytosis increases the amount of uric acid. In infants the number of nucleated cells is proportionately larger than in adults and the amount of uric acid formed is correspondingly large. In the fasting state, the white blood corpuscles are reduced and the uric acid is also diminished. Meat diet increases the number of white corpuscles and consequently the formation of uric acid. Quinin and atropin diminish the number of these corpuscles and by so doing lessen the amount of uric acid formed; while pilocarpin, antifebrin and antipyrin have been found to increase both. The increased formation of uric acid and xanthin in leukemia, phosphorous poisoning, acute febrile diseases, especially pneumonia, cirrhosis of the liver and pernicious anemia, now finds an explanation.

I should like to follow out this line of my subject and to discuss the significance of that condition which is sometimes designated as a uric acid diathesis, but time will not permit.

With the aid of Drs McClintock and Novy, I have demonstrated that some of the nucleins have germicidal properties. We experimented with nucleins obtained from yeast, eggs, the spleen, thyroid gland, and testes. All of these were found to be distinctly bactericidal. The results of this work were published in detail last year and it is not necessary to go over the subject in this paper. Kossel, of Berlin, has confirmed our statements concerning the germicidal action of the nucleins.

Dr. McClintock and I have also demonstrated that the germicidal constituent of blood serum is a nuclein. This nuclein is undoubtedly furnished by the polynuclear white corpuscles. Having demonstrated that the nucleins are germicidal, it remained to be ascertained whether or not they might be employed to prevent or arrest the growth of germs in the animal body.

I will detail some attempts made to render animals immune to certain diseases, by first treating them with nuclein and subsequently inoculating them with the germs.

The diplococcus of pneumonia is a germ which in its virulent form is, practically without exception, fatal to rabbits, causing death on the second or third day. Immunity to this germ has been secured by Emmerich, and others by previous treatment with the attenuated germ and with sterilized cultures. The following experiments were made in order to see whether or not immunity to the diplococcus pneumoniae could be secured by previous treatment with nuclein.

The solution used in all of these animals contained about 2 per cent. of yeast nuclein:

EXPERIMENT 1.

Rabbit, weight 1,732 grams: Was given subcutaneously one c. c. of nuclein solution November 6, 7 and 9. On November 11, two days after the last nuclein treatment, this animal was inoculated with a virulent culture of the micrococcus. A control, weighing 1,520 grams, was inoculated at the same time and with the same amount of the culture. The control was found dead on the morning of November 13 and the treated animal on the morning of the 14th. The treated animal survived the untreated one twenty-four hours. Both animals showed the characteristic effects of the germ.

EXPERIMENT 2.

Rabbit, weight 1,222 grams: Was given subcutaneously one c. c. of the nuclein solution, November 6, 7, 9 and 11. Immediately after the last nuclein treatment, the animal and a control, which weighed 1,325 grams, were inoculated intra-abdominally with 0.2 c. c. of a virulent culture of the germ. On the morning of November 13, the control was found dead. The treated animal was evidently sick and weighed only 1,145 grams, showing a loss of 67 grams, and it continued to lose weight until November 24, when it was reduced to 990 grams. After this it slowly gained, weighing 1,075, December 1; 1,347, January 23; and 1,465, February 27. On the last mentioned day it was killed and found to be sound in every organ.

EXPERIMENT 3.

Rabbit, weight 1,130 grams: Was given subcutaneously one c. c. of the nuclein solution November 6, 7, 9, 11, 13 and 18. Immediately after the last nuclein treatment, this animal and a control weighing 1,325 grams were inoculated intra-abdominally with 0.2 c. c. of a virulent culture. On the morning of November 20, the control was found dead. The treated animal sickened, lost flesh and died November 27 from the effects of the germ.

The explanation of the failure to secure so good a result in this case as in the preceding is easily seen. In this experiment, five days elapsed between the last and the preceding injection of nuclein, and two days between that and the one preceding it. In other words, the intervals between the nuclein treatments were too long. This teaches us that the effects of nuclein are transient and that in order to receive any real benefit from its use it must be administered repeatedly and at comparatively short intervals. This lesson must not be lost sight of when we come to consider the therapeutical uses of nuclein.

EXPERIMENT 4.

Rabbit, weight 1,735 grams: Was treated subcutaneously with one c. c. of the nuclein solution on November 6, 7, 9, 11, 13, 18, 21, 23 and 24. Immediately after the last nuclein treatment it was inoculated intra-abdominally with 0.2 c. c. of a virulent culture of the germ. At the same time, four controls, weighing 1,395, 1,590, 1,210 and 1,400 grams, received in the same manner like quantities of the same culture. On the morning of November 26 all the controls were found dead. The treated animal lost weight and weighed December 1, 1,540 grams. After this it gained in weight, advancing to 2,200 by January 23 and to 2,460 grams by February 27. On this last mentioned date, this animal was killed and found to be normal in every respect.

EXPERIMENT 5.

Rabbits Nos. 1, 2, 3, 4, 5, 6, 7 and 8, weighing respectively 580, 595, 625, 600, 610, 537, 522, and 387 grams, were treated subcutaneously with the nuclein solution as follows: March 9, 0.3; March 10, 0.5; March 13, 0.6; March 14, 0.7; March 15, 1.0; March 17, 1.0; March 19, 1.0 c. c. Immediately after the last treatment, all were inoculated with 0.2 c. c. of a virulent culture of the diplococcus. At the same time, control rabbits, A and B, weighing respectively 550 and 365 grams were inoculated in like manner with the same culture. On the morning of March 21, both controls and rabbits 2 and 8 were found dead. All the other treated animals remain well and healthy to-day (May 3). In this experiment, immunity was conferred upon 75 per cent. of the treated animals, while all of the controls in all the experiments died.

At this point in my experimentation, the following interesting question suggested itself: Is the immunity thus secured due to the direct germicidal action of the nuclein, or does the nuclein act by stimulating some organ whose duty it is to protect the body against bacterial invasion? An attempt to answer this question was made in the following experiment:

EXPERIMENT 6.

Rabbits Nos. 1, 2, 3, 4, 5, 6, 7, and 8, weighing respectively 344, 400, 415, 391, 365, 414, 287 and 417 grams, received injections of two c.c. of the nuclein solution intra-abdominally March 20, immediately after each had been inoculated with 0.2 c.c. of a virulent culture of the diplococcus of pneumonia. At the same time, rabbits, A and B, weighing respectively 394 and 397 grams, were inoculated with like amounts of the same culture, but received no nuclein. On the morning of March 22, all of these animals were found dead, and section showed that they died from the effects of the germ. Evidently when used in this way, the nuclein affords no protection against this germ. This confirms the view which I have before expressed, that the production of immunity is an educational process. I can hardly believe that as much of the nuclein as two c.c. existed in the body of any one of the animals which had been rendered immune, but this amount failed to protect when injected into the body immediately after inoculation. I conclude from this that the immunity which had been secured by repeated injections of smaller quantities of the nuclein was not due to the direct germicidal effects of this substance, but to its stimulating effect upon some organ. I will return to this point later.

It seemed desirable to test the immunizing effects of nuclein upon some other species of animal. Guinea pigs were selected and the results are given in the following experiments:

EXPERIMENT 7.

Guinea pig, weight 487 grams, was treated with nuclein solution as follows: October 23, 0.2; October 24, 0.4; October 25, 0.6; November 3, 0.6; November 4, 0.8; November 6, 1.0; November 7, 1.0; November 9, 1 c.c. November 11, two days after the last nuclein treatment, this pig (now weighing 560 grams) was inoculated with 0.2 c.c. of a virulent culture of the pneumonia germ. At the same time, a control pig, weighing 492 grams, was inoculated with a like amount of the same culture. The control died November 15, and the treated one November 21. Both

animals showed the characteristic lesions and the germ was recovered in pure culture from each. Evidently in this case, the nuclein gave partial, but not complete, protection.

EXPERIMENT 8.

Guinea pig, weight 514 grams, had the same nuclein treatments as the preceding and an additional one of one c.c. November 11. Immediately after the last treatment it was inoculated. The same animal, used as a control in the preceding experiment served a like purpose in this. The treated animal died November 22.

EXPERIMENT 9.

Pigs 1 and 2, weighing 299 and 317 grams, had the same nuclein treatments as the preceding, with the addition of one c.c. each on November 13 and 18. Immediately after the last treatment, these animals, together with a control weighing 965 grams, were inoculated with the germ. The control died November 23. Of the treated pigs, No. 2 died from the effects of the germ December 1, and No. 1 was killed December 19 and found to be normal. When killed, this pig weighed 525 grams.

EXPERIMENT 10.

Pigs 1 and 2, weighing 317 and 364 grams, were treated with the same nuclein solution as the preceding, with the addition of one c.c. each November 18 and 21. November 23, two days after the last nuclein treatment, they were inoculated with the pneumonia germ. A control, weighing 617 grams, was inoculated with the same amount of the culture at the same time. The control died November 27. The treated animals were killed February 22 and found to be normal. They weighed 785 and 695 grams respectively when killed.

EXPERIMENT 11.

Pigs 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10, weighing 314, 335, 330, 265, 240, 275, 283, 435, 300 and 392, had on five successive days 1 c.c. each of the nuclein solution. Immediately after the last treatment, each pig received 0.2 c.c. of a virulent culture in the abdominal cavity. At the same time, two controls weighing 320 and 400 grams, were inoculated with the same culture. Both controls died on the fourth day, while all of the treated animals survived.

From the experiments detailed above, I draw the following conclusions:

1. Rabbits and guinea pigs may be protected against virulent cultures of the diplococcus of pneumonia by previous treatment with hypodermatic injections of a solution of yeast nuclein.

2. The immunity thus secured is not due to the action of the nuclein, as a germicide, directly.

3. The process of securing this immunity is an educational one, and, most probably, depends upon the stimulating effect of the nuclein upon some organ, whose function it is to protect the body against bacterial invasion.

4. The longer the nuclein injections are continued and the more frequently they are administered, the more complete is the immunity which is secured.

5. In order to obtain this immunity, the inoculation with the germ must follow soon after the last treatment with the nuclein.

I have made some attempts to render guinea pigs immune to tuberculosis. So far the results have been

not altogether satisfactory and in some instances contradictory. However, I will give these results, hoping that they may throw some light on the subject, and may possibly lead to something better.

In the first place it is desirable to ascertain whether the nuclein has any germicidal effects upon the bacillus tuberculosis outside the body.

EXPERIMENT 12.

August 8, 1893. Stirred up a large loop of a virulent sputum with one part of a 2 per cent. yeast nuclein solution diluted with five parts of sterilized, physiologic salt solution. Immediately injected three c.c. of this mixture into the abdominal cavity of pig 50, weighing 330 grams. August 18, killed the pig. There was a very slight, but perceptible, tubercular thickening of the border of the omentum. Result, failure.

EXPERIMENT 13.

August 8, 1892. After the above-mentioned mixture of sputum and dilute nuclein solution has stood for one hour in an incubator at 38 C., 3 c.c. of it was injected into the abdominal cavity of pig 51, weighing 625 grams. September 27, killed this pig, now weighing 575 grams. Found a tubercular nodule in the abdominal wall at the point of inoculation. This nodule was the size of a pea and contained caseous matter in which a few granular bacilli were found. The border of the omentum was thickened and this was tubercular. Result, failure.

EXPERIMENT 14.

August 9, 1892. Injected three c.c. of the above-mentioned mixture of sputum and dilute nuclein solution, after it had stood for twenty-four hours in an incubator at 38 C., into the abdominal cavity of pig 42, weighing 360 grams. August 18, killed this pig, now weighing 390 grams, and found it normal in every respect. The point of inoculation could not be detected. Result, positive.

EXPERIMENT 15.

August 18, 1892. About five c.c. of thick, ropy, virulent sputum was placed in an Esmarch dish, covered with twenty c.c. of the nuclein solution undiluted. After this had stood for twenty-four hours in an incubator at a temperature of 38 C., it was examined microscopically and the tubercle bacilli were found to be present in great numbers and to stain normally. August 19, one loop of this sputum was stirred up with one c.c. of salt solution and injected into the abdominal cavity of pig 52, weighing 402 grams. September 1, this pig, now weighing 415 grams, was killed and found to be normal. Result, positive.

