ON EARLY AND LATE REMOVAL OF ABDOMINAL TUMOURS.

By Sir SPENCER WELLS, Bart.

Late President of the Royal College of Surgeons of England.

Twenty or twenty-five years ago, when the removal of any abdominal tumour was very seldom attempted—when ovariotomy was on its trial—when uterine tumours were generally considered as beyond the art of the surgeon—early operation was the rare exception to the general rule only to act when the necessity for attempting to save life from great or immediate danger was so evident that failure could lead neither to surprise nor blame. The operation might not succeed in saving life; but it scarcely shortened it, and the patient only lost a few days or weeks of a suffering life. Then as ovariotomy rose to the position of lithotomy among surgical operations—when it became known that from a mortality of 70 or 80 per cent. the recoveries soon equalled the deaths, and then advanced rapidly with increasing knowledge year after year, until almost all the favourable cases recovered, and almost every death was in a case recognised, before operation, as more than doubtful, it became needful to utter a word of warning against indiscriminate or thoughtless proceedings. Afterwards, when the strictest hygienic precautions were supplemented by antiseptics, and improvements in operative detail were generally adopted, success became so great that ovariotomy not only took its stand as by very far the most successful of any capital operation in surgery, but the risk attending it in a favourable case could truly be calculated as little, if at all, greater than that necessarily attending any case of natural childbirth; and, as a necessary consequence, early operations could be advised with less hesitation.

Then, as ovariotomy led to the removal of uterine tumours, and the terms hysterotomy, hysterectomy, myomotomy, and fibro-myomotomy crept into surgical literature, much the same change in professional opinion and practice has been going on. At first, it was only after an error in diagnosis, not discovered until the operation had been begun or completed, that a large solid uterine tumour was removed. Knowledge so acquired, and success thus occasionally obtained, led to more accurate diagnosis, and more frequent operations; and, just as in ovariotomy, to improvements in all the details of practice, and to a rate of mortality which has diminished rapidly, success having been attained under such unfavourable conditions as a few years ago would have justified any surgeon in refusing to comply with the earnest prayer for relief from an almost dying woman.

Again it became needful to sound a note of warning, and to suggest that the analogy between ovariotomy and hysterectomy must not be carried too far—that in many respects the two operations, especially as to the

time when they should be performed, stand upon very different ground. A considerable proportion of ovarian tumours, sufficiently large to cause suffering or some inconvenience to a patient, or to lead her to seek for medical advice, sooner or later absolutely demand operative treatment. An equally large proportion of uterine tumours do not require any treatment, cause very little suffering or inconvenience, and disappear partially or entirely not very long after the cessation of menstruation. It is only in exceptional cases that hæmorrhage, or unusual effects of pressure from tumours of moderate size, or excessive growth of the tumour, lead to a consultation as to the removal of a uterine tumour. In cases of ovarian tumour, removal is the rule of treatment. With uterine tumours it is the exception, not so rare as it used to be, but still the exception ; and in cases where excessive periodical loss of blood is the reason for operation, the alternative proposal has to be taken into account of removing both ovaries and cutting off the supply of blood instead of removing the uterine tumour. No such alternative proceeding can be considered in a question of ovariotomy ; unless drainage in cases where it is impossible to completely remove an ovarian cyst can be considered as analogous.

Many writers on this question of early or late operation seem to be remarkably forgetful of the fact that the surgeon cannot do exactly as he pleases with his patients. In many cases where he would have liked to operate early, he does not see the case until the tumour is very large and the patient in extreme suffering. In others his advice must be modified by the circumstances of the patient. She may be a poor woman who must earn her living, or a rich one who can obtain every appliance that can afford relief ; and although many patients are ready to act as they are advised and willingly submit to what is thought to be best in their own case, many others cannot or will not shake off their hopes and fears, their affections or their interests, and the surgeon, while giving information or advice, must leave the decision to the patient or her relatives. There are patients upon whom it is quite right to operate much earlier than the necessity of the case demands. A marriage has been arranged and cannot be indefinitely postponed ; or a married woman wishes to accompany her husband to India, Australia, or elsewhere, or to join him there, and as an invalid can do neither ; or a sensitive girl is distressed by remarks on her appearance. On the other hand, there are patients who determine, in spite of urgent advice, to defer operation as long as possible. A widow whose children are entirely dependent upon her annuity—a wife devoted to the care of a sick husband or child, must think of others more than of herself, and every surgeon of much experience has met with both classes of cases. He is not playing with chess-men. He is dealing with intelligent human beings, who are influenced by their emotions and passions, and are very seldom free agents ; and he can do little more than say what, to the best of his knowledge and belief, will be the probable course and duration of a tumour if left alone, what is the amount of risk probably attendant upon its removal, and what security can be reasonably offered that recovery from the operation means a complete cure—in other words, that there will be no return of the disease.

Here again the contrast between uterine and ovarian tumours is remarkable. A woman who recovers, in any form of non-malignant disease, after ovariotomy is restored to complete health. If one ovary only is removed she may bear children of both sexes. The probability of disease occurring on the other side is not more than 1 in 100. If both ovaries are removed, this small drawback is removed ; but young women become sterile.

All this has been completely established, but we are still imperfectly supplied with facts as to the subsequent conditions of women after removal of large portions of the uterus, with or without removal at the same time of one or both ovaries. I know of several when after some years the health has remained surprisingly good. The details of such cases may be found in my last work on ovarian and uterine tumours. I have seen other cases where it has been impossible to remove the whole disease. Subserous myomata have been removed, while mural growths have been left, and the patient may have been relieved, but not cured. In the present day such a case would probably be subjected to removal of both ovaries as well as to myomotomy. But before any general rule of practice can be laid down, or any really accurate information or trustworthy advice can be given to a patient who has a uterine tumour, we must have as full and as precise histories of long series of cases as we have obtained with regard to ovarian tumours and ovariotomy. We shall probably have, at the Copenhagen Congress, from Professor Olshausen, of Halle, very important additions to our knowledge in this direction, and we have still to learn much as to the effect upon uterine growths and out-growths of the removal of the ovaries. Vague unsupported assertions have little influence upon the opinion of a thoughtful or sceptical profession. And just now something more than a word of caution against rash, dangerous, unnecessary operations is called for. We are startled by reports of the removal of the normal ovaries of young women suffering from nervous disorders which may be exaggerated or imaginary ; and it is to be feared that our professional honour is at stake ; that statements are publicly made which, when challenged, cannot be substantiated ; and that abdominal surgery in its latest developments is open to the denunciation hurled against the earlier ovariotomists ; and that, with more reason than in 1850, Lawrence's question must be repeated, whether such operations "can be encouraged and continued without danger to the character of the profession," and West's assertion that "a fundamental principle of medical morality is outraged," cannot now be satisfactorily refuted.

CLINICAL REMARKS ON PERITONITIS.[1]

I.—PERITONITIS OF PELVIC ORIGIN.

By W. T. GAIRDNER, M.D., LL.D.,
Professor of Medicine in the University of Glasgow.

We have recently had under observation several cases which I have been obliged to designate as "peritonitis," and I wish to make some remarks on the various forms of disease indicated under that rather comprehensive nosological expression. Two of these cases were, in fact, quite acute, characterised by much pain and general distress, and even by danger, on admission ; another, and perhaps yet another, were by no means acute, but had possibly or probably been attended by acute symptoms some time before. Cases of this kind, although not among the most common of the incidents in our ward-experience, still occur so frequently that in the ten years this hospital has been open we have quite a large group of them ; and it is worth while to make to-day some general remarks bearing on these cases, and on the whole subject.

Now, the first principle I have striven to impress

[1] Summer Clinical Course in the Western Infirmary, Glasgow, May and June, 1884.

upon you in the diagnosis of these cases, is that in dealing with any disease that has a name, and especially a name ending in "*itis*," you must beware of the too easy fallacy that because the disease under observation corresponds roughly, or even in detail, with a general description in a book, or in medical tradition, its diagnosis, pathology, treatment are thereby to be settled forthwith. This principle, as one applying to medical diagnosis in general, may be said to be true of all diseases; it is especially true of peritonitis. You have not made a *diagnosis* by calling it peritonitis, nor yet by adding that it is acute, sub-acute, or chronic. You may be right so far, but it is not more than the first beginnings of a true diagnosis. On the other hand you may be wrong; it may be only nerve-pain, or hysteria, or pain due to some organic disease more deeply seated than you were counting upon, and attended by acute and even inflammatory symptoms. Generally speaking the symptoms will not lead you astray, if you take care to follow them up by investigations into the state of all the organs or functions that can probably be implicated, but if you stop short of this, you will assuredly fall into error, sometimes into gross error, in regard to what is most essential—*the management of your individual case.* In one of these cases now under treatment, we did for a time fall into such error, though perhaps under the circumstances excusably; and it was owing to the omission of just one of the investigations that I am now insisting upon, with a view to your education and improvement.

The first step towards a diagnosis in a case having the conventional symptoms of peritonitis, is to keep it steadily in view that true peritonitis, and especially acute peritonitis, is rarely, if ever, "idiopathic" as it is called; that is to say, it is not a disease standing by itself, implicating only the peritonæum, and without relation to any other organic disease as its cause; but rather one which derives almost all its clinical significance from the inquiry into its cause; one which is to be treated and managed, as well as judged of with respect to its prognosis, according to its cause in most instances, if only you can succeed in making out the true sequence of events. This was most strikingly illustrated by a case which occurred to us nearly eight years ago, when Dr. Frank Shearer, now of Paisley, was my resident assistant, and preserved a careful and detailed note of the facts. The symptoms were of the most acute and deadly kind of peritonitis, as described in the text-books; there was hardly a doubt, from the first, that the poor young girl was dying, and she died in fact in less than twenty hours after her admission, the temperature rising steadily till it was nearly 105° F. in the axilla, and 106° in the rectum at the time of her death; and with this peculiarity (which you will find very characteristic of such cases) that while the thermometric notes showed this steady rise, "the face was covered with a livid flush, and her hands became gradually colder and her nails more livid, till at the time when the thermometer in the axilla registered 104·7°, her hands were of an icy coldness." These facts will probably recur to you, if you take note of them now, when you meet with another case like that of M. T.; but that may very well not be soon, for such extreme cases are rather rare. My object, however, in referring to this case, is not to comment in detail upon the symptoms, but to tell you about the *post-mortem* examination. I was entirely "at sea" as to the cause of the peritonitis in this case; for the opportunity of observing it in detail was wanting; the girl was dying, and all we could do in the way of treatment was to relieve her agony a little by fomentations of the abdomen, and by opium. But we had ascertained that she had not the history of a perforated bowel or stomach, not of typhoid fever for instance, nor of a long-standing dyspepsia, nor of chronic disease of the intestines; only of an illness reported somewhat similar to the one for which she was admitted, but much milder, about a year previously, which, it was said, had only lasted for a week. The typical symptoms and physical signs of peritonitis were all present, but there was nothing to reveal its source unless we had made a pelvic examination, and this I can hardly take blame to myself for not doing in this obviously dying girl. But in making the *post-mortem* examination, I said by anticipation, that going merely on the known fact that acute, and especially fatal, peritonitis is so rarely *idiopathic*, we might expect to find a cause, and might possibly find it in the pelvis; and in the pelvis accordingly it was discovered; the left ovary being the seat of an abscess, which had enlarged it to the size of a hen's egg; this abscess, communicating by three perforations, completely covered up by adhesions, with Douglas's space. Strange to say, although the peritonitis was quite diffuse and general, causing recent matting together of the intestines all over the abdomen, there was no direct communication to be discovered between the ovarian abscess and the general cavity. The ovarian disease had been in the first instance completely enclosed by local adhesions, some of them perhaps corresponding with the attack a year before death; and at a much later period some change, not more distinctly definable, had converted the local into a general and diffuse peritonitis.

Now this case, I think, contains a great lesson for all of us. For although we could do almost nothing for this girl, seeing her as we did *in extremis*, and within twenty hours of her death, it is abundantly plain that at an earlier period something might have been done, by vaginal incision and drainage, to deal with the local abscess, and avert the fatal and diffuse form of peritonitis. But had the case been less desperate when admitted, it is equally plain that the one chance of treating it properly would have been missed had the diagnosis been allowed to rest at the point of declaring it to be simply an acute peritonitis, and omitting a vaginal examination.

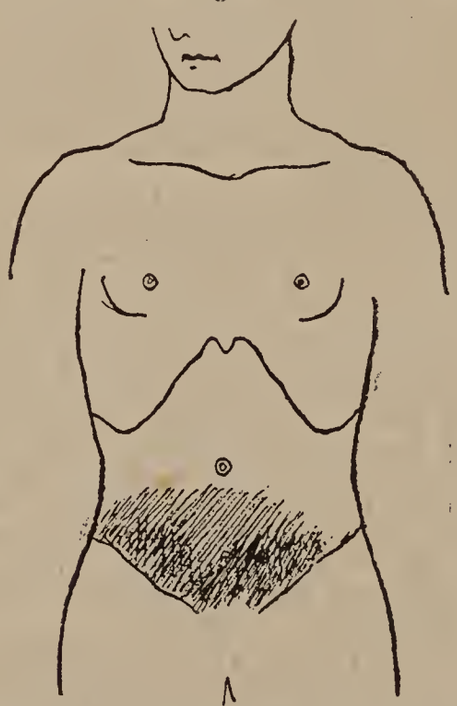
The moral, from the practical and clinical point of view, that I wish you to draw from this case, although you did not see it for yourselves, is—never be satisfied, in any case, with a diagnosis of peritonitis *only*, whether acute or chronic. Seek always, and everywhere, for a local cause in some organs or system of organs; and seek with persistence and thoroughness by examining the history, the symptoms, the physical diagnosis in its largest and most comprehensive sense. You may possibly fail, not because there is no local cause, but in some instances, at least, because you have not been able to discover one. But if you fail, when all is done, you will have done your best; and if you succeed, you will have got the key to your case, and with it, perhaps, a most important and necessary guide to the prognosis and the treatment.

Among our cases now in the ward, there was one, at least, in which the local cause was self-evident; and in this case, Lizzie McN., æt. 20, the local cause was pelvic (though quite different from the former case, and far more obvious); so obvious, in fact, was the cause, as not to be a trial of diagnostic skill at all. This was an average, though a rather severe, case of a very common affection among puerperal women, especially in such as are neglected in the after treatment. In its milder and more localized forms this disease used, in my day, to be called *pelvic cellulitis*, and was supposed to be an inflammation of the broad ligament; it is now, ever since the exhaustive researches of Bernutz, considered as involving almost always more or less of peritonæal inflammation, and, therefore, is called *pelvic peritonitis;* or, by those who, like Dr. Matthews Duncan, prefer a name founded on its origin and seat, *peri-metritis*, *i.e.*, an inflammation both of the womb

itself and of all the parts surrounding it, *including* the peritonæal investment. I do not stop now to give you a general history of this disease, referring you with all confidence to Dr. Duncan's recently published clinical lectures,[2] or to his special work on the subject, published in 1868, for fuller information on all the points which you do not find in your ordinary text-books. In the case before us the history and the symptoms were equally clear and unmistakable. The girl is a *primipara*, and was delivered exactly a month before her admission to the Western Infirmary. Two days after delivery she took "a weed," *i.e.*, a severe rigor with pain in the lower part of the abdomen, and cessation of the lochia. On the tenth day after delivery she had partially recovered, but was only able to be out of bed for a few hours; and at this date, very wrongly in my opinion, she was dismissed from the place where she was to have been treated during her confinement, and was sent home. You know what even married women will do under these circumstances to keep up appearances; and this poor girl seems to have found no way out of the difficulty, but to hang about on her feet when she was quite unable to work, and ought to have been lying flat on her back in a state of absolute repose. She became, as might have been expected, worse and worse, and a week before her admission to our wards was obliged to take to bed again, utterly prostrated by abdominal pain, no doubt with fever and also with sickness, vomiting, and diarrhœa, all of which persisted in a high degree at the time of her admission.

The state of this woman's abdomen to physical diagnosis on admission was remarkably characteristic of a *severe* case of pelvic peritonitis, extending secondarily beyond the limits of the pelvis. This rough diagram

Fig. 1.



shows what is written in greater detail in the report, according to Dr. Gemmell, who had charge of the wards for me during the last seven days of April, and before I had seen the patient myself; when, however, I found the essential facts but little different. What existed in the pelvis at this time, and for weeks afterwards, cannot be so easily shown, but it is easily to be described as the usual state of the parts in these cases—absolute fixity of the womb, as if it were wedged in a mould of plaster of Paris; dense induration of all the parts around, especially towards the right side; fulness towards the vagina in this situation, and exquisite tenderness on very moderate pressure with the finger. Evidently there was a risk here of abscess forming towards the vagina, and also no inconsiderable risk of the peritonitis (as in the case mentioned before) becoming general, and still more acute, and, therefore, deadly; but experience also tells us that many of these cases, even when as bad as this one, or worse, may undergo perfectly favourable resolution spontaneously; and the opinion of the best authorities is, I think, unfavourable to a premature interference with the knife.[3] We had, therefore, no hesitation in leaving her to the operation of internal remedies, aided by (what she should have had from the first, and what would have saved her, in all probability, from most of these complications) the most absolute rest possible in the recumbent posture. The only internal remedy of great importance used was opium, gr j. every four or six hours, on admission, and for more than a fortnight afterwards, and then every eight hours till she required it no longer; and along with this fomentations to the parts affected. I show you here a chart of the temperatures taken (as we always take them in acute cases) many times in the twenty-four hours, so as to be sure that we have really the maxima and minima. You will observe that they present oscillations extending often to three or four degrees Fahr., several times to five, once to nearly six degrees; but in this instance the quite sudden fall between night and morning from 102·8° to 97·2° was an exceptional fact, and probably portended some risk of collapse from diarrhœa or otherwise. As a rule the temperatnres seldom came within normal range except for a very few hours, and the maxima were 104°, 103°, 102°, during the first fortnight of our treatment. Then came a period of minor oscillations; 1° to 2° at most, but still abnormally high temperatures, extending over three or four days, and then greater oscillations again, but rather less than at first, extending well into the fourth week from admission, which corresponds with the eighth week, counting from her delivery; and then, at last, what may be well termed a crisis, or complete defervescence, for in two days we have a subsidence of temperature from 103° to 97°, and ever thereafter steadily normal temperatures, with all the circumstances of a complete and satisfactory convalescence.

I have no hesitation in saying to you that this case, and those of a like kind in respect of their cause, though now for years carefully studied and well understood clinically, are to me always fraught with a new sense of surprise, in respect of the remarkable evidence they afford of the restorative powers inherent in a sound constitution, under circumstances which, pathologically speaking, we should call very unpromising. And these cases are accordingly very important to be deliberately considered in reference to the general subject of peritonitis, as well as from their great interest in connection with the puerperal process. What they show is, that peritonitis, even of great extent and of a very acute character, is by no means always the extremely deadly disease it has sometimes been represented as being; and that its hopelessness in certain cases depends more on its cause than on the mere fact of the peritonæum being inflamed. In this instance we had, beyond all doubt, not only grave inflammation within and beyond the pelvis, but what Dr. Duncan calls "adhesive perimetritis," forming an indurated and resistent mass of intestines and other structures well up to the umbilicus. Yet the resolution has been apparently complete and progressive. The disease has dissolved away, as Dr. Duncan elsewhere expresses it, "like snow off the streets." What the precise *pathological* expression to be applied to the resolution in such a case as this, or what results it leaves behind, I have never been able exactly to ascertain; but as a clinical fact

[2] "Clinical Lectures on the Diseases of Women." 2nd Edition, 1883.

[3] See on this point particularly pp. 210 and 233, of Dr. Duncans Clinical Lectures above mentioned.

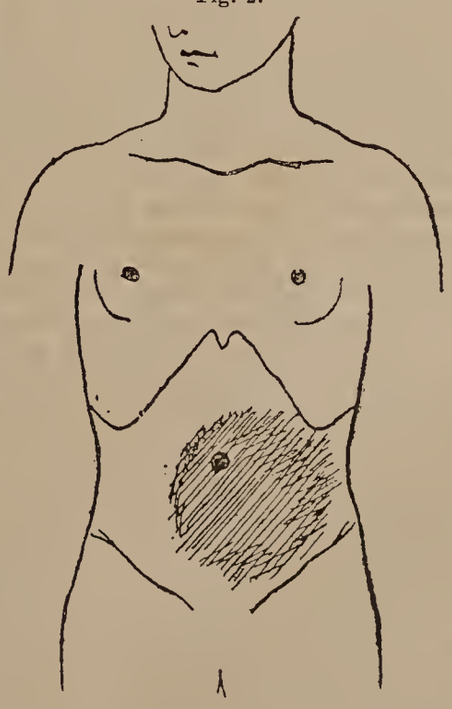
there is no doubt of the completeness of the cure in many instances, and I hope and believe it will be so in the case of Lizzie McN. I am even justified in affirming (because I know the fact) that women in whom equally grave and serious disturbance of parts has taken place once, may be capable of bearing children afterwards ; a fact difficult to explain from the point of view of the ovarian physiology and pathology, but a fact, none the less.

My personal experience of these cases is nothing like so large, of course, as that of a professed gynæcologist like Dr. Duncan, or even of many general practitioners, but still I have seen a good many of them, when, as often happens, they drift into our hospital wards, as well as in general consultation practice. One of the latter is strongly impressed upon my mind from its being that of the wife of an old friend, and a physician of much experience, as well as from its having been considered by Dr. Duncan sufficiently rare to demand very special notice, at p. 219 of the work already referred to. You may take the following brief narrative as the general physician's statement, his being the gynæcologist's ; they are not in any respect inconsistent, or essentially different. The case was brought under my notice first by correspondence, as the lady in question lived a long way from Glasgow. What was told me was, that after a delivery with some unusual incidents (which you will gather best from Dr. Duncan's narrative), the period had long been overpassed during which local inflammations are most apt to occur, and still there was fever, oscillations of temperature extending over several degrees, and keeping everybody anxious, although there was no great local suffering. Was it tuberculosis, acute or sub-acute ? The temperatures, I must confess, looked rather like this, indeed were almost exactly of the kind noticed in such cases ; but on the other hand, there were to be reckoned the eminently good antecedents of a woman who had borne nine children without accident or injury to her health, a good family history, and the entire absence, so far as her husband could discover, of local signs of tubercle. Her symptoms, in fact, were very similar to those of our patient last-mentioned, except that (if I remember aright) the local pain, indeed the pain altogether, and the pelvic symptoms in the early stage, had not been such as to attract nearly so much attention. I was not at all satisfied in my own mind, and proposed, after some interchange of letters, to go over and see her personally. This was, I suppose, at a date after the confinement later than the extreme date of the fever chart I showed you in Lizzie McN.'s. case, certainly not earlier than the tenth week. There was so little pain in the abdomen that it could all be handled, and even compressed without any complaint whatever ; but the state of the parts, from umbilicus to hypogastrium and flanks, assured me at once that changes had taken place there quite adequate to account for all the fever. As Dr. Duncan was interested in this case, like myself, both through personal friendship and professional connections, I was very glad to feel that in declaring this opinion, and also the complete immunity, so far as could be discovered, of this lady from tubercle, I was at liberty to cast off all further responsibility, with the knowledge that he was to be sent for next day. You will observe that he calls it a case of "remote" perimetritis, meaning thereby that the inflammatory changes were (as in the first very acute and fatal case I mentioned to you) far outside the pelvis, and not quite *demonstrably* in connection with the uterus ; and it was also, perhaps, remote in another sense, viz. : that the most serious and dangerous local changes occurred "long after the liability to perimetric attacks following delivery had ceased to be dreaded." In this respect, no doubt, the case tended to ambiguity of diagnosis. Nevertheless, the diagnosis, when once made, was perfectly clear, and the favourable issue in all respects has abundantly justified it. I may add that it is the case of this lady which was *first* in my mind when I affirmed a moment ago that after such accidents it is still possible for the pelvic organs to perform all their normal functions. How this should be so at all, under the circumstances, is to me still mysterious enough. When we consider the extremely delicate adjustment of the fimbriated extremity of the Fallopian tubes to the ovary, and the frequency with which this physiological arrangement becomes, in fact, impossible through adhesions, it is not less than marvellous that the power to conceive and bear children should ever be maintained after an attack of this kind. It is good to know that it is so, even if we remain puzzled as to the *how*.

It is stated in Dr. Duncan's report that this lady suckled her child till near the end of the second month. That was, perhaps, remarkable, but not quite so remarkable as another case I had, where a woman suffered an attack of extremely acute, and obviously septic fever, ending in a horribly stinking abscess, which discharged in the right groin for a considerable time, and owing to which she may be said to have swum for her life. But notwithstanding every persuasion on her own account and her infant's, this woman would not give up her child to a nurse. She suckled it throughout, and had plenty of milk ; and, though she was wasted to a shadow, the child throve apace, and was as fine an infant as ever I saw. The mother also recovered in time, became pregnant again at the end of two years, and came under my care a second time far on in the after-treatment, for symptoms similar in kind, but much milder, from which she once more recovered. But I am not sure, in this case, that there was any, or if any, much peritonitis ; there was an abscess around the womb, and its connections were towards the groin, and up in the direction of the sheath of the psoas and iliacus muscles.

The other case which I have mentioned to you in this connection as being at first one of ambiguous diagnosis, is that of Mrs. McN., æt 34, now in the ward, though apparently quite convalescent. This woman was admitted just before I returned to take charge in the very end of April, and her case was regarded and treated, with ample reason for the diagnosis so far, as one of rather acute peritonitis. She had sickness and

Fig. 2.



vomiting even five weeks before admission, but of the history and progress of the case up to that time we have no accurate information, only we know positively

that, when admitted, she had the symptoms and physical signs of a diffuse, almost general, peritonitis, which would have been exceedingly alarming, and of the gravest prognosis, had it not been that the temperatures were comparatively little disturbed. Although the abdominal tenderness and pain were extreme, and the percussion-dulness widely diffused (as indicated in the annexed diagram), there being also very marked semi-solid resistance, extending even above the umbilicus into the left hypochondrium, and, in fact, more or less present throughout the abdomen, we did not recognise fluid as being present, according to the physical tests. It was a case, therefore, of *adhesive* peritonitis; and the fever, if ever high, had ceased to be so almost about the period of her admission; since the temperature after admission never exceeded 100·4° in the axilla. I was not very anxious about the immediate prognosis on this account, even although not satisfied as to the cause. Opium in the usual doses, and fomentations, had already pretty effectually dealt with the worst-looking symptoms before I saw her; and I did not care to disturb her unnecessarily, as I thought. But in lecturing to you a few days afterwards upon the case, I was obliged to put, as it were, five questions, and to answer them each in a negative sense. These five questions are as important for your instruction now as they were then, and you will find them in your note-books, with my commentary. They were as follows:—(1) Typhoid fever, with incipient perforation? Suggested on her admission to Dr. Gemmell as at least a possible cause, so far supported by the pain, distension, vomiting, &c., but negatived by the temperatures and the absence of spots. (2) Obstruction of the bowels? Constipation had been extreme, but after the free use of enemata we were able to infer that there was neither mechanical obstruction nor fæcal accumulation in the descending colon. (3) Perityphlitis? (Dismissed after careful consideration of the details of the physical diagnosis). (4) Pelvic cause? (Dismissed, as will presently appear, on unsatisfactory and insufficient grounds). (5) Tubercular peritonitis? (A view fairly to be entertained in all such cases when other causes are excluded; but, so far as actual evidence could be obtained, not borne out by the previous history, or the state of any organ after careful examination).

I had hardly completed this necessary review of the facts and probable causes in your presence, before I began to entertain a misgiving about No. 4; the presumed absence of a pelvic cause. The patient was a widow, her husband dead for four years, her last child born eight years ago; and her recovery from this confinement, at the time and since, apparently perfect. With all the experience of maternity arising from three pregnancies with normal confinements, she had at no time expressed any suspicion as to the state of her uterine organs, and her menstruation had continued regular up to about three weeks before the first symptoms; which, therefore, may very probably have coincided, more or less closely, with a menstrual period; but even when the question was directly put to her she appeared to entertain no misgivings on this point. Although extremely constipated, she had had no pain in defecation, and the only urinary symptom she could be brought to admit, even by a direct question, was some uneasiness, not during, but after, micturition. The urine was normal. Still I had misgivings, and accordingly the hospital report bears that on the 15th of May, I was "led to review the evidence on which it was concluded, perhaps too hastily, that the disease had not a pelvic origin." At this time, it was stated, "while the acute symptoms have altogether subsided, and clear percussion is coming back in all the regions above the umbilicus, the lower part of the abdomen still gives very unsatisfactory percussion. On examining *per vaginam*, the uterus is found impacted to a considerable extent, and the os and cervix displaced high behind the pubic bone, while a very considerable hardness, perfectly devoid of any feeling of fluctuation, or of much tenderness on palpation, is felt to be interposed between uterus and rectum." These facts were corroborated by my colleague, Professor Leishman, who in addition was able to ascertain that "the uterine sound passes three and three-quarter inches in the normal axis. Dr. L. considers it to be an elastic and doubtfully fluctuant tumour, occupying the pouch of Douglas; and that it may be either a blood tumour, or ovarian in origin. This, however, can only be determined by watching the progress of events."

The *dénoûement* of this interesting, and probably rather rare, case is still in suspense, but up to the present date everything has gone on perfectly well. The lesson it affords to you, and to all of us, apart from the ultimate issue, has been already sufficiently insisted on in these remarks.

[An examination *per vaginam* at the date of returning the proof of this lecture (July 2nd) shews that even now the uterus is still impacted in the pelvis, though without the slightest tenderness on palpation or suffering of any kind; and, what is very remarkable, the position of displacement high in the pelvis, adverted to above, has been exchanged for one more than usually within easy reach of the forefinger, so that without entering the vagina much beyond the proximal joint, it is able to be inserted into the os uteri.]

(*To be continued.*)

CLINICAL LECTURE

ON PERFORATING ULCERS OF THE SEPTUM NASI.

By JONATHAN HUTCHINSON, F.R.S.,
Emeritus Professor of Surgery in the London Hospital College.

Gentlemen,—I believe there is a very general belief that perforating ulcers of the septum of the nose imply syphilis. I feel sure that this inference is often incorrect, and think that I shall be able to convince you that there is a form of chronic ulceration which often results in perforation of the cartilaginous part of the septum, the causes of which are very obscure When it occurs in young persons, there sometimes appears reason for associating it with that state of health which produces common lupus, but when it happens to those of middle age or more advanced life, it is not usually attended by any conditions of ill-health or concomitant phenomena which justify us in associating it with any special diathesis.

I am speaking now more particularly of a very slowly progressive ulcer, which is usually located just within the nostril, or about half an inch from the edge of the columna. It always begins first on one side, and does not affect the other until a considerable interval has passed, and there is usually a period of several months, or perhaps years, of superficial opposite ulcers before the final perforation takes place. During this stage the patient probably pays but little attention to the ailment, or simply acquires the habit of picking the sores. Alarm is taken when there is a hole, though not by any means always then. I have found these holes in several persons who made no complaint of them, and came under care for other maladies. Destruction of the septum is of course common enough in syphilis. It is the fact of its frequency which has led to the widespread belief that all perforations are syphilitic, and which renders it neces-

sary for me now to try to prove that some are not. In a general way the ulcers which are syphilitic, that is, in an active sense, are, I think, pretty easily distinguished. They progress more rapidly than those which I have now to describe, and they usually begin further back, and involve the vomer itself. Respecting the precise relations of some of those with which I am now dealing with syphilis, I must, however, speak with caution. Although not in any active sense syphilitic, that is, not to be cured by the internal use of specifics, there are in not a few cases facts which make it not improbable that they may have a remote connection with a taint. Just in the same way there are some forms of chronic skin disease of a lupoid type, which appear to have a remote connection with syphilis, but which are cured best by local treatment. Whilst thus, however, admitting that some of my cases may possibly have been remotely due to syphilis, I unhesitatingly assert that several others, exactly like them in all their features, were certainly not so. Of this negative fact the evidence is, I think, conclusive.

The first case which I recollect to have attracted my attention to this subject was that of a gentleman named C., who was sent to me by the late Dr. Arthur, of Commercial Road, many years ago. He had a very large perforation of the septum, but without deformity. I always thought it syphilitic, but he always protested that he had never had any form of venereal disease. He had no other indications of disease, and as his ulcer did not heal under specific treatment, but slowly progressed during many years, I was obliged to give up the suspicion. This patient has now been dead several years, and I believe that his ulcer at the time of his death was still not quite healed. He was about 45 years of age, and seemingly in good health.

The next case which I shall cite is one of the last that I have seen, and a very typical example of the affection.

Case II.—The case of Mrs. S. had caused very considerable anxiety both to the patient and her medical advisers before I saw her. She was a lady about 44 years of age, apparently in excellent health, and not the subject of any special diathesis. She had a hole through the septum which would have admitted the tip of the little finger. It was in the usual place, that is, just within the nostril, and every part of it was easily in view. The posterior and lower part of its edge presented an ulcerated surface, and some small granulations. All the rest of the edge of the hole was quite soundly healed, but there was not much swelling about it. She was sent to me by Mr. E. R. Butler, of Cromwell Road, and had previously been seen by my friend, Mr. Bellamy. Iodide of potassium had been given, and nitric acid had been carefully applied. The question of most importance was whether the disease was malignant, and on the other hand, whether it was of a specific nature. It had certainly progressed rather rapidly, for Mrs. S. assured me that the perforation had only been complete for about six weeks, and progressed in spite of treatment.

I was told, however, that it had been threatening for upwards of two years, and that it had been preceded by the usual stages of an adherent scab, without pain or irritation. This scab had appeared first on one side, and subsequently on the other also. As soon as perforation occurred, the ulcer had spread rather rapidly. Part of the ulcerated edge had been cut away for microscopic examination, but nothing definite had been revealed.

In this instance I had no hesitation in putting aside the suggestion of specific disease, for there was not a tittle of evidence to support it. Nor, I must admit, was there any more in favour of the diagnosis of struma or lupus. Neither the patient nor any of her relatives, as far as she knew, had suffered from chronic skin diseases. It was difficult to avoid a fear that it might be allied to the rodent ulcer. I do not, however, think that it is.

Let me relate to you next a case which is a very close parallel to it, and of which the cure proved that it was not malignant.

Case III.—Miss T., a lady of 44, stout, florid and apparently in good health, was sent me by Dr. Hughlings Jackson on account of acne rosacea of the face.

She was the sister of a well-known medical man, and there was no reason to suspect either specific disease or scrofula. She had suffered much from headache, cold extremities, and general nervousness, and had extreme vesical irritability, so much so that at one time I suspected the existence of stone. Amongst other things she complained of a little soreness of her nose. I examined it and found an opening through the cartilaginous septum about big enough to receive a cedar pencil, but not quite round. It had clean red edges, with some superficial ulceration around their margin.

On questioning Miss T. as to her symptoms, she said that she had been aware of some little obstruction in the nose about a month. It had bled a little occasionally, and she had noticed some whistling in drawing her breath which had annoyed her. Beyond these she had had no symptoms whatever, and had no suspicion that any ulceration existed. I cauterised the edges of the ulcer with the acid nitrate of mercury, and gave her some yellow oxide ointment. Under these measures the ulceration soon healed. She was under my observation for six months afterwards, on account of her other maladies, and there was during this time no spreading of the ulcer in the septum. It seemed to be soundly healed.

(*To be continued.*)

ON SOUNDING FOR IMPACTED GALL-STONES.

By Dr. GEORGE HARLEY, F.R.S.

That within the last fifty years the whole theory and practice of Medicine has undergone a complete revolution, no one seeks to deny. That a new era dawned upon our art when the microscope, stethoscope, test-tube, and thermometer crossed the threshold of the sick-chamber, all readily admit. But there are still amongst us many who insufficiently appreciate the immense collective advantages which have accrued to Rational Medicine from the hundred and one trifling physical aids to diagnosis which have been introduced during the last couple of decades. This arises from the majority of persons overlooking the fact that a few easily recognisable physical signs are worth a whole cart-load of describable symptoms in the detection of obscure disease. For while symptoms are, even at best, merely fluctuating quantities, not alone from their intrinsic value materially depending upon the mental capacity, moral courage, and veracity of the narrator, but from their very significance being complex ; a physical sign, when correctly interpreted, has always the same definite and indisputable value, from its being an independent factor, which the interrogator sees, feels, or hears for himself. Added to this, the knowledge of the fact that the cable of symptomatology is nearly "payed-out," and consequently the onward career of Rational Medicine to her legitimate goal—that of an exact science—must in future almost entirely depend on the acceptance and judicious application of easily workable physical aids to the recognition of internal diseases, induces me to avail myself of this favourable opportunity of making known to my professional brethren an instrumental method of indubitably ascer-

taining the existence of impacted gall-stones. A point of no mean importance, seeing how many difficulties beset the symptomatic path of diagnosis in this most fatal form of affection. Before proceeding to do so, however, it is advisable for me to make a few prefatory remarks on the clinology of biliary concretions. For, judging from the reports of the speeches made at our metropolitan as well as our provincial medical societies, when the subject of gall-stones is discussed, a woeful amount of ignorance regarding both their symptomatology and pathology is prevalent in the profession. This may to some appear strong, if not even ungenerous, language. But everyone who has given attention to the reported remarks of some of the speakers, hospital physicians as well as surgeons, in the discussions which have followed the reading of recent papers, will acknowledge that they are perfectly justifiable. I even doubt not that some of the speakers themselves, after they peruse the facts I shall presently adduce, will feel that this stricture is by no means uncalled for.

One of the commonest of the false statements enunciated is that gall-stone affections are not generally dangerous. Exactly the contrary is the case; the general ignorance of the fatality of gall-stone cases being due to the unfortunate frequency with which patients succumb to them without the medical attendant's having had the remotest idea of the true pathology of the case he was treating. The reason of this is not far to seek, for it lies, I believe, in the fact of his having been falsely taught that all dangerous gall-stone cases are associated with jaundice and paroxysmal pain; whereas it actually happens that the majority of fatal gall-stone cases are unassociated with either the one or the other of them. Incredible as this may appear, it is nevertheless perfectly true. For there is no jaundice, and no paroxysmal pain (indeed, in the first instance very little pain of any kind whatever) when a gall-stone ulcerates its way out of the gall-bladder. Should the stone in this case enter the peritonæum, a fatal peritonitis is the result. Should it enter the intestines, if large it kills the patient by ileus; if small, it passes safely down the intestines until it reaches the ileo-cæcal valve where it often sets up such an amount of irritation as speedily induces a fatal enteritis. The unsuspected gall-stone may kill even more rapidly still. As when in the course of its perforating career it opens a blood vessel, which, if it pours its contents into the stomach, leads to the mistaken diagnosis of hæmatemesis; if into the intestines, gives rise to bloody stools. Or it may burst into the peritonæal cavity and the patient become suddenly collapsed, and die without either a single trace of the hæmorrhage or its exciting cause being visible to reveal the true nature of the case. That such fatal cases of gall-stone perforation are far from uncommon I know from personal experience. No less than four, and strangely enough all in gentlemen of above forty years of age, have fallen under my notice within the last year. One died six hours after I saw him, another within twelve, a third within forty-eight, while the fourth happily recovered, and that, too, notwithstanding that pure blood was passed both by mouth and rectum.

As it may appear to some a novelty to be told that gall-stones are so often fatal without so much as their existence having been suspected, and a single illustrative example is more impressive than a whole column of general remarks, I shall briefly relate one of the fatal cases just referred to, which has the additional advantage of showing how, even when gall-stone symptoms exist, one may be entirely misled in both diagnosis and treatment, from their not being in exact accordance to what is regarded as orthodox law. Early in the present year I was summoned to Brussels to see a Belgian gentleman, aged 58, along with Mons. Capart. On reaching the patient's bedside I found him exsanguine, and almost pulseless. He complained of dull pain in the lower part of the liver, with great tenderness on pressure in the region of the gall-bladder, which was not distended. The liver was of the normal size, and there was no jaundice. The history I received was, that he had always been a bilious subject, and had suffered from painful dyspepsia, that he once had jaundice, and passed a small gall-stone. The dyspeptic symptoms not improving under treatment, he betook himself to Paris, and consulted the gentleman who was recommended to him as being the leading physician. After a careful examination of his case it was diagnosed "hepatalgia," and a course of electricity was prescribed. Feeling no better after several weeks of daily galvanism he returned to Brussels. His symptoms gradually became more severe, and four days before I saw him he was suddenly seized with coffee-ground vomiting, and tarry-looking dejections. Seeing that the case was undoubtedly one of gall-stone perforation, and that the patient was already blanched from loss of blood, I naturally enough prognosed that if the hæmorrhage was not immediately arrested, death was inevitable. For twelve hours he rallied under treatment, but within the next twenty-four, pure blood began to come away, both upwards and downwards, and in less than forty-eight hours from the time I first saw him he was a corpse.

The prevailing ignorance regarding the fatality of gall-stones may also in a measure be due to the fact that not only are the poor far less liable to them than the rich, but when they seek relief for them in hospitals, the prominent sign instead of the pathological conditions giving rise to it is often treated as the disease; as well as that from its being no rare occurrence for gall-stones of considerable size to be met with at the autopsies of patients who, during their sojourn in the hospital, never manifested a single symptom of them, even hospital physicians have been led to regard them as harmless. The entire absence of both signs and symptoms in many gall-stone cases is, however, readily explicable, without its entailing a belief in their non-dangerous nature. For it is due to the fact that, from the majority of gall-stones being slowly formed in the gall-bladder itself, they give rise to no signs or symptoms as long as they remain there. No, sometimes not even to biliary functional derangement, though the viscus be choke-full of them. This is on account of a gall-bladder not being essential to life, as is proved by the fact that people have grown up to adult life without having ever possessed a vestige of one. And many species of animals have normally no gall-bladders, for example the horse and the deer. There is nothing then surprising in the fact that gall-stones, though fatal things, may yet be found at necropsies in the gall-bladders of persons who never complained of them. Indeed, it would rather be surprising if it were otherwise, seeing that they are usually formed there, and that their career of discomfort and mischief only begins when they attempt to get out of the gall-bladder either by directly perforating through its coats, or by forcibly entering the cystic duct.

From the remarks which fell from the speakers, at the discussion on my recent paper on "Gall-Stone Sounding," at the Royal Medical and Chirurgical Society, it further appears to be very far from generally known that, notwithstanding that a dozen—even a thousand—gall-stones may exist for years in a patient's body, without giving rise to a single sign or symptom by which their presence can be suspected, all the most marked signs as well as symptoms, given in text-books as indubitable evidence of the existence of dangerous gall-stones, may be present without a single stone or biliary concretion of any kind whatever existing in the sufferer's body. This is a startling fact no doubt, but

it is nevertheless quite true, as I shall now proceed to show. For :—

(*a*) Gall-stones never produce jaundice, pipe-clay stools, nor bilious urine, except when they become impacted in a duct. And the only ducts in which their impaction leads to this result are the hepatic and common bile ducts.

(*b*) Not only can their presence in these ducts in the majority of cases be recognised, but even differentiated. And what is more, their impaction in the intra-hepatic as well as in the cystic duct can also be detected, though in these cases there is no jaundice, no pipe-clay stools, and no saffron-coloured urine. In order to make this perfectly plain I shall put the matter in the form of an easily comprehensible table.

other equally potent obstructing cause acts in precisely the same way as an impacted stone does. This is no mere supposition, it is a fact.

(*c*) For it is found that the identically same signs of jaundiced skin, pipe-clay stools, bilious urine, &c., are met with when the hepatic or the common bile duct is obstructed by entozoa, cancerous or other tumours growing within them. Or when by external pressure a tumour of the head of the pancreas, of the pylorus of the stomach, or of the liver itself blocks up the channel of the duct. An additional common cause of permanent obstructive jaundice, is the closing up of the duodenal orifice of the bile duct by a cicatrised ulcer. All of which non-gall-stone forms of obstruction not unfrequently baffle even the most skilled specialists to differ-

THE PRESENCE OF THE SIGNS AND SYMPTOMS IS INDICATED BY THE FIGURES. THE ABSENCE BY THE LINES.

Gall-stones Impacted in.	Distended Gall-bladder.	Enlarged Liver.	Jaundiced Skin and Eyes.	Pipe-clay Stools.	Saffron or Black-coloured Urine.	Rigors or Chills.	Flatulent Dyspepsia.	Vomiting or Nausea.	Hepatic Tender-ness.	Spasmodic Pain.
The Common Bile Duct... ...	1	2	3	4	5	6	7	8	9	10
Hepatic Duct	—	1	2	3	4	5	6	7	8	9
Cystic Duct	*	—	—	—	—	1	2	3	4	5
Intra Hepatic Ducts	—	—	—	—	—	—	—	1	2	3

* Although the gall-bladder is in these cases never distended with bile, if the impaction be complete, and is continued sufficiently long, it may become distended by white mucus-secretion. For the *modus operandi* in the formation of white liquids in the gall-bladder, see the writer's book on the Liver, where its physiology as well as pathology is given in detail.

After having thus shown how comparatively easy it is not only to diagnose, but even to differentiate the various forms of impacted gall-stones, the reader may perhaps wonder why I take so much trouble to make known an instrumental method for detecting them. Here is my reason, and a very potent one it is. More than twenty years' experience of gall-stone cases has not only convinced me that many patients annually die from the effects of impacted biliary concretions, whose lives might in all probability be saved were the obstructing body artificially extracted ; but at the same time made me painfully conscious that, as has just been shown, all their most characteristic signs and symptoms may be manifested by a patient who has not a vestige of a biliary concretion of any kind whatever within his body. I believe therefore that it would not only be injudicious, but criminal for any physician to recommend to a patient to submit to what a hospital-surgeon had the temerity, at the debate on my paper, to deliberately propose doing as a means of diagnosis. Namely, to incise a patient's abdomen, cut open his gall-bladder, stitch its edges to the lips of the wound in the abdominal parietes, and then search for the impacted stone in it ; showing that his idea was, that dangerously obstructing calculi are to be found in gall-bladders. Moreover, be it noted that this formidable diagnostic procedure was proposed by him as being simpler than the operation of sounding with a trocar not bigger than a knitting needle. I shall now show how this venturesome form of surgical prospecting is unjustifiable. For even should an inoffensive calculus be accidentally found in the gall-bladder, it would not as a sequence follow that the patient's abdomen had been necessarily and advantageously incised. For the following potent reasons :—

(*a*) It is in no case the stone itself which produces the dangerous symptoms, but solely the obstruction to the flow of bile into the intestines. In so far then as the stone is concerned, did it not prevent the passage of the bile into the duodenum, it would in all probability lie as inoffensively in the bile duct as stones are known to lie in the bile reservoir.

(*b*) It being the obstruction then, and not the stone itself which is the real source of danger to life, any

entiate. It is scarcely surprising then that I strongly advise practitioners to make themselves perfectly sure of the obstruction being due to a gall-stone before proceeding to lay open their patient's abdomen in the sanguine expectation of finding one.

Although my method of sounding for stones may not be entirely devoid of danger—for no operation on the human abdomen is, not even the simple one of tapping—it certainly has the advantage of being less rash, as well as less dangerous to life than that of cutting down with a knife, either on ducts or gall-bladders, in search for gall-stones which may have no existence. Moreover, I have already performed the operation successfully, and what has been done once may be done again. The instrument employed was a six-inch long French exploring trocar, of somewhat less diameter than an English No. 1 catheter. And I now recommend that it should be provided with a blunt-nosed steel pilot, to be introduced after the trocar has been inserted into the abdomen, and before the search for the stone is proceeded with.

After the patient is put under the influence of an anæsthetic, the operation of sounding may be performed in the following wise.

1st. Push the trocar through the abdominal parietes in the direction of the common bile duct.

2nd. If the instrument impinges on no hard solid, withdraw the stilette and judge of the situation of the cannula's point by observing what kind of fluid flows from its free orifice—bile, abdominal serum, blood or intestinal fluid.

3rd. Being satisfied that the point of the cannula occupies no dangerous position, introduce the blunt-nosed pilot, and proceed to search about in all directions for the stone. The presence of one will be readily recognised by the fact that no hard substance whatever exists in the neighbourhood of the gall-bladder and bile ducts. And a gall-stone when struck, either in the gall-bladder or ducts, gives the same characteristic sensation to the fingers as a urinary calculus.

As several of the speakers at the debate on my paper objected to this plan of sounding, on the ground of the danger of peritonitis being induced by the bile escaping into the peritonæal cavity, notwithstanding

that I had cited a case where no less than thirteen pints[1] were removed by tapping from the abdomen of a boy whose gall-bladder had been ruptured three weeks previously, and they ought to have known that both distended gall-bladders and bile ducts have been beneficially tapped, I deemed it advisable to see what would actually be the result of puncturing a distended gall-bladder with my exploring trocar. Especially as one of the speakers had, forgetting that the coats of bile ducts and gall-bladders are elastic, inconsiderately suggested that the moving about of the instrument would enlarge the puncture.

Accordingly, along with Prof. Schäfer, I performed the following experiment :—A dog which had been kept fasting for 26 hours, in order that his gall-bladder might be fully distended, was rendered insensible with chloroform. The abdomen was opened, and into the distended gall-bladder I inserted my trocar. Twisted it about and then withdrew it. No spurt of bile whatever took place. Nothing more than an oozing followed. The oozing even soon ceased, from the coats of the gall-bladder (which, be it remembered, are even very thin in a small dog) contracting as the viscus emptied itself. In order, then, that all risk of a dangerous exudation of bile into the peritonæal cavity may be avoided, it is merely necessary to withdraw some of it before removing the cannula.

In those cases where the obstruction has given rise to great distension of either the bile duct or the gall-bladder, and from the orifice of the cannula bile flows when the stilette is withdrawn, it might perhaps be advisable to empty them of their biliary contents before proceeding to search for the suspected stone.[2]

I shall now give the history of the case of impacted gall-stone in which I successfully performed the operation.

(To be continued.)

NOTES ON THE RADICAL CURE OF HERNIA.

By W. MITCHELL BANKS, F.R.C.S.

Surgeon to the Liverpool Royal Infirmary, and Professor of Anatomy, University College, Liverpool.

If in writing these notes I may appear to be somewhat dogmatic, I must offer by way of apology two reasons :—first, that where it is necessary to be brief, one can hardly be otherwise than dogmatic; and secondly, that I am speaking, not from a theoretical point of view, nor from the knowledge gained from a few cases, but from a fairly extended experience. I have now performed the operation for radical cure on twenty-five cases of inguinal, seven cases of femoral, two cases of umbilical, and three cases of ventral hernia; as well as on thirteen cases of strangulated inguinal, eleven cases of strangulated femoral, and two cases of strangulated umbilical hernia. In all, sixty-three cases of every kind, ranging from the simplest possible variety, to some that may almost be termed gigantic. As regards the cases of strangulated hernia, the application of the radical cure being merely an accessory, it must of course be admitted that we do not derive from them any information as regards the safety of the operation, but, on the other hand, we obtain the same information as to its subsequent utility that we gain from cases primarily operated upon for radical cure.

The term "radical cure" misleading.—The term "radical cure," implying as it does a thorough and perpetual cure, has, I suspect, been rather deterring to the progress of the operation than otherwise. People have been led by it to expect too much, and have in consequence naturally been disappointed. It is popularly understood that a patient upon whom a radical cure has been performed, need never again wear a truss, nor ever again be in danger of his hernia coming down. This is unfortunately far from being the case. The instances where a light truss can be dispensed with are the minority; and, as regards a return of the hernia, I argue that any man in whom a hernia occurs, is naturally a man of lax fibre and patulous abdominal apertures. Now, it is not to be expected that you can make him better than he was before the rupture occurred; so that if you only make him as good, then you only make him a man of lax fibres and patulous abdominal apertures once more; and such a man ought always to wear a truss as a protection. No operation will ever convert him into a hard-fibred, tight-ringed man, so long as his anatomical construction is what it is. Whatever may be the case with children, we ought in adults only to hope to put the patient in the *status quo ante descensum;* in such a state, to wit, that a light support will keep any hernia from coming down. By viewing the operation in this light, we shall neither disappoint ourselves nor our patients, and we shall form a much truer estimate of the value of operative proceedings. For "radical cure of hernia," one ought to substitute "curative treatment of hernia by operation."

No little harm has been done by surgeons who have been so anxious to rush into print that they have at once published their one or two cases the very week the patients have left hospital. These are duly labelled "cured" and are reported as leaving without any trace of rupture. Such cases are simply worse than useless as regards the determination of the ultimate value of the operation. Let us see how the patients are twelve months afterwards, and let us know what they have been doing in the meantime, and then some good purpose will be served. In August, 1882, I read a paper at the meeting of the British Medical Association, at Worcester, on this subject, in which a table was given of over thirty cases, with what had become of them during periods of two years to five or six months. The present article not being a statistical one, I do not bring forward any figures, but I have nearly every one of the cases I have treated under observation, and trust before long to give a detailed report of their condition after the lapse of a sufficient period. At present, I only desire to say that I consider the operation a very valuable and useful one, and am sure that, as it gets more and more perfected, it will be the means of enabling many persons to live in comfort who have hitherto lived in distress, and will ultimately lead to a saving of human life; only too much must not be expected from it.

The cases suitable for operation.—As I am strongly of opinion that the majority of persons, even after the performance of the so-called radical cure, ought to wear a light truss, it follows that any person troubled only with a hernia of moderate size, which can be comfortably and securely kept up by a truss, ought not to be subjected to any operation whatever. His condition will not be *very* greatly improved, and he will have been exposed to the risk of a surgical proceeding. I have not unfrequently been consulted by patients who were willing to undergo the risks of an operation, merely to get rid of the bother of wearing a truss, even although admittedly quite easy and comfortable; but I have always refused to operate, telling them that

[1] Medical Chirurgical Society's Transactions, Vol. IV.

[2] Dr. Whittaker detected gall-stones in the gall-bladder by means of a hypodermic needle (*New York Medical Record*, 1882), and on one occasion, while I was exploring a liver, the trocar accidentally penetrated the gall-bladder and struck a calculus, which subsequently, at the autopsy, was found to be of the size and shape of an apricot stone.

after the operation they would be hardly any better off.

Again, nearly all cases of congenital inguinal, or umbilical hernia, occurring in children, are curable by the prolonged wearing of a truss, and, in the case of respectable parents who can afford to purchase good instruments, and have the intelligence to apply them, no further treatment need be contemplated. The great difficulty is with bad congenital inguinal herniæ in the infants of poor people, who can seldom get good trusses, and who are too negligent and too ignorant to apply them properly, even when they are given to them. Such cases are constantly turning up at hospitals and dispensaries, and when aggravated become legitimate subjects for operation. But before performing any radical cure, every possible means should be tried to secure the wearing of a truss, which can very generally be done, if only the mother can be got to throw herself into the treatment with the least approach to intelligent enthusiasm. The following may serve as an example of the sort of case which really stands in need of operation. The patient, aged $2\frac{1}{2}$, was a thin, miserable, pallid creature, whose mother was extremely poor, and as regards carrying out any surgical treatment, practically anencephalous. He had two large double scrotal herniæ, and as he was always yelling and crying, for reasons only known to himself, the scrotum looked generally as if it were at bursting point, while the inguinal apertures were greatly dilated. On the left side, I first tried Spanton's operation, keeping the screw in for about twelve days. A good deal of suppuration and a great deal of thickening resulted. For some weeks it seemed as if this were going to succeed, but by degrees the adhesions gave way, and the gut came down as badly as ever. So on the right side I removed the sac and stitched up the ring. The sac was extremely delicate and the cord very minute, so that it was a work of considerable difficulty to clear the former. A portion of sac was retained and sewn up, so as to make a tunica vaginalis, and the upper part was stripped up and cut away. Then we waited about three months to see how this would do. Although the child's conditions were exactly the same as before, the bowel could not force its way down now. So the left side—the one upon which the Spanton's operation had been done—was subjected to the same proceeding, and now, after two and a half months, holds thoroughly. As a truss fits quite easily, the child is to be provided with one and sent home, for, although there is not the slightest impulse on coughing, I don't think he ought to be trusted without support; it would only be courting the spoiling of a good job. If he wears a truss for four or five years he will be safe. In noting the failure of Spanton's operation it is not with the view of decrying it, as I think very highly of it for cases of inguinal hernia of mild character where there is no adherent omentum. But so serious was the rupture in this case, and so great the amount of expulsive force which the child seemed able to bring to bear, that no operation which depended solely upon inflammatory adhesion and nothing else could possibly hold up against the strain. At the Liverpool Children's Infirmary, where much excellent work in the way of radical cures has been done, I believe that the opinion is that for really bad cases of congenital hernia, Spanton's operation is not sufficiently curative, and that the only thing is removal of the sac and closure of the pillars of the ring.

If it be admitted that in adults the only ruptures which need be tackled are those which cannot be satisfactorily kept up by a well made truss, we must next note the reasons why the said ruptures are not amenable to the operation of a supporting instrument. The first consists simply in the enormous size of the rupture itself, combined with great patency of the hernial aperture. Many ruptures by reason of neglect become so huge that no instrument can possibly hold them up, except by the exercise of a pressure which soon becomes unbearable. There is no doubt that these great herniæ most emphatically stand in need of radical cure, but there has been a natural tendency to fight shy of them on account of the magnitude and danger of the operations which have to be performed. I have lately been attacking specimens of very great size, and am beginning to get over my dread of them, but there is no doubt that some of the operations have been very extensive and have given rise to no little anxiety. Like ovariotomy, they were certainly of a kind that would have subjected any one who did them and failed to a criminal prosecution forty years ago. In the case of very large ruptures, it is, therefore, only right fully to explain to the patients that they run a not inconsiderable amount of risk, and to leave pretty much with themselves the decision of what is to be done. For, after all, one must remember that a person with a very big and very troublesome rupture may live long enough, and do plenty of good work; consequently, a death from an "operation of convenience," which, perhaps, has been urged upon the patient by the surgeon, is a source of great regret and mortification to him, as I myself experienced in the only fatal case which I have yet had. Of course, in this, as in every other surgical operation, one must take into account the age and strength of the patient. To operate upon a broken down used up old man of three-score and ten with a rupture as big as his head, is only to court destruction. The operation is one which must not be done recklessly, but which must have a strong motive for its performance and an almost certain promise of success.

One of the largest cases I have attacked, was in the person of a very big fat woman of 45, who came some months ago from the Isle of Man. She had a rupture which no instrument could keep up, and which was rendering her useless, so she was willing to submit to anything. It was a right inguinal hernia, which had made its way down into the labium. From the inguinal ring to its lowest point, it measured 15 inches, and its girth at the widest part was 20 inches; in fact it reached most part of the way down her thigh, and practically obliterated the vagina. The tips of four fingers could be pushed into the ring. The contents consisted of bowel alone and were completely reducible, which was very fortunate. Before commencing the operation, I reduced the hernia, and then entrusted to an assistant the duty of keeping it up, which he accomplished by stuffing the fingers of both hands into the ring, and pressing up as hard as he could. The process of dissecting out so large a sac, was as might be expected a long and tedious one, involving the tying of innumerable small vessels. Luckily, however, there was no spermatic cord to trouble about, as I gathered up with the sac any vestiges of round ligament that remained, so that there should be nothing to pass through the canal afterwards. During this proceeding the ether caused the patient to retch and cough a great deal, and so tremendous was the force exerted, that twice the bowels rushed down into the partially dissected sac, in spite of the utmost exertions of the assistant at the ring to hold them up. Had the sac been opened they would have been all over the table; however, chloroform was administered, and then the patient became quiet. I have very often had to leave off ether in these cases, owing to the impossibility of going on with the operation while the patient was coughing and straining. When the sac was completely dissected out, the neck was so large that I did not venture to tie catgut round it, but stitched it through and through from side to side, cut it off, and then stitched it over the cut edges again. Then the pillars were pulled together in all

their extent by five very thick wire stitches; and finally, a great piece of loose skin about the size of a page of this journal was swept away. A bystander jocularly remarked that the sac would have made a very respectable peritonæum for a five year old child. The parts healed excellently, and the patient is now at home in perfect comfort wearing a good firm truss to prevent any descent.

The second reason why certain ruptures are not amenable to the action of trusses is the presence of adherent omentum in the hernial sac, by which the ring is always kept open, and a sort of inclined plane produced, down which the hernia is always free to descend, seeing that no truss can possibly stop up the hernial aperture in an effectual manner. In the majority of cases of femoral rupture, the first thing to descend is a small piece of omentum. This becomes adherent to the sac, and cannot be returned. It grows hard in texture, and its neck becomes narrow and pedunculated, so that it has all the feeling of a deep-seated enlarged gland. In that condition it may remain for a long time, the patient being unable to wear any truss, until some extra exertion forces down a small knuckle of bowel, which straightway becomes acutely strangulated. From the rapidity with which the sharp edge of Gimbernat's ligament cuts into the bowel in these cases, they are usually most dangerous. From which it comes about that a patient with a small femoral hernia consisting of adherent omentum goes about in constant danger of his life, never sure that a piece of bowel may not at any moment follow. Now, the dissecting out of these small femoral sacs, and the separation and removal of their contained adherent omentum, is so easy and so safe a proceeding that I should have no hesitation in always strongly recommending an operation in such cases. The instance of E. A., a housemaid, aged 32, is tolerably characteristic of these cases. Nearly four years before her admission to the Infirmary in March, 1881, she discovered by accident that there was a small lump in her groin. It seemed to go away, or at any rate it did not give her any trouble, and so she did not pay any attention to it. In June, 1880, after a good deal of exertion she was attacked with severe pain in the groin, lasting for some hours. In August occurred another similar attack, and then she applied to a medical man, and was fitted with a truss. Again, in November, two more attacks, and now the lump in the groin became stationary, and she wore her truss upon the top of it. In January and February, 1881, the lump gave her so much pain and trouble after any exertion, such as lifting furniture, that she applied for assistance. I cut down upon it, opened the sac, and found a piece of adherent omentum in it about the size of a large marble, which, along with the sac, was tied and cut off. I saw the patient the other day, three years after the operation. She has been at work as a housemaid, not wearing any truss, but simply taking care not to give herself any violent strains. There is not the slightest impulse on coughing, and she has been therefore perfectly cured. The usual history of such cases, when left alone, is that some day an extra effort is made, great shock and sickness follow, and the patient has to be cut to relieve a little knuckle of bowel often no bigger than a walnut, but acutely strangulated by the knife-like margin of Gimbernat's ligament.

Turning to inguinal herniæ, it will almost always be found that those which, being of a small or moderate size, cannot be supported by a truss, have at the bottom of this difficulty the fact that there is present a thin, flattened piece of adherent omentum, which is really quite irreducible, but which, when the bowel is put up, feels only like a very thick sac. Its presence, however, is most potent for evil, as it quite nullifies the retaining power of any truss. P. S., a strong, healthy sailor of 32, on admission to the infirmary told us that, about five years previously he first detected a small lump opposite the external inguinal ring, which used to disappear when he lay on his back. Very slowly it increased in size, until at last it no longer went back of its own accord, but had to be pushed back. For four years he had worn a truss, which seemed to act efficiently at first, but latterly was not of much use. A week before admission he had occasion to jump some feet. The hernia suddenly bolted down, and could not be got up for some hours until he had had morphia and a hot bath. He suffered such pain during these few hours, that he felt obliged to come and request that some permanent relief should be given him. I dissected out the sac, and on opening it found a piece of condensed omentum intimately adherent to the neck and the part immediately below. This was separated and removed, and the usual operation performed. He was seen the other day, about eighteen months after the operation. There was not the slightest impulse on coughing. He is in perfect comfort and at his work, and only wears a light truss for the sake of security. The piece of adherent omentum was the cause of the failure of the truss, and, as his experience of the week before admission clearly showed, kept him in constant danger of strangulation. Its removal has enabled the other steps of the radical cure to take due effect, and has practically put him in safety.

To condense matters, therefore, my experience would lead me to say that an operation should be recommended (*a*) in children only when it is impossible to get the parents to pay any attention to the complaint; in short, in the children of the poor and ignorant; (*b*), in small femoral herniæ composed of irreducible omentum, always; (*c*) in inguinal herniæ incapable of support by reason of the presence of adherent omentum, always; (*d*) in all herniæ whose great size renders support by a truss impossible. Ventral and omental ruptures come in the same category as (*c*) and (*d*).

(*To be continued.*)

ON SOME CASES OF AGUE IN LONDON.

By H. B. DONKIN, M.B, Oxon., F.R.C.P.

Physician to Westminster Hospital, and to East London Hospital for Children.

A VERY well-marked case of ague which lately came under my notice seems deserving of being shortly recorded, both from the fact that it was apparently a genuine specimen of London origin and that it recovered very rapidly under the use of arsenic after resisting quinine. A boy about five years old was admitted under me at the East London Hospital for Children, on January 17th of this year, suffering from "feverish attacks." The temperature for the first few days was taken only morning and evening, but on the 21st it was observed that the nature of the attacks of fever was characteristically aguish. The spleen was felt three inches below the ribs, and was hard. The liver also was felt slightly below the ribs. No other abnormal sign or symptom was present except some discharge from the ears. From the 21st to the 28th the boy had well-marked attacks twice daily at intervals of about twelve hours, there being a tendency for the alternate paroxysm to be of a milder character and sometimes unaccompanied by rigor. The high temperatures during the attack varied between 103·5° and 106·5° F. On the 28th quinine was given in four-grain doses every twelve hours, with no effect, the temperature on the 30th rising to 107°. On February 1st the quinine was given every six hours, after which date till the 7th the attacks took place about every twenty-four hours. The quinine was then given every four hours. There

were no decided rigors after this till the 12th February, though there were occasional slight rises of temperature. On the 12th the boy had a very decided rigor (temperature 105°) and another about twelve hours after. The boy felt quite well in every way between the attacks and was cheerful, but was occasionally sick after the quinine. On the 14th the quinine was given in five-grain doses. The attacks then became less regular, but took place at least once a day. An abscess appeared about this time on the buttock, which was opened on the 21st, and the quinine was discontinued. There was no marked change in the symptoms. On the 25th, Liq. Arsenicalis (one minim every two hours) was ordered. On the 26th he had a rigor (temperature 105°). But after this the temperature never rose considerably again. On the 28th it touched 100°, and then remained normal till the boy was discharged well on the 29th March, though he probably had an intervening attack of varicella. On the 3rd of March a careful examination showed all discoverable splenic enlargement to have disappeared. The arsenic was discontinued on the 6th March.

This is perhaps the best marked case of ague apparently originating in London that I have seen. The boy had never been away from Shadwell, where his parents had lived for long, near the river. I saw, however, several cases of undoubted ague occurring in those who had never, to their recollection, been in malarious districts, and who had always lived in London, while I was seeing out-patients at Westminster Hospital; about ten cases approximately, in a period of eight years. These cases, like that referred to above, seemed generally to improve best on arsenic. The affection is probably commoner than is generally believed in the riverside parts of London. Two cases have quite lately come under my notice in the S.W. district. One was that of a medical man whose observation of his own case may be thoroughly relied on. He had lived in Belgravia for several years, and had never had a similar attack. Suddenly he was taken with chilliness (not with defined rigors) and the sequent phenomena of ague. For five days these attacks recurred about the same hour, with much pain in head and neck, and some in limbs. No other symptoms. After 15 grains of quinine in three doses the symptoms permanently disappeared. The second case was a patient of the first. He was a gentleman who had lately removed from Hampshire (where he had always been in good health) to a well-drained house near Victoria Station. After about a week of daily well-marked attacks in January of this year, which were diagnosed as ague, he was given 10 grains of quinine, and 8 minims of Liq. Arsenicalis a day. He began to improve, and was well by the end of another week. At the end of April he had a similar attack with sore throat, but less severe, and improved rapidly on quinine. It may be mentioned here that on the fifth day of this second attack he had a general erythematous rash, followed a week later by desquamation. During the whole of this time he was in constant intercourse with a household containing eight or ten young people, all of whom subsequently remained perfectly healthy. A scarlatinoid rash in ague has been described, with cases, by Dr. Cheadle in a paper published in the *British Medical Journal* for April 13th, 1878, and containing also valuable remarks on the occurrence of ague in London. Dr. Cheadle's cases which showed this rash were all in children, and he further observes that he had not seen it in adults.

Lastly, I would mention that during the last few years I have known of two cases of severe ague in residents at Kew, one of whom only had had an attack some years previously, in India. Most of the cases that I have referred to above were of the quotidian form.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

THE MIDDLESEX HOSPITAL.

COMPRESSION OF BRONCHUS BY A "CURED" AORTIC ANEURYSM—COLLAPSE OF LUNG—BRONCHIECTASIS LEADING TO ULCERATION OF PLEURA AND PECTORAL ABSCESS—DEATH.

(Under the care of Dr. SIDNEY COUPLAND, F.R.C.P., Physician to the Hospital.)

Thomas S., aged 39, a labouring man, was admitted into the Middlesex Hospital on May 19th, 1882, complaining of cough, dyspnœa, and giddiness. His previous health had been good, but for the past twelve months he had suffered from a cough, which he attributed to having received a severe wetting. He also suffered frequently from a pain in the chest, mostly in the morning, and he had been compelled to abandon work for three months past.

He was a sparely nourished large boned man, with an anxious expression; no cyanosis; no clubbing of extremities. Skin hot and dry; tongue furred. A notable difference was found on examination between the two sides of the chest. Although there was no appreciable flattening, the left side barely expanded at all on inspiration, was less resonant in front than the right side, and absolutely dull over the back. The right side was fully resonant, both front and back. No breath sounds were audible on auscultation over the left lung, except faint and distant breathing at the angle of the scapula, presenting a marked contrast with the right, where the breath sounds were harsh, accompanied by dry sonorous rhonchi and a few mucous *râles* in all parts. Vocal fremitus and resonance were absent on the left side; the former over the whole lung, the latter still slightly preserved at the base. The man's cough was troublesome and paroxysmal; expectoration copious, mucoid, and acerated.

The cardiac impulse was best perceived in fifth left interspace, two inches below and slightly to the inner side of nipple line; sounds faint; no bruit. Liver dulness extended from sixth rib to costal margin.

Ordered poultices, ammonia and ether mixture and benzoin inhalations.

At first there was considerable hectic, the temperature ranging between 100° and 103·5° to 104°, From the end of May onward the range was lower, but a very irregular pyrexia occurred throughout. The most troublesome symptom was the cough, which was accompanied by profuse bronchorrhœa, the quantity of sputum in the 24 hours averaging during the first four weeks between 20 and 30 ounces, and never during the whole course of the illness (except towards the close) falling below 14 ounces. The urine was scanty, high coloured, free from albumen. A few of the daily notes may be extracted from the long record.

May 31st.—Temperature 101°, pulse 120. Absolute dulness over left chest in front, from the third rib downwards, throughout axilla, except at apex, and over the whole of the left back. Hardly any movement of the left side, and almost entire abolition of vocal fremitus. In lower axilla, on deep inspiration, some distant bronchial breathing audible, but absolutely no breath-sound to be heard over the back. Heart's apex beat is feebly felt in normal situation; but there is also distinct epigastric pulsation. An ex-

ploratory puncture was made with a hypodermic syringe in the left axilla, seventh space, but only a drop or two of bloody fluid was withdrawn, microscopically consisting of blood corpuscles, many leucocytes, and some molecular *débris*. It was not thought advisable to aspirate.

He now began to suffer from profuse sweatings, which continued throughout, unchecked by remedies.

June 12th.—Temperature 100.2°. Is emaciating rapidly. Cough very troublesome and expectoration very profuse (30 ounces in 24 hours). No expansion of left chest. Complete dulness from clavicle to base with increased resistance. Amphoric breath-sound in subclavicular fossa; absence of breath-sound elsewhere in front. Dulness as before over whole of left back, but amphoric breathing now audible in interscapular region and below the angle of scapula, together with mucous *râles* and sonorous rhonchi. Right side of chest fully resonant, exaggerated breathing, with abundant *râles* and rhonchi.

June 15th.—Temperature 101°, pulse 144. Had an attack of dyspnœa for the first time since admission; a similar attack recurred twice on the next two days. The left leg and foot have became œdematous, the limb feeling hot and the skin reddened.

June 19th.—Cyanosed. Breathing laboured. Can only lie on left side with comfort. Still very marked œdema of left lower extremity extending to the hip.

June 22nd.—Right foot has became œdematous. The plugged left femoral vein can be distinctly felt.

July 3rd.—Temperature 98·2°, pulse 144. Cough still very troublesome, especially at night. The swelling of left thigh has disappeared, but the leg and foot are still œdematous. During the next three weeks very little variation is noted. He had become permanently cyanotic, and continued to have the profuse bronchorrhœa; but no appreciable change occurred in the physical signs.

August 5th.—Temperature 98·4°. The œdema is now limited to the left foot. No pulse can be detected to-day in the right radial or brachial artery, but there is no change in the appearance of the limb. Physical signs now include high pitched dulness over left front, absolute dulness over left back; amphoric breath-sound in region of angle of scapula. Right lung over resonant; harsh breathing; scanty *râles*. His condition was now very pitiable; he had become excessively emaciated and weak.

August 16th.—Complained of sharp shooting pain in left breast.

August 22nd.—A swelling the size of a pigeon's egg has appeared about an inch above the left nipple at the seat of pain. The swelling, which was first noticed two or three days ago, has rapidly increased within the past twelve hours. It is exquisitely tender, fluctuating, non pulsatile. At 4 p.m. Mr. Lyell punctured the swelling with a grooved needle, and some thick pus escaping he incised it with a bistoury. Pus mingled with bullæ of air escaped, and air passed in and out of the aperature with expiration and inspiration respectively. Some oiled lint was inserted into the wound. Immediate relief from pain was given by this incision.

August 24th.—There has been free discharge from the wound; the discharge and the sputum have become fetid.

August 26th.—Temperature 98·7°. Discharge very copious, and less fetid; it is ejected with every cough. Cavernous breathing now audible in the scapular region.

September 3rd.—Died.

The *post-mortem* examination was made on September 4th, by Mr. Sutton, who found the incision to be over the fourth costal cartilage on the left side, the cartilage itself being divided. The sinus led into the lung, which was firmly adherent to the chest wall. A large tumour bulged forward into the anterior and middle mediastina. It proved to be a sacculated aneurysm of the transverse aorta, involving the left bronchus and compressing the lung, which was firmly adherent to the sac. The sac was filled with laminated clot, and the left common carotid artery was occluded. The left lung, which was reduced to a mere stratum between the aneurysm and chest wall, was riddled with bronchiectases containing fetid fluid; and it was into one of the cavities thus resulting that the incision had been made. Fortunately it did not penetrate to the aneurysm. The right lung was emphysematous. The left vagus and its recurrent branch were destroyed by the aneurysm. The liver was fatty, spleen soft, kidneys normal.

Remarks.—Although as the case progressed the possibility of the symptoms being dependent upon an intra-thoracic tumour was kept in view, no suspicion of aneurysm was entertained during life, and yet the conditions found after death clear up many obscurities in the clinical features of the case. The aneurysm, which had undergone "spontaneous cure" had so compressed the bronchus as to render the lung quite useless and had thus given rise to the universal bronchiectasis. The physical signs, viz., dulness, absence of vocal fremitus posteriorly, suppressed breathing, except the area of amphoric breath-sound at the scapular angle, and the immobility of the left side, are all explained by the condition to which the lung was reduced, and the profuse bronchorrhœa must doubtless be attributed to the same cause. Had a laryngoscopic examination been made, it is highly probable that much light would have been thrown on the case, for owing to its position the aneurysm had exerted no pressure upon veins, and owing to its consolidation positive aneurysmal signs were also wanting; but, as the *post-mortem* showed, it had completely destroyed the recurrent and vagus nerves. In spite of this, dyspnœa was never a prominent symptom, and the voice was not obviously altered. The connection of the abscess in the thoracic wall with a pulmonary cavity became evident as soon as the former was incised.