EXPERIMENT 16.

Feb. 3, 1894. Stirred up one part of virulent sputum with five parts of nuclein solution and allowed to stand in an incubator at 38 C., for four days. At the expiration of this time, microscopic examination showed the tubercle germs present in large numbers and staining well. February 9, inoculated pig 120, weighing 300 grams, with the sputum. February 29, killed the pig, now weighing 340 grams, and found it to be perfectly normal. Result, positive.

It might possibly have happened, had these pigs been allowed to live longer, that some of them, found free from tuberculosis, would have developed the

disease. Further experiments upon this point must be made.

EXPERIMENT 17.

Pigs 122 and 123, weighing respectively 202 and 495 grams, received hypodermatic injections of yeast nuclein solution (2 per cent.) as follows: February 10, 0.1; February 12, 0.2; February 13, 0.3; February 14, 0.4; February 15, 0.5; February 17, 0.5; February 19, 0.6; February 21, 0.7; February 23, 0.8; February 24, 0.9; February 26, 1.0; February 27, 1.0; February 28 1.0; March 1, 1.0

March 1, these pigs, now weighing 289 and 557 grams respectively, together with a control (No. 134, weight 20 grams) were inoculated with a pure culture of the bacillus tuberculosis. The control was found dead March 26. Section showed a small nodule at the point of inoculation. The omentum was thickened and tuberculous. The spleen, both kidneys, and the lower lobe of one lung are involved.

March 26, pig 122, weighing 339 grams, was killed and found to be perfectly normal. April 23, pig 123, weighing 597 grams was killed. There is a nodule as large as a filbert at the point of inoculation. This contains caseous matter filled with bacilli. The omentum contains numerous caseous nodules, in which germs are found. Other organs are normal. Whether No. 122 would have developed tuberculosis, had it been allowed to live longer, no one can say.

EXPERIMENT 18.

Pigs 124 and 125, weighing 227 and 255 grams, received the same treatment as Nos. 122 and 123 with the addition of one c.c. each on March 2 and 3. Immediately after the last treatment, these pigs, now weighing 340 grams each, were inoculated with a virulent sputum. At the same time a control (No. 135, weight 242 grams) received the same inoculation.

April 3, the control (weight 282 grams) was killed and the omentum, spleen and liver were found filled with tuberculous nodules.

April 3, No. 125 (weight 400 grams) was killed. With the exception of a small nodule containing caseous matter with few bacilli, at the point of inoculation, no abnormality could be found.

April 24, No. 124 (weight 455 grams) was killed. There were a few small nodules in the omentum. These contained bacilli. In all other respects the animal was normal.

While all of these animals were infected, the disease had made most extensive and rapid progress in the untreated one.

EXPERIMENT 19.

Pigs 126 and 127 (weight 215 and 300 grams) received one more nuclein treatment, March 5, than Nos. 124 and 125. Immediately after last treatment, these pigs (weight 314 and 475 grams) were inoculated with a virulent sputum. At the same time a control (No. 137, weight 332 grams) was inoculated with a like amount of the same sputum.

April 25, the control (weight 365 grams) was killed. There is a small tubercular nodule at the place of inoculation. The inguinal glands on both sides are greatly enlarged and tuberculous. The spleen is much enlarged and tuberculous. The omentum contains numerous tubercular nodules.

April 25, No. 126 (weight 365 grams) was killed and found to be perfectly normal in every respect.

April 25, No. 127 (weight 580 grams) is reserved in order to see whether it will become tuberculous.

EXPERIMENT 20.

Pigs 128 and 129, weighing 307 and 230 grams, received one more nuclein treatment than Nos. 126 and 127. Immediately after the last treatment, they (weight 480 and 340 grams) were inoculated with sputum. At the same time a control (No. 138, weight 315 grams) was inoculated with the same sputum.

April 25, the control (weight 427 grams) was killed. There was a tubercular nodule as large as a filbert at the point of inoculation. The inguinal glands on both sides were enlarged and tuberculous. The spleen was enlarged and filled with pin-head tubercles. The liver was filled with pin point nodules.

April 25, No. 129 (weight 427 grams) was killed. There was a pin-head nodule at the point of inoculation and the large gland in the omentum was enlarged to the size of a pea and tubercular. All other organs were normal. No. 128 has been reserved in order to observe the result of further time.

These experiments seem to indicate that previous treatments with nuclein retard, but in the majority of cases do not prevent, the development of tuberculosis from subsequent inoculations. I have made a number of experiments in which the nuclein treatment was not begun until some days after the animals had been inoculated. The following statements detail some of the results obtained:

EXPERIMENT 21.

Dec. 27, 1892, four glycerin agar tubes of the tubercle bacillus were rubbed up with twenty c. c. of beef tea, and guinea pigs Nos. 9, 10, 11, 12, 13, 14, 15, 16, 18 and 19 were inoculated by injection into the abdominal cavity. Nos. 7, 8 and 17 were used as healthy controls. Of those inoculated, Nos. 9, 11, 13, 14 and 18 were selected for treatment, while Nos. 10, 12, 15, 16 and 19 were kept as untreated controls.

The weights of these animals December 27 were as follows:

No. 7—747 grams.	No. 12—667 grams.	No. 16—607 grams.
No. 8—889 grams.	No. 13—724 grams.	No. 17—747 grams.
No. 9—709 grams.	No. 14—525 grams.	No. 18—629 grams.
No. 10—759 grams.	No. 15—744 grams.	No. 19—560 grams.
No. 11—614 grams.		

The solution used in the treatment of this series is known as solution C, and it was obtained in the following manner: Some brewer's yeast was extracted with dilute alkali and filtered. The filtrate was precipitated with dilute hydrochloric acid. The precipitate was re-dissolved in alkali and re-precipitated with acid several times. Finally the precipitate was dissolved in .25 per cent. of potassium hydrate. This solution gives the biuret, xanthoproteic and Millon reactions. It contains a nuclealalbumen which is soluble in a 0.2 per cent. solution of hydrochloric acid, but is precipitated on the further addition of acid. The amount of nuclealalbumen in the solution was determined and found to be .9 of one milligram per cubic centimeter. This solution was found during the experiment to be too alkaline, the excess of alkali causing sloughing of the tissue. After this was discovered the solution was diluted with a sterilized 6 per cent. solution of common salt, and then neutralized by the addition of dilute acetic acid. However, the fact that the solution was too alkaline was not discovered until some

of the animals had been seriously injured by the treatment, as will be subsequently shown.

Of the healthy controls, all remained in perfect condition. The fate of each of the untreated tuberculous animals was as follows:

No. 10 died Jan. 7, 1893. Post-mortem examination showed internal hemorrhage, clots of blood being found under the liver and stomach. Undoubtedly some small blood vessel was wounded at the time of inoculation and the slow oozing of blood had led to death. The site of the wound could not be located. It is probable that the needle punctured the liver. The extent of the tuberculosis was surprising. The border of the great omentum was a mass of tuberculous nodules. The surface of the liver was dotted with tubercles and the germ was found not only in all these nodules, but also in a bloody exudate in the pleural cavity.

No. 12 was killed by chloroform April 3, 1893. Post-mortem examination showed the great omentum to be a tuberculous mass. One lump was as large as a hickory nut and was filled with cheesy matter. In fact, all of the tuberculous nodules contained caseous substance. This was very soft, and I suppose that it would soon have broken down and spread the disease to other parts of the body. Other organs than those mentioned above were normal.

No. 15 died Jan. 13, 1893. Post-mortem showed extensive tuberculosis. The liver was dotted with tuberculous nodules. The kidneys and spleen also showed numerous pin-head points of infection. The germs stained in a normal manner. The pleural cavity was again found filled with a bloody exudate. The lungs were infiltrated and solidified in places. There was no noticeable phagocytosis.

No. 16 died Jan. 12, 1893. The liver was filled with fine tubercles, from those barely visible to those the size of a pin-head. The fringe of the omentum was tuberculous. There was an exudate in the pleural cavity. Germs were found in all of these places and stained normally.

No. 19 was pregnant at the time of inoculation, and gave birth to one pig January 10. After this, the animal seemed to improve. It was killed May 24, 1893. The post-mortem examination showed a widely extended tuberculosis. The great omentum contained tubercles as large as almonds. These were filled with a creamy matter, in which millions of germs were found. A tuberculous nodule as large as a filbert was found in the lower margin of the liver, and smaller nodules existed in other parts of this organ. Tubercles of the size of a pea were found scattered through the mesentery, peritoneum and diaphragm. The kidneys were also tuberculous. The spleen and lungs remained unaffected. The germs found in the places above mentioned stained normally. The treatment was begun six days after the inoculation.

The following table will show the dates of treatment and the amounts of solution C injected. These injections were made under the skin over the abdomen:

The large injections given Nos. 9 and 12 on January 12 caused extensive sloughing of the skin. The fate of the treated pigs was as follows:

No. 9 received, as is shown in the above table, four c.c. on January 12. Before the injection, the animal seemed to be dying. The respirations were shallow and rapid, and the peculiar pumping motion of the body which had been observed in other guinea pigs just before death was very marked. After this large injection, and notwithstanding the sloughing of the skin which followed, the animal improved. February 16, No. 9 was killed, on account of the extensive sloughing which now existed on the abdomen. The fringe of the omentum was lined with tubercular nodules from the size of a pin-head to that of a hazel nut. The base of the liver was tuberculous. Tubercular nodules were found on the diaphragm and in the pleura. The lungs were free from disease. All of the above-mentioned nodules contained numerous bacilli, which showed granular degeneration. Phagocytosis was marked. The spleen was enormously enlarged and weighed 18.2 grams. Two glycerin agar tubes were inoculated with the germs taken from this animal. These tubes did not develop. One of the nodules from the omentum was rubbed up with 1.5 c.c. of beef tea, and the whole of this was injected into the abdominal cavity of guinea pig 28.

Guinea pig 28 was killed May 23, 1893. It weighed at the time of inoculation 490 grams, and on the day it was killed, 610 grams. The animal was found to be very fat, apparently well, and the post-mortem examination failed to reveal any trace of tuberculosis or any other trouble.

No. 11 had an injection of six c.c. of the strongly alkaline solution of nuclein on January 12. The condition of this animal at that date was practically the same as that of No. 9, and both seemed to be in a worse condition than No. 15. After this injection, this animal gradually decreased in weight until it died March 3, at which time it weighed 375 grams. The skin over the thighs and arms was covered with thick scales. Over the abdomen there was quite a slough, and the skin was adherent to the muscular walls. The condition of the skin and the sloughing were due to excess of alkali. The fringe of the omentum was lined with tubercular nodules, one of which was as large as a hazel nut. These were filled with germs, many but not all of which showed the granular degeneration. Tubes were made from these, and although slow to develop, both showed an abundant growth on April 3. The lungs were somewhat congested, but not tuberculous. The fluid usually found was present in the pleural cavity. The liver was dark and congested, but not tuberculous. The spleen weighed 5.85 grams. At the same time that the tubes were inoculated, guinea pig 30 was also inoculated with a tubercular nodule from the omentum, rubbed up in beef tea.

No. 30 was killed May 30. This animal was well nourished, having gained in weight from the day of inoculation, March 3, from 480 grams to 587 grams. The only abnormality which could be found in the animal was a nodule not larger than a flaxseed in the great omentum. On cutting this open it was found to contain a cheesy matter, and this, after proper staining formed a most interesting study. The cheesy mass was made up of polynuclear cells, the nuclei taking the blue stain so deeply that they might have been mistaken for micrococci. After searching through many fields, the granular debris of a bacillus was found, and in the whole of the contents of the nodule less than a dozen of these remnants of bacilli were detected.

No. 13 was killed April 2, 1893. It weighed at this date 797 grams. There was a tubercular nodule under the skin of the abdomen at the place of inoculation. This was as large as a small cherry. It contained cheesy matter. There were also three very small nodules in the great omentum. All of these nodules contained the bacillus, which showed a marked beaded degeneration. Four glycerin agar tubes were made from these nodules. On May 23, two of these tubes showed no growth, while the other two showed slight growth. No animal was inoculated with this material.

No. 14, having lost in weight until it was reduced to 300 grams, died April 20. There were two small tubercular nodules one-eighth of an inch in diameter in the omentum. There were no other signs of tuberculosis in any part of the body. No tubercle germs could be found anywhere. The spleen was enlarged and adherent. This organ contained a small abscess, cultures from which developed a small bacillus giving bipolar staining. The kidneys were diseased, whitish on the surface, and the cut surfaces showed infiltrated blood. The contents of one tubercular nodule were rubbed up with three c.c. of beef tea and one c.c. of this was injected into the abdominal cavity of guinea pig 31.

No. 31 was killed Oct. 20, 1893. It weighed at the time of inoculation 792 grams, and at the time of killing 920 grams. The animal was very fat, and post-mortem examination showed no abnormality.

No. 18 was killed May 24, 1893. The animal was well nourished. Post-mortem examination showed only two small tubercles. One of these was in the great omentum and about the size of a small pea. This contained cheesy matter, in which only a few germs could be found. The other was of about the same size and was found in the lower margin of the liver. In this the germs were relatively somewhat more abundant, but were absolutely few. All other organs were normal. Guinea pig 37 was inoculated with the contents of the nodule taken from the omentum.

No. 37 was killed Oct. 20, 1893. At the time of inoculation it weighed 414 grams, and at the time of killing 720 grams. This animal was found to be in a perfectly healthy condition in every respect.

The germ with which these animals were inoculated was evidently markedly virulent. It is impossible to tell how far the disease had progressed in each animal when the treatment was begun. I think that I am justified in concluding that the progress of the disease was retarded and the virulence of the germ reduced (as was shown by the results of the secondary inoculations) by the treatment.

EXPERIMENT 22.

April 28, 1893, pigs 7, 8, 17, 26, 27, 32, 33 and 34 were inoculated with a pure culture of the bacillus tuberculosis.

The weights of these pigs, April 28, were as follows:
 No. 7—987 grams. No. 26—705 grams. No. 33—597 grams.
 No. 8—1147 grams. No. 27—685 grams. No. 24—950 grams.
 No. 17—972 grams. No. 32—717 grams.

Nos. 7, 8, 17, 26 and 27 were treated, while Nos. 32, 33 and 34 were left without treatment.

The solution used in the treatment of these animals was one of paranuclein, obtained from the yolks of eggs, of unknown strength.

The fate of each of the untreated animals was as herewith given:

No. 32 was killed Oct. 20, 1893. At this time it weighed 945 grams, a gain of more than two hundred grams since the time of inoculation. Examination showed two tubercular nodules in the omentum. One was as large as a hazelnut, while the other was smaller. These were filled with bacilli, normal in appearance and staining well. All other organs were normal.

No. 33 was killed Sept. 22, 1893. It then weighed 885 grams, a gain of nearly three hundred grams since inoculation. The omentum was filled with tubercular nodules. These contained numerous bacilli. Many of the mesenteric glands were tuberculous and the peritoneal covering of the stomach was dotted with pin-head tubercles. All other organs were normal.

No. 34 was killed Sept. 22, 1893. At this time it weighed 1,020 grams, a gain of 70 grams since inoculation. There was a tubercular nodule the size of a hazelnut in the omentum. This contained a purulent fluid, in which a few bacilli were found. These germs stained poorly. The rest of the omentum was thickened but not nodular. The lungs contained numerous tubercular nodules.

The treatment of Nos. 7, 8, 17, 26 and 27 was begun May 2, four days after the inoculation. The amounts received by each of these animals are stated in the following table:

May	2	3	4	5	8	9	10	11
No.	c.c.	c.c.	c.c.	c.c.	c.c.	c.c.	c.c.	c.c.

8	.	2.5	2.5	2.5	1.66	1.	1.	1.
17	.	2.5	2.5	2.5	1.66	1.	1.	1.
26	.	2.5	2.5	2.5	1.66	1.	1.	1.
27	.	2.5	2.5	2.5	1.66	1.	1.	1.

May	12	15	16	17	18	19	22
No.	c.c.	c.c.	c.c.	c.c.	c.c.	c.c.	c.c.
7	1.	1.	1.	1.	1.	1.	1.
8	1.	1.	1.	1.	1.	1.	1.
17	1.	1.	1.	1.	1.	1.	1.
26	1.	1.	1.	1.	1.	1.	1.
27	1.	1.	1.	1.	1.	1.	1.

The fate of these animals was as follows:

No. 7 was killed Sept. 24, 1893. At this time it weighed 1,010 grams, a gain of 37 grams since inoculation. Examination failed to reveal any abnormality.

No. 8 was killed Feb. 20, 1894; weight 1,240 grams a gain of 100 grains since inoculation. Post-mortem showed an excessively fat animal. At one point the omentum was slightly adherent to the liver. On carefully detaching the parts, a nodule the size of a pea was found. This nodule contained cheesy matter in which no germs could be found. In all other respects this animal was normal.

No. 17 was killed Oct. 20, 1893, weight 1,015 grams,

a gain of 43 grams since inoculation. Examination failed to reveal any abnormality.

No. 26 was killed Oct. 17, 1893, weight 845 grams, a gain of 140 grams since inoculation. The omentum contained a large amount of fat. In this fat I found one nodule the size of a flaxseed. I could find no germs in this. In the lower border of the liver a nodule the size of a pea was found. This contained caseous matter in which a few germs were found. In all other respects this pig was normal.

No. 27 was killed Sept. 27, 1893, weight 750 grams, a gain of 65 grams since inoculation. Examination showed tubercular nodules in the great omentum. These contained purulent matter with a few bacilli. All other organs were normal. The condition of this animal did not differ materially from that of the untreated ones.

It should be remarked that about the middle of May, Nos. 26 and 27 seemed quite sick. On May 19, they weighed 630 and 552 grams respectively. It is evident that the germ used in this experiment was not very virulent. Three out of five of the treated pigs were practically free from tuberculosis.

In what manner may nuclein be of therapeutic value? What properties has it which may be of service in the treatment of disease? What is its physiologic effect? These questions can not yet be answered in detail and without reservation. In the first place, I may say that I believe the nucleins to be wholly free from poisonous properties. I have injected subcutaneously in man one and one-half ounces of a 2 per cent. solution of yeast nuclein at one time, without harm other than the temporary irritation caused by the large volume of fluid injected, and I have administered six and eight ounces of the same solution during twenty-four hours by mouth without ill effect. In some persons, however, a much smaller amount than those mentioned above, given hypodermatically, may cause a marked elevation of temperature. In one patient, the hypodermatic injection of forty drops or more of the 2 per cent. solution of yeast nuclein, frequently tried, invariably caused the temperature to rise from 2 to 4 degrees. This patient is a large, apparently robust man, weighing 195 pounds, in whom tuberculosis of the neck of the bladder had been recently detected. It should be stated that this man suffered more or less constantly from muscular rheumatism. In a few instances, the injection of eighty drops or more has been followed by a chill and an elevation of temperature. In some of these an erysipelatous redness has appeared about the point of introduction, but this has always disappeared after twenty-four hours without treatment.

In each of three young men, who were, so far as I could ascertain, in good health, the subcutaneous injection of eighty drops of a 2 per cent. solution of spleen nuclein caused an elevation of temperature of 1 degree at the end of the third hour. In these cases the temperature gradually rose and fell in the same manner. In tuberculous patients, the effect of repeated treatments is a lowering of the temperature.

I have employed daily injections in patients for six months and longer, without seeing any evidence that the nucleins may produce injurious effects when thus continued.

We have, in the nucleins, substances which we have long desired, *i. e.*, non-poisonous germicides. We

reasonably expect to find that such substances possess therapeutic value. The following brief reports will illustrate the character of some of the cases in which I have employed nuclein with benefit:

Case 1.—Membranous Tonsillitis—Leida S., 10 years old, was seen about 8 P.M. Both tonsils were swollen and covered with a thin white membrane, through which the dark red of the inflamed gland could be seen here and there. The temperature was 102.4 degrees. The tongue was slightly coated. The bowels had moved once during the day. A 2 per cent. solution of yeast nuclein was diluted with an equal volume of sterilized salt solution and the patient was instructed to use this as a gargle every hour until she should go to sleep and to continue the same the next morning. Nothing else was prescribed. The next day about 11 A.M., the little girl came to my office with temperature normal, and throat free from soreness. The membrane had disappeared and the tonsils were much reduced in size.

I have records of some twelve cases similar to this. In all, the fever disappeared within twenty-four or at most forty-eight hours. In none of these was anything, save the nuclein, administered.

These cases are very suitable for the use of nuclein, and especially for yeast nuclein. The germ present in the membrane belongs to the pyogenic organisms, and these are, as we have found by experiment, especially susceptible to the germicidal effects of the yeast nuclein, while they are much more resistant to spleen nuclein.¹ In the second place, the membrane is spread out in a thin layer and therefore the application of the nuclein is direct. Solutions of nucleins diffuse through membranes very slowly and consequently the thinness of the tonsillar deposits is favorable to the rapid action of the germicide.

Case 2.—Streptococcus Diphtheria.—On the evening of April 14, the throat of Denwood Burt, a boy 3 years old, was found to be filled with a thick grayish membrane, which covered the posterior wall of the larynx and extended on each side in front of the pillars of the fauces. The child was very restless and its temperature in the axilla was 102.5 degrees. The only remedy employed was a 2 per cent. solution of yeast nuclein diluted with an equal volume of sterilized salt solution. The child was not old enough to gargle and stoutly resisted every attempt to employ the remedy. An atomizer was used through both the nose and mouth. The spray was used three times during the night of April 14, six times during the 15th, twelve times each during the 16th, 17th and 18th. The temperature ran as follows: April 15, 100 at 12:30 P.M.; 101 at 6:30; and 100 at 8:00; April 16, 8:30 A.M., 98.5; at 8:00 P.M., 101.2; April 17, 12:00, 99.2; 6:00 P.M., 99; April 18, normal all day. The membrane gradually disappeared and was all gone by the evening of April 17.

I have records of three other cases similar to this, but in these the patients were old enough to gargle and the membrane disappeared and the temperature fell more rapidly. I have not had an opportunity to test the value of the nucleins in diphtheria caused by the Löffler bacillus. In the cases mentioned, the streptococcus was present.

Case 3.—Indolent Ulcer.—Mr. Stauch, a printer about 40 years old, had been under treatment in Detroit and Ann Arbor for more than a year for an indolent ulcer of the leg. Various stimulating and antiseptic washes and dressings had been applied. The ulcer measured one and one-quarter inches in length and half an inch in breadth at the widest part. I had this patient under observation some four weeks before I resorted to the nuclein. During this time, I used a mercurial wash and attempted to administer potassium iodid. However, the latter produced a severe acute coryza, and although it was repeatedly discontinued and begun again, the same unpleasant result followed each time. When I began the nuclein, nothing else was used. I injected into the

tissue about the ulcer 80 minims of a 2 per cent. solution of yeast nuclein. In all, eight of these injections were made. The ulcer healed perfectly, and although two months have passed since the last treatment, there has been no return. The injections caused a burning sensation at the time, but immediately after each treatment the patient walked half a mile to his work and he stood at his case each working day of the week.

This is the only case of the kind in which I have employed nuclein.