Medical Times and Gazette.

SATURDAY, JULY 5, 1884.

Our Paris correspondent writes:—The cholera still continues to be the topic of the day, and the Academy of Medicine was thronged yesterday to such a degree, that members were obliged to enter by a side-door, it being impossible to pierce the crowd. The building, which is altogether insufficient for its purpose, and unworthy of the illustrious Society which meets there, was full to overflowing, and contained several hundred persons. The fact that Drs. Brouardel and Proust had returned from the South, and were about to communicate their report to the Academy, had attracted this extraordinary rush. A slight skirmish had preceded the battle. Dr. Brouardel, having the day before communicated his views to the Board of Health, was opposed by Dr. Fauvel, who clings to his views with characteristic obstinacy. The Academy presented something of the appearance of the Chamber of Deputies on field-days; there is, in fact, something almost political in the functions of that learned body,

which is constantly consulted by the Government on subjects of public importance—such, for instance, as the question of trichinosis, which nearly created a commercial war between France and the United States.

Dr. Brouardel stated, amidst universal attention, that when he started with Dr. Proust for Toulon, with ministerial instructions, he felt inclined at first to consider the epidemic as one of cholera nostras; but that, after a careful investigation of the facts, he and Dr. Proust were obliged to alter their opinion, and recognise the existence of real Asiatic cholera. The first case which occurred at Toulon began on June 14th, the second on June 15th, both on board the *Montebello*, a ship which has been lying in port for the last fifteen months. The first patient died at the end of the week, the second expired in twenty-four hours; both cases were considered as cholera nostras. On the 22nd, a boy at the grammar school was taken with cholera and died in six hours. The *Lycée* was immediately evacuated, and the boys dispersed. On the 23rd there were nine deaths from cholera, and since that time every day has been marked by a small number of fatal cases. The existence of cholera was therefore evident; but the question at issue was whether it had penetrated from abroad, like Asiatic cholera, or had spontaneously arisen in the port. All the investigations of the Commission remained fruitless, and it was impossible to discover the fissure through which the disease had penetrated into a place protected by an intricate system of regulations. The transport ship, *La Sarthe*, had been peculiarly incriminated; but the opinion of the Commissioners is, that no blame can attach to that unfortunate craft.

Such was the only reason which prevented the Commissioners from first recognising the existence of Asiatic cholera, which, according to the French notions, never breaks out spontaneously in the ports of Western Europe, and invariably comes from the East. But a few days later one of the boys dismissed from the school at Toulon, went to Marseilles, and died there of cholera. Since then, six other cases have occurred in the same city. At the same time, the transport ship, the *Shamrock*, was on the point of starting for Tonkin with 1,100 men on board, when a case of diarrhœa occurred in a sailor who rapidly recovered. From motives of prudence, Dr. Brouardel ordered the ship to Hyères, where first one case of cholera occurred, then a second one, and quite lately, a third. The troops were immediately disembarked, and the whole cargo laid out for disinfection. These facts seemed unmistakably to prove that Asiatic cholera did exist at Toulon. One objection still remained—there had been no cases spontaneously developed within hospital wards. This last impediment was overthrown by a letter from Dr. Cunéo, which states that two *interior* cases have occurred, the first at the *Hôpital Principal*, the second at the *Hôpital Saint Mandrier*. And, lastly, two cases of algid cholera have occurred at La Valette, a healthy village, four miles distant from Toulon, in which a labourer, coming from that city, had died of cholera a few days before. Now, as the two above-mentioned inhabitants of La Valette, had not gone for several months to town, they evidently had contracted the disease from the first patient who died in that locality. Dr. Brouardel concluded his speech by declaring that we evidently stand in presence of an epidemic of Asiatic cholera, although we cannot discover the loophole by which it has gained an entrance.

Dr. Fauvel replied in a set speech that without doubting the sincerity of his opponents, he persisted in believing that the epidemics, both of Toulon and Marseilles, were entirely due to local causes, and would die out without spreading farther. He insisted on the fact that the death-rate from cholera remained extremely low. In conclusion, he blamed the Commissioners for spreading alarms which had a disastrous effect upon French trade. A murmur of universal disapprobation met this last remark. But Dr. Fauvel, who is universally considered as a most upright, most enlightened, and most honourable man of science, is, unfortunately, afflicted with the same infirmity as the ancient Assyrian kings whose word could never be recalled. No culprit in those times could hope for a reprieve when his sentence had been followed by the awful words "The king hath spoken." Dr. Fauvel should, therefore, be extremely cautious not to let the sacred utterances drop too soon from his consecrated lips. But in the present case his usual prudence seems to have been at fault. He distinctly stated last week, at the Academy, that the cholera at Toulon was not epidemic but sporadic; and sporadic it must therefore remain, all logic to the contrary notwithstanding. Dr. Fauvel laid himself open to the sharp rejoinder of M. Pasteur, who said in substance that the only serious argument brought forward by Dr. Fauvel was the low rate of mortality in the present epidemic. But in the celebrated and disastrous cholera of 1865, in that very same city of Toulon, the death-rate was very low during the first fortnight, and then rose to an alarming height. The conclusions of Dr. Fauvel were therefore null and void.

It seems evident, concludes our Paris correspondent, that the disease, the very name of which terrifies Europe, has distinctly broken out in the South of France. Whether it will die out there, or spread farther, is a question at issue; but if ever it arrives at Paris, you may be perfectly sure that it will cross the Channel and reach London, in the shape of some unavoidable carpet-bagger, whom no quarantine will stop in his progress. In the present state of communications in Europe, it seems impossible that cholera, if ever it breaks out in some central and highly-frequented spot, should not spread everywhere, with the exception perhaps of some favoured localities. The best remedies against that inevitable evil are sanitary precautions and immediate medical treatment. The Municipality of Paris have already taken proper measures, and have prepared special hospitals and special wards for the reception of any cases that may occur. The Festival of July 14th will be put off at Marseilles and Toulon. It would be advisable to adopt similar measures at Paris. An old American friend of mine

told me, that in former days, when the yellow fever annually visited New Orleans, the first cases invariably occurred on the 5th July. A curious coincidence, which might perhaps be explained by the copious libations attending the anniversary of the Declaration of Independence on the 4th July. It is evident that, in presence of epidemic diseases, the celebration of national festivals is not unattended with danger. Our Republican Government would therefore act wisely in postponing the ceremony to a more fitting time.

In reply to questions put to the President of the Local Government Board, as to what steps are being taken to protect the country against the introduction of cholera, it has been pointed out that the subject was very carefully considered last year, when an outbreak of cholera occurred in Egypt. Revised "Cholera Regulations" were then drawn up and issued, and are still in force. Under these regulations an officer of the Customs may detain any vessel on its arrival in English waters if he has reason to suspect that it is infected with cholera; and having done that, he must give notice of the detention of the vessel to the sanitary authorities, who must cause their Medical Officer of Health, or some other medical man, to visit and examine the vessel. Or a Medical Officer of Health may visit and examine any vessel that he may suspect of being infected with cholera, or of having come from some infected port. When a medical officer has certified that a ship is infected, no one can leave it without the medical officer's permit; and should any person be found to have cholera, he must be sent into hospital. Doubtful cases may be detained on board the ship or in hospital, until the nature of their illness has been clearly made out; and provision is made for the disinfection of the vessel, and of all infected clothing, bedding, &c. Sanitary authorities have been appointed at our ports, and it is the duty of their sanitary officers to deal, in accordance with the prescribed regulations, with all infected ships and all cases of infectious disease coming into port. These regulations, which are the outcome of our present knowledge and experience of the modes by which the spread of cholera can most certainly be prevented, are now in force, and will remain in force not for any definite period only, but until they are repealed.

The adjourned discussion on the second reading of the Medical Bill was resumed on Thursday last week by Dr. Farquharson, who was willing to accept the measure, because it would put an end to the agitation and turmoil that have for so long beset the profession. But he felt, he said, but little enthusiasm for it. If passed in its present form it would, he thought, injure all and probably ruin some of the Corporations in England; while in Scotland it was feared it would lower the standard of examination. Mr. Peddie also contended that it would have a very injurious effect on the Corporations. It was further feared that the Crown nominees on the Medical Council would be Englishmen residing in or near London, and that therefore medical matters would be ruled more in the interest of England than of Ireland and Scotland. The Extra-Mural School in Edinburgh would also, he thought, be very injuriously affected by the measure, and that would be a great calamity. Dr. Lyons spoke at some length to the same effect. He thought the measure might lead to the extinction of the Medical Corporations, even in London, and still more surely in other parts of the country; and that he thought would be a very serious matter, and he should consider it his duty to see that it was fully considered in Committee. He greatly regretted the omission of the two Corporations of Apothecaries from the Bill. He trusted the House of Commons would restore them to the position to which they were entitled, and he would himself do his utmost to amend the Bill in that respect. Mr. Buchanan thought the Bill ought not to be pressed on the House when there were other measures of much greater importance requiring consideration. But it appeared to him that the measure would meet with little opposition if Government would accept the amendment suggested by Sir Lyon Playfair. Some other members spoke briefly, and the Bill was read a second time, the hostile criticism of it having come entirely from Scotland and Ireland.

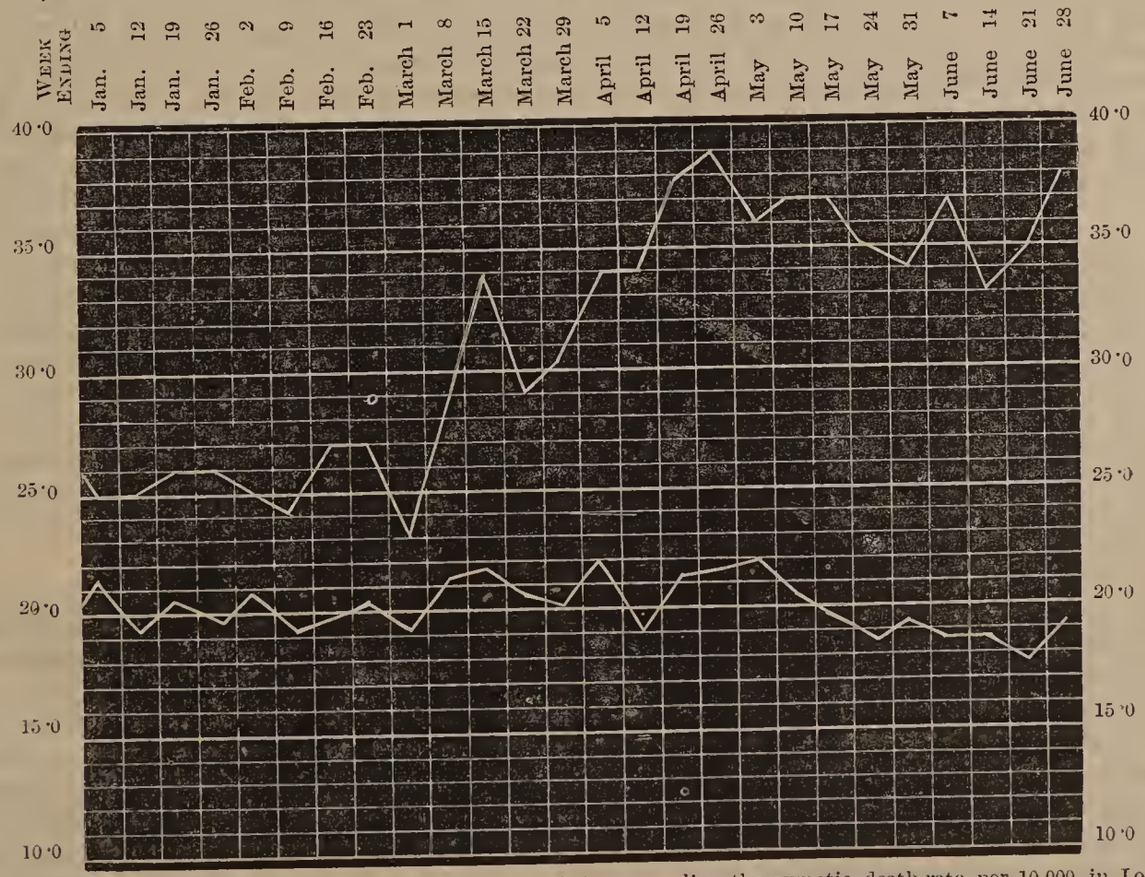
Monday this week was named for taking the Committee stage of the measure; but when, owing to the collapse of the Vote of Censure debate, motion was made to go into Committee on the Bill, it was obstinately opposed, on the ground that no one expected it could be reached, and that therefore many of the Members interested in it were absent. Mr. Mundella assured the House that he wished only to go into Committee *pro formâ*, and that Members should have ample opportunities for putting down their amendments; but the Irish Members rushed into the fray, and it was not till after very prolonged disputing, and numerous divisions, that the House was permitted to go into Committee; and that being done, progress was immediately reported.

An important Conference of Delegates from the Irish Corporations, and from certain of the Scottish Corporations and Universities, and the Royal College of Surgeons of England, took place in London yesterday (Thursday). The Conference was attended by Mr. Marshall, Mr. Cooper Forster, and Mr. Trimmer, representing the College of Surgeons; Dr. William Moore, President of the King and Queen's College of Physicians, and Dr. J. W. Moore, Registrar of that College Dr. Edward H. Bennett, President of the Royal College of Surgeons in Ireland, and Dr. Jacob, Secretary of Council, together with Drs. Kidd and Barton, Professor Struthers, of Aberdeen, and Dr. McVail, of Glasgow. The Conference unanimously agreed to support Sir Lyon Playfair's amendment as to the appointment of Coadjutor Examiners at Final Examinations to be held by the Licensing Bodies recognised by the Bill, in lieu of the Final Examination of the Medical Boards. It was further agreed to recommend that the Irish Medical Board should be formed of an equal number of representatives from each of the four Medical Authorities recognised by the Bill, and that the representation of the Scottish Corporations on the

Board for Scotland should be increased from three to five members. It was also arranged that amendments should be sought for, giving to the Irish and Scottish Divisional Boards three representatives each on the Medical Council. To make room for these two new members it is suggested that there should be only four Crown nominees instead of six. By a majority of votes it was agreed that the direct representatives in the Medical Council should be *ipso facto* members of the respective Medical Boards. A Scottish amendment, that all mention of undergraduates should be omitted from Clause 36, was adopted, as was also an amendment of the Irish College of Surgeons, providing for an assessment out of the Medical Council Fund for the maintenance of libraries and museums and the public purposes of the Corporations. Lastly, an important proposal of the Irish College of Surgeons was adopted, to the effect that students at the time of their matriculation should associate themselves with a medical authority recognised by the Bill, passing sessional examinations held by that body, or some kindred University or College.

The number of deaths registered in London last week was one above the average, and the death-rate rose to 19·1, having been 17·8 in the preceding week. The deaths from zymotic diseases, 292 in number, exceeded the average by 30, and the 218 deaths from respiratory diseases exceeded the average by 4. The most satisfactory features of the return are the fall in the number of deaths from small-pox, and the comparatively low mortality from diarrhœal disorders. In the preceding return 59 small-pox deaths were recorded, and the cases in hospital were stated to number 1,316. Last week the deaths from small-pox only numbered 49, and the cases under treatment had fallen to 1,290. During the week 160 new cases, however, were admitted, so that the epidemic at present must be regarded as scotched rather than killed. Measles and whooping-cough still continue very fatal in spite of the warm weather. Last week between them they killed 158 persons, 58 of whom were under one year old, and 93 between the ages of one and five.

The present weekly return ends the half-year, and we append a graphic representation of the health of the metropolis during that period. It is unnecessary to say much in explanation of it. For the first two months of the year, both the general death-rate and the zymotic death-rate were remarkably low for the time of year, but the first three days in March were cold, and the result was at once seen in a marked rise in the deaths from respiratory diseases, and from those zymotic diseases which mostly occur through the respiratory organs. The fatal prevalence of measles and whooping-cough, once started has persisted up to the present. In the first quarter of the year there were respectively 549 and 1,104 deaths from these diseases in London; in the second quarter the numbers were 1,024 and 1,296. The total number of deaths in London from zymotic disease was in the first quarter 2,699, in the second quarter 3,687, or nearly 1,000 more, just two-thirds of which is to be accounted for by the greater fatality of the two diseases we have mentioned. The general death-rate of the first quarter was 20·4 per 1,000; that of the second quarter 19·9. The former is comparatively much the more favourable return; for while the death-rate of no recent first quarter had been less than 22·1, the rate for the second quarter of last year was 19·5, or 0·4 less than the rate



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the first half of the present year.

for the second quarter of this year. The most favourable feature of the health of the past half-year is, that there have been no upward leaps of the general death-rate,—such as have been not uncommon in the corresponding portions of preceding years. The health of a community ought above all things to be equable, and the line of its death-rate should be like an undulating plain—without peaks or abysses.

Two Conferences were held at the International Health Exhibition on Thursday and Friday in last week, under the auspices of the Social Science Association. Mr. F. S. Powell read a paper dealing with the indications for further sanitary legislation in extra-metropolitan England. He showed the necessity for consolidating certain local Acts, and applying them to the country generally, and advocated the enactment of further sanitary reforms, including a measure providing for the notification of infectious diseases. Mr. H. Collins, who dealt with the measures essential for the maintenance of healthy dwellings, took a somewhat different line, and deprecated over-legislation. The thing to aim at was, he thought, improved administration, including uniformity both in area and mode of action. The papers were followed by discussion. On Friday Dr. J. H. Bridges read a paper, entitled, "What, if any, restrictions in the interests of health should be enforced in connection with the employment of girls and women in workshops and factories?" He recommended that the employment of women for six weeks after childbirth should be prohibited, but thought the extension of the Workshop Act to domestic industries impracticable, the machinery of inspection being already applied as far as was safe, possible, or expedient. The remedy for undoubted evils must be sought in other directions, viz., first, an extension of women's unions, and, secondly, an improved state of public opinion, leading every one to refrain from purchasing articles for which there was reason to believe the maker had not been fairly paid. After the Conference, Surgeon Major Evatt gave a lecture on "Ambulance Organisation in War and Peace."

We are glad to see that the Council of the Royal College of Surgeons have been induced by the Poor-Law Medical Officers' Association to make a strong representation to the President of the Local Government Board with regard to the grievances of the Poor-Law Medical Officers. Their letter, ratified at the last Council Meeting, points out that the Poor-Law Medical Officers' Superannuation Act of 1870 recognised the expediency of making provision for superannuation allowance to those medical officers who had faithfully and for long periods discharged their duty to the State; but the Act was permissive, and Boards of Guardians were allowed to exercise the power thus given *at their discretion*. Thus it arose, as the Council have been credibly informed, that "aged and indigent members of the profession, after holding office for periods varying from twenty to forty years, have been refused by the Board which they have faithfully served any superannuation allowance whatever. In some instances the refusal has been accompanied by an offer of the workhouse or out-door relief." Hence the Council most earnestly press the consideration of the subject on the attention of the Local Government Board, and solicit its aid in remedying an obvious and serious hardship to certain members of the medical profession. They urge the Local Government Board to make full *enquiry* into the particulars of all cases in which refusals to grant superannuation allowances to retired medical officers have taken place; and also to consider whether, by the issue of a *memorandum*, founded on the results of such enquiry, some influence could be brought to bear upon guardians or other like authorities, to guide them in the just and expedient exercise of their function of granting these allowances. In the event of this end being unattainable except by more stringent means or *compulsory legislation* the Council would beg the Local Government Board to intervene, so far as they can, to promote by such means as they may think fit the placing of Poor-Law Medical Officers, on their retirement or superannuation after efficient and honourable service, under such *conditions of security* in respect to retiring allowances as now prevail in regard to public servants in the various Government departments. The Council, we are informed, are prepared to petition the House of Commons if their representations to Sir Charles Dilke are fruitless; but it is to be hoped that they will be saved from the necessity of such a step. The Government in other departments has always recognised the granting of pensions as one of the chief means of securing faithful service from its officials.

The Health Report on the Borough of Birmingham for the year 1883, compiled by the Medical Officer, Dr. Alfred Hill, is, as usual, full of valuable information connected with the sanitary history of the past year. Not the least interesting feature of this Report is a carefully arranged disease map, showing the distribution over the town of the deaths from the three diseases—measles, scarlet fever, and typhoid. Notwithstanding the unwelcome presence of both small-pox and scarlet fever during the year under notice, Dr. Hill records that, like each of the four preceding, it is one of a series which claim, compared with their immediate predecessors, a large saving of life. This, he thinks, points to the beneficial results which accrue from the vigorous prosecution of sanitary measures; but it should be borne in mind, he adds, that the recent cool summers and mild winters have exerted a highly favourable influence on the public health, and have caused the improvement recorded in the health of Birmingham in recent years to be greater than it otherwise would have been.

Spennymoor, a small village in the neighbourhood of the Whitworth Collieries, in Durham, has lately succeeded in attracting the attention of the Local Government Board to its misdeeds in matters sanitary and otherwise, and a report from Dr. Parsons is the result. One point by which Spennymoor is distinguished from most urban districts is by its high death-rate, which is mainly due to the excessive mortality among children. The proportion of children who die in their first year

is a third greater in Spennymoor than in England and Wales. Amongst the causes of this high death-rate in children, the following are given, viz. :—the feeding of infants on artificial food from their birth ; the gossiping and drunken habits of the mothers, who spend a large portion of their time in each other's houses or in the public-houses, the children being meanwhile left to the tender mercies of perhaps a girl of eleven or twelve, or else left to play about on the doorstep by themselves. Many of the women too are in the habit of taking opium, which cannot but be injurious to the infants at the breast. The last cause suggested is the most serious of all ; it is that the burial club system is responsible for many of the deaths. The only way to meet this, as it seems to us, is that in the event of the death of a child insured in one of these clubs, the doctor's bill and the funeral expenses should be paid by the club, but the parents should not be allowed to receive any money directly in respect of such death.

Our Edinburgh correspondent writes :—The inaugural meeting of a "White Cross" Society, connected with the University and Extra-Mural Medical Schools, was held on Friday the 27th ultimo, in the surgery class-room, Professor Crum-Brown in the chair. This society is founded on the lines laid down by Miss Ellice Hopkins, in her recent lecturing tour here ; and it may be commended as a well meant, though as yet untried mode of attacking the "social evil." It can scarcely be said that the attack has been made any less easy by the repressive measures adopted by the municipal authorities here during the past five years. Driven from their former haunts, the "unfortunates" have been scattered here and there over the city, and in many cases the working man, tempted by the high rent offered for his spare apartment, has given shelter to those whose coming and going among his children can only be followed by peril and disaster to them.

The success of the Edinburgh Students' Union becomes daily more secure. The idea was mooted shortly before the Tercentenary Celebration, and was actively taken up by the Students' Representative Council. Since then a considerable portion of the necessary capital has been subscribed, and a general appeal for funds is about to be made, bearing the imprimatur of the Chancellor, and other dignitaries of the University. The scheme was at first regarded somewhat askance by those in high places, but since then a new view has been taken of it by some of them, and the present appeal is the result.

The Final Oral Examinations at Edinburgh are in full progress. The number of candidates is greater than ever, and judging from the lists, the rejections are bearing a more healthy proportion to the passes than they were accustomed to do formerly. The papers on Medicine, Surgery, and Medical Jurisprudence represented the demands of a high standard ; but that on Midwifery might with every advantage have been somewhat more ambitious. That men from whom is demanded a six-months' attendance on Midwifery should be examined by a paper containing three questions, two of which might quite reasonably be asked of nurses after a few months' training in a lying-in hospital, seems rather anomalous.

The Edinburgh University Assistants' Club, a body comprising past and present assistants to the Professors in the University, has forwarded a memorial to the Lord Advocate, urging their claims to some share of the attention of the Commissioners under the Universities of Scotland Bill, at present before Parliament. The chief grounds of complaint are the unsatisfactory status they at present possess in the University, together with the inadequate amount and irregular source of their incomes. Taking everything into account it cannot be said that the request of the club is an unreasonable one. When one considers that in more than one of the important chairs in the Medical Faculty the chief part of the actual teaching is undertaken by the assistants, it can hardly be said that the pittance which they receive by way of salary is a fair return for the work they do. While they perform the greater amount of the real teaching, in the Medical Faculty at any rate, they are rewarded by a salary which would be unhesitatingly rejected if offered to an assistant in a colliery practice. The memorialists deprecate the suggestion that the salaries of the assistants should be paid by the professors, and so be regarded in the light of a deduction from the incomes of these starved beneficiaries. Yet it seems somewhat anomalous that the unexampled prosperity of the University during recent years should confer no benefit on anyone save the occupants of the chairs. It cannot be said that the teaching staff has kept pace with the increase in the number of students : there can be no doubt that the staff of some of the chairs is miserably under-manned, and it seems at least sound economy that a portion of the large sums paid in the shape of fees should go to the remuneration of those who do so much of the real teaching. Perhaps a judicious depletion of the plethoric incomes of some of the holders of some of the chairs might tend greatly to the efficiency of the latter. It is well-known that in one of the most important chairs of the Medical Faculty, the time of one of the chief demonstrators is for a large part of each day during the early weeks of the session occupied in collecting the fees and making up the class-lists of the professor, and this, too, at a time when the organisation of such a class demands more than all the efforts of a staff notoriously inadequate as regards numbers. It is to be hoped that the Lord Advocate will see fit to give the prayer of the memorial his best consideration.

A very interesting event took place in Aberdeen last Saturday, when Dr. Manson Banff and Dr. Davidson Wartle were entertained at dinner by their medical brethren on the occasion of their completion of 50 years' practice. There was a large gathering of the profession, showing how widely known, and in what high esteem both men are held in the North of Scotland. During the afternoon Dr. Manson and Dr. Davidson were each presented with congratulatory addresses.

Dr. Francis Richard Cruise, Vice-President of the King and Queen's College of Physicians, and Consulting Physician to the Mater Misericordiæ Hospital, Dublin, has been appointed Physician in Ordinary to the Lord Lieutenant of Ireland, in room of Dr. Thomas Nedley, now Surgeon to His Excellency's Household.

At their meeting on Saturday, June 28, the Provost and Senior Fellows of Trinity College, Dublin, appointed Dr. Charles Bent Ball, Surgeon to Sir Patrick Dun's Hospital, as Examiner and Lecturer in Operative Surgery, instead of Dr. Richard L. Butcher, resigned.

We are asked to state that the Committee appointed by the Clinical Society of London to enquire into the results of the treatment of spina bifida by the injection of iodo-glycerine solution are continuing their work. The Committee will be glad to receive for examination and dissection any specimens of the deformity, especially early fœtuses. Clinical histories, with careful description of the tumour previous to injection, and subsequently, will also be gladly acknowledged. Communications may be addressed to the Honorary Secretary of the Committee, Mr. Parker, 8, Old Cavendish Street, W.

The celebrated alienist, Moreau de Tours, died last Wednesday, at the age of 80. He was principally known by his psychological remarks on the effects of haschisch, and by his great work entitled *La Psychologie Morbide*, the ground-work of which is the celebrated paradox, which gave great offence at the time, "*Le Génie est une névrose*"

The Cavendish Lecture will be delivered by Mr. Timothy Holmes on Friday evening the 11th instant, at 8 p.m., before the West London Medico-Chirurgical Society at the West London Hospital. Mr. Holmes has chosen as his subject "The Medical Treatment of the Poor of London."

The annual election of Fellows into the Council of the Royal College of Surgeons took place on Thursday last. The vacancies arose from the resignations of Sir Erasmus Wilson, Mr. Holden, Mr. Gay, Dr. Humphry, and Mr. Thomas Smith. Of these Mr. Smith alone sought re-election. Owing to the activity which Fellows and Members have been shewing with regard to College management, the polling was looked forward to with some interest. Nevertheless, only about 277 voters were present, and of these five were disqualified by reason of irregularity in filling up the voting papers. The following is the list of candidates, together with the number of votes recorded for each :—

Mr. Lawson	158,	including	2	plumpers.
Mr. Durham	154	„	8	„
Mr. T. Smith	152	„	6	„
Mr. Berkeley Hill	127	„	3	„
Mr. Allingham	108	„	8	„
Mr. Pemberton	103	„	6	„
Mr. Gant	77	„	2	„
Mr. Cowell	55	„	5	„
Mr. Barwell	51	„	1	„

The five first-named were accordingly elected. It is a matter for regret that Mr. Pemberton, the only representative of provincial Fellows, was not elected. We fear that no alteration of the by-laws will secure adequate representation for them, unless they take some little trouble in the matter themselves. In the evening the usual dinner took place at the Albion Tavern, Mr. Lund (of Manchester) in the chair.

On Thursday afternoon the President of the Ophthalmological Society entertained a large number of the members at luncheon, and subsequently there was a meeting of the Society at Chandos Street, when papers were communicated by Mr. Nettleship, Mr. Lawford, Mr. Adams Frost, and the President. We are obliged to defer our report of the meeting, and any comments on the papers until next week.

THE MEDICAL TIMES.

With the present number of the *Medical Times*, which will be sent to every practitioner whose name is in the "Medical Directory," we begin the second volume of our new series. We appeal with confidence for the support and sympathy of the profession. The experience of the last six months has proved that there is ample scope for a journal conducted on the lines on which the *Medical Times* is conducted, and we are assured on all sides that there are many readers who take the warmest interest in its progress. It is unnecessary to dwell on the principles which actuate the management of the journal. It is sufficient to say that it claims and strives to represent—with honesty, independence, and single-mindedness—the best thought of the profession. It tries to deal faithfully with the many difficult problems that are presented to it, without reference to personal interests or professional prejudice. It does not expect in all cases to carry the whole profession with it, or to uniformly secure the approval of its contemporaries. But it does strive to write so that it shall never have cause to regret what it has written. During the past six months every effort has been made to improve the arrangements for securing fresh and accurate intelligence of the progress of medicine in different parts of the world. The number of correspondents in the chief cities has been largely increased, and care has been taken that the substance of all important articles published in foreign medical journals shall be presented to the reader with as little delay as possible. In the department of clinical work, the aim has been to secure careful records of representative and interesting cases, and, in the series of Clinical Papers, to deal with important problems in such a way as to stimulate thought. The importance of making every part of the journal equally interesting and readable has been and will be fully recognised, and the efforts of the staff will be sufficiently repaid if what they have thought worth writing is thought by others worth reading.

THE MEDICAL ACT AMENDMENT BILL.

The adjourned debate on the second reading of the Medical Bill, if it can be called a debate, was resumed on Thursday se'nnight, and was very soon finished, and the bill read the second time. No serious opposition appeared to be offered to the measure, and the discussion was rather a friendly conversation, interspersed with a few criticisms, than a debate. Sir Lyon Playfair, speaking as a representative of Scottish Universities, objected that if the final examinations are to be conducted by the new Medical Boards, the examining bodies in the United Kingdom will be increased instead of being decreased in number; and he suggested that the Boards might be authorised to send as many assessors as they may think fit to co-operate in the final examinations of the Universities and of the Corporations that may be willing to receive them. Should those bodies not be willing to admit assessors from the Boards, then indeed the examinations must be conducted by examiners appointed by the Boards, but he thought he could answer for the willingness of the University of Edinburgh and the other medical authorities in Scotland to accept the presence and co-operation of assessors from the divisional Board, rather than that candidates shall be burdened with the additional expense and harassment of a double examination. It is difficult to believe that Sir Lyon Playfair can intend to press such a change in the character of the Bill as he has thus suggested, or that Government can entertain it for a moment. If the system of assessorship that he proposes is yielded as regards the final examination of any licensing body in the United Kingdom, it must be permissible also in respect of all the licensing bodies in the three divisions of the kingdom; and thus one of the objects which the Bill is most especially intended to aim at—the attainment of an approximation to uniformity of standard for the final examinations—would be made more difficult than ever, if not simply impossible. We do not believe that the presence and co-operation of a few assessors from a Medical Board would be able to influence in any appreciable degree the results of the final examinations of a licensing body; and moreover, the system sketched by Sir Lyon Playfair—we do not find that he has distinctly formulated it yet as an amendment—would be impracticably cumbersome, complex, and expensive.

Colonel King-Harman has given notice of an amendment, to give the Corporations in Ireland equality of representation on the Medical Board with the Irish Universities. At present each of those Universities is granted four representatives, while the Corporations are given only three each; and the proposed amendment will take away one representative from each of the Universities. This amendment is supported and urged by the King and Queen's College of Physicians; and there is much to be said in its favour. It seems absurd to give the Royal University, which is only an examining body of mushroom growth, equal representative power with the University of Dublin. The King and Queen's College is a teaching as well as an examining body, and Government has already made so many changes in the constitution of the Irish Board, that they may very well gracefully yield the disputed matter, and make one change more. But the next amendment formulated by the King and Queen's College is a much more serious one. They propose to enact that the Medical Council instead of the Medical Boards shall frame the schemes for the final examinations, and for securing equality of curriculum, standards of examinations and fees; and they propose a very lengthy new clause in the Bill and various amendments for effecting this change. They urge that the principle of entrusting the duty of framing rules and schemes for examination, &c., to the Medical Council alone was recognised in the Medical Act Amendment Bills of 1870, 1878, 1879, and 1880, and that the Medical Bill of 1878 was specially amended in that direction. But a good deal has taken place since then; the Royal Commission on Medical Bills has, for instance, been appointed, and strongly recommended the establishment of the Medical Boards; and it can hardly be seriously expected that Government will consent to accept any part of this amendment. The College further propose to add to Clause 36 of the Bill words providing for the application of a portion of the surplus of the Medical Council fund to the payment of "expenses incurred for public purposes by any Medical Corporation of the United Kingdom in connection with the examinations." This is one of the minor details of the Bill with respect to which Government may be inclined to accept amendments, in order to conciliate opposition. Finally, the College strongly object to the privileges that the Bill grants with regard to the fees to be charged by each Medical Board for its final examination, to university graduates, and undergraduates; but they are willing that the proposed privileges shall be accorded to graduates in Arts, and to undergraduates in Arts, qualified to obtain degrees in that faculty. This amendment again is one that, if it is pressed, the Government may fairly be induced to accept. Deputations from Scotland and from Ireland have during the week had interviews, we believe, with Mr. Mundella, to press upon him the various amendments that they desire to make in the Bill; and we have elsewhere noticed the important conference held on Thursday by representatives of English, Scottish, and Irish licensing bodies as to what changes in the measure shall be unitedly urged. From these facts, and the numerous formulated amendments we have noticed, it is clear that the opposition to the Bill as it now stands will be much more serious than was shadowed forth during the discussion on the second reading. But though it may be expected that Mr. Mundella will be as generous and conciliatory to his opponents as possible, in order to aid and speed the passage of the Bill, it is, we take it, quite certain that he will not yield to any alteration of the essential provisions of the measure.

CHOLERA PROSPECTS.

A cholera scare recurs with such regularity every midsummer, that most sensible persons have ceased to attach much importance to these cries of alarm; but we must confess that this time it does not appear to be so devoid of foundation as on many previous occasions. Of course, all depends on whether the present out-

break at Toulon is cholera or not. We object to the word Asiatic, since it begs the question of its origin by assuming that it cannot arise *de novo* elsewhere, which we are by no means prepared to maintain, although we hold it to be a specific disease as distinct from diarrhœa in general, as enteric fever is, and although its spontaneous origin in Europe has not as yet been proved, while its importation, directly or indirectly, from Asia has been again and again. It may, and so may enteric fever, be remotely evolved from the same elements as the diarrhœas, but while the latter are sure to make their appearance wherever sewage-sodden soil, and tainted water are brought into a state of active putrefaction by such a high temperature as we are now enduring, or enjoying, they are not transportable to places where such conditions do not exist. Whereas cholera certainly is, although it will never take a firm hold of a community whose surroundings, especially the water supply, are of the best. Herein lies the difference, herein the danger and the means of escape.

We do not know anything personally of the sanitary condition of Toulon; but if all we read and all we hear is true, there can be no doubt that all the conditions exist there for the production of an epidemic of virulent septic, or, to revive Murchison's useful word, pythogenic diarrhœa. Such epidemics may follow in other towns under like conditions but otherwise quite independently of the original outbreak: thus it is by no means certain that the cases at Marseilles had anything to do with those at Toulon. But if it be the true cholera, it will slip through sanitary cordons, evade the paper quarantines of Italy and Spain, and make its appearance in those towns in most frequent and direct communication with that where it has first effected a landing. If the ground be saturated with organic matter, and swarming with bacteria of various kinds, the water contaminated with sewage, and the air of the streets stagnant and tainted, it will find a rich soil and carry off its victims by hundreds; but if we set our houses and towns in order, jealously watching over every conceivable pollution, our positions may be attacked, but the enemy will either fail to effect a lodgment even for a day, or we shall be able to repulse him with but trifling losses. At the same time we trust that strict supervision will be exercised over all suspicious shipping, for though sanitary cordons on land are utterly futile and quarantine by sea not always effective, our insular position and distance by sea from the usual points of departure of cholera, the Mediterranean and Baltic ports, give us no small advantage, and render "blockade running" by infected craft less easy than it is among narrow seas and adjacent islands.

THE MEDICAL BILL.—A petition from the Foreign Graduates' Association of Great Britain, signed by Dr. H. J. Hardwicke, president, has been presented to the House of Commons by the Right Hon. A. J. Mundella, in favour of admitting to the register all foreign degrees obtained after examination and before the passing of the new Medical Bill by duly registered practitioners, and also protesting against any attempt being made to modify Clause 69 in a sense prejudicial to the holders of foreign degrees.

SUMMER'S MIGRANTS.

THE placarding of tourist arrangements at the railway stations and a perceptible flavour of *Bradshaw* in the world's daily conversation, advertisements of yachting costumes, and of guide-books to all places under the meridian or the midnight sun, warn us that the period of the wholesale exodus from home and the replenishment of sea-side lodgings, of fresh trials for paterfamilias and of the yearly triumph of the landlady is upon us It may therefore be pertinent to glance at the *raison d'être* of this annual ebb and flow of holiday taking humanity, and to consider how far the means commonly adopted are calculated to attain the end which is ostensibly in view.

Man is, by inheritance probably, a migratory animal. If we accept the suggestion of Sir James Paget that his love of field sports and other forms of out-door recreation is a survival of the habits of savage ancestors whose life was necessarily mainly a hunting one, we may also be allowed to trace the periodical yearning for change of air and of locality to which few are insensible, and which in spring and summer affects some people with a passion almost irresistible, to the fact that our forefathers once lived for generations under conditions which compelled them from time to time to shift their homes in accordance with the altered conditions upon which their livelihood depended. During summer, regions were habitable and stocked with game which in winter were bare or inaccessible, and man's migrations were mainly determined by the difficulty which he experienced in providing himself with food and shelter. As the race became more civilized, and as individuals learned to bend and shape Nature to their needs, the necessity of following her lead in all things became less imperative, until the dwellers in permanent towns, furnished with provident store and shelter against the rigour of winter, secure of shade from the summer's heat, and with more or less power of obtaining supplies from a distance, became able to defy the tyranny of her seasonal compulsion. But the root of the old race-habit would still remain, ready to bloom vigorously once more on the recurrence of conditions such as those which originally favoured its acquirement, and even making itself felt, now and again, under circumstances in which we might have least expected to observe it. So the tourist hurrying to the lakes in a tweed suit is but an unconscious reproduction of his Celtic forefather in woad; the school-boy with his realistic visions of running away from home and discovering a desert island, is only passing through a developmental stage corresponding to an important epoch in the early history of his race; and it may be that those rolling stones of humanity whose persistent vagabondage it is our custom to deplore are merely extreme instances of reversion to the type of an ancient and respectable, if nomadic ancestry. The rapidity with which the custom of an annual summer visit from home to the seaside—one, in its present form, of such recent growth—has gained and increased its hold on public favour, points to its being the revival, or modified survival, of an old habit rather than the institution of a new one. The hurry of modern life, necessitating alternative periods of com-

parative repose as a set-off against the spasmodic expenditure of energy at high pressure, justifies the principle; the increased locomotive facilities of the age have rendered it more feasible; and, finally, fashion has chosen to endorse it and has labelled it a social duty. This last item is, indeed, the most unsatisfactory part of the business. The health-value of what is popularly called "going for a change" depends, like that of all recreation, mainly upon the degree of spontaneity with which it is undertaken. Once divest the process of its birthright of pleasurable free-will, and substitute for that the rigid dictum of fashion, and you might as well replace the exhilarating gallop across the breeze-swept downs by an hour's compulsory exercise in the treadmill; not only must the specified road be taken, but it must be travelled after a particular style; choice and freedom must be drilled into uniformity; fashion would drive her votaries in a rut and deny their right to the king's highway.

To those who take their pleasure wisely, a holiday is careless only in the best sense of that word. A certain amount of thought expended in the consideration of time and place and method is always well repaid. The wearied brain-worker needs change of scene and of occupation far more than does the handicraftsman and in a different way; a man's natural tastes, in things that is, which do not form a part of the business of his every-day life, may be consulted with advantage; but to exchange bustle for mere idleness, or the stereotyped fatigues of the London season for the stereotyped gaiety of a fashionable watering-place, is to burlesque the restorative methods of true holiday making. People of nervous organization, and the comparatively feeble in health of course do wisely to avoid long and tedious journeys, and scenes involving much excitement, in fact, any inducements to mental or bodily fatigue. The air of sea-side places, dense with watery vapour, is a most powerful agent in abstracting energy in the form of heat from the human body; and those who are deficient in vital force, frequently find themselves improving more rapidly in health on elevated plateaux, where the rarer air, even though colder than that of places at a lower altitude, is far less chilling and exhausting.

Just as children are often greatly benefited by the change from an inland home to the seaside, so not a few are made to suffer by the heedless way in which the fashion is apt to be enforced on all. In the absence of any special indication to the contrary, we may safely say that the infant is always best at home. The desirability of change for older children will vary with their individual temperament, with the natural conditions and surroundings of their home life, and with their state of health for the time being. We would not leave out of consideration the good moral effect of change of scene upon children, provided they are old enough to appreciate it, and not so sensitive as to be over-stimulated by it; but, putting this aside for the present, we may say at once that there are some families of children so fortunately situated that they really do not ordinarily need a change at all. Those, for instance, whose home is by the river side, in a wooded valley, but who, by a twenty minutes' walk, can reach the broad expanse of moorland, where the air is redolent of furze and heather, and charged with the crisp energy of the not distant sea, may obtain all the most bracing effects of change of air on an average at least every other day throughout the year. And for others whose daily surroundings are less perfectly contrasted, it is desirable that a wise method be observed in the choice of the time no less than of the place of the annual outing. No small proportion of the children who will soon be in temporary possession of a large section of our coast-line will have come from homes in or on the very borders of the country. But to leave the country when the country is at its best, while the woods are still unfolding their delicate drapery, when the hay-fields are in their glory, and before the later summer drought has dimmed the green freshness of the hedgerows, is surely a wanton sacrifice of some of the season's most enjoyable bounty. A month or two later, when vegetation has begun to fail and the leaves to turn; when a mist rises at sunset, and the dew lies long on the grass in the morning shadows, is the time to choose for the change to the seaside; taken then, it adds some weeks to the pleasantest memories of summer, while it restores and fortifies the system against the fogs of autumn and the raw asperities of degenerate winter weather. There are many other details which merit consideration. It would often be better for a family to rent a farm-house or cottage in the country—perhaps at but a short distance from their own home—rather than incur all the trouble, worry, and fatigue which a long railway journey to the coast entails upon young children. In any case it is, of course, to be understood that the sanitary condition of the temporary home and of its neighbourhood should be at least as good as that of the permanent home always ought to be. If "sending the children to the sea" is merely to result in their being monotonously promenaded in faultless attire along the esplanade of some fashionable watering place, it is only making a pretence of doing that which had better, under such circumstances, be left unattempted. On the other hand, to crowd half-a-dozen young children together with their nurse and parents into a stuffy railway carriage for an eight or ten hours' journey to a place where they will be packed into lodgings of dubious salubrity, without provision for amusement within doors during bad weather, and with the prospect of a necessary repetition of the wearying journey on the way home, is to seek health for them neither wisely nor well, and in the face of conditions which she is apt to shun.

CLINICAL PAPERS.

XIV.—Graves's Disease.

Notwithstanding the fact that upwards of half a century has elapsed since this disease was first recognised, and that since then it has been the subject of many papers at the hands of various and eminent writers, the fact remains that if a student of the present day is asked in an examination what is the pathology of this disease, he would be quite justified in saying he did not know. He might afterwards qualify his answer by a description of the various theories which from time to

time have been put forward, but no objection could be taken to his assertion that the pathology of the disease is still unknown.

One obvious conclusion from this fact is that the disease is not of an inflammatory nature. Had it been so it would seem impossible that it should so long have eluded the keen and penetrating eye of the histologist of modern times; for at present, although changes have been described in the cervical ganglia of the sympathetic, and by some observers in the central nervous system, others equally competent have been unable to detect similar changes when they have had the opportunity of looking for them. We have used the word inflammatory as we believe advisedly, for, putting aside for the moment all new growths, the only lesions that the microscope reveals to us are more or less inflammatory in their origin or nature. There are many diseases to which a similar line of argument might be applied, such as epilepsy, chorea, and the like. But it is not so much the object of the present paper to discuss the nature of the lesion as to endeavour to indicate its probable seat, and from this point of view it matters not whether it be inflammatory, or due to some unknown molecular disturbances possibly reflex in their origin.

Although there is a great deal to be said against the custom so prevalent in other countries of naming diseases after individuals, there is always this to be said in its favour, viz.: that it involves no theory as to the cause of the disease. To us it has always seemed that the name exophthalmic goitre might in some respects be held responsible for the deficiency of our knowledge of the disorder under consideration. It is true that the name does not imply any expression of opinion as to causation, but it tends to narrow our conception of the disease by seeming to throw undue stress on what are after all only two very striking features of it, neither of which is absolutely necessary to the diagnosis.

Until a few years ago it was commonly taught and generally accepted that palpitation, with increased frequency of the heart's action, enlargement of the thyroid gland, and prominence of the eyes, were the sole manifestations of the disease. And in a general sort of way it was held that these phenomena indicated something wrong with the sympathetic ganglia in the neck; for it was a matter of general knowledge that filaments went to the heart from one of these, and that branches from all of them were distributed to the blood vessels in the neighbourhood. It was not necessary, nor, indeed, quite convenient, to inquire whether the symptoms were due to irritation or paralysis of the sympathetic; nor, where these were surmised to co-exist, was it satisfactorily explained how the same lesion could be at once irritative and paralytic. And even when these difficulties had been partly argued away, it still remained necessary to explain how an irritative lesion could be an abiding one.

A wider view, however, is now taken of the disease, and it is shown that the heart manifestations are but part of a wide-spread disturbance of the vascular system as evidenced by the general loss of tone in the arteries throughout the body, seen in the flushing and perspiration which are so common and sometimes so annoying to the patient. Amongst other manifestations which cannot well be explained on the hypothesis of disorder of the cervical sympathetic, may be mentioned the febrile condition, the attacks of diarrhœa to which these patients are liable, quite apart from any dietetic indiscretion, the hyperæsthesia of the legs, and a symptom to which attention has but recently directed, but which will escape notice unless especially looked for, viz., a very fine tremor of the hands. All of these may be attributed to disturbed vaso-motor innervation and they are not to be regarded as complications, but rather as the perfectly natural result of the disease. They point clearly to one of two things, either to a general disorder of the sympathetic system throughout the body, or to some central lesion influencing the vaso-motor centre in the medulla oblongata. Besides the generally accepted belief that symmetry points to central disease, there are some considerations in reference to the heart which suggest strongly the latter conclusion to be the correct one. It has been shown by physiologists that paralysis of the vaso-motor nerves, by allowing the vessels to dilate too much, would undoubtedly increase the frequency of the heart's action, and would also increase its blood supply, and that irritation of the accelerator nerves of the heart would also cause palpitation, so that there is no need of advancing the hypothesis of paresis of the vagus; but a recent writer has brought forward some facts which, nevertheless, suggest very decidedly that paralysis of the vagus does play a part in producing the well-known condition of the heart. After giving some evidence that it is the right vagus, and not the left, that supplies the cardiac branches, he shows that in cases where the exophthalmos is unilateral, if it be on the left side only, there have been in some cases no heart symptoms, but if on the right side only, heart symptoms were always prominent. If subsequent investigation should confirm the correctness of these observations, the conclusion that paralysis of the vagus plays an important part in the production of the heart disturbances will be irresistible, and an almost final argument will have been gained in support of the theory of the central origin of the disease.

H

REVIEWS AND NOTICES OF BOOKS.

A NEW BOOK ON THE HEART.[1]

Among the host of text-books and monographs which come now from the medical press, it is thoroughly gratifying to occasionally find some which do not bear obvious marks of being written either to order or for the mere sake of writing. Neither inaccuracy nor airing of crotchets, two faults which so largely disfigure our literature, can be charged against the work which is now before us. Those who have read Dr. Bramwell's previous book on the spinal cord would rightly expect to find the result of careful labours set forth with systematic clearness in anything that came from his pen; and they will not be disappointed in their perusal of this treatise on the diseases of the heart.

[1] Diseases of the Heart and Thoracic Aorta, by Byrom Bramwell, M.D., F.R.C.P.E. Edinburgh: Young J. Pentland, 1884.

Although this book deals systematically with the subject and therefore contains much that is to be found in other works, especially in those of Walshe and Sibson, it has two characteristics which entirely preclude the objection that it is superfluous, and, moreover, give it a right to rank among the most useful of English text-books. In the first place the matter is arranged with great clearness and the style is particularly intelligible, being neither redundant nor over-condensed. In the second place, there are signs throughout the work that it is not simply a careful compilation, but that the author has thought out for himself the problems he discusses, and has made the subject his own by assiduous work, both clinical and pathological. We can well believe what the author states in his preface, that he has been "constantly thinking and talking about the subject, and steadily accumulating the material necessary for the production of such a work."

The first chapter is devoted mainly to cardiac physiology, with especial reference to its practical application by the physician. Here the author, unlike too many writers, has wisely kept out of his pages unnecessary details which can be found in their proper place in works on anatomy; and, in his physiological sketch has concisely given the results of the latest researches on the nervous supply of the heart, and the probable functions of its various factors; making especial use here of the writings of the Cambridge School of Physiology. In the next chapter a *résumé* is given of the general pathology of the heart both in its structural and functional aspects; and the third chapter deals with general symptomatology and the methods of physical examination. Here we have an excellent formula for case-taking given at length; and a perhaps over-elaborate discussion of the manner of production of that form of dyspnœa known by the composite name of "Cheyne-Stokes." Throughout this chapter Dr. Bramwell insists on the frequency of cardiac lesions existing at least for a considerable time without obvious symptoms; a fact which, though widely known, is often forgotten by teachers and students, as evinced by the frequent practice of treating a cardiac lesion on the ground of its discovery alone. A clearer exposition than we find here of the various causes which may account for abnormalities in physical signs could not be wished for; it is in fact so full and clear that the reader is thereby almost saved the trouble of thinking for himself. There is perhaps a tendency here and there on the part of our author to an explicitness almost amounting to tediousness, but this is doubtless a fault on the right side, and will be welcome at least to beginners. The statement, however, that the syllables *lupp dupp* "give a very good idea of the normal character of the cardiac sounds," we certainly cannot endorse; nor do we think that Dr. Bramwell has amended matters in this instance by changing our old friend *lubb*, which has done such long, though questionable service, into the still more useless *lupp*. How the same consonants can be said to represent the termination of the two sounds of the heart our ears at least cannot explain to us; but the matter is of less importance than text-books usually give to it. The numerous diagrammatic representations of the murmurs will be found useful, and not the least, because often ignored that of the mitral murmur which is heard during the diastole but is not strictly præ-systolic. In this context of murmurs, we could wish that the author had omitted the first word from an apparently favourite phrase of his, viz., "The *differential* maximum intensity of a murmur," this word being most often superfluous as he uses it, and apt to cause some obscurity. A very full discussion of the views of various authorities on the so-called functional murmurs, especially those occupying the pulmonary area, leads the author to the conclusion that the generally accepted, or "purely pulmonary" theory is the most probable; but he touches very lightly on the *rationale* of the explanation he espouses. The question of the anæmic murmur, though presenting but little clinical difficulty, is always a pathological bugbear to writers and teachers, and like many other questions of purely vital mechanism will perhaps never be set at rest. The author is probably perfectly right in the view that he takes, but his successfully destructive criticism might with advantage have been somewhat shortened.[2] This chapter ends with a clear and sufficiently full description of the examination of the pulse, and a well and numerously illustrated exposition of the use of the sphygmograph.

The subject of pericarditis is well handled by Dr. Bramwell. Its morbid anatomy is extensively illustrated by drawings, and its diagnosis plainly set forth with the aid of differential tables which will be the delight of examinees. The frequent clinical relationship of pericarditis to pneumonia is, however, not sufficiently brought out, and indeed is but just hinted at under the heading of secondary pericarditis due to inflammation or new growths in adjacent organs. Whether or not there is most often a "rheumatic" nexus between pneumonia and pericarditis, the concomitant or sequent occurrences of these two inflammations should be specially pointed out in a work of this importance. Due stress is laid by the author on the very frequent involvement of the muscular substance of the heart in pericarditis, a fact known to many observers and especially insisted on by Sturges, but too frequently overlooked. The similar involvement of the myocardium in endocarditis is also well pointed out in the subsequent chapter on *endocarditis*, and obviously has important bearings on the great value of prolonged rest after attacks of rheumatic fever even where there is little or no evidence from physical signs of the occurrence of valvulitis. While giving the requisite weight to absolute rest in the treatment of pericarditis, our author touches on perhaps somewhat dangerous ground in recommending immersion in a cold bath even where hyperpyrexia exists, though he appears alive to the difficulty which suggests itself by advising that the patient should be at once removed from the bath "if any serious symptoms of cardiac depression arise." He also mentions, unfortunately without original comment, the use of aconite in pericarditis. The same somewhat uncertain sound as regards the treatment of heart

[2] Similar remarks would be applicable to a *brochure* by Dr. J. K. Fowler, "On the Origin of Anæmic Murmurs," just published by Messrs. Churchill, which, though giving an account of the various views on the subject, contains little of novelty save a suggestion that there may be a connection between the degree of anæmia and the appearance of the different "anæmic" murmurs.

inflammations is heard in the discussion of the administration of salicin or salicylate of soda. He advises the discontinuance of at all events the latter of these drugs in rheumatism when endocarditis occurs, on the ground of its uselessness in this complication and its tendency to produce cardiac depression. In his section on *myocarditis* he distinctly teaches that where there is evidence of this affection neither of these drugs should be given. But considering his reiterated and valuable insistence on the occurrence of some degree of myocarditis in most rheumatic affections of the heart, and the admitted great frequency of both obvious and latent endocarditis in rheumatism, the author's strong recommendation of salicin in full doses in acute rheumatism, as a prophylactic against cardiac mischief, is not in strict logical sequence with his own teaching. In one paragraph indeed there would seem to be almost a direct contradiction, where we read the words : "In the treatment of acute rheumatic endocarditis I would strongly advise the administration of full doses of pure salicin ;" were it not for the probability from what follows that the word "endocarditis" has slipped in here by a mistake, and that acute rheumatism alone was meant. And in the last place, before leaving the subject of therapeusis, it must be mentioned that some little confusion is evinced on the question of the treatment of so-called pernicious anæmia by arsenic. There is no doubt in the minds of most that arsenic is a valuable drug in many cases of obstinate anæmia ; and it was given in anæmia before Dr. Bramwell himself first publicly recommended it in the so-called pernicious form of the disease. Cases too of apparently the idiopathic form have doubtless recovered with, or perhaps owing to, the use of arsenic ; but Dr. Bramwell himself somewhat naïvely says that he has met with cases where it has failed, and that he knows of no means by which to distinguish the cases of progressive anæmia which are curable by arsenic from the cases which resist this drug. Surely then, according to the author's own showing, if the word "pernicious" means anything, or if the previous clinical knowledge of this obscure affection is not to be ignored, there is no justification for the rather sweeping statement on page 464 that many *undoubted* cures by arsenic of this previously *intractable* disease have taken place. (The italics are our own).

The chapters on the valvular diseases of the heart and the various affections of the heart-muscle itself are full and thoroughly satisfactory, and give ample evidence of careful study and extensive personal experience. It is much more easy when reviewing a book like this to pick out the blemishes which are few and far between than to emphasise its points of value which are numerous enough to recommend it as one of the best text-books on the subject for the student. The different nature of the symptoms of chronic valve disease, especially those of the aortic and mitral valves, is clearly set forth, and the indications as to treatment leave nothing to be desired. In the discussion of the whole of this very important class of affections Dr. Bramwell is perhaps at his best. The great frequency of aortic valve disease alone, as the result of affections of the vessel apart from acute inflammation, is more than once alluded to ; but it might have been stated with still more emphasis that rheumatic endocarditis but very rarely produces disease of the aortic valves alone.

The subject of cardiac neuroses is dealt with in a very short chapter, but the teaching conveyed thereby is sound, practical and clear ; and the book ends with a most valuable one on diseases of the aorta, in which good use is made of rich pathological material. The illustrations are of great merit, and cannot fail to give a vivid idea of the conditions underlying the often obscure symptoms of intra-thoracic disease. The matter of differential diagnosis is treated very explicitly here, as indeed throughout the book, forming one of its most prominent characteristics. A careful perusal of this work will well repay the student and refresh the memory of the busy practitioner. It is the outcome of sound knowledge and solid work, and thus devoid of all "padding," which forms the bulk of many monographs on this and other subjects. The material is treated with due regard to its proportionate importance, and the author has well and wisely carried out his apparent intention of rather furnishing a groundwork of knowledge on which the reader must build for himself by personal observation, than of making excursions into the region of dogma and of fancy by which his book might have secured a perhaps more rapid, but certainly a more evanescent success than that which it will now undoubtedly and deservedly attain.

On the formation of Uric Acid in Animals ; its relation to Gout and Gravel ; by P. W. Latham, M.D. Cambridge. Deighton, Bell, & Co., 1884.—Probably not many of our readers would find themselves competent to follow Dr. Latham through the elaborate and somewhat abstruse chemical problems here set forth. The outcome of it all is, if we have read him aright, that the appearance of uric acid in the blood is the result of the non-transformation of glycocine into urea. This may be, and often is, due to a sluggish liver, but this will not account for all cases of gout, for instance, for its occurrence in people not specially addicted to good living, but who have a hereditary tendency to it. Such cases would be better accounted for by the supposition of a weak spot in the medulla near the nucleus of the vagus. On this theory it would be easy to understand the association that has so often been observed between gout and diabetes. A similar line of argument will explain why mental worry and fatigue are such potent factors in bringing on an attack of gout. This hypothesis, too, affords an explanation of the fact that gout does not attack a non-predisposed individual before middle life. So long as the kidneys throw off the uric acid as fast as it is formed, not much harm comes, but when they begin to do their work inefficiently, the uric acid travels about in the blood, and finds out the weak spots in the nervous system. With considerable ability, Dr. Latham proceeds to derive support for his views from the effects of treatment, the object of the latter being of course to diminish the formation of glycocine, or if it is already formed, to get rid of it. From this aspect, the correctness of his views would seem to be well established.

A Plea for the Cure of Rupture ; by Dr. J. H. Warren. Boston : Osgood & Co ; London : J. & A. Churchill.—Dr. Warren, whose name is well known in connection with the subject of hernia, and more especially in regard to its treatment by subcutaneous injection, proceeds, in the little work before us, to consider the subject of inflammation in its relation to tissue change. Quoting from our most esteemed pathologists, he points out that "whenever artificial or pathological irritation has determined a growth of embryonic elements, if the irritation cease, this new growth always tends to return to the original form of the tissue, which

served as a matrix." His treatment consists in the injection, subcutaneously, of an irritant solution into the fibrous structures surrounding the neck of the sac, with the intention of setting up a "growth of embryonic tissue," which is to close the openings that allow the passage of the hernia. The author develops his theory with great ability, and demonstrates his practice with precision and clearness; and he appends a long list of cases, in which his treatment has been successfully practised. We have only once seen this plan tried: the syringe Dr. Warren particularly advocates was used, but the result was *nil*. On the other hand, we have now seen and practised other methods, which, perhaps on that account, seem to promise a more certain cure, and to which, for many reasons, we should give preference; with antiseptic precautions—the value of which our author appears fully to realise—a cutting operation which permits the surgeon to see what he is about, can now be undertaken almost without any risk to the patient, and we feel sure that such an operation is, in the nature of things, at all times preferable to a subcutaneous one for the radical cure of a hernia. Nevertheless, we would recommend all those who are interested in hernia, to read Dr. Warren's book which, we may add, is an admirable specimen of the printer's art.

The Pathology and Treatment of Venereal Diseases; by Drs. Bumstead and Taylor. 5th Edition. Revised and Re-written by Dr. Taylor. 139 Woodcuts and 13 Chromo-Lithographic Figures. London: H. Kimpton; Philadelphia, Lea and Sons. 1883, pp. 906.—In the preface, Dr. Taylor pays a well-deserved tribute to the memory of his former master and *collaborateur*, Dr. Bumstead, whom he compares to the "still living" Ricord in France, and to the late Sigmund in Germany, as the American "pioneer and master" of this department of medicine. We are really, therefore, concerned with a book written more or less entirely by Dr. Taylor, whose knowledge and fitness for his task may not unfairly be gauged by the great improvement which the fourth edition manifested over the third, and not less by the great improvements which have been made in the present edition, though so short an interval has elapsed since the former edition was issued. The book is very similar in scope and general arrangement to the well-known English work on the same subject by Mr. Berkeley Hill. Both are alike full and explicit in detail, and founded on a large and varied experience; such differences in doctrine as may be found being but the legitimate independence of view which two individuals may exercise in the decision of difficult or doubtful points in pathology. Thus, in the hereditary transmission of syphilis by the father, Hill believes that the mother is likewise necessarily infected; but Taylor, on the other hand, thinks that the father may transmit syphilis to his offspring "even without the infection of the mother." That two such conflicting opinions should exist on what, *à priori*, one would imagine a very simple question, is not a little curious. Another distinguished surgeon in London thinks the mother is infected, but that it is in a very modified form. Hill, on the contrary, believes that the infection taking place, runs its usual course; and if the surgeon fails to detect the initial lesion, the fault lies in the difficulties of adequate examination, and not in its absence. The chapters on hereditary syphilis are those with which we are least satisfied; they appear to us to lack the ring of personal observation which largely characterises many of the other chapters. Most of the subjects are dismissed very briefly, and, as they stand, consist chiefly of the opinions of others. Under syphilitic dactylitis, the author describes a condition which we believe to be strumous in the great majority of instances. The chapters on treatment are good. The author is a firm believer in mercury during the initial and secondary stages, and of iodide of potassium, or a combination of the two for the tertiary state.

The Cinchona Barks, Pharmacognostically considered; by Professor Flückiger. Translated, with some additional notes, by Frederick B. Power, Ph. D., with eight lithographic plates and one woodcut. London: J. and A. Churchill. It is doubtful if, in the two centuries that have gone by since the cinchona barks came into general use as febrifuges, such another signal victory over disease has been recorded in the annals of medicine. Amongst the crowd of modern remedies, the cinchonas and their alkaloids continue to claim one of the most important chapters in Materia Medica. Professor Power has done good service in presenting Flückiger's admirable monograph in the vernacular form. For Englishmen and Americans, who are called on to deal with malaria over so large an extent of the world's surface, the subject has an especial interest; and the rapid extension of the cultivation of the trees in our Eastern dominions bids fair soon to attach a very practical value to a familiarity with it on the part of army surgeons and colonial practitioners. Professor Power's translation has been made with care and appreciation; and his amplification of the author's section on the methods of assay, which erred a little on the side of brevity, has added considerably to the utility of the work. The translator's avowed aim at a literal rendering may explain, if not excuse, the occasional appearance of a dialect which is neither English nor, as we charitably believe, American.

Histological Notes for the use of Medical Students: by W. Horscraft Waters. London: Smith, Elder & Co., 1884.—A useful little book, not pretending to teach histology, but merely to put the student in the way of learning, to guide him into a systematic method of work, so that nothing shall be passed over. The book seems well adapted for the purpose for which it is intended.

ABSTRACTS AND EXTRACTS.

BILLROTH ON EXTIRPATION OF THE KIDNEY.

Operative interference in cases of renal calculus or other intractable conditions of the kidney is gradually becoming accepted as an orthodox surgical procedure. Recognising this important fact, Professor Billroth has recently delivered an address on the subject of extirpation of the kidney, which will serve to establish the operation still more firmly in its position among the recent advances in abdominal surgery. Although unable to record any striking series of personal successes, he analyses with considerable minuteness the recorded results of others. Since the operation was first introduced by Simon fifteen years ago, there have been nearly 150 such cases put upon public record. For statistical purposes, however, these are far too few to form a basis for any trustworthy conclusions. The operations themselves have varied very widely. The nature of the disease for which the operation was undertaken, and, above all, the condition of the opposite kidney, are points so vitally important in determining the issue of each case, that no general comparison of cases can as yet be profitably made.

In all new operations also, it must be remembered that many cases are unsuccessful owing to the late stage of the disease in which the radical cure is attempted. The importunities of patients clamouring for relief at any cost cannot always be disregarded, and many operations are undertaken under pressure, which would never be attempted if the unbiassed judgment of the surgeon were left untrammelled.

Of 132 cases of extirpation of the kidney, 70 recovered and 62 died. For prognostic purposes such figures are worth absolutely nothing, but at any rate, they prove that in more than half the cases it is at least possible for recovery to take place after removal of one kidney. In classifying cases for operation, a special place must be reserved for those in which the removal of the kidney is really accidental, that is, in which the tumour to be removed has been diagnosed as non-renal, or in which such a tumour has become so firmly adherent to the kidney as to necessitate removal of the whole mass. Healthy kidneys have occasionally been removed, and sometimes successfully after injury, or for the relief of incurable urinary fistul[illegible]. In one case of the latter, Professor Billroth him-

self operated with partial success, which, owing to the general enfeeblement of the patient's powers, was not maintained. In certain cases also of floating kidney, the healthy organ has been completely removed. Of 14 such operations, 8 were successful and 6 unsuccessful, partly from inanition and partly from peritonitis. Twelve of those cases were operated on through an anterior incision, and two through the loin.

Attempts at fixation of a movable kidney have hitherto failed, but in Professor Billroth's opinion, "we must not relax our efforts towards further search in this direction, and the devising of some new method of fixation, or by some other means to prevent the movable kidney from exercising a drag on the stomach. Perhaps one of these days a happy thought in this direction will occur to some one."

Extirpation of the diseased kidney may be undertaken for renal suppuration, hydronephrosis, or renal tumours. Professor Billroth himself has never performed complete removal of the kidney for renal abscess. In deciding to operate, the really important point upon which success or failure may turn, is the condition of the opposite kidney. In a few cases the establishment of a fistula and free drainage from the pelvis of a suppurating kidney may be followed by the passage of clear non-purulent urine from the bladder. There can then be no reason to doubt the health of the remaining organ. But in certain other cases, the passage of pus with the urine persists, notwithstanding such free drainage. In either case the indications are not really trustworthy, but at present no better guides can be relied upon. Looking to all these conditions, and also to the variety of mischances to which such a procedure is liable, it must be allowed that the success of the operation in 22 cases out of 40 is really somewhat astonishing.

With respect to nephrectomy in cases of hydronephrosis, it must be borne in mind that such cases have occasionally been cured without operation, and, further, that they are not of necessity fatal. The diagnosis in the first instance is beset with difficulty. "The anatomical relations of the sac of a hydro-nephrosis," says Professor Billroth, "the relation of its contents to the ureter, and the indications given by their chemical composition, in which both urea and uric acid may be entirely wanting; the diagnosis by palpation and percussion, all these are very difficult matters, and I will not go closer into them at present. Like the diagnosis of abdominal tumours in general, they form but a contribution to the history of diagnostic failures, which are ever and anon demonstrating to us, *ad oculos*, the limits of our art." Nine cases in all are recorded of the extirpation of a hydronephrosis, and of these the majority were originally diagnosed as ovarian tumours. Six were completely cured and three proved fatal.

The statistics of nephrectomy for new growths are less satisfactory. Of 33 operations, 20 failures are recorded as against 13 successes. "One can hardly wonder" (at these results) "when one reads with a shudder of what has been attempted in this direction. It seems to me that here at least one has gone a little too far." In two cases operated on by Billroth himself and not hitherto published, good recovery took place. The first case, in which a large myxo-sarcoma was removed by abdominal section, and the second in which the lumbar incision was made, may be taken as type cases of the two forms of operation. Following Czerny, with his unprecedented experience of 18 cases of nephrectomy, Billroth expresses a decided preference for the lumbar operation. Although the removal of a healthy kidney through the loin may be effected with the greatest ease in the dead subject, it is quite a different matter to remove a suppurating kidney. The most important points are the finding and properly securing of the ureter, and of the renal artery and vein. The healing of the wound does not appear to be attended with any special risks, although abscesses may occasionally form.

Nephrectomy by means of laparotomy is attended with much greater risks owing to the exposure to septic infection of the peritonæal surface. The serous effusion which takes place from the edges of a fresh wound is the fluid above all others favourable for the development of all kinds of micro-organisms, and all possible means must be employed to prevent the access of this fluid to the peritonæal cavity. Professor Billroth observes, in conclusion, that operative interference in the cavity of the abdomen can only bring relief in a certain class of cases. "It is now the task of the present day to recognise and define still more clearly the class of cases in which surgical measures are of use. If we have here and there pushed the limits of surgical benevolence somewhat too widely, we may, without discredit, retract them a little as our experience extends, but at the same time fix them upon a still firmer basis. If the surgeons of to-day will not fancy themselves to be such all-powerful fellows, but will be content to follow with modesty the example of their brethren the physicians, indefatigably investigating and combining, we may yet succeed in bringing cure, or at least temporary relief of their troubles to still more unfortunate sufferers. This is, and always will be, the ultimate aim of our common scientific and humane endeavours, and the real end and object of our noble calling."

MEDICINE.

Croupous Pneumonia in Damp Weather.—A vast amount of literature upon the subject of acute pneumonia has been published during the last twenty years. So vast indeed that it might well be supposed that the last instructive word must have been uttered a long time ago, and that the writings of to-day can only contain oft-repeated facts clothed in a varied form of literary dress. A recent paper by Dr. A. Seibert, of New York (*Berl. Klin. Wochenschrift*, No. 18, 1884), however, attacks the very difficult question of the influence of the weather upon the occurrence of the disease, and brings forward certain considerations which have received but little attention in most of the standard text-books and special treatises upon this subject. Sudden changes of temperature, and the prevalence of certain winds at various seasons of the year, have been held responsible for the causation of the disease by almost all writers. According to many authors the climatic conditions which give rise, or predispose to, croupous pneumonia, are not identical with those which are associated with the occurrence of the general catarrhal affections of the respiratory organs. Dr. Seibert's experience leads him to hold an exactly opposite view to this, and in support of his own belief he enters into a critical examination of the works of others upon the same subject, with the following results. The prevalence of pneumonia during the colder months of the year is proved by the statistics of several observers. In almost all their tables the disease is shown to be at its lowest during July, August, and September. Dr. Seibert's cases prove that this rule holds good in New York as well as in Europe. The frequency of catarrhal affections during the same period, was denied by Professor Jürgensen, but a later series of observations, emanating from the same school, have been carefully tabulated by Keller; the tables showing beyond dispute that the cases of the catarrhal and of the croupous forms of inflammation have occurred in close correspondence with one another. The precise atmospheric conditions, however, have not been sufficiently clearly defined, the relative moisture of the air during any given period being roughly estimated by the amount of rainfall. The fallacy of this method of reckoning is demonstrated by Dr. Seibert with considerable force. A month's rainfall may simply imply the amount of rain which fell on one excessively wet day, the remaining days being dry and fine. A still greater fallacy is that which assumes that rainfall is under any circumstances a trustworthy criterion of the relative moisture of the air. The air may often be comparatively dry upon a rainy day, and is frequently very moist on a day when no rain falls. To determine with any approach to accuracy the relation of the atmospheric conditions to the prevalence of this or that disease, it is absolutely necessary to observe the *daily* changes of barometric and hygrometric readings. With low barometric pressure there is frequently associated a relatively moist condition of the atmosphere, and observation both in America and Europe has shown the connection of pneumonic attacks with both these states. In a long series of cases the commencement of the disease was found to be coincident also with a sudden fall in temperature, the relative moisture remaining the same. The fact that in the

cool and cold periods of the year the moisture of the air rises and falls with its temperature is generally well recognised, and Dr. Seibert's cases go to prove that it is especially during periods of variation from this rule that both acute pneumonia and catarrhal affections of the air passages are most prevalent. The ordinary teaching of climatologists is fully in accord with this view. Cold moisture is always more or less obnoxious to the physiological perfection of the body, and is especially liable to produce catarrh, but the question whether a previously catarrhal condition of the mucous membrane is essential for the development of the specific exciting cause of croupous pneumonia must remain as yet undetermined.

Muscular Infarcts.—After some remarks on the rarity of this occurrence, M. Giraudeau (*Revue de Médecine*, June), relates two cases where this took place. The first was a woman, aged 60, who suffered from generalised atheroma, and who a few days before her death presented a hard swelling about the middle of the thigh, which had appeared after a sharp pain which had seized her quite suddenly at that spot the evening before. At the *post-mortem*, the sartorius was found to be ruptured, and the swelling was due to an effusion of blood at this point. On examining the ends of the muscle, it was found that one-fourth was healthy, the other three-fourths being firm and rather pale; the hæmorrhage had presumably come from the healthy part. On microscopical examination, the muscular artery nearest to the diseased area was found to present marked sclerotic changes. In his second case a similar thing happened in the pectoralis major of a woman, also the subject of generalised atheroma. The extreme vascularity and richness in anastomoses of the muscular tissue must be assumed to be the chief reason why infarcts are so seldom found in this region. The following conditions are necessary to their formation:—(1) The arterial system must have lost its elasticity, the walls being thickened and rough, so that the rate of the circulation is thereby impeded. (2) The heart too must have lost its tone so that the patient gradually falls into a state of asystolism. Under these circumstances there is established a general state of anæmia, and when an arteriole becomes occluded by thrombosis or embolism, the anastomotic circulation is insufficient even in so vascular a tissue as the muscles to maintain the nutrition of the part.

Disseminated Sclerosis.—In a series of articles in recent numbers of the *Progrès Medical*, M. Marie has studied the relationship between disseminated sclerosis and the infectious diseases, of which typhoid fever is taken as the type. He considers it to be generally admitted that disseminated sclerosis is a vascular disease, and that it is due to arteritis, and he goes on to point out that arteritis is a frequent result of the infectious diseases, and that just such a scattered process is produced as is typical of disseminated sclerosis. This disseminated arteritis appears often at a late stage of the primary ailment, or during convalescence, or even sometimes when the cure had seemed to be complete. Even when it appears at so remote a period, M. Marie believes there is a causal relationship at work, and regards it as a late manifestation rather than as a late complication of the typhoid fever, or other disease upon which it followed. The final outcome of these papers is, that disseminated sclerosis is no longer to rank amongst the diseases of the nervous system, but is to be regarded as the localisation in the cerebro-spinal centres of the vascular determination of various general disorders, which seem to be always of an infectious nature. The author considers that these manifestations bear much the same relation to typhoid or other fever that secondary or tertiary symptoms do to primary syphilis.

OBSTETRICS AND GYNÆCOLOGY.

Ovariotomy in Russia.—In the *St. Petersburger Med' Woch.* (Nos. 15–18), Dr. Krassowski tabulates all the particulars of 128 ovariotomies which he has performed during the twenty years, December, 1862, to January, 1883, and the following are the conclusions at which he arrives from a consideration of these cases, which he states have been observed with most scrupulous exactness:—(1) Of the 128 ovariotomies (by which 178 cysts were removed), 70 were followed by recovery, and 58 by death, *i.e.*, a mortality of 45 per cent. Among them 113 were complete (91 single, with 51 deaths; and 22 double, with 10 deaths); 9 incomplete, with 6 deaths; and 6 mixed, *i.e.*, the cyst removed entirely on the one side and imperfectly on the other, with 2 deaths. The mortality of the partial and mixed ovariotomies amounted to 53 per cent. (2) With respect to the *contents of the cysts*, these were colloid in 117, serous in 5, dermoid in 3, and papillomatous in 2. In 84 cases (with 41 deaths), nutrition was much impaired; while in 44 cases (with 17 deaths), this was in a good condition. (3) *Age of the patients.*—While 69 of these were between 20 and 40 years of age, and 39 were between 40 and 60, only 7 were between 15 and 20. The results were more favourable between 15 and 30 (with a mortality of 35·5 per cent.), than between 30 and 50 (47 per cent.), or between 50 and 60 (61 per cent.) (4) Of the 128 patients, 33 (with 13 deaths) were virgins, 30 (with 13 deaths) childless married women, and 65 (with 32 deaths) women who had borne children. (5) In relation to *the menses*, in 20 these, under the influence of the disease, entirely stopped, in 11 they were more, and in 5 less abundant than normal, and in 9 more, and in 6 less frequent. In 50 they were completely normal. In 21 cases they had already become arrested at the climacteric period, and in 6 from unknown causes. After completed double ovariotomy, menstruation was never observed to recur. (6) Of these 128 ovariotomies, 24 were performed in private practice either at St. Petersburg or its vicinity, with 11 deaths or a mortality of 45·8 per cent., and 104 in hospital practice, with 47 deaths or 45 per cent. Those operations, which were performed at a little distance from St. Petersburg, were the most successful; but although in the hospital cases the greatest care was taken as to temperature and cleanliness, there were always too many persons allowed to be present, and in one of the hospitals in which 33 operations (with a mortality of 48 per cent.) were performed, the room employed was small, crowded, and lighted by petroleum. (7) The mortality, according to *season*, ranged from 66 per cent. in January, to 60 in May, 50 in November, and 70 in December; while in April, June, July, and August, it varied from 0·36 to 14 and 20 per cent. (8) *Adhesions* to the *different organs.*—In executing the 128 operations there were found no adhesions in 36 cases (with a mortality of 30 per cent.) and 92 with adhesions and a mortality of 51 per cent. The adhesions were easily separable in 17 cases (with a mortality of 47 per cent.) and required cutting instruments, &c., in 75 cases, with a mortality of 52 per cent. This last category of cases is treated at considerable length, quite beyond our space. (9) The *weights* of all the cysts operated upon amounted to 3,750 lbs. apothecaries', or about 1,343 kilogrammes. The heaviest weighed 76 lbs., and the lightest 1 lb. 7 oz., the mean weight of all the cysts being 29 lbs. (10) As to the influence of *prior treatment*, puncture was resorted to in 28 cases with no definite results, but the mortality was only 36 per cent. where paracentesis was preferred prior to the operation. In 96 cases internal and local medicinal agents had been employed. (11) A table is given of the age of the tumour, but this is admitted to be founded upon very uncertain data. (12) *Chloroform* was used in all cases, the largest quantities administered having varied in four cases from 5 oz. to 7 oz., and the operations lasting from two to three hours. The entire amount consumed in the 128 operations amounted to 22½ lbs., apothecaries', or 8,061 kilogrammes. Collapse ensued in two cases during, and in six afterwards; but these were restored by drawing out the tongue and hypodermic injection of tincture of musk. (13) The shortest *duration* of the operation was 25 minutes, and the longest 4½ hours; the mean duration having been 1 hour and 41 minutes. (14) A table is given of the *length of the incision* in all the cases, the inference being that this exerts no influence on the issue of the operation, this being chiefly due to the amount and nature of the adhesions. For Dr. Krassowski's observations on the management of the pedicle and dressing the wound, and the employment of drainage tubes, which are of considerable interest, we regret that we we have not space.

Partial Inversion of the Uterus by a Fibroid.—Dr. Werth, of Kiel, contributes to a recent number of the *Archiv für Gynäkologie*, a case in which, after removal by the scissors of a submucous fibroid which seemed to be polypoid, it was found that the tumour had partly inverted the uterus, and that in cutting through what appeared to be its pedicle a piece of the uterine wall had been removed, leaving a hole leading into the peritonæal cavity. The cut surface bled very freely, and Dr. Werth, finding it impossible to arrest the hæmorrhage, enlarged the opening (which was on the posterior wall) downwards, continuing it into the os. Even after this had been done, the hæmorrhage could not be controlled, and so as a last resource the uterus was removed. The patient did well. Dr. Werth discusses the question whether the inversion was present before the parts were interfered with, or was produced by traction on the tumour, and comes to the conclusion that it was not produced by traction. He suggests that in any case in which a polypus has a base broad enough to make it possible that a partial inversion may co-exist, it will be well to pass a ligature through the pedicle before cutting off the polyp, so that if a bit of the uterine wall should be taken away with the tumour, it may be possible to bring the margins of the gap together by suture. Dr. Werth's paper concludes with a useful collection of cases in which uterine tumours were complicated by inversion.

Hydramnion in Extra-Uterine Pregnancy.—An interesting case of this kind is reported by Dr. R. Teuffel, of Chemnitz, in a recent number of the *Archiv für Gynäkologie*. It is important as exemplifying a rare source of error in diagnosis. The patient was 36, and her last child had been born fourteen years previously. Menstruation stopped in March 1881, and the usual symptoms of pregnancy were noticed. In August, 1881, the patient suffered from severe and long-continued abdominal pain, and was medically treated for inflammation of the bowels. September 25th, 1881, labour like pains came on, with hæmorrhage, and the expulsion of a membrane, this latter being seen only by a midwife. Birth was daily expected but did not follow, and fœtal movements were still felt in October and November, after which they ceased, and the size of the belly began to slightly diminish. In 1882 the abdomen began to increase again, she felt well, and in March, 1882, menstruation reappeared. When she came under treatment she was wasted, sleepless, suffered pain, but was not feverish; the circumference of the belly was 116 centimetres (46 inches), it was dull, with resonance in the flanks, fluctuating, with solid masses here and there to be felt. A firm rounded swelling occupied the pelvis, pushing the uterus upwards, forwards, and to the right. There was no œdema of legs or other parts. The case was diagnosed as one of ovarian cyst, and an exploratory puncture was made. The fluid withdrawn gave a sediment on standing, in which striated muscular fibre was identified. Feverish symptoms followed the puncture, with pain, diarrhœa, and vomiting, and in ten days the patient died. On autopsy the cyst was found to contain a full-term macerated child and several litres of amniotic fluid. There was neither effused blood, nor signs of peritonitis, so that the immediate cause of death remained a mystery.

The Enucleation of Uterine Fibroids.—A recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* contains a valuable clinical paper on this subject by Dr. R. Lomer, of Berlin. He points out that the advances in abdominal surgery made of late years alter very considerably the point of view from which we should regard the enucleation of fibroids. Enucleation is in many cases very difficult and attended with considerable danger, while fibroids can often be removed by abdominal section with much less risk, or made to shrink away by removal of the uterine appendages. Enucleation must, therefore, in the future be reserved for cases in which the fibroid is so situated that its removal by enucleation is easy, or in which an abdominal operation is attended with more than usual difficulty. These cases are specified as follows (*a*) fibroids of the cervix, (*b*) submucous and interstitial fibroids in which the process of expulsion into the vagina has begun. In cases in which no dilatation of the cervix has taken place, enucleation should be rejected as too dangerous, it being better to operate by laparotomy. In cases in which labour is obstructed by cervical fibroids, the possibility of enucleation should be the first thing considered. Dr. Lomer discusses the chief difficulties and dangers encountered in the performance of enucleation, but does not throw much light upon them. This portion of his paper is rather a comparison of the experience and suggestions of different authors, than an expression of Dr. Lomer's independent judgment.

Elastic Pressure in Inflamed Breast.—Dr. Manning, writing in the *Philadelphia Medical Reporter* (January 26th), after observing on the desirability of extending the practice of elastic pressure as a means of arresting incipient inflammation in the early stages of whitlow and inflammation of the joints, &c., particularly directs attention to its great utility in inflamed mammary gland. Adhesive strapping, which is often recommended for preventing or relieving such inflammation, is, he observes, found very unsatisfactory in practice; while the treatment of threatening abscess by elastic pressure can be conducted quickly, safely, and pleasantly. Take a piece of rubber, known among dentists as coffer-dam, about eight inches square, with a hole large enough to admit the nipple. Tie a tape to each corner of this, and carry them round the body and over the shoulders, so as to press the gland equally and firmly against the ribs. This supports the breast as in a sling, and relieves the pain due to weight and dragging. The same appliance to an over-secreting gland causes the secretion to disappear in a few days; and when the breast has already suppurated, it relieves suffering and hastens convalescence.

Pruritus Vaginæ.—Dr. Hach stated at the Riga Medical Society (*St. Petersburger Medicinische Wochenschrift*, March 22nd), that, in a very obstinate case, in which various external and internal means had been employed in vain, he had met with complete success from dusting the mucous membrane of the vagina with iodoform. Beyond slight redness of the vagina, no diseased appearances were observable. Dr. Rulle stated that he had often employed iodoform balls in this affection, but had derived better results from the watery extract of opium, and small injections of cold water. He believed that this pruritus often arose from a slight dilatation of the rectum, just above the sphincter ani, which gave rise to detention of fæces there.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, June 4th, 1884.

H. Gervis, M.D., F.R.C.P., President, in the Chair.

The following Specimens were shown.

Dr. Malins. Prolapsed uterus removed with a fatal result.

Dr. Walter, of Manchester. Ovarian cyst which ruptured into the abdominal cavity, the fluid being afterwards partially discharged through an ulcerated umbilical hernia.

Dr. Aveling. Meyer's dilators for any cavity.

Dr. Graily Hewitt and Mr. Shattock. A specimen of spondylolisthesis.

Dr. Priestley. A drawing of chronic papillar inflammation of the vulva.

Dr. Barnes. An ovary showing commencing cystic disease.

Dr. Mansell-Moullin. Fundus uteri, removed for inversion, of four years' duration.

Dr. Horrocks. Placenta from a case of triplets.

Dr. Heywood Smith. Guyres' electric speculum.

Spontaneous Absorption and Recovery, after Pulmonary Thrombosis.

In this paper Dr. W. S. Playfair recorded a case of serious illness and recovery, following a protracted and difficult labour. He analysed the symptoms and

attempted to show that they could only be explained on the hypothesis of a thrombosis deposited in the pulmonary artery becoming spontaneously absorbed. He pointed out that the possibility of recovery under such conditions had not been sufficiently recognised. A second case was also recorded in the paper.

Dr. BROADBENT had seen the second of Dr. Playfair's cases. There were no pelvic signs, but there were the following signs connected with the chest—one or two paroxysms of dyspnœa, a peculiar murmur over the right auricle, followed by the signs of pulmonary embolism; the auricular murmur was replaced by a systolic pulmonary murmur, and obscuration of the pulmonary second sound. The left tibial vein had been inflamed, and the right iliac vein afterwards became obstructed. Recovery was complete, except that the right leg was still swollen.

Dr. GALABIN thought that, in view of the facts of pathology, Dr. Playfair had in his earlier writings attributed too much to thrombosis. In the case related by Dr. Broadbent he considered that the clot, first formed in the right auricle, had become detached, and formed an embolus in the pulmonary artery.

Dr. BARNES referred to a former contribution to the "Obstetric Transactions," showing that in many cases embolism followed thrombosis. He was sure he had seen cases recover from pulmonary embolism.

Dr. WILTSHIRE had seen a case of recovery after puerperal pulmonary thrombosis. He agreed with Dr. Playfair's diagnosis of the second case, but thought the first case was one of ulcerative endocarditis.

Dr. BROADBENT replied to Dr. Galabin that he did not think there had been embolism of the trunk of the pulmonary artery, but that the clot had extended into it from the auricle, and an embolus detached from it had settled in the left lung. An embolic clot, if free, would not lodge in the pulmonary artery. He thought clots were removed rather by disintegration than absorption.

Dr. PLAYFAIR in reply stated that many of the objections had already been answered elsewhere; that thrombosis occurred within a few days after delivery, embolism not till the lapse of two or three weeks, a period required for the softening and detachment of a clot. He did not believe that either case was due to ulcerative endocarditis; the murmur must continue as long as the clot remained.

On Fœtal Revolutions.

Dr. J. MATTHEWS DUNCAN, in a paper on this subject, thought that revolutions as distinct from rotations had been too much neglected in studying the mechanism of delivery. He showed the difficulty introduced by the peculiar curvature of the genital passages, which was nearer a parabola than a circle (circle of Carus). He showed that special mechanisms, as of the delivery of the head,—extension flexion,—were imperfectly described and misunderstood because not studied as parts of the change of fœtal altitude necessitated by the revolution. Revolution generally involved extension of the whole fœtal body. The various forms of revolution observed in different presentations and conditions of the fœtus were then described.

The PRESIDENT expressed his approval of the paper.

Dr. GALABIN criticised the accuracy of Dr. Duncan's description of the principles of geometry, and objected to the fœtus being likened to a viscous mass; although it was plastic to some extent, it came mechanically under the head of rigid bodies. Version illustrated this.

Dr. CHAMPNEYS pointed out the importance of accurate knowledge of mechanics in practice, for instance in the delivery of the head. The head is born by a movement of extension with advance; if the advance is forgotten and extension artificially produced, the larger fronto-occipital instead of the smaller sub-occipito-frontal circumference distends the vulva and the perinæum is unduly stretched; he was convinced that laceration often occurred from this cause. The words revolution and rotation were familiar to all, and were most useful for teaching purposes,—a wheel rotates round its axletree, the moon revolves round the earth and also rotates. Viscosity could hardly be denied in the face of the various forms of expression of more mobile parts or their retardation, and the fœtus could not therefore be regarded simply as a series of rigid levers.

Dr. MATTHEWS DUNCAN in reply endorsed Dr. Champney's remarks, and stated that the movements, as described by him, had been so described by all previous good observers, and that his descriptions were not innovations, as Dr. Galabin implied.

ACADEMY OF MEDICINE IN IRELAND.

MEDICAL SECTION.

FRIDAY, APRIL 18th, 1884.

Dr. HENRY KENNEDY in the Chair.

Progressive Muscular Atrophy and Labio-glosso-laryngeal Paralysis.

DR. J. MAGEE FINNY read a paper to show the identity of progressive muscular atrophy and progressive bulbar paralysis. He drew attention to the rarity of labio-glosso-laryngeal paralysis. Erb wrote his article in Ziemssen's Cyclopædia of Medicine from a personal knowledge of but nine cases, and he himself had met with but three cases—one while a student, and the other two the subjects of the paper. Each of these diseases occurs perfectly independently of the other. Of Erb's nine cases, six were of pure bulbar paralysis. Nevertheless, progressive bulbar paralysis was one of the commonest terminal complications of progressive muscular atrophy; and, on the other hand, any atrophic lesions might be found with or subsequent to the occurrence of bulbar disease. He did not discuss the relative merits of the myopathic or neuropathic theories of the origin of the two diseases; but he referred to the light thrown on the essential identity by the microscopic demonstrations of Charcot, and more recently Fox, of the lesion engaging the grey nuclei on the floors of the fourth ventricle and the multipolar cells of the anterior grey cornua of the cord at the same time, by the analogy of these parts as revealed by anatomy and physiology, and by the striking clinical resemblance of the symptoms. The two cases, the subject of this communication, were men of the labouring class, both from the country, one aged fifty, the other thirty-nine, who came under his care in the spring of 1882. In both the disease began without any discoverable cause, predisposing or exciting, in the tongue by impairment of speech and difficulty of deglutition; and after five or six months evidence of progressive muscular atrophy was perceived, although it was very probable that its occurrence was considerably earlier. The bulbar symptoms were extremely well marked in each, though one differed from the other by the amount of glossal atrophy and the involvement of the lips. Fibrillary movements were noticed in the tongue of both and in the lips of one. The constant dribbling of saliva, the difficulty of pressing the lips to blow smoke, or to spit, the difficulty of carrying the particles of food to the back of the mouth, were all well marked, while speech was reduced to "aye" and "no" in one patient and to a few monosyllables in the other. In both, the dental and labial letters were impossible; and in one, suffocative attacks from the food entering the larynx were frequently imminent. The amyotrophic changes were well marked in the neck and upper extremities of one, and of both arms and legs in the other. Fibrillary movements were most distinctly seen in all the paralysed muscles. Sensation and tendon reflexes were unimpaired, and there was no paralysis of the bladder or rectum. In one, treatment by barium chloride and frequent galvanism and Faradism seemed to arrest the progressive muscular atrophy, and even to restore to the deltoids the power they had lost, while the bulbar symptoms remained unaltered, though not increased. The other case was rapidly wasting, and the bulbar symptoms were worse. Both cases left hospital, and their future progress was unknown.

Dr. C. J. NIXON observed that in bulbar paralysis there was always to be found a constant lesion in the motor roots

of the nerves and the motor ganglia and the medulla. In all the *post-mortem* examinations there had been found constant trophic change in the motor roots of the nerves, whereas in 19 recorded cases of progressive muscular atrophy no change whatever was found in the motor roots, and another peculiarity was that the first sign was the atrophic condition of the muscles, while there were some cases recorded where with distinct bulbar paralysis there was no atrophy of the muscles at all. The absence of atrophy of the muscles could be explained by assuming the disease to be confined to the motor cells in the anterior grey horns, while the trophic cells in the neighbourhood had escaped the disease. He asked how Dr. Finny explained the number of cases met with by reliable observers where there had been no disease found in the cord at all in cases of progressive bulbar atrophy. Another point was as to what distinction they were able to draw between cases of progressive muscular atrophy and the acute or subacute forms of poliomyelitis. In poliomyelitis they first had paralysis and subsequently atrophy, whereas in progressive muscular atrophy they first had atrophy, and then in proportion to atrophy of the muscles they had loss of motor power. There was a great amount of evidence to show that those diseases were to a large extent hereditary.

The CHAIRMAN pointed out that there were cases recorded of local origin in which there was no disease found in the spinal marrow or the brain.

Dr. FINNY, in reply, acknowledged that Dr. Nixon had touched upon more points than he had dealt with in his communication; but he thought it was hardly time yet to come to any positive conclusion in comparing the two diseases, the number of observations on progressive muscular atrophy being much larger than that on bulbar paralysis. The microscopic examinations in the latter were very few, whereas the other disease had been the subject of general observation for many years. It was not in his power to explain the observations of Charcot as to the absence of lesions in the anterior grooves of the cord in progressive muscular atrophy. If his theory was correct, one of the essentials must be an ascending neuritis, and this passing through the muscles should show itself in the anterior roots before it reached the grey matter in the cord. There might be no lesion of the anterior cornu at all. In infantile palsy rapid inflammation or other lesion took place in the multipolar cells; whereas in muscular atrophy the same process was going on much slower and partially progressive muscular atrophy existed; but there were many cases where before the atrophy was fully confirmed they had paralysis, and that in bulbar paralysis. In Charcot's case the lung was perfectly normal, but after death the examination showed it was in a very advanced stage of fatty degeneration. The amount of atrophy was somewhat due to the nutritive nerve-cells, which must preside over those parts. As to the ætiology of the disease, so far as his knowledge went, there was little known about it. He did not agree with Dr. Nixon that hereditariness was shown to be a factor in those cases. It was not so in his cases, which he had brought forward, not to prove any special theory as to the origin of the disease, but to illustrate the close affinity existing between the two diseases.

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE VIII.

METEOROLOGY.

THE number of exhibitors in this department is remarkably small, and many of the best known firms are not represented. We were especially surprised at missing the familiar name of John Browning.

The first thing that caught our eye on entering, was an ingenious form of thermometer, intended for use in churches and places of public assembly, which can be read at a distance of several yards. It is shown by Watson, of 313, High Holborn (1354), and consists of a good sized thermometer so delicately poised on a spring balance about its centre of gravity that the smallest rise or fall of the mercurial column above or below 65° F. causes it to deviate from the horizontal position, while a long index needle fixed to the upper end of the tube indicates the temperature on a boldly graduated scale in the form of an arc extending about 45° either way. The tube itself being also graduated in the ordinary way serves to show whether the mechanism is in proper working order or not. Both scales run from 32° F. to 105° F., as wide a range as is required for the purposes for which it is intended.

Mr. Denton (1357) exhibits a number of clinical and other thermometers, for which he claims that, from some peculiarity in their construction, the glass is liable to no appreciable amount of subsequent contraction. M. Desprez has found that, as a rule, clinical thermometers, if graduated soon after being filled, give at the end of the first year a reading of ·5 of a degree Fahrenheit above the truth, and that the shrinking continues for about five years when the error reaches ·8°. These of Mr. Denton having been marked at Kew before being filled, were found at the end of six months either absolutely correct or not more than ·1 or ·2 at the most in error, and no further alteration was observed after one or two years. Considering the constantly increasing demand for clinical thermometers, this is no small advantage. His lens-fronted clinical, or, as he somewhat absurdly calls them, "health" thermometers, magnify the mercurial column enormously and are extremely easy to read.

Mr. Casella (1363) and Messrs. Negretti and Zambra display rich collections of meteorological instruments of every kind, including continuously self-registering barometers, in which the curves are marked by a pencil on a revolving drum. The former for some reason does not exhibit his very ingenious and, as we thought, successful minimum thermometer, which will be known to many of our readers from the description in Professor Balfour Stewart's work on heat, in which the metallic index is dispensed with, and a lateral pyriform chamber receives the mercury as the temperature rises, while the minimum is indicated by the column of mercury in the stem. Mr. Casella has a very simple form of thermometer for announcing when any given maximum is reached. It is a horseshoe tube, the terminal dilatation of the upper arm being filled with alcohol, which, expanding, moves a long index of mercury occupying the bend and part of the tube on each side, the arms along which this index moves being graduated in opposite directions, and therefore, if the instrument be in order, indicating the same temperature. When the index has advanced in the lower arm as far as the desired maximum temperature, it comes into contact with the ends of two platinum wires, closes an electric circuit, and rings a bell. Messrs. Negretti and Zambra have a similar but more complicated set of instruments for announcing maximum and minimum temperatures alike.

Of more practical value and highly ingenious is a set of thermometers arranged by Messrs. Negretti and Zambra for automatic hourly records of temperature. The thermometers themselves are of a very peculiar construction. Just above the bulb is a twist and a constriction, and above this a lateral chamber, or pocket, into which the mercury passes, instead of rising in the stem. If the thermometer be inverted, the column breaks off at the constriction and falls into the stem, at the other end of which is a small dilatation, and the temperature is read off on the stem, which is graduated from this end towards the bulb, in fact, upside down.

In the arrangement before us, twelve such "tip up" thermometers are held by clamps moving freely on their axes, and their stems are enclosed in glass tubes which are more than counterpoises for the bulbs. The clamps are placed so low that the thermometer is only kept erect by a bent pin, against which a prolongation of the enclosing tube rests; and these pins are connected with a series of spindles and cams, themselves in electric connection with a clock. Every time the long-hand of the clock reaches XII. it presses on a small brass spring, closes the circuit, and causing the next in order of the bent pins to perform half a revolution, leaves the corresponding thermometer free to capsize and by the dropping of the mercury in its stem to leave a record of the temperature at that moment.

It will thus be easy for a single observer, by two visits

daily, to keep a record of the hourly variations of the temperature by night and day.

Mr. Negretti has turned the same form of thermometer to account for deep-sea observations, though the arrangement of revolving fans, &c., seems rather too delicate and complex to withstand the pressure at great depths. A simpler pattern without mechanism, and inverted only by the resistance of the water in being drawn up, seems more likely to work in practice.

In anemometers, barometers, &c., we did not notice anything really new.

Among the charts on the walls of this annexe is one published by the S.P.C.K., showing the mean annual rain-fall in all parts of the British Islands by different shades of colour and by contour lines as it were, iso-ombral lines we might call them.

The Meteorological Society exhibits a series of interesting charts, showing by varying shades of colour from deep and light blue, violet purple, lilac pink, and red, the monthly temperature of the sea on the coasts of Great Britain and Ireland, which might be of great use in choosing a place for sea-bathing at any given season. Generally speaking, the sea is warmer on the West Coast and colder on the East, but there are some curious seasonal variations. For instance, the sea on the West Coast of Ireland is by far the warmest from April to October, but between November and March it is cooler than the more equable Irish Channel. Again, the Devon and Cornish Coast is always warm, but that of Kent and Sussex is warmer in September and October, though cooler at any other time than that of the S.W. In winter and spring the Coast of East Kent is decidedly cold, in autumn the reverse. The coldest part of the English Coast is found at some point between Yarmouth and Scarborough, varying with the month. But great as is the annual range of temperature between Margate and Folkestone, it is exceeded by that observed in the estuary of the Severn, where the extremes of cold in winter and of heat in summer are no doubt due to the admixture of fresh water brought down from the Welsh Highlands.

In another place are a couple of sheets showing the mean temperature in different parts of the world, as well as the maxima and minima observed at a number of places from Melville Island to the Red Sea. But the list is very imperfect, and a grand opportunity has been missed of explaining to the public the illusive character of so-called *mean* temperatures, and of the importance of annual and diurnal variations in determining what is known as climate. We might venture to suggest that it is not too late to make good the omission.

Mr. Lecky, of 3, Lorton Terrace, Ladbroke Grove, shows, along with several graphic representations of the prevalence of sunshine in successive years, a couple of self-registering sunshine readers, spherical lenses which concentrate the sun's rays on strips of prepared blue paper marked for the hours and fixed to a brass arc. One of these is adapted for our own latitude, the other capable of being adjusted to any.

Other charts on the walls show the relation between temperature and the death-rate, and the prevalence of the several classes of disease.

In the garden is a small meteorological station in charge of a Swede who accompanied Baron Nordenskiold to Spitzbergen, and the late expedition sent out by our Government to Fort Ray. He showed us two records of sunshine taken by Mr. Lecky's instrument on Thursday and Friday of last week. The former indicated almost unbroken sunshine, the latter recorded but a couple of hours, and that faintly, for although the sky was nearly cloudless and the temperature higher than on the previous day, there was a "haze" which, though not concealing the body of the sun, interposed a screen sufficient to prevent the action of its rays on the paper.

City Orthopædic Hospital.—A well attended dinner, presided over by the Lord Mayor, was given in support of the funds of this hospital, at the Holborn Restaurant, on the 26th ultimo.

GENERAL CORRESPONDENCE.

VACCINATION AND SMALL-POX.

[To the Editor of the Medical Times.]

Sir,—I write partly because the facts that I am about to narrate, backed up as they are by previous occurrences of the same character, may assist those who would convince impartial or even reasonable but ignorant persons of the value of vaccination; more especially, however, because they tend to support M. Pasteur's late assertion that inoculation *after* the bite of a mad dog will prevent the occurrence of hydrophobia in the person or animal bitten.

When a medical student at the University of Edinburgh, and attending dispensary patients after my third winter session, we had an epidemic of small-pox, chiefly among the Irish in the old town. Among other patients I was called to see three Irishmen, each affected with small-pox, each married, and each, with his wife and a newly-born infant in a cradle, living in one room entered from a narrow wynd and a steep stair. On my second visit to each I vaccinated these infants, but in all three symptoms of small-pox showed themselves immediately after. In one the vaccine puncture showed symptoms of having taken, ran on to the second or third day thereafter, then stopped till the small-pox, which now showed itself unmistakably, had run its course, and then taking up its running ran its natural course, even including its first days, to the normal number of days. In a second case the vaccine and the small-pox ran their course side by side, or in other words contemporaneously. The course of the third case differed from both, but I have now but an imperfect remembrance of it.

In all three cases however, *the small-pox was modified*, there was no exacerbation on the eighth day, and eventually all three bore good vaccination marks, while there was not the slightest small-pox scar to be found on any part of their bodies.

I am, Sir, yours, &c.,
BRINSLEY NICHOLSON, M.D.,
Deputy Inspector General (H.P.)

MEDICAL NEWS.

THE INTERNATIONAL OTOLOGICAL CONGRESS AT BASLE.

The arrangements for the Otological Congress, which will be held at Basle from the 1st to the 4th of September next, are now complete, and the programme will shortly be published. The Congress will be opened at 10 o'clock on September 1st by an address from the President of the last Congress, Dr. Sapolini, of Milan, which will be followed by an address from the President of the Organising Committee, Professor Burckhardt-Merian, and by the election of the officers of the Congress. The work of the Congress is divided under three heads, in connection with each of which several papers will be read. The following communications have already been announced.

(1) *Normal and Pathological Anatomy.*—Papers will be communicated by Professor His on the development of the external ear; by Professor Politzer, on the normal and pathological histology of the ear, and on the condition of the cochlea in the deafness of leucocythæmia; by Professor Moos, of Heidelberg, on the lymphatics of the tympanum; on lacunar caries of the neck of the malleus; and on villous growths on the internal wall of the tympanum; by Dr. Brünner, of Zurich, histological specimens, illustrating the normal anatomy of the ear; by Dr. Bezold, of Munich, anatomical specimens of the ear obtained by corrosion; by Professor Kuhn, of Strasburg, on the anatomy of the internal ear in vertebrates; by Professor Burckhardt-Merian, specimens illustrating the normal anatomy of the ear.

(2) *Physiology, Methods of Examination.*—Communications will be presented by Professor Moos, on the cause and diagnosis of auditory disturbance in cases of cerebral tumour;

the diagnostic value of the musical pitch test; by Dr. Jellée, of Paris, on the symptomological value of the musical pitch test applied to the vertex; by Dr. Löwenberg, on a new method of examining the propagation of sound in the external ear; by Professor Burckhardt-Merian, on the comparative value of the different methods of examining the auditory function. Dr. Merian will also show a new ear trumpet, and Professor Cozzolino, of Naples, will show a very simple and sensitive electro-microphonic audiometer.

(3) *Pathology and Therapeutics.*—The following papers will be read: by Dr. Grazzi, of Florence, on the parasites of the ear, with microscopic demonstrations; by Dr. Ménière, of Paris, on a case of chancroid of the middle portion of the external meatus, rapidly healing; and on contractions of the external meatus, and their influence on hearing; by Dr. Boboni, of San Remo, on the diseases of the ear produced by sea-bathing; by Professor Cozzolino, of Naples, on the anatomical classification of the varieties of deafness according to their pathogenesis; by Dr. Noquet, of Lille, on the reflex phenomena produced by chronic purulent otitis of the middle ear; by Dr. Guye, of Amsterdam, on the causes of ear affections in measles and scarlatina; by Professor Politzer, on the operative treatment of deafness arising from old-standing purulent otitis of the middle ear; by Dr. Boucheron, of Paris, on deaf-mutism from otopiesis; by Dr. Sapolini, on a cause of temporary or permanent hyperacousia and dysecæa, cophosis, treatment; by Professor Longhi, of Milan, on sulpho-carbolate of zinc in purulent otitis; by Dr. Bendelack Hewetson, of Leeds, on the injection of glycerine of carbolic acid (B.P.) into the external meatus for the cure of otalgia and inflammation of the tympanum; and on the therapeutic results daily of a nasal douche of concentrated solution of carbonate of soda in catarrhal affections of the middle ear; by Dr. Kirschner, of Wurtzburg, or the ear affections of diabetes; by Professor Longhi, of Milan, two cases of chronic affection of the labyrinth following jaundice and cold injections into the external meatus; by Dr. Hartmann, of Berlin, on the anatomical relations to be considered in trephining the mastoid process; by Dr. Morpurgo, of Trieste, ought operations on the mastoid process to be undertaken early or late?; by Dr. Novaro, of Turin, on trephining the mastoid process; by Professor Cozzolino, on the use of the galvano-cautery in affections of the ear; by Dr. Löwenberg, on the nature and treatment of ozæna; by Dr. Thomas Barr, of Glasgow, on adenoid growths in the nasal-pharyngeal cavity. Dr. Siebenmann, of Klosters, will show preparations of the parasitic fungi of the external ear, and Dr. Moresco a syringe for injecting solutions into the tympanum.

University of Durham.—The following were the successful candidates at the examinations held in the Easter Term, 1884:—

Degree of Doctor in Medicine, for Practitioners of fifteen years' standing—

William Edmund Cant, F.R.C.S., L.R.C.P.; William Henry Dawson, M.R.C.S., L.S.A.; Edward Walford, M.R.C.S., L.S.A.; John Rostron Woodcock, F.R.C.S.; Samuel Woodman, F.R.C.S., L.S.A., L.R.C.P.

Degree of Doctor in Medicine—

William Crump Beatley, M.B., M.R.C.S., L.S.A.; Christopher Vise, M.B., M.R.C.S.

Degree of Master in Surgery—

Frederick William Cock, M.R.C.S.; Charles Egerton Jennings, F.R.C.S., L.S.A.; Joseph Armstrong Hutchinson, M.B., M.R.C.S.; Hugh Rayner, M.R.C.S.; Arthur Walton Rowe, M.R.C.S.; John Valentine Salvage, M.R.C.S.

Degree of Bachelor in Medicine. First-class Honours (in order of merit)—

Frederick William Cock, M.R.C.S., University College; Arthur Walton Rowe, M.R.C.S., St. Mary's Hospital.

Second-class Honours (in order of merit)—

Hugh Rayner, M.R.C.S., St. Bartholomew's Hospital; Cecil Morgan Hendriks, M.R.C.S., University College; William Rice Edwards, M.R.C.S., London Hospital.

Pass List (in alphabetical order)—

Frederick Bryan, St. Thomas' Hospital; Clement Cornelius Caleb, King's College; Arthur Willan Dawson, Liverpool Royal Infirmary, and King's College; Henry William Dixon, Durham College of Medicine; Francis Washington Everard Hare, M.R.C.S., St. Thomas' and St. Mary's; Charles Egerton Jennings, F.R.C.S., L.S.A., London Hospital; Joseph Smith Revely, Durham College of Medicine; Charles Frederick Rumboll, M.R.C.S., St. Bartholomew's, and Durham College of Medicine; John Valentine Salvage, M.R.C.S., Guy's Hospital.

University of Dublin.—At the Summer Commencements of Trinity Term, held on Thursday, June 26th, 1884, in the Examination Hall of Trinity College, the following degrees in Medicine and Surgery were conferred by the University Caput in presence of the Senate.

Baccalaurei in Chirurgiâ:—

Henricus Theodorus Bewley, Guilelmus Bullen Day, Johannes Samuel Fenton, Nicolaus Carolus Ferguson, Guilelmus Maxwell Hewson, Samuel Hickson, Hugo Nugent Kenny, Robertus Morrow, Thomas Parr, Georgius Guilelmus Powell, Guilelmus Travers Swan, Ludovicus Werner, Reginaldus Joscelyn Windle.

Baccalaurei in Medicinâ:—

Henricus Theodorus Bewley, Guilelmus Bullen Day, Henricus A. Ellis, Johannes Samuel Fenton, Nicolaus Carolus Ferguson, Guilelmus Grandy, Guilelmus Maxwell Hewson, Guilelmus Lucy Hickey, Samuel Hickson, Hugo Nugent Kenny, Josephus Vincent Manning, Robertus Morrow, Daniel Robertus O'Sullivan, Thomas Parr, Georgius Guilelmus Powell, Guilelmus Robertus Roper, Georgius Scarr, Henricus Shackleton, Telford Smith, Guilelmus Travers Swan, Ludovicus Werner.

Doctores in Medicinâ:—

Guilelmus Thomas Briscoe, Jacobus Chute, Johannes Loftus Cuppaidge, Fredericus Conway Dwyer, Thomas Carson Fisher, Thomas Carolus Moore, Carolus Thomas Poland, Guilelmus Robertus Roper, Henricus Shackleton.

Royal College of Surgeons of England.—The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Board of Examiners, on the 30th ultimo, 1st and 2nd instant, and when eligible will be admitted to the pass examination, viz.:—

R. H. W. Johnston, J. W. Pare, A. W. Hughes, Edwin Morton, Edmund Antrobus, W. M. Eaton, and E. L. Lees, Students of the University of Edinburgh; J. P. Cavenagh and William Hartford, of the Dublin School of Medicine; Julius Coronel, of Amsterdam; S. P. Alexander, of the University of Glasgow; C. E. Gooding, J. B. Loring, and G. B. Rowell, of McGill College, Montreal; Charles Whisken, H. C. Sugden, J. R. S. Park, J. P. J. Gornal, F. C. Andrew, W. H. Haslop, J. R. M. Brennan, William Armstroug, and James Elias, of the Manchester School of Medicine; John Bailey, E. M. Quinby, C. L. Warke, and Randle Leigh, of the Liverpool Infirmary; R. E. Johnson, J. W. Holmes, and William Dunbar, of the Sheffield School of Medicine; C. G. May, of the University of Cambridge; F. W. Ramsay, Newcastle-upon-Tyne School of Medicine; C. G. Hutchinson, W. J. C. B. Pitt, and W. H. Date, of the Birmingham School of Medicine; T. H. Godfrey, of St. Thomas's Hospital.

Thirty-three candidates were referred for three months, and four for six months.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, June 26th, 1884:—

Edgar Beaumont, 30, Gipsy Hill, S.E.; Frank Hinds, Gondhurst, Kent; Robert Lawson, Unthank, St. Andrew's, Fife, N.B.; Jenkyn Lewis, Llanon, Cardiganshire; William Thomas Rees, Llauboidy, Carmarthenshire; Walter Oliver Steinthal, 14, John Street, Hampstead.

At the recent Examination for Prizes in Botany given annually to Medical Students by the Society of Apothecaries, the successful candidates were adjudged as follows:—

(1) Ernest Henry Starling, of Guy's Hospital, (A Gold Medal)
(2) William Beecroft Bottomley, of St. Mary's Hospital, (A Silver Medal and Books).

Naval Medical Service.—Fleet-Surgeon E. T. Mortimer has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets.

The City Coronership.—Mr. S. F. Langham, the recently elected coroner for the city of London, has appointed Mr. Wynne E. Baxter, C.C., solicitor, to be his deputy, and this selection has been officially approved by the Lord Chancellor.

University of Dublin (*School of Physic in Ireland*).—The Provost and Senior Fellows of Trinity College have awarded the Surgical Travelling Prize, value 100*l.*, to Charles R. Kilkelly, and have granted an extra prize of 25*l.* to Henry J. Bewley, in consequence of his superior answering.

Adelaide Hospital, Dublin.—On Saturday, June 28th, the "Hudson Scholarship" and other prizes were presented to the successful candidates at the midsummer examination in the lecture theatre of the institution. The Right Hon. Judge Warren presided. After an interesting address from Dr. Head, Physician to the Hospital, the chairman presented a gold medal and a cheque for 30*l.* to Mr. H. J. Bewley, the winner of the Hudson Scholarship;

the silver medal and a cheque for 10*l.* to Mr. W. B. Day; the Medical Prize to Mr. J. D. Wynne, and the Surgical Prize to Mr. Healy.

Sanitary Institute of Great Britain.—The anniversary meeting of the institute will be held in the theatre of the Royal Institution on Thursday, July 10th, at 3 p.m. The chair will be taken by the Right Hon. Earl Fortescue, and an address will be delivered by H. C. Bartlett, Ph D., F.C.S., entitled, "Some of the Present Aspects of Practical Sanitation," and the medals and certificates awarded to the successful exhibitors at the Exhibition at Glasgow, in 1883, will be presented. The anniversary dinner will take place at 7 o'clock on the evening of the same day, at the Holborn Restaurant, Dr. Alfred Carpenter in the chair.

New Infirmary at Fulham.—On the 26th ultimo Sir Charles Dilke opened the large new infirmary which has lately been added to the Fulham workhouse. The infirmary will accommodate 446 patients, and its total cost (without furniture) will amount to 51,422*l.* The building comprises a central block, in which are placed the whole of the official and administrative departments, with dwelling accommodation for the staff. The pavilions for males and females are to the right and left of the central block respectively. These main blocks are three storeys in height, and consist of wards 96 feet long and 24 feet wide, containing 32 beds each, with the necessary offices attached. The appliances for ventilation, lighting, water supply and security from fire, and sanitation and drainage, have all been most carefully considered and carried out.

Robert Koch and the Prevention of Cholera.—The Berlin Correspondent of the *Philadelphia Medical News*, June 7, comments as follows upon this passage of Koch's speech on returning thanks at the Berlin banquet:—"He was well aware that the discovery (of the cholera bacillus) would not contribute very much to the improvement of the therapeutics, but he believed that his experience in Egypt and India would allow him to make some practical propositions concerning the prevention of cholera, and that, perhaps, if only the Governments concerned would agree upon his plan, it might be possible to restrict the disease to its mother-land—India." Words of such vast significance, on an official occasion, from the lips of a man of Robert Koch's reserve and modesty, deserve our highest attention. Careful readers of the reports sent from Egypt and India will remember a somewhat dark and obviously abbreviated passage about the mode of cholera importation, studied in the quarantine harbours. This passage, together with the fact that the third report was not published at all, allows the conclusion that the German Government is in possession of most important positive propositions about the effective prevention of cholera importation, which are not yet ripe for publication.

APPOINTMENTS.

Fourns, Newcome Whitelaw, M.D. Brussels, L.R.C.P. Edin., M.R.C.S.—Anæsthetist to St. John's Hospital for Diseases of the Skin.

Davies, J. T., L.R.C.P., M.R.C.S.—Resident Medical Officer to the Denbighshire Infirmary, *vice* Williams, resigned.

Faulkner, Herbret, M.R.C.S. Eng., L.R.C.P. Edin., and L.M.—Medical Officer to the Seventh District, Depwade Union, *vice* Mr. Heynes Hardwicke, resigned.

Gubb, A. S., L.S.A.—Resident Obstetric Assistant to the Westminster Hospital.

Hull, Edward Gordon, M.D., and Bach. Surg. Dub.—Medical Officer to the Withern District, South Union, *vice* Dr. James Hurley, resigned.

Jolly, Samuel Aird, L.R.C.P., L.R.C.S. Edin., L.C. Phys. and Surgs. Glasgow, L.S.A. Lond., L.M. Edin. and Glasgow.—Medical Officer to the Puddletown District, Dorchester Union, *vice* Mr. Robert Slade, resigned.

Lawrence, S. C., M.R.C.S., L.R.C.P.—House Physician to the Queen's Hospital, Birmingham.

Maples, Reginald, M.R.C.S., L.R.C.P., L.S.A., and L.M.—Medical Officer to the Workhouse, and the Kingsclere District, Kingsclere Union, *vice* Mr. Septimus Edwards, resigned.

Meeson, Alfred, L.R.C.S. Edin., L.S.A. Lond.—Medical Officer to the Second District, Township of Toxteth Park, *vice* Mr. Thomas Fox Morrish.

Pairman, Thomas Wyld, L.R.C.P. Edin., L.R.C.S. Edin.—Medical Officer to the Fifth District, Williton Union, *vice* Mr. Jonathan Crocker, resigned.

Tomkins, H. H., M.R.C.S.—Assistant House Surgeon to the Infirmary for Children, Liverpool.

Traill, M. W., L.R.C.P., M.R.C.S.—Honorary Surgeon to the Sydney Hospital for Sick Children.

Williams, William Montague Venables, L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the Prees District, *vice* Owen Westwood, resigned.

VACANCIES.

County and County of the Borough of Carmarthen Infirmary.—House Surgeon. Salary £100 per annum, with board, lodging, fire and light. Candidates must be registered to practice both in medicine and surgery, unmarried, and free from the care of a family. They must have a knowledge of the Welsh language, and will be required to enter into an agreement not to practice in the County of the Borough of Carmarthen for a period of five years. Applications, with testimonials, as to ability and character, to be sent to Mr. H. Howells, 11, Morley Street, Carmarthen, on or before July 12th.

County Lunatic Asylum, Snenton, Nottingham. — Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Candidates must be registered under the Medical Act, unmarried, and they must produce testimonials of good moral character. Applications stating age with testimonials, addressed to the Chairman of the Committee of Visitors, to be sent under seal to Samuel Bunting, clerk, on or before July 9th. The election will take place on July 17th.

Cumberland Infirmary, Carlisle. — Assistant house-surgeon. Salary £40 per annum, with board, lodging and washing. Applications, with testimonials, to be sent in to the committee, not later than July 8th.

Liverpool Royal Southern Hospital.—Second and third house-surgeons. Salaries, 80 and 60 guineas respectively, with board, &c. Candidates must be doubly qualified and registered. Applications and testimonials to be addressed to the Chairman of the Medical Board, not later than July 10th.

Llandilofawr Union.—Medical Officer to the Western District, in succession to Mr. W. L. Jones, deceased. Area, 2,351 acres. Population, 2,311. Salary, £27 per annum.

Society of Apothecaries of London.—Examiner in Medicine. (*For particulars see Advertisement.*)

Stone Union.—Medical Officer to the Stone District and the Workhouse, in succession to Mr. G. H. Hopkins, deceased. Area, 20,373 acres. Population, 9,768. Salary, £25 per annum. Salary for Workhouse included in that for the District.

Toxteth Park Township.—Assistant Medical Officer to the Workhouse, in succession to Mr. Alfred Melson, resigned.

DEATHS.

Parsons, A. D., L.R.C.P., M.R.C.S., at Matham Dawlish, on June 30th, aged 36.

NOTES, QUERIES, AND REPLIES.

NOTES FROM BRAZIL.

[TO THE EDITOR OF THE MEDICAL TIMES.]

Sir,—I write on May 30, having before me the Number of May 3—received on the 25th. When I came to Brazil there was a monthly post from Europe, and here, in the then back country, the latest news was of 75 days on an average. Brazil is now so cruelly victimised by *Progress and Civilisation*, that any one with my ideas and family traditions would be more at ease in many secluded corners of Europe. We even have the *Telephone* in full activity here, *but not in my house*. As an Edinburgh M.D. I feel there is something antagonistic to the traditions of a *Physician's* gravity and status, in his being at the disposition of this most democratic form of communication. What I want to say is, that up to the date mentioned no one thought proper to notice my request in the Notes and Queries, *Medical Times* of March 29th, as to the harmlessness or danger resulting from the reuniting in the same formula or prescription of cherry laurel water with bicarbonate of soda or potash. I wish much to obtain an authoritative statement on the subject, owing to the assertion of several physicians here to the effect of the danger of such a combination. I received from Messrs. Ledger, Smith, & Co. a polite note, repeating what the same gentlemen published in the *Medical Times* of April 5th, and accompanying a prospectus of the "Medical Digest."

The newspapers have just announced the death, in the Province of Goyar, of *Senhorinha Gomes de Jesus*, at the age of 154 years. Though there, perhaps, is no irrefutable authentic evidence of the exact *algarism* or figures, the statement cannot be *à priori* rejected, when one considers the frequency in this country of persons attaining the age of 110, 120, 130 years. Centenarians are common in some districts, and formerly were more so. It is worthy of note that many centenarians die in consequence of falls. Reading an article on *Beriberi*, lately published in the *Medical Times*, I see that it is mentioned that Sir Joseph Fayrer suggested the possible parasitic nature of the disease. I, therefore, avail myself of this opportunity to announce that the *Microbe* of Beriberi has been found and demonstrated in the Physiological Laboratory attached to the National Museum in Rio de Janeiro, by Dr. John Baptist de Lacerda, the same who introduced the permanganate of potash as a remedy in snake-bite. It is alleged that this *Microbe* is identified with a microbe found in rice. This disease causes great mortality in the Northern Provinces of Brazil, and is unfortunately coming (slowly) southward. In order to give an idea of the state of Pharmacy in this country (where it is rigorously separated from the Practice of Medicine), I enclose an edital announcing the sale of the stock of a

Pharmacy in Rio de Janeiro, under execution for debt. It is probable that at the time of seizure the stock was much exhausted. By the name of the creditor it would seem that he is some positive, matter-of-fact Englishman.

A few days ago there died of *Morphœa* a man whom, about three years, I treated successfully for *Tetanus*. Is it not reasonable to suppose that the Leprosy was the consequence of the violent perturbation of the nervous centres which accompanied the Tetanus? Is not the case favourable to the idea (for me a truth) of the cerebral origin of Leprosy?

I am, Sir, yours &c.,

RICHARD GUMBLETON DAUNT, M.D. Edin.

Campinos, S. Paulo, Brazil.

Dr. Thompson, Launceston, Tasmania.—Letter and enclosure received.

COMMUNICATIONS RECEIVED—

Messrs. ADAMS & FRANCIS, London; THE SECRETARY OF THE ROYAL INSTITUTION, London; Mr. CHATTO, London; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; THE REGISTRAR-GENERAL FOR ENGLAND, London; THE HON. SECRETARY OF THE TRAINED NURSES' ANNUITY FUND, London; THE SECRETARY OF THE UNIVERSITY COLLEGE SCHOOL OF MEDICINE, Durham; Mr. HAY Hull; THE SECRETARY OF THE SANITARY INSTITUTE OF GREAT BRITAIN, London; Dr. MITCHELL BRUCE, London; Dr. H. CAMPBELL POPE, London; OUR EDINBURGH CORRESPONDENT; OUR DUBLIN CORRESPONDENT; OUR ABERDEEN CORRESPONDENT; Dr. WILLOUGHBY, London; Messrs. MOIR & SON, LIMITED, London; Dr. HARDWICKE, Sheffield; Mr. A. J. HARVEY, London; OUR PARIS CORRESPONDENT; Dr. GAIRDNER, Glasgow; Mr. JONATHAN HUTCHINSON, F.R.S., London; Dr. GEO. HARLEY, F.R.S., London; Sir SPENCER WELLS, Bart., London; Dr. LIONEL BEALE, F.R.S., London; Mr. H. H. CLUTTON, London; Mr. VANDYKE BROWNE, Reading; Dr. KRIEKENBECK, Ceylon; Dr. PHILIPSON, Newcastle-on-Tyne; Mr. ARTHUR G. GODSON, London; THE EDITOR OF THE BRITISH MEDICAL JOURNAL; DEPUTY INSPECTOR-GENERAL NICHOLSON, South Norwood; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; Mr. WYNTER BLYTH, London; Dr. HEBB, London; Dr. CLIFFORD BEALE, London; Dr. WOLFE, Glasgow; Dr. DONKIN, London; Dr. ATTFIELD, London; Mr. CANTLIE, London; Messrs. LOEFLUND & Co., London; THE SECRETARY OF THE LONDON SOCIETY FOR THE ABOLITION OF COMPULSORY VACCINATION, London; THE SECRETARY OF THE INTERNATIONAL HEALTH EXHIBITION, London; Mr. T. M. STONE, London; Mr. JOHN ABBEY, Oxford; Mr. POWELL, London; Dr. SHARKEY, London; Mr. MITCHELL BANKS, Kissengen; Dr. CURNOW, London.

BOOKS RECEIVED—

Leamington as a Health Resort — Braithwaite's Retrospect of Medicine, January to June, 1884—Report on the Sanitary Condition of the Hackney District, for 1883—Scientific Basis of Electicism in Medicine, by C. A. F. Lindorme, Ph.D., M.D.—Report of the Health of Liverpool, during the year 1883—The Encyclopædic Dictionary, Part 6—The Alps and how to see them, by J. E. Muddock—International Health Exhibition, Water and Water Supplies, and Unfermented Beverages, by John Attfield, Ph.D., F.R.S., &c.—The Sanitary Chronicles of the Parish of St. Marylebone, during May 1884—Report of the Rotunda Hospital, for the year ending November 3, 1883—On the Origin of Anæmic Murmurs, by J. K. Fowler, M.A., M.D.—Speech by the Right Hon. Sir Lyon Playfair, K.C.B., on the Medical Act Amendment Bill—Lectures on General Nursing, by Eva C. E. Lückes—West African Hygiene, by Chas. Scovell Grant, M.D.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet — British Medical Journal — Medical Press and Circular — Centralblatt für Chirurgie — Gazette des Hôpitaux — Gazette Médicale — Pharmaceutical Journal — Wiener Medicinische Wochenschrift — Révue Médicale — Gazette Hebdomadaire — Nature—Boston Medical and Surgical Journal—Louisville Medical News — Centralblatt für Gynäkologie — Le Concours Médical — Centralblatt für Klinische Medicin—Philadelphia Medical News —Le Progrès Médical — New York Medical Journal — Students' Journal and Hospital Gazette — New York Medical Record—The Edinburgh Clinical and Pathological Journal—The Philadelphia Medical Times—Centralblatt für die Medicinischen Wissenschaften —Berliner Klinische Wochenschrift—Maryland Medical Journal—Weekblad—Société Médicale—The Berkshire Bell—The Australian Medical Journal—Revista de Medicina—El Ensayo Medico—The Therapeutic Gazette—The Boy's Own Paper—The Girl's Own Paper—The Leisure Hour—The Sunday at Home—Friendly Greetings—The Journal of Mental Science—The Canada Medical and Surgical Journal — National Anti-Compulsory Vaccination Reporter—The Veterinarian—The Polyclinic—Belfast Evening Telegraph—The Birmingham Medical Review—Archives Générales de Médecine—The Glasgow Medical Journal—Edinburgh Medical Journal—The Analyst—El Repertorio Medico—The American Journal of Neurology, &c. — The Bristol Medico-Chirurgical Journal.

APPOINTMENTS FOR THE WEEK.

Friday, July 4 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—At 8 p.m., Living and Card Specimens:—Mr. S. Snell, "Bony Tumour of Conjunctiva;" Dr. Walter Edmunds, "Drawing of Optic Disc from a Case of Tumour of Brain;" Dr. Brailey, "A Case of Sympathetic Neuro-retinitis;" Mr. Anderson Critchett, Operation Cases (1) "Conical Cornea," (2) "Tattooing and Iridectomy for Leucoma;" Messrs. A. Critchett and Juler, "Result of Strabismus Operation." At 8.30 p.m., Communications:—Mr. S. Snell, (1) "Some observations on Miner's Nystagmus," (2) "On Certain Congenital Defects of the Eye;" Dr. Walter Edmunds, and Mr. J. B. Lawford, "An Analysis of Cases of Intra-ocular Tumour with respect to the existence of Optic Neuritis;" Mr. Spencer Watson, "Severe Concussion of the Brain followed by temporary Blindness with Anosmia;" Mr. Nettleship, "Case of Hæmorrhagic Glaucoma, Pseudo-glioma, Death from Meningitis."

Saturday, July 5.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, July 7.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, July 8.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Wednesday, July 9.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m. London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday, July 10.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

CLINICAL LECTURES ON THE TREATMENT OF DISEASE.

Delivered in King's College Hospital,

By J. BURNEY YEO, M.D., F.R.C.P.,

Physician to the Hospital.

Lecture III.

Catarrhal conditions of the Respiratory Passages.—Acute and Chronic Laryngeal Catarrh.—Acute Bronchial Catarrh.

Gentlemen, — The remarks I made in my last lecture with regard to the management and prophylactic treatment of persons who are pre-disposed to attacks of acute nasal catarrh, apply with equal force to those who are prone to suffer from attacks of acute laryngeal catarrh. The treatment appropriate to the acute attack itself is also by no means dissimilar. In the early stage the advantage of small doses of opium or morphine in allaying irritation and relieving the cough is most marked. It is well to combine them with small doses of ipecacuanha or tartarised antimony. The administration of an eighth of a grain of acetate of morphia with one twelfth of a grain of tartarised antimony every four or five hours; or 4 or 5 grains of the compound ipecacuanha powder every five or six hours, will usually relieve most of the distressing symptoms—the tickling cough, the soreness in the larynx itself, the difficulty in swallowing sometimes present, and the hoarseness or impairment of voice. Warm alkaline drinks are also of much value in thinning the tenacious adhesive mucus which often hangs about the glottis and upper part of the larynx, and is difficult of expulsion; for this purpose a third of a tumblerful of Ems, or Bourboule, or Apollinaris Water, to which a tablespoonful or two of hot milk or whey may be added, should be drunk every two or three hours.

When it is not easy to get these mineral waters you can prescribe the following mixture, which answers quite as well:—

℞ Sodæ Bi-carbonatis, ʒ j.
Sodii Chloridi, gr. xviii.
Spr. Chloroformi, ℥ xxx.
Aquæ Anisi ad ʒ vj.

M. ft. mist.

Of this mixture two tablespoonfuls should be taken every two or three hours with two tablespoonfuls of hot water or milk.

Counter-irritation and warmth in the shape of a small poultice of mustard and linseed applied over the larynx are of great service. Some, however, prefer cold compresses

It is of the greatest importance to avoid all causes of further irritation. The patient should therefore be kept to the house, and in one uniform temperature.

All exercise of the voice should be forbidden, and the desire to cough should be resisted as much as possible. Violent efforts at coughing irritate and injure the inflamed mucous membrane covering the glottis.

The inhalation of the vapour of hot water or of infusions of demulcent herbs or warm alkaline sprays is useful when the cough is hard and dry and there is difficulty in softening the tenacious and scanty mucous secretions. Direct local applications are rarely advisable in cases of acute catarrhal laryngitis, but they are of great service if the catarrhal condition persists and the case becomes chronic.

Acute laryngeal catarrh is usually a mild and easily managed disease, but it often occurs with troublesome frequency in persons who have to use the voice much in singing or speaking, and it is then more difficult to treat, and tends to become chronic.

But acute laryngitis in young children is often a grave malady on account of the attacks of nocturnal dyspnœa (laryngismus stridulus, or false croup) which frequently accompany it. These attacks often assume a very alarming aspect and are constantly mistaken for attacks of true croup, especially by anxious parents.

A young child becomes affected with what is apparently a mild catarrhal affection, attended with a little sneezing and coughing, but without any dyspnœa or other alarming symptom, but in the middle of the night it wakes up with an alarming attack of dyspnœa accompanied with loud stridulous inspiration, a dry hacking cough, and hoarseness of voice. The dyspnœa is often intense and is attended with great restlessness and anxiety. Careful inspection of the throat will satisfy you that the attack is not due to any membranous or diphtheritic exudation. It is due to the fact that the larynx and glottis in young children are small and imperfectly developed, and the catarrhal swelling of the mucous membrane, together, probably, with the accumulation during sleep of dry tenacious mucus on the margins of the glottis, are sufficient to cause considerable laryngeal stenosis and inspiratory obstruction. In some cases spasmodic contraction of the laryngeal muscles no doubt contribute to the dyspnœa. As a rule, these attacks of dyspnœa pass off after a longer or shorter interval and are unattended by danger; but the attacks have such a serious and alarming appearance, and the anxiety of the little patient's relatives is generally so great that some active treatment is urgently demanded to allay their fears and is usually rewarded with much apparent success.

If the child is a vigorous one no harm, and possibly some good, may be done by the application of a leech, or perhaps two, over the manubrium sterni. It is a proceeding which usually commends itself to the parents, and it is a mistake to suppose that the abstraction of a small amount of blood in such cases can do any harm. Hot sponges applied to the laryngeal region are useful; and while some think highly of a few small and rapidly repeated doses of aconite in these cases, others think better of emetic doses of ipecacuanha and tartarised antimony. Certainly a sixth of a grain of tartarised antimony with 30 or 40 minims of ipecacuanha wine, mixed with a teaspoonful of warm water, will cut such attacks short in a striking manner.

If, however, there is œdema of the glottis, which cannot be thus relieved, and scarification is impossible or fails to be efficacious, while the dyspnœa continues to be alarming, then tracheotomy must be performed.

Attacks such as these are usually limited to childhood; but it does occasionally happen that œdema of the glottis suddenly sets in in the course of an acute laryngitis in the adult. In such cases, if the dyspnœa is alarming and the laryngeal stenosis cannot be overcome by scarification, no time should be lost, but recourse had speedily to tracheotomy. Happily these cases in adults are very rare.

We have in the next place to consider the treatment of *chronic laryngeal catarrh.*

Repeated and neglected attacks of acute laryngeal catarrh lead to the establishment of a chronic catarrhal condition of the larynx, which is often tedious and difficult of cure. It is often brought on by overtaxing the vocal organs in public speaking, singing, &c., so that it is common to find this affection amongst clergymen, public singers, and actors.

It is also, in some cases, due to an extension of a catarrhal condition from the pharyngeal mucous membrane, as in drunkards, and inveterate consumers of tobacco. The hoarse voice of drunkards is well known. It also forms a part of the morbid changes which affect the larynx in phthisis and syphilis. We shall here only consider briefly the treatment of the simple form of chronic laryngeal catarrh, characterised by three prominent symptoms—hoarseness, cough, and expectoration.

The treatment of this troublesome affection requires, first of all, the removal of the exciting cause. Absolute rest of the organ must be insisted upon in the case of public speakers, actors, and singers, and the advantage they often derive from a few weeks' residence and treatment at such spas as Les Eaux Bonnes or Mont Dore probably depends as much, if not more, on the enforced repose and the healthiness of the out of door life, in pure tonic air, they lead there than on the use of the very feebly mineralized waters of those springs.

Local applications are mainly to be relied upon in the treatment of this disease. These are applied to the larynx by the physician himself, usually by means of a brush and with the help of the laryngoscope.

Various astringent remedies are employed for this purpose, and each physician usually has his favourite remedy. Ziemssen extols the use of strong solutions of nitrate of silver, 16 grains and upwards to the ounce, and they are, doubtless, amongst the most efficacious remedies: the good effect lasts much longer than that of milder astringents, so that an application once a week or once a fortnight will suffice. Others prefer the chloride of zinc (20 grains to the ounce) others chloride of iron (20 grains to the ounce), alum (10 grains to the ounce), tannin (10 grains to the ounce), and so on.

In the intervals of these applications the use of astringent or alkaline sprays may be beneficial. A Siegle's steam spray producer is the best apparatus for their production and application. As an astringent, a solution of tannin, 5 grains to the ounce, is perhaps the best. The spray should be applied twice a day for about five minutes each time.

In cases where the mucus secretion is scanty and tenacious and difficult of removal from the mucous membrane and vocal cords, warm alkaline sprays are of much value. A solution of carbonate of soda and common salt, about 5 grains of each to the ounce, is one of the best.

Three or four ounces of Ems or Bourboule water, drunk with a little hot milk, night and morning, will also be found useful in promoting the solution and expulsion of dry, inspissated mucus.

From the number of priests, singers, and actors with laryngeal catarrh one finds frequenting the springs of Mont Dore and La Bourboule, and also the sulphur springs of Eaux Bonnes and Cauterets in the Pyrenees, we may conclude that they derive benefit either from these waters, or from the course of life prescribed for them at those places.

We now pass on to the consideration of the treatment of *catarrhal inflammation of the bronchial mucous membrane* in its acute and chronic forms.

It is extremely important, especially when a ten-

dency to bronchial catarrh shows itself in young children, or in persons advanced in life, or indeed at almost any period, to adopt careful prophylactic measures.

In the case of young children, not only should they be carefully guarded against exposure to chill, to cold currents of air and to rapid and great changes of temperature, but every opportunity should also be taken to brace and harden them so as to diminish the morbid sensitiveness of surface upon which this liability to catarrhal attacks depends. This must, of course, be done with sound judgment and great care. In the warm season cold affusion, cold douching or sponging should be cautiously practised, together with vigorous friction of the surface; and sea water should be employed for this purpose when practicable.

Abundant exercise in the open air, warmly and suitably clad, with flannel next the skin, is of great use also. But exposure on raw, cold, windy days must be especially guarded against, particularly with very young children. Draughty apartments are also to be avoided; and the same remark applies to churches and places of amusement. Many a fatal bronchial catarrh has been acquired in cold, damp, draughty churches.

The general nutrition of young children with this predisposition must also be carefully looked to, especially if there is any tendency to scrofula or rickets, and it is in such cases that the tonic influence of the phosphatic salts of lime and iron is particularly noticeable. Parrish's chemical food has, justly, obtained a wide renown in such conditions.

When possible, residence in a dry or an equable warm climate should be adopted, and cod liver oil should be given in scrofulous cases.

With old people great caution is necessary in protecting them from exposure to changes of temperature, to draughts, to cold, damp air, and from residence in cold, damp localities. They should pass the winter, when possible, in a warm, equable, sunny climate, or if this is not possible, such persons should be content during the bad weather of our British winter and spring to remain in a set of apartments kept at a uniform temperature.

Prophylaxis by means of suitable climatic and general hygienic conditions of life forms a very essential part of the management of these cases.

The treatment of acute bronchial catarrh or acute bronchitis will, necessarily, have to be modified according to the particular form of the malady with which we may have to deal, and according also to the state of the person attacked.

Acute bronchial catarrh may and often does occur as a comparatively slight malady, unattended with any risk or danger if ordinary care and caution in its management be adopted. On the other hand, it also often occurs as one of the most serious and dangerous maladies, frequently fatal, and taxing all our skill in its treatment. Much of its seriousness depends on the age and vigour of the patient attacked, and on the extent of the bronchial surface involved. An attack of acute bronchial catarrh may be limited entirely to the larger division of the bronchi and show no disposition to spread beyond them. These are the light cases, but an attack of acute bronchial catarrh may also be diffused over a wide extent of the bronchial surface and extend even to the finest ramifications of the bronchial tubes. When this is the case, it is, as you know, termed capillary bronchitis; these are cases of the gravest import. Such attacks prove very fatal to children and to feeble and aged persons, and are of great gravity even when affecting robust adults.

Let us in the first place consider the treatment appropriate to a case of acute bronchial catarrh in a previously healthy adult, and limited to the larger bronchi. Such an attack will usually be attended with a slight degree of fever; there will be more or less cough, usually at first dry (that is, without much expectoration) and painful, attended with a feeling of soreness or rawness referred to the upper sternal region. Dry, sonorous, rhonchal and sibilant *râles* will be heard over both sides of the chest, loudest over the upper part. Usually there is but little dyspnœa, unless the attack should be complicated with some spasmodic asthma. Such attacks are popularly spoken of as "severe colds on the chest."

The patient should be kept in bed in a room, the temperature of which should not be lower than 60° F. nor higher than 65° F. The air of the room should be kept moist and unirritating by causing the steam of hot water to be freely diffused through the apartment. Warm mucilaginous or slightly alkaline drinks may be given according to the taste of the patient—barley water, linseed tea, thin gruel; but you will find many patients prefer a mixture of hot milk and seltzer, or Apollinaris, or soda water. These alkaline drinks have a beneficial influence on the secretion from the inflamed mucous membrane, and tend to thin it, to diminish its tenacity, and so promote expectoration, and in this way they relieve the cough.

But there is no remedy with which I am acquainted which relieves this distressing dryness of the mucous membrane in the early stage of acute bronchial catarrh so completely as tartarised antimony. Small doses of this drug, combined with small doses of morphine or opium, you will find most efficacious in relieving attacks of acute bronchial catarrh. The opium relieves the irritative cough by lessening the sensitiveness of the bronchial mucous membrane; and the antimony greatly increases the secretions from it, and so relieves the dryness and swelling which accompany the first stage of bronchial catarrh.

When there is much fever, and the temperature at the outset reaches nearly 103°, a few doses of aconite will be found useful at the commencement of the treatment.

It is important that these remedies should be administered in a suitable form and combination, and in appropriate doses. I would therefore suggest to you the following prescriptions:—

(1) When there is not much fever, and the chief object is to relieve the cough, and the dryness and soreness of the mucous membrane by promoting expectoration, I would give this mixture:—

℞ Vini Antimonialis, ʒ iii.
Liq. Morphiæ Acetatis, ♏ cxx.
Liq. Ammoniæ Acet. ʒ vj.
Aquæ Lauro-cerasi, ♏ cxx.
Syrupi Mori, ʒ iv.
Aquæ ad ℥ vj

M. ft. Mist.

A tablespoonful every two or three hours.

It should be given less frequently as the symptoms are relieved.

(2) If there is much fever, then give the following:—

℞ Tinct. Aconiti, ♏ xxiv.
Vini Antimonialis, ʒ ii.
Liq. Morphiæ Acet. ♏ lxxx.
Liq. Ammonia Acet. ℥ i.
Aquæ Camphoræ ad ℥ viii.

M. ft. Mist.

Two tablespoonfuls every two or three hours.

Much relief is also given by a hot poultice of linseed and mustard, applied over the top of the chest in front, and sometimes also behind, between the scapulæ.

An aperient is often necessary and useful. One or two grains of the extract of aloes at bedtime, and the following morning two teaspoonfuls of Carlsbad salts

in half a tumblerful of hot water, will be found a pleasant and effectual purge.

With this treatment in those milder forms, the acute stage will rarely last more than a day or two, and the white, scanty, frothy, sticky expectoration of the first stage will be replaced by a more abundant, muco-purulent secretion. Patients who have had previous attacks see this change in the character of the secretion with much pleasure, because they know that it is an indication that the attack is passing off. It is now desirable to discontinue the antimony and the opium, or to give it only at night for the relief of cough.

An alkaline mildly-stimulating expectorant is now useful, such as the following :—

Sodæ Bicarb. gr. lx.
Sodii Chloridi, gr. xxiv.
Ammoniæ Carb. gr. xxiv.
Syrupi Tolutani, ℥ iii.
Infusi Senegæ ad ℥ vi.

M. ft. Mist.

Two tablespoonfuls every six hours, and a pill of a grain and-a-half of quinine, and half-a-grain of powdered ipecacuanha may at the same time be given twice or three times a day.

Expectoration is also greatly aided in these cases by an occasional dose of some warm alcoholic beverage, such as a tablespoonful of brandy or whisky in a wineglassful of hot milk and water, three or four times a day.

With this method of treatment you will usually succeed in carrying patients safely and pleasantly through these commoner and slighter forms of acute bronchial catarrh, and convalescence will usually be rapid and complete.

We must next consider the treatment most appropriate to the graver forms of acute bronchitis : to those cases in which the catarrhal inflammation is diffused over a great extent of the bronchial mucous membrane, and affects not only the larger tubes, but those also of medium size, and sometimes even the smallest ramifications.

Such cases when they occur, even in vigorous adults, are very grave and require most careful management ; but when they occur, as they often do, in young children or in old and feeble persons, they are attended with the greatest danger.

When the finer bronchial tubes become attacked, and their calibre is diminished by the inflammatory swelling of their lining membrane, and when many of them become blocked up by the accumulation in them of viscid secretion, you can readily understand how imminent must be the danger of death by apnœa.

Let us ask ourselves what are the objects we have in view in the treatment of such cases? They are these :—

(1) To diminish the inflammatory hyperæmia and swelling of the bronchial mucous membrane.

(2) To thin and liquify the catarrhal secretion when it is dry and scanty.

(3) To lessen it when excessive.

(4) To promote its expulsion from the air passages and so obviate their obstruction.

(5) To allay excessive sensibility of the bronchial mucous membrane.

(6) To maintain and promote the circulation in the lung, and prevent pulmonary venous engorgement and distension of the right side of the heart.

(7) To reduce fever and maintain the general strength.

The several details of treatment by which these indications may be carried out, will have to be modified and adapted to individual cases.

Much will necessarily depend on the age and vigour of the patient, as well as on the stage which the disease has reached when it first comes under treatment. Remedies most appropriate in the earliest stage, and in a young and vigorous adult, might be altogether unsuited to more advanced stages, to a young child, or to an old and feeble person.

We will first consider the treatment of a severe attack of acute bronchitis in a young and robust adult seen at its onset. As in the milder cases the patient's room must be kept at an equable temperature of about 65°, and the air of the apartment must be kept moist and unirritating by the free diffusion through it of the vapour of water.

If there is much oppression of breathing, and a sense of dryness and pain referred to the upper part of the sternum, the withdrawal of a little blood by means of half-a-dozen leeches applied over the sternum will be a judicious measure, and with this may be associated dry cupping over the back of the chest and in the interscapular region. This measure will constantly afford much relief in robust persons when the dyspnœa and sense of oppression are severe.

In most cases it will be advisable to apply large linseed and mustard poultices over the front and back of the chest ; and when the skin is too tender to allow of further counter irritation, a hot jacket-poultice of linseed meal must be used instead.

Of internal remedies I am quite of Stokes' opinion that "there is no remedy that possesses such a decided power over acute bronchitis" as tartarised antimony ; but its success depends much on its early administration : when the bronchial mucous membrane is dry and tumid, and before secretion has become abundant, and when the skin is hot and dry, and the pulse hard and frequent. It should be given in small repeated doses, combined with other diaphoretics and with opium. I have already given you appropriate formulæ.

Warm alcoholic drinks must be given to keep up the force of the circulation, while, at the same time, they favour diaphoresis, reduce fever, and promote expectoration.

Two or three ounces of hot milk or whey, with an equal quantity of seltzer or soda water, and a tablespoonful of brandy or whisky should be given every three or four hours.

Free evacuation of the bowels should be regularly obtained so as to favour the descent of the diaphragm, and afford as complete expansion of the lungs in breathing as possible ; and by unloading the portal system of veins, any tendency to distension of the right side of the heart is to that extent relieved.

It is necessary to insist strongly on the importance of using the greatest discretion in the administration of opium in these cases of severe diffused acute bronchial catarrh. The more diffused the catarrh, the more cautious must we be in the administration of opium. In old people and in young children opium is scarcely admissible, and even in adults, where there is much obstruction to the entrance of air into the lungs from the abundance of secretion in the air passages, opium is a very dangerous remedy.

The effect of opium is to check cough and diminish secretion ; the former it does by lessening the sensitiveness of the bronchial membrane, and the latter by modifying the capillary circulation in it. But in cases of "suffocative" bronchitis, while we might desire to diminish the secretion, we dare not deaden the sensitiveness of the bronchial mucous membrane, or do anything to check the cough. We depend upon the cough to clear and set free the obstructed air passages, and we only desire to make it more efficient to this end.

It is extremely important to bear this in mind with regard to the use of opium in bronchial catarrh ; a dose of opium given injudiciously may produce a fatal

somnolency, quiet the cough, and block up the air passages.

If you give opium at all in such cases, give it only in very small doses, and only when the patient is watched by some thoroughly trustworthy person; but never give it at night to produce sleep, however trying the cough may be, or however urgent the patient or the attendants may be for a sedative.

Remember that opium is rarely ever admissible in the severe diffuse bronchial catarrhs of old persons and young children. When it is very necessary to secure a few hours' sleep, it is better to give from 5 to 20 grains of chloral, with an equal quantity of bromide of potassium or sodium.

With regard to inhalations, Oertel recommends, in the earliest stage, the inhalation of "cold air" according to a method described in his work on "Respiratory Therapeutics," or that of warm aqueous vapour or spray, alone or in combination with mucilaginous or narcotic agents; but when the temperature is high, and the expectoration is scanty and difficult, and the mucous membrane dry, he advises inhalations of Ems water, or weak solutions of sal ammoniac or carbonate of soda, combined with inhalations of cold air.

For the purpose of relieving excessive hyperæsthesia with constant tormenting tickling cough, he warmly recommends the inhalation of a spray containing Extractum Conii Maculati (as employed by Lewin).