As has been stated, the action of nuclein in giving immunity to the pneumonia germ is not due to its direct germicidal effect. To what is its action due? This is a most important question. In my paper on "Immunity and Cure in the Infectious Diseases," read before the Pan-American Medical Congress last September, I stated that we must look for curative agents in these diseases in one or the other of the following classes: 1, non-poisonous germicides of cellular origin; 2, substances which stimulate the activity of those organs whose function it is to protect the body against these diseases. Now, while we have in the nucleins, substances of the first class (and the action of yeast nuclein in membranous tonsillitis and in streptococcus diphtheria must be due to its direct germicidal action), I believe that the nucleins belong also to the second class mentioned above. The phagocytic theory, developed by Metchnikoff, teaches that the polynuclear white corpuscles are the natural defenders against bacterial invasion. This theory seemed to be disproved by the researches of Nuttall and others, who showed that blood serum freed from corpuscular elements has germicidal properties. However, McClintock and I have shown that the germicidal substance in blood serum is a nuclein, and certainly the most probable source of this nuclein found in blood serum is the polynuclear white corpuscle. Now, the administration of nuclein increases these corpuscles. This is a point which my colleague, Dr. Huber, has kindly consented to investigate, and at present I will give only some general statements of the results which he has thus far reached. These may be condensed as follows:

1. The subcutaneous injection of nuclein increases the number of white blood corpuscles.
2. This increase occurs in both healthy and tubercular persons.
3. With like quantities of nuclein injected, the increase varies with the person. It may be slight, and it may be three-fold.
4. This increase occurs principally in the polynuclear cells.

It is evident as a rule as soon as the third hour after treatment and generally disappears after the forty-eighth hour.

If the nucleins shall prove of any value in the treatment of tuberculosis, it will most probably be due to the fact that they increase the polynuclear white corpuscles.

I have been using nuclein in the treatment of tuberculosis in man since May 1, 1893. At first I employed only yeast nuclein, but now I am using spleen nuclein in some cases. When sufficient evidence has been obtained either to reject or recommend the treatment, the results will be communicated to the profession. I may say, however, that only in initial cases may we expect any benefit, and even in regard to these I must have more abundant material and a longer experience before I can speak with any certainty.

¹ The fact that nucleins from different sources affect one germ more seriously than another is one which promises to be of importance in the pursuit of these investigations.

ORIGINAL ARTICLES.

REPORT OF CASES OF ABDOMINAL SECTION AT ROBINWOOD HOSPITAL FOR WOMEN, FROM MAY 1, 1893, TO JAN. 1, 1894.

Read before the Detroit Gynecological Society, April 4, 1894.

BY C. A. KIRKLEY, M.D.
TOLEDO, OHIO.

It is to be regretted that the entire profession has not yet realized the importance of timely operation in destructive disease of the abdomen and pelvis. By *timely* is meant as soon as operation is clearly indicated. To delay, until the surrounding parts have become involved, or until perforation of some of the viscera has occurred may be mainly attributed the fatal and sometimes imperfect results after operation. The question of palliation and delay in cases of ovarian cyst has long since been settled, not only in the minds of specialists, but also in the minds of the general surgeon and practitioner. Why should any better results be expected from palliation in cases of ovarian abscess, destructive inflammation of the tubes and ectopic pregnancy?

Dr. Chas. P. Noble in his interesting report on "Abdominal Surgery at the Kensington Hospital for Women," very truly says that, "without operation it is only by accident that such cases ever become well, and those who do become well run many risks which could be avoided by prompt operation—risks far exceeding those of the operative treatment." Given a case in which an operation is necessary, nothing can be gained by delay and much may be lost. *Dernier ressort* operations are usually unsatisfactory operations and very frequently fatal. Every fatal result is a reproach to the profession, and especially to gynecologists. While operation for abdominal and pelvic disease should be held in reserve, like every other remedy it should be applied while there is yet hope. The proper time to operate is not easy to determine in all cases. Every case is peculiar in itself, and treatment can only be determined by the condition and peculiarity in each case. Tubo-ovarian inflammation coexisting with chronic endometritis may, and sometimes does get well after curettage, irrigation and drainage, but if disorganization and supuration have occurred, as can usually be told by the clinical history and physical signs, any other treatment than total extirpation of those diseased organs is irrational and therefore unscientific. The existing sentiment against removal of the uterine appendages is entirely right, if applied to healthy appendages, which have been and are yet needlessly removed, only by unskilled and untrained hands; but when those organs become so disintegrated and disorganized by disease that the health and life of the patient are in constant peril, that sentiment that is so solicitous about "unsexing" and "mutilating" women and would permit them to die on that account is entirely wrong. Only those who occupy an advanced position have ever practiced or sanctioned the removal of the uterine appendages, except in cases in which function and therefore structure have already been destroyed by disease. Celiotomy is clearly indicated in all such cases, and no other treatment will do the slightest good.

As will be seen in the following report, the chances for recovery in the two fatal cases would have been much better had the operation been done sooner.

The Robinwood Hospital for Women began its career May 1, 1893. It was built and equipped for the care and treatment of women afflicted with diseases peculiar to their sex. Its foundation principle is the well-known fact that such diseases can be more successfully dealt with in a special hospital. The following report emphasizes this fact as applied to abdominal and pelvic disease. Other gynecological cases have been treated, but are excluded from this report. The abdominal cases have been very interesting and the satisfactory results obtained will be seen by a glance at the following table. A number of these cases have been considered of sufficient interest to justify a report in detail:

No.	Date of Operation.	Residence.	Age.	Social Condition.	Occupation.	Medical Attendant.	Disease.	Result.

Case 3.—Came under Dr. Hixon's observation in December, 1892. She was then greatly emaciated and had been discharging pus per rectum for some time. Dr. Hixon at once recognized the condition of things, and advised immediate operation which was declined. When the patient came to Robinwood on May 4, 1893, her condition was anything but encouraging. She was extremely emaciated, abdomen tympanic, temperature 102, and pulse 120. She has had a miscarriage produced a year or more ago, and dated her illness from that time. The dangers of abdominal section were clearly stated to her but she readily consented to the operation. On opening the abdo-

men, adhesions were encountered in every direction and had to be separated with great care, owing to the danger of injury to surrounding structures. Owing to the disorganized condition of the parts within the pelvis, and the extent of the opening into the rectum, its closure was not attempted. The operation was not prolonged; there was very little hemorrhage and very little shock. The abscess contained three or four ounces of pus. Irrigation was thoroughly employed and drain tube inserted. There was slight secondary hemorrhage which soon ceased, but in the exhausted condition of the patient considerable prostration followed. Saline infusion was resorted to twice during the night with apparent temporary benefit. On the following day the condition had slightly improved, the patient expressing herself as feeling much better. The temperature never rose above 99 nor the pulse above 120, except immediately after the operation when the pulse was 160. Death occurred from exhaustion on the fifth day. This case forcibly teaches the danger in delay. Had she consented to an operation when urged by Dr. Hixon her life could, no doubt, have been saved.

Case 10—Was one of unusual interest. The patient was not at all emaciated, but a decided pallor and a countenance expressive of pain clearly told of her illness. She had not been free from pain and tenderness in the lower part of the abdomen for four years. When 15 years old, she had a slight show, the first and only time, followed by a seven months illness. At intervals of four weeks since that age, "cramps" have come on lasting two weeks unless relieved by something. There is constant leucorrhœa, albuminous in character, and constant headache. The body of the uterus could not be felt at all though the cervix was normal, and a distinctly fluctuating mass could be felt in the cul-de-sac of Douglas. She had been treated constantly for a year and a half, mainly by galvanism, with a view as she said, of bringing on her menses, before she applied to Dr. Hollister who at once and very kindly referred her to me. The diagnosis was infantile uterus with diseased adnexæ—probably hemato-salpinx. Some kind of an operation had been done about a year ago—presumably division. Abdominal section revealed hydrosalpinx and a broad ligament cyst as large as a goose egg. Whether appendages were naturally developed could not be told, as they were a degenerated mass on either side, as large as a small orange. The body of the uterus was no larger than the end of one's thumb, and about an inch in length. At the end of three months the patient removed to another State and up to that time there had been no return of pain.

Case 11.—Was under observation for about six months prior to operation. She was married in 1881, and stated that she had been pregnant twice a year for the last twelve years. The condition in which her appendages were found would make that statement, to say the least, improbable. The menses would be missed, she states, in the spring and again in the fall, at which times she would apply to so-called doctors who would insert "something" into the uterus, the menses soon after reappearing. She evidently considered herself pregnant at these times and deliberately and systematically had abortion produced. She was very frail, much emaciated and very anemic. She was never free from pain. The uterus was enlarged, movable and tender to the touch. The menses have always been regular; began when

she was 16 years old; have been very profuse for the last four or five years, and attended with great suffering. She has had several attacks of pelvic peritonitis. Her ill health began about nine years ago, and for the last four or five years she has had "local treatment for womb trouble." Each tube and ovary contained at least an ounce of pus. Recovery was uninterrupted, the temperature never rising above 101 nor the pulse above 99.

Case 14—Presented some interesting features. The patient had been under the care of my friend, Dr. R. E. Jones, of Gomer, Ohio, who kindly referred her to me. She was the mother of one child now 14 years old. Though very much emaciated, she had not an unhealthy appearance. She had a goitre of considerable size which had given her no trouble for the last few years. There was slight edema in the left leg and foot. The abdomen was very much enlarged; dimensions as follows:

Largest circumference (at umbilicus)	41	inches.
Ensiform cartilage to umbilicus	10.5	"
Umbilicus to symphysis pubis	12	"
Right, A. S. S. of ilium to umbilicus	11	"
Left, A. S. S. of ilium to umbilicus	11.5	"

The veins were enlarged; the lower part of the abdomen was hard and quite tender, and the upper part distinctly fluctuated. The uterine cavity measured 4.5 inches. The cervix was apparently flexed at the os internum and the os externum was patulous. The menses had been somewhat irregular during the last three years but always normal in quantity and began at the age of 13. Specific gravity of urine was 1.018, diminished in quantity and contained 5 per cent. albumen. Patient had never been seriously ill, though for the last seven or eight years her health had not been as good as usual. She first noticed the abdominal enlargement, which for the last three months has been very rapid, in December, 1892.

The operation was especially undertaken to relieve the patient of the large accumulation of fluid which was supposed to be ascitic. Instead, however, it was contained within a thin-walled cyst springing from the summit of the solid and degenerated mass within the lower part of the abdomen and pelvis; after careful examination of which, total extirpation was decided upon. The incision was extended from the umbilicus to within an inch of the os pubis. Dense adhesive bands were found in every direction, and enormous blood vessels were tied and divided as the work of removal progressed. Each ovary was fibrocystic, as large as a goose egg, and the tubes contained two to three ounces of serum, all of which were intimately connected with the degenerated uterus. The cyst springing from the top of the mass contained about two gallons of clear fluid (sixteen pounds). The lowest estimate of the solid mass removed was twenty-five pounds. A low estimate of the weight of the tumor would be forty pounds.

A description of the tumor may not be uninteresting: Springing by a pedicle as thick as a woman's wrist from the summit of the tumor near the origin of the cyst was a liver-sized, liver-colored, and liver-shaped fibrous mass—extending over the entire anterior surface of the tumor—which was first removed. A humorous assistant observed: "You have got her liver now." There then remained three distinct portions which were removed *en masse*. The central portion was the degenerated uterus, covered with nodules varying in size. Its degeneration extended

toward the right and left, forming equally large portions, thus presenting a central and two equally large lateral masses, and still all in one. The right mass was soft and the left hard. The tumor, as a whole, is an example of the cystic, fibro-cystic, fibrous, and edematous myoma; certainly unique in my experience.

An operative peculiarity is worthy of mention, and the excuse for its adoption was the collapsed condition of the patient, which made increased haste to complete the operation necessary, as she had already been under anesthesia three-quarters of an hour. The degeneration had almost obliterated the cervix, thus making abdominal fixation impracticable. Time was too precious to attempt the ideal method—total extirpation. The Staffordshire knot was therefore applied to the short supravaginal portion of the cervix. This may not have been in accord with good surgical principles and may have been unnecessary, as there was not the slightest hemorrhage from the stump. The value of a few minutes' time under such circumstances can hardly be overestimated. This defect in the technique gave me no little uneasiness afterwards.