The following is a suitable formula for such a spray, to be inhaled warm:—

Extracti Conii Maculati, gr. iii.
(dissolved in rectified spirit).
Aquæ Lauro-cerasi, ℥ xx.
Potassæ Carb. gr. viii.
Aquæ Destil. ℥ i.

M. ft. inhal.

This may be inhaled every two or three hours, and can be employed in cases where it would not be right to use opium.

Cron has published cases of acute bronchial catarrh which he submitted to the action of compressed air, saturated with warm, aqueous vapour charged with sal ammoniac, and he states that the most severe cases were cured rapidly and agreeably.

In the acute bronchial catarrh of children, especially those accompanying infective diseases, such as measles and pertussis, I have found the frequent inhalation of a warm spray containing carbonate of soda and glycerine of carbolic acid of the greatest service in promoting the expulsion of the plugs of tough mucus which tend to accumulate in the bronchi of young children, and obstruct respiration.

I use the following proportions:—

Sodæ Bicarbonatis gr. x.
Glycerini Acid Carbolici ℥ i.
Aquæ Destil. ad ℥ i.

By means of a Siegle's steam spray producer the spray should be allowed to play freely before the child's mouth and nose so that he *must* inhale it with the inspired air.

The advantage of procuring profuse diaphoresis in acute bronchitis has been fully dwelt upon by Niemeyer; whether it acts by derivation from the bronchial mucous membrane, or in some other way, it is certain that profuse sweating is constantly attended with marked relief to the catarrhal symptoms

As soon as the first stage is over, and the scanty and tenacious glairy secretion has been replaced by an abundant muco-purulent one, we must discontinue the use of tartarised antimony, and replace it by small doses of ipecacuanha; and now is the appropriate period for the administration of the stimulating expectorants, such as squills and senega, in combination with carbonate of ammonia.

A suitable formula is the following:—

Ammoniæ Carbonatis, grs. xxxii.
Tincturæ Scillæ, ℥ lxxx.
Sp. Chloroformi, ℥ cxx.
Infusi Senegæ ad ℥ viij.

M. ft. mist.

Two tablespoonfuls every four or five hours.

When the cough remains troublesome, it may be advantageous to add to each dose of the above mixture five minims of wine of ipecacuanha, and thirty minims of compound tincture of camphor.

On the other hand, as convalescence advances, the tincture of squills in the above mixture should be replaced by one dram doses of tincture of cinchona.

In all such cases symptoms of debility and loss of power must be immediately encountered by the free administration of alcoholic stimulants.

In debilitated persons, and when we do not encounter the case in its earliest stage, a combination of carbonate of ammonia, ipecacuanha (in small doses), and bark, with warm alcoholic stimulating drinks, and the inhalation of warm alkaline sprays to thin the secretions—these are the measures to be relied upon, and not tartarised antimony or opium.

With young children, who cannot expectorate, we must give occasional emetics. Ipecacuanha is the best, and if the child is robust, tartar emetic may be combined with it. Twenty grains of powder of ipecacuanha and a quarter of a grain of tartarised antimony, mixed with a tablespoonful of syrup and water, will usually have the desired result. The effect of the emetic is not only to promote expectoration, but by the mechanical compression of the lung it induces, it tends also to relieve congestion. The sticky mucus which accumulates in the child's mouth after vomiting should be carefully removed.

Some use the hydrochlorate of apomorphia as an emetic in these cases. One twentieth of a grain injected hypodermically can usually be relied upon to produce vomiting in ten minutes. When a child cannot be induced to swallow an emetic, this is obviously a valuable alternative.

Emetics are also useful in cases other than those of children, when, owing to debility of the bronchial muscles, the catarrhal secretions are retained in the air passages. This state "may be detected when, immediately after the act of coughing, the *râles*, instead of subsiding for a time, persist with scarcely any diminution. In such an emergency, should the expectorants fail, an emetic is imperatively indicated." (Niemeyer).

In young children who do not know how to cough, besides the removal of the accumulated secretions by means of an emetic, the child may be roused to more active respiratory efforts by putting him in a hot bath, and sprinkling cold water on the chest while in it. Nor should he be allowed to fall into a prolonged or deep sleep, but should be aroused from time to time, and the spray of solution of carbonate of soda and glycerine of carbolic acid applied as I have already described.

In cases in which there is a tendency to a maintenance or recurrence of fever, quinine must be given. Many other details in connection with the treatment of bronchitis will be considered in my next lecture, which will be devoted to the treatment of *chronic bronchial catarrh*.

Treatment of Ear-ache.—It is said, that by the following simple method almost instant relief of ear-ache is afforded. Put five drops of chloroform on a little cotton-wool in the bowl of a clay pipe, and then blow the vapour through the stem into the aching ear.—*New York Medical Record*, May 24.

CLINICAL LECTURE

ON PERFORATING ULCERS OF THE SEPTUM NASI.

By JONATHAN HUTCHINSON, F.R.S.,
Emeritus Professor of Surgery in the London Hospital College.

(*Continued from page 7.*)

My next two cases have for their subjects those in whom specific disease had undoubtedly occurred. There had been, however, a long interval in each. In both there was an entire absence of other specific symptoms at the time of the perforation of the septum, and in neither did the ulcer spread rapidly, as is usual in those of a specific nature.

Case IV.—Mr. B. F. consulted me in August, 1883. He was a married gentleman, aged 39, with two healthy children. He appeared to be in perfect health, but was hypochondriac in several directions, and especially in reference to specific disease. For this he had, he said, been treated by the late Mr. Startin in 1867, but had never had anything excepting the primary local symptoms. One year before coming to me, he had, whilst living in Australia, suffered from some eruption on his nose, and had discovered that there was a sore inside it. On each side of the cartilaginous septum, about half an inch up, was a grey-based sore about the size of a fourpenny piece, which was always covered by an adherent scab. This scab was extremely thin, almost paper-like, and the sore below usually bled when it was detached.

I treated Mr. F. for several months, applying the acid nitrate of mercury lightly about once a month, sometimes to one side sometimes to the other. I gave him also some small doses of mercury, but at the end of the treatment felt less and less inclined to believe that he had any just ground for his suspicion that the ulcers were specific.

He told me that he could remember in boyhood that his nose used to be sore, and that he used to pick it. And he gave me also the curious fact that his father had a hole through his septum. This formed, so far as he could remember, when he was about 50, and he thought in connection with the habit of picking the nose; he lived thirteen years afterwards, and except a certain amount of local irritation had no serious trouble from his nose.

The result of treatment in Mr. F.'s case was, that the ulcer healed without actual perforation, but the septum had become exceedingly thin, and I have little doubt that on some future occasion it will give way under a relapse of ulceration.

Mr. F. has for the present returned to colonial life.

Case V.—Mr. H. is a wool-stapler, aged about 40, and in excellent health. There is no doubt that he has suffered from specific disease, but it was many years ago, and excepting his nose there is no reason to suspect that it lingers in his system. He has one child in excellent health. When Mr. H. first came to me, the perforation was already large and would easily have admitted the end of a thumb. It had destroyed not only the cartilage but a considerable extent of bone, and at its posterior edge, where ulceration was still going on, the edge of the vomer was bare. From the history it appeared that the ulceration had begun in the usual position, and slowly and steadily advanced backwards, eating its way more like a rodent ulcer than a specific one, thus it had never caused any exfoliation of fragments of bone, and never been attended by any acute inflammation or any fetid discharge. I have treated this gentleman, seeing him once in three months, for about two years, and have made repeated applications of the acid nitrate of mercury to the posterior and spreading edge; he has also taken for a long time small doses of mercury. I believe that the ulcer is at length quite healed, and may say that since I have had him under care there has been no real spreading, although I was never able until lately to say that the healing was complete in all parts. The exposed bone seemed to hinder the scarring, and it would not exfoliate.

Case VI.—Mrs. A., aged 46, was under my care in November, 1883, for an ulcer on the septum which had not perforated. It was on the right side about one inch above the border of the columna; it had a scab on it and bled very readily when this was detached. It was nearly round and about half-an-inch across. She believed it had remained in its present state, or at any rate without any material advance, for four or five years; and in confirmation of her suspicion said that she had consulted Mr. Carr Jackson on account of a sore nose as far back as 1878. It must not, however, be held to be by any means certain that the ulcer on the septum was present then. I cauterised this ulcer, but have since lost sight of my patient and cannot tell you whether it has healed or not.

Case VII.—Miss M., a governess, aged about 26 years, was sent to me by her brother, who is a medical man, on account of an ulcer in her nose. She was in great distress and anxiety, for a younger sister had lost her nose, both lips and a large part of her face by lupus. I have subsequently had this younger sister under treatment and can tell you that beyond question her disease is simply lupus. It began, I believe, on the nose, and it has destroyed the septum further back than is usually seen. To return to my first patient. I found a little ulcer in the septum with slightly raised edges, leaving a hollow that would have held about half a pea. I cauterised this ulcer carefully but freely with the acid nitrate of mercury and it healed absolutely and soundly. Miss M., however, came to me about a year later with soreness in the other nostril for which we had to adopt similar measures. I have little doubt that in this case we ought to consider the ulcer as lupoid in character. It will be seen that the patient is much younger than most of those in my series.

Case VIII.—In March, 1883, Dr. Carden, of Bath, brought to me a gentleman, aged 42, an Australian colonist, apparently in excellent health. He came on account of an ulcer in the right nostril on the septum. It was as big as a fourpenny piece but ovoid in shape. The cartilage itself was exposed, and the whole of the sore had a grey base. In the opposite nostril, the mucous membrane over the corresponding part was dry and slightly abraded. There was no actual perforation, but clearly the tendency was steadily in that direction. The ulcer had been known to be present for about ten months. There was no reason to believe that specific disease was even possible. Our patient had a healthy family, and he absolutely denied that he had ever been exposed to risk. He had taken much iodide before I saw him without any advantage to the ulcer. The fang of his right canine tooth and its alveolus were exposed, and I picked away a small scale of the latter from over the fang. There was nothing, however, in the condition of these parts which was suspicious either as regards lupus or syphilis. During the month that this gentleman remained under my care, I touched the ulcer three times with the acid nitrate of mercury. It got much better, and I believe that it healed, but have no positive evidence on this point as our patient has returned to his Australian farm.

Case IX.—Mrs. F., a lady, aged 37, having five living children in good health, was under my care in May, 1882, on account of a perforating ulcer of her septum. She had taken a great deal of iodide of potassium, and had not cured it, and also the green iodide of mercury up to slight ptyalism. Mr. T. H. Bartlett, of Birming-

ham, who sent me this patient, sent also a very complete history of her case, and it comprised some very suspicious facts although nothing that was quite conclusive. Thus, although there was no history of any primary or secondary disease, and although her five living children were in good health, Mrs. F. had had two or three premature confinements, and she had herself lost her uvula with a small part of the soft palate. The ulceration of the palate had occurred about two years before I was consulted and a little after the first symptoms in the nose had been noticed. It had apparently been arrested by the iodide of potassium and had now healed soundly. I cauterised the edges of the ulcer in the nose with the acid nitrate of mercury, and ordered tonics and a mild mercurial ointment; we no longer gave any specific internally. In May of the present year, in answer to my enquiry, Mr. Bartlett was kind enough to inform me as follows: "Mrs. F.'s nose is quite well, and has been so since she saw you. She has since had three early miscarriages and no completed pregnancy. Her health is good and her nose gives her no trouble." If we grant that the loss of uvula &c., and the healing of the parts under the iodide are in this case proof beyond question that there exists a specific taint, it may still be urged that the ulcer of the septum was cured by local treatment and did not get well under the internal administration of specifics.

Case X.—Miss M., aged 50, a governess, was under my care in June 1873. Her nose had fallen considerably owing to the destruction of the septum. She had also suffered from common lupus of the end of the nose in a very chronic form. The first symptoms inside the nose were in 1860, whereas the skin at the end of the nose was not affected until 1868, and did not ulcerate till after an attack of low fever in 1872. The disease began, she said, by obstruction in the nose, and next she had ulceration of the septum, for which she was brought to me by her medical attendant, the late Dr. King, of Hackney. I saw her but once, and cauterised the sore. Dr. King repeated the cauterisation and it healed perfectly, and remained sound some years. There was no reason to believe she had had syphilis, either inherited or acquired. When I saw her on the second occasion the septum had been very extensively destroyed. The disease, as you will note, had been exceedingly slow. My impression is, that we have in this case a good example of a disease which was really lupus, beginning by ulceration of the septum of the nose. It is the only case which I can produce to you in which the perforation of the septum and lupus of the skin were actually coincident in the same patient. In another instance I have already mentioned that one young lady had a perforating ulcer, and her sister common lupus. This case is also exceptional, in that the destruction of the septum has been extensive enough to cause deformity. In my other cases there was no falling in whatever.

Case XI. — Dr. Alexander Reid, of Canonbury Park, brought to me a very interesting example of this disease. It occurred in the person of a very healthy looking gentleman, aged about 50, living at the seaside. There was a history of syphilis thirty years ago, but so far as he knew he had been quite well ever since. The sore in the septum of the nose had first shown itself two or three years ago. It had been extremely slow in progress, and had not yet caused perforation. It was covered by a thick adherent scab which made it look much larger than it really was. When this had been removed a very superficial ulcer was all that remained. Vigorous specific treatment had been used (not by Dr. Reid) for some months before I was consulted, and without any definite benefit. Taking this into consideration, together with the facts that our patient had a healthy family and no concomitant symptoms, I felt no hesitation in believing that the ulcer was not specific and in advising that only simple measures should be adopted. I touched it lightly with the acid nitrate of mercury and ordered a yellow oxide ointment. At his next visit, a month later, it was very much improved and appeared likely soon to heal.

Case XII.—The case of the Rev. Mr. G. is of some interest in connection with this matter. He is now nearly 60 years of age. Many years ago he was salivated by Mr. Critchett on account of an attack of neuro-retinitis, and his case is mentioned by me as an instance of the benefits of mercury in my article in "Reynold's System of Medicine." It is now more than thirty years since his primary disease. Of late years he has suffered a good deal of annoyance from a superficial form of specific lupus on both legs. This is never attended by any deep ulceration, but has crept superficially over large areas. It is always benefited by the iodide internally, and mercurial ointments, but he never perseveres long enough to get it quite well.

On April 1st, 1884, he came to me on account of a little ulcer in his nose. I found on the septum in the left nostril a sore about as big as a split pea covered with a dry scab, on the detachment of which it bled a little. The ulcer was, however, remarkably quiet and there was no inflammation on the parts around it. Its conditions were very similar to those of the lupus on his legs.

In this instance it is difficult not to admit that the cause of the ulceration on the septum is the same as that of the lupoid sores on the legs and that both are remotely connected with the specific taint. You will note, moreover, the very long interval which has passed and the extremely chronic and very slowly progressive character of both maladies. They are syphilitic, no doubt, but only in a remote degree.

The twelve cases which I have brought before you do not comprise by any means all that I have seen. They are sufficient, however, I think, to illustrate and prove the statements with which I set out. Chronic perforating ulcers of the septum nasi occur not unfrequently under conditions which preclude the suspicion of syphilis. Sometimes they are of the nature of lupus, and the younger the patient the more likely it is that they have this relationship. They are most common after middle age, and in not a few patients at this period of life it is impossible to assert anything with confidence as regards their cause. Even when there is a clear history of syphilitic antecedents, if the ulceration be very slow and without tendency to diffuse inflammation or to exfoliation of bone, it will usually be found that internal treatment by specifics does very little good whilst local treatment will cure. The best local treatment is the repeated careful application of the acid nitrate of mercury and the use of the yellow oxide ointment.

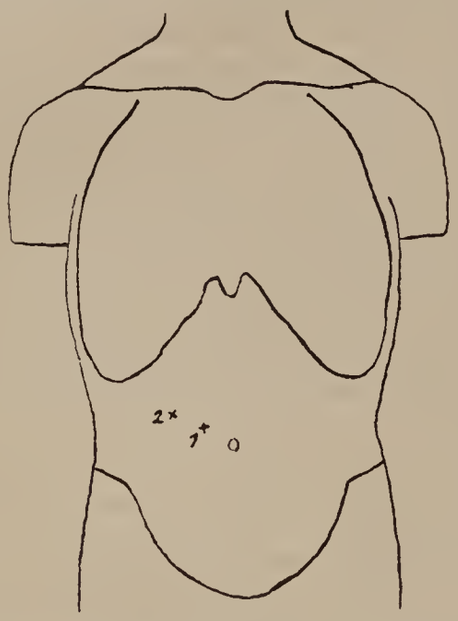
ON SOUNDING FOR IMPACTED GALL-STONES.

By Dr. GEORGE HARLEY, F.R.S.

(*Continued from page* 10.)

The patient, a delicate constitutioned lady, aged 36, married, and the mother of several children, had for many months suffered from all the worst signs and symptoms of obstructed common bile duct. Not only was her abdomen greatly distended with ascitic fluid; but she was so weak and near to the point of death that both Dr. Diver—her regular medical attendant—and I, believed that the only chance of prolonging her life lay in the artificial removal of the obstruction. Before, however, calling in an operative surgeon to perform bilotomy, we deemed it prudent to make perfectly sure that the obstruction of the bile duct was

due to the presence of a stone, as neither of us had any wish to see the poor sufferer's abdomen unnecessarily opened. Accordingly, a day or two after a gallon of ascitic fluid had been withdrawn from her abdomen, she was made insensible with A. C. E. anæsthetic mixture (given because of her having a weak heart). I then introduced an exploring trocar (in the manner before described) at a point midway between the lower margin of the liver and the umbilicus; but an inch and a half to the right of it. Fig. 1.



The instrument was then slowly pushed upwards, outwards and backwards in the direction of the common bile duct; but although it was inserted up to its hilt (six inches) in the still distended ascitic abdomen no hard substance was encountered. In order to ascertain the exact position of the cannula's point, I withdrew the stilette to see if any, and what kind of fluid would flow from it. As nothing but ascitic fluid came away, its point was known to be free in the abdominal cavity, so I proceeded to search with it in all directions for the suspected stone. The search proving unsuccessful, the instrument was withdrawn and reinserted an inch higher up, a little more to the right. Fig. 2. On again pushing it in the direction of the common bile duct, just as it reached its full depth of six inches, its point not only impinged upon, but stuck in a hard substance. The sensation communicated to the fingers, as well as the faint sound emitted when this was tapped against with the blunt end of the cannula, left no doubt upon my mind that it was a calculus. The next point was, if possible, to ascertain its size, by pressing the end of the cannula firmly against it, and running the point of the instrument round it. The impression so derived was that the stone was of the size and shape of an ordinary hazel nut. As no blood whatever flowed from the punctures, either during or after the operation, these orifices were simply covered over with a piece of sticking plaster, and the abdomen bound up.

The sounding having thus completely confirmed the symptomatic diagnosis, and further shown that the obstructing stone was no bigger than a moderately sized hazel nut, it was deemed advisable, before subjecting the patient, in her exceedingly weak state, to the severe operation of bilotomy, to delay a few days in the hope that under the influence of medicine, the stone might pass along the duct into the intestines. Most fortunate this determination turned out to be; for at my next visit—six days after the sounding—I found all the signs and symptoms ameliorated. The stools had not only already become of their normal colour (which they had not been for many weeks), but the urine had lost its bilious hue, and the skin was less jaundiced. Besides which, the previously distended gall-bladder was now no longer perceptible to the touch. Changes which, when considered collectively, led to but one conclusion, namely, that the duct was free—that the stone had passed. As it had not, however, been found in the stools, it was thought to be still within the bowels, experience having taught me that stones after having safely reached the intestines do not always immediately come away, but often remain in them for weeks, sometimes even for months.

No untoward symptom resulted from the operation. Everything went on well until the eleventh day after the sounding, when pain and tenderness were complained of in the right iliac region. The pulse became rapid. The temperature rose, and signs of enteritis speedily followed, no doubt from the usual cause in such cases, namely, the irritation produced by the stone getting lodged in the ileo-cæcal valve. Its ordinary concomitant, peritonitis, supervened, and notwithstanding that the patient had regained considerable strength during the eleven days of convalescence after the sounding, she sank and died twenty-seven days after the operation, which had so fortunately led to the accidental dislodgment of the stone, after its having been for so many weeks previously firmly and dangerously impacted in the duct. A theory of the cause of the sudden extrusion of the stone shall be given presently. Meanwhile I will give the result of the necropsy, which consisted of an examination of the liver, its biliary appendages, and their intestinal attachments, all of which parts were kindly forwarded to me by Dr. Diver. Their examination yielded the following interesting information :—

1st. The gall-bladder, in so far as bile was concerned, was found empty, for it contained not more than half a drachm, clearly proving that the obstruction to the outflow of the bile had ceased before the patient's death.

2nd. The gall-bladder contained thirteen biliary calculi. The three largest lay in a row, and fitted on to each other's ends by facets. The largest of all, which lay with its broadest end downwards against the orifice of the cystic duct, was seven-eighths of an inch long, and six-eighths of an inch broad. In contact with its upper facet was an angular cornered stone of the dimensions of a moderately sized hazel nut, against the upper end of which lay the smallest of the three. It differed from its two companions in being facetted at its lower end only. The gall-bladder was contracted upon the stones.

3rd. The fact of the calculus impinging on the orifice of the cystic duct having a facet at its lower end of the same size as that at its upper, and there being no stone to correspond either in size or shape to it in the gall-bladder or bile ducts, leads to the irresistible belief that the calculus which belonged to this facet must have not only escaped from the gall-bladder, but from the common bile duct during the lifetime of the patient.

4th. The fact of all the signs of an obstructed bile duct having suddenly vanished after the sounding, favours the theory that the passage of the stone from the bile duct was in some way or other directly connected with the operation.

5th. The extrusion of the stone from the duct after having been so long and so firmly impacted in it, may be accounted for in the following manner :—

Assuming that it was as angular at its corners as the hazel-nut sized one found in the gall-bladder, it is easy to imagine that it was sticking angular-wise in the duct when the sounding was performed, and that the pressure exerted on its corners, when the cannula was being passed firmly round it in order to ascertain its size, altered its position in the duct; and

from its assuming a more longitudinal one (the other stone was slightly oblong) it was enabled to slip along and out of the duct into the intestines.

Now comes the important question :—

Of what practical good is the narration of this case ?

I reply—Of great practical good, if its teachings are properly considered. For its history clearly establishes the following points :—

A. That the presence of an impacted gall-stone may, under similar circumstances as the above, be indubitably ascertained by instrumental means.

B. That not only can the exact position and probable size, but under favourable circumstances even the very shape of an impacted gall-stone be instrumentally ascertained.

C. That the operation of sounding for gall-stones in the way here advocated is as safe in skilled hands as the tapping of a distended gall-bladder or ovarian cyst.

D. A knowledge of the clinical facts adduced may possibly deter enterprising surgeons from laying open the abdomens of patients in search for gall-stones which not only possibly but even probably have no existence whatever.

E. While the fact of being able to indubitably ascertain the existence of a gall-stone without undertaking the severe operation of incising the abdomen, on the mere chance of finding one, may induce physicians to recommend patients suffering from suspected dangerously impacted biliary concretions to submit to the operation of sounding, with the ulterior view, if a stone should be detected, of advising its extraction, seeing that in a number of instances the removal of the stone from the duct by the surgeon's knife offers the only chance of saving the patient from an untimely grave.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

CHARING CROSS HOSPITAL.

CASE OF DIFFUSE BRONCHIECTASIS OF THE RIGHT UPPER LOBE.—DIAGNOSIS FROM TUBERCULAR PHTHISIS.

(Under the care of Dr. MITCHELL BRUCE, F.R.C.P., Physician to the Hospital.)

(Reported by Mr. HUZZEY, House Physician.)

ALICE S., age 22, single, was admitted into the hospital on October 12th, 1883.

The patient stated that her father and mother were alive and healthy ; she had three brothers alive ; one had died of consumption, another of acute bronchitis. She had five sisters, all strong and well.

Previous History.—Patient was never ill until three years ago, when she had bronchitis for four months. Since then she has had a slight cough, but no further illness until three weeks ago, when she felt weak and faint, and the cough increased. For two days she had slight hæmoptysis, the blood being of a bright scarlet colour.

Present Condition. —Patient is a well nourished, rather hysterical-looking, but delicate young woman. Chest fairly well shaped, without striking impairment of movement. Rhonchal fremitus is felt under right clavicle ; vocal fremitus weak over both fronts, not felt behind. Both back and front of chest slightly hyperresonant ; resonance behind reaches to the bottom of the tenth interspace in the scapular line. Breathing on the left side is a trifle harsh, and accompanied occasionally by a few sonorous and sibilant rhonchi. On right side it is almost obscured by *râles;* so far as it is heard, its character is not much altered. The *râles* consist of tough creaking sounds, heard all over right side, especially on inspiration. The creaking sounds are altered in character but do not disappear on coughing. Voice sounds throughout are natural. Cough spasmodic, worse in the morning. Expectoration consists of pellets of thick tenacious muco-pus Appetite good ; tongue slightly coated ; pain in epigastrium, increased after food ; feeling of sickness, without actual vomiting. Pulse 96, regular and weak. Temperature varies daily between 98° and 101° or 102°. She was ordered to take 3-grain doses of iodide of potassium with carbonate of ammonia ; and ether and ammonia during the attacks of convulsive cough.

October 18.—Patient was seen during a severe fit of coughing. The act is attended by an appearance of great excitement and anxiety, lividity of the face, perspiration, and violent muscular struggling. When the patient is assisted, she resists restraint and screams in a hysterical fashion.

December 5.—Condition much improved. Coughing fits by no means so severe. The sputum contains no bacilli. Right subclavicular region flat and less movable ; vocal fremitus, as on left, moderate ; rhonchal fremitus distinct ; percussion impaired without absolute dulness ; and the same over clavicle and in supra-scapular fossa. Respiratory murmur over right upper lobe covered by abundant large tough *râles* or rhonchi, peculiarly coarse, dry, friction-like in character. Posteriorly and inferiorly these become more abundant, much smaller, and more moist. They are disturbed by cough, but increased rather than diminished. Over base, coarse respiratory murmur is mixed with the rhonchi. Bronchophony and pectoriloquy all over front, down to nipple level ; absent below that. Over left lung generally loud, coarse, rhonchoid respiration. No pulsation to right of sternum ; cardiac apex normal.

January 6th, 1884.—Discharged, much improved.

Remarks.—Dr. Bruce pointed out that the chief interest of this case lay in its close resemblance to true tubercular phthisis, and the method by which its nature was diagnosed. On admission the patient was believed to be suffering from ordinary phthisis ; but a study of the signs and symptoms quickly revealed the true nature of the case to be diffuse bronchiectasis of the right upper lobe. The most striking symptom was convulsive cough, not unlike pertussis in all its characters, but even more violent. This kind of cough, which is peculiarly suggestive of retention of bronchial and pulmonary products, does not appear to be sufficiently appreciated as a diagnostic symptom of chronic pneumonia, bronchial dilatation, or basic cavity. In the present case it was exaggerated by the hysterical behaviour of the girl. The physical signs, though closely simulating those of phthisis, were really distinctive : the thick croaking *râles*, unaffected by repeated cough, and attended by little change in the respiratory murmur (where audible), clearly corresponded with the condition suggested by the peculiar cough. The diagnosis was tested by repeated examination of the sputum, which contained no tubercle bacilli. The importance of a correct diagnosis in such a case is obvious. Therapeutically it indicated saline expectorants ; and the combination of iodide of potassium and carbonate of ammonia quickly increased the amount (liquidity) of the sputum, with remarkable relief of the cough.

ROYAL INSTITUTION OF GREAT BRITAIN.—Professor Arthur Gamgee, M.D., F.R.S., has been appointed Fullerian Professor of Physiology for three years.

Medical Times and Gazette.

SATURDAY, JULY 12, 1884.

Our Paris correspondent writes :—The cholera continues to be the prevailing topic of the day. The epidemic seems to be steadily increasing, the largest daily number of fatal cases reported at Toulon being 25, and at Marseilles 30. It must be remembered that, considering the intense emigration which has taken place, and the dispersal of the garrison, the population of Toulon may be at present estimated at 50,000, or in round numbers, one-hundredth of the population of London. To establish a comparison, therefore, between the two cities, it is necessary to add two cyphers to the right hand of each figure—25 deaths at Toulon represent 2,500 deaths in London. Now, if 2,500 deaths from cholera were registered in London in a single day, there would probably be, to use an elegant transatlantic expression, "a general stampede of citizens." "Internal" cases have occurred in ample numbers in the hospitals. Dr. Borel, a naval physician of high rank, died a few days ago, and was buried with great solemnity. He was the first medical victim of the epidemic. Since then, medical students and attendants have also been struck down. Sœur Macedonie, a sister of charity, who died of cholera the other day, well deserves to have her humble name put down among those who did their duty to the last. Two other sisters of charity have just been removed to the hospital ; and the disease, in spite of all sanitary precautions, has made its appearance in the naval prison. At Aix, three cases of cholera are reported ; and one has occurred in the vicinity of Grenoble, at Goncelin. Cases are also reported in Italy, at Saluzzo, and at Verona. It is also stated that a few cases have occurred in Spain.

The state of things which results from the sanitary precautions established by various governments and municipalities is both laughable and painful. At Perpignan, for instance, travellers on arriving at the station are locked up, and disinfected by the emanations of burning sulphur. Two ladies subjected to that treatment were nearly suffocated. Not only the lungs and eyes of travellers, but also their watches and jewels are injured by such fumigations, which are more likely to kill off delicate subjects than to stamp out the seeds of disease. In other places, travellers are obliged on arrival to strip off their clothes, and plunge into a bath saturated with sulphate of copper—worse than the mutton broth of workhouse celebrity. On the Spanish frontier, people coming from France are obliged to spend a week in the lazaretto of Irun ; and, as that delightful abode cannot supply a sufficient number of beds, one has to spend first a week at Hendaye, on the French frontier, before being allowed to spend another week in the Spanish pest-house. Such measures are better calculated to breed cholera than to prevent it, for a single case occurring in these dense but artificial agglomerations would be sure to create a local epidemic, which most undoubtedly would penetrate the Spanish frontier. The most stringent measures have also been taken upon the Italian frontier, and many French journals insist upon similar precautions being taken within France itself. But travelling under such conditions would become absolutely impossible, and the uselessness of such proceedings has long ago been demonstrated. It is clearly possible to check the propagation of cholera by sea ; it is clearly impossible to check its propagation by land.

In a remarkable and impressive speech delivered at the Academy of Medicine on Tuesday, Dr. Rochard, who has just returned from Toulon where he has been inspecting the fleet, insisted upon these views. "We stand," he said, "in presence of an averred epidemic of Asiatic cholera. Let us face the danger like men. Let us consider the present visitation as a solemn warning. Let us remember that when proper sanitary measures were enforced in the Red Sea, the evil was averted for a space of sixteen years, while, as soon as these measures were laid aside, cholera invaded Egypt, and from thence after a short pause, sprang upon Europe. For the present epidemic," said he, "unquestionably comes from Egypt, not from Cochin-china." The eminent speaker then proceeded to give some facts and figures concerning the chief features of the disease as observed at Toulon. He stated that its intensity was perhaps less severe than on former occasions. In 1835, Toulon lost 1,656 inhabitants from cholera ; in 1849, 751 ; in 1854, 1,135 ; in 1865, 1,331. Up to the 7th of July, the deaths from cholera have amounted to 159. But the inhabitants remember that on former occasions the disease made its appearance in a mild, insidious form, and suddenly rose to an alarming degree of intensity. Such is the chief cause of their present fears. Dr. Rochard states that premonitory diarrhœa has existed in all cases, even in the most rapid ones, terminating fatally in the space of six hours. This diarrhœa lasts in general a few days, sometimes a few hours. Vomiting and cramps appear in succession. Algidity and suppression of urine constantly follow. In fatal cases, most patients die in the stage of typhoid reaction. The proportion of deaths is about one in every five cases. Hypodermic injections of morphia have not proved beneficial, Dr. Rochard prefers atropine and sulphuric ether. Inhalations of oxygen, as performed by Dr. Troncin, have proved beneficial, especially when the patient was in a comatose state.

After this communication, the Academy voted a proposition, to the effect of requesting the authorities to postpone the celebration of the 14th of July, considering that under the present circumstances the agglomerations which the National festival necessarily produces would create an imminent danger. Similar resolutions had previously been voted by the Board of Health and the Society of Public Medicine and Professional Hygiene. And yet, in spite of all, the festival will be celebrated. The opposition, it is said, must not have an opportunity of charging the Republic with want of proper courage. It might well be replied that bravery on the field of battle and on all proper

occasions is a very different thing from foolhardiness; that there is no disgrace in bending under the pressure of natural forces, and that cholera is one of those foes "quos opimus fallere et effugere est triumphus."

It is stated in one of the daily papers that the Medical Act Amendment Bill is to be withdrawn, as it is hopeless to attempt to pass it this session; and judging from Mr. Gladstone's statement to his supporters on Thursday, we can fully believe it. We quite agree with the President of the Edinburgh College of Physicians, who says, in a letter to the *Scotsman*, that he and many others prefer the Bill as it is to the Bill with Sir Lyon Playfair's amendment; but we are inclined to go further, and to prefer no Bill at all to one so changed from its original shape and intention, as it would have been changed if the Playfair amendment had been accepted by Mr. Mundella. For one reason, it is a pity that the Bill is to be withdrawn before it reaches a further stage, for it is stated by another daily paper, that an amendment of a novel character, originating with Dr. Lyons, was to be submitted in Committee. This amendment would have proposed to authorise the appointment of two practising physicians or surgeons, of not less than twenty years' standing, as life peers, to act as Lords of Appeal in Ordinary in medical cases. Of course it would not have been accepted, but its discussion even would have been of some use.

The hybrid committee has rejected the Lower Thames Valley Drainage Scheme, in spite of Mr. Harrison's very favourable report. The report, though not published, was communicated to the committees of promoters and opponents and by them to other persons directly interested therein. Mr. Harrison approves of the scheme in nearly every detail, the process for purification proposed; a combination of precipitation by sulphates of aluminium and iron, with lime to give an alkaline reaction, and subsequent filtration by irrigation being in his opinion the best system known. After referring to the success which has attended it at Coventry, Hertford, and other places, he says, "I am confident that under good management the treatment of the sewage as proposed would not create any nuisance in the neighbourhood, that the effluent might be discharged into the Thames at all times of the tide without any injurious effect on the river and that it would soon be found that the sentimental grievance would soon give way to the acknowledged benefit afforded to the district by the establishment of the works." Dealing with the objections urged against the scheme by the inhabitants of Kew, Mortlake, and Richmond, Mr. Harrison states that these places will all be immediately and very materially benefited by the sewage works, and that even if the works were conducted in the most careless manner they would not experience anything like the nuisance to which they are at present periodically subjected by the emptying of their own and their neighbours' cesspools, to say nothing of the danger incident to the proximity of these to wells in the more rural part of the district, and he feels satisfied that whatever check the establishment of these works may for the moment give to building operations, the advantage of having an efficient system of sewerage will be appreciated, and before long building will be resumed and probably on a greater scale than hitherto. He disposes very shortly of the objections made by the various rowing clubs, by reminding them that at the present time a large amount of sewage does find its way into the river in its crude state, and as every one knows, causing local nuisances and general pollution, whereas, on the new system, no sewage whatever would be admitted until it had been so treated as to have become perfectly clear and free from the slightest odour. Such an effluent does not interfere with the use of a river for boating, bathing, fishing, or any purpose except drinking at or near the point of discharge. As regards the objections brought forward by the landowners, they are such as would have been urged against any spot that might have been chosen and which, if attended to, would effectually block any and every proposal that could possibly be made for the removal of an acknowledged and yearly increasing evil—the pollution of the river by the existing sewers and the impediments to the construction of sewers in places where there are none as yet.

Mr. Nettleship's paper on Thursday week at the Ophthalmological Society's afternoon soiree, if we may be guilty of using such an expression, was interesting both to physicians and surgeons. To the former especially on account of the good evidence it afforded of the possibility of a neuritis being local and limited in extent. We lack positive evidence in any of the cases as to the exact nature of the affection, but their course enabled Mr. Nettleship to exclude a good many causes of neuritis with certainty. Indeed the best argument that could be urged against the diagnosis of local neuritis in these cases would be that we have, so far as our knowledge goes, at present no corresponding affection of the nerve trunks throughout the body, and it is not easy to see why the optic nerve should be thus liable to an affection from which the other nerves are singularly exempt. Cases do every now and then crop up in which it seems likely that a paralysis is due to peripheral neuritis, but they are few and far between. On the other hand it is to be remembered that it is much easier to recognise neuritis in the optic nerve than in any other, and many cases of neuralgia may in reality be due to neuritis.

Mr. Hutchinson's case of proptosis, which concluded the business of the afternoon, was worthy of a larger audience, and was an ample reward to those who had given up their afternoon in order to attend the meeting. An abstract of the case will be found in our report on another page, but one feature of it seems to have escaped notice, and that is, that the proptosis was confined to one eye in varying degree for three years, and a few days after this eye had been lost by suppurative inflammation the other eye became protruded. It is difficult to frame any rational hypothesis which would explain such an occurrence as this. It would seem to afford an argument against the idea of the

affection having a central origin, and this view would be further supported by the benefit derived from the local application of ice. The treatment by ice seems to have been suggested by its success in some cases of exophthalmic goitre, when applied to the thyroid. It is evident that we are here in the presence of a disease, a satisfactory explanation of which has yet to be given.

At the Annual Meeting on Friday evening, Mr. Snell read a paper on miners' nystagmus, from which it would appear that in Staffordshire, at any rate, it is only those who are employed in one particular kind of work, viz., that known as "holing," who are liable to nystagmus. This he attributed to the cramped position they were forced to occupy, and to the muscular fatigue which the strain put upon the eyes necessarily involved. This formed the text of the best discussion which we have heard at this Society all the session, the point being whether the disease was, as suggested by Mr. Snell, due to muscular fatigue, or whether there was not in reality a disturbance of the co-ordinating mechanism in the central nervous system.

Mr. Priestley Smith undertook the defence of the latter view, and pointed out with much force that these movements were always bilateral and synchronous, a fact strongly suggestive of their having a central origin. The co-ordinating centres in question required the stimulus derived from retinal impressions; this was evident from the case of infants born with cataract or disease of the optic nerves, in whom nystagmus was present, but might be recovered from if the sight were gained at a sufficiently early age. The conditions under which the miner worked, in a bad light and surrounded by black walls, would naturally produce a feeble stimulus to fixation. Other speakers followed on the same side and urged that fatigue of the centres was more readily induced than fatigue of the muscles, and that writer's cramp and other analogous diseases were probably of central origin. It seems to us that, although the central theory is very taking, we ought not to adopt it until some explanation is afforded of the fact, for such at present it appears to be, that nystagmus is not equally common amongst all forms of miners.

At the Epidemiological Society on Wednesday last, a pleasant evening was passed in the discussion of the protective power of vaccination, enlivened by details of antiquarian interest relative to the prevalence of small-pox in the 16th and 17th centuries at home and abroad. The attendance, however, was very small, and it was agreed that this the first experiment of a July meeting was so far a failure that it should not be repeated.

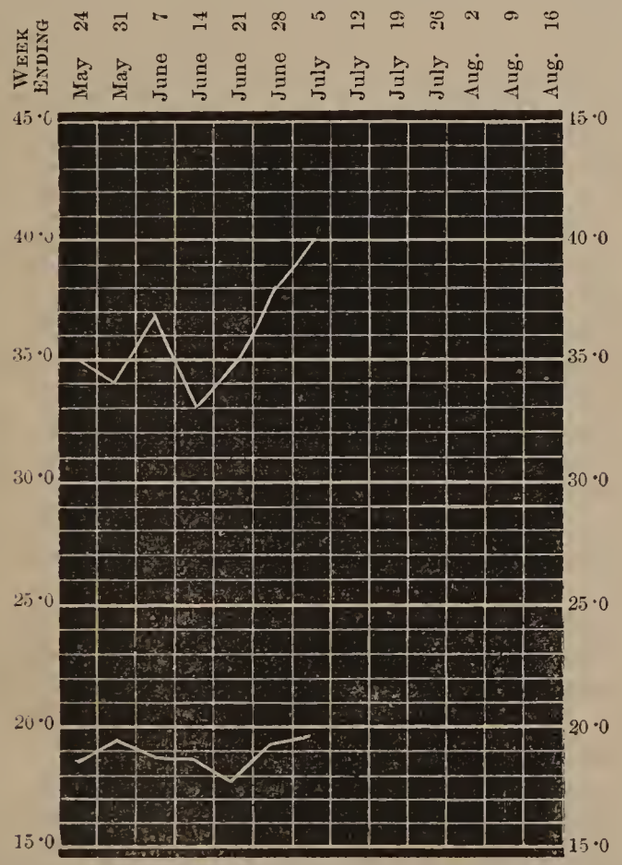
On Thursday week the London School Board had a long discussion on educational over-pressure. A proposal was made, and vigorously supported, that a special committee should be elected to enquire into the matter, and subsequently an amendment was proposed which was practically a vote of confidence in the Code and in the School Management Committee. Neither, however, was carried, and the discussion, after lasting for two hours, was adjourned. There can scarcely be two opinions outside the Board as to the desirability of a special enquiry into the question. As Mr. Bousfield said in the course of the debate, the public has had statements before it which it is absolutely necessary should be enquired into. The minds of the parents of School Board pupils are much exercised on the matter in London and everywhere else; and it is becoming quite the fashion amongst those who attend the out-patient rooms of children's hospitals to put down every sort of ailment to over-study. The doctors, of course, and indeed all who have made up their minds that over-pressure exists as a serious evil, ought to be careful how they play into the hands of the party—still a large though silent one—which believes that the poor are best left uneducated. But no considerations ought to stand in the way of full and free enquiry. The question is a large and pregnant one—one of the large problems which will demand a considerable share of our attention in the future. Hitherto we seem to have been so intent on the hygiene of the body that we have been apt to ignore the hygiene of the mind.

At the Health Exhibition on Wednesday evening, the Society of Arts and the Committee of the Exhibition gave a *conversazione*, which the many thousands who were present will not readily forget. The scene in the gardens with the myriad many-coloured lights, the plash and glitter of the fountains, the strains of the bands, and the crowds moving about under the trees, was as exceptional a one in this country as the evening was exceptional. Everyone was there, though not perhaps in the sense in which that phrase is used in the Society journals. There was genius somewhere at work in the organisation of the *fête*, which has distinctly given Hygeia a lift-up in the estimation of many.

A *matinée*, in aid of the funds of the East London Hospital for Children, was given at the Royal Avenue Theatre on the 26th ultimo. The house was quite full, and there is every reason to believe that a considerable sum of money will be realised. Speaking from a medical, and not from a dramatic standpoint, we are inclined to agree with our contemporary, *The Lancet*, in thinking that incidents in hospital life are at least extremely risky for stage-treatment. Having laid the scene of two acts in "The Accident Room," however, the author showed great tact and good taste in avoiding anything like offensive realism, for there was nothing said or done which could shock the most sensitive. Indeed, in these days when every young lady is supposed to have attended ambulance classes, and to hold a certificate of competency to apply a first dressing to any of the thousand and one accidents which may occur in every-day life, it was somewhat surprising that the audience looked on so quietly while Dr. Bevan clumsily bandaged the supposed lacerated scalp, which applied for help. Sister Grace is a charmingly drawn character, and found in Miss Winfred Emery a very satisfactory exponent. To our thinking Benbow, the old porter, was a most life-like character, no mere creature of the brain, but a type

familiar to most of us ; Mr. Grove's impersonation was perfect. Some of the lay journals appear to have been scandalised by Sister Grace and Nurse Joyce falling in love with the doctor. They appear to have forgotten that among the first qualifications for a good nurse, a gentle and sympathetic disposition ranks high. We ourselves, therefore, fail to see anything unnatural, and far less reprehensible in such a manifestation of character, simply because the woman happens to have charge of a hospital ward. Of the dramatic excellence or failings of the piece we do not presume to speak ; but we regret for its own sake that it was not better stage-managed. A play that can hold the attention of a critical and cultured audience, however friendly, during a hot mid-summer's afternoon, inducing both tears and laughter, in the words of the *Echo*, must be "very much above the average."

The temperature of last week, which was more than 5° above the twenty years' average, sent up the deaths from diarrhœa from 29, the previous week's figure, to 104 (76 of them occurring in infants under one year), but brought down the deaths from measles from 78 to 56, and those from whooping-cough from 80 to 53. The mortality from the other zymotic diseases remained about the same, but the increase under the head of diarrhœa being in excess of the decrease under the heads of measles and whooping-cough, the total deaths from the zymotic class were more numerous than they had been for many weeks, and the zymotic death-rate stood at the highest point it has yet reached since we commenced our weekly chart in January.



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the past seven weeks.

In spite of all this the deaths from diarrhœa were 23 below, and the total number of zymotic deaths was only one above, the corrected average. The total number of deaths—1,508—was 5 above the average, the deaths from respiratory diseases being as many as 30 more than usual in this week of the year—no doubt another result of the heat. The deaths from small-pox were about the same as in the previous week—30 against 29 ; but 266 new cases, said to be of a severe type, were admitted into hospital, and the total number under treatment on Saturday, viz., 1,368, was higher than in any previous return. In the 28 great English towns, both the general and zymotic death-rates showed a rise, the one from 19·2 to 19·5, the other from 3·1 to 3·4. In the eight Scottish towns the process was reversed, for while the general death-rate rose from 20·6 to 21·8, the zymotic death-rate fell from 3·6 to 3·2. The mean temperature in the latter towns was 50·5°, or less than 2° above the average.

Messrs. Bower and Keates are to be the victims of yet another lawsuit, and it is quite possible that the profession may have to subscribe a further sum towards indulging the litigious passion of the prosecuting father. We cannot, and we suppose we must not, enter into the legal subtleties which induced the judges on Wednesday week to grant a new trial. But we may perhaps be allowed to say this, that every man in the profession, and the vast majority of men outside it, will be irritated against the legal system which permits a single individual to expose to such a series of persecutions those who have done so much to serve him and his.

One turns from Dr. Clifford Allbutt's recent gloomy prognostications of the growths and evils of out-specialised specialism, by which he thinks "science loses, practice loses, and the good-fellowship of a great profession is dissolved," to those cheery and invaluable aids by which science gains, practice gains, and the good-fellowship of a great profession becomes built up and indissolubly cemented. We are pleased to learn that the arrangements for the coming re-union of the Members of the British Medical Association at Belfast, are being rapidly and satisfactorily completed, and that everything points to likelihood of the approaching annual meeting in the commercial capital of Ireland being one of the most useful, pleasant, and memorable in the annals of those members of the medical profession who indulge in the luxury and privilege of meeting each other face to face at these yearly gatherings. This is the first visit of the association to the North of Ireland, and we doubt not that it will result in as happy recollections as have been associated with the memory of the meeting in Cork a few years ago.

It is, however, a matter for regret that a phase of the Belfast meeting has attracted an amount of attention altogether out of proportion to its importance. Some weeks ago a series of papers were scattered broadcast amongst the profession in England and elsewhere, and were brought prominently under the notice of several of our contemporaries and the medical public. The objects and motives of the writer of these productions were evident upon the face of them, and were pointed out, and condemned

by the medical press. Unfortunately, denunciation of anything malicious or scurrilous sometimes only causes more importance to be attached to it than it deserves, and we hope that the annotation in the *Lancet* of last week, with the spirit of which we fully agree, will not lead any one to seriously believe that the anonymous author of the abuse levelled against some of our most respected men deserves to be immortalized by an all round criticism by the medical press of the country. Our object in referring to the matter is to state that, having taken the trouble to accurately ascertain the condition of affairs in Belfast, we are glad to be able to say that the result was just what we anticipated. All reports show that the meeting promises to be a great success, and that the very best *esprit de corps* prevails amongst the profession there, and that never in the local history of the profession has there been such a hearty, liberal, and united response to any movement. If it were necessary to quote facts to show the good feeling and sympathy with the meeting which pervades the great bulk of our professional brethren in Belfast and the North of Ireland, we might say that the number of medical men who have already subscribed to the fund for defraying the expenses of the meeting is nearly 200, being not far from double the number of those similarly aiding in a very successful annual meeting of the association held not long since in the centre of densely populated England. It is to be hoped that it is not too late to repair whatever mischief may haply have been done by the circular to which we have referred. We should be very sorry to think that its anonymous writer, who, as far as we can ascertain, expresses the opinion of no one but himself, should have so far succeeded in his object as to prevent any one attending or taking part in the meeting. We hope, however, by stating the plain facts of the case (and this is our sole object in referring to it), that if any member has been influenced by the unfair and ungenerous statement of this unknown writer, he will now know that there awaits for him a hearty and brotherly reception from the united medical profession in Belfast and the North of Ireland.

The passing of Gathorne Hardy's Act of 1867 may be said to have created a revolution in the method of dealing with the sick poor in the Metropolis, providing as it did for their treatment in establishments under separate management, and quite distinct from the workhouses. The various Boards of Guardians have loyally carried out the provisions of the Act, and in all districts of London are to be found parish infirmaries specially designed and erected for the care and treatment of sick paupers, a medical superintendent being in charge of each infirmary. One of the finest institutions of the kind is that provided by the Guardians of St. Marylebone, at Notting Hill, which was opened by the Prince and Princess of Wales in 1881, that occasion being the first on which Royalty has assisted at any ceremony in connection with a Poor-Law establishment. The St. Marylebone Guardians soon found the same difficulty that has been experienced elsewhere, of obtaining suitable trained nurses, of which they require a staff of 56; and finding that the efficiency of the working of their large infirmary was likely to be much impaired by the scarcity of nursing help, decided upon the step, till now novel in Poor-Law administration, of erecting a building as an institution for training nurses. This establishment, which comprises accommodation for 40 probationers and nurses, with every proper convenience for their comfort, and including a lecture room, the cost of which is 1,200*l.*, has been erected adjoining the infirmary, and will be opened by H.R.H. Princess Christian on the 22nd inst. In the regulations for the carrying on of this much needed work, the guardians are acting in connection with the Council of the Nightingale Fund, who are associated with them in this desirable object, the working of which will be watched with great interest by those who know the difficulties connected with the nursing of the sick and infirm who come under the care of the Poor Laws.

At the concluding meeting of the Vienna Society of Physicians, Dr. Julius Wagner, Prof. Leidesdorf's assistant in the Clinic of Psychiatry, showed some cats from which he had removed the thyroid gland. He recalled to the Society the lectures which had been delivered in 1880, by the late Dr. Nathan Weiss, on tetanus after total extirpation of the thyroid gland, and said that as it was known that severe nervous disturbances of various kinds had occurred in persons in whom the thyroid gland had been removed, he, at Dr. Leidesdorf's suggestion, commenced a series of experiments on different animals, to elucidate the point. The animals on which he had operated, whether cats or dogs, did not survive the operation, at the latest, more than eleven days. Most of them were young and did not present any symptoms of disease immediately after the operation, but ten or fifteen hours later the following symptoms appeared: muscular tremor over the whole of the body, especially the extremities, though also visible in the muscles of the head, the ears, and the tongue; epileptic convulsions and tonic spasm; death with symptoms of tetanus. The result of the autopsies was uniformly negative, the recurrent nerves, to the lesion of which tetanus had been attributed, being found quite healthy. The symptoms were similar to those which were to be met after extirpation of the kidney. Two of the animals from which he had removed only one half of the thyroid gland, survived the operation and were healthy. Two of the young cats shown to the Society were affected with muscular tremor, while the third presented symptoms of tetanus; these were cases in which the whole of the thyroid gland had been extirpated. The President, Professor Billroth, remarked that in the human subject such symptoms were, fortunately, not very common after total extirpation of the thyroid gland, and were to be seen only in nervous and hysteric individuals. He had performed the operation under the most difficult conditions; he had removed the thyroid gland from women who had been far advanced in pregnancy without any evil consequence, the women had been delivered of healthy children at full time, and discharged from hospital perfectly well. He had no experience as to the consequences of extirpation of the thyroid

gland in children, but Kocher had observed cases in which nervous symptoms had occurred in children after such operations ; the symptoms consisted, however, only in psychical disturbances, not in tetanus. It might, therefore, be possible that such an operation was only dangerous in young individuals, and that its danger diminished with the advance of years.

In the present rage which prevails for the celebration of the jubilees of persons and institutions, the celebrated hospital of Vienna was not likely to be passed over ; and accordingly the *Wiener Medicinische Wochenschrift* announces that its 100th anniversary is to be commemorated on the 15th August, on which day, the Emperor Joseph II. called it into existence with "*Saluti et solatio ægrorum*" for its motto. We are convinced, says the *Wochenschrift*, that the whole world will send its deputations, for the renown of this great hospital, with its distinguished investigators, professors and medical officers has penetrated to every point of the earth's surface. Its rich material has been spread abroad by thousands who have visited it, and by the books which have emanated from it. The journal, however, has some misgivings whether the occasion will be worthily dealt with.

The *Allgemeine Wiener Medicinische Zeitung* announces that Dr. Bernhard Kraus, its chief Editor, is the recipient of numerous honours in connection with the London Health Exhibition. The Minister of the Interior has delegated him as reporter to the Government on the Exhibition, to which end he is to receive every aid from the Austrian Embassy. The Common Council of the city of Vienna has also appointed him their delegate, and the Doctoren-Collegium has entrusted him with a similar post. "We specify these honours conferred upon our Editor," says the *Zeitung*, "with peculiar satisfaction, and rejoice that so important a trust has emanated from bodies of such consideration." A little strongly worded, perhaps, for the occasion ; but Dr. Kraus is an active and bustling personage who will have plenty to say on the matter.

The post of director of the syphilis wards of the Vienna General Hospital, rendered vacant by the retirement of Prof. Zeissl, has just been conferred on Prof. Auspitz. "We have never doubted, since the declaration of the vacancy," says the *Wiener Medicinische Wochensehrift*, "but that it would be filled up by Professor Auspitz, notwithstanding the number of well qualified candidates. He will now have the opportunity of justifying the hopes and expectations that have been aroused by his appointment."

The Polish Association of Physicians and Naturalists has just held its fourth meeting under the presidency of Dr. Szokalski, at Posen, amidst the warmest congratulations of the Polish inhabitants. Besides the 300 Polish naturalists and physicians who were present, many of whom came from great distances, a large number of Czechs were also present, as well as a deputation of Polish physicians from Berlin.

The International Society of Ophthalmologists has founded a gold medal, which will be awarded for the first time next year to the author of the most remarkable production in the department of Ophthalmology. The committee has taken great pains to ensure its satisfactory execution. On one side is the dedication surrounded by a laurel crown, and on the obverse the portrait of Albrecht von Graefe, 1828–70.

At the commencement of the summer course of his surgical clinic at Kiel, Professor Esmarch unveiled the busts of two of his celebrated teachers and predecessors, von Langenbeck and Stromeyer. He also delivered an address to his class, which he concluded by calling for three cheers for the Nestor of German Surgery, von Langenbeck.

The large collection of busts of celebrated *savants* which adorns the University Library at Bonn, has recently had added to it that of the famous physiologist, Theodore Schwann. His brother, the head of the printing establishment at Dusseldorf, has presented the bust in the name of the family. Schwann was a Rhinelander and a student at Bonn.

The special committee appointed by the Académie de Médicine to prepare a list of candidates for the vacancy among the foreign correspondents in the Section of Surgical Pathology, returned three names, that of Dr. Deroubaix, of Brussels, being on the first line, Surgeon-General Longmore, C.B., of Netley, on the second, and Prof. Macleod, of Glasgow, on the third. When the Academy met for the election, there were 52 members present, of whom 31 voted for Surgeon-General Longmore, 18 for Dr. Deroubaix, and 2 for Prof. Macleod.

The following are the prize-questions of the Academy of Sciences which have a bearing upon medical science : —(1) The Lacaze Prize in the Physical Sciences will consist of three sums of 10,000 francs each, to be distributed in 1885 to the authors of the works or memoirs produced during the preceding two years, which have most contributed respectively to the progress of Physiology, Physics, and Chemistry. They are not to be divisible, and they are to be open to foreigners. "I may in this way," says M. Lacaze in his will, "by the foundation of these three prizes of no inconsiderable value, to be awarded every two years, induce throughout Europe, and perhaps elsewhere, a series of researches in the natural sciences, which are the least equivocal basis for all human knowledge ; and I believe that the decision and distribution of the recompenses by this illustrious body will be an additional title to the esteem and respect which it enjoys throughout the world. If the prizes are not gained by Frenchmen, they will at all events be distributed by Frenchmen, and by the first learned body of France." (2) The Montagne two Prizes for Botany, for 1885, of 1,000 francs and 500 francs, may be bestowed on the authors of works or memoirs of importance, having for their object the Anatomy, Physiology, and Development or the Description of the Lower Cryptogams

Similar prizes may also be awarded in 1886. (3) The Grand Prize in the Physical Sciences, for 1885, consisting of a medal 3,000 francs in value, will be awarded to the author of the best printed or manuscript work On the Intimate Structure of the Tactile Organs in one of the Natural Groups of Invertebrates. The candidates must describe the external conformation of these organs, the mode in which their function is performed, and the internal structure of the terminal portion of their nerves. (4) The Bordin Prize, for 1885, a medal 3,000 francs in value, for a Comparative Study of the Animals of the Fresh Waters of Africa, Southern Asia, Australia, or the Islands on the Southern Ocean, examining also very attentively the zoological relations subsisting between these animals and the marine species which more or less nearly approach them. (5) The Da Gama Machado Prize, for 1885, a medal 1,200 francs in value, will be given for the best memoir on the Coloured Portions of the Tegumentary System of Animals, or on the Fertilizing Matter of Animated Beings. (6) The Montyon Prize or Prizes in Medicine and Surgery will be adjudged annually to the authors of works that exhibit well-defined discoveries of improvement in the Art of Healing, or of means which render an Occupation less Unhealthy. (7) The Bréant Prize of 100,000 francs awaits the discoverer of the cure of Asiatic Cholera, or of the cause of this terrible scourge. The donor, anticipating that his advent was not likely to be immediate, directed that, in the meantime, the interest of the prize should be annually presented to those who advance our knowledge concerning cholera, or any other epidemic disease ; or, finally, to anyone who will indicate the means of radically curing that French pathological puzzle termed *dartres*. (8) The Godard Annual Prize, a medal of 1,000 francs, will be adjudged for the best memoir on the Anatomy, Physiology, and Pathology of the Genito-Urinary Organs. (9) The Chaussier Prize of 10,000 francs will not be awarded until 1887, when it will be given for the best work on Medicine, whether Practical or Legal, which has appeared during the preceding five years. (10) The Dusgate Prize of 2,500 francs, awarded every five years, will be given in 1885 for the best work on the Diagnostical signs of Death, and the Prevention of Precipitate Interments. (11) The Montyon Prize for Experimental Physiology, consisting of a medal of 750 francs in value, is awarded annually. (12) The Cuvier Prize, a medal 1,500 francs in value, will be awarded in 1885 for the most remarkable work either on the Animal Kingdom or on Geology. We have not enumerated the prize-questions for 1884, as all essays, works, &c., have to be sent in before the 1st of June of the respective years.

It may be interesting to quote some figures adduced by Professor Brouardel in proof of the great service the *morgue* may render to medico-legal education. About 1,000 bodies are brought to that receptacle annually. Under his auspices there were performed, in the presence of students, 357 autopsies in 1882, the number of bodies brought in that year having been 960, and, as he observes, more than half the 600, which were removed without the performance of autopsies, would have been capable of being so utilised, including deaths from hanging, drowning and precipitation, and sudden deaths.

A correspondent of the *Scotsman*, writing in view of the advent of the drowning season, advocates a new method of producing artificial respiration, said to have been discovered and successfully practised by a miller on his own son some years ago. The boy fell into the millrace, went under the millwheel, and after being in the water from five to ten minutes, was taken out apparently lifeless by his father, who threw him over his shoulder and ran home with him a distance of eight hundred yards. "With the jolting on the man's shoulders the child's lungs began to play," and recovery ultimately took place. "Were the same means tried for bathers and others apparently drowned," continues the writer, "it would save many valuable lives." We venture to doubt it. If the public cannot or will not master the details of the ordinary scientific methods of artificial respiration, the simplest plan for them would be first to hold the body so that the water may drain from the mouth, and then by rather rapidly repeated pressure on the sternum to favour the entry of air into the lungs.

The *Philadelphia Medical Reporter*, in a recent number, quotes some "rather startling figures," which have been published by the Bureau of Statistics, showing the consumption within the United States of proof spirits, wines, and malt liquors. The figures given exhibit the consumption per head of these articles in 1883, as compared with the average of the three years ending 1878. The increase is returned at 34·40 per cent. in the consumption of spirits, 30·65 of wines, and 77·81 of malt liquors. "Prof. Elliott, of the Treasury Department, estimates the total population in 1883 at 54,163,000. Upon that basis we have for that year a consumption of 10·18 gallons of malt liquors per head, 1·42 of distilled spirits, and a fraction below a half gallon of wine. We here see that in spite of temperance societies, and all the efforts of the prohibitionists, the consumption of all varieties of intoxicating liquor has greatly increased, not only absolutely, but also in proportion to the growth of the population. As a community, as a nation, we are more given to inebriate indulgence than we were five or six years ago."

FOREIGN AND ENGLISH VIEWS OF CHOLERA PREVENTION.

The appearance of cholera in Egypt, and its supposed introduction into the town of Damietta by a fireman of an English steamer, gave rise to a chorus of abuse on the part of almost all the foreign medical journals. Editors in Berlin and Vienna vied with each other in heaping obloquy on us for our disbelief in the efficacy of quarantine. Subsequent experience, and the teachings of those of their own leaders who have taken the trouble to investigate the question more calmly, have considerably modified the tone of opinion with respect to the epidemic which the outbreak at Toulon is believed to threaten. The English view of the question is becoming more and more

appreciated, and Professor Billroth's comforting assurances that hygienic measures are fully capable of checking any outbreak, will go far to allay panic wherever such measures are in force. In Vienna, however, a strong feeling of uneasiness exists, a feeling grounded on the undeniable fact that the "beautiful city" is by no means well prepared to meet contingencies in this respect. "Most of our sanitary laws exist upon paper only in times of peace," says a writer in the *Wiener Medicinische Wochenschrift*; "let us hope that this at least will not be the case when an epidemic threatens." Notwithstanding the reassuring tone of his late speech, it may be noted that Billroth himself felt bound to conclude with the following significant sentence: "Let no one lay the blame upon us doctors if after all the cholera should come; we have given warning enough." Vienna knows only too well the meaning of a cholera epidemic, and a paper published last autumn by Professor Drasche showed in glowing colours the gross neglect of common precautions which has from time to time been responsible for the broadcast distribution of the disease. When the linen of cholera patients soiled with fresh dejecta is deliberately introduced into a public wash-house, no surprise need be aroused by a rapid spread of the disease among the unfortunate servants and washerwomen who are brought in contact with it.

An account of the present position and progress of the cholera appears this week, also from the pen of Dr. Drasche. In tracing the course of events during the last year, he expends a vast amount of holy horror upon the audacity of the English authorities in allowing troopships and others to move from one port to another with cases of cholera on board, and instances the case of the *Crocodile*, which arrived in an "infectious state" at Plymouth, after touching at Malta and Gibraltar. "It is only to be wondered at," he says, "that Europe has not already been infected with the poison." He overlooks the fact that, notwithstanding the enormity of the crime "against all international precautions," no sort of harm has resulted in any of the ports which he names. If ever the cry for universal quarantine be raised again, we may fairly assume that it emanates from some source which recognises its own inability to adopt the precautions of reason and common sense. A marked contrast to its tone of previous years is presented by the *Berliner Klinische Wochenschrift*. There is no longer to be observed the querulous tone of indefinite complaint against the English views which marked the beginning of the Egyptian epidemic, but rather a full recognition of their value, and a determination to act in their spirit in any precautionary measures which may be necessary.

In France it would appear that the English view as to the prophylaxis of cholera has made less progress. It is true that one great authority, M. Rochard, laughs at the disinfecting measures adopted at the railway stations as *chinoiseries*, but at the same time he traces the epidemic at Toulon to the relaxation of quarantine regulations at the time of the Alexandria bombardment, and says nothing about those home measures of hygienic reform which, according to the English view, would, if strictly carried out, render the importation of cholera from abroad a matter of comparative unimportance. The childishness of the views held generally in France as to the prophylaxis of cholera are well expressed in an old quatrain which is quoted in a French paper:—

Tiens tes pattes au chaud,
Tiens vides tes boyaux,
Ne vois pas Marguerite,
Du choléra tu seras quitte.

The lines, no doubt, embody excellent advice, but, unfortunately, personal precautions are useless in the midst of collective neglect. The French, indeed, appear to rely too much upon the efforts of the central Government, and the carefulness of the individual; they trust everything, as it were, to the general in command and to the private, forgetting that if cholera is to be kept at bay it must be by the efforts of subordinate officers and separate battalions working together in harmony. In other words, it is on the local authorities that the successful prevention of cholera depends. The State has an important function in keeping them up to their work, but without their cordial co-operation it is helpless.

A TAX ON FOLLY.

That the tax on patent medicines is to all intents and purposes a tax on folly will be generally admitted by those to whom this journal is addressed. The tax, of course, comes out of the pockets of the consumers, and a man or woman who habitually consumes remedies of which he knows neither the composition nor the mode of action, can hardly expect to be excluded from the category of fools. There are, it is true, one or two well-known patent medicines which, by their proved efficacy in certain cases, have raised themselves out of the ruck of common nostrums, and are occasionally prescribed by the faculty, who are practically familiar with their composition and mode of action, and perfectly realize the limits of their usefulness. But even in the case of these, the patient who administers them to himself can hardly be acquitted of an act of folly. It is common even for doctors to blunder through their credulousness as to the efficacy of drugs, and it is not to be expected that a layman, utterly uninstructed in the limitations of the drug-cure, should be able to use or recommend medicaments without danger to himself or his friends. The strange thing is that, with folly so rampant, the Government should receive but little more than £150,000 a year from their taxation of this special form of it. If folly were taxed all round the National Debt would soon, doubtless, be as extinct as the Dodo; but the Government has elected to tax only one sort of folly, and the question is whether it is worth while retaining such an anomaly for so paltry an addition to the revenue. There are many good reasons why the patent medicine duty should be abolished, and a simple Act passed, obliging all makers of secret remedies which contain poisonous ingredients to state on their wares the name and quantity of such poison or poisons, and bringing all such remedies within the provisions of the Poisons Act. That a fatal quantity of poison can now be bought under the guise of patent medicine by anyone who chooses to apply for it, and that without complying with any of the provisions by which the

sale of other poisons is regulated, is one of the crying anomalies of the present system, and one which demands speedy legislation, even if the Government cannot see their way to repealing the duty altogether.

There are, however, as we have said, good reasons why the patent medicine duty should be swept at once and for all into that limbo of defunct duties of which it is the solitary survivor. In the first place the stamp of the Government is misleading. It is well known that many ignorant persons are betrayed by it into believing that the Government vouch for the efficacy of the remedy to which it is attached, and some of the manufacturers of secret medicines have not scrupled to make capital out of this ignorance. There is no reason on earth why the interests of the *soi-disant* discoverer of a specific remedy should be granted greater privileges than the concoctors of other secret preparations not medicinal. When faith in the virtues of unknown drugs and combinations of drugs was general, there might be some excuse for encouraging the invention or discovery of nostrums, but now that more rational views are held as to the efficacy of remedial agents, both singly and in combination, the State ought not to go out of its way to give a special imprimatur to quack drugs. It ought rather to encourage amongst all classes the adoption of that principle of ethics which is so firmly held in the medical profession, viz., that the discoverer of a useful remedy is bound by his duty to humanity to make known his discovery to all the world. Another reason for repealing the duty is, that it takes twice as much out of the pocket of the consumer as it puts into the pocket of the State. The manufacturer, the wholesale, and the retail dealer, must all have their profit on the value of the stamp as well as on the value of the medicine, so that for every three-halfpence accruing to the State, the purchaser probably pays as much as threepence.

If these general considerations, however, are not sufficiently forcible to impress the powers that be, there is another argument derived from the recent action of the Inland Revenue department, which will perhaps have more weight with practical politicians. This department, which if it had the power would not scruple to tax the very air we breathe, has obtained a decision in the Law Courts in regard to the schedule of the Patent Medicines Act (52 Geo. III, Cap. 150), which practically reduces the Act to an absurdity. In this schedule "foreign medicines of all kinds, except drugs," are distinctly mentioned as coming within the provisions of the Act. Until lately a liberal interpretation has been extended to this formula, but it has recently been decided that by "drugs" only crude drugs are meant, and the Inland Revenue officials accordingly hold that all tinctures, liquid extracts, pills, and active principles prepared out of this country and its dependencies cannot be sold or exposed for sale unless they have paid the Government duty and bear the Government stamp. The practical result of this has not yet been widely felt, but unless the Government is speedily induced to control the activity of its subordinates, doctors will soon find that they are debarred, by that professional rule which rightly forbids them to prescribe patent medicines, from using many remedies the value of which is generally admitted. All the preparations which are imported from Germany, France, and America, will be henceforward "tapu" to us, unless we are content to break the unwritten law that forbids us to use patent remedies. Some of the preparations in question, can only be prepared from fresh plants, and to place a stamp duty on all of these will simply be to prohibit their use entirely; while in the case of others in which the dried flowers, leaves or root can be used, to favour English preparations at the expense of foreign ones, may delight the hearts of those who yearn for protective duties as a means of encouraging native industry, but was hardly to be expected under the *régime* of the present Government. We have no doubt that the obnoxious clause will be repealed, or that a timely hint will be given to Somerset House to moderate its ardour, as soon as the real working of the new interpretation is made plain. At the present juncture the Government can hardly afford to lay itself open to the taunts of the Opposition for covertly encouraging protective duties.

It is obvious, of course, that the recent legal decision bears most hardly on the large American wholesale houses who have lately brought so many new drugs to our notice. These drugs, as a rule, have no doubt failed in English hands to justify the loud encomiums with which they have been ushered in. The number of them which will eventually be thought worth a place in our pharmacopœia is probably very limited. But in any case, it is right and proper that they should be thoroughly and openly tried, and the sooner they find their proper place the better. If they are worth anything —we are speaking now of those which can be made from fresh plants—it is not right that we should be debarred from using them, as we shall be if they are to be liable to the stamp duty. If they are worth nothing, the conversion of them into patent medicines will only give them in many eyes a mystery and a prestige which they do not deserve, and prevent them from falling into that desuetude which, stamp or no stamp, will be their ultimate fate. We trust that the effect of this new interpretation of an antiquated measure may open the eyes of the Government to the necessity for enquiring into the whole question; and for our part we shall not be sorry if the result of their enquiries should be the abolition of a duty which we think we have rightly called "a tax on folly."

GUESSWORK: ITS USE AND ABUSE.

Guesswork is very universal in its application. It may be defined as the formation of an opinion on grounds insufficient for certainty. Its use frequently seems to arise from a morbid attempt to obtain credit for almost superhuman penetration, by presenting a rapid solution of a difficult question. Innocently amusing at times, its employment occasionally becomes serious, and may lead to disastrous results. Although it is to be met with in every phase of life, it is perhaps most frequent and most annoying in the realm of popular medicine Most people among the laity delight in jumping at a conclusion as to the nature of an illness, the modern development of descriptive bulletins appearing in some measure to result from this craving. Diagnosis,

ætiology, prognosis, and treatment are guessed at in turn, and the last is mercilessly criticised, should it not harmonise with experience under perhaps totally different circumstances. To those prone to thus giving their opinions every articular swelling is gout, every aching pain is rheumatic, and all cases of both should go at once to some pet watering-place, if they wish to be saved life-long torments. Guesswork in medicine is not, however, confined to these advisers who, perhaps, do little good or harm, beyond tending to unsettle confidence in the medical attendant. It exists in all its glorious simplicity as the method employed in "counter prescribing." *Rien n'est sacré pour un—pharmacien.* Cough mixtures, originally evolved perhaps by titled physicians for titled patients, are often dealt out indiscriminately for any form of pulmonary, gastric, or hepatic trouble manifesting itself by a cough. The least hint of the source of the combination casts a halo around the precious bottle, which might cure almost anything by its moral effect. The chemist comes in for his share of reflected light, and his books are revered as containing the results of years of study on the part of the physician. They are mines of wealth and health, which, in judicious hands, give out their treasures without the painful formality of sitting in a consulting room for hours, and paying the exorbitant fee exacted by custom. So long as every one is satisfied, little can be said except on moral grounds against this rough-and-ready prescribing. The money expended thus is mostly the fair equivalent for the advice given. Prescriptions are, however, like complicated pieces of machinery; they work efficiently when guided by the master-hand, but they may refuse all action, or may lead to irreparable damage, when ignorantly meddled with. Sometimes we meet with individuals who glory in their rude health sufficiently to enable them to make disparaging remarks on their well-meaning chemist; in a document recently brought under our notice this proud statement occurred, "I have no medical attendant; I generally go to a chemist, my health requiring no further skill." Rude and ungrateful, but true in regarding counter-prescribing as mere guesswork from beginning to end. The sick person makes the first guess as to the nature of his complaint, and puts the result in the form of an original proposition. The chemist makes the second guess from the data thus given him, and his answer takes the form of mixture, pill, or powder. With a few exceptions, as in "Alice in Wonderland," most propounders of riddles have the advantage of knowing whether the answer given is right or wrong; here it is a case of *fiat experimentum*, the chemist's patient tests the correctness of the solution by practical experience, and, if this proves to be unsatisfactory, he has the melancholy consolation of believing that the prescription employed was full of potential energy, but did not suit his case, turning like a lion from an unworthy prey.

From what has been said of this simple form of guesswork, it must not be imagined that its employment is universally reprehensible, or that its use is purely confined to the outskirts of the medical profession. It resembles alcohol in being widely used, often to excess, and so much abused that in the torrent of invective its true work is apt to be overlooked. It is misused when it is forgotten to be a mere guess, and when we act on the assumption of its being a proven fact. Every great scientific theory has commenced in a guess, or, to speak of it more respectfully, a flash of genius or inspiration. That theories, medical or otherwise, are merely convenient guesses at truth, to be employed as working hypotheses, liable to modification or rejection as further facts are brought to light, essentially forms the distinction between a scientific and an unscientific guess. Every diagnosis is at first more or less of a guess.

The original guess may be raised to a high condition of probability by the course of disease, by alterations of temperature, the development of physical signs, the appearance of a rash, &c., but frequently these may be misleading, and absolute certainty can be obtained only by *post-mortem* examination. A riddle may have numerous answers besides the right one; in disease, a consideration of the same data may lead to a dozen different conclusions. It would be painfully interesting if the commentaries, written by the candidates at such an examination as that for the London M.D., were published collectively. It is notorious that the diagnoses arrived at from the same facts vary considerably, and much ingenuity must be expended in endeavouring forcibly to twist these stubborn articles into a pillar of strength, in which, it may be, every particle is proclaiming its protest against misuse. In the examinations of our daily life, however, guesswork must always play an important part, its value depending largely on the degree of flexibility exhibited by the medical man. He who starts with a wrong diagnosis, and refuses to modify his originally expressed opinion, in view of fresh facts, will more certainly lose the confidence of his patients, than he who frankly admits his error. Guesswork, invaluable as an aid when scientifically used, only becomes a direct evil when it leads to an uncompromising dogmatism.

REVIEWS AND NOTICES OF BOOKS.

Transactions of the Epidemiological Society of London. New Series. Vol. II. London: David Bogue. 1883.—Several of the papers have been already fully reported and discussed in our pages, as that of Dr. Norman Chevers, on the Site of London, and that of Surgeon-General Cunningham, on Indian Epidemics. Sir G. Smart's account of the so-called Epidemic Diseases of Seamen is of no small historical as well as medical interest. The report of Dr. Seaton, on the Influence of Small-pox Hospitals on the Propagation of the Disease, founded on an enquiry into the outbreak at Nottingham, is a masterpiece of judicial impartiality, and deserves careful study as showing how a distribution of cases, due to importation and other causes, may simulate extension from a hospital though clearly independent of it. But the most important contributions are those of Surgeon-General De Renzy, C.B., and Dr. Ewart, who take for their respective themes the state of the British troops, and of their families in India. Surgeon-General De Renzy's especially is calculated to moderate the exaggerated ideas entertained in many official quarters, as well as elsewhere, of the results of the sanitary improvements that have been carried out at a cost of

several millions during the last twenty years, in consequence of the Report of the Royal Commission, which was published in 1863. The death-rate of the British troops during this period averaging 25 per 1,000, and only once rising above 31, has been exultingly contrasted with the 69 per 1,000 from 1800 to 1856, as showing an annual saving of life to the extent of 44 per 1,000, forgetful of the facts that the former period included a long succession of hard-fought and bloody campaigns, while the latter, commencing just when the effects of the hardships undergone during the mutiny had worn off, has, with the single exception of the last Afghan wars, been one of uninterrupted peace; that the proportion of troops invalided to Europe annually has increased from 28 to 40 per 1,000, and of those stationed in the hills from 12 to 26 per cent. But as Mr. De Renzy shows, the deaths from cholera, fever, dysentery, and diarrhœa, constitute 47 per cent. of the whole, and if we exclude these, occurring for the most part as epidemics, the death-rate in time of peace will be found after all to have been very little reduced. The persistence of their influence is seen in the wide fluctuations observed in the death-rates of particular stations in consecutive years, fluctuations not met with in towns whose sanitary condition is satisfactory. Thus at Morar we find a rate of 12 per 1,000 immediately followed by 65, at Allahabad 16 by 55, and at Peshawur 3 by 141. The truth is, that while new barracks have been erected regardless of expense, and no pains have been spared in the improvement of the soldiers' accommodation, food and general comfort, the sources and storage of the water supply have most unaccountably been neglected, and are nearly everywhere as bad as can well be conceived. What the causes of pollution are, all who have any acquaintance with Indian life know too well; they are, as the Commissioners themselves admit, "such as are usually met with among uncivilised and semi-civilised people," but which would not be tolerated for a day in the most poverty-stricken village in Europe. In two places, as if by way of experiment, a pure water supply has been introduced with results striking enough to convince the most incredulous. Bombay, from being one of the most unhealthy, has become one of the most healthy cities, and the European community has long enjoyed an almost complete immunity from cholera; even in Calcutta, though cholera still prevails among the natives who use the old sources, the Europeans have entirely escaped the late epidemic, and in Fort William, than which a more naturally unfavourable site could not be imagined, the death-rate of the troops, which had long averaged 69 and had latterly risen to 102 per 1,000, has, since the water was laid on from the new works, sunk to 10·6 per 1,000. Yet a long succession of directors-general and principal medical officers, from Morehead and Beatson to Muir and Cuningham, persistently refuse to see any connection between water polluted with sewage and insufferably hot, and the prevalence of disease. Dr. Ewart's figures present an appalling picture of preventible disease, the more painful to contemplate because the causes of this slaughter of innocents are more complex, and therefore not so easily obviated, even if the authorities could be brought to a sense of their duty. The mortality among soldiers' wives in India now averages 24 per 1,000, against 8 in England; of this 24 more than half are directly, and a further number remotely due to diseases peculiar to tropical climates, while their children, taking all ages together, die at the rate of 66·8 per 1,000, and those of soldiers at home at 27·4 If we take infants under five years only, the mortality varies from 87 to 138. Yet in the European Female Orphan Asylum at Calcutta, the Lawrence, and other schools, may be seen children as robust, healthy, and ruddy as any in England. In fact, though it is probable that those who remain in India through the period of puberty have less physical and moral vigour than those who are sent home, there is little doubt that up to six, eight, or ten years, the conditions of well-regulated life in India are even more favourable than in England. Improper feeding and general mismanagement of their infants by debilitated mothers, living amid surroundings in every way unfavourable and depressing, are the causes of a mortality which cries aloud for the most serious consideration.

The Leamington Waters; by F. W. Smith, M.D. London: H. K. Lewis. 1884.—There can be no doubt about the reality of the reaction which sound common sense has caused of late years in favour of the English Mineral Spas. These health resorts, which had been too much neglected during the last thirty years—the prevailing fashion having filled the Continental Spas with English invalids—appear now to be about to regain all their old popularity. And to this revival of prestige there is no valid reason why "leafy Leamington," with all its advantages of situation and surroundings, should be an exception. At any rate, such a work as that by Dr. F. W. Smith, following closely upon the article in our own columns (of April 12th) by another Leamington physician, must be commended as opportune in conception, and as supplying a well-recognised want, since no treatise upon the once famous mineral waters of Leamington has seen the light since 1843. Dr. Smith's little work of sixty pages is dedicated to the Medical Profession; but it will be of almost more utility as a guide to the general public, since the medical uses of the waters are necessarily, in a work of these dimensions, but superficially considered. From a literary point of view, it is not remarkable for elegance of style or diction, but it represents, no doubt, much labour and honest investigation.

On Insanity and Nervous Disorders Peculiar to Women. By Thomas More Madden, M.D.—In this pamphlet is reproduced the substance of previous papers by the author, the purpose of which was to call attention to the increasing prevalence of mental and nervous disorders, especially amongst women, and to describe the character, causes and treatment of these affections. Secondly, to point out that many persons who are not mad, but who are merely suffering from the reflex nervous consequences of unrecognised and curable utero-ovarian disease, are improperly confined in lunatic asylums. And thirdly, to suggest as a remedy for this abuse (1) That in future certificates of insanity should be given only by specially appointed Medical Inspectors of Lunatics; (2) That private lunatic asylums should be abolished as such; (3) That all patients in lunatic asylums should be treated by extern or visiting physicians. The whole of this somewhat extended programme is discussed in some seventeen pages, and in a style that is adopted and appears to be intended more for the less intelligent section of the laity than for professional readers. The positive teaching of the pamphlet is superficial, pretentious and bad, and the introduction of cases of marvellous recoveries of the author's patients is in very dubious taste.

A Statistical Inquiry into the Nature and Treatment of Epilepsy; by A. Hughes Bennett, M.D. London: H. K. Lewis, 1884.—This consists of a reprint, with only slight modifications, of three papers which have appeared in one or other of the medical journals during the last few years. The first deals with the subject of ætiology, the second and third treat of the use of the bromides in epilepsy The first is not a paper that lends itself readily to criticism, but it is evident that it is based upon patient and long continued clinical observation. The general results arrived at in the other papers are to the effect that in a very large proportion of cases (nearly 95 per cent.) the bromides either cure epilepsy or have a decidedly beneficial effect, and that their prolonged use does not seem to be productive of toxic effects in the epileptic; at any rate they are much better tolerated by epileptics than by healthy people.

Diabetes Mellitus; by Harvey J. Philpot. London: Sampson Low, Marston, Searle, and Rivington, 1884.—When a man writes a book on a special subject like the present, we think the least he can do is to have something new to tell us, either in reference to causation, pathology, or treatment. Even if his facts have not been well observed, and his conclusions are hasty, still there is some excuse for him. But the author of the work under consideration tells us in his preface that he has no new facts or new views to give us, and that his work is merely a summary of what is already known, and he offers neither apology nor excuse for

adding one more to the ever increasing number of books that had better not have been written, or at any rate published. In a series of Diet-rolls for diabetes, gout and dyspepsia, Mr. Philpot has endeavoured to direct the treatment of patients on alphabetical principles. All we can say for them is, that if the dyspeptic can cure himself by following the directions and selecting his diet from the list given him he will be a cleverer man than most of the patients that we are accustomed to deal with.

ABSTRACTS AND EXTRACTS.

DERMATOLOGY AND SYPHILIS.

Paget's Disease of the Nipple.—Dr. Sherwell, of Brooklyn, New York, after narrating (*American Journal Medical Sciences*,) two cases of this disease which have occurred in his practice, enumerates what he regards as its diagnostic signs: 1. The subjective symptoms, as itching, burning, &c., are the symptoms of eczema and not those of ordinary cancer, but they are much more marked than in ordinary eczema. 2. Of the objective symptoms, the discharge resembles and comports itself just as in eczema, although the colour of the surface is, perhaps, occasionally more livid. Sir James Paget compares the appearance to that of balanitis—an excellently apt illustration. 3. The term applied by Mr. Henry Morris to the disappearance of the nipple, as a "melting away" best describes its gradual obliteration. "Certainly, nothing like rapid ulceration takes place in typical cases, scarcely what could be signified by the name of erosion. It disappears." 4. The retraction of the nipple or tissues immediately beneath, if retraction there be, is not to be distinguished as such, as is so easy in ordinary cancer. 5. "The 'malignant papillary' feature, as described by Thin, was a marked feature of my first case, but much less so in the second. It is a very diagnostic point, and would of itself, I think, instantly resolve any doubt as between Paget's disease and a true eczema." 6. "The extreme length of time may be cited in my cases before the appearance of anything like positive evidence of carcinoma. Sir James Paget gives the limit as to this of two years. In my first case twelve years elapsed from the beginning of the attack to death, this not seeming in any way connected with the skin lesion. In the second case considerably over the time mentioned by him was passed." Dr. Schweinitz also gives (*Philadelphia Medical News*, February 2nd) a minute account of a case of this disease, accompanied by microscopical illustrations, together with a complete list of other reported cases. From these he considers himself justified in inferring: 1. The malignancy or malignant tendency of the disease. 2. The tendency of the changed epithelium of the ducts to travel downwards, and produce carcinoma of the breast. 3. The propriety of excising a breast thus affected before any tumour of the gland itself can be detected.

The Curative Effect of Acute Febrile Diseases upon the Throat Lesions of Congenital Syphilis.—Dr. J. N. Mackenzie, who in 1880 called attention to the comparative frequency with which the throat is involved in congenital syphilis, now publishes a paper (*New York Medical Journal*, May 31), in which he states that while such pharyngeal ulcerations are usually most stubborn in their refusal to heal under treatment, "they sometimes cicatrise, as if by magic, on the accession of an acute disease." He refers especially to scarlatina, measles, and chicken-pox, blood diseases which have special tendencies to local manifestations in the throat, and which in themselves "present a certain analogical resemblance to syphilis." He also holds that in children the existence of syphilis appears to mitigate the severity, and favourably to influence the course of these maladies; and that they are more prone to be contracted during the period of latency—"the sleep of the virus"—of congenital syphilis. On the other hand, the virulent influence of the diphtheritic process appears to be aggravated by the co-existence of a syphilitic taint. The modification which an intercurrent febrile affection seems apt to exert upon the manifestations of constitutional syphilis, leading to their more or less permanent dissipation, or to their intensification, has received some attention, chiefly from the syphilographers of the French school. Thus, cutaneous syphilides, exostoses, and ulcerations have been noted as disappearing during the course of erysipelas, acute rheumatism, cholerine, variola, febrile furunculosis, vaccination, and also during pregnancy. Hence originated from time to time the suggestions as to the artificial production of erysipelas (Sabatier, 1831), vaccination (Luconski), and even of small-pox (Garrigue, 1870), as therapeutic agents in the treatment of obstinate cases of the disease. While believing that a reciprocal antagonism exists between the poison of syphilis and that of a number of acute diseases, especially with respect to inflammation and ulceration of the naso-pharynx, Dr. Mackenzie also affirms that simple catarrhal inflammation of this region "occasionally disappears completely and is permanently cured during the course of an acute febrile disease."

The Ætiology of Eczema in Early Childhood.—Eczema in early childhood has hitherto generally been considered to be a manifestation of scrofula, as in many cases it undoubtedly is. Dr. Bohn, however, asserts that neither scrofula nor rickets can be considered to be the cause of the numerous cases of eczema of the head and face that occur in children during their first few years of life, especially as the great majority of these cases occur in infants not six months old. Most of these children are particularly well nourished, and appear to be otherwise in perfect health. Dr. Bohn asserts that the only general statements he can make about them are, that they are usually constipated, passing hard yellow or white stools, and that they are all too fat and have fatty livers. The treatment he recommends is based on these observations; the first step is to cure the constipation, the second to regulate the diet so that an excess of fat or fat-forming food shall be avoided, *i.e.*, the substitution of animal broths for some of the milk. The eczema should be treated locally in the usual manner.—*Jahrbuch für Kinderheilkunde, Band XX., Heft I.*

An Elastic Skin.—In the *Philadelphia Medical News*, an account was lately given of a German in one of Dr. Dühring's wards in the Pennsylvania University Hospital, who is designated as the "elastic-skin man," and who is probably the same person who was last year in the Vienna Hospital, and who has been exhibited in England. The skin seems normal in appearance until it is touched, when it is found highly extensible and elastic over the entire surface of the body. For example, it may be drawn from the sternum almost over the entire face, or from between the scapulæ over the back of the head: and when it is let go it flies back to its place. It is more elastic when drawn transversely to the natural lines than when drawn parallel to them. The skin is extremely soft, and none of the movements made with it give any pain. Pulling it out and holding it in front of a light, the circulation in it is beautifully seen. The condition is congenital, and is supposed to be due to the absence of subcutaneous connective tissue; but it is a question whether this is not present and attached to the fasciæ of the muscles instead of to the corium.

Glycerised Iodine as an External Application in Small-pox.—Dr. Bartholou, an army-surgeon, relates in the *Lyon Médical*, February 3rd, some additional cases, in order to show the great advantage which may be derived in very bad cases of small-pox, by painting the surface with the following mixture:—tincture of iodine 30 parts, glycerine 60 parts, and iodide of potassium ¼ part. The application is not unpleasant to the patient, and may be made from the fifth or sixth day of the eruption to the eleventh or twelfth. During this period, it is repeated four times daily, and powerfully contributes to the absorption of pus, and the desiccation of the pustules, after which it is discontinued.

REPORTS OF SOCIETIES.

THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, JULY 3RD, 1884.

JONATHAN HUTCHINSON, Esq., F.R.S., President, in the Chair.

Cases of Retro-ocular Neuritis.

MR. NETTLESHIP read a paper on some cases in which acute inflammation seemed to take place in some small part of the course of the optic nerve. They were characterised by failure of sight in one eye, often accompanied by neuralgic pain in the temple and orbit, and pain on moving the eye. The disc often became more or less atrophic in a few weeks; the result was variable from complete recovery to total blindness. Two illustrative cases were quoted, the first being that of a lady, aged 34, in whom an attack of central amblyopia in the right eye was associated with pain in and around the eyeball, and followed by pallor of the disc. The patient had previously suffered from sciatica and several of her relations had had gout or arthritis. The second case was that of a man, aged 50, who had rapidly and completely lost the sight of his right eye, and who presented no sign of cerebral disease; there was no evidence of syphilis or gout, the only thing being that some time previously the patient had had diplopia from paresis of the right inferior rectus. The failure of sight was usually at its worst in three days, except in the most severe cases; recovery when complete usually required about six weeks. The pain, which was often circumorbital, began before the dimness of vision, and there was a sense of stiffness on moving the eye quickly. In the majority of cases examination of the field of vision revealed the existence of a central defect; sometimes the field was contracted, at others this sign was absent. Changes in the disc were by no means constant, even in the worst cases. The cases had to be distinguished from embolism of the central artery, from progressive atrophy where one disc was affected before the other, and from uniocular neuritis due to disease of the corresponding lobe of the brain. The greatest difficulty would be to distinguish them from the rare cases where a single violent papillitis occurred with severe localised pain. In some of his cases the symptoms might be explained by a periostitis of the optic canal; in others the mischief could not have been so far back; in some a rheumatic origin seemed probable. The majority of the patients were between 25 and 40. At least five of the twenty-four had had syphilis, and there was a good probability of it in six others. In four cases the affected eye became permanently blind; in eight more or less damage was done; twelve (exactly half) recovered.

The PRESIDENT said that Mr. Nettleship had dealt with an interesting and obscure subject in his very able paper. He had himself seen only one case of this class. The patient was a young lady with a marked arthritic history; one eye only was affected, and became quite blind, but without much pain; subsequently there was slight papillitis; the patient ultimately recovered, almost completely; three years later she had a threatening of the same condition in the other eye, but recovered completely. He believed that in this case the loss of vision was due to a gouty inflammation of the optic nerve.

Dr. STEPHEN MACKENZIE asked if the blood had been examined, because in leucocythæmia papillitis and a diffuse inflammation of the retina occurred, and had been ascribed to thrombosis of the orbital veins. Thrombosis might explain some of Mr. Nettleship's cases. It was known that after some fevers, typhoid especially, thrombosis was liable to occur, so it was important to know how long after the fever in these cases the symptoms had appeared. He did not think that all the cases belonged to one group, they ought not to be referred to the arthritic diathesis without very good evidence.

Dr. C. E. FITZGERALD had seen, about two years ago, a young lady who had dimness of vision on the left side. There was no ophthalmic abnormality beyond some haziness of the margin of the disc, but there was some pain on movement of the bone. Under treatment vision was completely recovered; but the symptoms recurred in a few months, and later the right eye was affected with intense neuritis, and the patient lost power in the right leg and arm. The nature of this hemiplegia was very obscure, and but for the neuritis would have been considered hysterical. Subsequently the neuritis subsided, and she began to recover; the vision of the left eye returned almost completely. The patient gave a history of some rheumatic trouble.

Mr. NETTLESHIP said that the blood had not been examined, but the patients were not anæmic, nor in a bad state of health. In all of the cases in which the conditions came on after fever the interval was not great—not more than a few weeks. In one instance the fever was either typhoid or malarial fever, and the loss of vision came on within a month. He believed that the cases were probably not all of the same nature. In very bad cases it was probable that there was periostitis of the optic canal; in slighter cases there was probably neuritis only, whereas in others there were, perhaps, small gummata on the optic nerve; this, however, was only conjecture.

Central Amblyopia.

Mr. LAWFORD read notes of a case of central amblyopia coincident with peripheral contraction of fields. The patient, a lad aged 18, noticed failure of vision about five weeks after a fall. He also had some general nervous symptoms, for which he was an in-patient at Guy's Hospital. The central scotomata, at first absolute for form, became, as recovery progressed, scotomata for colour only. Eventually, perfect acuity of sight was attained, and the limits of the fields of vision became normal. The other nerve-symptoms also disappeared in the course of six months.

Sympathetic Ophthalmitis.

Mr. W. ADAMS FROST read a case of sympathetic ophthalmitis subsequent to the excision of the exciting eye. A man, aged 25, was admitted into St. George's Hospital, on November 3rd, 1883, for iritis of the right eye. There was no history of syphilis or rheumatism; and the patient traced the commencement of the affection to some hair entering the eye while he was clipping a horse a month before admission. There was conjunctival and ciliary injection, and on the inner side a few vessels encroached on the cornea. The lower half of the cornea was thickly studded with punctate opacities, and there were numerous posterior synechiæ. Tension was normal. A week later, there was slight prominence of the ciliary region above, and an upward iridectomy was performed. The staphyloma increased in size; the eye became very painful, and the anterior chamber shallow. On December 15th, iridectomy downwards was attempted, but no iris was removed. The pain being severe, the eye was enucleated on February 2nd, the left eye being then normal; but, five days later, slight conjunctival injection and punctate opacities on the cornea were noticed, but neither pain nor tenderness. Atropine, exclusion of light, and pilocarpine injections were used. On March 19th, there was a single fine posterior synechia. The cornea was clear. $V = \frac{6}{6}$. The globe of the excised eye was bisected, and one half was

mounted in glycerine jelly. The other half was examined microscopically by Mr. Jennings Milles (the microscopical sections were shown at the last meeting). He reported that the ciliary staphyloma was formed by a nodule consisting of inflammatory cells closely packed. The sclerotic over this was much thinned. The iris was firmly adherent to the lens, and its parenchyma infiltrated with small round cells. The choroid was thickened in its whole extent, especially in the region of the papilla.

Mr. NETTLESHIP asked whether it was possible that any hairs had penetrated the cornea, and mentioned a case observed by Pagenstecher, in which the centre of a peculiar growth on the surface of the iris was found to be occupied by some hairs of an insect.

Mr. FROST, in reply, said there was no mark of any corneal wound, and Mr. Milles had found no particles of hair; but that the case was not seen till a month after the accident, and small particles might easily escape notice. The patient himself connected the entry of the hair into his eye with the occurrence of the inflammation in the most positive manner.

A Remarkable Case of Proptosis.

The PRESIDENT showed some photographs of the patient whose case he proceeded to narrate. The patient was a Hindoo gentleman, who came to him for extreme proptosis of the left eye, having not long before lost his right eye from a similar affection. The eye was extremely protruded, mostly downwards, and the lower lid was everted. The movements of the eye were not much interfered with, but there was a good deal of chemosis. The edge of the lacrimal gland, which was greatly enlarged, was felt on a level with the upper margin of the orbit. The upper lid hung loosely, but the lids could not be closed. The face was puffy, especially in the parotid region, and under the jaw. The other eye had been attacked in a precisely similar manner about three years previously, and after varying for two years had finally become so prominent, that a few months before he came under observation the lacrimal gland had been removed, as also a firm lobulated mass which occupied the upper and outer part of the orbit and turned out, on microscopical examination, to be composed of fibro-adipose tissue; suppurative inflammation, set in after this operation and the eye was lost. Within a few days of this time the hitherto healthy eye became protruded, which naturally greatly alarmed the patient. As in the case of the other eye, there had been variations in the degree of proptosis, and looking to the ill effects of operative interference in the other eye, it was decided to try the local application of ice. This was sedulously applied to the eye, to the forehead, and to the nape of the neck for a week without intermission; the patient at the same time took small doses of iodide of potassium. At the end of this time there was a decided improvement, the ice was continued for some time longer and after a time mercury was given in combination with the iodide. The result was that the patient was practically cured, and had since remained well. In reference to the nature of the case it was pointed out that the enlargement of the lacrimal gland could not be regarded as in any way causal, it was coincident but nothing more. There must have been some swelling of the fibrous or fatty contents of the orbit which caused the protrusion; whatever it was, it was capable of spontaneous diminution, it was prone to relapse, and was, as well as the enlargement of the various glandular structures, under the influence of iodide of potassium. Malignant disease could be negatived from the fact that there had been no recurrence in the eye first affected. The disease was analogous he believed to a group that had been described by Brodie, and more recently by Mr. Morrant Baker, where there was a tendency to the formation of ill-defined, but more or less lobulated masses of fibro-fatty tissue in the region of the neck, but in none of the cases that he had seen was there proptosis or enlargement of the lacrimal gland, though he had in one case found enlargement of the parotid gland in association with fatty masses in the neck, Though the condition was remarkably local it was not one of new growth, but rather of hypertrophic development, there being no tendency to general obesity, He suggested that one reason why glands of different function should be associated in the enlargement, was that the hypertrophy was due rather to increase of the connective tissue elements than of the gland structure itself. Exophthalmic goitre might possibly be a member of the same family, and he noted that his patient was excitable to the verge of insanity. In conclusion he pointed out that these fatty outgrowths underwent great changes in connection with the state of health of the patient, and that much benefit was often derived from change of air.

Dr. STEPHEN MACKENZIE asked whether any change had been found in the thyroid body or any pulsation in the vessels of the neck, or whether palpitation or evidence of disturbance of the heart's action had been observed. Mr. Hutchinson's case had some alliance apparently with Graves' disease. The primary cause of the proptosis in that disease was overgrowth from over vascular supply, and it was well known that ice was useful in diminishing the vascular disturbance, and reducing the proptosis. It was therefore interesting that ice should have had so marked an effect in this case, as, though the patient was also taking iodide of potassium, it was evident that a great deal of the benefit was due to the ice. He asked as to what the dose of the iodide had been. As regarded the enlargement of glands of different functions, he pointed out that a wide spread vascular disturbance of nervous origin would account for such a state.

Mr. GEORGE WALKER had met with a curious case of proptosis in a woman who was violently struck on the eye. He found that by compressing the carotid, the proptosis was diminished, the discomfort decreased, and the circulation in the arteria centralis retinæ stopped. He attributed this condition to aneurysm at the apex of the petrous portion of the temporal bone, which had by pressure obstructed both the venous and lymphatic circulation. The carotid was ligatured, and the proptosis almost completely disappeared; he suggested that in Graves' disease, simple dilatation of the internal carotid might produce the proptosis by causing similar obstruction.

Mr. EALES related the case of a man, aged 45, in whom an acute attack of headache was followed by proptosis, most marked on the left side; the lacrimal gland was enlarged and pushed forward; the condition was alleviated by treatment, but recurred.

Mr. W. H. JESSOP, who had seen most of Mr. Morrant Baker's cases, was anxious to learn whether the second case referred to by Mr. Hutchinson improved under treatment with iodide of potassium.

Prof. BROCKMAN (of Madras) inquired as to the nationality of the first patient, whether he was a Hindoo or Eurasian. Elephantiasis was common among the Eurasians, and not unfrequently was accompanied by proptosis. In these cases, benefit resulted from the use of mercury and iodide of potassium; possibly Mr. Hutchinson's case was of this nature.

The PRESIDENT replied that the patient was of mixed Hindoo and European blood; his case had excited as much interest in India as in England, so that it was probably not of the kind referred to by Mr. Brockman. He had not seen iodide of potassium produce any result in the cases of fatty growths such as Mr. Morrant Baker had described. He did not think that the mechanical theory of the proptosis in Graves' disease advanced by Mr. Walker would bear examination. In Mr. Morrant Baker's cases there was, it was true, a tendency to nervous excitement, the patients exhibiting marked irritability of temper; but the first

patient whose case was described presented no such phenomena. Still he thought the case was very much more nearly related to Mr. Morrant Baker's cases than it was to exophthalmic goitre; there was no enlargement of the thyroid gland, no irritability of temper, nor cardiac disturbance. It might perhaps be found that, with the fatty masses, gland-enlargement in various situations occurred. The dose of iodide was at first small, about three grains three times a day, and never exceeded fifteen grains three times a day. He was inclined to attribute the greater part of the relief at the first to the sedulous use of ice, for it was very marked within forty-eight hours. He was still in some doubt as to how much of the recovery could be attributed to the iodide of potassium.

The Society then adjourned.

Friday, July 4th, 1884.

Jonathan Hutchinson, Esq., F.R.S., President, in the Chair.

Sympathetic Neuro-retinitis.

Dr. W. A. Brailey showed a patient who stated that, on March 6th, her left eye was cut by a broken jug. Before this there had been no symptoms of disease, either local or general. The wound passed in the antero-posterior direction through the ciliary region. Two weeks later, she had pain in the right eye, and the sight began to fail. She first applied at Guy's Hospital three weeks after the accident. Vision was then very imperfect ($\frac{6}{60}$); the optic disc was a little swollen; the margins blurred; the vessels pale, rather contracted, and in some cases edged with faint white streaks for a short distance into the retina. The vessels near the yellow spot were rather larger and more numerous than usual, and also somewhat tortuous. Vision had gradually improved up to $\frac{6}{24}$; but the optic disc had grown flatter and paler. The exciting eye (left) had caused no pain since the first week. He thought the case was an instance of a neuritis of the anterior part of the optic nerve, produced sympathetically.

The President observed that the case was probably the first well authenticated instance of optic neuritis as a sympathetic affection.

Mr. Adams Frost referred to a case of neuritis occurring in the course of a sympathetic ophthalmia, where the inflammation of the media was very trifling.

Miners' Nystagmus.

Mr. Simeon Snell read a paper on the cause of Miners' Nystagmus, and stated that he had long held the opinion, as the result of clinical experience, that the cause of the disease was to be found in the peculiar manner in which the miner performed his work, whatever secondary influences other surrounding circumstances might exert. He had seen no evidence to support the theory of central disease, and believed the poor illumination of the "safety lamp," and other causes mentioned by writers, were insufficient to account for the affection. He described the various classes of men engaged in a coal pit, and the kind of work performed by them. The disease appeared to be confined to the "coal getters." He had previously stated that, in his experience, men suffering from this affection had been engaged in work which necessitated their lying on their sides. Some of the "coal getters" were employed in this manner, in what was termed "holing," the process of "driving a cutting under the seam of coal," and the hole made might reach a yard or more underneath the coal. This was done to facilitate bringing down the coal by wedges. The hole made might be only 18 inches to 2 feet high, and a man working in this would be cramped up and lying on his side. Further experience had corroborated the opinion expressed nine years ago, and though cases were constantly under observation, he believed they had all been engaged in the manner mentioned. He stated also that he had descended into a pit, and as anticipated found the men occupied in "holing," and working on their sides affected (four out of six examined), whilst other coal getters and other workers in the pit appeared to be free from it. Other evidence in support of this view was educed from the cases mentioned in Mr. Oglesby's paper (*Ophth. Soc. Trans.*, vol. ii.), and also the opinion of Dransart (*Annales d'Oculistique*, 1877), that all the sufferers had worked in shallow inclined bearings. Mr. C. S. Kilham had also, at Mr. Snell's request, examined in Durham over 500 colliers, and found not a single instance of nystagmus; in none of these pits were the men occupied in work compelling their lying on their sides. Dransart had held the disease to be due to fatigue induced in the elevators, by the frequent upward gaze of the miners at work. Mr. Snell explained that working in the manner mentioned, it followed that the eyes were frequently thrown into an oblique position upward to the left or right—a position much more fatiguing than simply looking upwards. The muscles affected would thus be the superior rectus, the inferior oblique, left internal rectus, and right external rectus —if looking to the right or substituting the right internal rectus and left external rectus if looking to the left. He considered the nystagmus arose under conditions recognised as "chronic fatigue" in other regions, and analogous to writers' cramp, &c. Recovery took place if the patients ceased their work in the pit, in a variable time; it was quite possible that changing the manner of work would be quite sufficient. Strychnia and other remedies appeared to be useful as adjuvants.

The President said that Mr. Oglesby's paper had conveyed to him the impression that the constrained attitude was an important factor in the production of the nystagmus, but that the long hours of work and the bad light added to the influence of the muscular fatigue: clearly writers' cramp was the malady most analogous to the nystagmus; but it was easy to imagine, in both cases, that there was a lowering of central activity, so that the disease was not purely local.

Mr. Priestley Smith said that nystagmus must be regarded as an evidence of disturbed function in the centres governing the combined movements of the eyes, as the movements, though not necessarily equal, were always bilateral and synchronous. Retinal impressions supplied a stimulus to these co-ordinating centres, which was essential to their functional activity, as was seen from the fact that children born with diseased optic nerves or with cataract became nystagmic, a condition remediable provided that the defective sight was cured at a sufficiently early age. The difficulty of steady fixation in the dark was one he had personally experienced, and the miner worked in a bad light and surrounded by black walls, conditions producing a feeble stimulus to fixation. In reply to an observation of Mr. Nettleship's, he suggested that the bilateral movements of the eyes were governed by two centres connected by commissural fibres, and ordinarily incapable of separate action. Cases of unilateral nystagmus were however exceedingly rare.

Dr. Brailey thought that muscular fatigue best accounted for the nystagmus, and that it must in great measure be attributed to the position assumed by the miner. He pointed out that fixation was a great stimulus to the muscles as well as to the nerve centres.

Dr. Angel Money alluded to a case of voluntary horizontal nystagmus that he had lately seen in a young girl.

Mr. Eales favoured the central theory. He pointed out that some of the patients were in a condition approaching night blindness. He had observed the case of a man who for twenty years had worked by naked lights without any nystagmus, but in whom the condition was produced soon after the introduction of the safety lamp.

Mr. Nettleship thought it would be difficult to account for a case of unilateral nystagmus on the theory of lesion of the nerve-centres.

Dr. Stephen Mackenzie believed that writers' cramp

and other fatigue paralyses were due to central disturbance. Any cause that tended to exhaust the nerve centres tended to produce tremor and other muscular disturbances. He regarded Mr. Priestley Smith's arguments as to the central origin of this form of nystagmus as conclusive, and he pointed out that in insular sclerosis and other nerve diseases nystagmus was clearly dependent upon disease of the central nervous system.

Mr. Adams Frost had formerly lived for about two years in the colliery district of North Staffordshire, where miners' nystagmus was common. The Davy lamp was in use there, and "holing" practised. The photographs which had been handed round, depicted the miner's position in this operation very accurately. He thought it extremely probable that in the mines in which the Davy lamps were not used, "holing" was not common; in the operation of holing it was not necessary to fix very accurately, and, indeed, as the hole was often a yard deep, it was not possible.

Dr. Beevor observed that muscular fatigue alone did not seem capable of producing tremor, for instance, the fatigue of muscles by the Faradic current did not produce it.

Mr. M. McHardy suggested that in the analogous malady, writers' cramp, there was some interference with nervous conductivity.

Mr. Snell, in reply, said that the condition was not symmetrical. If the imperfect light and black walls were the efficient causes, why was not the disease more widely diffused? The light by which the holers worked was not materially worse than that used by other workers in the coal-pits, yet nystagmus was entirely confined to the holers.

Model Apparatus for demonstrating Operations on the Eye.

Mr. J. Streatfeild, after commenting on the difficulty of demonstrating ophthalmic operations to a large class owing to small dimensions of the organ, and the impossibility of all the members of a class of students catching even a glimpse of the manipulations, explained the construction and uses of a large model made for him by Hawksley, of Oxford Street. The model was made on a scale exactly ten times that of the actual eye, and the models of the eye-instruments were on the same scale, excepting the handles of the instruments had been altered and shortened. The apparatus, which consisted of the front of an eye, permitted of rotation in every direction, and the eye could be fixed in any desired position. The sclerotic and the eyelids were constructed of white felt. The cornea was made of stout glass of the right curvature. The iris was imitated in thin sheet india-rubber, with a round hole for the pupil. The cataractous lens was made of xylonite. The internal and external rectus muscles of the eye were represented by pieces of linen bandage. With this apparatus could be represented the *modus operandi* of peripheral section of the cornea, of iridectomy, of extraction of cataract, and of squint operations. The anterior chamber could only be entered for iridectomy, cataract extraction, &c., in the usual place, at the sclerotico-corneal junction. Here at any part of the upper half-circumference, the knife, forceps, pricker or curette, could be entered between the felt sclerotic and the glass cornea, which gave way for their admission, and resumed its natural position when the instrument was withdrawn. The sheet india-rubber of which this imitation iris was made, could be seized with the (model) iris forceps at any part, drawn out of the eye, more or less, and so much cut off as might be desired in the demonstration. With this large apparatus, other matters besides the operations only could be demonstrated. Mr. Streatfeild illustrated his remarks by performing a cataract extraction on the model.

Cases of Congenital Defects.

Mr. Simeon Snell related the following cases of imperfect development: (1) Congenital cysts in the lower eyelids with (apparent) anophthalmos. The patient was an infant of a few weeks. In the left lower eyelid, a large cyst, with bluish tint, was situated; it extended deeply into the orbit. On being tapped, the fluid escaping was straw-coloured, and corresponded, on analysis, to that examined from similar cases recorded as "congenital cysts with anophthalmos." Subsequently, the cyst-wall was partially excised, and it was thought that a rudimentary globe was detected at the back of the orbit. In the right lower eyelid, at first, there seemed to be a very small cyst; it was not tapped, and a year later it was hardly apparent. Here also a resistance, particularly at the later period, was detected in the orbit, and was thought to indicate the presence of a rudimentary globe. Both orbits were normally developed, and completely lined with conjunctiva. (2) Congenital cyst in lower eyelid with micro-ophthalmos; the infant was under the care of Mr. W. M. Jones, of Wath. The cyst filled the orbit. After dissecting it out, a micro-ophthalmic eye came into view. The cornea was well formed, there was a coloboma at the lower part of the iris, and the eye was possessed apparently of some vision. An ophthalmoscopic examination was made, and, as far as could be made out, the child was almost moribund with tubercular peritonitis. The coloboma extended into the choroid, but did not reach to the optic disc. The cyst in the eyelid presented a bluish tint; the fluid was straw-coloured. Mr. Snell quoted the recorded cases, and remarked on the various causes assigned for the origin of these cysts by Talko, Mauz, Van Duyse, and others. The theory advocated by Van Duyse, that they arose from the encysting of a staphylomatous coloboma, was held to correspond with their association with micro-ophthalmic or rudimentary globes. (3) A case of absence of eyeball on one side. (4) Micro-ophthalmos of the left eye, with coloboma of the optic nerve-sheath, and coloboma of the choroid in the right eye. The fundus in the left eye displayed the rare condition described as coloboma of the optic nerve-sheath; the coloboma was six or eight times the size of the optic nerve, perhaps being the largest recorded. On the left side, V = fingers, possibly more; on the right, V = $\frac{10}{50}$. Between the optic disc and the periphery below, a pearly white patch was situated; the edges were well marked, and pigmented; otherwise, the fundus was normal. This was considered to be congenital, and to be due to arrest of development (coloboma of the choroid). In neither eye was there a cleft of the iris, nor any deformity beyond those named. Nystagmus, affecting both eyes, was present. (5) Remains of hyaloid artery. The attachment to a vessel in the centre of the optic disc was clearly made out; at this point it was a little more funnel-shaped. Anteriorly, it was attached to the posterior lens-capsule, where it occasioned a striated opacity. V = fingers at one foot. The eyes were myopic. (6) Coloboma of upper eyelid, situated at the junction of the inner with the middle third. There was also a lipoma of the conjunctiva.

On a preliminary Precaution to be taken in cases of Cataract Extraction when there is, or has been, any Lacrimal Obstruction or Catarrh.

Mr. J. F. Streatfeild read a paper dealing with a class of cases of cataract requiring extraction, in which an unsuccessful result meant absolute failure and total loss of the eye—those cases, namely, which were complicated by lacrimal obstruction, or catarrh; the operation, in such cases, involved an almost certain failure of the worst kind; and, as the cause of failure in these cases had been overlooked or misunderstood, this catastrophe seemed to have been almost as inevitable as it was complete. When suppuration followed purulent infiltration of the corneal wound, when it occurred as the direct and immediate consequence of the extraction operation, it was the common, almost invariable, beginning of the suppuration of the whole eye. These cases were of course not common, because the absolute loss of an eye after cataract extraction operation, from any cause, was a rare event; but absolute loss of vision was, as a rule, the result of suppuration. Of the last six absolute losses after extraction at Moorfields, three were the result of suppuration. He had had two such cases within the past year—one in private practice, and the other at Moorfields. The cause of this suppuration, after cataract extraction, he was inclined to think was generally some lacrimal obstruction, and secretion of purulent matter from the outlets of the tears, in connection with the eye operated on. No surgeon would think of operating for extraction when there was any lacrimal catarrh, or at least when there was any purulent regurgitation from the lacrimal sac, or indeed any pus of any kind, or from any part of the mucous sur-

faces within the palpebral aperture ; but the state of the lacrimal mucous membrane was difficult to investigate, and it was liable to be considered to be in a healthy state when it was not so. A purulent discharge from either mucous tract, but especially from the lacrimal mucous membrane, was likely to recur at any time, especially if an operation on the eye had been done. An inconspicuous quantity of pus would be sufficient to infect the corneal section. In the case of J. L., a thin and healthy countryman, aged 68, admitted into the Moorfields Hospital on July 4th, 1883, with mature cataracts, both the lower lacrimal puncta were somewhat everted, and, consequently, there was an overflow of the tears in either eye. The lower canaliculi were slit. Pus was found in the lacrimal sac on either side. After this, the nasal ducts were probed every day, or nearly every day, for ten days, and the cure seemed to be complete. On July 16th, the left cataract was extracted. On the day after the extraction, a purulent infiltration of the wound at the upper part of the cornea had begun, and spread rapidly from thence ; the eye was very soon lost for all practical purposes, and, on July 23rd, it was excised. The patient left the hospital on August 2nd. On November 24th, he was re-admitted ; there was some lacrimation of the right eye, but no evidence of any pus in the discharge from the sac at this time. The lower canaliculus, which had been slit, was patent. The eye was in all respects healthy, with the exception of the opaque lens. Now, this was a very unsatisfactory state ; there was no difficulty in passing the large probes, and there was no pus to be seen in the discharge, but recovery was not complete. Mr. Streatfeild resuscitated the old operation for the total obliteration of the lacrimal sac, the canaliculi, and all the lacrimal mucous surface, which used occasionally to be performed twenty years ago for chronic obstinate discharge from, and distension of, the lacrimal sac, from obstruction of the nasal duct. On December 10th, the upper canaliculus of the right eye was slit, from the puncture to the lacrimal sac ; when the bleeding had stopped, the eyelids were held widely apart, the eye itself being covered and protected, and the pointed end of Paquelin's thermo-cautery was passed rapidly in the direction of first one and then the other canaliculus, along them, and quite into the sac. He then made a skin-incision over the lacrimal sac, rather longer than the whole of its extent, downwards and a little outwards, between the root of the nose and the lower eyelid ; this was then continued into the mucous cavity itself ; and, when the bleeding was arrested, the two edges of the deep incision were held widely apart, and the broader end of the cautery was very freely and repeatedly applied to all parts of the exposed mucous surface, from the top to the bottom of the sac. The cavity was stuffed with carbolic oiled lint. On January 1st the wound had healed, and the sac and the canaliculi were apparently obliterated. There was slight lacrimation, but there was no pus, or any muco-purulent matter in the eye. On April 23rd he was again admitted. There was then a depressed scar in the place of the lacrimal sac, and a small hole leading down in that direction ; there was also an indication of a part of the lower canaliculus. The following day, the cautery was again applied to the fistulous orifice and to the remains of the lower canaliculus, and on May 8th for a third time. On May 20th there seemed to be no trace of the canaliculi remaining, and no indication left of a lacrimal sac. There was now no discharge upon the conjunctival surface at any time ; the flow of tears was not much, and it was no longer troublesome. On June 2nd the cataract of the right eye was extracted. The eyelids were washed with a (1 in 40) solution of carbolic acid before the operation, and boracic acid ointment (ten grains to one ounce of vaseline) was smeared on the dressing. A weak solution of boracic acid was used subsequently every day to bathe the eye, and the same ointment was re-applied with the after dressings. Slight ciliary congestion with photophobia occurred about a fortnight after the operation, but he made a good recovery. The objections to the obliteration of the lacrimal sac were not practically very strong ; and, in the cases in which he advocated a revival of this obsolete practice, it seemed to be absolutely necessary in order to succeed in operating for cataract subsequently.

Owing to the lateness of the hour, the following papers were taken as read :—

Mr. Nettleship : Examination of a glaucomatous eye, in which retinal hæmorrhages were present, and were distributed in a manner suggestive of obstruction to the descending branches of the cerebral vessels.

Dr. Edmunds and Mr. Lawford : Optic neuritis in relation to cerebral tumour.

Mr. Cant : Cystic tumour of iris.

Living and Card Specimens.

Mr. Simeon Snell showed a section under the microscope of a specimen of bony tumour of the conjunction. It was removed from the right eye of a girl, aged 13, and had probably existed since birth, but had caused no inconvenience until shortly before she came under observation.

Dr. Walter Edmunds showed an ophthalmoscopic drawing from a case of cerebral tumour, presenting appearances like those of albuminuric retinitis. There was well marked double optic neuritis with hæmorrhages round the disc, there were also bright radiating lines at the yellow spot. The retinal veins were not tortuous.

Mr. Lang showed a little child with a growth on the iris of a possibly tubercular nature. The eye had been noticed to be a little blood-shot about the middle of May. When first seen a month ago there were several growths on the lower part of the iris, and the cornea was hazy ; the growths had since been steadily increasing in size, and there was pus in the anterior chamber.

Mr. A. Critchett exhibited a patient with conical cornea, on whom he had operated.

Also with Mr. Juler he showed a case of squint cured by operation, and a leucoma of cornea, treated by tattooing, and the formation of an artificial pupil.

Mr. W. Adams Frost showed two cases of double optic neuritis in children. In the one case, which was a girl, aged 10, the failure of vision had been preceded for several months by very severe headaches, accompanied by vomiting, and these still persisted. There was slight parcsis of the left external rectus, but no other paralytic affection, Knee-reflex normal. The patient was a very healthy-looking and intelligent child. There was no history of any personal illness or family tendency. The other case was a girl aged 7. When first seen on May 1st vision was said to have been failing a week. There was well marked papillitis in both eyes. No history of headache or any illness could be obtained at the time. A few weeks later the child was attacked with severe occipital pain, and vomiting, and the headaches without vomiting have recurred frequently since. No paralysis of any ocular muscles. Left eye has improved slightly under small doses of mercury.

Annual General Meeting.

The Reports of the Treasurer and Council were received and adopted. The following officers were elected for 1884-5 —President—Jonathan Hutchinson, F.R.S. Vice-Presidents —Sir William Bowman, Bart., F.R.S. ; C. E. Fitzgerald, M.D. (Dublin) ; Henry Power ; *Thomas Reid, M.D. (Glasgow) ; *T. Shadford Walker (Liverpool) ; J. C. Wordsworth. Treasurer—J. F. Streatfeild. Secretaries—John Abercrombie, M.D. ; W. A. Brailey, M.D. Council —George Cowell ; G. A. Critchett ; R. Marcus Gunn ; George Johnson, M.D., F.R.S. ; Stephen Mackenzie, M.D. ; Charles Macnamara ; E. Nettleship ; Priestley Smith (Birmingham) ; *Simeon Snell (Sheffield) ; *T. Sympson (Lincoln) ; *John Tweedy ; W. Spencer Watson. The gentlemen whose names are marked with an asterisk (*) were not in the Council, or did not hold the same office, during the preceding year.

Some alterations in the rules, and regulations for the library were then agreed to.

The Army Medical Department. — One of the important results, says the *Standard*, of the recent Report of Lord Morley's Committee on the Army Medical Service will be a careful revision of surgical and medical equipment for hospital and field use, with the adoption of the latest improved appliances. Various changes are under consideration in the Army Hospital Corps, with a view to a fuller recognition and development of this valuable force.

THE WEST LONDON MEDICO CHIRURGICAL SOCIETY.

FRIDAY, MAY 2, 1884.

DR. THUDICHUM, President, M.D., F.R.C.P., in the Chair.

Radical Cure of Hernia.

MR. SWINFORD EDWARDS showed three cases in which he had performed the radical cure for hernia. The first case was that of a man, aged 40, who was admitted into the West London Hospital with a strangulated inguinal hernia. Taxis under ether failed. The sac was opened and the constriction, which was situated at the neck of the sac, was divided in the usual way, and the bowel returned into the abdomen. Some prolapsed omentum was ligatured and removed, after dividing some adhesions between it and the sac. The sac was now freed from the scrotum, care being taken to avoid any injury to the cord in so doing. The sac having been pulled down as far as possible, a cat-gut ligature was tied round the neck and the sac removed. Having well defined the external abdominal ring, the pillars were brought together with three silver wire sutures. The operation was completed by bringing the soft parts together, after the insertion of a drainage tube by means of silver wire. The wound healed by first intention, excepting at three points situated over the deep silver sutures. These were removed at the end of three weeks, the patient being discharged three weeks afterwards, wearing no kind of truss, there being no impulse on coughing. The temperature never exceeded 100°. The patient is now, a year afterwards, following his usual occupation, wears no truss, and has no return of the rupture.

The second case was that of a lad, aged 19, who was operated upon six months ago for reducible inguinal hernia. The operation was undertaken at the patient's own desire, as he wished to be freed from the inconvenience of wearing a truss. The steps of the operation were as in the previous case, excepting that cat-gut was used to bring the pillars of the external abdominal ring together instead of wire. The wound in this case (as, indeed, in all Mr. Edwards' cases, with the slight exception of the previous case, where complete union by first intention was prevented by the irritation caused by the use of silver wire for the abdominal ring) healed by first intention. The temperature never rose above 100°. The patient was discharged, wearing no truss, one month after the operation. This patient was examined by various Members of the Society, and pronounced cured. There was found to be some impulse on coughing, due to a slight varicocele, which had been noticed at the time of the operation.

A little girl, aged 12, was the third case shown. She was admitted into the hospital with a reducible inguinal hernia of the right side, of two years' duration. The same operation was performed in this case. The temperature never rose above 99°, and the wound healed by first intention. She was in hospital altogether about a month. Several members examined this case and found no increased impulse on coughing. The little patient has not worn a truss since the operation, now ten weeks ago. In these cases strict attention was paid to antiseptics, both at the time of the operation and in the subsequent dressings. The spray, however, was not used. Mr. Edwards laid great stress upon employing thorough drainage, iodoform next the wound, plenty of gauze packing, and over all equable elastic pressure, by means of an Esmarch's bandage. With regard to the femoral variety of hernia, Mr. Edwards said that he contented himself with ligature of and cutting off the sac, not caring to meddle with either the femoral ring or the saphenous opening, on account of the close proximity of the femoral vein. He recommended this operation, as brought forward by Mitchell Banks, in all cases of strangulated hernia, where the state of the intestine admitted of its being returned, and in cases of reducible hernia, where the wearing of a truss was insufficient or irksome.

Mr. EDWARDS, in reply to Mr. Lunn, said he would have the operation performed on himself if he had a hernia.

Dr. THUDICHUM said the operation did not vary from Wood's, except in cutting off the sac.

Mr. BRUCE CLARKE said Wood did not insist on suturing the pillars of the ring, and also invaginated the scrotum.

Mr. KEETLEY stated that the injection of fluids into the canal had been practised in America and Germany with success. He considered Wood's and Wutzer's operations were practically abandoned.

Littré's Hernia.

Mr. KEETLEY read some remarks on a case of Littré's Hernia. The patient was a woman, aged 40, with a right femoral hernia. Obstruction was only partial, and symptoms had existed for five days before admission into hospital. There was vomiting, but the bowels moved occasionally, and there was in addition local pain and tenderness. The sac was opened and reduction was easy. A portion of the intestinal wall, about the size of half-a-crown, was strangulated and of a very dark colour. The sac was excised and its neck tied, antiseptic precautions being used throughout. The patient did well for 24 hours, the local symptoms having been quite relieved. Delirium afterwards came on, and death ensued in 30 hours. At the *post-mortem* examination the strangulated portion was found quite black, and the blackness had also spread for an inch or two upwards and downwards. The affected region of the intestine, for the distance of about a foot, was narrowed in calibre, the greatest narrowness being at the point of strangulation. Intestines empty and pale, and no peritonitis.

Mr. BRUCE CLARKE said it was important to decide what should be done with the gut in the case of a small portion being gangrenous; he considered that excising the gangrenous portion and reuniting the bowel by sutures, was a treatment well worth trying.

Dr. THUDICHUM said the influence of position in reducing hernia was very great; for instance, putting the patient on his knees and elbows, or even inverting him.

Mr. BECKINGSALE asked if taxis had been employed before the operation.

Drs. OWLES and CULVER JAMES, Messrs. EDWARDS and LAWRENCE, also took part in the discussion; and, in reply, Mr. KEETLEY said the affected portion of gut was ileum,—that taxis had been employed, and that where he felt convinced the gut could not recover, he would excise, as suggested by Mr. Bruce Clark.

Extra-Uterine Pregnancy.

Dr. ALDERSON read a paper on a case of Extra-Uterine Pregnancy. The patient was a healthy married woman, aged 30; she had one daughter then twelve years old. She had been ill with congestion of the womb before marriage, and had a severe attack of menorrhagia, lasting five weeks, shortly before her second marriage in 1879. Dr. Alderson attended Mrs. H. for the first time, 4th August, 1880; she had been under medical treatment from the previous May, for a slight brown vaginal discharge. A sound had been passed, and occasioned much pain, both at the time and afterwards. On Dr. Alderson's visit, Mrs. H. was in bed, and was evidently suffering from severe uterine congestion, and other symptoms, due apparently to a retroflexed uterus. For the next three or four weeks the patient suffered severely from sharp attacks of acute peritonitis, and symptoms that were attributed to pelvic cellulitis and membranous dysmenorrhœa, for on the 22nd August she passed per vaginam a large tough membrane, the exact cast of the uterus and Fallopian tubes. After this there was a brief interval of comparative ease. The improvement not continuing, Dr. Wiltshire was called in consultation, September 2nd, and after careful examination diagnosed the case "as a cataclysmic hæmatocele into the peritonæal cavity, probably due to the rupture of an extra-uterine fœtation, most likely of the tubal variety, the Fallopian tube having burst." On September 8th, Mrs. H. had a dangerous attack of acute peritonitis. Opiates by the mouth, rectum and vagina, and in fomentations, gave great relief, and some sleep resulted; in the morning her temperature was reduced 2°, and her pulse from 130 to 120. The patient continued to make good progress, and on September 13th, the temperature was normal, and the pulse 100. The external swelling was much less and showed comparatively little tenderness. The tumour could not be felt in the vagina, but per rectum

there was a prominent firm obstruction, about two inches up, completely plugging the passage. The bowels had not acted for three days, and so great was the obstruction that neither the finger, nor the tube of a Higginson's syringe would pass beyond it. On September 20th, this obstruction to the bowels still continuing, she consented to removal to the West London Hospital, where she was admitted the same day, under Dr. Wiltshire's care, and remained in the hospital for twelve weeks. The journey thither apparently caused the bursting of the fœtal abscess, as a copious mattery discharge from the rectum commenced the same afternoon. This discharge continued, more or less night and day, for three weeks. The patient never suffered any acute pain afterwards, and dates the commencement of her convalescence from this attack of suppurative diarrhœa. Her bowels were never confined after her admission into hospital. All her stools were carefully examined, and on October 12th she passed per rectum portions of fœtal bones, and the last piece of bone on May 24th, 1882. The interest of the case is perhaps the apparently entire recovery of the patient, and that the fœtal head can be felt as a hard globular swelling per rectum. Dr. Alderson called attention to the earlier symptoms by which extra-uterine fœtation might be known or at least suspected. He thought the clotted chocolate discharge, this patient's first symptom, was most probably the escape of the amniotic fluid. Dr. Aldersou asked the opinion of the Society as to the most appropriate treatment after the early diagnosis of extra-uterine pregnancy. Should the aim be to destroy the life of the fœtus by galvanism or injection, and thus arrest its growth and avert hæmorrhage? Might the bones of the fœtal head (which are said never to suppurate), and the other remains of the fœtus become a lithopædion and harmless? Would the patient have suffered less, have had a better chance of longer life, and of life under more favourable circumstances, had any operative measures been resorted to during any period of Dr. Alderson's attendance? He concluded his paper by remarking that Mrs. H. had escaped death from acute peritonitis, from collapse, hæmorrhage, acute suppuration, and other dangers of extra-uterine fœtation. Was meningitis, apoplexy or sudden death still a possible termination that might be expected?

Mr. Gunton Alderton had seen three cases of extra-uterine fœtation, in two of which the bones were discharged per rectum, but in the third case he did not know the final result. He thought the prospect of leaving these cases to nature not so very gloomy.

Dr. Venn said that where retroflexion was present, vomiting was a rarity. In Fallopian cases the cyst usually burst about the third month. As regards diagnosis it was arrived at by a process of elimination. He recommended abdominal section in cases where the cyst was discovered before rupture. When discharge of bones occurred through the rectum it should be encouraged to continue, but he advised no interference when they were encysted. The galvanic current appeared to be the best means of destroying the fœtus.

Mr. S. Edwards asked if there were any statistics in these cases comparing those operated on with those where the bones passed per rectum.

Dr. Owles did not think it advisable to use the uterine sound where pregnancy might exist.

Dr. Alderson, in replying, thought Dr. Alderton fortunate in having seen three cases of extra-uterine fœtation with two recoveries, and added that in his patient the uterus was still more tender than normal, and the patient had much pain if the monthly period was delayed, and suffered then from severe headache. The use of the sound had certainly caused the patient a great deal of pain; until the sound was passed she was able to walk about and continue her household duties as usual. It caused some inflammation, although it could have hardly caused the fœtal death, as pulsation in the cyst was detected some time afterwards. With regard to fatality after operation, he had seen it recorded as high as 67 per cent. In 24 cases of primary operation by Parry, only one survived.

At the conclusion of the meeting, Dr. Thudichum announced that an annual lecture would be given under the auspices of the Society, to be called "The Cavendish Lecture," in honour of the distinguished chemist who resided in the West of London, and who was an ancestor of the Duke of Devonshire, the President of the West London Hospital. He had much pleasure in announcing that Mr. Timothy Holmes would deliver the first lecture early in July.

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE IX.

Food.

Aërated Waters.

The manufacture of aërated waters is an industry attaining gigantic proportions. The old clumsy methods of developing carbonic acid gas, of charging and corking the bottles have given way to machinery and plant of a very complicated and expensive character, enabling the maker to turn out daily, at a cheap rate, quantities of aërated fluids, which under the earlier system would have been impossible.

It is obvious that the industry is one that may from time to time be a most valuable assistance in preventive medicine. When fever taints the well, or malaria lurks in the stream, distilled water, the mawkishness of which has been neutralised by gas, affords safety.

There are at least seven exhibits of mineral waters at the "Healtheries"; three of these we have carefully examined and trust that the others which have not passed through our hands are equally free from metallic and organic impurity.

Mr. H. D. Rawlings, of Nassau Street, Berners Street, W., displays every kind of aërated and medicinal water. His soda water we find to have an alkalinity equal to nearly 4 grains of carbonate of soda in the pint, the total solid residue per pint being 8·2 grains; the water is free from any metallic or other contamination.

The potash water is more than double the strength of the soda water, having an alkalinity equal to 11·2 grains per pint, and on evaporation a pint leaves a solid residue equal to 14 grains. The same remarks as to purity and freedom from lead or copper apply here also.

Rawlings' lithia water leaves a residue of 8·3 grains to the pint, and is what it is represented to be.

Rawlings' lemonade has an acidity equal to 3½ grains of citric acid per pint; the taste is pleasant, it is free from lead or copper, and well charged with gas.

The British and Foreign Mineral Water Company have also a very complete exhibit, including, besides the usual assortment of effervescent drinks, a model of the admirable machinery used. The processes they employ ought to render contamination by lead or copper an impossibility, nevertheless, we decline to take anything for granted, and have therefore also submitted various samples to analytical examination.

The potash water is in strength equal to 4½ grains of potassic carbonate per pint; it is free from metallic contamination.

The lemonade is practically the same in strength as Rawlings' lemonade, it is likewise pure and free from lead.

The third exhibit which has been specially examined is that of Messrs. Pitt, City Road. Their products are good and pure; the soda water in alkalinity is equal to 2 grains of sodic carbonate per pint.

These determinations of alkalinity and general strength are sufficient to show that no common standard is adopted by different makers. If at the bar of a public-house a bottle of potash water is demanded, the customer may be supplied with a bottle containing four, forty, or any intermediate number of grains of potassic carbonate, and the same remark applies to all the artificial medicated waters. Since lithia and potash waters are not infrequently prescribed, it really would be of some convenience, both to medical men and the public, if a common standard of strength was adopted, and the strength stated on the label.

We notice that nearly all the aërated water manufacturers have introduced what they call "*tonic* water." These

tonic waters are feebly acidulated waters, saturated with carbonic acid gas, and made bitter by various bitters, such as nux vomica, hop, chirretta, quassia, &c. The chief customers for the "tonic waters" are gentlemen with white tremulous tongues, who have no appetite for breakfast, but manage to excite some feeble craving for food about 11 or 12 in the day; in short, they are drawn from the ranks of dissipated people. The "pulling together" by the daily use of bitters is wrong; it is analogous to the practice of the malingerer, who applies the salve to his ulcer in the day, but tickles it up with a bristle at night. There are many organs and functions which may be stimulated, but reaction is inevitable; the stomach that has to be goaded at 11 a.m. by tonic waters or gin and bitters, requires to have the cause of its torpor removed, and not excited to a temporary activity which, from its artificial nature, cannot be maintained.

Biscuits and Flour.

The old established biscuit firms are well represented at the Exhibition; for instance, Messrs. Peek, Frean and Co. show the "Oswego," "Health," "Charm," "Wreath," "Milk," "Café," "Abernethy," and many other kinds. They have been specially successful in their "Cocoa-Nut Biscuits;" the delicate and easily-destroyed cocoa-nut flavour is fully preserved, and the white albumen seems to be a component part of the biscuit.

While on this subject we must not omit to notice "The Tunbridge Wells Water Biscuit," the texture of which is almost that of fine lace, and though of considerable surface their average weight is no more than five grains. In striking contrast to these are "Scott's Midlothian Biscuits," made of pure oatmeal, brittle and solid; on a packet of which a man could do a day's walking, cycling or shooting.

The different exhibits of all kinds of wheat, barley, and oats, both ground and entire, to the uninitiated look very similar; and from the general excellence of the samples the juries, aided as they will be by technical knowledge and chemical experiment, may find it difficult to satisfy their own minds.

Mr. George S. Mumford shows fine samples of wheat, pea, lentil, and other flours.

Mr. R. D. Farnworth has also samples of whole meal, of oatmeal, of Hungarian flour, &c., of the highest excellence.

Besides these, Messrs. A and R. Scott, of Glasgow, Mr. Andrew Aikman, of Edinburgh, the well-known Glen Mills Company, the firms of Turner and Company, of Brown and Polson, and a few others, exhibit every kind of meal, making as a whole a very representative show of what the miller can accomplish.

The Bread Reform League Company, of which Miss Yates is the indefatigable secretary, has of course an exhibit. Bread made of whole meal is extremely nice, and may possibly, from its more complicated composition, be the proper thing to eat; but the theory of the greater nutrition of whole meal is based entirely upon its greater nitrogenous content, and it has been too rashly assumed that the greater nitrogenous content represents greater albuminoid content, which by no means follows. The food chemists of a former age burnt flour and grain up, estimated the nitrogen, multiplied it by various factors, varying from 6·47 to 6·00, and returned it as albuminoids; but the more recent food-chemists have shown that to operate in this way is wrong, and that to arrive at the true albuminoid, the nitrogen of alkaloidal and nitrated matters abounding in the outer covering of the grain must be subtracted. True it is that these matters may, for aught we know, have a high office in the economy, but this remains to be proved; the work hitherto done showing satisfactorily enough that a larger proportion of the nitrogen of whole meal floats down the entire length of the intestinal canal unabsorbed than in the case of white flour; and that if it is a question of content of true albuminoids, whole meal suffers in the comparison.

The Library of the Royal College of Surgeons will be closed on Friday the 18th inst., and Saturday the 19th inst., for the purposes of the examinations.

OBITUARY.

HENRY HURRY ILES GOODEVE, M.D., F.R.C.P., &c.

Dr. Henry Goodeve, whose death took place on the morning of June 17th, at the ripe age of 77, was in several respects a remarkable man, and had filled many responsible positions with great credit and public advantage. He was born at Portsmouth, of a Norfolk family, and on his mother's side claimed kindred with the famous Sir John Hurry, the companion of Montrose. His father was married three times, and left male issue by all these marriages. Of the first family Mr. William James Goodeve, a surgeon in Clifton, and lecturer on anatomy, was father, by Lady Frances Jemima Erskine, of the present Earl of Mar; and of the third was Dr. Edward Goodeve, long known and honoured in Calcutta, and afterwards British Commissioner at the Constantinople Cholera Conference. Henry Goodeve entered early into active life. Before he was 22, he had assisted his elder brother as lecturer on anatomy, had taken part in the conduct of the *Athenæum* with his cousin Frederick Maurice; had graduated at Edinburgh, and had married Miss Isabella Barlow, the faithful and constant helpmate of his useful life. Having obtained an appointment in the East India Company's service, he was for four years stationed at Rampoor. During this period he received, while tiger hunting in a jungle, a frightful bullet wound, which divided the facial nerve and produced permanent facial paralysis. On the first establishment of the Calcutta Medical College, he was appointed Professor of Anatomy. He subsequently devoted himself zealously to obstetrics, and for ten or eleven years had the largest practice in Bengal. He acquired and retained the friendship of several distinguished men then in India, and particularly of the late Sir Ronald Martin, and of Dr. O'Shaughnessy (now Sir William Brook), the pioneer of Indian telegraphy. He found time also, in spite of his public duties and overwhelming private practice, to initiate reforms and found charitable and medical institutions in Calcutta, which still bear testimony to his zeal, benevolence, and judgment. At length, however, these incessant labours began to tell upon him. He returned to England on leave, and after one brief visit to the scene of his toils, retired from the Company's service with the grant of a special pension for distinguished merit. This retirement he utilized for the development of a scheme he had already conceived, viz., the extension to high-caste and other Hindus of the benefits of English education. He brought with him to London four young Brahmins, placed them at University College, and superintended their career. Some of them highly distinguished themselves, notably the late Dr. Soojoocoomar Chuckerbutty.

After several years' residence in London, the Crimean war offered an opportunity to his active spirit, of which Dr. Goodeve was not slow to avail himself. He volunteered for service and was appointed Inspector of Civil Hospitals, in which capacity he acted at the Renkioi Hospital, as colleague of Sir Spencer Wells, and the late William Robertson and Holmes Coote, under the superintendence of Edmund Parkes. Returning to England at the close of the war, he designed and erected for himself a picturesque mansion, on what is probably one of the finest sites in the South of England, overlooking the gorge of the Avon, near Bristol. It is noteworthy that this was the realisation of a definite project, formed in early life, before his departure for India. The last twenty-four years of his eventful life were spent in this new home, but his leisure never degenerated into inactivity. He was a very laborious and conscientious county magistrate, a regular visitor of the county lunatic asylums, reformatories, and industrial schools, an early promoter of the volunteer movement, and for years a captain of the Bristol Rifles, and with the hope of promoting the prosperity of the city of his adoption, he became a director of the Avonmouth Docks and Port and Pier Railway. On the death of his wife, he accepted the Presidency of the Bristol Boarding-out Society, having always been a strong advocate of domestic life as opposed to the aggregation of young people. Of late years his health, but

nct his spirit, began to fail; he suffered from weakness of the heart and from plugging of the veins, and at last died, after about ten days' illness, from congestion of the lungs and kidneys.

His manly and well-proportioned figure, his open cheery countenance, to which the effects of his wound gave a singularly martial air, will long be missed in Bristol and in Gloucestershire; but not so much as his genial hearty greeting, and his warm, kind, youthful heart that "loathed the wrong, and aye upheld the right." His friends, sometimes regretted that no public mark of distinction, on the part of Government, ever rewarded his long and distinguished public services. But most of them were accomplished at a period when the achievements of the heroes of medicine were even less recognised than now. He never had leisure for much writing, but "Goodeve's Hints on the Management of Children in India" has gone through seven editions, and in its latest form continues to be the treasured counsellor of Anglo-Indian mothers in the Mofussil.

GENERAL CORRESPONDENCE.

SIR SPENCER WELLS ON EARLY AND LATE REMOVAL OF ABDOMINAL TUMOURS.

[To the Editor of the Medical Times.]

Sir,—I agree entirely with Sir Spencer Wells in his paper as published in your issue of to-day, and if all the dreadful things he relates are really occurring, something ought to be done to save our profession from ruin.

I would desire only to point out that, as it is very unlikely that Sir Spencer would have published his diatribe unless he had been in possession of trustworthy information, if he withholds that information now, he will share the guilt of those whom it implicates.

I am, &c.,
LAWSON TAIT.

Birmingham, July 5.

THE MEDICAL COLLEGE HOSPITAL OF CALCUTTA.

[To the Editor of the Medical Times.]

Sir,—I am in no way concerned to defend the construction or the management of the above hospital since it passed away from my personal direction, more than thirty years since. I likewise have no desire to revive any of the controversies connected with it—in the which by the way I have never taken part, although I believe I know more of, and had more to do with, its early history than any of those now surviving who then shared in its duties and responsibilities. If Time be the great destroyer, he is likewise the great healer, and my memories of it, when sad at all, are that so many of my valued and respected fellow-workers have since "gone on," rather than that our work contained imperfections due to, and inseparable from, the limited knowledge of hospital construction of the time, and I would fain believe to no shortcomings on our part in making the best of the means and instruments at our disposal. Many of your readers will probably have heard for the first time of the existence of such an institution from the unsparing and trenchant condemnation of Dr. Chevers, together with his sad memories of the existence of pyæmia and its allies during his incumbency, which certainly did not prevail when it was in my charge, as the statistics I then collected seemed to me to show.

My object in addressing you is simply to place before yourself and your readers, without comment or remark, another view of the question respecting the amount of responsibility for those affections, fairly due to faulty construction. It is extracted from a resolution of the Government of Bengal in "The report on the Calcutta Medical Institutions for 1878," dated July 11th, 1879, which is a strictly official document, with which I had no connection, direct or indirect, and which I leave to tell its own tale.

Para. 10. "*Medical College Hospital.*—Exclusive of 546 house-patients in the ophthalmic hospital, there were 4,602 indoor-patients treated during the year, of whom 2,541 were Christians, and 2,061 natives. The death-rate was 13·56 per cent., as compared with 10·83 in 1877, and 13·62 in 1876. Excluding moribund cases, the death-rate was 11·2 per cent. of the number treated. One hundred and eighty-four surgical operations, classified by the principal as capital operations, were performed during the year, or remained under treatment at the end of 1877, and of these only 22 died. The death-rate per cent. was 11·96, as compared with 17·03, 21·81, 22·72, 19·75, and 25.92 in the five preceding years. Adopting, however, the system of classification used by the surgeon-general in preparing his general statement of important operations performed in all the Calcutta medical institutions, it appears that the death-rates per cent. in the Medical College Hospital were 11·08 in 1876, 8·3 in 1877, and 4·7 in 1878, as compared with corresponding death-rates of 11·06, 8·4, and 7·09 in all the Calcutta hospitals in the same three years. These figures appear to the lieutenant-governor to show conclusively that the want of success in the treatment of surgical cases in former years was mainly due to causes other than the faulty construction of the building; the recent statistics, when analysed, entirely refute the conclusions that have been drawn from the returns of 1876 and previous years, and confirm the views recently adopted by Government as to the erroneous nature of the conclusions which had been drawn from the earlier surgical mortality, and as to the destructive character of the policy based upon them."

I am, &c.,
F. J. MOUAT, M.D.,
Formerly First Physician of the Medical College Hospital of Calcutta, and Secretary to the Institution.

London, July 8th, 1884.

INVENTIONS AND IMPROVEMENTS.

ANTISEPTIC CHARCOAL WAFER BISCUITS.

Under this name the same firm have introduced a very palatable form of charcoal biscuit, which professes to be made of the finest willow charcoal, and flavoured with pure ground ginger. These biscuits provide a very pleasant mode of administering vegetable charcoal.

THE IMPROVED ZOEDONE.

The Zoedone Company, 80, Coleman Street, E.C., have recently made considerable alterations in the manufacture of their staple article, and profess to have considerably improved both its quality and flavour. That their allegations in this respect are justifiable, no one who tastes the drink as now produced can deny. Zoedone as originally introduced to commerce, contained too much sugar, and had too pronounced a flavour, so that many people who welcomed it at first as an agreeable alternative to other effervescent drinks — alcoholic and non-alcoholic — found that they rapidly tired of it, and complained in some cases that it interfered with digestion. It will be found we think that Zoedone as now prepared has neither of these disadvantages. It is a refreshing and thoroughly palatable beverage, and can be safely recommended as a drink especially in cases in which iron is indicated.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At the ordinary meeting of Council, held at the College on Thursday last, the first business was the election of President, when the choice fell on Mr. Cooper Forster, the Senior Vice-President; Mr. Savory and Mr. Holmes were elected Vice-Presidents. Messrs. Lawson, Durham, Hill and Allingham, the newly-elected Members of Council, took their seats for the first time. The gentle-

men, whose names have been given in a previous number, were duly elected to the various Lectureships in connection with the College and Museum. Mr. Heath's resolution was carried, *nem. con.*, in the somewhat altered form as follows:—"That at the ordinary meeting of the Council in November next, the Council do consider the mode of electing the President and any alterations suggested in the method of proceeding in the election. Sir Erasmus Wilson was put in nomination to receive the honorary gold medal of the College, the ballot to be taken at the next meeting of the Council, on Tuesday, August 5th. Mr. Charles Stewart was admitted to his office as conservator, and elected Erasmus Wilson Professor for the year. A letter from Mr. Alfred Coleman was then read, in which he resigned his office as examiner in dental surgery, on account of ill-health. The resignation was accepted with an expression of regret as to the cause. The Council, acting on legal advice, declined to comply with a request of certain dental practitioners of Nottingham that they would move the Medical Council to investigate the case of a person alleged to have infringed the Dental Act, and to have been guilty of disgraceful conduct in a professional respect. A letter from the Assistant Secretary of the Local Government Board was read: it stated that the Board were prepared to consider, when referred to, any cases of superannuation of Poor Law Medical Officers where hardships were said to have occurred, but that the Board could not consent to take the action suggested by the Council. A subscription of 25*l.* was voted towards the repairs of the church of St. Giles in the Fields. The Council then adjourned.

Royal College of Surgeons of England.—The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Board of Examiners, on the 4th instant, and when eligible will be admitted to the pass examinations, viz.:—

H. A. Clarke, of the Liverpool School of Medicine; E. H. Barret, of Charing Cross Hospital; R. W. Clayton, of St. Mary's Hospital; A. B. Stevens and W. S. Whitcombe, of St. Bartholomew's Hospital; and R. H. M. Roberts, of St. Thomas's Hospital.

Twelve candidates, having failed to acquit themselves to the satisfaction of the Board of Examiners, were referred to their anatomical and physiological studies for three months, and five for six months.

The following gentlemen passed on the 7th inst., viz.:—

H. R. Williams, W. R. Garrould, and B. S. Johnson, of University College Hospital; H. T. Kelsall, C. E. Scudamore, H. E. Owen, and H. A. Debenham, of the London Hospital; J. E. Appleton, of St. Mary's Hospital C. H. West and G. A. Wybourn, of Guy's Hospital.

Twelve candidates were referred for three months, and four for six months.

The following gentlemen passed on the 8th inst., viz.:—

A. E. Gresham and H. E. Whitehead, of St. Bartholomew's Hospital; Arthur Kingsford and W. E. Carter, of University College Hospital; G. E. Haslip, Robert Hitchings, and J. F. Vincent, of the London Hospital; E. F. Gardner, C. A. Lumley, and Sidney Woodhams, of Guy's Hospital; S. G. Vinter, of St. Mary's Hospital; and G. McNair, of King's College Hospital.

Ten candidates were referred for three months, and one for six months.

The following gentlemen passed on the 9th inst., viz.:—

C. H. Ashford, Charles Lyddon, and J. E. Nihill, of St. Bartholomew's Hospital; G. T. Giddings, A. A. Kempthorne, Charles Collier, and J. T. C. Williams, of the London Hospital; E. M. Callender, of St. Mary's Hospital; T. G. Scott and F. T. Frost, of Guy's Hospital; W. J. Gilpin, F. P. Kitson, and R. B. Hughes, of University College Hospital; Ernest Dalton, of Charing Cross Hospital.

Eight candidates were referred for three months, and two for six months.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, July 3rd, 1884:—

Mordaunt, George Dundas, 4, St. Thomas' Street, S. E.; Frederic Charles Larkin, 109, Radcliffe Street, Everton, Liverpool; William Adolphus Maggs, 16, Hanover Square, W.; Solomon Peake, Coventry; Edmund Raghib, 43, Park Road, Wandsworth; Edward Lloyd Williams, 2, James Street, Buckingham Gate, S. W.; Robert Richard Williams, Llanberis, N. Wales.