The shock was terrible. Whisky was given hypodermatically every few minutes during the latter part of operation, and when put to bed she was given $\frac{1}{2}$ grain of strychnia and $\frac{1}{2}$ grain of morphia. She rallied well, however; the pulse varied from 116 to 130, and the temperature from 99 to 102 until the beginning of the fourth day, when she had a violent chill, the temperature rising to 105 immediately afterward and the pulse to 150. The abdominal incision was separated to the peritoneum, which having entirely united the abdomen was not reopened. Fluctuation could be distinctly felt in the cul-de-sac. The os was sufficiently patulous to admit a good-sized rubber drain tube which was passed through it into the pelvic cavity. A free discharge of pus followed and in four hours the temperature had fallen to 101 and the pulse to 130. From this time on, recovery was uninterrupted, and she left the Hospital in five weeks after the operation in excellent condition.

This desperate case points out the propriety of at least explorative operation in such cases, and the possibilities of abdominal surgery, though it is doubtful if even an exploration would have been made in this case had not the patient's sufferings been so great from the accumulated fluid.

Case 17.—Came under observation Sept. 27, 1893. She was markedly septic and had had two profuse uterine hemorrhages within the last two months. The lower part of the abdomen was slightly enlarged, produced by the enlarged, tender and movable uterus. The patient had never been pregnant. The menses had been irregular for the last seven months, with dysmenorrhea, and a purulent offensive leucorrhœa had been constantly present. Irregular chills had annoyed her for the last few weeks. Pulse 90, temperature 100. The first sign of ill health was about a year ago, when she discovered a "lump" in her abdomen on the right side and very low down. The striking symptoms were chills followed by fever; extreme pallor and emaciation; pain, tenderness, hemorrhage and an offensive purulent leucorrhœa.

Hysterectomy was performed Oct. 3, 1893. The cervix made a good pedicle, and was therefore secured in the lower angle of the incision. The anterior and

right lateral wall of the tumor was a suppurating mass, and its estimated weight was four pounds. The highest temperature reached was 103 on the second day. Recovery uneventful.

Case 19.—Came under observation Oct. 31, 1893. Dark complexion, very anemic, considerably emaciated, never pregnant. More or less fever for last two months; normal temperature at this time; the abdomen was about as large as it would have been had she been five months pregnant. The uterus was situated low down in the pelvis, fixed and three and one-half inches deep. The cervix was slightly hypertrophied. The menses reappeared regularly, have been profuse the last three months, amounting to severe hemorrhage, succeeded by an offensive purulent leucorrhœa. There was constant pain and tenderness in the lower part of the abdomen on the right side. The abdominal enlargement was symmetrical. The clinical history, confirmed by the physical signs, would seem to indicate that a suppurating myoma was probably the pathologic condition. On opening the abdomen, the large, red and fluctuating tumor was exposed. A trochar was thrust into it, and more than two quarts of pus drawn off. The sac consisting mainly of the right tube and degenerated ovary were enucleated from their bed within the pelvis and ligated off. The left ovary was as large as a hen's egg, and undergoing cystic degeneration. The pus tumor enveloped the fundus and body of the uterus in such a way as to completely fix that organ. The pelvic cavity also contained a parovarian cyst as large as a hen's egg. The symmetrically enlarged and hard abdomen, the fixed uterus and the hemorrhage were the misleading symptoms. Not the slightest fluctuation could be detected before opening the abdomen. Death occurred on the fifth day from septic peritonitis, the infection, no doubt, occurring during the operation, though the irrigation was thorough and though not more than half a drachm of pus escaped within the pelvic cavity.

My acknowledgments are especially due Drs. Col-lamore and Van Pelt who have so kindly assisted me in most of these operations, also Drs. Reed, Chapman, Tracy, Hollister, Donnelly, Bodman, Gardner, Cherry and Craver. To the gentlemen who have so kindly referred cases to Robinwood Hospital for treatment, I extend my sincere thanks. Without their friendly support much less would have been accomplished.

MIND A PRODUCT OF BRAIN ENERGY.

BY CHARLES J. LEWIS, M.D.

CHICAGO.

"What distinguishes the practice of the medical profession, in treating the diseases and repairing the injuries of the *genus homo*, from that of the veterinarian? . . . It is the *worth* of man, he being a rational being, the other being an animal destitute of reason. . . . I would further define the mind as the superintending, the guiding power of corporeal manifestations; it directs all the movements of the body, over which it has complete control; it is to the body what the engineer is to the steam engine, the body being but a mere machine suited to develop the operations of the mind, and preserved and kept in order by the organic functions."

The above question, with its answer in two parts,

is from an article by Dr. John M. Farrington, in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* of March 31, 1894.

Herein, the Doctor utters words to the effect that members of the *genus homo* are intellectually superior to members of the *genus equus*. This is freely admitted to be a statement of facts in the case as to their differences in intelligence *now*. But is he sure, as he says in the body of this long article, that the difference is due to man's brain possessing an inherent power to employ the senses to form ideas, in a manner more advantageous than would the same organs, other means being equal, in the horse? We have evidence that the horse "remembers, combines and reasons."

Let us go back into pre-historic times. In those dull, dim days man and horse, we will assume, were inhabitants of the same fauna. We will also assume though, that man had slightly the larger brain, but that his organism in none of its parts was better adapted for making a record of his experiences—such as naming things, recording sentiments and the like, than was the organism of the horse. Although a larger brain is granted to man, if he could not make a better use of it for perfecting devices for recording his solved problems—wrought-out facts—than was possible for the horse, it is at once apparent that both man and horse would travel down the ages shoulder to shoulder at the same rate of speed, in the acquirement of knowledge.

Man, with a hand armed with thumb and fingers, can make a *record* of his ideas which can be more easily deciphered and appropriated as personal experiences, than could be any *new experiences* by those who succeed him. New experiences require many verifications before admittance into the realm of facts. The horse not having such a limb-instrument as the hand, was and still is incapable of making a record which will be interpretable after the death of the individual experiencing. Thus each oncoming generation of the horse species makes the same round after round of experiences, without an appreciable advancement, simply because their ancestors left no intelligently recorded heritage, either in the description of their enforced slavery under man or of a stock of useful knowledge. The trust the horse hands down to its succeeding generations we herein show to be exceeding small, thin and easily rusted-out of tradition's memory. Not any smaller, thinner nor more easily rusted-out heritage, however, than would be the trust of a *handless, toeless, and a recordless humanity*. This points to another rendering of the following by the Doctor: "That there is a union of the mind with the body, and he who ignores the mind of man in treating his diseases may well be classed with the veterinarian."

The second part of the answer, "that the mind is to the body, what the engineer is to the steam engine," we are hardly prepared to hear as coming from a member of the medical profession of to-day. However, since I am not hitherto responsible for the medical training of any member of my chosen profession, I cheerfully grant the widest scope of opinion. If a living human being is identical with a dead steam engine which can not modify its output of force, then a comparison between the two is permissible. If not, then not. A steam engine is constructed in such a manner that when a part is worn out, it can be replaced by a new one. But can a hopelessly cirrrosed

liver, or an opaque cornea, or a single ganglion-cell in that part of the cerebral cortex known as the granular formation of Meynert, after having lost their function be restored to usefulness again? To this there can be but one answer. The difference, then, between a machine and an organism, lies in the fact that the latter can modify or wholly inhibit an action stimulated by a sensation. But when the steam in the steam-chest of an engine receives an impression from the engineer, it has but one thing to do, namely, to move the piston which turns the drive wheel. It has no choice; it can not assume the position—I may or I may not move the piston. From this we learn that there is nothing gained by comparing things that are clearly dissimilar in their make-up and uses.

All human thought points to the fact that non-living matter yields a different expression from matter which is alive. From this we have accustomed ourselves to declare that there is a difference in the make-up and uses of the two kinds of matter, whether this is so in their ultimate constituent parts or not. To strengthen this diverging view, we need but consult modern biology. H. J. Campbell (1892), makes the statement that the embryonic cells of a fertilized ovum coalesce into three layers; the epiblast (external layer), hypoblast (internal layer), and mesoblast (middle layer). These membranes continuing to develop from food sources, finally enlarge so as to form all the complicated structure of an adult.

Without enumerating them, we will assume that the tissues having their origin in the mesoblast and hypoblast will be coordinate in development with those from the epiblast.

The embryonic membrane—the epiblast—is the outer of the three layers. It is also called ectoderm, and neuro-epithelial layer. This layer is of special interest to the physiologic psychologist, in that from it is developed the nervous and some other tissues of the body. And there is another point of interest connected with this tissue, in the relation which it holds to the others, as one of its names indicates—namely, neuro-epithelium. By this we see that the outside of the body—the epidermis—is formed from this layer, making thereby for the outside of the body a membrane which has its rise in common with the nervous tissue. Hereby the body has sensory tissue overlying its entire outside, fitting it for sensing environing motions from any possible direction.

There is something remarkable in the statement that the epidermis which covers the body is of the epiblast. Not in the fact of this fact; but in the failure of psychologists hitherto, to fully comprehend the advantages accruing to the animal organism therefrom. In the oncoming of animal life, sensibility made its first appearance in the skin as a special sense. Now by adding to this a clothing—*epithelium*—derived from a tissue in common with the nervous system, every spot of the outside of the body becomes a living sentinel to give information of impingement by environing objects. When these would portend harm, the organism could choose between contending with them and fleeing to a place of safety; or, if pleasurable, it could remain in quiet and enjoy them.

The bodies of all living beings are cellular, and divided into two chief classes—the protozoa and metazoa. An amœba is a single-celled animal, and of the protozoa, while man is of many cells—metazoa.

After we have observed and named every cell and every cell colony in the human embryo, and having become conversant with the action of these protoplasmic bodies in the adult, whether singly as in the protozoa, or in a colony as in the human eye, then, and not until then, will we be able to divest ourselves of the training we have had in mythological lore. A part of this lore is the very prevalent notion that mind, at least in part, has some mysterious origin other than products of vibratory or molecular motions proceeding from the five end-organs into the brain. I do not deprecate the efforts that men have made in the past, but shall simply aim at bringing into view the methods of the past, and contrast them with those of the present.

As to voice: Voice is a sound symbol produced by the organs of speech, interpretable by the center for hearing. The noises made by mammals lower than man by their vocal organs are not regarded by man as speech, on the ground of not being comprehended by him as uttered symbols of ideas. The vocal organs in man and all mammals are essentially the same, while the expression of speech is dependent upon the process of ideation and perception.

The making of these *uttered* symbols of ideas, comprehensible by the visual center of the cerebral cortex, has been effected by a system of graphic characters called letters. Presumably, man's first record of an idea was through depicting the object it represented by some such crude procedure as marking its form with a rod in the sands of the seashore. The stimulus to this might have been the beholding of one's image in the still water near by. But what could be the stimulus which ultimated in representing a sound by a symbol, such for instance as a letter of the alphabet? The *comprehension* of this momentous act marked the initial point of advancement which secured for man an advantage in the race for the acquisition of power over all others of the animal kingdom. Possibly the stimulus might have been a struggle between two individuals of different clans who, though having different languages, nevertheless attempted to understand each other's speech. One being resourceful, attempted to make known to the other his ideas by marking in sand or dust, or some impressionable surface which chanced to be at hand, a picture of some object which might be familiar to both.

Upon comprehending that sounds which were cognizable by the center of hearing could be represented by names recognizable by the center of vision, nothing could be more obvious than that out of man's natural curiosity a few individuals in each generation would become devoted to the work of correcting, improving and enlarging the processes of making an intelligent record of speech. To this end, man soon discovered that his hands were very important factors.

The monkeys—quadrumania—though *four*-handed, have not as yet, awakened to their potentialities in the direction of using their fore-limbs for making a record of ideas which were understandable by succeeding generations. Owing to this, their ideas are few and necessarily of the simplest character. After one of the Simian tribes has obtained only a faintly comprehended notion that he could represent a speech-symbol in such a manner as to have it typify, as though made for the eye, presently others would become associated with him in its development, and

the process thus inaugurated would be a substantial beginning of an era of progress. Why it is that some individual of the quadrumania has not taken this initial step of advancement, as well as man, I leave for the future to answer.