The following gentleman also on the same day passed the primary professional examination:—

George Frederick Burd, St. Bartholomew's Hospital.

Royal College of Physicians of Edinburgh.—The following have passed their examination, and been admitted Licentiates:—

Thomas Lyons, Brompton, England; Bertal Hapton Scott, Nottinghamshire; Alex. Gillespie, Canada; Frank Broadbent, Collingham, Notts; Frank Pearse, Exeter; John Traherne Williams, Tetbury, Wilts; Alfred Hanson, Cornwall; Thomas Sheedy, Liscarroll; Wm. Frederick Charles Rogers, Cornwall; James Cole Pincott, Chepstow; Wm. Hooper Pinches, London; Walter Edmund Shoreland, Bristol; George Jones Revell, Devonshire; Jas. Stuart M'Cullough, Georgetown, Ontario, Canada; John Edward Wesley Anderson, Boston, Ontario, Canada; John Standish M'Cullough, Georgetown, Ontario; Ernest Amos Hall, Hornby, Ontario; Maitland Thompson, Workington, Cumberland; George Frederick Seaman Arthy, Macclesfield; Coniston Spackman, Faringdon, Berks; William John Chambers, Ontario; Richard Johnson Martin, Little Hulton, Lancashire; Robert William Quennell, Brentwood, Essex; Edward Arthur Hardwicke, Rotherham, Yorks; Arthur H. Dixon, Trebinshun, Breeon.

The Royal University of Ireland.—A public meeting of the University was held on Saturday afternoon, the 5th instant, when the following degrees were conferred by the Right Rev. Monsignor Neville, *pro*-Vice-Chancellor:—

The Degree of Doctor of Medicine.—Henry Anderson, Robert Bell, John C. S. Burkitt, Howard Carr, Jacob Fairbrother, John S. Fogerty, John D. Kenny, Michael O'Brien, Leonard Redmond, and Robert H. Sproule.

The Degree of Bachelor of Medicine.—Patrick A. Daly.

The Degree of Master of Surgery.—Robert Bell, Joseph J. Brownlee, John C. S. Burkitt, Howard Carr, John S. Fogerty, James C. Hood, Geo. J. W. Johnston, Alexander Lindsay, Robert M'Elwaine, Archibald P. B. Moore (in absentiâ); Michael O'Brien, Richard M. Ralph, Leonard Redmond, Robert H. Sproule, James Torrens, and Samuel Wallace.

The Diploma in Obstetrics.—James C. Hood, James F. Hunter, Alexander Lindsay, Samuel Wallace, and Patrick R. White (in absentiâ).

Army Medical Department.—We learn that there will be 30 appointments offered for competition at the next examination, which takes place in August, instead of 19 as previously advertised.

At the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on the 8th instant, Sir W. N. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of 70*l.* was distributed among the several applicants.

Woolsorter's Disease.—This disease is again reported to have broken out at Bradford. Three fatal cases have already occurred, in one of which the disease was present in a peculiarly aggravated form.

St. Thomas's Hospital.—The annual prize-giving was held on July 9th, the Archbishop of Canterbury presiding, when the dean was able to read a goodly list of honours gained by St. Thomas's men elsewhere.

Hospital Fete.—On the 23rd of this month a hospital *fête* is to be held at the International Health Exhibition, under the patronage of their Royal Highnesses the Prince and Princess of Wales, when, doubtless, the attendance will be very large, and the Hospital Sunday and Hospital Saturday Funds will be materially enriched.

The Scarlet Fever Convalescent Home, Stanmore.—Miss Mary Wardell's Convalescent Home for Scarlet Fever, Brockley Hill, will be opened by Her Royal Highness the Princess of Wales on Monday, July 14th, at 4.45 p.m., and Her Royal Highness has further consented to receive purses of 5*l.* and upwards on behalf of the institution.

National Hospital for the Paralysed and Epileptic.—A meeting will be held on Monday next, when Lord Shaftesbury will preside, to make an urgent appeal for 12,500*l.*, to complete the new block in Queen Square, which is to be called the Albany Memorial Building with the special sanction of the Queen.

Lord Ashley has been appointed to and has accepted the position of President (under Royal Charter) of the Belfast Royal Hospital, Convalescent Home and Throne Children's Hospital. His lordship, who has only recently taken up his residence in Belfast, where he succeeded to the estate of the late Marquis of Donegall, is deeply interested in

hospital work, and has already shown the keenest desire to heartily throw himself into hospital management. The institution is to be congratulated upon having obtained the services of a member of a family whose name is immortally associated with nearly every good and benevolent work.

The Social Science Congress.—The following are the special questions which have been arranged for discussion in the Health Section at the next Social Science Congress, which is to be held at Birmingham on September 17–24. (1) What is the best method of dealing with (*a*) town sewage, (*b*) the products of house and street scavenging, and (*c*) the products of combustion? (2) What are the best means, legislative or other, of securing those improvements in the dwellings of the poor which are essential to the welfare of the community? (3) How far may the average death-rate of a population be considered an efficient test of its sanitary condition; and by what means can the high death-rate of children be reduced?

Death of Inspector-General Irwin.—Mr. Ahmuty Irwin, R.N., C.B., late Inspector-General of Her Majesty's Hospitals and Fleets, died last week at Southsea. He was son of the late Very Rev. Dean Irwin, Vicar-General of Ardfert, Ireland, became a licentiate of the Royal College of Surgeons (Ireland) in 1850, and Hon. M.D. of Dublin in 1881. Mr. Irwin was nominated a Companion of the Order of the Bath (Military Division) in 1874.

The Volunteer Medical Association.—At the United Service Institution on Friday (to-day), Surgeon-General Lawson will read a paper before the members of the Volunteer Medical Association on "Army Stretchers and Waggons." This association is formed on the model of the Army Hospital Corps; it is intended to be an auxiliary to that body, and is being actively supported by the medical staffs of various London hospitals. Membership is purely honorary, and thus far the entire expense has been borne by the association itself: but if it succeeds in obtaining the full authorisation from the War Office it will be entitled to a moderate capitation grant. The organisation is said to be making rapid progress, and its members regularly undergo ambulance and military drill.

Charitable Bequests.—The late Miss Ann Ball, late of Ball's Pond, has bequeathed 100*l.* each to the dispensary formerly called Aldersgate Street Dispensary; the Ball's Pond Dispensary; the Hospital for Sick Children, Great Ormond Street; the Sea-Bathing Infirmary, Margate; the Royal Bethlehem Hospital for Lunaties; St. George's Hospital; the Free Hospital, Gray's Inn Road; the Children's Hospital, Shadwell; the Crêche Hospital, Stepney Causeway; the Hospital for Children and Adults, Tottenham Green; and 200*l.* capital stock of the East Indian Peninsular Railway Company each to St. Bartholomew's Hospital; St. Thomas's Hospital; Guy's Hospital; the Metropolitan Hospital, Bishopsgate; the London Hospital, Mile End; and the German Hospital, Dalston.

Cremation in the United States.—Cremation seems to be making its way in Pennsylvania, in spite of the opposition which it has had to encounter. A Philadelphia correspondent states that a new crematory is to be built near that city, and that Dr. Joseph Leidy, who had been reported as opposed to cremation, has published a statement disclaiming that feeling, and expressing his gratification that the late Dr. Gross directed his remains to be incinerated.

Yellow Fever Inoculations.—Dr. Domingo Freire, of Rio Janeiro, the discoverer of the so-called microbe of yellow fever, writes to the *New York Evening Telegram*:—"I still continue the vaccinations, 406 having been already inoculated without the slightest disadvantage. Yellow fever is now raging at Rio. As soon as it is over I will write, giving the results respecting those vaccinated. For the present I can only say that the exemption is confirmed. In about two months I hope to be able to publish a full report of my researches in regard to yellow fever.

Death of Professor Göppert.—Professor Heinrich Robert Göppert, born in Lower Silesia in 1800, became one of the most famous of botanists and palæontologists, the long series of whose writings in the various Academical Transactions contributed in a remarkable manner to the great development which these two branches of science have undergone in the present century. Since 1827, he has taught first as Docent and then as Professor in the Breslau University. As its Director he brought the Botanic Garden into a high state of perfection; and his collection of the Fossil Flora has been, since 1874, one of the glories of the Breslau University Museum.

A Veteran Sanitarian.—Mr. George Alfred Walker, M.R.C.S., L.S.A., who by his efforts to remove burial abuses earned the sobriquet of "Graveyard Walker," died on Sunday, in his 75th year, at Barmouth, where he had lived in retirement for many years. Dr. Walker rendered signal service to his country as a sanitary reformer, more particularly in the crusade for the abolition of intramural interments. In 1840 he gave evidence for some days before a Select Committee on the health of towns in the House of Commons on the sanitary condition of London and its graveyards. He was author of "Gatherings from Graveyards," "The Graveyards of London," "Interments and Disinterments," and other works.

The Cholera Virus.—Mr. Vincent Richards, in an additional note in the *Indian Medical Gazette* for May, observes that the few further experiments which he has made seem to show that the specific poison contained in choleraic alvine evacuations is not invariably present in these; and at times, even when present, it appears to have lost much of its power—and that especially at the end of an epidemic. All these modifications will require time to investigate, owing to the only occasional opportunities of making experiments and the difficulties inherent in the subject. "If," he adds, "the cholera virus here alluded to is of the nature of a chemical compound, we can understand how, under exceptional insanitary and climatic circumstances, it might be spontaneously generated. We are all familiar with the fact that cholera generally follows in the wake of such calamities as famine and floods; and just as the innocuous saliva of the dog under the operation of some unknown chemical change may become a virulent poison, so the local conditions of filth and climate may convert a non-specific into a specific agent. No doubt all this is hypothetical, but it seems to me that it explains more satisfactorily than any other theory the apparently erratic behaviour of cholera virus."

Precautions against Cholera.—The Local Government Board have issued a circular to the various sanitary authorities in England and Wales transmitting copies of a memorandum by Dr. Buchanan, the Medical Officer of the Board, on the precautions which should be taken against cholera. The memorandum is practically the same as that issued in July, 1883, but the Board have again drawn attention to the matter, to induce the authorities to take such measures as the sanitary conditions of their districts may demand. In the opinion of Dr. Buchanan, former experience of cholera in England justifies a belief that the presence of cases of cholera at various spots in the country cannot cause much injury to the population if the places receiving the infection have had the advantage of proper sanitary administration. At the meeting of the Dublin Corporation on Monday, a letter was read from Dr. Cameron in reference to sanitary precautions, with a view to guarding against any spread of disease in the city. It also proposed that at the next meeting of the Public Health Committee, sixteen additional sanitary sub-officers should be appointed for temporary duty for the purpose of carrying out an inspection of the sanitary accommodation of the city which was deemed absolutely necessary. A telegram from Mr. Gray, M.P., urging immediate action in the subject, was read, and the matter was referred to the Public Health Committee.

Danger of False Teeth.—Cautions are constantly being given concerning false teeth, and persons will still persist in wearing them when dangerously loose. A woman stumbled in one of the streets of Pesth the other day, and when persons ran to her assistance they found her already dead. A set of false teeth had been shaken out of place by the fall and produced suffocation.

PROPOSED MONUMENT TO DR. RUSH.—Dr. Gihon, on moving a resolution at the late meeting of the American Medical Association for the appointment of a committee, to consider the propriety of erecting a statue to the memory of Benjamin Rush, observed that among all the monuments to great men for which Washington is noted, there is not one to a physician. The name of Rush is especially worthy of honour, for apart from the substantial work done by him in the development of science, he was intimately associated with the early history of his country, being a member of the Continental Congress, a signer of the Declaration of Independence, and in various ways a leader in the cause of liberty.

APPOINTMENTS.

BASS, F., L.R.C.P., M.R.C.S.—Assistant Aural Surgeon to the Newcastle-on-Tyne Dispensary, *vice* George Chalmers, M.B., C.M. Edin., resigned.

CARTER, D'ARCY, B., L.R.C.P., M.R.C.S.—Assistant Surgeon to Sir Titus Salt's Hospital, Shipley.

DREW, JOSEPH BOWERMAN, L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the Workhouse, Buntingford Union, *vice* Dr. David Smith, deceased.

FREEMAN, C. D., M.R.C.S.—Assistant House Surgeon to the Royal Berkshire Hospital, Reading.

HALPIN, R. F., M.R.C.S.—House Physician to the Royal Hospital for Diseases of the Chest, City Road, *vice* Mr. Waller, whose term of office has expired.

HEATON, CHARLES WILLIAM.—Re-appointed Analyst for the Parish of St. Martin-in-the-Fields, Strand Union, for a further period of one year.

HUGHES, T.—Public Analyst for the Borough of Newport, Monmouthshire.

JONES, J. T., L.R.C.P.—House Surgeon to the Flintshire Dispensary, *vice* R. M. Witham, M.B., resigned.

KNIGHTS, JAMES WEST.—Re-appointed Analyst for the County of Huntingdon, for a period of one year. Salary, £5 5*s*. and fees.

MURPHY, JAMES, B.A., M.D., &c.—Honorary Surgeon to the Sunderland Infirmary, *vice* Dr. Ayre Smith, resigned.

PATERSON, D., M.B.—House Surgeon to the Glamorgan and Monmouthshire Infirmary and Dispensary, *vice* P. R. Griffiths, M.B., resigned.

PEDLEY, R. D., M.R.C.S., L.D.S.—Dental Surgeon to the South London Medical Aid Institute.

WHITE, W. H., M.R.C.P.—Pathologist to the Royal Hospital for Diseases of the Chest, City Road, *vice* Dr. Gabbett, resigned.

VACANCIES.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary, £150 per annum (with an allowance of £30 per annum for cab hire), furnished rooms, fire, light and attendance. Candidates must be registered and possess both a medical and surgical qualification. Applications, together with original testimouials and certificates of registration, to be forwarded to the Secretary, on or before July 22.

BRISTOL DISPENSARY.—Surgeon. Candidates must possess a diploma in surgery from the Royal College of Surgeons of England, Scotland or Ireland, or from the Faculty of Physicians and Surgeons of Glasgow, and in addition to such diplomas in surgery, must possess a legal qualification to practise Medicine in Great Britain and Ireland, and be duly registered according to the regulations of the Medical Act. For salary and other particulars, apply to Mr. E. Stock, 57, Queen-Square, Bristol, to whom testimonials must be sent on or before July 31st.

CHESHIRE COUNTY ASYLUM, PARKSIDE, MACCLESFIELD.—Assistant Medical Officer. Salary to commence at £120 per annum, with furnished apartments, board, attendance and washing. Candidates must be registered and doubly qualified, unmarried, and not over 30 years of age. Applications, with testimonials to be sent to Dr. Sheldon, Medical Superintendent, on or before July 19th.

COUNTY AND COUNTY OF THE BOROUGH OF CARMARTHEN INFIRMARY.—House Surgeon. Salary £100 per annum, with board, lodging, fire and light. Candidates must be registered to practice both in medicine and surgery, unmarried, and free from the care of a family. They must have a knowledge of the Welsh language, and will be required to enter into an agreement not to practice in the County of the Borough of Carmarthen for a period of five years. Applications, with testimonials, as to ability and character, to be sent to Mr. H. Howells, 11, Morley Street, Carmarthen, on or before July 12th.

GUILDFORD UNION.—Medical Officer to the Farncombe District, in succession to Dr. G. F. H. La Fargue, deceased. Salary, £60 per annum.

LUTON UNION.—Medical Officer to the Workhouse, in succession to to Mr. R. O. Arnold, resigned. Salary, £75 per annum.

MERIDEN UNION.—Medical Officer to the Meriden District and the Workhouse, in succession to Dr. Partridge, deceased. Area, 17,789 acres. Population, 4,158. Salary, £55 per annum. Salary for Workhouse £25 per annum.

ROYAL SEA BATHING INFIRMARY, MARGATE.—Resident Surgeon. (*For particulars see Advertisement.*)

ROYAL LONDON OPHTHALMIC HOSPITAL, BLOMFIELD STREET, MOORFIELDS, E.C.—House Surgeon. (*For particulars see Advertisement.*)

SAINT COLUMB MAJOR UNION.—Medical Officer to the First District, in succession to Mr. E. Fulford, resigned. Area, 10,807 acres. Population, 2,457. Salary, £26 5*s*. per annum.

SCARBOROUGH UNION.—Medical Officer to the Scarborough District, in succession to Dr. Megget, resigned. Area, 2,348 acres. Population, 30,246. Salary, £130 per annum.

SEDGEFIELD UNION.—Medical Officers to the Sedgefield and Bishopton Districts and the Workhouse, in succession to Mr. T. Thompson, deceased. Sedgefield—Area, 14,115 acres. Population, 2,811. Salary, £15 per annum. Bishopton—Area, 9,677 acres. Population, 868. Salary, £15 per annum. Salary for Workhouse, £5 per annum.

STAFFORDSHIRE GENERAL INFIRMARY, STAFFORD.—House Surgeon and Secretary. Salary to commence at £100 per annum, with board, lodging and washing. Every candidate must possess a diploma or degree in surgery from the College of Surgeons in London, Edinburgh or Dublin, or from one of the Universities, and a qualification in Medicine which shall entitle to register, and they must produce unexceptional testimonials of moral conduct. Applications, accompanied by diploma or certificates of registrations, with copies of testimonials. to be sent under cover to the Secretary, addressed to the Committee of Selection, on or before July 24th.

STAMFORD UNION.—Medical Officer to the Stamford District, in succession to Mr. J. M. Heward, deceased. Area, 9,671 acres. Population, 10,602. Salary, £65 per annum. Salary for Workhouse, £35 per annum.

THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY ROAD, E.C.—Assistant Physician. (*For particulars see Advertisement.*)

THE GENERAL HOSPITAL, BIRMINGHAM.—Resident Medical Officer. (*For particulars see Advertisement.*)

WOKINGHAM UNION.—Medical Officer to the Wokingham District, in succession to Mr. T. H. Cresswell, resigned. Area, 18,565 acres. Population, 6,471. Salary, £90 per annum.

DEATHS.

ANDREWS, C. A., Brigade-Surgeon, at Bangalore, Madras Presidency, on June 12th.

HEWARD, J. M., M.R.C.S., of Stamford, at Bath, on June 29, aged 54.

IRWIN, AHMUTY, M.D., C.B., Inspector-General of Her Majesty's Hospitals and Fleets, retired, at Southsea, on July 3rd.

WALKER, GEORGE ALFRED, M.R.C.S., L.S.A., at Ynysfaig, near Dolgelly, N. Wales, on July 6th.

NOTES, QUERIES, AND REPLIES.

ON THE TREATMENT OF CHOLERA.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—The man suffering from cholera has been suddenly deprived by diarrhœa of an enormous quantity of the fluid part of his blood. This loss is one of simple transudation, increasing as the powers of life decrease. This *sudden* loss produces intense prostration, and renders the heart powerless to perfect the circulation. The body thus deprived of oxygen, speedily runs into decomposition, even before life is extinct. Have we any agent by which we can collect and press forward these scattered and lethargic drops of blood to the heart, and enable it to renew the circulation, and with it the blessings of oxygen to the body? My reply is emphatically—Yes! Flannel bandages from the toes to the trunk, around the abdomen, and from the fingers to the body, will effect this object perfectly. Remark that the effect is gradual, increasing with every turn of the roller, but would be in full force in about twenty minutes. By thus exposing the blood in the lungs to the action of oxygen in its diluted form, as it is in the air, instead of pure oxygen, the reaction would neither be too rapid nor too dangerous. In confirmation of my views, I have this day learnt that it is the custom in India to wear a double roll of flannel around the abdomen, as a preventive to cholera. The other advantages resulting from the use of the flannel bandages are—(1) That they prevent the escape of heat from the body of the poor creature who is already in a state of refrigeration. (2) By their firmly and equally grasping both flexor and extensor muscles alike, they are steadied, and rendered much less likely to be affected with spasmodic action or cramp. (3) By their steady *elastic* pressure and support of about 160 pounds, they persistently keep up and sustain the circulation of the blood, which they had previously restored. (4) That the oxygen thus well secured to the blood, will, I believe, prove quite sufficient to neutralise the original poison, and also destroy its effects. (5) That this much can at least be claimed for their use, that they remove from nature a stumbling block, which prevented her from exercising her marvelous recuperative powers. Diluted sulphuric acid is the best medicine to arrest the flux from the bowels, acting also as a tonic. It should be given in five minim doses about every half hour, with rice gruel. By adopting this plan, the natural process is brought about, that of the starch being converted into grape sugar. Plenty of white of egg, well whipped up, so as to nourish the body and convey oxygen into the stomach, which it will appropriate, should be given. Opium, in small quantities, and other stimulants should be given according to the necessities of the case. May it not be well, through the medium of wet sponge over the thorax, to apply a continuous but gentle current of galvanism, so as to stimulate the heart's action, keep alive the respiratory movements, and thereby assist in the maintenance of the functions of the body?

I am, Sir, yours &c.,

HY. ARMSTRONG RAWLINS, M.R.C.S.

6, *Sutherland Gardens,*
Maida Vale.

Graves's Disease.—Consult (1) *Dublin Journal of Medical Sciences*, for March and April, 1883. (2) *Ophthalmic Review*, for June, 1884.

Examination for the Membership of the Royal College of Surgeons—Primary Examinations:—The following were the questions on Anatomy and Physiology submitted to the 234 candidates for the diploma of membership of the Royal College of Surgeons on the 27th ultimo, when they were required to answer four, and no more, out of the six questions, viz.:—

Anatomy, from 1 to 3 o'clock.—1. Describe the Elbow-joint. 2. Describe the Dissection necessary to expose the Extensor Brevis Digitorum from its origin to its insertion. 3. Give the Attachments and Nerve-supply of the two Pterygoid Muscles. What structures are in relation with the External Pterygoid? 4. Describe the Dissection required to expose the Middle Third of the back of the Forearm as far as the bones and interosseous membrane. 5. Describe the Cæcum, giving its investments, relations, and blood-supply. 6. Give the course and relations of the first part of the Right Subclavian Artery. Enumerate the Arteries with which its branches anastomose.

Physiology, from 4 to 6 o'clock.—1. Describe one complete cycle of the Heart's action. Give the relations of the sounds and impulse to the several events you name. 2. Give an account of the structure of a small Bronchial Tube. Assign to each of the textures its function, and explain its exact mode of action. 3. Describe the structure of the Mammary Gland. State the facts which tend to prove that milk is a secretion and not the result of filtration. 4. Explain the mechanism of Reflex and of Voluntary Micturition. 5. Describe the structure of a Lymphatic Gland. What is known of its function? Give the facts on which your statements rest. 6. What are the Physical and Chemical changes that accompany the contraction of Striated Muscle?

Pass Examinations.—It is stated that as many as 360 names have been entered for the ensuing pass examinations for the diploma of membership of the Royal College of Surgeons, being the largest number on record.

COMMUNICATIONS RECEIVED—

Dr. W. Hitchman, Liverpool; Dr. Sharkey, London; Dr. Fredk. Taylor, London; Dr. Clifford Allbutt, Leeds; Mr. Geo. Rendle, London; Mr. Lawson Tait, Birmingham; Mr. A. Savory, London; Dr. A. D. Macdonald, Liverpool; The Secretary of the Sanitary Institute of Great Britain, London; The Secretary of St. Thomas's Hospital, London; The Secretary of the Apothecaries' Society, London; Dr. J. Beddoe, Clifton; The Secretary of the National Dental Hospital, London; The Bedell of the Royal College of Surgeons, London; Dr. Pye Smith, London; Dr. F. T. Roberts, London; Mr. J. T. W. NOTES ON THE RADICAL CURE OF HERNIA.

By W. MITCHELL BANKS, F.R.C.S.

Surgeon to the Liverpool Royal Infirmary, and Professor of Anatomy, University College, Liverpool.

(Continued from page 12).

Points in the operation.—Before every operation for femoral or inguinal hernia it is of the greatest importance that the pubes, scrotum, and inner side of the thighs should be shaved, and carefully disinfected by repeated washings with carbolized water. Unless this is done thoroughly, any attempt at carrying out antiseptics, properly so-called, must end in failure. During the process of cutting down upon the sac, the very minutest vessels should be tied, and this should be most carefully done during the whole operation, so that, when the sac comes to be opened, no blood may flow into the peritonæal cavity. The great mistake in one's first operations is in thinking that the sac has been reached long before it has. In this way two or three extensive strippings are often made, and then, after all, another layer or two are found. By these strippings the cellular tissue is torn up, as a result of which troublesome sloughing and suppuration are apt to occur. At its lowest part the sac is always more or less adherent to the tunica vaginalis in inguinal hernia, and at that point requires very careful separation, otherwise the tunica and its contained testicle are apt to be pulled bodily out of the scrotum. No very serious harm results from this, even when it does happen, but it tends to that tearing up of the scrotal tissues which has just been deprecated. As regards the structures of the cord, the only one about which there need be any anxiety is the vas deferens. Very early on in the process of clearing the sac it ought to be found, and kept carefully in view during the whole operation. As for injury to the vessels or other constituents of the cord, this does not seem to affect the testicle at all. In the case of congenital inguinal herniæ, there is always much more difficulty in separating the cord than in any other form, and in young children, in whom the peritonæal tube is very thin, it is most difficult. In congenital herniæ it is necessary to divide the tube a little way above the testicle, so as to make a tunica vaginalis, which ought to be stitched up with fine catgut. The rest of the tube is then stripped up to the ring, and tied and cut off in the usual manner.

The treatment of omentum contained in the sac.—When the sac has been dissected out, and the contained bowel pushed up into the abdomen, there is often a strong temptation to ligature it at once without opening it. I do not consider this a prudent thing. I think the sac should always be opened and examined, because, although one may feel absolutely certain that no bowel remains, there is often a very thin slip or tag end of flattened omentum lying just outside the

ring, and adherent around the neck of the sac. Now if this be cut across with the sac, its inner end still remains attached to the abdominal wall opposite the internal inguinal aperture and acts as a pioneer for more omentum and for bowel to come down. Concerning the removal of omentum, whether adherent or not, not the slightest dread need be entertained of cutting away any amount of it. Recollecting what a source of anxiety a bit of omentum used to be, and how one was always warned against meddling with it if possible, I cannot but regard with astonishment the way in which one in the present day cuts away pouches of peritonæum and sweeps off huge masses of omentum apparently with impunity. Now that I look back upon it, this dread of omentum was without doubt the reason why many cases of operation for strangulated herniæ proved fatal. For instance, the sac being laid open, bowel and a piece of adherent omentum were found. The stricture was freely divided, and the bowel returned. Then the omentum, if adherent, was left lying in the sac, unless, indeed, it were so gangrenous that its removal was obviously imperative, and even then it was cut away with fear and trembling. Septic suppuration having taken place in the superficial tissues, spread to the sac, crept up along the omentum to the peritonæal cavity, and so caused death from putrid absorption.

One great comfort about large masses of omentum is that, however big they may be, they are always tolerably narrow at the neck of the sac, if they have been down for any length of time. It is quite satisfactory to find how, after two or three ligatures have been tried, a great bulk of fat can be cut away, only requiring that a comparatively small stump need be replaced in the abdominal cavity. Small pieces can of course be removed by one catgut ligature, but large masses must be split up into half-a-dozen portions if necessary, and these tied separately either with thick catgut, or, when hard and dense, with carbolized silk. I have removed many pieces as large as the fist, one three-quarters of a pound in weight, another a pound and a half, and another two pounds all but three ounces. The solitary point of danger is the bleeding. The amount of omentum removed and the number of ligatures put on seems of no consequence, but at any sacrifice of time and patience every possibility of hæmorrhage must be securely provided against before the stump is returned. In separating adherent omentum from the body of the sac, bleeding may be disregarded, provided no blood is allowed to run up into the peritonæal cavity. But at the neck of the sac, where adhesions are very prone to occur, the greatest care in separation should be exercised. It is most important that the adhesions at this part should, if possible, be broken down, as, if this is not done, the omentum stump remains fixed to the abdominal wall at the inner opening of the ring or even in the canal, and so remains as a persistent guide for something more to come down in its track. The omentum stump should be cut quite adrift from the abdominal wall, and when pushed up should tumble loose into the abdominal cavity. As far as I can see it does not matter how tight the ligatures are tied, the tighter the better. Only the omentum should not be cut off too close to the ligature, lest it slip. A good large stump should be left for safety's sake. In splitting the omentum up to allow of several ligatures being put on, too great care can hardly be exercised not to split up a big omental vein. These veins are excessively thin, and a very little pressure empties them. An empty one can be quite easily torn longitudinally, and then, as one side goes to each tied-up pedicle, it is kept permanently open, and when the stump is returned, and all pressure taken off, it bleeds furiously. This very accident once happened to me, and gave me a very great fright. The patient, Edward Haucox, aged 41, was admitted with a strangulated inguinal hernia, upon which I proceeded to operate. Having dissected out the sac, I opened it, divided the stricture, and reduced the gut. There remained a considerable mass of adherent omentum, which I split into three pieces with my fingers, and having tied each piece with catgut, I cut off the mass, and restored the stump into the abdomen. No sooner was this done than venous blood began to pour out of the external ring. Thinking my incision for dividing the stricture had cut some abnormal vessel, I slit up the neck of the sac and the external ring, and saw the nick I had made, from which no blood was coming. The bleeding evidently came from the abdominal cavity, as was shown by the fact that when a coil of bowel came down and plugged up the inguinal ring it stopped, but the minute this coil was pushed up by the finger the blood gushed out again. It was clear that the bleeding could only come from the stump of the omentum, which had been returned into the abdominal cavity, and that this must be found at all hazards. So I ripped up the inguinal canal, and then the abdominal wall along the outer edge of the rectus for a good way, but the omentum would not come in sight, so the ripping was continued to a point higher than the navel. By this time nearly all the bowels were rolling about the table or over the man's abdomen. At last the omental stump was found within an inch of the transverse colon, and from it blood was issuing, although the great gushing had stopped. I was in too great a hurry to note exactly what had happened, but put two catgut ligatures around the omental stump, and at once proceeded to replace the bowels; a task which took all hands to accomplish, as they slipped about like water. The peritonæum was stitched together with five catgut sutures; after that fourteen silver wire stitches were employed to unite the muscles, and then the skin was sewn up. Finally the sac was cut off and tied, and the ring pillars were brought together with a couple of wire sutures. Once or twice during the operation the patient seemed at death's door from shock and hæmorrhage, but by keeping his head low, and injecting him with ether, he was kept going. Fortunately he made a most excellent recovery, with only a couple of degrees rise in temperature during the first three days. He works as a painter and wears an abdominal belt to support the great line of incision, but no truss, as no hernia comes down. A case of this sort naturally gave one great anxiety for the moment, and I have ever since been scrupulously careful both in splitting up omentum, and in tying it afterwards.

Removing the sac and stitching the ring pillars.—The sac having been thoroughly separated and opened, and its contents having been disposed of, it should be well pulled down and tied as high up as possible, whether at the femoral or at the inguinal apertures. The great object of the whole proceeding is to restore a uniform surface to the peritonæal wall, and hence the higher up the sac is tied, the better is the chance of this being permanent. When this operation was first undertaken the theoretical critic at once started the objection that as the peritonæum was an eminently elastic membrane, you might take away the sac as cleanly as it was possible to do, but the distensile membrane would be immediately pushed out into another sac opposite the weak aperture. As a matter of fact this is not so, but, apart from that, the reasoning was not quite correct. The movement of the bowels over the front of the abdominal wall is, so to speak, a liquid movement. It is the searching sweep of a great wave slowly rushing up the face of a breakwater. If the breakwater can only preserve a smooth surface, with every joint well cemented, then it will stand, although there may be more than one weak place in its backing. But the moment the surface gives way at any point, there the water persistently presses in and in till the stones

around are undermined and a breach is made. Clearly, then, however we may strengthen our bulwark behind by stitching up the ring and applying a truss, the first thing to do is to keep its water surface—its peritonæal surface—free from any inviting pouch or depression. Indeed, in the case of femoral, umbilical or ventral ruptures this is all we can do.

Turning next to the pillars of the ring I employ two, three, or four silver wire suturcs to pull them together, inserted with a curved needle in a handle. Room must, of course, be left at the lower part of the ring for the spermatic cord to pass through. The wire should be thick ; so thick that a single knot on it will suffice to make it hold without any second knot or without twisting. Then it should be cut very close to the knot, so as to leave no sharp projecting ends. In the few instances where I have seen a wire suture work its way out, this point had not been attended to, and its sharp ends had irritated the tissues till they ejected it. With the ends cut close off, it is simply a minute circle of silver ; than which there is nothing less irritating. I adhere to the silver suture and strongly recommend its use for the one reason that its hold is certain and enduring beyond that of any other suture, while it is as harmless as any. Of course the theorist, who wants to use the latest novelty in sutures, has his cut and dried objections to the somewhat old-fashioned wire. It *must* be clumsy and cumbersome ; and it *must* come out ; and it *must* do this and the other. The simple answer is, it doesn't. It quietly embeds itself and is no more seen except in the rarest instances, where a great deal of suppuration has taken place. In the case of the man who had hæmorrhage from the omentum, recently narrated, some sixteen silver sutures were put in, and we never saw any of them again. Of course every surgeon may use what suture he pleases ; all that I object to is that persons should evolve out of the depths of their own consciousness arguments against the wire suture, when they have never tried it and don't know anything about it. Personally, I have tried all sorts and have decided upon the silver wire as the best.

When an inguinal hernia is not very large the approximation of the ring pillars is quite easy. But in the case of great ruptures all the parts about the ring and canal are widely separated and displaced. In such cases I always feel very carefully about with the forefinger of the left hand for the epigastric artery before thrusting the needle through the tissues. On one occasion I did discover it, and it was just where I was about to push in the needle. It would almost certainly have been pierced, a circumstance which might have given risc to not a little trouble and delay.

Descent of large intestine in inguinal hernia.—The discovery of a piece of large intestine in an inguinal sac is one of the most troublesome conditions I know. I scarcely think it can be of frequent occurrence. At any rate I have only seen it twice in my own practice. The following instance will show what occurs. The patient was an extremely big fat man, 32 years of age. who had had a left inguinal hernia in progress for several years. No truss had the slightest command over it, and it was becoming a serious hindrance to him in his work. As he lay in bed the tumour was about the size of a very big cocoa-nut. It was evidently composed mainly of omentum, but there was a considerable amount of bowel also. Steady squeezing reduced some of the bowel, but not all. He was kept for a fortnight on his back with the pelvis elevated on pillows, and a bag with about four pounds of small shot over the tumour. This certainly lessened it somewhat, but only, I suspect, by draining it of its blood and fluids generally. Accordingly an operation was agreed to. I cleared the whole of the front of the sac, which was of great size. It happened to be an extremely thin one, and in doing this I made two holes in it, out of which omentum tumbled in such quantities that I thought it best to get quit of it at once before further clearing the sac. The omentum formed a great mass, and had to be tied off in several portions with carbolized silk ; weighing two pounds all but three ounces when removed. The sac was now quite empty, but it was evident that behind it was something thick and soft, to the front of which it was adherent. A little further clearing up showed that this was a piece of large gut, probably sigmoid flexure, extending down about three inches below the outer ring. The sac formed its peritonæal covering in front, but posteriorly it had none, and when it was gently detached from neighbouring parts its muscular fibres could be quite clearly seen. On the first occasion, when a condition of a similar sort occurred to me, I thought I had adherent bowel to deal with, and laboriously worked away for a long time stripping off the peritonæum till I discovered my mistake. This time, fortified by experience, I simply loosened the free posterior surface of the bowel, and, with my finger, freed the sac round the outer inguinal orifice. Then I carefully stitched up the holes in the sac with catgut, and finally by steady pressure pushed bowel and sac up into the abdomen. Then the pillars were brought together, which was a work of some trouble, as the hole was so big that the outer one practically did not exist, so I pulled the inner one down to Poupart's ligament just in front of the femoral vessels. The case was only done a few weeks ago, but, as soon as the man can bear it, he will be fitted with a powerful truss which will almost certainly enable him to get about his work in comfort, whereas his former condition did not offer the faintest prospect of relief by support, but must have steadily continued more and more to disable him.

In such cases the one point is to be able to recognise early that it is great gut that is down—bare behind but having the sac coating it in front—and not to begin stripping it of peritonæum, under the impression that one is dealing with inflammatory adhesions, but to sew up the sac and push it and the bowel bodily into the abdomen.

Ventral and umbilical hernia.—The management of these forms of rupture I have found the most difficult of all. Seeing that those of them which require radical cure are invariably of large size and old standing, it happens that by long continued pressure the skin is usually adherent to the sac. Sometimes, even, there has been ulceration, and then the sac is covered only by cicatricial tissue. They almost always contain omentum, which becomes intensely adherent to the sac, and gets kneaded and worked up into hard, knotty masses with fibrous cords between them, and even small spaces, until the whole resembles a fibro-cystic tumour with pieces of fat scattered throughout it. It is most troublesome to clear away. Then the abdominal aperture is always of great size, and its margins are so thinned and fibrous in character, that any attempt at paring its edges, and pulling them together is hardly practicable except in a few instances. I have been obliged to content myself with removing the sac as close to the aperture as possible, and then carrying away all superfluous lax skin, so as to tighten up the abdominal wall as much as possible. An abdominal support must invariably be worn afterwards. The first case I did strongly impressed me with the necessity of this. The patient was a young powerful married woman, 25 years of age. She had a ventral hernia of large size which gave her great trouble. I operated upon it, and when she left the hospital everything seemed excellent ; no tumour, and no impulse on coughing. She came back a month or two afterwards, and things were quite satisfactory. She was warned to wear a support and said she would. Then I lost sight of her for two years, but found her out again. She had taken to drunken

ways, had never got any support, as she was told to do, and had neglected everything; so that her hernia had come back and was as big or even bigger than before. As an example of a very bad case I may cite one upon which I operated some two or three months ago. The patient was a stout healthy married woman of 35. Just below the navel were two large tumours. They were not unlike two great, elongated mammæ, diverging below, but united above, where they seemed to run into each other at a common neck. They both obviously contained bowel, and the left one omentum also. On straining in the erect position they became fuller and tenser, while in the recumbent position a certain amount of their contents could be returned, but not much. The great bulk was irreducible. The left one had given the patient a great deal of suffering for years, owing to constant ulceration of the skin covering it, so that there was hardly a bit of real skin on it: nothing but cicatricial tissue. There was in progress an ulceration about the size of a penny. The patient's life was rendered very wretched by this condition of things, and she was willing to encounter any reasonable risk for its cure. I attacked the left tumour and with the greatest care made a superficial incision over it. It was fortunate one did not go very deep, for it soon became apparent that over the most prominent parts of the tumour, where friction and ulceration had been greatest, the bowel was covered only by cicatricial tissue closely adherent to it; not even the sac could be distinguished. The bowel was transverse colon. Then ensued a most difficult and tedious job, that of separating this adherent cicatricial covering from the gut, so that it might be returned into the abdomen, It took nearly an hour to do it, and eventually at one spot I went clean into the bowel and made a hole in it which would admit the little finger. I turned its edges inwards and stitched it carefully up with catgut. By patient work the bowel was at last freed and pushed into the abdomen, an antiseptic pad being placed over the hole to keep the bowels in and the blood out. Then the omentum was pulled away from the sac, divided into sundry pieces, and tied as deep down as possible in the aperture. Having finished the left tumour I turned to the right one, but fortunately it turned out a much easier matter to manage than its fellow. It contained small gut, which was only slightly adherent, and was easily separated and reduced. Curiously enough, although there were two tumours, they both came out of one large aperture. Some fibrous bands had given a bias to the great intestine and omentum in one direction, and to the small intestine in another, and so they had formed separate sacs for themselves, having a common neck. This thickened neck I first stitched through and through from side to side, as close to the hole as possible, and then, shearing it away, stitched it again over the cut edges. I did so, because thorough union and adhesion of the neck of the sac were imperative, seeing that the hole was so big that it was with difficulty that the bowels were kept in by the hand during the operation. A violent fit of coughing or retching afterwards would have sent everything flying, unless this had been obtained. Finally a great piece of skin was swept away, which had covered the two tumours, leaving only one long transverse line across the abdomen, along which the skin was tightly braced up to give additional support. The patient suffered a good deal from shock as the operation took nearly two hours to do, and was most troublesome in its details. She had nothing but ice and opium for some days, lest the hole in the bowel, which we had stitched up, should give way. She made an excellent recovery, however, and is now going to be fitted with an abdominal support which will keep her in comfort.

Inguinal hernia with undescended testicle.—In those cases where the radical cure is undertaken for hernia coming down behind an undescended testicle, the latter ought always to be removed. Such a testicle may almost always be considered to be practically a useless organ. It will neither go up nor down, and remains just outside the ring, effectually preventing the efficient action of a truss. I have done this in two cases, and as the removal of testicle and cord leaves nothing to come through the ring and so keep it patent, a really perfect cure, without the necessity of wearing a truss, may be expected in such cases. The two patients upon whom I performed this operation, were both young sailors, and their testimony was almost identical. They each had an undescended testicle lying in the ring; they each fell a distance of some feet, giving themselves a considerable shock, and in each instance the testicle bolted down, followed by a knuckle of intestine. Great pain with symptoms of shock and strangulation followed. The bowel being reduced, the sac, testicle and cord were removed as far up as possible, and the pillars drawn together in all their extent. I saw both men more than three years after the operations. One was working as a fireman on board a steamer, and the other was a quarter-master; both most laborious occupations. They wore no trusses and had not a trace of impulse on coughing, the rings feeling as firm as any other part of the abdomen.

After treatment.—As regards dressing, I always use a perfectly new sponge, wrung out of carbolic solution. Its elastic pressure is most efficacious at once in holding the disrupted parts together, and in resisting the shock of straining from subsequent coughing or sickness. In spite of all antiseptics the cellular tissue of the scrotum and cord often suppurates pretty freely. After the second day or so, when one is pretty sure that the neck of the sac where ligatured is firmly adherent and closed, if suppuration should take place, the more complicated dressings may be left off, a few stitches taken out, the wound well syringed and dusted with iodoform, and then left to granulate up like any other wound.

The application of the radical cure to cases of strangulated hernia.—As regards the application of the radical cure to cases of strangulated hernia it is certain that in due time it will come to be considered a necessary part of the operation, wherever sufficient help is obtainable. But there is no doubt that in the case of a large inguinal or umbilical hernia the stripping of the sac and all the subsequent details of the radical cure involve a great amount of operative work, as compared with the simple process of opening the sac and returning the gut. Many a country surgeon does herniotomy over and over again during the middle of the night, with a single assistant, perhaps, and with the light of a couple of candles. Under such circumstances it cannot be expected that he should undertake an elaborate operation. But in hospital practice, or where there is plenty of assistance, the radical cure should always be undertaken, because, in addition to preventing further descent of the bowel, it renders herniotomy infinitely less dangerous. The old idea used to be that patients died from general peritonitis after herniotomy, chiefly on account of meddling with the peritonæum. This was a mistake. Peritonitis, pure and simple, is probably not a dangerous affair, as one may constantly observe in uterine affections, where the pelvic peritonæum is repeatedly inflamed, without any necessarily disastrous consequences. Moreover, the old bogey—the dreadful danger of even scratching the peritonæum—is defunct. It seems to be a very harmless membrane and will stand all sorts of rough treatment, provided you don't put poison into it. But to that it is amazingly sensitive, and sucks it up as sand does water. I have seen a good many autopsies after herniotomy, and my general impression is that in nearly all of them the external wound was dirty and often sloughy, that sanious pus had crept up the sac, that the peritonæum for some

way round the inner ring was covered with flaky lymph, that the strangulated piece of bowel and some neighbouring coils were also inflamed, and often glued by soft adhesions round the ring, and that, perhaps, an injected condition, or some peritonitic lymph might be found over some coils of small gut elsewhere. But that is not enough *inflammatory* mischief to kill a man. No, it is not the peritonitis but the septic absorption that kills. Many years ago, long before the radical cure was put in practice, I was convinced of this, and after reducing bowel and omentum, used to wash out the sac thoroughly, and then carefully stitch up the opening in it, so as to shut off the abdominal cavity. If, then, in a case of strangulated hernia the bowel is thoroughly wiped and cleansed, if no blood is allowed to run up into the abdomen, and if the sac is tied off, then the peritonæal cavity is securely closed against the entrance of all infection from without and the chiefest source of danger at once removed. To add to the safety of this proceeding the incision made to relieve the stricture should be of the smallest dimensions, and, in very many instances, none need be made at all. By a little patient boring with the forefinger, a large number of strictures will yield to dilatation. They are often only of the flimsiest nature, although from their situation quite sufficient to prevent all attempts at manual reduction.

As regards the fatalities which have occurred in the 26 cases of strangulated hernia upon which the radical cure has been performed, they are, of course, of no use whatever in determining the danger to life of the radical cure *per se*. But they are distinctly of service in showing whether the addition of the radical cure to the ordinary operation for strangulated hernia has rendered that operation more dangerous or more safe. Out of the 26 cases there have been 3 deaths, or as nearly as possible 1 death in every 9 cases. This I imagine is a very good average, especially as there were some extremely bad cases among them. In 12 out of the 26 cases omentum had to be removed, the masses in some instances running from half-a-pound to a pound in weight. One was a case where eight inches of bowel were removed ; another was the case of bleeding from the omental stump, mentioned in the paper, where the abdominal wall had to be slit up. In one patient the hernia had been reduced *en masse* twenty-four hours after its first appearance, but, being believed to be safely returned, it was only the continued persistence of marked symptoms of strangulation which caused the patient's removal to the infirmary a week from the time the bowel was first nipped. In another the sac contained bloody serum along with nine inches of gut of a very dark claret colour, covered with lymph and with extravasations of blood beneath its peritonæum ; so bad, indeed, that returning it into the abdomen seemed a very risky proceeding. Of the patients who died, one was an old, worn-out bronchitic man of 77, who succumbed a week after the operation, more from bronchitis than anything else. Another was a woman over 70 with a large umbilical hernia, involving the removal of a great deal of omentum ; and the third was a gentleman over 60, with a very weak heart. At the time of life of these patients any surgical proceedings, even the smallest, might kill, far less such a serious matter as a strangulated hernia followed by operation. In none of the three did the general symptoms point to septic poisoning.

The fatal case, among the 36 instances of uncomplicated radical cure, occurred in a male child of two years and two months. He had a congenital inguinal hernia, which, at the time of birth, was as big as an egg. It had increased to about twice that size. About six months before his admission he had for some reason been tapped, which, I suspect, made matters worse, and helped to produce the adhesions subsequently found. He had been in a hospital for ten weeks, where every effort had been made to get a truss to act, but in vain. The hernia seemed to consist of bowel alone, but was absolutely irreducible, so that no truss could possibly be worn. At the operation there was found small intestine adherent firmly to the sac, and also great intestine, which looked like a piece of ascending colon. Great difficulty was found in separating the small intestine, and many points on its surface bled so sharply that they had to be tied with fine catgut. As for the great intestine, I did not in this case quite recognise the relation of it to other parts, and attempted to strip it of peritonæum when I ought to have left it alone. The operation took a very long time, and the child never got over the shock. It lay in a kind of stupor, moaning at intervals, and died about thirty hours afterwards. After death a piece of the small gut was found, with the ligatures on it, congested and with bright spots of ecchymosis on it. For about two inches the peritonæum had been stripped from the ascending colon and the exposed surface was covered with flaky lymph. There was no general peritonitis. About a teaspoonful of pus was found beneath the skin of the scrotum. To operate on this child was really a necessity, as the hernia, which was quite irreducible through adhesions and quite incapable of support, would have certainly rendered him practically useless in after life. But this was only small consolation. The number of cases reported in England is as yet too limited to form any just judgment of what the mortality from the radical cure is likely to be, and can only be satisfactorily determined by individual men publishing their own complete lists of cases, whose number shall be sufficient to give the necessary average : just as was done by Spencer Wells, and Keith with ovariotomy. To try to get any average from isolated cases reported in the journals is of no use. I have known many a surgeon publish a couple of successful ones, and after that, meeting with a fatal one, the "*subsequent proceedings interested him no more.*" As I have never yet operated unless there was a very clear call for curative measures, the result has been that most of the operations have been by no means trifling, and in not a few instances very serious in character. I have, therefore, no hesitation in detailing my failure, seeing that one death in 36 cases, occurring during the period when one is getting one's knowledge and experience, is not such a serious matter. It is to be hoped that in future a death will be much rarer still, but that the operation will ever be pronounced free from danger cannot reasonably be expected.

In conclusion, I must once more apologize if I have appeared at all egotistical in the observations just made, seeing that it is almost impossible for anyone to write the history of his own experiences, and what they have taught him, without laying himself open to that imputation. I do not consider that my views are by any means final, but trust that every year will add to our power of perfecting a valuable piece of surgery.

SOME OBSERVATIONS ON ENDEMIC FEVERS IN INDIA.

By Surgeon J. PEDLOW, M.D.
Army Medical Department.

The Croonian lectures on the climate and fevers of India, by Sir Joseph Fayrer, and the reports on enteric fever in India, published in the Departmental Blue Books, have again directed attention (more particularly that of medical officers serving in the country with British troops) to many unsettled points connected with their ætiology and pathology. For some years past there has been a growing tendency to consider all

*

Indian fevers with symptoms of congestion or ulceration of Peyer's patches or solitary glands as enteric, without reference to origin, and despite very great irregularity in their symptoms, while the older authorities looked upon these lesions, in the majority of cases, as in no way specific but merely the result of the visceral congestion so commonly seen in severe cases of endemic fever.

The gradual reduction in official returns of the number of cases of climatic fever of a continued type is due more to the definition of enteric fever given in the "Nomenclature of Diseases," published by the College of Physicians, than to the disappearance from British cantonments in India of the endemic influences which produce them. Enteric fever is there defined as "a continued fever, characterised by the presence of rose-coloured spots chiefly on the abdomen and a tendency to diarrhœa with specific lesion of the bowels." These true rose-coloured spots are only exceptionally met with in the Indian type, and diarrhœa occurs in scarcely three-fourths of the cases. In many cases the temperature has frequent remissions during the course of the fever, often falling to normal, yet, when a morbid condition of these intestinal glands is suspected, it is necessary, in the absence of any allusion in the Nomenclature to the existence of any such lesion in remittent fever, to look upon such a condition as the anatomical expression of a pythogenic disease and to consider the case one of enteric fever. It is difficult to account for the stress which has been laid upon these lesions in the small intestine as characteristic alone of enteric fever. They are constantly met with in chronic dysentery, cholera, and hepatitis. Some years ago Dr. Gordon, late Surgeon-General, Madras, in his report on enteric fever in that Presidency, pointed out that the symptoms of a protracted attack of cholera, and the intestinal lesions found after death, were indistinguishable from those of the former affection. Moorehead, also, in his work on Indian diseases, when describing the pathology of dysentery and cholera, goes minutely into the changes which inflammatory action produces in the solitary glands of the ileum and in Peyer's patches. Taking a wider practical view than that now more commonly accepted in India, he was of opinion that any active or passive congestion of bowel, whatever the cause, would produce a similar congestion in its glands, with structural lesions or ulcerations if severe or protracted. It occurs, he states, in a transient form in simple ague and probably also in diarrhœa. He also gives details of severe remittents, in which these lesions were well marked. Coming to more recent authorities, Aitken states, under the head of remittent fever, that in young and robust men, recently arrived in India, there is often a tendency to a considerable amount of vascular excitement with marked symptoms of determination of blood, either to the head or to the abdominal viscera, at a very early stage in the fever. The pathological sequence of this determination of blood to the ileum would be, I think, as Moorehead states, ulceration. Fayrer also quotes numerous authorities, to the effect that tropical continued fever, not pythogenic in origin, may have the characteristic lesions of the home type. In notorious fever haunts, such as moist jungle grounds at the foot of hills, localities far away from the populous districts where enteric fever is supposed to abound, severe remittents are often met with at certain periods of the year. In these cases cerebral and visceral complications occur at an early period of the disease. To consider them cases of enteric fever and subsequently justify the diagnosis by an appeal to the condition of the intestinal glands, would be without a precedent as the nature of these fevers is known. Yet in cantonments we rely upon that very condition as a proof that the case is enteric.

In young soldiers dying from continued fevers in cantonments in India, no doubt these lesions are as a rule demonstrated, but in soldiers of some years' service, in whom the symptoms point to the same disease, they are frequently absent. On the other hand, they have often been met with in rapidly fatal cases of severe fever in which such a condition was not suspected. In three cases considered enteric, I found the spleen and the mucous membrane of the small intestine much congested, while Peyer's patches were atrophied and without evidence of recent change. In a second class of cases, with similar symptoms, the intestinal lesions varied from slight to severe congestion of these patches with congestion of the mucous membrane. In a number of cases, some with and some without ulceration, the cerebral symptoms were the most prominent feature throughout. In one exceptional case, in a patient aged 33, which ended fatally on the fifteenth day, the only lesions I found were an inflamed liver and congested kidneys. In this case there was high fever throughout, and constipation followed by diarrhœa with stools supposed to be characteristic of enteric fever. In a second case which ended fatally on the third day of illness, I found the spleen much congested and Peyer's patches enlarged and surrounded with a bright zone of inflamed mucous membrane as large as a penny. The mucous membrane also of the lower portion of the ileum was much congested and thickened, but without breach of substance. The membranes of the brain were inflamed, much serum was effused and the frontal convolutions were covered with a thick coating of recently exuded semi-consistent lymph. On admission the patient was very delirious with a temperature of 101·2°, from this he passed into a state of coma, with a temperature of 105°, and died in that condition 36 hours after being brought to hospital. Many of these cases, in which the lesions varied, differed considerably from each other during life, but anyone studying a consecutive series of them in the same station would be led to the conclusion that they had a common climatic origin and were different types of the same disease. When we consider the inflammatory nature of this class of fevers it is hard to see why so much diagnostic significance should be attached to the minute changes in these glands which result from that condition. If they become atrophied, as probably occurred in many of my cases, the spleen, liver, and, probably, the meninges of the brain would point to the real character of the fever.

When we come to consider mild types of Indian fever, this specific ulceration becomes a real stumbling block, and it is consequently very difficult to define where so-called simple continued fever ends, and so-called enteric commences. During the prevalence of the latter, we constantly meet with numerous cases of this simple continued fever, in which, as a rule, the fever period does not extend beyond eight or ten days, often in febricula less. In these cases there is as a rule a high evening temperature with partial morning remissions, and frequently the condition of the tongue and the bowels indicates intestinal irritation, probably some congestion. Often there is obstinate constipation and pain in the bowels, at other times there is bilious diarrhœa, which passes off in three or four days. That they are mild cases of endemic fever due to the operation of the same causes which produce the more severe form with visceral lesions hardly admits of a doubt. Imperceptibly they pass into it, and no sharply-defined line can be drawn between them. In some of these cases, as will be seen, after there were no good grounds for suspecting the existence of enteric complications, when the patients were convalescing, some unknown cause brought about a relapse, and a well-marked attack of a more severe type with visceral lesions followed. In other cases, almost similar as regards the original attack, convalescence was uninterrupted.

With regard to remittent fevers also there is the same difficulty. They too have frequent relapses, and if in the relapse there is evidence of bowel mischief, they come under the head of enteric fever. A fatal case of this affection in British soldiers is consequently now uncommon, compared with what was formerly the case.

The varying mortality in different outbreaks of continued fevers, and even in different corps serving at the same time in the same station, is often a common cause of perplexity, both as regards diagnosis and treatment. In the soldier of four or five years Indian service admitted to hospital with fever there is, owing probably to the atrophic condition of the intestinal closed glands, a marked falling off in the tendency to the severe enteric complications, which show themselves in the case of his younger comrade probably lying beside him. Consequently, in a regiment with a larger proportion of soldiers having the longer service, the mortality will be smaller, though the fever from which both suffer may be returned enteric. There is no doubt that the increase in the functional activity of the liver, which is a common cause of diarrhœa in new arrivals, is also shared by these glands, especially in the young adult.

In the Madras Presidency 54 cases out of 175 proved fatal; a mortality of over 32 per cent., as against about 18 per cent. at home (Gordon). This very high mortality is due, in a considerable proportion of cases, to the early supervention of acute meningeal inflammation. Now Moorehead, in his description of remittent fever, attributes a fatal result in fully one-third of his cases to cerebral complications of this nature, and he states that the proportion of deaths from this cause is still greater in the remittent fevers of sthenic Europeans. On analysing my own cases during the past five years, I find that out of a total of 24 fatal ones, death at an early period was to a great extent due to cerebral mischief. In two of these, death took place on the tenth day of estimated illness, and in the others on the third, fifth, seventh, and fourteenth days. On looking into the details of the *post-mortem* examinations in such cases, the intestinal lesions were found to vary from slight congestion to severe ulceration of Peyer's patches. The liver, kidneys, and spleen were often all congested, and the membranes of the brain much inflamed, and large quantities of serum were effused. Lymph in some places was found lying in a thin layer over the convolutions. Now Jenner describes this complication as an infinitely rare one in enteric fever, yet in India for nearly half a century it was looked upon as a very characteristic lesion in severe remittents.

This and other deviations from the home type of enteric fever are so common in continued fevers in India, that an analysis of a series of consecutive cases of febricula, simple continued, remittent, and enteric fever, all met with by me in the 1st Battalion, Oxfordshire Light Infantry during a period of nearly two years, may not be devoid of interest, as showing how difficult it is to draw sharply-defined lines between them, even when they occur at the same time.

During this period, from January 1882 to the present time, the regiment in question has been quartered in Bangalore, Madras Presidency. Its strength for the year 1882 was 854, of which 451 were 26 years of age and upwards; 392, between 20 and 26; and the remaining eleven, under 20. For the year 1883 its strength at the beginning of November was 896, of which 483 were 24 years of age and upwards; 400, over 20 and under 24; and the remainder under 20. In this year over 400 men were 26 years of age and upwards.

A draft joined the regiment on the 14th November, 1883. Its strength was 197, and the average age about 22, but up to the present none of them have been attacked with any form of fever. As a rule, fevers are absent at this time of year in Bangalore, and the health of British troops is good.

The actual age and the numbers of those attacked with the different forms of fever in both years are shown in the following table:—

	Enteric Fever.		Remittent Fever.		Simple continued Fever.		Febricular.	
	No. of Cases.	Age.	No. of Cases.	Age.	No. of Cases.	Age.	No. of Cases.	Age.
	1	14	2	20	2	21	1	16
	1	19	3	21	1	22	2	19
	4	20	3	22	4	23	2	20
	7	21	1	23	2	27	2	21
	11	22	2	24			6	22
	3	23	3	25			2	23
	2	24	2	26			2	24
	2	25	2	27			1	25
	1	26	1	28			1	28
	1	27					1	30
	1	28					1	33
							1	36
Totals	34		19		9		22	

It will thus be seen from this table that in all these fevers the age of greatest prevalence was from 20 to 25. The cases of enteric above the latter age were ill-defined, and with but slight evidence of intestinal complications. The distribution in each year was as follows:—ten cases returned enteric were admitted in 1882, and twenty-four in 1883; on the other hand, thirteen cases of remittent fever were admitted in 1882, and only six in 1883. There were seven cases of simple continued fever in 1882, and two in 1883. In 1882 there were only three cases of febricula, as against nineteen in 1883. With regard to period of prevalence—from the date of the arrival of the regiment in Bangalore until the 6th March there were no cases of any fever. Between this latter date and the 8th July, the first eight cases of remittent were admitted, and the first six cases of simple continued came in between the 11th March and the 16th April. The first four cases of enteric fever, all of whom died, were admitted between the 26th May and the 18th June. Between the 8th July and the 6th August, there were no admissions for any of these fevers. On this latter date a case of febricula was admitted, and was followed by a second on the 7th, and a third on the 20th. On the 19th of following month a case of remittent was admitted. There was a second in October, and three in November, one of whom died on the fifteenth day. The last case of fever in that year, one of remittent was admitted on the 25th November. In this second period, six cases of enteric were admitted between the 16th October and the 13th November, of which two died. It will thus be seen that the enteric fever period proper was very limited, 24 days in the first outbreak, and 31 days in the second outbreak. Now if these cases of enteric fever are dissociated from all the other fevers occurring in this year, the tendency would be to limit enquiries into causation to these two particular periods. In reality, a minute analysis of the majority of the other cases, if not all, shows that in the absence of many of the characteristics of the home type of enteric, the diagnosis was a matter of difficulty, and consequently they were returned simple continued fever, febricula, or remittent, though many points indicated their common origin and relation to each other. There were no cases of any continued fever in December.

(*To be continued.*)

University of Aberdeen.—Mr. J. A. McWilliam, A.M., M.D., London, has been appointed Assessor Examiner in Physiology and Zoology, in room of Dr. Jas. Anderson, London, resigned.

PLASTER OF PARIS IN THE SURGERY OF CHILDREN, AND MR. CHURCHILL'S FIXATION APPARATUS.

By JOHN A. SHAW,
Registrar, late House-surgeon Victoria Hospital for Children, S.W.

It is surprising how common amongst children are cases where treatment aims at either rest to parts, relief, or prevention of deformities. The restlessness and fidgeting of children makes it most difficult to obtain absolute fixation of a broken or deformed limb by means of ordinary splints and bandages. Their limbs and joints are so small and delicate that, no matter how carefully a splint is padded and bandaged, it is as a rule clumsy, and must be applied too tight, if the position is to be kept up or the child prevented from wriggling out of it. It is commonly supposed that the apparatus which is found sufficient to encase the limb of an adult will, with slight modifications, suffice for the limb of an infant, or young child, but this is very far from being found so in practice. The points of application are so limited, and the skin so tender, that it is absolutely necessary to distribute the pressure and encase the parts.

The value of plaster of Paris splints in some shape or form is deserving of more prominent notice, especially as so many cases find their way to the out-patient room, patients who have come long distances from the country, either old consolidated deformities beyond relief, or cases of commencing curvature requiring a jacket, or other deformities requiring a splint or apparatus of some sort.

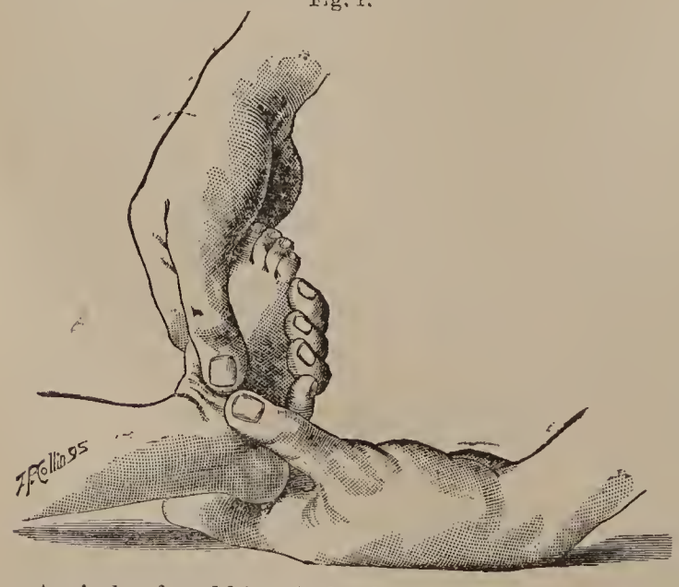
The following are examples of cases which are constantly under treatment at the Victoria Hospital :—

(1) *Talipes Varus.*—In these cases it is difficult to adapt a suitable apparatus. The usual appliances are troublesome and as a rule expensive. The smaller the foot the more unsatisfactory the apparatus, and notwithstanding all efforts, the foot will twist round to its original deformity. Scarpa's shoe, with its many screws and straps causing pressure on localized spots, is an apparatus which cannot be used with advantage in severe cases. The price too is prohibitory for poor people.

Mr. Churchill has simplified matters considerably by introducing an apparatus which he has kindly allowed me to describe.

The foot is first carefully and powerfully manipulated, the ligaments stretched, and the bones moulded as much as possible to the correct position.

Fig. 1.



A circle of webbing is fixed with letter clips round the foot, a strip of thick perforated tin about one inch wide is bent at right angles, the short arm of which goes across the sole of the foot, level with the joint of great toe, and is clipped to the webbing previously applied. The long arm goes more than half way up the leg, and to the end of this arm a piece of string is attached. By pulling the string the foot is levered into a proper position, and is easily kept so by a plaster of Paris bandage applied while the extension is being kept up. The muslin clings to the jagged edges and perforations in the tin, and holds the foot with a firm grip. A flannel bandage must of course be previously applied to the foot, ankle, and leg, and the jagged perforations of the tin cling to the flannel so as to prevent rotation of the limb within the case.

The child may be allowed to walk about with this encasement, after it is properly set. In this way the astragalus and os calcis will be further moulded into the proper position by the weight of the body. Should the plaster of Paris break away, a new case must be applied after carefully moulding the tarsal bones as before.

Talipes Valgus.—In these cases the fixation apparatus is the same, but the tin must be applied to the inner side of foot and leg so as to invert the foot and stretch the peronei and extensor muscles of the leg. The arch of the foot is generally so much collapsed that the child walks upon the inner side, and in addition to the tin, Mr. Churchill generally recommends a sausage-shaped pad, made so firm that the weight of the body will not materially compress it in walking, and this is placed across the sole of the foot, so that the tarsal and metatarsal bones shall be raised gradually into their normal position, and the arch of the foot be restored by centre compression.

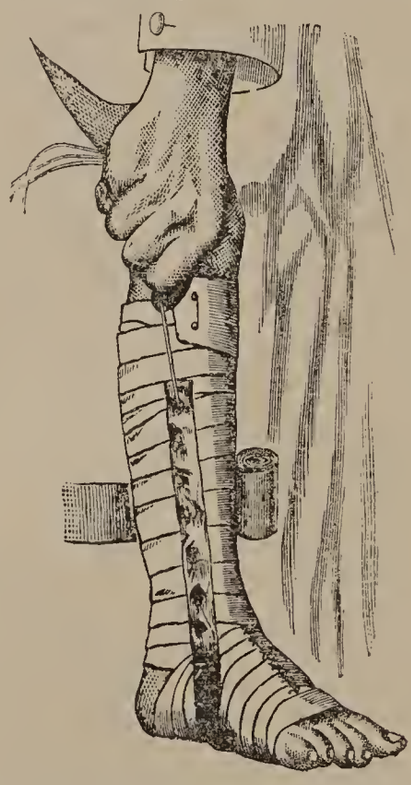


Fig. 2.

In modified cases, where there is simply relaxation of the internal lateral ligament and flat-foot, the sausage pad with a spica bandage of plaster of Paris around the ankle will suffice.

(2) Fractures of femur and tibia, complete and incomplete, and separation of epiphyses, are common with children. The fibula usually escapes.

These can be treated well with a combination of wood or tin splint and plaster of Paris bandage. Venetian blind laths are very useful for this purpose as they may be easily embedded in plaster of Paris without being bulky or projecting unduly from the side. The

perforated tin as above described is also serviceable in all cases where the longitudinal splint is required. This combination of plaster of Paris and splint is most useful, and maintains a most perfect rest and apposition of the broken fragments.

For instance, in fracture of the femur, the usual perinæal band is constantly wetted, loose, and useless; while the long outside splint and bandage cannot be adapted sufficiently tight to ensure the requisite rest and apposition of the fragments. In the double splints and elastic or weight and pulley extension the upper fragment moves with the child, and with every movement there is a cry of pain. Either at once, or, perhaps more safely, after the primary swelling of soft parts has ceased, a flannel bandage is applied from the ankle with spica round hip joint, and then round abdomen to thorax. On this one layer of plaster of Paris bandage is applied to cover all the flannel. Next an outside thin narrow splint from axilla to ankle; a little wool may be applied over the prominent points of pressure, and while extension is kept up another layer or two of plaster of Paris bandage is applied over all. As soon as dry the case may be varnished, which keeps it from being soiled. The child, thus having its pelvis and thigh fixed, may now be moved about without any pain or displacement of parts, and the result is most satisfactory. The plaster of Paris is apt to rub at the fold of the buttock, but a little care will obviate this.

The same method answers well in fractures of the leg. There is little or no displacement when the fibula escapes, which it usually does from its flexibility and protected position.

In fractures round the elbow joint, which are very common, passive movement should be begun early.

(3) *Curvatures of Spine.*—Chiefly angular but also lateral. Sufficient extension can often be obtained by an attendant lifting the young children up by the arms, and raising the chin and occiput in high curvatures, so that the use of the pulleys is avoided.

The jacket should always clip the anterior iliac spines; if sinuses exist, window holes may be cut in the jacket over them.

Jury masts can be easily and cheaply made by a carpenter according to instructions.

A good broad soft pad sewn to vest, and hanging down from nape of neck, completely counteracts the pressure and pain of the upright bar and curve of jury mast. The usual costly leather straps to raise and sling the head are irksome and painful. The ordinary calico roller bandage may be used instead; one strip goes from one hook of the cross-piece, under the chin to the other hook. Another piece in the same way under the occiput, and these are connected and sewn together by a small transverse piece below the ears. The comfort and simplicity are evident.

(4) *Rickets.*—To prevent further deformity and bending of lower limbs, either plaster of Paris alone or with outside and inside wooden splints, as previously described, and projecting below feet.

(5) *Osteotomies for Genu Valgum.*—Antiseptic dressings, put up at once in salicylic wool and a case of plaster of Paris.

(6) *Excision of Knee.*—A posterior narrow splint of metal, kept in place by a clip of plaster of Paris above and below the joint. The metal clip is curved posteriorly and antiseptic treatment readily applied to incision.

(7) *Diseases of Joints.*—(*a*) In early stages of hip joint, and later after excision, when the wound is consolidated, a spica of plaster of Paris.

(*b*) In fixation of joints for strumous disease, especially knee, and if sinuses exist, holes may be cut over them.

(*c*) To prevent contraction of knee, before or after straightening.

Precautions.—The fear of causing undue pressure often prejudices the surgeon against the use of plaster of Paris, but with ordinary care there is no danger.

A flannel bandage should envelop the parts comfortably; often it is found the flannel is put on too tight and not the plaster of Paris. Of course, if there is obvious pressure, pain, or swelling, the case must be cut down. Often a little judicious clipping or stuffing with wool, or in case of a joint, the application of an ice bag, will render it unnecessary.

The instruments now made make it most easy to cut down plaster of Paris cases.

It is safer, perhaps, for the child to be especially watched during the first twenty-four hours, and to be within reach of relief, and the friends should always be cautioned against pressure symptoms at any time occurring.

Jackets should not be applied to rickety, bronchitic, or phthisical children, or in any case of fear of embarrassed breathing. A laced poroplastic jacket might then take its place. It should also be remembered that some children improve and grow so rapidly on being sent into the country, that the jackets previously applied get too small and must be cut down and fresh ones applied.

Urgent pressure symptoms are extremely rare if ordinary care is taken.

CASE OF INTESTINES ADHERENT BEHIND UTERUS, CAUSING INTENSE PAIN, RELIEVED BY ABDOMINAL SECTION.

By LAWSON TAIT, F.R.C.S.

S. B., aged 32, presented herself at the Birmingham Hospital for women early in November last, complaining of constant pelvic pain dating from her last confinement, and much aggravated by the patient having "strained herself" six weeks before. On examination, the uterus was found to be somewhat fixed with a mass behind it, very tender on pressure, and clearly cystic. But for the fact that she complained of no increase of pain before or during menstruation, I should have diagnosed the case to be one of occluded and distended tube. As it was, I made no diagnosis, but advised abdominal section. This the patient readily agreed to, and I performed it on November 8th. I found a good deal of matter in the pelvis, and a coil of intestine adherent in the cul-de-sac. I undid the adhesions without much difficulty and closed the abdomen. She left the hospital on November 28th, and has been entirely free from pain since. I have just seen her (July 7th), and find that she has had no return of her old symptoms, and is in perfect health.

This case is a very instructive one, for the physical signs were precisely those of pyo- or hydro-salpinx; and if it had happened that the patient had suffered much at menstruation, I certainly should have set it down as a case of one or other of those diseases. Suppose that, under this belief, I had acted as some (who have had no experience) advise, suppose I had tapped from below, I should have done no good; I should probably have made my patient worse; I might even have killed her. On the other hand, following my rule of opening the abdomen, I was able, with very little difficulty, to cure completely a condition which distressed the patient, which put her in constant risk of her life, and for which no other remedy was possible.

REPORTS OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

GENERAL HOSPITAL FOR SICK CHILDREN, PENDLEBURY, MANCHESTER.

A CASE OF GENERAL MILIARY TUBERCULOSIS—TUBERCLE OF CHOROID—DEATH.

By HENRY ASHBY M.D., M.R.C.P.
Physician to the Hospital.
(From notes by H. Chester Nance, M.R.C.S., Resident Medical Officer.)

Mary Ellen D., aged 8 years and 10 months, was admitted to hospital on March 31st, 1884, with the following history :—Father strong ; mother died of a tumour (aged 41) ; three other children dead ; no history of phthisis. Patient was well and strong up to a week ago, but her friends have noticed that she has been getting thinner for some time past. A week ago complained of pain in side, cough, and poor appetite ; does not sweat at night, and has no diarrhœa. On admission on the eighth day of illness, it was noted that she was a well-nourished healthy-looking girl ; pulse 120, evening temperature 103·6°, cheeks flushed, and skin moist. At the right apex the percussion note was high-pitched both anterior and posterior, expiratory murmur prolonged, elsewhere and in left lung normal. Examination of other organs gave negative results.

9th day (of illness). Temperature 98°—102·6°, some rhonchus heard at right apex ; appetite poor ; tongue coated.

12th day. Temperature has varied for past three days from 100° to 102° ; tongue dry and brown ; bowels open after syrup of senna ; abdomen retracted ; vomited at 7 a.m.

13th day. Pulse 120, temperature 99°—102° ; is dull and apathetic ; vomited twice in the night ; headache ; tongue furred and dry. Edges of optic discs are distinctly blurred, veins rather full ; situated below and to the outer side of the right disc are two small apparently raised spots of a yellowish colour, not surrounded by pigment, a small artery passes in front of one.

15th day. Temperature 98°—101° ; is quite sensible, but complains of headache and sleeps a good deal in the day-time, though restless at night ; tongue furred, abdomen retracted.

17th day. Pulse 72, slower than a day or two ago. Temperature continues hectic, 98°—102° ; is heavy and drowsy. Three tubercles seen in each eye, they are some distance from discs, are behind the vessels, and apparently raised.

19th day. Very drowsy, but can be roused for milk ; slight convulsion in the evening.

20th day. Deep coma ; Cheyne-Stokes' respiration ; arms rigid, elbows flexed, legs extended and rigid.

21st day. Death.

Post-mortem—Body fairly well nourished, rigor mortis well marked. *Mediastinal glands*: one or two pigmented and cheesy. Surface of lungs covered with fine grey tubercles, also on costal pleura, no lymph. *Lungs* in condition of inspiration, œdematous, gorged with blood, infiltrated everywhere with fine grey tubercle ; in central part of lung some pneumonia. *Liver*: a few miliary tubercles on surface, one here and there on section, some also on inferior surface of diaphragm, no lymph. *Kidneys* contain miliary tubercles. *Spleen*: tubercles on surface and on section ; there is a small wedge of cheesy material on the upper surface. Heart, peritonæum, stomach and intestines, no tubercle. *Brain*: no lymph anywhere, but fine tubercles present on the vessels in the Sylvian fissures and elsewhere ; lateral ventricles distended, no softening, but brain substance everywhere firm and healthy. *Eyes*: some four or five tubercles in each choroid, they are greyish in colour, and stand out prominently. On microscopical examination they show typical giant-cells and several are becoming cheesy in the centre.

Remarks.—This case of acute tuberculosis was an unusually rapid one, the duration being about three weeks, though the acute symptoms were preceded by more or less loss of flesh and cough. The physical signs in the lungs were never very marked, being limited to a high-pitched note at the apices, some rhonchus and prolonged expiratory murmur. The most interesting feature of the case was the presence of miliary tubercles in the choroid. These were first noted on the thirteenth day of the disease (unfortunately this was the first ophthalmological examination), and also a slight amount of papillitis. On this day decided symptoms of meningitis set in and the ophthalmoscopic examination confirmed the diagnosis of acute general tuberculosis. How long the tubercles had existed before being discovered, it is impossible to say, but I am inclined to think that other tubercles seen in the last day or two of life were not present when the examination was made on the thirteenth day. Dr. Mules made a coloured drawing of the fundus during life, which he exhibited at the Ophthalmological Society.

Medical Times and Gazette.

SATURDAY, JULY 19, 1884.

Our Paris correspondent writes :—The 14th of July was expected with a certain degree of apprehension on all sides, owing to the vaticination of impending danger, and the fear of evil consequences from the huge agglomeration of human beings, which is said to be one of the leading causes of cholera. Nothing occurred, however, to justify the misgivings of the public. The day came and went, like many others, and saving some political incidents, left no immediate mark of its passage. The heat was enormous, and that of the following day (the 15th) was even worse, especially in the neighbourhood of Paris. At L'Isle Adam, for instance, the thermometer rose to 38° Centig., or 100° Fahr. in the shade. Cases of diarrhœa, and even of cholera nostras, are said to have appeared ; but there has been hitherto no real case of true Asiatic cholera in Paris. In the meantime, proper precautions have been taken in case of an invasion of the epidemic. It had at first been proposed to create *cholera wards* in all the hospitals of Paris ; but from fear of dissemination this plan has been thrown up, and two special buildings have been set apart for the purpose of receiving patients labouring under that disease.

In the south the epidemic still maintains its ground. The deaths at Marseilles daily amount to seventy on an average, and at Toulon their number has somewhat increased, the last number reported being thirty-six. A large number of doctors, students, nurses, sisters of charity, and officials have paid their tribute to the visitation. The Mayor of Toulon, M. Dutaxta, was

also the subject of a very severe attack ; but according to the latest news received, he is already much better, and will probably escape with his life. The infected region has at length received a ministerial visit, which if it had sooner taken place would have put at once an end to a variety of unpleasant criticisms upon the conduct of the Government, and might have been productive of some good. It must be acknowledged, however, that when once their decision was taken, our Republican ministers acted their part with a good grace, and created at Marseilles a favourable impression. The numerous and contradictory directions given by various authorities to the public have created much confusion. M. Pasteur publicly blames Dr. Koch for having in his printed instructions deprecated the use of water even for the most legitimate purposes. M. Pasteur very properly remarks, that a profusion of water is the only means we possess of keeping our streets clean, and that the disinfection of clothes and other property having belonged to choleraic patients will always remain imperfect if water is excluded. He observes, lastly, that among the precepts laid down by Dr. Koch some are universally adopted and had long been so before he spoke ; while others are founded on mere hypothesis, devoid of proof. Nothing proves hitherto that the germ of cholera when once dried up can never revive ; nothing proves that the diffusion of cholera never takes place through the atmosphere, and on all these points we are too much in the dark to deduce a practical line of conduct from theoretical principles, the validity of which is not hitherto established.

The Government having requested the Academy of Medicine to state its opinion as to the best measures to be adopted, the whole sitting of that learned body was taken up with the discussion of Dr. Brouardel's report, the conclusions of which had already been noted by the Board of Health. These conclusions, which were adopted by the Academy, are substantially the following :— (1) Land quarantines are useless and injurious, and cannot be recommended. (2) Disinfection of travellers and their luggage is equally useless and injurious. (3) Medical attendants should be posted at every railway station, to take charge of all travellers who appear to be affected with cholera, and to convey them to a proper place of isolation and treatment. (4) Individual precautions are the best preservative against cholera, and these ought to be carefully enforced by public authorities and observed by private persons.

At the same meeting the celebrated histologist, Professor Cornil, was elected a member of the Academy in the Section of Morbid Anatomy (*Anatomie pathologique*), by a majority of 64 votes out of 74. Public opinion will fully ratify the choice, which was generally anticipated.

A correspondent writes : You, in common with other medical authorities, seem to be fairly assured that if cholera invades our shores it will gain no sure foothold, and probably will not spread far beyond its port of disembarkation. In expressing this assurance, I will not go so far as to say that medical writers are reckoning without their host, or without their guest, if cholera is to be our guest ; but they are certainly forgetting the vastly increased intricacy of our sanitary arrangements since the last epidemic, and the new and as yet unknowable conditions which this has introduced into the problem. Cholera probably more nearly resembles typhoid in its mode of communication than any other zymotic disease, and the experience of the last decade has shown that while sanitary improvements have markedly diminished the general prevalence of the latter affection, they have allowed of—nay, rather facilitated—its bursting out in widespread epidemics such as were unknown before the era of extensive systems of drainage, and of water and milk supply. The presumption, then, is that cholera, if it ever penetrates beyond the coast-line, *may* do the same.

A single cholera stool, gaining access to the source of a large water or milk supply, might presumably decimate a population reckoned by tens of thousands, while the same stool, finding its way into a stagnant sewer, might exhale its poison into a thousand houses, where there is no efficient means of cutting off the invasion of sewer gas. Again, where a water system is arranged for a constant service, but owing to deficient supply—a very likely contingency in a dry summer—is made intermittent, it has been shown that sewage may easily gain access to the water-mains and be distributed broadcast whenever the water is turned on. These facts have often enough been pointed out in connection with typhoid, but seem to have been ignored in calculating the prospects of cholera in this country. It is worth while calling attention to them in order to forewarn our sanitary authorities, the profession and the public. By working in harmony these can do much to strengthen those weak points by which the security of our sanitary system is to be gauged. By gaining or giving the earliest information of suspicious cases, by isolating them and disinfecting their excreta, by watching over the sources of our water supply, and by thoroughly flushing and disinfecting the sewers, they may hope to reduce the danger to a minimum ; while individuals, by resolving to partake of no water or milk which has not been well-boiled, will probably save themselves and their families from infection, and at the same time conduct a most interesting experiment in cholera prevention.

It would be futile to attempt to foretell the fate of the Medical Bill. It will in all probability be considered in Committee on Monday next, and the Government will honestly endeavour to make progress with it. But it is threatened with dangers from without and from within—liable to be thrust aside by other more pressing business, or to be torn to pieces in the selfish struggles of the corporations. The Government have not acted wisely in the matter ; they have been too squeezable. Forgetting that their original measure had the support of the whole profession, outside the corporation cliques, they were persuaded to listen to authorities who, however eminent for their services to

the profession, must be regarded as on this point fatally biassed. The ministers who have charge of the Bill have made concessions to this and that examining body, only to find that they have excited the opposition of other examining bodies. They ought to have recognized that it was impossible to please all the corporations. If they had shown "a stiff upper lip" and not attempted to please everybody, there might have been some chance of success. But the moment they accepted the Lyon Playfair amendment, in which course they were no doubt actuated by the best of motives, the prospects of the Bill's passing went down to zero.

The deputation from the Senate of the London University which interviewed Lord Carlingford on Tuesday, pointed out with great clearness the fatal objections to the Lyon Playfair proposal. They showed in the first place that it was totally inconsistent with the recommendations of the majority of the Royal Commission, and thus robbed the Bill of one of the chief arguments in its support; secondly, it was contrary to the spirit of the Bill as it came down from the House of Lords; thirdly, if adopted it would aggravate the evils which the Bill was intended to remove; and fourthly, it would place the Senate of their University in this difficulty, that in granting and withholding their own degrees they would be obliged to accept the decision of examiners whom they had not themselves appointed, and whom they could not, in the event of incompetence, dismiss. It is indeed not fair to ask a body which has a reputation like that of the London University, to submit to a system which might practically reduce its degrees to the level of an ordinary pass examination. With half its examiners appointed by an independent body, the Senate could have no guarantee that its degrees would be kept up to that high standard, on which alone, as at present constituted, the success of the University depends. The deputation had a long discussion with Lord Carlingford and Mr. Mundella, and as a result of their arguments it is possible that the Lyon Playfair proposal may be discarded in favour of the plan supported by Professor Huxley and Professor Turner, of Edinburgh, viz., the appointment of assessors and examiners who would visit the various examinations and report on the manner in which they were conducted. Many of the same objections may be urged against this proposal which were advanced by the deputation of the London University against the Lyon Playfair amendment. But the main argument against it is, that the Medical Council may assess and report as much as it likes, but it will find very great difficulty indeed in applying pressure to any corporation which obstinately ignores its representations. The proposal is not one which the medical profession generally will approve.

The foul condition of the river Thames has been the subject of various questions put in the House of Commons, and it was satisfactory to learn a few nights ago from the President of the Local Government Board, that the whole of the sewage collected at Barking and Crossness is now completely deodorised before it is discharged into the river, that this deodorisation will be continued so long as the weather is dry and hot, and that especial attention is being given to the flushing of the sewers. But the fouling of the river is no new complaint, and as the Metropolitan Board of Works have discovered that the sewage can be fully deodorised at the effluent stations, it does not seem too much to insist that that process shall in the future be carried out at all times of the year. There can be no longer any excuse for polluting the river in any avoidable degree even when the weather is neither hot nor dry.

The river above London is in a still worse condition than is that portion of it under the care of the Metropolitan Board of Works; and unhappily there appears to be very little hope that the latest scheme for its purification will be approved. The Lower Thames Valley Joint Sewerage Board again presented a scheme of main sewerage and sewage purification to Parliament this Session, and for a time it seemed probable that their Bill had a good chance of success. But it is now known that, to use Sir Charles Dilke's words, the Select Committee to which the Bill was referred have determined to accept the grave responsibility of reporting altogether against it. The Joint Sewerage Board was appointed so long ago as in the year 1877, for the purpose of dealing with the sewage from nine urban sanitary districts, and ten contributory places; but every scheme that the Joint Board have presented for approval has been condemned. The Select Committee consider that the Board failed because they attempted to deal with the problem submitted to them by the total diversion of the sewage or by its treatment by irrigation at one particular place; while the Committee are of opinion that the several authorities forming the Joint Board could successfully purify the sewage of their respective districts. It is therefore recommended that the combined districts be divided into four or five districts, each of which shall manage its own sewage.

This appears to be perilously like going back to the chaos of discordant authorities that preceded the Joint Board. Meanwhile the nine suburban districts and the ten contributory places in the Lower Thames Valley discharge their sewage into the Thames without any attempt at previous purification; and all the evils and dangers attendant on that proceeding have of late been greatly aggravated by the remarkable lowness of the river, a condition which, according to some authorities, is due in considerable measure to the very large amount of land-water taken by the London Water Companies. We are thus brought face to face with two very large questions of great difficulty and perplexity—the scientific and sanitary sewerage of the Lower Thames Valley, and the Metropolitan Water Supply. The settlement of both questions is of immeasurable importance to the health of the Metropolis, and will ere long compel the attention of even party politicians.

The Prince and Princess of Wales paid their first and presumably their last visit to Miss Mary Wardell's

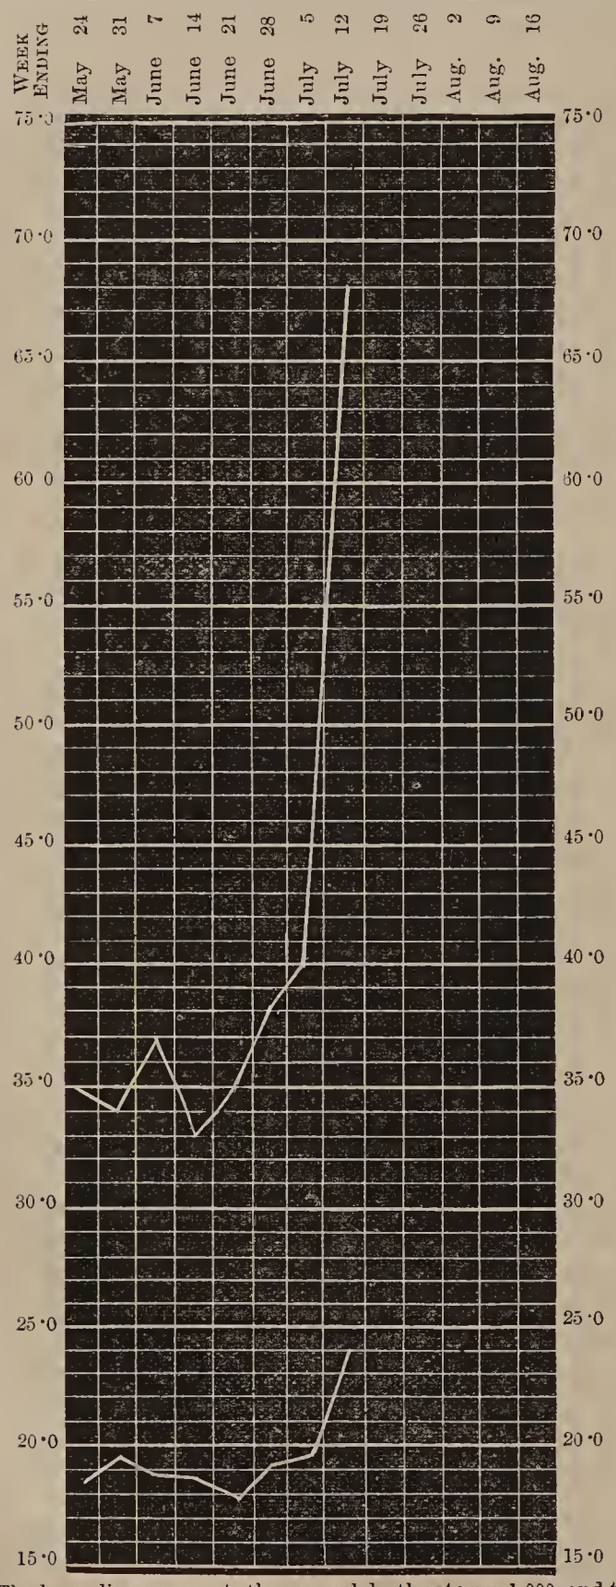
Convalescent Home for scarlet fever patients on Monday last. The ceremony of opening the home, which was conducted with some circumstance, reminds one of the dedication of a nun, or some analogous function—a day of festivity followed by an isolated life of benevolence. From the moment that the first scarlet fever convalescent is received into the Stanmore Home, it will be shunned by the world in spite of its beautiful surroundings, and its commerce with the public will be limited to the necessities of its existence. As to the usefulness of the home, there cannot be a divided opinion. It will save many a scarlet fever patient from the sad sequels of that treacherous complaint, many a seaside lodging from infection, and many a father and mother from an acted lie. In connection with this institution the name of one of our profession, now no longer with us, ought to be for ever remembered, that of Dr. A. P. Stewart. Without Dr. Stewart's assistance it is quite possible that Miss Mary Wardell might not have been able to establish the home. It would have been founded sooner or later, but not under its present favourable auspices.

Dr. Norman Chevers, the President of the Epidemiological Society of London, will open a two days' Conference at the International Health Exhibition on the 22nd instant, at 2.30 p.m., Mr. Shirley Murphy acting as secretary. The President's opening address will deal with "Health in India," after which Dr. Squire will read a paper on the "Change of Type in Epidemic Disease." On the following day, July 23rd, conferences will be held at 11 a.m. and 2.30 p.m. At the former a paper will be contributed by Surgeon-General Pringle, on "Leprosy in India, and the best means of preventing its increase"; and the behaviour of typhus in England during the present century will be discussed. In the afternoon a consideration of the present aspect of cholera in Europe will be opened by Inspector-General of Hospitals, Robert Lawson, M.D. The Society is certainly to be congratulated on the completeness and practical interest of its programme; but the interest, unfortunately, just now is greatly at the expense of the public. No one, probably, would rejoice more thoroughly than the President and Fellows of the Epidemiological Society if their discussion, on cholera, for instance, could have been of a more scholastic nature.

The success of the International Health Exhibition, with the prospect of a large balance at the end of it, is beginning to make the mouths of sanitary schemers water in anticipation of a division of profits. As Sir James Paget said at the banquet at the Mansion House on Saturday, the success of the Exhibition will not be apparent for many years in so far as the question of health is concerned; but it will be apparent in a few months in so far as the question of money is concerned. It will be well, however, to remember the experience of the Fisheries Exhibition, and not to encourage too exorbitant hopes. On one point an expression of opinion may perhaps be allowed. If there is any surplus to be disposed of, it should be devoted rather to preventive than to curative objects. The Parkes Museum, which was in some sense the mother of the present Exhibition, has the first claim, both from its usefulness and its necessities, to a subsidy. The Sanitary Institute might also fairly expect to be remembered. But the most advantageous way of investing a surplus would be to found a central hygienic laboratory, wherein might be conducted, under competent professors, every sort of research bearing upon the prevention of disease. There is simply no end to the number of practical enquiries for which the science of hygiene is waiting before it can lay a claim to even moderate perfection, and every generation probably will see new problems arise. Sir James Paget says, what we want is ambition for health. We, on the other hand, believe that what is wanted is knowledge. Preventive medicine looks on helplessly while the race is fast becoming edentulous, and not only offers no preventive, but does not even think of looking for one; leaving the scientific problem to be worked out, at their own expense, by half-a-dozen enthusiastic dentists. If all that a hygienic laboratory should effect were to be the discovery of a means of successfully forestalling decay of the teeth, the millions who are visiting the Health Exhibition would feel that the profit on their shillings had been applied to a most worthy object.

On Monday last the Lord Mayor presided at a meeting at the Mansion House, summoned in support of the proposal to establish a convalescent hospital and home of rest for the wage-earning classes. It is intended that it should be self-supporting to the extent of one-fourth of the expenditure, but we cannot understand from the reports in the daily papers whether the payments of those who are to enjoy its advantages are to be provident, that is, made week by week or month by month during good health, or only to be exacted during residence in the home. In either case, however, the proposal is worthy of that support from Royalty and the medical profession which it received at Monday's meeting. Sir Risdon Bennett, Sir Andrew Clark, and Sir W. MacCormac all spoke in its favour, and a council was forthwith appointed to carry out the scheme. It is perhaps open to doubt whether it is wise to make a further call on the charitable to support what may be regarded as more or less of a luxury, when hospitals which provide for the actual necessities of the poor are languishing all round for want of funds. But, on the other hand, it may be argued that a well-conducted system of convalescent homes, by clenching the cures wrought in hospital, and by preventing serious illnesses by timely aid, will to some extent lessen the need for hospital accommodation. In any case the council when they have established the home will do well to take adequate precaution that its benefits are kept for those who are in actual physical nced of them, and not sponged upon by those who simply want a cheap holiday. It is far too common nowadays for benevolent governors to send persons to convalescent homes who are in as robust health as life in London admits of. For such the true hygiene, as well as the true charity, is to make their daily lives more healthy.

The prominent fact in the return of the deaths in London last week is the excessive mortality from diarrhœa. At this time of year one expects to find catarrh of the alimentary tract very fatal to weakly children under one year of age, just as catarrh of the respiratory tract is fatal to the same class of the population in the depth of winter. These two diseases are the means whereby nature chiefly protests against the survival of the unfit, and there is less to regret in an extensive mortality from them than there would be in a similar prevalence of typhoid or smallpox, which do



The lower line represents the general death-rate per 1,000, and the upper line the zymotic death-rate per 10,000 in London, for the past eight weeks.

not make such a wise selection of their victims. Still, a mortality of 336 persons in one week from diarrhœa —262 of them under one year of age—shows a little too much zeal on nature's part, and it is difficult to believe that some at least of these infants might not have been saved by skilful care and nursing, to figure eventually as very capable members of the community. The average mortality from diarrhœa in the corresponding week of the last ten years being 221, the present return shows a death roll half as large again as usual. The temperature, however, in the early days of the week was excessive, and even in the best nurseries it was impossible to keep milk—the staff of infant's life—from turning sour, in spite of the borax and boracic acid which dairymen use so largely when the thermometer rises above 70°.

It is of course the diarrhœa mortality which has sent up the zymotic line in our chart so high, but the mortality from all the other zymotic diseases except measles and scarlet fever was above the average. Altogether, 540 deaths from this class of diseases were registered in London last week, or 127 above the corrected average. Smallpox killed 36 persons, or 24 above the average; whooping cough killed 57, or 6 above the average. The 15 deaths from diphtheria were 4 above the average, while typhoid, the mortality from which has of late been steadily mounting, was fatal to more than twice as many persons as usual in this week of the year. The deaths from respiratory diseases, viz., 206, were less than in the previous week, but exceeded the corrected average by 10. The general death-rate was 24·0 per 1,000, and was exceeded only in Nottingham, Birkenhead, Liverpool, Preston, and Halifax. Diarrhœa was not very fatal in the 27 large provincial towns, the deaths from it not having exceeded 160, whereas if children had died in them at the rate that they did in London, the mortality would have nearly reached 400. It is worth while enquiring why diarrhœa should have been so excessively fatal in London, compared with other large towns in which the sanitary conditions are not a whit more favourable.

It was given to Sir Charles Dilke on Wednesday last to make, in the House of Commons, the most satisfactory statement that has been made by any Minister of the Crown during the present Session of Parliament. The House was in Committee of Supply, and during a conversation on the Vote for the Local Government Board, Sir C. Dilke said that the National Vaccine Establishment has lately been obliged to apply to the Treasury for power to take extra premises, and that the Establishment was daily increasing its operations to such an extent that hereafter it would be necessary to propose a separate Vote for it. To every person of wholly sound mind this evidence of increased activity in the vaccination department must be highly acceptable.

The Second Professional Examination in the University, writes our Edinburgh correspondent, began on Friday last, and was continued during the present week. The division of this examination into two sections, the first including anatomy and physiology,

and the second materia medica and pathology, is finding favour with an increasing number of students, and the arrangement was undoubtedly a step in the right direction. The preparation for this examination when it included all the subjects was a tax on the capacity of candidates which few could endure with comfort; and it moreover conduced to perfunctory preparation in one or other of the subjects in the hope that a good appearance in the others would make up for any deficiency in it. Now more thorough preparation is ensured, and the tendency to "cram" diminished.

The Final Oral Examinations came to a conclusion on Friday last, and the list posted on that day showed a considerable number of rejections. Some of the unfortunates are, however, consoling themselves on the understanding that they are to have a second trial in a day or two. This process of second trial is a relic of the grandmotherly fashion in which this examination in years gone by was conducted. Formerly, none but the blackest of the sheep were remitted for another year's sojourn among the flock; recently, alma mater has been in the habit of returning a considerable number to her nurturing care; but her heart relents at the sorrow of some of the disappointed ones, and she picks out a few of the most deserving and gives them another opportunity of demonstrating their fitness for life outside the fold. It is to be feared in the event of the Medical Bill becoming law, either with or without the Playfair amendment, that the candidates will find the new board of examiners somewhat less complacent than the present; and in any case it is to be hoped that we have seen the last of this somewhat weak and vacillating process of deciding on a candidate's fitness to pass.

We understand that a very large number of candidates, far in excess of the ordinary number, have entered for the Final Double Qualification Examination of the Royal College of Physicians and Surgeons of Edinburgh. This probably includes a considerable number of the *waifs* from the three kingdoms, who, fearing the passing of the new Act, dread the effect of a somewhat more carefully organised board on their somewhat dubious chances of success.

The Directors and Medical Officers of the Royal Infirmary, Glasgow, have under consideration the advisability of appointing assistants to the several medical officers, independently of the resident assistants. This is a move in the proper direction, and apparently has the unanimous concurrence of both lay and medical managers, and it is to be hoped that it will be the means of lessening, if not entirely removing, much of the friction which has from time to time disturbed the workings of the institution. The vacancies which are soon to take place in the staff of both medical and surgical departments are to be keenly contested. For the medical appointment we hear that Drs. J. W. Anderson, Gemmell, Alexander Robertson, and McVail are in the field. Dr. Anderson has been a long time on the dispensary staff, and latterly has been doing duty as Visiting Physician in the wards of Dr. Charteris since the resignation of the latter.

The proposal to amalgamate two of the Dublin Schools of Medicine, to which we alluded a few weeks ago, has fallen through in consequence of an adverse vote at a meeting of the Council of the Royal College of Surgeons in Ireland, on Thursday week, the 10th inst. By a majority of eight to six votes it was decided that it was not advisable to take steps to ascertain the feasibility of an amalgamation between the School of the College, and the Carmichael College of Medicine.

At a meeting of the Senate of the Royal University of Ireland, held on Wednesday, July 9th, a number of additional examiners were appointed to assist in conducting the autumn examinations. Among them, and in the Faculty of Medicine, was Dr. John F. Hodges, appointed an Additional Examiner in Sanitary Science. It was arranged that the Medical Examinations of the University shall be held twice in each year viz., towards the end of April and in the month of October. Candidates failing to pass at either of these examinations will be allowed to present themselves again at the succeeding examination. There will be an honours examination in connection with each of these medical examinations. One First Class Exhibition and one Second Class Exhibition, out of the number already assigned to the several medical examinations respectively, may be awarded at the April examination; while the residue of such exhibitions may be awarded at the October examinations.

The city of Vienna has to deplore the loss of three distinguished physicians in a single week. Professor Edward Jäger v. Jaxtthal, the eminent oculist, the master of all the masters in "opthalmoscopy," as he was called by one of his pupils, is dead, and there cannot be two opinions that the medical faculty has sustained a heavy loss by his death. The reputation of Edward Jäger was not limited to his own city; he was well-known abroad on account of his great scientific merits. His ophthalmoscope, his atlas, and his reading types are known to every oculist; his last scientific work was devoted to the investigation of general diseases and diatheses by means of the ophthalmoscope.

Besides his medical work, he devoted a considerable part of his time to the study of general social problems; and a few years ago he published a *brochure* on the reforms needed in the scheme of instruction in vogue at the Austrian universities. He was famous not only for his extensive knowledge, but also for his skill as an operator, and many of his pupils, as Professor Mauthner, of Vienna, Professor Hermann Cohn, of Breslau, and Professor Schnabel, of Innsbruck, have achieved a reputation in science which has shown them to be worthy of their master. Edward Jäger was born in 1818, at Vienna, and was the son of Frederick Jäger, a famous oculist of his time. In 1854 he received the rank of Privat-Docent of Ophthalmology in the medical faculty of Vienna; in 1857 he was named Extraordinary Professor of the same faculty, and a year later he became "Primarius" of a ward for diseases of the eye, which had been recently established in the Vienna General Hospital. When, a year ago, Professor Arlt had to resign his chair in obedience to the law which demands the

retirement of every teacher who has reached the age of seventy years, the "ordinary professorship" naturally fell to Edward Jäger. The Professoren-Collegium had thus an opportunity of repairing a blunder which had been committed long before, Jäger having been passed over when it was his turn to be elected "ordinary professor." The Professoren-Collegium knew very well that they would soon be compelled to proceed to another election, for Jäger was already aged 66, and weak in health. They did, however, what they could, profiting by the opportunity of bestowing on their colleague an honour which, however, he was destined to enjoy only for a short time. He died on the 5th July, in his summer residence at Penzing, near Vienna, having reached the age of 67.

The "Father" of the Vienna Hospital, and its oldest Privat-Docent, Dr. Kolisko, died on the 7th July, at the age of 73. He was famous in the diagnosis of diseases of the chest, and in 1857 the ward for these affections, which had before been under the direction of Skoda, was entrusted to him. Hofrath Dr. v. Vivenot, one of the most amiable and good-hearted physicians of Vienna, died on the 30th June, in his country home at Lilienfeld, aged 77. He was the founder of the society for the support of the widows and orphans of physicians who did not belong to the "Widows' Society of the Doctoren-Collegium." He also founded the Society of Physicians of the First District, of which he was for many years President, as well as Archduchess Sophia Hospital. On account of his numerous benevolent actions he was the recipient of many Austrian and foreign orders. In him Vienna has lost a noble benefactor.

At meetings of the "Professoren-Collegium" of the medical faculty of Vienna, held on the 21st and 28th June, the officers for the year 1884–5 were appointed. Dr. Vogl, Professor of Pharmacology, was elected dean of the faculty, and Dr. Gustavus Braun, Professor of Gynæcology, sub-dean, Dr. Adolphus Lorenz (Emeritus assistant to Professor Albert in the clinic of surgery), Dr. Wittelshöfer, and Dr. v. Pfungen (assistant to Professor Meynert in the clinic of mental diseases) were named Privat-Docents. Many candidates for extraordinary professorships were proposed by the different professors of the medical faculty. If all these candidates should be admitted by the committee which is appointed to enquire into their respective merits, and if this admission should be confirmed by the ministry of education, the medical faculty of Vienna will be almost too well supplied with extraordinary professors. Professor Billroth recommended his assistant, Dr. Wölfler, Professor Albert supported Dr. Hofmokl, Professor v. Dittel proposed Dr. Englisch and Dr. Utzmann. Professor Ludwig favoured the claims of Dr. Manthner, and Professor Leidesdorf brought forward Dr. Urbantschitsch.

Professor Billroth addresses, through the *Centralblatt für Chirurgie* for June 28, "a scientific and humanitarian request to his colleagues," in relation to neuroma of the stump after amputation, being induced thereto by the terrible sufferings of two cases he has under treatment. He has desired his assistants to work out the subject in order to ascertain what are the causes of the production of the affection, and especially as to the duration of the effects of operation or the other modes of treatment employed; and he will be greatly obliged by any of his colleagues furnishing him with the results of their experience on these two points. The recorded cases give little that is satisfactory. The extensive excisions of the neuroma which he has performed in these cases have, in Professor Billroth's hands, been followed by no good result, or this has only been temporary, which may have been due to the affected nerves having already become too far diseased. As it happens, he has never had the opportunity of observing painful neuroma after any of his own amputations, and he asks whether they are met with also in the union by primary intention in the modern antiseptic treatment of wounds? The employment of electro-puncture, successful in Lücke's hands, failed in a case in which he used it, and more information is required concerning its application.

Mr. Victor Horsley has demonstrated the fact that both nerve-endings and fibres exist in the sheaths of nerves. The existence of sensory nerves supplying the endoneurium of nerve trunks has been previously surmised, and it has also been demonstrated that sensations in nerve trunks may be localised. This is frequently the case in neuralgia, and the new facts observed by Mr. Horsley render explicable the beneficial results of nerve-stretching in this disorder. There appear to exist both Pacinian bodies and tactile corpuscles, the former lying in the epineurium, and the latter on the perineurium covering the primitive bundles. The fibre supplying the end bulb is always single, "running in a distinct sheath of connective tissue furnished by the endoneurium" and taking origin "either from anastomosing branches of primitive bundles, or from the bundles themselves as single or double fibres following the arrangement of the connective tissue bundles of the epineurium." Mr. Horsley surmised that "by stimulation of such nerve endings, in addition to those found in muscle and around joints, information was gained of the position of the limbs and so-called muscular sense." The discovery of these nerve terminations within nerves is of the highest importance, and throws a new light upon many obscure points in neurology. The communication was made at the recent meeting of the Physiological Society, and at the Royal Medical and Chirurgical Society.

It is well known to many that the late Claude Bernard and his wife did not live on the best of terms; in fact some years before his death they separated, the main reason being that she was a most determined anti-vivisectionist. Since Madame Bernard has been a widow, she has been under the influence of somewhat mystic ideas, one of which is, that if she can save the lives of as many dogs and cats as were immolated by her husband, their souls may yet meet in Paradise. Impelled by this hope, she repaired to the highways and by-ways, collecting all the stray dogs

and cats she met with until she accumulated some forty or fifty of each in her house at Colombes. As she lived in a street adjoining neighbours, this naturally soon gave rise to protests, and at last she was fined five francs for having disregarded a decree of the mayor for the abatement of the nuisance. Appealing against this she declared by her advocate, that she did not wish to annoy her neighbours by these dogs, which she considered it to be a sacred duty to collect, and that she was willing to move elsewhere ; but at the same time she did not wish to be out of pocket by doing so at once, as she had paid her rent in advance. She therefore wished to avail herself of a flaw in the mayor's decree, in which he had inaccurately termed her house an "infirmary" for dogs and cats. If this decree were quashed before another with a proper designation could be put into force, the time for which she had paid her rent would have expired and she would take herself off. The obdurate tribunal, however, would listen to no such argument, and dismissed her appeal.

In his presidential address at the twenty-fifth Annual Meeting of the American Medical Association, Dr. Austin Flint spoke at some length very forcibly on the relative positions of orthodox practitioners and, in the euphemistic language of the Code of the Association, those "whose practice is based on an exclusive dogma to the rejection of the accumulated experience of the profession and of the aids actually furnished by anatomy, physiology, pathology and organic chemistry." Dr. Austin Flint groups together as irregular practitioners all who assume distinctive names, such as homœopathists, eclectics, botanics, &c., on the ground that this indicates to the general public a special claim for consideration as being distinct from, and opposed to, the general body of practitioners, thanking heaven, in a way, that they are not as other men are. Aware that this classification will include many who have taken medical degrees, he exhorts them to renounce the "sectarian designation" and the hostility to the profession thereby involved. These steps and conformity to the rules of medical ethics are, he considers, *alone* necessary to throw open the portals of the regular profession to these erring brothers. *Alone* forsooth! May we not almost hear them crying out with Shylock's bitter cry—

> "Nay, take my life and all . . . . .
> You take my house when you do take the prop
> That doth sustain my house ; you take my life
> When you do take the means whereby I live."

Deprived of their name, and of their proud isolation they would truly be in a parlous state in most cases.

At the adjourned meeting of the Royal College of Physicians, held on Thursday last, reports were received and adopted from the Council, and from the Medical Bill Committee. The President reported that he had expressed to the President of the Local Government Board the readine s of the College to afford every assistance in their power to meet any outbreak of cholera, and to prevent the spread of the epidemic. Sir Charles Dilke had replied that the College could do good service by issuing a paper of instructions to the public, such as they prepared on a former occasion when an outbreak of disease was apprehended. A large Committee of the Fellows, including Physicians of each of the large Metropolitan Hospitals, with some other Fellows who have had large practical knowledge of the disease, as Sir Joseph Fayrer and Sir Guyer Hunter, was appointed to draw up a paper of instructions ; and to give advice and assistance to the Local Government Board in any other way that may seem useful.

PATHOGENIC MICRO-ORGANISMS.

The great difference of opinion that prevails among skilled observers as to minute organisms known as bacteria, and the varied results obtained from their experiments by means of cultivation and inoculation in connection with disease, should teach an important lesson, as we have more than once had occasion to insist, to impetuous practical men who, with insufficient personal knowledge of the subject, are too ready to popularize other men's work. The issue of the questions raised by this study is possibly of the gravest practical importance ; and it is nothing less than lamentable to contemplate in the writings of medical men the over-ready assumption of inadequately demonstrated facts, and the host of illogical inferences and applications which appear to them to result therefrom. In a previous leading article we glanced at the lack of evidence there was for the dogmatic teaching that, because it is most probable that the bacillus tuberculosis of Koch is the essential cause of tuberculosis in animals, therefore phthisis in men is solely due to the same organism ; and the further inference that phthisis is contagious, is clearly, as Dr. Andrew has lately insisted, not only "not proven" but even in a great degree unlikely. Once more, at this time, when the subject of cholera is engaging the minds of the profession and the public, we see the most doubtful and hotly debated points as to the genesis of the disease taken widely for granted by the uninitiated in science, both within and without the ranks of medicine ; and we cannot but hope that some recent utterances of such a well known worker in pathology as Dr. Klein, will have great influence in causing many to pause and consider before they attempt to teach the public what they may probably have to unlearn themselves. In an article in *Nature*, for July 10th, the substance of which is reproduced in another column, we have clearly set before us, presumably by Dr. Klein, what is really ascertained with respect to the organism lately detected by Dr. Koch in the discharges of cholera patients. The writer points out that though Koch has failed to find the comma-shaped bacillus which occurs in cholera in any other malady, and notably in diarrhœa, a very similar or identical organism was observed by himself in the dejecta of patients who suffered from an epidemic of diarrhœa in Cornwall, in 1883. But further, even if this bacillus were peculiar to cholera, it is so far not proved to be *pathogenic*, but only pathognomonic ; for animals are apparently insusceptible, and inoculation experiments have had no result. The theory of Koch that this comma-shaped bacillus, found only in the intestinal contents, is the cause of cholera, is bound up, says Dr. Klein, with the assumption that the cholera poisons enter the system by the alimentary canal alone. This objection, of course, has weight only in proportion to the belief that

the respiratory system also is an avenue of approach for the contagium. In that case it would be reasonable to expect to find the bacillus in the blood and tissues. But though Dr. Klein apparently goes beyond what is proved when he states that the cholera poison is certainly inhaled as well as swallowed, he doubtless makes a point against those who implicitly acknowledge the "comma" bacillus as the cause of cholera before any direct evidence by inoculation is forthcoming, when he shows that their primary assumption is at least open to question.

In his lately published report to the Local Government Board on the "Relation of Septic to Pathogenic Organisms," Dr. Klein gives us ample material for reflection on this subject generally. The practical outcome of this paper is to throw doubt on M. Pasteur's statement that a culture of *bacillus anthracis* that has become inactive on sheep always yields further cultures which, although full of the typical anthrax bacilli, are nevertheless no longer pathogenic. By a series of experiments Dr. Klein claims to have proved that there is no evidence whatever that a harmless micro-organism can be changed into a harmful one, or *vice versâ*; and he believes that pathogenic bacteria are virulent *ab initio*. The experiments which have led him to this conclusion are given in detail; and are well worthy the perusal of all who would form clear ideas on this subject. The fact of the cultivated bacillus affecting different species of animals in various ways Dr. Klein attributes to varying conditions of growth. High temperatures, or a different soil, or other conditions, may cause the bacilli, although remaining themselves the same, as can be experimentally shown, "to embody or appropriate, chemically or otherwise, some new or different substance, which produces the alteration for a particular species of animals." If Dr. Klein's experiments are to be regarded as having satisfactorily contradicted those of M. Pasteur with respect to the attenuation of the anthrax virus, their practical influence, even though it be exerted in a negative direction, cannot fail to be very great. For it is on his results with the anthrax poison that M. Pasteur has built his hopes, and those of so many others, for the day of protective inoculation against many of the infectious diseases of mankind. Dr. Klein completely denies Buchner's statement that the hay-bacillus can be transformed by various cultivations into the anthrax bacillus, and that the latter may be made to assume the harmless properties of the former; supporting his denial by detailed experiments, and showing apparently good reason, from his own experience, for believing that in some of Buchner's observations the culture of hay-bacillus must have been accidentally contaminated by anthrax-spores.

One more important observation is made by Dr. Klein touching the methods of cultivation of bacilli, which, as much as anything else in his valuable and suggestive paper, serves to point the moral with which this article began. He argues that the culture of bacilli on solid material, rich in gelatine, does not exclude the possibility, or even in some cases the *probability* of some poisonous material being retained, arising from the original source, and apart from the organisms themselves. In some instances he gives ample evidence that this is probably the case. It would seem from these considerations that there is good reason for medical men to hesitate at present in the formulation of their creeds and doctrines in the matter of the ætiology of infectious diseases; for when men like Klein, and Pasteur, and Buchner, and many others are at variance at the outset of the enquiry, it is puerile for most practical physicians to try conclusions with one another.

THE *ROIS FAINÉANTS* OF THE MEDICAL SCHOOLS.

To an observant eye, the old episode of the *rois fainéants* seems likely to be re-encountered in the case of our medical schools, where the time-honoured Lecturer, as lord paramount of education, is beginning to be edged to the wall by his active and accommodating subordinate, the Demonstrator. The prominence of the latter in the schools is of modern date. Not so long since, he was hardly heard of, except in connection with the anatomical department; now no school is complete without its staff of highly trained "practical" teachers in at least half a dozen of the earlier subjects, and the academic Oliver already asks for more. The growing importance of the Demonstrator, and the interest which students for the most part feel in laboratory work, are among the most hopeful features of medical education. True science is an acquaintance with things, not with statements, and the development of laboratory courses may be not unfairly taken as a measure of the extent to which the scientific spirit has invaded primary professional study. The doubling, however, of the recognised course in so many of the subjects involves some very serious considerations, not only on account of the additional expense entailed on the schools, but more particularly on account of the inroad it makes on the already overtaxed time of the student. The years allotted to the curriculum are few, the subjects crowded into it are many; there is a formidable list of lectures to be attended in the earlier years; and it is not surprising if the unfortunate student, between lectures, demonstrations, dissections, journeys to and fro, and intervals of waiting, is heard to complain that next to nothing of the day is left him for reading and private preparation, or for practical work in the hospital wards. The need of an extensive re-arrangement of the conditions of medical study, if men are to be turned out reasonably efficient practitioners after four or five years' tuition, is becoming gradually recognised, and we trust that at no distant date the whole subject will meet with the thorough consideration and bold reform which it both deserves and demands.

The ostensible basis of medical education, as at present constituted, is the traditional method of teaching by formal courses of lectures, and to the maintenance of this ostensible basis nearly one half of the present regulations of study are directed. In any satisfactory enquiry the entire lecture system, as it stands, will have to be placed on its trial, and its case proved very completely before it is allowed to absorb in the future as much of the student's time as it does in the present. We ourselves entertain little doubt

that it will be found, on investigation, open to very material modification, for it is becoming more and more obvious in the schools that many of the required courses, as now carried out, fill no actual place in the pupil's scheme of study, and represent no real element in his instruction. The lecture-system is to outward appearance so firmly rooted, its maintenance has been so uniformly insisted upon by the licensing bodies, that it may appear slightly presumptuous to question its entire and unqualified excellence. To describe a scheme of education so imposingly organised, so elaborately guarded, as little better than an empty show would seem the most audacious of paradoxes. Yet it is probable that no inconsiderable number of those most conversant with the working of the London medical schools would be ready to go far in support of the apparent paradox. We entertain a strong suspicion that, even by earnest students, attendance on one-half the courses of lectures given is regarded as a mere form to be gone through for the sake of a certificate, with little hope of any further benefit; and that, but for the compulsory regulations, lectures would as often as not be delivered to empty benches. Probably not a few lecturers themselves are conscious that they occupy a false position, and form part of a system which is at best a respectable anachronism, a simulacrum of teaching, a decorous shell from which the living tissue has well-nigh disappeared.

In days when books were scarce and dear, the lecturer was necessarily the centre of education, the one possible agent of general instruction. Outside his class-room were no sources of information; no manuals were to be had but the note-books that his pupils assiduously filled. Attendance on lectures was synonymous with attention to study; to be absent from the class was to be an idler. Nowadays the position of oral teaching has become materially modified. For three centuries the lecturer has fought a hard battle with the powers of machinery. The printing press has enabled a few great teachers to speak to the world at large without restriction of time, number, or space. The text-book has been arrayed against the lecturer, and has ousted him from many points of the line. Exceptional men alone can uphold the ancient position unimpaired. In the hands of a Huxley the lecture may still be made an unrivalled means of primary scientific instruction. But Huxleys are not be had for the asking, and certainly cannot be regarded as the rule in the staffs of London hospitals. The knack of tuition is not an universal gift, and in its higher degrees is possessed by few. The selection of lecturers, in the London schools at any rate, is and must be very much a matter of chance, or to speak accurately, is conditioned by other than educational considerations. The London lectureships are, in fact, mostly filled by members of the hospital staffs, who have reached their position by dint of attainments that do not necessarily involve either exceptional proficiency in the subjects they are detailed to teach, or even a pronounced capacity for teaching at all. Here and there a born lecturer appears in the class-rooms, but the general average of the systematic oral teaching is far from high. In the metropolitan schools, which are practically private enterprises, this can hardly be avoided; but it must be frankly borne in mind in discussing the subject. That a school taught by Huxleys and Humphrys would be an ideal engine of instruction, everyone would be disposed to admit; but the practical question is this—does the kind of lecture-teaching which the schools can actually be relied on to provide possess such undeniable advantages over mere text-book learning as to justify us in maintaining a general requirement that without it no student shall be considered to have been properly taught, or be allowed to present himself for examination? Unless an unmistakable affirmative can be given to this question, the present regulations must be adjudged an hindrance, and not a help to education. An affirmative answer, we confess, we should ourselves greatly hesitate to give. A good lecturer is doubtless a priceless possession; to be anything less than good, *non concessere columnæ*.

The exclusion of oral instruction from the modern schools is by no means our aim. Far from it. In any system of scientific teaching worth the name, the oral instructor must hold a place, and an essential one; but that place is not precisely the one that he was called upon to fill in a bookless age. One half of the old-fashioned oral teacher's work is now done, and fairly well done, ready to his hand by some one or other of the numerous manuals open to his choice. The modern teacher is required to work with, rather than to supplant, the printed text. He is not needed to dictate the note-book, which may be had ready made for a few shillings, but to explain and illustrate it, to test the knowledge derived from it, and above all, to ensure that it becomes a knowledge of facts, and not a mere familiarity with phrases. In a word, the teacher's essential place is at the laboratory table by the student's side, not in the rostrum over his head. A demonstrator he *must* be. A lecturer he *may* be with advantage if possessed of the special capacities needed for the work; but the work is not indispensable, and had better by far be left alone than done ill. By the existing regulations the schools are taxed to provide a luxury, while many of the necessaries of scientific instruction are left to chance. For the time and the work of both students and teachers there is ample and pressing need. The scanty clinical knowledge which the average student carries away from his school, is matter of daily remark; the deficiency of clinical instruction, and the want of time to profit by it, is becoming an equally common student's complaint in not a few of the schools. There is plenty of scope for the talents and energies of the most brilliant hospital staff in teaching the higher branches of professional knowledge in the wards and out-patient rooms, without becoming enforced schoolmasters in the primary subjects. It might well raise a smile, were not the cause so serious, to see, as is daily seen in the London hospitals, an accomplished physician or surgeon hurrying from the wards, where his smallest word is caught by eager ears, to spend an hour in reading a chapter of elementary anatomy or materia medica to a first year's audience, one half of which makes little attempt to conceal its weariness and inattention.

We have ventured to broach a very important subject, one upon which much difference of opinion may

be anticipated, and one which ought not to be taken up except in a cautious and deliberate spirit. It is, nevertheless, at a time like the present, when so much that concerns medical education is being consigned to the melting-pot, that the process of recasting may, if ever, be expected to be carried out. We trust that the new licensing boards, of whatever elements they may be formed, will regard it as one of their primary duties to make a searching enquiry into the whole question of the requirements of professional study; and that their regulations will not be enacted without a full and practical investigation into the working of the medical schools as they exist, and into the needs and difficulties of the modern student. For our own part we should not be sorry to see the schools altogether reorganised upon a tutorial rather than a professorial basis, as being more in consonance with the needs of the time. At the head of each we should like to see an official more nearly analogous to a college tutor than the present deans, provided with assistants if necessary, to conduct frequent examinations and keep a personal watch on every pupil attending the school. Under his direction should work a staff of practical teachers in anatomy, physiology, chemistry, morbid anatomy, operative and "minor" surgery, pharmacy, and toxicology. The total disappearance of botany and materia medica may be taken as a matter of course. Upon these "practical" courses, for the reasons stated above, we hold that personal attendance should be strictly enforced. If the resources of the school admit of really good lectures in any or all of these subjects, so much the better; but they cannot be deemed essential, and may safely be left an entirely optional matter. In the higher subjects—the various branches of medicine and surgery, in therapeutics, and jurisprudence, systematic courses will probably be always appreciated by the advanced student, and provided by the schools; but the first care of the hospital staff should be the provision of adequate and well organised clinical instruction, both in the wards and in the out-patient rooms, coupled with frequent short lectures, as informal and practical as possible, and given, if that may be, in immediate connection with the bedside teaching. Nor should any student be allowed to present himself for examination who has not given far fuller proof of his attention to this all-important portion of his professional education than, we fear, is at present exacted either by the licensing bodies or by the school authorities. Some such reform as we have sketched we are convinced will ere long be found desirable, and the historically interesting office of lecturer must not be allowed to stand in its way. The years allotted for study are too few to admit of any portion being given to merely ornamental teaching; the most practical methods, the greatest economy of time are imperatively required. The lecturer as absolute sovereign has had his day. The demonstrator and practical teacher are the men of the hour. They are even now absorbing into their duties all that is essential of the former's work. The throne remains to the lecturer, buttressed as it is by compulsory regulations, but the sceptre is departing from him. Childeric, if wise, will yield the place to Pepin while he can still do so with grace.

INFESTED FOOD.

The recent unfounded mackerel scare is fresh within the recollection of our readers. According to the original report mackerel and beer were placarded as *arcades ambo*. We confess to regarding the "free consumption" of the latter in hot weather as being the agent responsible for mischief, when mischief ensues from their joint ingestion, and believe that the fish is only an accessory after the act, standing thus in the same category as the salmon, which sometimes serves as the nominal and convenient scape-goat for the post-prandial discomforts of the wealthier classes. It is, of course undesirable that any cheap and nutritious form of food should be laid under an unmerited ban; and it is monstrous that our poorer neighbours should be scared from the enjoyment of what is both wholesome and palatable by the bogus menace of a too successful practical joke. It must, nevertheless, be admitted that we are only on the threshold of a complete knowledge of this subject, for the true comprehension of which more thorough investigation is still needed. If the interest to which the public has lately been roused in the matter leads to fuller research and exacter conclusions, we must be grateful even for evidence which appears at first sight but to disclose new perils and to establish the reality of risks hitherto only speculative. The more light we have, the better can the road be seen; and whether it serves to give him timely warning and recognition of real dangers, or causes the phantom shapes to vanish in the clear dawn of fuller knowledge, the traveller cannot be otherwise than thankful for its aid.

All the animals commonly employed as food by man serve, in some cases habitually, sometimes only exceptionally, as the "hosts" of parasitic organisms. Broadly dividing the latter into two great groups—those habitually occupying some part of the interior of the intestinal canal, and those which burrow into or amongst the general tissues of their host—it is obvious that the latter are by far the more dread-inspiring. Without respect for time or place, and by the nature of their habitat secure from the action of all ordinary remedies, some of them can penetrate to organs of the greatest delicacy and of the most vital importance. Fish are known to be commonly infested by these pests, and some of them at least appear to be transferable to man, presumably through the use of fish as food. Thus, in 1869, Professor Lockwood, in America, discovered the *Koleops anguilla*, a minute entozoon, which he had found embedded in the adipose tissue on the entrails of the common eel. Four years later Professor Welch, of Netley, published a description of an identical, or very similar, parasite, which he had obtained from the dissection of a soldier returned from India, and expressed his opinion that this group of worms would prove common in fishes. The latest addition to the list of known tissue-boring pests is derived from the common pigeon. It is the larval form of a burrowing mite, the *Pterolichus falciger* of Meguin, the *Hypoderas columba* of Murray. It is about 1·5 m.m. in length, and is said to occur "most abundantly in the connective tissue about the large veins near the heart; but a few may be found under the

skin in the region of the arm-pit." At a recent meeting of the New Jersey State Microscopical Society, Professor Lockwood exhibited some specimens taken from a male pigeon which had been kept for a day in fifty per cent. alcohol. The larvæ had been kept for five or six days in seventy-five per cent. alcohol before they were examined. Each specimen presented a crater-like depression with a slightly puckered edge; from the bottom of this crater, a petiolate body bearing a flattened knob, in the centre of which appeared a distinct oval pore, was observed to rise, and this little organ continued to retract and project itself "with a slow but perfectly rhythmical motion," until, the alcohol evaporating, its movements ceased.

It must not be forgotten that, with very rare exceptions, these parasitic organisms must find their way into the bodies of their human hosts only in company with food or drink, and that the several processes of mastication and of gastro-intestinal digestion, as these can and should be performed by healthy people—not to mention that of cooking, which in most cases precedes the others—are a very efficient means of securing the destruction of the vast majority of such unwelcome intruders. It is true that such an instance as that just cited, in which an entozoon in its early larval stage survived several days' immersion in alcohol considerably above proof, seems to afford evidence not only of depraved tastes, but, what is of more importance, of the possession of a remarkably persistent vitality. We do not know, however, what would have been the result of subjecting it to the fiery ordeal of the digestive action of a healthy human stomach. Herein possibly lies a hint for hopeful investigation and enlightenment. Let the rival inventors of the various pepsins and other digestive ferments now so freely advertised take steps for publicly demonstrating the efficiency of their various preparations upon selected specimens of such parasitic organisms as have not yet been definitely classed in respect of their power of wreaking mischief upon possible human hosts. If the parasite prove to be one certain of succumbing to the peptic forces of his unwilling entertainer, the public will only have learned another lesson in the advantages of the pursuit of health, and will know that their greatest safeguard against the evils which they have lately come to dread is to so order life that good digestion may always wait on appetite. On the other hand, should the entozoon emerge from the test unscathed, it will be entitled to increased respect, and its inferior hosts will be deservedly regarded with something stronger and better founded than mere suspicion; always assuming, of course, that the digestive ferments employed in these investigations possess the peptic virtues claimed for them.

London School of Medicine for Women.—The Dean of Westminster, presided on the 10th instant at the annual distribution of prizes at this school. Mrs. Garrett Anderson stated in her report that there were now forty women on the Medical Register, and Mr. Stansfeld, M.P., the treasurer, said that the expenses of the year had been less by 300*l.* than in the previous year. The students' fees, however, covered only two thirds of the expenditure. The chairman delivered a brief address, after which the prizes were distributed.

REVIEWS AND NOTICES OF BOOKS.

ENGLISH SURGERY.[1]

[Second and Concluding Article.]

In a former notice we made a few general remarks on the editorial arrangement of this System, and briefly reviewed some of the articles contained in the first volume. We shall now conclude our task by noticing, as concisely as possible, some of the more important articles contained in the second and third volumes. As in the first volume, we find that many of the articles are merely reprints of those contained in the two former editions, and as such they cannot claim to be considered as either complete or so modern as might have been wished in such a representative work as the present. In the article on Diseases and Injuries of the Eye, very little change has been made, although it has had the advantage of being "edited" by Mr. Hulke, a most able and distinguished ophthalmologist, and although immense progress has been made in this department, since Mr. Dixon first laid down the lines of the original article. We are sorry to see perpetuated in this present article one piece of advice which we confess we have hitherto regarded with indulgence as probably an oversight in the last edition. In the section on Syphilitic Iritis in Infants, when speaking of treatment, the Editor says, "I would remark on the absolute necessity for their being suckled and not brought up by hand. The milk of a healthy wet-nurse would, of course, be preferable to that of an infected mother; but in the lower classes of society, among whom this disease is exclusively met with, the services of a wet-nurse can hardly be obtained." We sincerely hope that no practitioner of medicine of the present day would deliberately put a syphilitic infant to a healthy wet-nurse, in whatever station of life it happened to be born. The nurse would run a great risk of infection, and the doctor who advised such a procedure would probably be visited with heavy penalties in any lawsuit which might arise under the circumstances. Our own experience leads us to think that the mother is the best nurse in these cases, and that the infant will thrive notwithstanding. The mother certainly will take no harm, and this is more than can be said for a healthy wet-nurse. "Mercury should be given at once; and as hydr. c. cretâ is very uncertain in its chemical composition, I always make use of calomel. . . ." On this point also we must join issue, believing as we do that grey powder, when prepared by a careful and competent chemist, may be relied on as a most safe and efficacious preparation, and one which can be continued for a far longer time than calomel. In any case, mercurial inunction is more useful and more easily applied than either, and "in the lower classes of society" this is a matter of great consequence. The section on Tumours of the Choroid and Retina might well have been enlarged, and the minute pathology more carefully treated. A few words, too, on tubercle in the choroid, and some general remarks on optic neuritis as a diagnostic sign in various conditions of the brain, with and without injury, would have added much to the value of the article, and would have been quite as much in keeping with the surgical nature of the System as, say, chlorotic retinitis. One word concerning the

[1] A System of Surgery: Theoretical and Practical. Edited by T. Holmes, M.A, Cantab., and J. W. Hulke, F.R.S. Third Edition, in 3 Vols. London: Longmans, 1883.

drawings. They look as if they were re-impressions of the plates used in the last edition, and cannot now be considered as typical of the diseases they pretend to represent. Whatever may have been thought of them when originally drawn, ophthalmoscopy and disc portraiture have made such strides since then, that they can hardly now be regarded as satisfactory.

Mr. Dalby has re-written the chapter on Injuries and Diseases of the Ear. It is short and concise, yet full of practical detail and suggestion. The advantage of this plan (of re-writing) over that more generally adopted throughout the work of interpolating notes in brackets or otherwise, is abundantly manifest, and the reader is never at a loss to know to whom to attribute the statements he meets with in reading for information. The chapter on Diseases of Muscles is edited by Mr. Barker. He follows in the lines of his predecessor so exactly as to include in this chapter infantile paralysis, and pseudo-hypertrophic paralysis, though these conditions are now known to depend on nerve lesions. The pathological nature of the former lesion especially has been elucidated since the second edition of the System was issued. On the other hand, a primary disease of muscle, sterno-mastoid tumour, is not even referred to. Dr. Brown Séquard, who in former editions wrote on Diseases and Injuries of Nerves, in association with Dr. Lockhart Clarke, has now sole charge of these interesting affections. His essay is divided into three parts: (1) The immediate effects of nerve lesions; (2) The remoter consequences; (3) Suture and stretching of nerves; the last-named section being, of course, quite new. Throughout, there is an elaborate study of authorities, besides an immense amount of personal experience brought to bear on the subject matter; from the English standpoint, however, some of the views expressed are rather heterodox. In many places the author palpably betrays his foreign nationality, while his style throughout lacks much of the lucidity and elegance of diction which, with the notable exception of Professor Max Müller, can only be expected from one accustomed to write and speak English as a mother tongue.

The article entitled Orthopædic Surgery only deals with the subject very partially, and the reader has to refer to several other essays to supplement the information contained therein. Dr. Little's article is chiefly on club-foot, and analogous muscular or tendinous contractions, with a short account of genu valgum, and its mechanical treatment by instruments (the question of osteotomy is discussed elsewhere.) The author's views on the causation of club-foot are quite unaltered. He appears to regard the congenital and the non-congenital (the acquired) form as practically identical, and as the latter is so obviously the result of impaired nerve function, either local or central, he concludes that the former must necessarily have a similar origin, and that "primordial malformation" and "pressure of the walls of the uterus" upon the affected limb are quite untenable as causes of the deformity. It is impossible to enter here into a discussion on this subject, but if the deformity always depended on a lesion of "certain ganglionic cells in the medulla spinalis," it is obvious that the author's statement that "the completeness of recovery in the great majority of cases of congenital varus constitutes one of the triumphs of surgical art," would hardly be true. Nothing is said about the result of treatment of the acquired forms: of those especially which follow an injury to a nerve, or those—the adaptive forms—of talipes, which frequently follow infantile paralysis. In this class of cases, the contrast is most marked—the cold, withered limb, which appears steadily to shorten as the patient grows, the constant tendency to relapse after years of unremitting care the moment this care is relaxed, are so many points of difference which appear to us conclusive proofs that the congenital form of talipes—in the vast majority of instances—differs radically from the acquired form.

The article on Diseases of Joints, which has had the advantage of being re-written by Mr. Barker, is systematic in its arrangement, while comprehensive and ample in detail. To the question, whether it is possible to diagnose between the femoral and synovial forms of hip disease, he answers in the affirmative as regards the earlier stages. This question of determining the precise seat of the disease is one of great importance; we confess that hitherto it has baffled us, and the more we see of the disease the more we doubt the possibility, *especially in the early stages*, of saying in any given case whether the disease has commenced in the bone, or in the soft structures connected with the joint. In a few cases of very acute onset, it is true, a reasonable guess can be made; but in the majority of cases, coming on insidiously, and often with a very imperfect history, we are fain to admit that there is little to differentiate one form from another. Mr. Barker is also responsible for Diseases of the Spine. This essay, too, has been carefully revised, and in some points remodelled, and constitutes a very excellent account of a very troublesome disease. Speaking of Sayre's plaster jacket, the author says, "This corset is unsuitable for infants and very young children." In this, though staunch advocates of the jacket, we quite concur. Fortunately spine disease is exceedingly rare, in our experience, at this tender age.

Mr. Haward's article on Diphtheria and Croup is a very fair though brief statement of the relations of these diseases (if not identical) to each other. He acknowledges the value and the use he has made of the Report of the Royal Medical and Chirurgical Society, which attracted so much attention a few years ago, and his own views on the pathological questions involved are very nearly identical with those expressed in that report. While taking, as we are disposed to do, a broad view of the term "surgery," we are nevertheless somewhat surprised to find such a chapter as this in the System, in the arrangement of which such a "rigorous economy of space" has had to be so strongly enforced. On the other hand, we observe, with disappointment, that the surgical aspect of diphtheria is hardly touched on. It can scarcely be maintained that the indications for tracheotomy are laid down as one would expect to find them in a work which professes to take high rank as an exposition of the theory and practice of English surgery. Again, the question of after-treatment is not even alluded to, although by common consent the success of the operation depends entirely on its being carefully and appropriately carried out. When such an important subject as this is passed over in silence in our leading work on surgery, we can hardly be surprised if statistics continue to justify Mr. Haward's remark, "that the fatal termination is not averted to any great extent by this operation."

Mr. Birkett's essay on Hernia is one of the most practical and valuable in the volume, and is evidently the work of an author who is master of his subject. A similar criticism applies to Mr. Holmes' essay on Diseases of Arteries, with which the third volume begins. The whole subject of arterial disease, including, of course, aneurysm, is here considered in an exhaustive and authoritative manner. In no other language is there such an able dissertation on this subject. Sir Henry Thompson's articles on Lithotomy and Lithotrity, are what one would expect from such an experienced operator. The short essay on Calculus in the Female, however, is not of equal merit; it is theoretical rather than clinical, and lacks the personal character which distinguishes the other papers by the same author. Mr. H. Lee's article on Venereal Diseases is decidedly below par, being a very poor exposition of the subject

as it at present stands. The chromo-lithographs, if not actually misleading, require a considerable exercise of the imagination to see in them the typical conditions which they are supposed to represent. Among the articles in the appendix, we find the Surgical Diseases of Childhood, by Mr. Holmes, which has not by any means been brought up to time; it includes sections by Mr. Brodhurst, and Dr. Little. The chapter on Surgical Diagnosis and Regional Surgery, by Mr. Godlee, is an able summary of the application of anatomical facts to practical surgery, which we need hardly remark is characterised by the accuracy that distinguishes all Mr. Godlee's essays. We may conclude by saying that the volumes throughout are embellished with woodcuts, and that there is a copious and well arranged index, which makes reference to any of the subjects both easy and complete. The printing is clear, and very few clerical errors have been passed over. Messrs. Longman deserve credit for the manner in which the work has been issued.

ABSTRACTS AND EXTRACTS.

THE CHOLERA GERM.

A WRITER in *Nature* for July 10th, whose initials, "E. K.," give a very sufficient clue to his identity, subjects Dr. Koch's discovery to a more searching criticism than it has yet met with.

All we can say, he writes, is that Koch has shown that in cholera evacuations there exist, besides micrococci and straight bacilli, other organisms also characterised by this —that they are curved or comma-shaped. Whatever else has been said by Koch, his followers, and critics, scientific and daily papers, as to these "comma-shaped" bacilli being the cause of cholera, is simply and purely a supposition, which, as we shall presently show, is wanting in the most essential elements. First and foremost, Koch has been unable to find anything of this "comma-shaped" bacillus in the blood or tissues in any stage of cholera. Now all experience on cholera teaches that, whatever its cause may be, the alimentary canal is not the only passage through which the cholera-poison enters the system, but that its entrance through the respiratory organs is also an established fact. For this reason it is necessary to assume that, as in other infectious diseases, it passes in the stage of incubation of the disease through the blood and system. The symptoms of cholera, the whole nature of the disease, shows that it is not a local distemper of the alimentary canal, but that the latter is merely a symptom of the malady as much as in typhoid fever the distemper of the ileum and spleen, or in scarlatina that of the skin, throat, and kidney. Had Koch found the "comma-shaped" bacillus in the blood or the tissues, *e.g.* the blood-vessels of the alimentary canal, mesenteric glands and spleen, the nature of this "comma-shaped" bacillus would have been as obscure as ever, but still there would have been some sure element in the chain of surmises. Of course it might be argued, and as a matter of fact it is argued by Koch in the reports to his Government, that the bacillus, having found entrance into the cavity of the intestines, there multiplies, and produces some ferment, which, absorbed into the system, sets up the whole chain of appearances constituting the symptoms of cholera. This is quite possible, and to a certain limited extent is borne out by experience, notably in the case of putrid or pyæmic poisoning, where, owing to the presence of putrefaction in a wound, the products of putrefaction—the sepsin—absorbed in sufficient quantities into the system, create the above disease, often terminating fatally. In this case no specific organisms are detected in the blood or tissues; their presence is limited to the wound only, and their effect is merely this, that some ferment—ptomaine or some other substance—produced by them is absorbed into the system. That this should also be the case in cholera is, as we just said, possible, but it is not probable, for the simple reason that the cholera virus in a large percentage of cases enters the system by the respiratory organs, and therefore it must be assumed in these instances to pass into the general circulation, and consequently, if it is to be identified, must be identified in the blood or tissues. The practical consequences of an assumption that the cholera-virus passes into the system exclusively by the alimentary canal, and that it has its breeding-ground in the latter only, are so great, that before acting on such an assumption the basis for it ought to be established, which it certainly is not.

Secondly, is it a well-established fact that this "comma-shaped" bacillus is present only in cholera evacuations? If it should be found that this bacillus is absent from the alimentary canal in all other diseases, then we could at best recognize it as pathognomonic, but it by no means follows that it is also pathogenetic. I have lately had the opportunity of inspecting this "comma-shaped" bacillus in specimens prepared by Koch, from the rice-water evacuations, and also in artificial cultures, and I have fully convinced myself of its reality. But I possess prepared specimens of evacuations of patients suffering from severe diarrhœa (in an epidemic outbreak of diarrhœa in adults in Cornwall, in the autumn of 1883, and investigated by Dr. Ballard, Inspector to the Local Government Board), in which specimens, besides micrococci and straight bacilli, there are undoubtedly present bacteria which, in shape and size and mode of staining, so closely resemble the "comma-shaped" bacilli of cholera that I am unable to discover a difference between them. I have, however, not made any artificial cultivation of them, and therefore cannot say whether there exist any differences between the two, notably as regards their mode of growth.

Here is one other point to which we wish to draw attention: as Cohn (*Beiträge zur Biologie der Pflanzen*, Heft ii.) has shown, and as is now generally accepted, a rod bacterium which is characterised by being curved is regarded not as a bacillus but as a vibrio: and it is not quite clear why, unless for the sake of novelty, Koch, generally accepting Cohn's terminology, should in the case of the cholera bacterium have deviated from it, and should not rather have spoken of it as a vibrio, because a vibrio, and particularly a *Vibrio rugula* (sp. Cohn), is the organism which he describes as a "comma-shaped" bacillus.

SURGERY.

TREATMENT OF HÆMORRHOIDS.—Prof. Verneuil observed in a clinical lecture at La Pitié (*Gazette des Hôpitaux*, May 8), that just as once he had observed that while the classic works on surgery took many pages on the treatment of ingrowing nail, this really could be told in six lines or less, so the treatment of hæmorrhoids, upon which so much has been written for so long a time, may be summed up in two methods, viz., cold enemata and gentle laxatives in mild cases, and forced dilatation in the severer cases. Still upon no disease has there been more written than upon the importance, the prognosis, and the treatment of hæmorrhoids. The earliest writers protested against any surgical intervention whatever, regarding these tumours as a benefit and their suppression as a danger. And even at the commencement of this century, the advocates of abstention maintained that they acted as a kind of emunctory, attributing to them a function analogous to menstruation, the arrest of which might have its inconveniences. Others with more reason asserted that their removal was attended with danger, and it is true that some of the procedures employed, when the surgical arsenal was less complete than at present, might be dangerous. At that time incision was resorted to as a palliative when the hæmorrhoids appeared externally; and Prof. Verneuil, when Lisfranc's interne, practised this operation which sometimes was followed by fatal pyæmia, and at all events remedied nothing. Excision was next resorted to which was just as dangerous by reason of the formidable hæmorrhage it gave rise to, necessitating the very objectionable practice of plugging the rectum, persons dying either from the bleeding or the plugging. Ligature, which succeeded to excision, had also its dangers, for it sometimes proved fatal, giving rise

to extremely violent pain, the formation of gangrenous *débris*, sometimes followed by phlebitis and pyæmia. Later the actual cautery was resorted to, and more than one of M. Verneuil's colleagues still employ it; but, although the procedure was efficacious and not dangerous, the suffering which it entailed, prior to the discovery of chloroform, was too horrible to allow of it being persisted in. An important improvement was produced by the ecraseur, but this, although it gave rise to some excellent results, had the serious inconvenience of being succeeded by a circular cicatricial ring, which in the end gave rise to stricture of the anus, although in a less degree than after the actual cautery. To obviate this, the hæmorrhoidal protrusion was divided into two, three, or four segments, or caustic points (made of Vienna caustic or chloride of zinc, &c.), were inserted. Prof. Verneuil also obtained good results without much pain, from punctuated interstitial cauterisation by means of the galvano-cautery, and still better ones from the thermo-cautery, plunged into the protrusion at various depths; but from an early period he employed Chassaignac's ecraseur both for operations on the tongue and for hæmorrhoids; and at this time he discovered the true pathogeny of hæmorrhoids by injecting them in the dead body with suet and Prussian blue. But it was not till twenty years afterwards that he made any use of his discovery. In the meantime, Recamier had devised the treatment of fissure of the anus by dilatation; and Maisonneuve adopting this practice extended it to hæmorrhoids when very painful, and in this way cured both these and the fissure of the anus which so frequently complicates them. Prof. Verneuil and Dr. Fontan, of Lyons, both resolved, unknown to each other, to put Maisonneuve's practice into force, even when the hæmorrhoids were unattended with fissure. This recalled to the mind of the former his researches on the pathogeny of hæmorrhoids. According to these, hæmorrhoids are caused by a strangulation of the superior mesenteric veins which traverse the wall of the rectum, within a muscular ring, and then expand over the mucous membrane of the gut. This strangulation gives rise to the formation of a more or less voluminous trunk, just as the ring of the soleus muscle, by a strangulation of the veins, causes varices of the leg. Thus, it suffices to cause a cessation of this muscular contraction to relieve the strangulation, and to allow of the hæmorrhoid emptying itself and the circulation being re-established in its normal condition. The violence employed in forced dilatation causes the cessation of the contraction and the radical cure of the hæmorrhoids. In order that the dilatation may succeed, it is not sufficient to practise it merely by the fingers, which act only on the lower fibres of the rectum. It must be practised (the patient being placed under chloroform), first with Ricord's speculum and then with that of Lisfranc, which permits a sufficient dilatation. It should be made slowly and progressively for about half-a-minute. The result is marvellous, a radical cure being obtained without any danger in a week. Dilatation is the operation *par excellence*. If the hæmorrhoids are sphacelated, the dilatation must be delayed until all complications have disappeared.

Ligature of the Common Iliac.—In an article in its number for April 5th, the *Philadelphia Medical News* gives a summary of the results of this operation in 79 recorded cases, not including cases by Beugnot, Dummreicher, Lamprière, and Medoro, the original references to which were not attainable by the compiler. Grouping these cases into four classes, it is found that the vessel has been tied under the following conditions: — (1) For hæmorrhage, whether primary or consecutive to the ligature of other trunks, or during the performance of other operations: 28 cases with 24 deaths (35·71 per cent.) and 4 recoveries. (2) For the cure of aneurysm: 43 cases with 28 deaths (65·11 per cent.) and 15 recoveries. (3) For pulsating tumours simulating aneurysms: 5 cases with 4 deaths (86 per cent.) and 1 recovery. (4) As a preliminary step to prevent hæmorrhage during the removal of a tumour or amputation at the hip-joint: 3 cases, all proving fatal. "With such a gloomy record before us (a mortality of 74·68 per cent.), we cannot endorse the view of Packard, that it would probably be sound surgery to resort to preliminary ligature of the common iliac to prevent hæmorrhage at the hip; nor can we agree with Kümmell, who holds that the procedure is preferable to ligature of the external iliac, for aneurysm of that vessel seated high up, and of the femoral artery, because it is far less liable to be followed by gangrene of the lower limbs, than the latter operation."

Nocturnal Incontinence of Urine.—Mr. J. F. Anderson, writing in the *Australian Medical Journal* for March, calls attention to a plan of treatment which he says he has found very successful, and which consists in setting in motion an electrical current whenever the smallest quantity of uriue is passed during sleep, inducing contraction of the perinæal muscles, stopping the flow, and awaking the patient, so that he can empty the bladder voluntarily. "Placed at the head of the bed I have a battery, attached to the poles of which are two long insulated wires, that pass underneath the pillow and down the patient's back, terminating in two small exposed copper loops, placed at a little distance apart on the perinæum. One of these wires before reaching the perinæum is brought round to the pubes, and then passes down inside a small indiarubber bag, shaped like the upper part of an ordinary male urinal, but closed at the bottom. At the lowest part of the bag this wire is filed clean through, leaving the two metallic ends exposed, and about an eighth of an inch apart. Into this bag the penis is put. Now set the battery in motion, and let the patient go to sleep. As long as the bag is empty no current passes, but let the smallest drop of urine be voided, it immediately passes to the bottom of the pouch, fills the interspace between the filed ends of the wire, and so completes the circuit—the current passing through the body from one copper loop to the other. Immediately the perinæal muscles contract, and the patient is awakened. After a little he comes to associate passing of urine while asleep with getting an electric shock, wakes up, and so a cure is produced. Of course there are straps, buckles, &c. required to keep everything in place."

Dislocation of the Tendon of the Long Head of the Biceps.—In an elaborate and interesting article published recently in the *American Journal of the Medical Sciences*, Dr. White, Surgeon to the Philadelphia Hospital, enters into a critical review of all the supposed cases of this accident which have been hitherto published, and arrives at the following conclusion:—"A careful study of the foregoing evidence has convinced me of the impropriety of basing upon it either a dogmatic assertion or denial of the existence of this lesion. The Scotch verdict of 'not proven' represents the opinion at which I have arrived, and which may be more formally expressed as follows:—Although for more than a hundred years cases of the supposed luxation have been reported or alluded to by surgical writers, yet they have been so poorly observed or so carelessly described, that they fail altogether to carry conviction." He follows up this retrospect by the relation of a case which has occurred in his own practice, and which, by the carefulness of the observations that were made, and the minute analysis of its symptoms, carries a conviction that the diagnosis was correct. Still, the narrator is not too dogmatic in the assertion that it is a true example of this dislocation. At all events, it is a most instructive description.

Gonorrhœa.—Dr. Constantin Paul recently stated at the Paris Therapeutical Society, that in the treatment of gonorrhœa he now employs injections of corrosive sublimate, as recommended by Dr. Fauti (three solutions being used, containing respectively 1·40, 0·60 centigrammes, and 0·12 grammes of sublimate to 100 grammes of water), and the results obtained are very remarkable. He observed that the isolation, culture, and even inoculation of the microbe of gonorrhœa, to which the name of *gonococcus* has been given, would seem to have demonstrated the specific character of the micro-organism; and experiments have shown that a solution of sublimate in the proportion of 1 part to 20,000 effects its certain destruction. A trial of injection of this microbe "accepted by a woman," made by M. Paul, did not give conclusive results, inasmuch as the acute urethritis, which was produced after five days' inocu-

lation, disappeared in 48 hours He is continuing his researches, and in the meantime recommends his colleagues to investigate the efficacy of the 1 to 20,000 parts solution in various stages of gonorrhœa.—*Gazette Hebdomadaire*, May 2nd.