For obvious reasons much of the acumen of our forefathers was expended in the direction of establishing language; that is, in forming or agreeing upon words or names for the various objects which cast reflection upon their sense-organs. The five senses are also called end-organs.

Owing to the undeveloped state of the art of making a record of names of things observed in earlier times, success in this direction did not come before printing was invented. This made it possible for the dissemination among the people of all names agreed upon. This stimulated the scholars everywhere to a more constant and systematized effort to collate all fact-words known, and this in turn brought into existence a class of experienced workers in collating fact-words into groups or special departments of science. Among these I might mention mathematics, logic and more recently, the physiology of the brain. Many words, among them sun, moon, stars, day, night, water, man, animal, became permanent through tradition. But for all newly coined words tradition was a very tedious method of giving them permanency. Among objects or supposed objects having names given them in early times, I might mention alchemy, necromancy, witchcraft, soul, spirit, God, mind. This class of words are aptly said to belong to a class of objects which is supposititious when viewed in their commonly supposed meaning. And rightly, too, for it is undetermined, even in our time, whether any reflected motion passes from them to form by impingement an image upon any one of our five end-organs. This fully accounts for the vague and varied opinions held concerning their import.

As stated above, since we now have a quick means—the press—of disseminating the names of things, there has arisen among us a widespread desire to memorize them, *i. e.*, to increase our knowledge. Students find that they are aided very materially in obtaining more knowledge of things but partially understood, by asking questions and by comparing the new answers with the old.

A, B and C, are persons conversing. A asks B what mind is. B replies that "the hand does not feel, the tongue does not taste, nor the eye see, but the mind through the medium of the organs and the brain feels, tastes and sees." Turning to C, he asks the same question, and C answering, says: "Mind is the sum total of one's comprehended impressions." In B's answer we have an affirmation that mind is an entity—has an independent existence of its own, and that the end-organs and brain are only incidental and very unimportant appurtenances. While C declares that mind has arisen in its totality from sense-impressions that have gone to the cerebral cortex and by it cerebrated into ideas which are comprehended. To comprehend a thing is to differentiate it from all other things. Can B be sure that he has differentiated mind from sense-organ and brain? Unless he is certain that he has so differentiated, obviously he is affirming without knowledge.

C demands a hearing for his statement on the ground of the preposterousness of having mind in a being that was devoid from birth of even a faintest trace of either of the five senses, thus making it im-

possible for it to experience a single sensation. That is, that it could neither smell, taste, hear, see nor feel. Manifestly, a being of this simple description would be less complex than the sensitive plant. Yeal it would be a *no-sense* being. Having no organs to sense wave-motions reflected from objects, what the premise for affirming that such an organism can give forth expressions that are indisputably sequences of ideation?

These statements permit the declaration, that we have ground for an enduring hope in the progressive character of humanitarianism, as expressed by those who maintain that the raw material out of which ideas are made are the *motion-things* we call sense-impressions. And further, that this unitary font of human intellection, has already been placed upon a permanent basis. Nevertheless, the student-teacher should ever evince a hearty zeal in teaching his pupils, among other things, that the senses of taste and touch are stimulated only by objects in actual contact, while the senses of smell, of sight and hearing are exercised only by reflections from objects that are always out of impact; *i.e.*, at a distance. Herein Ziehen is right in saying that it is from sense-impressions that the brain can build up ideas, to which I will add, that it is from these ideas being regarded as a whole, we have what we are pleased to call mind.

The hope of the race is now, as heretofore, in the student who is ever on the alert and questions the position of state, of church and of philosophy, as to their individual worth; if either makes for an enlarged personal freedom it shall be fostered; but if either shall be found to retard personal advancement, it, through neglect shall be permitted to enter upon the period of senile atrophy.

The earth—man's home—is for the enlightened. Only they who are loyal to this spirit are destined to survive. They alone have in them the functional activities of organic life. A human being who pits his organic life against his spiritual, is an anomaly, and one or the other of these opposing forces will sooner or later yield to its unfitness.

The argus-eyed student is always conservative and patient, but ere long physiology's shrill voice will call upon the differentiators of things—builders of facts—to join their forces, and all the obstacles to human betterment growing out of the mythological aspect of mind, however formidable, will go down before the advance of an enlightened people.

Yes, mind is a product of brain energy.

Out of the myriad observations made by myself and others of sensations after having been modified by cerebral tissues, I have synthesized their ultimates into one sentence, namely,

Mind is the sum-total of one's comprehended impressions.

IMMEDIATE CAPSULOTOMY FOLLOWING THE REMOVAL OF CATARACT.

Read before the Medical Society of the State of Pennsylvania,
May 17, 1894.

BY L. WEBSTER FOX, M.D.

PROFESSOR OF OPHTHALMOLOGY MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA.

All ophthalmic surgeons endeavor to obtain perfect vision after the removal of a cataract. On account of its prevalence, the loss of one of the most valued of the senses, and the restoration to vision by

a bloodless and painless operation have concurred to render this operation an object of the highest attention to surgeons; and the progress of improvement in the operation has been commensurate with the advances made in surgery elsewhere in the economy. Unfortunately, with all our skill and knowledge, success does not always follow the removal of an opaque lens. The many contingencies incident to the healing of the wound, the distortion of the cornea, the subsequent change in the media caused by iritis, or a thickening of the posterior capsule—one or all of these factors play a very important rôle in the subsequent restoration to vision.

The opaque lens, with its capsule, obstructs the vision, causing blindness of the patient. To remove this obstruction requires considerable dexterity; to restore vision, absolute cleanliness and most careful after treatment. The most disheartening factor in a cataract operation is that sooner or later the posterior capsule thickens, and again dimness of vision follows; the lessening of the sight is not so great as it was before the removal of the lens, but still the patient is debarred the comfort of reading, writing, or attending to business matters in which it is necessary to have perfect vision. It is to prevent this latter change that I advocate the splitting or parting of the posterior capsule at the time of the primal operation.

Having had the opportunity of following many operators, good, bad and indifferent, and noting the after results, I frequently saw excellent vision follow bungling manipulation. The surgeons did not possess that delicate sense of touch so essential in making the corneal incision, snipping the iris, lacerating the anterior capsule, and delivering the lens. They lost courage, or their hand became so tremulous after they had ruptured the capsule that the operation would have been a failure had they not taken a lens scoop in hand, entered the eye, and fished out the cataract and its capsule, with always more or less loss of vitreous. With very great care in the after-treatment many of these patients would recover, and in the majority of cases which did recover no capsule interfered with their visual acuity. It was witnessing such operations that led me to think that a parallel process carried out, however, on more delicate operative lines, at the time of the primary operation, would still lessen the dangers that such harsh measures would be sure to excite.

The ancient method of removing cataracts from the direct line of vision was by *couching*; that is, passing a delicate needle through the sclerotic coat on the temporal side of the eye-ball, posterior to the ciliary bodies; pressing it forward and into the crystalline lens. Then, by a backward sweep of the point of the needle, lens and capsule were torn from their position, and deposited down and out in the vitreous chamber. Celsus, the celebrated Roman physician, who lived at or about the commencement of the Christian era, describes, and is generally esteemed the father of this operation. It was not very satisfactory in its results, according to the data obtainable from the earlier writers. Fabricius, who flourished in 1600, speaks with great despondency of this operation; later on, Hiester, 1711 says: "Though the operation is easy to be performed, the success is so very precarious that among a great number of persons, couched by the most distinguished oculists, very few met with the desired

results; and upon the vast number of patients upon whom the celebrated itinerant Taylor operated, not one in a hundred recovered his sight." He further says that in several different places he saw many miserable objects in tormenting pain, arising from inflammation consequent upon the operation, and that of those who regained their vision, there was scarcely one in ten who did not sooner or later lose it again. For eighteen hundred years this puncturing of the eye-ball, with its most deplorable results, was the only method held out to the blind. It was the outgrowth of an accident which gave birth to the rival plan of extracting the opaque lens through an incision of the transparent cornea. It was the failure to remove a cataract which had escaped into the anterior chamber by couching, that led M. Mery to recommend, in the year 1707, the practice of extraction in all other cases of this disease. It was left, however, for Daviel, the celebrated surgeon of Paris, 1745, to bring forward this method as one infinitely less dangerous than couching. From that day to this the incision is made through the cornea, or along its margin, and the percentage of loss is to-day what the gain of vision was one hundred and fifty years ago.

PRELIMINARY TREATMENT ESSENTIAL IN CATARACT OPERATIONS.

I deem it of the greatest importance to interrogate all cataract patients presenting themselves for an operation, as to their general habits and family history, and to make a careful examination of the urine, restricting meat diet and increasing a vegetable one; while last but not least, placing the patient, one week before the operation, on the mixed treatment, also paying particular attention to bathing both eyes with a boracic solution containing sulpho-carbolate of zinc; examining the eyelashes and particularly the nasal cavities. If any catarrhal affections are found in these cavities it is of paramount importance that they receive the proper treatment before an operation is performed. The day before the operation, the patient is given a warm bath and a saline purgative, kept in bed, and his face washed with Castile soap and water, then washing the skin around the eye to be operated upon with ether, following this again with a 1-5000 solution of corrosive sublimate after a German method (Schweigger).

The reason I call attention to these minute details is that the patient may suffer from some defect which would not affect an eye in a comparatively healthy state, but might exercise an extremely pernicious influence on the eye after the irritability following the operation. The effect to be dreaded is inflammation, and therefore every measure calculated to prevent its occurrence must be taken. There are still a few ophthalmic surgeons who think it quite unnecessary to take these preliminary precautions, but happily the number is growing less year by year.

At the time of the operation still greater precautions are taken; the patient's face, neck and mouth are thoroughly cleansed, clean underclothing, over which, and fitting close to the neck, a sterilized sheet is wrapped, head bandaged in a sterilized towel, and the eye irrigated with an aseptic fluid, as hot as the patient can bear it. The instruments are also sterilized; all fluids, such as atropin and cocain, are sterilized in a Llewellyn flask. The operation is performed then in the usual manner.

After the delivery of the lens (cataract) and all cortical matter is washed out of the anterior chamber, I proceed with the rupturing of the posterior capsule,—the subject of my paper. The instrument used is a gold enameled hook, made as delicately as is consistent with keeping its shape. It is of malleable steel, so that it may be bent to any angle which I find is convenient, especially when the eye of the patient lies deep in the orbit. The hook is passed into the anterior chamber, and behind the lower pupillary margin of the iris, on its flat side. It is then rotated backward, hooked into the capsule, drawn gently upward to the mouth of the incision, rotated on its flat side again, and then taken out of the chamber. By this means, the capsule is torn and the vitreous presses forward between the rent. Very little or no vitreous shows at the mouth of the wound. If it does, I snip it off.

When the operation is performed after the simple method (without iridectomy), the same manipulation is carried on with but one exception; and that is, the line of incision is not so long. The ophthalmostat is removed, and the eye-ball again irrigated with the hydrostatic eye-douche, followed by dropping one drop of sterilized atropia solution into the eye; the lids closed and thickly anointed with vaselin, which has been sterilized by boiling; over this specially devised eye-pads, which have also been sterilized by heat, held in place by adhesive strips, which keep the bandages securely fixed, permitting the patient to change his position in bed as often as is desirable. In twenty-four hours the dressings are removed, and both eyes bathed with warm water and irrigated with the sulpho-carbolate solution, another drop of atropia applied, and similar eye-pads adjusted with as much care as at the primal operation; and so continued from day to day until the eye is out of danger.

Is this a new operation? Some of the older writers of fifty years ago hint at the removal of the lens and its capsule, but they are not explicit enough to say that they did so. The only authority that I can find saying so positively, is Richard Middlemore, who, on page 138, Vol. ii, in his great work on "Diseases of the Eye," published in 1835, after speaking of the removal of the lens, when the pupil is not clear, on account of the thickening of the posterior capsule or the hyaloid membrane, says: "In every such instance, I have found it absolutely essential to the successful result of the case, to lacerate the posterior capsule and hyaloid membrane, and permit the escape of a portion of the vitreous humor." Coming nearer to our own day, I must say a few words about the distinguished surgeon who left his impress upon all who witnessed his wonderful skill as an operator. I have reference to the late Dr. Richard J. Levis, of this city. I have had the opportunity of examining quite a number of patients from whom cataracts were removed by this eminent surgeon. In nearly every instance the posterior capsule was evidently ruptured at the time of the primal operation. Whether this was a constant practice of Dr. Levis' I am unable to say, but I am sure he realized the importance of removing the posterior capsule at the time of the original operation. Pagenstecher, of Wiesbaden, is also an advocate of removing the lens and its capsule at one sitting. Hasner, another German ophthalmologist, is an advocate of this radical operation. It has recently come to me indirectly that Dr. Knapp,

of New York, is also lacerating the posterior capsule at the first operation.

Is the operation always successful? Laceration of the capsule alone does not prevent the hyaloid membrane from becoming slightly translucent. When this takes place, we may follow with a needle operation, and not provoke cyclitis by trying to tear a tough inelastic tissue.

I have been in the habit of performing this operation in alternating cases, for ten years. In those patients upon whom the operation was performed, I had to repeat a needle or capsulotomy (scissors) in about 15 per cent. of the cases; where it was not performed, in about 75 per cent. In the 15 per cent. of the cases where it did not succeed, I can only attribute it to a very thick posterior capsule, the vitreous receding after closing of the eye-ball, and thereby not keeping the capsule separated, but practically closing again. My experience has led me to believe that there is less danger of inflammation of the eye-ball in immediate capsulotomy, than in a subsequent operation.

The elder operators recognized the gravity of puncturing an eye-ball with a needle, and hailed with delight the improved method which completely revolutionized statistics. My own experience is fast leading me to adopt the cutting the cornea with a keratome and the incision of the capsule with a De Wecker's scissors, disregarding the needle altogether. With the preliminary treatment, and with the aseptic methods now employed, success is almost always assured, while with the treacherous needle almost every surgeon has had occasion to regret his *modus operandi* in more ways than one.

GASTRO-HYSTEROPEXY AS A SAFE AND RELIABLE MEANS OF CORRECTING PROLAPSUS AND RETRO-DISPLACEMENTS OF THE UTERUS.

BY YOUNG H. BOND, M.D.

PROFESSOR OF DISEASES OF WOMEN, MARION-SIMS COLLEGE OF MEDICINE;
GYNECOLOGIST TO REBEKAH HOSPITAL, GRAND AVENUE
FREE DISPENSARY, ETC.
ST. LOUIS, MO.

By far the most frequent displacements to which the uterus is liable are the downward and backward, namely, the various degrees of prolapsus, retroversion and retroflexion. But few if any troubles in the entire field of gynecology impose more of suffering and misery than is entailed by the inflammatory consequences of these affections. The reflex disturbances and the general ill-health that usually follow often lead to melancholia, hysteria, and even more pronounced insanity. In many instances the physical health is wrecked, and the functions of the various systems of the body are so perverted as to lead to a condition of general impairment of nutrition, which predisposes to the activity of any inherited tendency to disease.

I should like to emphasize the significance of the phrase, "inflammatory consequences," in this connection; for it is to these that symptoms are chiefly due; for example, pelvic peritonitis, with adhesions binding the uterus, ovaries, Fallopian tubes and sometimes the bladder in unnatural positions; ovaritis and salpingitis terminating in cystic or pus formations; endometritis, cystitis, chronic constipation, etc. I am aware that these conditions some-

times predispose to or bring about the displacements in question, but I am satisfied that in very many instances they stand in the relation of cause rather than of effect; and I am convinced from ante-mortem observations that the generally accepted idea that pelvic peritonitis with its train of evils is almost uniformly due to salpingitis incident to endometritis, is an error; that in reality its most frequent cause, apart from post-partum sepsis, is the pressure and consequent disturbed circulation, friction, etc., of the retroposed uterus.

I shall not presume, before this intelligent audience, to make anything like a systematic and complete presentation of the history, etiology, symptoms, physical signs and treatment of these affections; such an exposition would be appropriate before a class of students, or adapted to the ends of a textbook. The purpose that I have in view in presenting this paper is to emphasize a pathologic and etiologic condition shared by all of these affections in their initial departure, from which proceeds a common and major principle of treatment. However, the fact should not be lost sight of that the individual affections call for special means in addition to the principle of treatment common to them all.

In order that I may make myself understood, it will be necessary that I recall to your attention the fact that in the erect posture the pelvis is placed so obliquely with reference to the trunk that the axis of its inlet is represented by a line drawn from the umbilicus to the middle of the coccyx. Now, as you know, the axis of the uterus corresponds with that of the pelvic inlet; hence the normal position of the uterus is such that the force of intra-abdominal pressure, which is perpendicular, falls upon its posterior surface, and operates not only from above but from behind. Temporary departures from this relation of the position of the uterus and the direction of intra-abdominal pressure are constantly occurring, but they are only temporary and therefore physiologic.

Any permanent deviation from their nominal relation becomes at once the prominent determining etiologic factor in the production of either a prolapsus, a retroversion or a retroflexion, and the particular displacement is determined by the condition or state of integrity possessed by the suspensory supports, namely, the long, the broad and the utero-sacral ligaments, together with the restraining supports or pelvic floor.

Now it can be appreciated that however prominent a part may be played by a breach in the pelvic floor, or by impaired suspensory supports, in predisposing to and determining the character of the displacement, yet the salient fact remains that they are but contributory agencies in their accomplishment; they determine the direction of retreat of the uterus from the cause operating above, namely, intra-abdominal pressure. For example, if of the suspensory supports the round ligaments be alone principally elongated, and the walls of the uterus not wanting in tonicity, we will have retroversion. If to a similar state of the suspensory supports be superadded a flabby condition of the uterine walls then we will have retroversion plus retroflexion. If the round, the broad and the utero-sacral ligaments be elongated, and the integrity of the pelvic floor is wanting we will have prolapsus.

It will be perceived that under normal circum-

stances the force of intra-abdominal pressure, falling upon the posterior surface of the uterus, acts as an agent in maintaining the proper position of the uterus by forcing it in a direction in which descent is physically impossible; but under other circumstances it becomes the essential displacing factor. The round ligaments might be elongated, but if in spite of this circumstance the uterus did not become retroposed so as to permit other than its posterior surface to receive the force of intra-abdominal pressure, we should not have retroversion. If the walls of the uterus were ever so flabby they would not bend appreciably were it not for intra-abdominal pressure. Were it not for the same pressure, lacerations of the pelvic floor would not result in loss of resiliency of the suspensory supports and consequent prolapsus.

Then the keystone in the arch of all these affections is found to be the same, viz., altered relation of the force of intra-abdominal pressure and that uterine surface to which it should be applied. The first step in prolapsus as respects the altered position of the uterus is a movement of the fundus backward, and the same is true of retroversion and of retroflexion; so that it must be apparent that defects in the uterine supports operate indirectly in accomplishing the displacements in question, and directly in determining their character. They permit a force which under normal circumstances serves to maintain the uterus in its proper position, to become the chief factor in the production of its displacement.

In dealing with aggravated cases of distortions, such as fall within the purpose of this paper, we have very largely lost sight of this, the central idea that should engage us in our methods of treatment. For, however we may seek to redress imperfections of the supports and repair lacerations of the pelvic floor, if we fall short of placing the uterus in such a position as respects intra-abdominal pressure as to cause it to cease to be an element in the production of displacement, we utterly fail to obtain satisfactory and enduring results; since it is only a question of time when the gathered up tissues of a colporrhaphy, perineorrhaphy, etc., will have yielded to the steadily continued, downward, intra-abdominal pressure. Experience has amply proven this observation, and the explanation of the fact is found in the circumstance that I have sought to make clear.

DIAGNOSIS.

To the end that treatment of these affections may be successful, it is a matter of prime and paramount importance that we should be able to make a reliable diagnosis. The gynecologist who is in the habit of proving his diagnosis through laparotomy work, if he uses the proper means and methods of physical exploration of the pelvic organs, will soon become so proficient that he can safely venture upon a positive diagnosis in fully 95 per cent. of his cases.

By method and means of investigation I mean that the patient, having been thoroughly anesthetized, must be placed in the dorsal position with the limbs well flexed upon the body, so as to cause the sacral curve to be brought well to the front, to the end that the axis of the pelvic cavity will conform as nearly as possible to that of the trunk. By this means the space between the fingers of the right hand that are in the vagina and rectum, and those of the left hand that are buried through the abdominal muscles above

the symphysis, will be materially lessened, so that each organ of the pelvis can be clearly outlined, and its form, position, consistency and mobility be readily determined. I usually employ the index finger in the vagina and the middle finger in the rectum simultaneously. The greater amount of information is obtained through the rectum.

TREATMENT.

The retroversion pessary finds its useful application in those cases of retroversion and retroflexion in which the uterus is not bound down by peritoneal adhesions; in which the ovaries are not prolapsed, and as is often the case, incarcerated in the cul-de-sac of Douglas; and in those in which the displacement has not lasted so long that the round ligaments and other supports have lost all power of regaining their resiliency. In such cases, having first relieved complicating conditions, such as laceration of the cervix and tears of the perineum, we can by the patient and judicious use of the intra-vaginal or Smith-Hodge pessary accomplish much for the relief of our patients; and recognizing the fact that the displacements usually manifest themselves after parturition, it becomes the imperative duty of the obstetrician to make a careful physical exploration of the pelvic organs within eight or ten weeks after accouchement, with the view to correct, in the manner indicated, any altered position of the uterus that may be discovered. For at that period the displacement, as a rule, has not produced inflammatory results which would negative the use of the pessary; since such cases generally remain uncomplicated for a variable period of time, often months, save possibly by the results of subinvolution.

The conditions and results of treatment are far different when the displaced organ or associated pathologic state has produced pelvic peritonitis, the adhesive products of which have fastened the uterus, and possibly the ovaries, in varying relations to each other in the cul-de-sac of Douglas with possibly suppurative results; so also are they different when the suspensory supports, from long-continued traction, have become so attenuated as to be practically paralyzed. Just as we are able to destroy the tendency of rubber to contract by overstretching, so likewise do the suspensory supports lose their function.

Prolapsus in the first degree can usually be corrected by the use of the pessary, after complicating conditions have been relieved, such as hypertrophy, elongation or lacerations of the cervix, or tears of the pelvic floor; but let the case become once well established, as is represented in the remaining degrees of prolapsus, and we have a condition of things represented by stretched and paralyzed suspensory supports; the cellular tissue is without elasticity; the muscles of the pelvic floor, if not torn, are atrophied and often have undergone fatty degeneration. Under such circumstances, with the conditions recounted it is idle, nay more, it is foolish, to expect anything like complete and satisfactory results from the methods of treatment usually pursued.

In the case of the adherent retroposed uterus, pessaries are inapplicable and forcible breaking up of the adhesions after the method of Schultz, through the uterine cavity, is dangerous and often ineffectual; in fact, all attempts to replace or otherwise interfere with a uterus that is bound down in its displaced

position by adhesions, other than through intra-abdominal procedure, are dangerous and to be condemned, for the reason that absolutely accurate knowledge of the pathologic conditions can not always be ascertained, and in consequence we may unconsciously compromise the life of a patient by causing the contents of a pus sac to be liberated into the peritoneal cavity; and further, it is a blind procedure, lacking all the elements of precision necessary to reliable and good ends. Here it is that a method of treatment presents itself which, in the hands of the clean and skilled surgeon, is both safe and efficient. I allude to hysteropexy, which, as you know, means literally a fixing of the uterus, and is applied to those procedures that have for their purpose the maintenance of the fundus of the uterus in connection with the anterior abdominal wall.

The methods of practicing hysteropexy pursued by operators thus far differ in many particulars; the operation has been practiced scarcely long enough to enable us to decide positively which is the most desirable method, and yet long enough to permit us to pronounce quite confidently upon its worth. Through it, in a sure and reliable manner, we place the uterus so that its posterior surface is opposed to intra-abdominal pressure, which, as previously stated, acts from above and behind in such a manner as to assist in maintaining the proper position of the uterus. We thus supply the keystone to the arch of uterine retention, without which in no uniformly reliable manner can the damaged pillars of support be made adequate to their requirements. It is astonishing how small a measure of force is necessary to keep the uterus antiposed when anchored ever so slenderly in its proper place.

Hysteropexy.—The general precautions pertaining to a celiotomy having been observed, the opening through the abdominal wall is made as low down as practicable, and no larger than necessary to admit of efficient and expeditious work. The patient is placed in Trendelenberg's position, by means of which the pelvis is freed of the confusing presence of intestines and omentum, and they are spared the injury of unnecessary manipulation. The walls of the incision are held outward and apart to admit of as free inspection of the pelvic organs as possible. Parenthetically I will say that the advantages in this direction are very great in subjects with thin abdominal walls, and the reverse in those heavily loaded with adipose tissue. Our manipulations in the abdomen are also facilitated and retarded by these conditions. By means of inspection and the sense of touch, accurate knowledge of the conditions and relations of the pelvic structures is obtained. If adhesions exist, they are broken up by means of the index and middle fingers; the ovaries and Fallopian tubes are brought up to the abdominal opening and carefully inspected, and if found to be seriously diseased they are removed, otherwise not. Small ovarian cysts are treated by clipping off a portion of the cyst wall. The fact that the organs are found adherent is not in itself sufficient justification for their removal. Next, the uterus having been lifted to the front is seized through its fundus with a double tenaculum and held by an assistant in such relation to the abdominal wound that the operator can readily pass a curved needle threaded with a heavy chromicized catgut suture through all the tissues of the abdominal wall except the skin, embracing sufficient of them

to secure a firm hold, then through the anterior and upper portions of the fundus and out similarly through the abdominal wall at the opposite side of the incision. The tenaculum is now removed and the assistant takes the catgut suture in its stead. The abdominal wound is then closed by interrupted sutures in the usual manner, with this difference: That the catgut suture that has transfixed the uterus is tied before, but not until the abdominal suture in closest relation to it has been drawn upon, so as to approximate the peritoneal surfaces. The tying of this last abdominal suture draws the skin over the catgut suture and thus buries it. This has been my method of operation, and the results have been uniformly good. In not a single instance has the uterus failed to remain in the position in which it was placed, and the outcome so far as the restoration of the general health is concerned has been all that could be expected, and in many instances singularly excellent. It has been the custom of some operators to abrade the anterior surface of the uterus, with the view of producing extensive peritoneal adhesions; of others, to transfix the uterus with many sutures, and pass the same through all the structures of the abdominal wall, using as a rule silkworm gut. I think that a larger experience will demonstrate that such extra precautions are unnecessary.

It may be asked by some one, Why not do Alexander's operation for the relief of these affections? The fact of the matter is that Alexander's operation has a very limited field of utility; it is entirely inapplicable to cases of adherent uteri, or where the adnexæ are diseased. It will accomplish scarcely more than a properly adjusted pessary when the round ligaments have not become permanently paralyzed; it will accomplish nothing when they have become so, for they are then merely greatly attenuated cords often very difficult to find. The element of danger as respects hysteropexy is great or almost *nil*, according as the operator is wanting in proper antiseptic precautions and pathologic knowledge, or the reverse. In the one case the patients usually die very promptly; in the other, they are scarcely conscious of discomfort after the expiration of the twenty-four hours following the operation.

The query may come to you, What will be the result in the event of pregnancy following hysteropexy? Our experience in this respect has been limited, but not altogether untoward. I believe that the use of a suture such as catgut, that undergoes absorption, will be conducive to good results in this direction.

REPORTS OF CASES.

During the year just passed, very few weeks have elapsed that I have not practiced hysteropexy in one or more cases, in connection usually with other surgical procedures; for such cases as call for this operation are usually complicated. So far I have had no deaths, and as yet the uterus remains as placed in every case. It is true that the length of time that has passed is not very great, yet it is more than sufficient for the institution of the initial steps of displacement, the absence of which, together with the results to other operators, justify a sense of assurance as to the ultimate outcome. I will not tax your patience by imposing upon you numerous and extended reports of cases. I shall merely ask your attention to such as exemplify a principle of treatment:

The first case that I will report is that of Mrs. F., aged 32

years, married, the mother of four children; ill health dates from a confinement five years previous to the time of consulting me in the early part of September, 1893. Her general health was horribly impaired; weight 105 pounds; suffering more or less all the time; utterly incapacitated for any duty. Physical exploration revealed an irregular mass in the cul-de-sac. Diagnosis: Retroflexed and adherent uterus, in connection with prolapsed, adherent and suppurating ovaries. Operation on Sept. 27, 1893: Adhesions broken up with great difficulty. Material assistance to this end was rendered by Dr. B. M. Hypes who elevated the parts by pushing with his fingers in the posterior fornix of the vagina. Ovaries and tubes removed and the uterus fastened to the anterior abdominal wall after the manner previously described. Patient made a good and prompt recovery. Weight now 137 pounds, ruddy complexion, magnificent spirits. Examination of the uterus made a short time since finds it in normal position, all pelvic induration gone, and seemingly the usual degree of mobility of the parts.

Case 2.—As illustrative of the conservative possibilities from hysteropexy, I report the following: Mrs. G., aged 27, married, the mother of three children, consulted me on Feb. 1, 1894; general health greatly impaired, dating from last confinement two years previous. Diagnosis: Uterus retroverted and bound down by adhesions; ovaries cystic, prolapsed and adherent. Operation on Feb. 19, 1894. Adhesions broken up, one ovary removed, uterus approximated to the anterior abdominal wall as before. Prompt recovery. Uterus in proper position at the present time. General health completely restored.

Case 3.—Multiple operations at one sitting. Mrs. L., aged 31, married, one child; ill-health dates from its birth about three years. General health greatly impaired; suffering constantly with pain in the back, down the limbs and a sense of downward pressure in the pelvis. Diagnosis: Laceration of the perineum, laceration of the cervix, prolapsus of the uterus and cystic ovaries. Chloroformed March 12, 1894, at which time was performed a double trachelorrhaphy, a perineorrhaphy, also one ovary was removed, the other treated by snipping off a portion of the cyst walls, and the uterus approximated to the abdominal wall in the usual manner. Length of time under the anesthetic less than one hour. Her recovery has been uninterrupted. The uterus at the present writing remains as adjusted.

Case 4.—Mrs. W., aged 38, mother of four children; fleshy; complains of constant pain in the region of the sacrum; very nervous and frequently melancholic. Diagnosis: Retroflexed and adherent uterus, ovaries prolapsed and adherent in the cul-de-sac under the uterus. Operation Feb. 23, 1894. Adhesions broken up, structures removed and uterus approximated as in other cases. Result, recovery. A recent examination of the patient reveals the parts in good condition and mobility measurably restored. The ovaries did not prolapse after the uterus was brought to the front.

Case 5.—Mrs. R., aged 39, mother of three children, consulted me in January, 1893; general health completely wrecked. Her features and expression were those of an old woman, shriveled by age; mental faculties so disturbed as to make her almost irresponsible most of the time; decidedly melancholic. Diagnosis: Retroflexed and adherent uterus, prolapsed and suppurating ovaries, also adherent; pachy-salpingitis. Operation Feb. 12, 1893. Adhesions broken up, diseased structures removed, and uterus fastened to the abdominal wall after the manner practiced by me. Result, complete recovery; general health, mentally and bodily, thoroughly restored. One who had seen the patient just prior to the operation would scarcely recognize her to-day as being the same person, for she is now the picture of health, having gained fully forty pounds of flesh. The uterus still remains in proper position.

It is my custom to curette the uterus almost invariably before performing hysteropexy for the reason that endometritis is generally an accompaniment of chronic displacement.

NICKEL STEEL FOR SURGICAL INSTRUMENTS.

BY EDMUND ANDREWS, M.D.

SENIOR SURGEON OF MERCY HOSPITAL, CHICAGO.

Nickel steel has become famous the world over for its capacity to form an impenetrable ship armor.

It is an alloy of steel with about 3.2 per cent. of

nickel. Its color and appearance are those of ordinary steel, but its qualities are remarkable. Its tensile strength is raised by the addition of the nickel to about 200,000 pounds per square inch, which is nearly as great as that of the best hardened steel, without any of its brittleness. On the contrary, it has extraordinary toughness, and resists cannon shot to a degree far beyond any armor plating before known.

The commander of the United States Arsenal in Springfield, Mass., informs me that he has tried to make rifle barrels of it, but he finds it almost impossible to turn it or bore it.

It seemed likely that qualities like this might be of use in certain surgical instruments. Having with much difficulty secured a piece of this steel, trimmed from the edge of an armor plate, I had it submitted to chemical and practical tests. The specimen had the following composition, in 1,000 parts: Steel, 996.747; nickel, 3.200. The carbon in the steel amounts to 0.031; phosphorus, 0.022.

To test its capacity to resist rust, I boiled a polished piece of it for twenty minutes in a sterilizer filled with hydrant water, along with instruments of ordinary steel. It resisted oxidation better than ordinary instruments, but there was not a complete exemption from that evil.

Mr. Degenhardt, a thoroughly experienced cutler and instrument maker, then took the metal in hand. He found it to possess immense tensile strength and stiffness, combined with remarkable toughness. A small cold bar could be bent short over upon itself without cracking. Drawn into fine wire, these qualities enabled him to make filiform bougies whose tips could be bent, without any danger of breaking, into any shape necessary to pass through a stricture. Excellent fine probes were made of the wire, which, though stiffer than silver probes of the same size, could be bent to any extent without breaking. I infer that the staff of Maisonneuve's stricture cutter could be made of it, with the advantage of having it decidedly more slender than the ordinary one, and therefore able to penetrate a smaller stricture, with a total exemption from any liability to break in using.

In a similar manner, stricture divulsors could be made of very small size.

It was my intention to have some very slender scissors, bistouries and tenotomes made for fine surgical work, but the instrument maker found that while the blades would not break, the edges turned, and could not be made to hold their cutting form by any mode of tempering known to cutlers. The same quality renders it unfit for saws, but its immense tensile strength would be very valuable in chain and wire écraseurs.

Lithotrites could be made of it, which would never snap off on a hard calculus and, owing to its great strength, slender instruments could be made of it for crushing calculi in children.

Steel can be alloyed with several metals, producing compounds with varied qualities, some of which would be of use in surgery. Tungsten steel is an exceedingly hard alloy. In the great rail and bar mills, where thousands of holes have to be bored through steel bars every day, the drills are all pointed with tungsten steel, in order to avoid the necessity of constant sharpening. It would be well could we have our bone drills made in the same way, as well as the locks of our hemostatic forceps, which now

wear out so quickly. Manganese, titanium, copper, and numerous other metals form alloys with steel, but the qualities of the compounds for surgical use do not seem to be well known. It is desirable that some metallurgist should take up this investigation and give us the results of his study.

65 Randolph Street, Chicago.

SOCIETY PROCEEDINGS.

College of Physicians and Surgeons of Philadelphia.

ORTHOPEDIC SECTION.

Meeting of April 20, 1894.

Dr. T. G. Morton presented, through Dr. Woodbridge, several cases of double equino-varus with removal of astragali:

Case 1.—Mary J. McK., one year, ten months old; living at Bryn Mawr, Pa. Congenital, uncomplicated talipes equino-varus. Operation of division of tendo Achillis performed Feb. 21, 1894. Posterior right angled tin splint for a week, followed by ordinary brace, side steel support. April 20, apparatus discarded every other day and plain shoe allowed. Foot in good position. Result perfect.