Treatment of Buboes by Aspiration.—In a note to the *Indian Medical Gazette* for June, Mr. Weston, of the Meerut Hospital, states that he has seen two cases of bubo successfully treated by the late Surgeon-Major Hogg, by means of the pneumatic aspirator. "The men," he says, "went out of the hospital much sooner than they would have done had the buboes been laid open. In one case the operation had to be repeated once. A pad and bandage were used after the pus had been drawn off. In our military hospitals, where the ordinary plan of laying open the bubo is practised, one often sees the resulting sore take on an unhealthy action, and, as a consequence, the men are kept in hospital for several months. It would be well, therefore, to give the aspiration treatment a thorough trial."

Iron *versus* Silver Sutures.—Dr. John Roberts, writing in the *Polyclinic*, Feb. 15th, says "what I call the 'suture folly' is the adherence of so many to the theory that silver wire only should be employed for suturing purposes. Nothing could be more fallacious. Do we use silver hare-lip or acu-pressure pins? Why then employ silver when iron wire is stronger and far cheaper? When large and gaping wounds require the sutures to stand much tension, silver wire must be very thick. Iron wire of much smaller diameter, and therefore much more flexible, gives an equally strong suture, and in addition to being better adapted to the purpose, is much cheaper. I recollect that, in hospital practice, nearly eight years ago, I discarded silver wire, which cost one dollar for each small coil, and bought, at a hardware store, enough iron wire, for 10 or 15 cents, to last many months. The nicest iron wire which I have seen, and which I now use for the purpose, because it is strong, very flexible, and free from elasticity, can be bought for 10 cents a spool. If it become a little rusty, it can be rubbed clean in a moment."—*Louisville Medical News*, May 31.

Modern Treatment of Hydrocele.—An able article in the *Philadelphia Medical News* for May 3rd, in which a review is given of the various modes of treating hydrocele which have been adopted of late years, and proof adduced that antiseptic incision, so frequently resorted to in Germany, is by no means the safe and radical cure which it has been asserted to be, is terminated by the following general statement:—"An analysis of the facts contained in the preceding paragraphs warrants the conclusion that antiseptic incision of the sac is too severe for ordinary cases, and that it should be reserved for those in which the vaginal tunic is much thickened, and for examples of recurrence after the employment of simpler methods. Although the injection of from 30 to 60 grains of liquified carbolic acid, as a curative measure, has not been as yet sufficiently tested, we think that we are justified in predicting that it will prove to be the simplest, safest, and least inconvenient of all the measures heretofore employed for the cure of the very common affection under consideration."

An Hereditary Malformation.—In the June number of the *Glasgow Medical Journal*, Dr. J. S. Muir records a remarkable instance of a family predisposition to deformity. Mr. M. says that his great-grandfather and grandfather both had some deformity of the feet or hands, as his father had told him so, but he does not know the exact nature of it. His father had a supernumerary digit on the left hand, and on his right foot he had six separate and complete toes. His uncle had six fingers on the left hand, and six complete and separate toes on the right foot. This man (the uncle) had five daughters and three sons; they all had six fingers on each hand, and six toes on each foot, one had webbed fingers. Mr. M. himself has an additional little finger on the left hand, and an additional little toe on the right foot. His brother has six fingers on each hand, and six toes on one foot and seven on the other. Mr. M's sister has no deformity. Mr. M. has had eight children, of these three girls and one boy were not deformed. One boy (the second child) had six toes on each foot. The sixth child, a girl, had an additional little finger on the left hand, the fifth metacarpal seemed to bifurcate near its proximal end, its shorter limb supporting the additional finger. Her right hand had a small abortive little finger. Her right foot had six complete and separate toes, her left foot was normal. The seventh child, a boy, had on his right foot an additional small toe united to the other, but with separate phalanges. The left foot had six separate toes and a well marked talipes varus. The left hand had an additional finger articulating with the fifth metacarpal bone. The right hand had an abortive little finger extra, and a webbed condition of the ring and little finger. The eighth child, a girl, had six fingers on each hand, both feet had double great toes, in the left foot the individual phalanges were quite separate, in the right the individual phalanges were inseparably united at their lateral borders, and there was one nail notched down the centre and not two separate nails as in the other foot.

Operation for Varicocele.—Relating two cases of varicocele which occurred at his Clinic at the Roosevelt Hospital, New York, Dr. Sands (*New York Medical Journal*, March 29th,) describes the following operation, which he has performed in many cases, as both simple in execution, and very satisfactory in its results. "It aims to obstruct the distended veins by a ligature of catgut applied subcutaneously. It is made to surround the veins by first transfixing the scrotum with a needle, and carrying the thread between the vas deferens and the veins: the needle having been passed through the scrotum, carrying the thread with it, is then passed in the opposite direction, from behind forward, entering and emerging through the same cutaneous punctures, but, instead of passing between the vas deferens and the veins in returning from behind forward, it is made to pass on the opposite side of the veins, so that when the ligature is tightened the veins are firmly constricted. The ligature and dressing being antiseptic, no suppuration follows. It is necessary to be sure not to include the vas deferens, as its functions may be destroyed. The operation itself is not very painful, but severe pain, which must be allayed by opium, usually follows it. I am not accustomed to administer ether before the operation."

REPORTS OF SOCIETIES.

ACADEMY OF MEDICINE IN IRELAND.

Medical Section.

Friday Evening, May 16th, 1884.

Dr. Henry Kennedy in the Chair.

Double Optic Neuritis with Paralysis of both Olfactory Nerves and Sensory Division of Right Fifth Nerve.

Mr. John B. Story exhibited a patient suffering from atrophy of both optic nerves and paralysis of the olfactory nerves, and of the sensory division of the right fifth nerve. The patient was an unmarried woman, aged 32, who had enjoyed good health till the winter of 1882–3, when she began to suffer from a violent pain in her head. The pain later on became so violent as to confine her to bed, where she remained for some months in the spring and summer of last year. She became after some time completely unconscious, and when her consciousness returned (about July, 1883), she found her senses of sight and smell totally lost, and sensation absent from the right side of her face, and the little finger and ulna side of the ring finger of her right hand. She noticed a defect in the sense of taste at the same time in the anterior portion of the tongue at the right side. The examination of the patient completely established the truth of her statements, with the exception of the paralysis in the skin of the fingers, which did not appear to have any real existence, at least then. Corneal and conjunctional sensibility was completely absent, and the palpebral and lacrimal reflexes connected with it,

while the cornea itself was perfectly healthy, and the tension of the right globe rather above that of the other eye. He considered the case to be one of cerebral tumour, but could not assign any definite locality to the supposed new growth. The atrophy of the nerves was undoubtedly produced by optic neuritis. He commented on the various theories explanatory of the connection between papillitis and brain disease, and upon the current views as to the production of neuro-paralytic keratitis. The secretion of saliva from the right parotid gland was, so far as careful testing with vinegar could ascertain, completely abolished, that from the left gland being perfectly normal.

The CHAIRMAN would connect the symptoms with a tumour at the base of the brain, implicating particular nerves or parts. There seemed to be less vomiting in this case than usual. He asked, had iodide of potassium been tried.

Dr. C. J. NIXON considered that if Mr. Story was perfectly satisfied there was a lesion of both nerves of smell, and at the same time a lesion affecting some of the fingers of the hand and the forearm, it would be perfectly possible to account for all the phenomena that existed on the idea of an isolated tumour. One of the most difficult senses to ascertain the absence of was that of the sense of smell. It was remarkable to find that with the implication of the sensory division of the fifth nerve there was complete loss of the sense of taste in the corresponding anterior portion of the tongue. This was directly in opposition to a case recorded by Althaus, in which he excluded the fifth nerve as administering to the sense of taste on the antero-lateral region of the tongue.

Mr. STORY, in reply, said the non-persistence of pain not infrequently characterised the growth of tumours of the brain, and the cessation of vomiting too had been not infrequently noticed. He had tried iodide of potassium for some weeks without alteration in the symptoms. In answer to Dr. Nixon, he pointed out that they were all familiar with the fact that loss of sense of smell followed paralysis of the sensory portion of the fifth. In this case a probe might be put up the right nostril without the slightest effect; but if the left were touched in the same way, she shrank with pain. Assafœtida, valerian, oil of cloves, or ammonia had no effect on the right side, whereas on the left she exhibited the movement consequent on inhaling strong smelling salts.

Reflex Paralysis.

Dr. C. J. NIXON read a paper on reflex paralysis, in which he summarised the different views which had been held in favour of, and against the theory of, this form of paralysis. He first examined the class of cases of paralysis which are usually cited as caused by reflex influence, also amaurosis from affections of the fifth nerve, and paralysis of the orbital nerves from a like cause. Having shown that those cases may be explained without reflex mechanism, he next examined the evidence as to the existence or non-existence of reflex paraplegia. Examining the views of Brown-Sequard, Gull, Leyden and others, and the experimental observations on the subject, he directed attention to the absence of any true conception of the mode in which paralysis by reflex action is brought about, except we understand it to be produced by inhibitory influence; so that reflex paralysis, if it have any meaning, must be inhibitory paralysis. This name had at least the advantage of suggesting the way in which the phenomena of the case were produced. Dr. Nixon thought, however, that there was no necessity to admit the existence of an inhibitory paralysis, as taking for instance the cases recorded, reflex paraplegia; they could arise in three different ways—as an ascending neuritis which sets up myelitis, from extension of inflammation along the veins to the spinal cord, or from a lumbo-sacral neuritis which descends along the sciatic nerves.

Dr. MCSWINEY called attention to the so-named reflex paralysis following wounds, of which Dr. Mitchell had given many examples, including paralysis affecting the upper extremities, right or left, where a wound had been received in the lower extremities, right or left.

Dr. BENNETT considered Dr. Nixon's paper open to the objection characterised by lawyers as pleading double. In his hospital experience Dr. Nixon had never seen a case of reflex paralysis, while he quoted instances of inhibitory nerve influence which he held to be another name for reflex paraplegia. It was difficult, therefore, to follow his argument.

Dr. WALTER G. SMITH, looking at Dr. Nixon's conclusions as a whole, said his views must in a great extent be felt to be in accord with those of modern teaching, supported by the pathology of nervous diseases; so that very few, if any, physicians or surgeons would now accept Brown-Sequard's teaching in his interesting lectures on paralysis of the lower extremities. To some, the doctrine of reflex paralysis was a convenient one, as it explained away so many obscure causes. But he reminded Dr. Nixon of the danger of the logical fallacy of taking the part for the whole. Dr. Nixon, as an iconoclast, had proceeded to demolish the theory of reflex origin. It might be true that he had done so in part, but it might not be true he had demolished the whole, especially considering their enormous ignorance of nervous physiology. Caution must therefore be observed in dogmatising too strictly as to what could or could not happen in the domain of the nervous system. Dr. Nixon did not allow sufficiently for the extremely important effects of local sensory irritations, which include both the skin and internal skin or mucous membrane; in other words, stimulation of a limited area of the sensory nerves. The curious thing was that no matter what part of the skin was stimulated similar effects followed. It was known that deaths occurred during early stage of inhalation of anæsthetics. Again, tickle the inside of the thighs and in a bright light the pupils would be seen to dilate. It was difficult to say what channel that influence travelled up, yet it was the influence of reflex action. Indeed, the number of channels by which the vomiting centre might be approached was notorious. Modern teaching had undoubtedly narrowed the field of reflex diseases, and while they should be thankful to those enquirers who had cleared away so much obscurity, it was too soon to urge anything positive as to the phenomena being a reflex arrest of function without speculating that the mechanism by which it was produced might not arise in the body.

The CHAIRMAN called Dr. Nixon's attention to a clinical aspect of the question. He had himself put on record a host of cases of children, from five to seven months old, who had suddenly lost power of one arm, and in these the scarification of a gum or an active purge produced a cure at once. Thus the reflex paralysis was in those cases due to irritation of the mouth or the accumulations in the intestines.

Dr. NIXON replied that he had used the term "inhibition" first as a step in getting rid of the theory of Brown-Sequard that the paralysis was due to reflex spasm of the blood vessels of the spinal cord. If not to that, it was due to something else, or to a number of things, and he took inhibition as one to which it might be due; and he had said there was no necessity for introducing this explanation of the theory of disease at all, inasmuch as it had been established that the paraplegia assumed to be reflex was due to causes which had been ascertained as an ascending neuritis, or a descending neuritis, or a neuritis established by the travelling up of inflammation along the veins. The received explanation of the results of the operations he had cited was that they were due to what was understood as the phenomenon of inhibition. If they were not satisfied that the cases of paraplegia recorded had most distinct and positive pathological lesions to explain them, then the theory of paralysis by inhibition was the one that would satisfy the scientific requirement best. But in the absence of necessity, there was no use introducing a new term into medical pathology. With regard to Dr. Walter Smith's observations as to the effect of stimulation, Brown-Sequard had mentioned that peripheral stimulus might act in three different ways, and it might influence secretion, or the condition of the blood vessels, or the muscles. In his papers before the Section he had confined his observations to the condition of the muscles that might be said to be influenced by peripheral irritation. He did not discuss the condition of the blood vessels, such as would be brought about from irritation of an extensive surface of the skin following a blister, &c. Dr. Smith seemed to have dealt with spasms

as paralysis. There was not the slightest doubt that peripheral irritations of various kinds, worms in the intestines, and teething, produced convulsive phenomena; but it was quite a different thing with irritation transmitted to the cord. Irritation was supposed to pass to the motor area, and yet the usual result was not attained. Although he had seen a great many cases of paralysis, he had never seen one that he could connect with any of those cases of local irritation such as teething, or that got well on suddenly lancing the gum, and he did not see why paralysis should be cured by such a simple procedure. The object of his paper was to show that such a thing was a physiological impossibility, and he did not believe they had records of paralysis produced by peripheral irritations such as worms in the intestines or teething.

EPIDEMIOLOGICAL SOCIETY.

WEDNESDAY, JULY 9th, 1884.

Inspector-General LAWSON in the Chair.

Small-pox and Vaccination.

DR. CORY, referring to the "The report of the Sub-Committee appointed to investigate the conditions affecting the protection against small-pox afforded by vaccination," which will be published at length in the Transactions of the Society, stated that the general conclusions at which they had arrived were that the protection, commencing with the first insertion of the lymph, increased day by day up to the ninth day, after which it gradually declined during a course of years. They believed that at the time and immediately afterwards the protection afforded by a single insertion differed little, if at all, from that conferred by several, but that the subject of vaccination lapsed, if he might be allowed the expression ,sooner from this state of salvation in proportion to the smallness of the result of the operation; in other words, that a child vaccinated in one place was for the moment as safe as one done in several, but that the protection afforded was of much shorter duration; and since the poor with whom the public vaccinator had to deal were from prejudice or apathy unlikely to present themselves for re-vaccination, it was of the highest importance that what would in most cases be their only vaccination should be as thorough and efficient as possible in order that the duration of the protection might be prolonged. Referring to a number of experiments demonstrating the progressive character of this protection, he observed that if one insertion were made on each consecutive day during the week, the result of each was more and more modified, that each ran a shorter course than the preceding, all reaching their full development together, but that on and after the ninth day no result whatever could be obtained. He had vaccinated some infants on superfluous fingers, which were amputated on the fourth day after the operation, and found that when these infants were then vaccinated in the usual place, the result was the same, the second vaccination reaching its height on the fourth day *i.e.*, the eighth from the performance of the operation on the amputated member, showing the constitutional effect then produced. On the question of insusceptibility, he stated that he had never met with such a condition among the 15,000 children whom he had vaccinated.

Mr. R. D. SWEETING then read some notes on the incidence of small-pox in each of the first three quinquennia of life, and on the influence of good and imperfect vaccination as shown by the returns of the hospitals for smallpox under the Metropolitan Asylums Board, for the years 1879, 1880, and 1881. In these three years there were 2,209 admissions of children under fifteen years of age, who had been more or less efficiently vaccinated. The numbers reported to have shown evidence of good and of imperfect vaccination respectively were in 1879, 146 and 315; in 1880, 131 and 297; and in 1881, 353 and 967, or a total for the three years of 630 good and 1,579 imperfect vaccinations; the latter forming 72 per cent. of the whole. The standard of good vaccination accepted by the Asylums Board, is lower than that laid down by the Local Government Board, so that the proportion of imperfect vaccinations would be still greater if the latter were taken. Dividing the patients according to age, we find that in the first five years of life the numbers of good and imperfect vaccinations were respectively 50 and 116, between 5 and 10 years, 194 and 497, and between 10 and 15 years, 386 and 966. The liability to smallpox increases in the same ratio in each class though it is always greater in the imperfectly vaccinated; hence the importance of re-vaccination not later than the tenth year for all, but especially for the latter, and earlier in the event of actual exposure to infection. He advocated the restriction of the power of vaccination to properly qualified public vaccinators in view of the scandalous amount of operations, unsuccessful, inefficient, or worse, performed by private practitioners; meanwhile he suggested that since attendance at school is now compulsory, all school children should be subject to inspection, and compulsorily re-vaccinated during the period of school life, earlier or later in proportion to the efficiency of the primary operation. In this connection he referred to a code of regulations enforced by the Board of Health of the State of Illinois in 1882.

Mr. C. E. PAGET followed with a very interesting report of an outbreak of smallpox in Chester, in the year 1774, by Dr. Haygarth, an intelligent physician who appears to have held the position of a self-constituted Medical Officer of Health to that city. The original document, which he handed round, is in the possession of the Regius Professor of Medicine, at Cambridge, but will shortly be reprinted and published. The population of Chester was then about 14,000 the total deaths were 546 or 34 per 1,000, and of these 202 or 14·4 per 1,000 of the population were from smallpox. The whole number attacked was 1,385, and the mortality therefore 14·5 per cent. Of the 202 deaths, 130 occurred in the last quarter of the year, and all were under 10 years of age, 51 being under 1 year, 38 between 1 and 2, 42 between 2 and 3, 49 between 3 and 5, and 22 between 5 and 10 years. Only 1 in 14 of the population escaped the disease, that is, had not contracted it at some time or other, and during the whole period of Dr. Haygarth's observations one-eighth of the total mortality was due to smallpox. Dr. Haygarth hoped much from inoculation, the best age for the performance of which, he found to be between the first and third month.

Dr. WILLOUGHBY read some similar statistics from the elaborate tables of mortality &c., in the city of Breslau, drawn up by Caspar Neumann and communicated by him to his friend Edmund Halley, the English mathematician, whose original MSS. were discovered by Dr. Grätzer, the present sanitary and registration officer of Breslau, in the library of the Royal Society of London. These tables relate to the years 1687–1691 inclusive. The population of Breslau was about 34,000; the total death-rate 34·4 per 1,000; the deaths from smallpox in the five years, 136, giving an average of 27 or somewhat under 2 per 1,000; the greatest number in any one year was 54, therefore very much less than in Chester, but the distribution according to age was the same, showing that in pre-vaccination periods smallpox was, in virtue of its intensely infectious character, a disease of childhood, as measles is now. Of the 136 deaths, 34 occurred in the first year of life, 75 between that and the fifth, 24 between the fifth and tenth, 2 between the tenth and fifteenth, and 1 after 40 years.

Dr. PRINGLE, adducing his Indian experience, observed that in that country smallpox was universal; even settlements of property being postponed until a child has passed the ordeal. Sixty per cent. of infants, and 40 per cent. of older persons die when attacked, and yet no precautions whatever are taken to avoid infection. The mortality after inoculation he put at 6 per cent., but his experience of the completeness of immunity conferred by efficient vaccination led him to put even more faith in it than was usual in Europe.

Dr. CORY, in reply to a question, said that he could find no difference in the visible results of animal and human vaccination, but that to afford the means of future observation on the relative degrees of protection it was his practice to scarify with animal lymph in the form of a cross and to make five separate insertions of humanized lymph.

Mr. MURPHY dwelt on the steady increase in the

mortality of the unvaccinated of late years, which was 14 per cent. in Haygarth's time, 35 in Marson's, and now 44, or in the case of infants, 66.

Mr. Corney asked whether goats could be used instead of calves, which in Fiji, whither he was about to return, were very scarce.

Dr. Pringle doubted this, referring to the severity of the analogous disease among sheep, as pointed out by Mr. Fleming in his able work on "Human and Animal Variolæ."

Dr. Willoughby expressed his great surprise that in a discussion, during which such frequent mention had been made of cow-pox and conjectures put forward as to its relation to small-pox, and the relative merits of the two kinds of lymph had been mooted, no one present had alluded to or seemed to be aware of Dr. L. Voigt's brilliant experiments at Hamburg, and his absolute solution of the question. He, too, had been struck by the apparent clearness of Fleming's conclusions, but was now convinced that they were utterly fallacious. Fleming agreed with the French school in discrediting the opinions of Jenner, and the alleged successes of Badcock, Ceeley, and others in the inoculation of calves with variola, and the evolution of vaccine thereby, and appealed to the disastrous results which followed the attempts of Macpherson in India and Martin at Boston, U.S.A., at repeating them, they having communicated unmitigated smallpox thereby. The French doctrine, he said, was that the sheep and goats suffered from a disease in all its characters resembling human variola, yet not protective against it, whereas the horse, cow, and camel were liable to a merely local affection devoid of danger to life, communicable only by direct inoculation, and yet though so unlike variola conferring immunity against it. This was, to say the least, paradoxical and improbable, but no number of failures to inoculate small-pox in the cow could outweigh one case of undoubted success, and such Dr. Voigt had achieved. After several failures, he had succeeded in inoculating a calf with lymph from a case of virulent small-pox in an unvaccinated patient. The first result was quite insignificant, but as he successively vaccinated others therefrom, the operation became easier, and the vesicles assumed more of the vaccinal character, until by the ninth or tenth cultivation they were indistinguishable from those produced by the most approved Beaugency lymph. After the twelfth cultivation Dr. Voigt's colleagues had no hesitation in using this new strain or stock, and indeed preferred it to all others. In short, Dr. Voigt had vindicated the reputation of our countrymen, Jenner and Ceeley, had proved that vaccine is only variola modified by passage through a foreign organism, and that all so-called spontaneous cases of cow-pox are accidental variolation or retro-vaccination; and hence the "spontaneous" eruption is always found on the parts most handled by man, and at the same time liable to abrasion, viz., the udders of cows, and the heels of horses. No increased energy was imparted to the lymph by a return to the calf, but rather the reverse, whereas there was no evidence of any deterioration of humanised lymph since the days of Jenner. If a new stock be desired, we must repeat the procedure of Voigt, difficult though it be.

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE X.

Clothing.

All articles of clothing admitted into the Health Exhibition profess to have the claim either of hygienic superiority or of historical interest. Certain materials are said to conduce to healthy conditions in preference to others, and these are exhibited and explained, whilst the form and constitution of different garments are the most prominent points which attract notice in the department of healthy clothing.

In materials we have Dr. Jaeger's woollen system largely illustrated in case 277. This German doctor whilst quoting Emerson that "the first wealth is health" says, that health is only to be obtained by clothing the body in wool, which when properly prepared and woven into suitable garments affords the maximum of protection from chill and damp with the minimum of impediment to the exhalations of the skin. Dr. Jaeger not only insists on clothing the body in wool, and discarding every other material, but he advises and supplies woollen bedding and sheets of the finest kind as being conducive to health. He says a sanitarily clothed person—viz., a person clothed entirely in wool, need have as little fear of draughts as of cold or wet, and may safely sleep, so protected, with an open window at all seasons of the year. The particular feature of Dr. Jaeger's special woollen garments, is their delicate and soft texture; they feel like spun silk, and do not irritate the most delicate skin. Adherents to this principle of clothing, and there are already many who have adopted it, call themselves "woolleners," and may be said almost to constitute a sect of believers in a form of the gospel of health. All these special garments of Dr. Jaeger's are of the natural brownish colour of the wool, and are neither bleached nor dyed; they are undoubtedly most agreeable to wear, though certain modifications in their form might reasonably be suggested to suit various figures and tastes. Many who do not feel bound to accept Dr. Jaeger's system in its entirety, yet acknowledge the great advantage of soft fine woollen under-clothing, and we have varieties of woven vests, combination suits, and flannels to choose from.

There are Indian gauze waistcoats, and all sorts of delicate woollen fibres exhibited by Messrs. Thresher and Glenny (317), who took prize medals for this species of sanitary clothing, long before hygiene became the popular subject of the day. Then we have brought before us a dress material which is said to rival Dr. Jaeger's wool in its excellence—the Nonpareil Velveteen (288), which is exhibited by Messrs. Mann and Son, Manchester, and is absolutely manufactured in part before our eyes. The operation of raising and cutting the pile on the fabric is accomplished by a young woman instead of a machine, for the process is said to be too delicate to admit of any but hand labour. The operator is armed with a long and extremely thin knife, which she runs along each fine thread, doing about three yards at every stroke. It takes 50,000 passes with the knife to cut the woven loops of 100 yards each and is work which requires as much skill and dexterity as is given to the manufacture of the best Lyons silk velvet, which indeed the Nonpareil Velveteen closely resembles in its soft and graceful folds, and its peculiar rich sheen.

As to the particular sanitary excellence of this material, which may justify its presence in a Health Exhibition, it is claimed that it is peculiarly hygienic on the score that so rich and elegant a material must of necessity be worn as a plain untrimmed garment, combining lightness and warmth, suitable for wear at all seasons of our ever varying climate. This opinion might be used to endorse many other fabrics of a similar kind, which may be equally healthy, though possibly less attractive. Materials for overcoats, ulsters and waterproofs are exhibited by various makers, made up and unmade. Benjamin and Son, of Ulster House (306), show coats and cloaks declared to be waterproof but not air-tight, and free from all injurious properties. The various forms of these garments and the devices for adapting them to the exigencies of riding or walking are too numerous to be described. In Cases 298, 300, and 305, waterproofs having a sort of velvety smooth exterior, others in æsthetic colourings, and many which boast of weighing next to nothing are to be seen. The Gossamer rubber garments which, though made in America, are exhibited by Messrs. Swan and Edgar (300), can be rolled up into the space of a few inches, are perfectly waterproof, have no offensive smell and never stick together or become soft and worthless, whatever the weather may be. All these are to be seen and purchased in the clothing department of the East Quadrant.

Every article of attire that by any possibility can injure or compress any part of the human frame, is exhibited in an improved and hygienic condition. Straps, such as braces and garters are superseded by other arrangements, and suggestions how to be "beautiful and strong" meet the feminine gaze at every stall. Improved stocking and sock suspenders, adapted to "Hoven's" clip (348) are suitable alike for children and grown-up persons, entirely super-

seding the use of the garter "which always interferes with the return of blood by the veins." Hands, feet, necks, and heads are equally provided for in this hygienic collection; not only are the iniquities of tight, pointed, high-heeled boots and shoes exposed, but digitated stockings with a little place for each toe, like gloves, appeal to many who suffer from the close contact of the toes when encased in an unventilated leather boot. A member of the French Academy has said that "In a woman a corn or a bunion is a crime which cannot be expiated even by a life of torture." It is very therefore necessary to begin early in life to wear truly hygienic foot coverings to avoid so terrible a punishment for ignorance or folly. Of boot and shoe makers who exhibit their special contrivances to this end there are very many. Messrs. Dowie and Marshall (249), whose motto is "the path to health is the foot-path," may claim to have led the way to reform in the matter of boots and shoes. The founder of the firm, Mr. James Dowie, more than sixty years ago commenced business with the determination that whatever shoes he made should be made to the feet. Since that time fashion has ordained all sorts of squeezing distortions for the foot, but Mr. Dowie has continued true to his original intention only to shape coverings for the feet as nature intended they should remain. For more years than most of us can remember, this system of shoemaking has received the approval of enlightened members of the medical profession.

The children's shoes exhibited are excellent, and there can be no doubt that if these boots are to be worn at all their use cannot be commenced too early in life. In all attempts to secure healthy and comfortable boots and shoes, it should be recollected that it is not sufficient they be roomy and large, but that they are made to suit the shape, character. and type of the individual foot. Messrs. Dowie and Marshall exhibit as a specialty a thick waterproof boot, which is ventilated by means of little tubes inserted into the sole, and communicating with the air from above, in order to keep the foot cool, but the advantages of this invention are, to our mind, not very great. In the wake of Messrs. Dowie and Marshall come many other bootmakers of hygienic pretensions. Mr. John Branch, of Bethnal Green Road, exhibits a reversible boot (262), which he has patented, its peculiarity being that each boot is made so that it can be worn on either foot, and thus the uncomfortable sensation arising from boots wearing over on one side is avoided, together with the slight physical distortion which may no doubt result from it. Other bootmakers bring their boots forward on the strength of their being made on hygienic principles, Mr. John Wise (261) and Mr. Francis Lanagan, of John Street, Bedford Row (263) amongst the number. The Hercules boot, made by Messrs. Allinson, of Northampton (251), is said, as its name indicates, to be of uncommon strength and durability, by reason of its excellent materials, and to have every advantage of form and shape to ensure comfort and wear.

The time-honoured practice of tight lacing and all the abominations of stiffened and boned corsets, and steel prisons for the female form, are so entirely opposed to hygienic principles, that substitutes for the old-fashioned and cruel stays afford a large field to inventors of this class of garments. Whether women do this injustice to themselves or not, they are generally agreed in theory as to the evils of pressure on important viscera, and those whose business consists in providing acceptable garments which shall be hygienic, and at the same time not unsightly, exhibit every variety of boneless, elastic, and patent corsets. Mrs. Thomas Steele (354), to whom was awarded a medal in the last Health Exhibition, has a variety of very neat-looking bodices and stays, and she asserts that much mischief is done to the female form by thrusting it into supports not specially made for it, but manufactured by the gross to fit any figure. Whatever those of the present generation may unfortunately feel obliged to do from habit, and therefore often from necessity, in the matter of wearing unnatural supports to the figure; it is of pre-eminent importance that our girls should be saved from such injurious articles of clothing which are often the pregnant cause of delicacy in after life. It must be confessed that many of the cases we saw filled with elegantly made stays, bandages, and belts, do not seem to contain hygienic so much as fashionable articles of the sort, and we should be sorry to endorse them all as uninjurious to any possible wearer. Exercises of various sorts, such as lawn tennis, rowing, and gymnastic evolutions, are now recognized as being equally appropriate and advantageous to either sex, and the impossibility of indulging in such games in the ordinary fashionable costume, induces many ladies to adopt an entirely distinct style of dress for such occasions. Loose dresses with easy elastic bodies, and short skirts are very desirable, and those who, like the Viscountess Harberton, advocate divided skirts as being convenient, healthy, and suitable for ordinary wear, show several varieties of their special costume in the Exhibition. The Rational Dress Society has travelling and lawn tennis dresses in case 272, and Mrs. Beck shows a hygienic dress with divided skirt in 271.

Hamilton and Co. (276), the co-operative skirt and dressmakers, exhibit a case of artistic costumes, designed with reference to comfort in wear and adapted to modern requirements. Close by this gallery are displayed the historical dresses of periods prior to the reign of Queen Victoria, and it must strike every one how similar are the modern devices for health, beauty and comfort to many that were worn by our ancestors. The high waist almost under the arms in those of the early periods before Queen Elizabeth precluded the possibility of compression, and the well-covered neck, then thought so decorous and becoming, was certainly more conducive to health than the bare shoulders and exposed arms, which are demanded at the present time by court regulations for presentation at the Queen's drawing rooms, as well as by fashion for evening wear in the ball-room. The ancient and historic costumes may well be studied, not alone to see what to avoid, and to note the advance of good taste and common sense, but to observe that in many details there has rather been retrogression, for a costume may be at once graceful and hygienic, healthful, beautiful, and artistic, if extremes be avoided and common sense be used under physiological guidance.

GENERAL CORRESPONDENCE.

THE MEDICAL COLLEGE HOSPITAL OF CALCUTTA.

[To the Editor of the Medical Times.]

SIR,—I think that the question mooted at p. 66 of your issue of to-day, whether hospitalism spared the Calcutta Medical College Hospital during Dr. Mouat's incumbency and impested it in mine, is likely to interest the profession only as a problem in epidemiology. Dr. Mouat says that pyæmia and its allies certainly did not prevail in the hospital when it was in his charge. I have mentioned that, writing in 1854,[1] of a time in which Dr. Mouat held that charge, Dr. Kenneth Mackinnon, then the highest authority upon medical questions in Bengal, remarked that wounds made in operating at that hospital were apt to take on an erysipelatous action, tending to sloughing. It would therefore appear that Dr. Mouat's recollection is at fault on this now unimportant point.

With regard to the comparative immunity from hospitalism of that building of late years, Dr. Mouat and I appear to be agreed. He cites the authority of a Government resolution, I that of Professor Partridge, Q.H.S., the senior surgeon, to the effect that, up to 1878, there was improvement in the condition of the surgical patients. Dr. Mouat may be right in holding this to be due to the state of the hospital. I am inclined to attribute it largely to antiseptic treatment in a building which, although still quite unfit for its purpose, underwent great improvement at the suggestion of Dr. Mouat's successors.

I am, &c.,
NORMAN CHEVERS.
Late Senior Physician and Principal of the Hospital.

London, July 12th, 1884.

INVENTIONS AND IMPROVEMENTS.

MITCHELL'S NURSERY BISCUITS.

These biscuits illustrate in a peculiar degree the way in which science is invading even such homely and ancient arts as that of the bread and biscuit baker. With the view of giving the highest quantities of flesh and bone-forming food in form suitable both to the simple tastes and frail digestions of the nursery, Mr. Mitchell, of the Regent Bakery Company, 42, Fish Street Hill, E.C., has introduced a nursery biscuit to which a certain percentage of gluten and of phosphate of lime has been added. Professor Attfield, who has analysed the biscuits, finds that they contain nearly 10 per cent. of albuminoids, chiefly gluten, and a quantity of phosphates, equal to 1·1 of bone phosphate, about a third being in the form of added phosphate of lime. He thinks that these additions give at least 10 per cent. of increased nourishing value to the biscuits. As to their practical value in the nursery dietary, no one could speak with any certainty until after a long course of comparative experiments; but we are justified in arguing, *à priori*, that if any form of food will help to stave off rickets and give children strong and sound teeth, these biscuits are as likely to do it as any that have yet been brought to our notice.

ANTISEPTIC CHARCOAL WAFER BISCUITS.

Under this name the same firm have introduced a very palatable form of charcoal biscuit, which professes to be made of the finest willow charcoal, and flavoured with pure ground ginger. These biscuits provide a very pleasant mode of administering vegetable charcoal.

HAY'S ORANGE AND LEMON CHAMPAGNES.

The number of aërated drinks which have sprung up in answer to the increased demand for non-alcoholic thirst-quenchers is really marvellous. Scarcely a week passes without some newly devised drink being brought under our notice. Hay's preparations compare very favourably with most of their rivals. They are prepared with essences made from fresh oranges and lemons, and the manufacturer has succeeded well in retaining the flavour of the fruit, and in producing pure and pleasant beverages.

MEDICAL NEWS.

Royal College of Surgeons of England. — The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Board of Examiners, on the 10th instant, and when eligible will be admitted to the pass examination, viz.:

Edward L. C. Smith and Richard W. Young, students of University College Hospital; Henry S. Smith, of St. Bartholomew's Hospital; Alexander J. Adie and Thomas Austin, of Charing Cross Hospital; Brown Clark, of London Hospital, and Edward H. C. Sullivan, of St. Thomas's Hospital.

Eleven candidates were referred for three months, and two for six months.

The following gentlemen passed on the 11th inst., viz.:

William H. Duce, William E. Redman, and John P. Millington, of University College Hospital; Evan J. Williams and Reginald J. Braye, of the London Hospital; John G. D. Cort-Warburton, E. Carden, and John Dallewy, of Charing Cross Hospital; Henry A. Haviland and Joe Iredale, of St. Bartholomew's Hospital; Richard E. E. South and Alfred E. Cox, of St. Thomas's Hospital, and Henry E. Craig, of Guy's Hospital.

Eight candidates were referred for three months, and three for six months.

The following gentlemen passed on the 14th inst., viz.:

Robert W. Cameron, of the Manchester School; G. P. Barton, Charing Cross Hospital; E. C. Anderson, of St. Mary's Hospital; R. H. F. Routh, N. A. Butterfield, T. J. Hall, and P. J. Clark, University College Hospital; F. R. Mallard and F. A. Mast, St. George's Hospital; G. S. Shute, Guy's Hospital, and W. J. Harris, St. Thomas's Hospital.

Eight candidates were referred for three months, and one for six months.

Two hundred and thirty-four candidates presented themselves for their primary examinations, as against two hundred and fifty-two at the corresponding time last year. Of this number, one hundred, having failed to acquit themselves to the satisfaction of the Board of Examiners, were referred to their Anatomical and Physiological studies for three months, and twenty-one for six months, a total of one hundred and twenty-one registered candidates.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, July 10th, 1884:—

Carmel Samut, Floriana, Malta; Hyde Marriott, Dial House, Stockport.

The Parkes Museum.—At the annual meeting held July 9th, Capt. Douglas Galton in the chair, a letter was read from the Duke of Westminster, regretting his inability to attend the meeting, and a report was presented by the Chairman of Council, showing the valuable work that had been carried out by the Museum during the past year. Twenty-one lectures have been arranged by the Council and delivered in the Museum by some of the best authorities on hygiene and sanitary science. These lectures have contained much valuable information, and have dealt with a majority of the subjects included in the scope of the Museum in a most useful and interesting manner. The Museum has been largely used by lecturers on Public Health, and other skilled teachers for practical demonstrations to various classes of students, &c., who for this purpose have been admitted to the Museum without entrance fee. In this way the special advantages offered by the Museum have been utilized for the purpose of instructing a large number of students and others who, by the nature of their several callings, may be expected in various ways to exercise an important influence in the promotion of health in connection with the construction of dwellings and otherwise; and the Council are glad to report that the facilities thus offered have been fully appreciated, both teachers and students having expressed a desire that further opportunities of the same sort might be afforded them. The members numbered 99 on June 30th, 1883, just after the opening of the Museum. They now number 260. During the year the Museum has been visited by 6,870 people. The lamented President, His Royal Highness, Prince Leopold, Duke of Albany in his inaugural address of May 26th, 1883, said that the sole object of the Museum was "to disseminate and to help others in disseminating the laws of health." The sphere of work thus foreshadowed by the late Duke of Albany has, as will be evident to those who peruse this report, become an accomplished fact in every particular. The Council cannot believe that the very moderate amount of money which is necessary for the permanent establishment of the Museum will be withheld, or that the public will allow an establishment, the welfare of which the late Duke of Albany had so much at heart, to languish for want of funds. The utility of the Museum has increased month by month. The Museum has clearly met a great public want, and the Council would again strongly urge upon the members, and upon all who are interested in sanitation, to use their personal influence, so to increase the number of members and life members that the future of so valuable an institution may no longer be a matter of doubt.

British Medical Association.—The annual meeting of the Aberdeen, Banff, and Kincardineshire Branch of the British Medical Association was held in Aberdeen last Saturday. The members of the association visited the Royal Infirmary, where a demonstration was given by Professor Alexander Ogston, showing how club-foot might be rectified at one sitting. There was also a demonstration by Dr. Angus Fraser of microscopical specimens of tubercle bacillus, and Dr. Garden showed a man with true Eastern leprosy. In the afternoon, the members dined together,

when a few happy hours were spent. Professor Alexander Ogston was unanimously appointed chairman for the ensuing year, as were the two secretaries, Drs. Garden and M'Kenzie Booth, and Dr. Hall was re-appointed treasurer. It was agreed to hold the next summer meeting of the branch at Laurencekirk.

Society for Relief of Widows and Orphans of Medical Men.—The usual quarterly court of directors of this society was held on Wednesday, July 9th, at 8 p.m., Sir Henry Pitman, V.P., in the chair. It was resolved that a sum of 1,257*l.* be distributed among 59 widows, five orphans, and three recipients of grants from the Copeland Fund. The expenses of the quarter were 39*l.* 17*s.* The treasurer announced the following donations:—Sir Erasmus Wilson, V.P., 100 guineas; Cæsar H. Hawkins, Esq., V.P., five guineas; Dr. Bissett Hawkins, V.P., 10*l.*; and J. Gregory Forbes, Esq., V. P., two guineas. Six new members were elected. The secretary reported the deaths of two. Applications were read for the first time from two widows, and grants were made to them. A discussion having occurred at the annual general meeting on the meaning of Law 66, and a wish expressed to have the law defined, the secretary read a letter from the honorary solicitor, Mr. Upton, from which it appeared "Eligibility depends on being the widow or orphan of a person actually a member for three years immediately preceding his decease, not on the payment of three subscriptions."

The West London Medico-Chirurgical Society.—The second annual dinner of this society was held on Tuesday, July 15th, at the "Star and Garter," Hotel, Richmond, under the Chairmanship of Dr. J. L. Thudichum, President of the Society. Much amusement was afforded by the "Menu" which had been rendered into classical Latin by Dr. E. Hart-Vinen, a feat of no ordinary difficulty. The after-dinner proceedings were enlivened by an excellent programme of vocal and instrumental music, given with much ability by the Misses Thudichum, Mr. Bere, and other ladies and gentlemen. Thirty-five members and visitors sat down to dinner.

Army Medical Department.—Deputy Surgeon-General T. W. Fox has been appointed to act as Principal Medical Officer of the British Army of Occupation in Egypt, Vice Surgeon-General J. Irvine, granted special leave of absence to England till September next. Dr. Irvine had medical charge of the Army of Occupation throughout the cholera epidemic of last year, and was specially commended for his services in connection therewith.

The Sanitary Institute.—The anniversary meeting was held on the 10th instant, Earl Fortescue presiding, when Dr. H. C. Bartlett delivered an address on practical sanitation. He took in a wide field, and alluded, in the course of his remarks, to the present epidemic of small-pox and the threatened one of cholera, to the disposal of refuse, the provision of good and cheap food, and the abatement of the smoke nuisance. In the evening the anniversary dinner was celebrated, under the Chairmanship of Dr. A. Carpenter.

Medico-Psychological Association.—The annual meeting will be held, under the Presidency of Dr. Henry Rayner, at the Royal College of Physicians, Pall Mall, London, on Wednesday, July 23, 1884, at 11 a.m., and 2 p.m.

The Cholera Epidemics of Paris.—In the epidemic of 1831, there were 18,402 victims of the disease; 19,184 in 1849; 11,520 in 1853–54; 5,357 in 1865–66; and 854 in 1873.

Cinchona Cultivation in India.—From an official statement of the trade of British India, just issued, it appears that the export trade in drugs has doubled during the last five years. As might be expected the increase is due to the development of the trade in cinchona bark, which now represents about two thirds of the total exports. During the last year the quantity of bark exported reached 641,608 lbs. while seven years previously it only amounted to 72,452 lbs. Madras contributed most largely to swell the exports, the cultivation of cinchona in that Presidency being more extensively carried on in private estates than in Bengal, where the principal cinchona estates are the property of the Government, which reserves a large proportion of the bark for local alkaloid manufacture. Most of the bark hitherto exported has come to London, but the demand from Italy is increasing. The manufacture of alkaloid seems to be seriously affecting the import of quinine from Europe, as last year it fell to 7,585 lbs. from 10,615 lbs. in the previous year. As matters now stand, it is stated officially in this report that imports of quinine, on account of the Government, have already practically ceased, and an opinion is expressed that in course of time quinine will no longer be imported into India, since that country will be able to supply all her wants from the plantations of Darjeeling and the Nilgiris.—*Indian Medical Gazette*, June.

Scholarships for Female Medical Students in Bengal.—The *Indian Medical Gazette* for June reports that the Bengal Government has determined, during the next ten years, to grant scholarships to all women who, having passed the First Arts Examination, desire to study medicine in the Calcutta Medical College. The scholarships are to be in value 20 rupees per month, tenable for five years—the duration of the curriculum for a degree at the College. This plan of granting stipends was regularly resorted to in the early days of the Medical College as an inducement to male students; and in the year 1838–39 there were 50 students in receipt of sums varying from seven to twelve rupees per month. "This unlimited grant of scholarships will undoubtedly have the effect of attracting a larger number of Brahmo and native Christian girls to the study of medicine in Calcutta; and the rule which enforces the passing of the First Arts Examination prior to their becoming students of medicine, will secure an older and a more highly educated class than that which is admitted into the Bombay and Madras Schools, where the entrance examination standard is relatively much lower. The resolution appropriately closes with the observation that only the experience of years can show whether the educated women of Bengal will avail themselves of the facilities now offered them, and prove, by real work, that they are fit for the duties and responsibilities which some of the more advanced among them are anxious to assume."

Sanitary Condition of Calcutta.—A memorial, praying the Lieutenant-Governor of Bengal to call the Calcutta Corporation to account for its neglect of sanitation, has received over 1,000 signatures, including those of the Chief Justice and Judges of the High Court, the Bishop of Calcutta, the Vicar-Apostolic of Bengal, the Surgeon-General, the President of the Chamber of Commerce, the Advocate-General, and the majority of the Bar; in fact, almost the entire European community. It is to be hoped that this strong expression of feeling will induce Mr. Rivers Thompson to deal with the matter promptly and vigorously.

A Siamese Student.—In the list of names of those who have recently passed the final examination for the degrees of M.B., C.M., at Edinburgh University, is that of Mr. Yai S. Sanitwongse. This gentleman was sent to Edinburgh ten years ago by His Majesty the King of Siam, for the purpose of receiving an education in medicine and surgery. Mr. Sanitwongse was educated at the Collegiate School, and although he has passed all his examinations at the University, cannot graduate till next year, being yet under age.

Precautions against Cholera.—With the view of preventing the importation of cholera into the United States, telegraphic instructions from Washington have been received at the American Consulate General in London, to appoint Medical Inspectors to examine all vessels sailing from London and Liverpool for the United States of America. The Consul-General has accordingly appointed Dr. J. Higham Hill, Health Inspector at London.

Army Medical Department. — Charles Frederick Staunton, M.D., Royal Artillery, died on Saturday at his residence in Dublin. He became an assistant surgeon in the Medical Department of the Army in 1830, surgeon in 1846, and was placed on half-pay in 1857. Mr. Staunton was the last surviving officer who served in the Euphrates Expedition.

Presentation to Mr. F. G. Hallett.—At the conclusion of the primary examination for the membership of the Royal College of Surgeons, Mr. Pick, as chairman, in the name of the Board of Examiners, presented a handsome silver service of salt cellars to the assistant secretary, Mr. Hallett, on the occasion of his approaching marriage. Mr. Pick alluded to the kindness, courtesy, and urbanity of the recipient to those with whom he had had to deal, and concluded by wishing him all happiness and success.

The *Matinée* recently given at the Avenue Theatre on behalf of the East London Hospital for Children and Dispensary for Women, at Shadwell, has resulted in an addition of 60*l.* to its funds.

"Our Confrère Prince Charles Theodore."—The Munich journals publish the following announcement, signed by the brother of the Empress of Austria, whose ophthalmological skill is well-known through his practice at Mentone. "All blind persons, or those suffering from disease of the eyes, may be received in a very comfortable establishment recently constructed at Tegernsée, Bavaria. Indigent persons provided with certificates explanatory of their position are admitted gratuitously."

Vital Statistics of Melbourne in 1883. — The Government Statist reports that the number of births registered was 10,093, or 33·09 per 1,000 inhabitants. The deaths numbered 5,923, or 19·42 per 1,000, or 1·42 below that of the preceding decennial. Of the births, 51·5 per cent. were male and 48·5 per cent. female, and of the deaths 54 per cent. were male and 46 female. Children under 5 years of age contributed 36 p r cent. of the total mortality. There is a considerable diminution of deaths from most zymotic diseases, except typhoid fever, from which there were 275 against 197 in 1882.

The Quiet Heroism of Doctors.—In an address delivered to the class of the Iowa College of Physicians and Surgeons (*Louisville Medical News*, May 31), Dr. Williamson cited for the admiration of his young audience the noble conduct of the medical profession at Norfolk, Virginia, on the occasion of a deadly invasion of cholera in 1848 (paralleled indeed in the great yellow fever epidemic of 1878), in which resident physicians became exhausted by over-work, or were carried off by the disease. A cry was raised for help and this was forthcoming from town and country, practitioners leaving their homes and friends, heedless of personal danger. "It was a time of deepest gloom. Silently they walked deserted streets, engaged in a combat wherein no martial music or battle's din was heard to support their courage. The pestilence came to an end, and so too did the lives of *forty* of those brave ones who had come forward at duty's call. They died and were hastily buried, and there their story ends. No stately shaft marks their resting-place. Few indeed ever heard that any such precious offering was then made on humanity's altar. And why? Because it is expected that practitioners be always ready to do just as they did. Nothing remarkable, therefore it is so soon forgotten. Religion may count her martyrs, patriotism may point to blood-stained fields, and science may boast of votaries whose lives went out in Arctic snows, but I know of no instances that transcend in moral heroism the self sacrifice of these forty forgotten worthies, and of none whose names more deservedly belong to the roll of the immortals."

Medical Experts.—Alluding to a discussion upon experts which has been going on, the *New York Medical Record*, May 31, observes "It can hardly be expected that expert testimony can be given candidly and satisfactorily, when the experts are specially called either to help plaintiff or defendant. The plans suggested for remedying the present evils all agree on this one point, that the Court should summon experts. Objection is made, nevertheless, to submitting the case to one or more persons, however skilful and impartial, for final settlement. This plan, which is followed in France, would settle matters too peremptorily to be satisfactory to the American mind. It would be better, therefore, that experts be appointed to whom technical and scientific questions be referred, to be examined and reported upon. These experts can then be cross-examined by counsel upon each side. Even if no such commission of experts be established, some good might be accomplished by putting certain restrictions upon those who are summoned as medical experts. At present the law can call upon medical students, quacks, and midwives to serve as experts. In cases of insanity this is especially unfortunte, and it is particularly in regard to this class of cases that reform in the methods of giving medical expert testimony should be brought about."

An American Doctor in Syria.—The *New York Medical Record*, June 14th, gives the following account of Dr. George Post, who has for many years been a medical missionary in Syria, in connection with the American Presbyterian Church. He has achieved a high reputation there, and if he were to give himself up to private practice he could amass a fortune rapidly. As it is he has a great many cases forced upon him, especially difficult surgical cases. If a Pasha breaks a bone he will have no one but the American missionary. But he prefers to give his services to the poor, and of such services there is no end. He is going on from morning to night, attending in the hospital without compensation, as well as lecturing in the college, writing books, and editing a medical journal. He has prepared a series of text-books on surgery, materia medica, zoology, and physiology, besides a concordance of the Arabic Bible, a large octavo volume. He has also been engaged recently in the preparation of a work on the flora of Syria and Palestine. This is not only the first work in Arabic on this subject, but the first comprehensive work in any language. It is expected that it will be of great value to students and all engaged in the work of Palestine exploration.

Alleged Importation of Lunatics into the United States.—The increase of the insane by importation was made the subject of resolutions at the recent meeting of the Association of Medical Superintendents of American Asylums for the Insane, by which Congress was asked to take measures to check the increase of lunacy from that cause—amounting, it was said, to one-third of all the insanity of the country.

University of Jena.—During the summer session 1883-84 162 students have enrolled themselves in the Medical Faculty, 100 being foreigners and 62 natives. In the winter session there were 142, and in the summer session of 1883 139 medical students.

Migration from the Country in France.—In a paper published in the *Journal de la Société de Statistique* for May, M. l'Abbé Tounissoux states that in official returns made since 1846, a distinction has been established between the *urban* population living in towns of above 2,000 inhabitants and the *rural* population occupying the other localities. The total superficies of France amounts to 52,857,199 hectares, viz., 3,103,490 for the towns, and 49,753,700 for the country. While the country comprises 94 per cent. of this superficies, but has only a mean population of 50 inhabitants to the square kilometre, while the towns have about 336. The migration into the towns has been exhibited in every census since that of 1846, so that while the urban population increased from 24·42 in 1846 to 32·41 in 1876, the rural population decreased from 75·58 to 67·56. According to the census of 1881, the total population of the 87 departments was 37,062,548, or an increase of 706,260, of which 561,869 is assigned to towns of 30,000 and upwards, and 204,591 to the rest of the population, although this last category forms five-sixths of all the population. The number of foreigners in France in 1881, it may be observed, was 1,001,090 or 2·68 per cent., having risen from 1·06 in 1851. The increase since 1876 has been 15·4 per cent. of Belgians, 45·6 of Italians, 38·9 of Germans, 18·2 of Spanish, 32·0 of Swiss, and 23·0 of English.

Omnibus Traffic in Paris.—According to the monthly return for March of the Paris Omnibus Company, there were made in that month 8,806 journeys, carrying 9,987,407 passengers. The tramcars transported in 3,949 journeys 6,687,310 passengers. In eight journeys by two tramcars 8,047 workpeople were carried in the early morning.

Experiments after Decapitation. — The head of Campi, who was recently decapitated, was taken to M.

Laborde's laboratory, who, together with M. Gley, made some experiments upon the body about an hour and a half after execution, the results of which may be thus summed up:—(1) Extreme contraction of both the right and left cavities of the heart. (2) Some blood from a dog having been transfused into the cranium by the carotid, the face passed from a state of lividity to the ordinary colour, and its muscles then contracted under the influence of the electric current. (3) After having exposed the internal and external intercostal muscles, M. Laborde passed electric currents through their attachments, and then observed that each electrical stimulation of the internal intercostals, and consequently each muscular contraction of these muscles, determined the depression of the upper ribs towards the lower, while it led to the elevation of the external intercostals. M. Laborde concludes from this that the external muscles serve for the purpose of inspiration and the internal muscles for expiration. (4) The movements of the brain were examined under the same conditions as those employed by M. Luys, that is with the cranial cavity communicating with the exterior, and the cerebral mass was seen to separate itself from the walls of the cranium during the different inclinations of the head. —*Gazette Hebdomadaire*, June 27th.

Medical Advertising.—The medical press of England, says the *New York Medical Record*, occasionally comes out with some stringent criticisms on the practice of advertising medical books in the daily papers. The general sentiment of the profession there is emphatically opposed to those public announcements of technical medical works with their authors' names and titles. A similar feeling prevails among the physicians in this country, and has very generally been respected. We observe, however, that of late several medical works have been advertised in the city papers and on the side-walks along with the other publications of the firms. Authors who allow this enlarge the circle of their readers, but they also weaken their own standing among their medical brethren. A good medical work cannot be made intelligible to general readers, and the very fact that attempts are made to secure such an audience, stamps the work at once as of questionable authority and value.

A Verdict by Averaging.—Dr. Sutton performed enterotomy on a lady at Pittsburg, removing four inches of the small intestine, and uniting the ends by suture. She recovered, and as her husband was reported to be wealthy, Dr. Sutton charged 1,000 dollars for the operation and 22 days' attendance. Payment was refused, and an action was brought. The jury returned a verdict of 330 dollars for the services rendered. Some of the jury thought that ten dollars would be a fair price for the operation, and one of them thought that, as he had once paid a doctor 30 dollars for an operation, this sum would be about right. They each put down the amount they would allow, and divided the aggregate by twelve, and fixed that amount as the verdict.

Communication of Scarlatina through a Letter.—Dr. Assmann, of Wohlan, reports that the family of an officer, residing at Dantzic, received a letter, giving an account of a case of scarlatina. The envelope of the letter was accidentally given to the youngest child to play with, and in six or seven days it had an attack of scarlatina, and within an interval of two or three weeks two of the other children contracted the disease. The conveyance of the disease by the letter acquires additional confirmation from the fact that for six months prior to the occurrence of the outbreak no case had occurred in the place.

Comparative Medicine.—Dr. J. C. Peters, as the result of extensive observation and research, the latter extending from Percival's work on hippopathology, published in 1834, to the London *Veterinarian* for September, 1883, has come to the conclusion that amongst the various diseases of animals communicable to man, and *vice versâ*, must be included "angina maligna, undoubted diphtheria, and both scarlatina and true measles." Amongst other evidence, he states that Dr. J. N. Stickler, of Orange, N.J., had successfully inoculated two colts with human scarlatinal virus.

APPOINTMENTS.

Beatley, William Crump, M.D. Durh., M.R.C.S. Eng.—Senior Assistant Medical Officer to the Somerset and Bath Lunatic Asylum, Wells.

Broughton, Henry Todd, M.R.C.S., L.M. and L.S.A. Lond.—Medical Officer to Heckmondwike District, Dewsbury Union, in succession to Mr. James Turton, resigned.

Carnelly, Matthew, L.R.C.P. Lond., M.R.C.S. Eng.—Medical Officer to the Wilford District, Basford Union, *vice* Dr. John Hall, deceased.

Chute, James, B.C., B.A., L.M. Univ. Dub.—Medical Officer to the Pembridge District, Kington Union, *vice* Mr. D. Wilson, resigned.

Collins, W. J., M.D., B.S., B.Sc. Lond., F.R.C.S.—Assistant Demonstrator of Anatomy at St. Bartholomew's Hospital.

Couch, John Quiller, M.R.C.S. and L.M. Eng., L.S.A. Lond.—Medical Officer to the Fifth District, Penzance Union, *vice* John Quick, transferred to First District.

Davies, J. T., M.R.C.S., L.R.C.P.—Resident Medical Officer to the Denbighshire Infirmary, *vice* Hammond-Williams, resigned.

Glynn, T. R., M.D.—Professor of Medicine in the University College, Liverpool, *vice* A. T. H. Waters, M.D., resigned.

Hardy, H. Nelson.—Divisional Surgeon to the P. Division of the Metropolitan Police for North Dulwich and East Dulwich Stations.

Hodges, John F., M.D.—Examiner in Sanitary Science, Royal University of Ireland.

Hughes, J. M., M.R.C.S., L.S.A.—Junior Medical Officer to Cornwall Works Dispensary, Handsworth, Birmingham.

Kempe, John Arthur, M.R.C.S. Eng., L.R.C.P. Lond.—Medical Officer to North Tawton District, Okehampton Union, in succession to Mr. J. H. Norman, resigned.

Lynam, R. G., M.R.C.S., L.S.A.—House Physician to the North Staffordshire Infirmary.

Pratt, William Sutton, L.F.P.S. and L.M. Glas., L.S.A., London.—Medical Officer to Third District, Daventry Union, in succession to Mr. F. B. Swaun, resigned.

Quick, John, M.R.C.S. and L.M. Eng., L.S.A. Lond.—Medical Officer to the First District and the Workhouse, Penzance Union, *vice* J. R. Quick, deceased.

Savill, T. D., M.D., M.R.C.P. Lond.—Assistant-Physician to the West London Hospital, *vice* Theodore Dyke Acland, M.A. Oxon., M.R.C.P. Lond., resigned.

Voelcker, John Christopher Augustus, F.R.S.—Analyst for the Borough. Remuneration, £1 1*s.* for each analysis.

Welsh, R. C., M.B., C.M. Edin.—Assistant House Surgeon to the Liverpool Dispensaries, *vice* Hadden, M.D., M.Ch., &c., resigned.

VACANCIES.

Addenbrooke's Hospital, Cambridge.—Physician and an Assistant Physician. (*For particulars see Advertisement.*)

Birmingham General Dispensary.—Resident Surgeon. Salary, £150 per annum (with an allowance of £30 per annum for cab hire), furnished rooms, fire, light and attendance. Candidates must be registered and possess both a medical and surgical qualification. Applications, together with original testimonials and certificates of registration, to be forwarded to the Secretary, on or before July 22.

Bristol Dispensary.—Surgeon. Candidates must possess a diploma in surgery from the Royal College of Surgeons of England, Scotland or Ireland, or from the Faculty of Physicians and Surgeons of Glasgow, and in addition to such diplomas in surgery, must possess a legal qualification to practise Medicine in Great Britain and Ireland, and be duly registered according to the regulations of the Medical Act. For salary and other particulars, apply to Mr. E. Stock, 57, Queen Square, Bristol, to whom testimonials must be sent on or before July 31st.

Cheshire County Asylum, Parkside, Macclesfield.—Assistant Medical Officer. Salary to commence at £120 per annum, with furnished apartments, board, attendance and washing. Candidates must be registered and doubly qualified, unmarried, and not over 30 years of age. Applications, with testimonials to be sent to Dr. Sheldon, Medical Superintendent, on or before July 19th.

Ecclesall Bierlow Union.—Medical Officer to the Fourth District, in succession to Mr. William McBeath, resigned. Area, 1,477 acres. Population, 35,709. Salary, £57 10*s.* per annum.

London Hospital Medical College, Turner Street, Mile End, E.—Two Assistant Demonstrators of Anatomy. (*For particulars see Advertisement.*)

Scarborough Hospital and Dispensary.—Assistant House Surgeon and Dispenser. Salary, £50 per annum, with board and lodging. Testimonials to be addressed to the Secretary not later than July 26th.

Staffordshire General Infirmary, Stafford.—House Surgeon and Secretary. Salary to commence at £100 per annum, with board, lodging and washing. Every candidate must possess a diploma or degree in surgery from the College of Surgeons in London, Edinburgh or Dublin, or from one of the Universities, and a qualification in Medicine which shall entitle to register, and they must produce unexceptional testimonials of moral conduct. Applications, accompanied by diploma or certificates of registrations, with copies of testimonials, to be sent under cover to the Secretary, addressed to the Committee of Selection, on or before July 24th.

St. Pancras, Middlesex.—District Medical Officer. (*For particulars see Advertisement.*)

Stronsay Parochial Board.—Medical Officer and Vaccinator. (*For particulars see Advertisement.*)

The General Hospital, Birmingham.—Resident Medical Officer. (*For particulars see Advertisement.*)

DEATHS.

BALFOUR, W. G., M.R.C.S., L.R.C.P., late of Alton, Hants, at Bombay, on June 15th.
KEELAN, N. W., L.R.C.P., L.R.C.S., at Roscau, Dominica, West Indies, on June 17th, aged 42.
MILLER, J. W. M., M.D., M.R.C.P., M.R.C.S., J.P., at Southsea, on July 9th, aged 64.
PARKER, W., M.D., at 37, Pultcney Street, Bath, on July 13th, in his 72nd year.
STAUNTON, C. F., M.D., R.A., at 35, Waterloo Road, Dublin, on July 12th, aged 83.

NOTES, QUERIES, AND REPLIES.

A Hard-Working Surgeon. — Under the above "caption," Asiatic and American Philosophical Journals have recently been giving very lengthened notices of "Five Hundred Sunday Lectures," by Dr. William Hitchman, M.R.C.S., Consulting Surgeon to Leeds Public Hospital for Cancer, Scrofula, and Diseases of the Skin. Their motto is sufficiently cosmopolitan, viz., "Live purely, exercise justice, love truth," while the topics of the times discussed by the Lecturer and subsequent debaters, have been so catholic as to embrace Biology, Physiology, Psychology, Natural Religion, and the Physical History of Maukind. The "Wickedness of Overcrowding" has also received much consideration. Some of the "Hitchman Lectures" are in Sanscrit and other languages.

COMMUNICATIONS RECEIVED—

Prof. GAIRDNER, Glasgow; Mr. LAWSON TAIT, Birmingham; Dr. CLIFFORD ALLBUTT, Leeds; Dr. BANHAM, Sheffield; Dr. F. T. ROBERTS, London; Mr. WYNTER BLYTH, London; THE SECRETARY OF THE AMERICAN EXHIBITION IN LONDON, London; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; THE PRESIDENT OF THE ST. THOMAS'S HOSPITAL AMBULANCE COMPANY, London; Dr. H. DONKIN, London; OUR DUBLIN CORRESPONDENT; M. H. W. PHILLIPS, Bradford; THE REGISTRAR-GENERAL FOR QUEENSLAND, Brisbane; THE PRESIDENT OF THE OTOLOGICAL CONGRESS, Bâle; Dr. SHINGLETON SMITH, Bristol; Dr. SAWYER, Birmingham; Dr. RAYNER, Hanwell; Dr. PEARSE, Plymouth; Dr. WOLFENDEN, London; OUR VIENNA CORRESPONDENT; Mr. J. BELLAMY, LOCAL GOVERNMENT BOARD, London; Mr. E. BELLAMY, London; THE SECRETARY OF THE SANITARY INSTITUTE OF GREAT BRITAIN, London; THE SECRETARY OF THE PARKES MUSEUM, London; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; THE PRESIDENT OF THE SOCIETY FOR THE STUDY AND CURE OF INEBRIETY, London; Mr. H. NELSON HARDY, Dulwich; Mr. GEO. H. R. WILLIS, London; THE HON. SECRETARY OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY, London; Mr. BLACKETT, London; Mr. MORTON SMALL, London; Dr. J. S. CAMERON, Huddersfield; Mr. GARTH WILKINSON, London; Mr. A. A. KNIGHT, London; THE CHAIRMAN OF THE BOARD OF GUARDIANS OF THE PARISH OF ST. MARYLEBONE; Dr. J. W. MOORE, Dublin; Dr. J. H. HILL, London; Dr. DRESCHFELD, Manchester.

BOOKS RECEIVED—

Memoir of the Nature of Diphtheria, by Drs. H. C. Wood and H. F. Formad—The Theory and Practice of Medicine, by J. S. Bristowe, M.D. Lond., &c.—Notes on Health in Calcutta and British Emigrant Ships, by W. H. Pearse, M.D., Edin.—Evolution of Epidemics and the Alliances of some Diseases, by W. H. Pearse, M.D., Edin.—Health Studies, by H. Sinclair Paterson, M.D.—Studies in Life, by H. Sinclair Paterson, M.D.—Annual Report of the London Temperance Hospital—The Right and Necessity of a Popular Veto on the Liquor Traffic—Medical Education.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet — British Medical Journal — Medical Press and Circular — Centralblatt für Chirurgie — Gazette des Hôpitaux — Gazette Médicale — Pharmaceutical Journal — Wiener Medicinische Wochenschrift — Révue Médicale — Gazette Hebdomadaire — Nature—Boston Medical and Surgical Journal—Louisville Medical News — Centralblatt für Gynäkologie — Le Concours Médical — Centralblatt für Klinische Medicin—Philadelphia Medical News —Le Progrès Médical — New York Medical Journal — Students' Journal and Hospital Gazette — New York Medical Record—The Edinburgh Clinical and Pathological Journal—The Philadelphia Medical Times—Centralblatt für die Medicinischen Wissenschaften —Berliner Klinische Wochenschrift—Maryland Medical Journal—Weekblad — Société Médicale—Scienze Mediche — Westminster Review—Popular Science News—Revue des Sciences Médicales—The Western Medical Reporter—The Medical World—The Chemist and Druggist—The Journal of the Vigilance Association—The Journal of the British Dental Association—The Canadian Practitioner.

APPOINTMENTS FOR THE WEEK.

Friday, July 18 (*this day*).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westmiuster Ophthalmic, 1½ p.m.

Saturday, July 19.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, July 21.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, July 22.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

INTERNATIONAL HEALTH EXHIBITION (EPIDEMIOLOGICAL SOCIETY'S CONFERENCE)—2.30 p.m.: President's Opening Address, "On Health in India;" Dr. Squire, "On the Change of Type in Epidemic Disease."

Wednesday, July 23.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

INTERNATIONAL HEALTH EXHIBITION (EPIDEMIOLOGICAL SOCIETY'S CONFERENCE)—11 a.m.: Surgeon-General Priugle, "On Leprosy in India, and the best means of preventing its increase;"—2.30 p.m. "Discussion on the Preseut Aspect of Cholera in Europe," opened by Inspector-General Lawson.

Thursday, July 24.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Contents.

HEALTH IN INDIA.[1]

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.,
President of the Epidemiological Society.

Bombay, a city delightfully situated upon an open bay, considered to be scarcely inferior in beauty to the Bay of Naples, was made over to us by the King of Portugal in 1661, as part of the dowry of Catherine of Braganza. When Dr. John Fryer visited Bombay, about eleven years later, he found the English President living with all the state of a Viceroy, having a council, a body-guard of cavalry, chaplains, linguist, mint-master, physician, chirurgeons, and domestics, silver staves to wait on him whenever he moved out of his chamber, trumpets to usher in his courses, soft music at his table, large milk-white oxen for his coach, standards borne before him, and a sombrero of state always carried over him; still "for all this gallantry," adds Fryer, "I reckon they walk but in charnel houses." "In five hundred, one hundred survive not; of this one hundred one quarter get not estates; of those that do, it has not been recorded above one in ten years has seen his country."

During the two hundred and twelve years which have elapsed since Fryer visited India, the British rulers of that country have lived quite as well as they did in his time, possibly too well; but, notwithstanding the spread of enlightenment, the improvement of medical science, and the introduction of large measures of sanitation, the Anglo-Indians of the present day have not wholly succeeded in throwing off their ancient habit of "walking in charnel-houses."

To those who have not fully considered the matter this may appear strange when I mention that, while the worst diseases of India—cholera, marsh fevers, and dysentery—are in a large measure avoidable by those who live prudently and comfortably, he who takes with him to that country a sound constitution, as most Europeans do, may anticipate complete immunity from many of the direst maladies of his native land, such as pulmonary consumption, cancer, rheumatic fever and heart-disease, scarlatina and typhus, gout and scrofula.

It is not easy to review, in a space of less than half-an-hour, the diseases which annually destroy about 5,000,000, in a population of 260,000,000, and to point out the means by which, under Providence, that vast mortality may be commanded and diminished. It is clear that none but large facts must engage our attention. I think that the consideration of these facts may afford some useful suggestions to our home sanitarians.

Practically, much good sanitary work was done in India, especially in ships, military cantonments, and

[1] An Address delivered at the opening of the Conference of the Epidemiological Society of London, at the International Health Exhibition, July 22nd, 1884.

prisons, long previous to the year 1858; but it was only after the promulgation in that year of the report of Sidney Lord Herbert of Lea's commission on the "*Regulations affecting the Sanitary condition of the Army, the Organization of Military Hospitals, and the Treatment of the Sick and Wounded*," that Government began to establish a sanitary system in India. The history of the introduction of that life-giving measure among our Oriental millions will afford a singular illustration of the forces which retard human progress, which has still to be placed on record. It is sufficient to say here that India did not receive the boon with any tokens of hearty appreciation or cordial gratitude.

Much has still to be done before the General Census, Birth and Mortality Returns of India can be regarded as being either full or accurate; still, as we now have them, they convey to us many importantly suggestive truths.

The census of 1881 showed that India then had a population of 253,891,821.

Fayrer gives the registered deaths from all causes in India, in the year 1879, as 4,975,042.

Among the principal causes of sickness and mortality in India are Famine, those Malarious Fevers, of which Ague is a type, Cholera, Bowel Complaints, and Small-pox.

I shall review these and the means necessary for their prevention with great conciseness.

Famine: We need only open the table of contents of Hunter's "Annals of Rural Bengal," to learn what dire consequences arose in that province during a season of scarcity. We have these headings—"Permanent effects of the Great Famine of 1769–70. The crop of 1769. Distress anticipated, but the land-tax raised. The famine declares itself. One third of the people perish. The living feed upon the dead. The December harvest (1770) restores plenty; but to a silent and deserted province."

The famine which ravaged Orissa in 1866, consequent upon the failure of the rice-crop of the preceding cold season, is supposed to have carried off at least a fourth part of the population of that great province. In the Pooree district alone, 213,944 deaths occurred in a population of 754,751.[2] Dr. Vandyke Carter calculates, from official returns, that, in the famine years, 1877 to 1879, the population of the Bombay Presidency lost an excess upon the ordinary rate of 188,326 by fever alone; and that, in 1877, their total deaths were 627,708, or 259,448 (41·3 per cent.) in excess of those of the previous year.[3]

Although declared famine does not constantly prevail as a cause of mortality in India, failure of crops in any year may produce it, and neither civil war nor pestilence works such lasting ill effects upon a population as it does. The means for its prevention must therefore be permanent and constantly available. Among the chief of these are *Irrigation Works* sufficiently extensive to obviate as far as possible the evil effects of dry seasons. Writing two years ago, Sir Joseph Fayrer showed[4] that there were then in India "12,750 miles of lesser or greater canals, whilst the total length of the distributing canals is unknown. In Northern India alone, however, it amounts to 8,300 miles. The area now irrigated amounts to 1,900,000 acres in Madras and Bombay, 300,000 in Behar and Orissa, 1,450,000 in the North-West Provinces, 1,350,000 in the Punjab, and 1,250,000 in Scinde; in all, 6,310,000 acres. A great and noble work assuredly! Still "what is this among so many?" The report exhibiting the moral and material progress and condition of India during the year 1881–82 shows that protective works, the first object of which is to forestall famine, are "constructed on a yearly allotment of 750,000*l.*, the moiety of the one and a half million set apart annually as a Famine Insurance Fund."

The extent of India is so great and the productive power of its acres is generally so large that famine has never visited the whole peninsula. Consequently, whenever the superabundant produce of provinces A B and C can with sufficient promptitude be conveyed to and distributed throughout the famine-stricken districts of province B, the evil effects of a season of scarcity will be reduced to a minimum. Therefore, *Railways and good Roads* are among the most efficient means of preventing and relieving famine in India. Little more than thirty years ago, I witnessed the opening of the first section of the railway line in India. Mr. Juland Danvers shows, in the report above cited, that, in 1881–82, the length of railways opened in India was, broad gauge, 6,959 miles; narrow gauge, 2,955. The grain-conveying power of these lines (which are shown in this map of India and which are in process of daily growth) is very inadequately represented by the statement made in this document that "The Great Indian Peninsula Railway carried to Bombay in 1881 about 500,000 tons of wheat alone, against 146,600 in 1880; and that the wheat railed to Calcutta amounted to 137,700 tons in 1880, and 304,400 tons in 1881.

Besides this, it was arranged many years ago by the Government of India, in the Public Works Department, that whenever a first-class road should be undertaken, its construction should be such as to admit of its being readily adapted for railway traffic.

I have long believed and argued that a poor and insufficient staple of food afforded throughout vast Indian districts, as among the *dasee* rice-eaters of Lower Bengal and the *kesaree dal* feeders of the Central Provinces, is a cause of disease and life-long starvation to multitudes far larger than those who are swept down by periodic famine. For many years past the Government have perceived the necessity for developing the agricultural resources of India, of improving the staple of grain, and of conserving and extending the forest and tree-growth generally, by which latter means it is to be anticipated that the rainfall will be increased and equalised, reducing the torrid heat of the climate, and fertilising the soil. In a Presidential Address delivered at the annual meeting of the Bengal Social Science Association in 1870, I showed, by statistical evidence, that what Dr. Tytler designated *diarrhœa hectica* is so prevalent a cause of death among the poor of Bengal Proper (it also occurs largely in other parts of India) that I had distinguished it as *Morbus Bengalensis*. I then stated that, having watched this disease closely for more than twenty years, in an extensive field, I was perfectly convinced that it is a gradual failure of the powers of digestion and nutrition, not to be remedied towards the last by any mode of liberal feeding, the patients dying, physiologically, in a state of starvation, however well they may be fed. I urged my distinct conviction that this inability of the system to receive nourishment is mainly due to the slow failure of the nutritive faculty, under a life-long system of feeding upon poor, bad, and indigestible food. I believe that a state of famine which, although almost imperceptible to the ordinary observer, is, on this account, more widely, stealthily, and surely destructive, constantly prevails in Bengal. Born of a famine-stricken race, nursed by a starved mother, working hard upon a food the use of which is slow starvation, the Bengali's life burns out rapidly, as the feeble light does in his poor *chiragh* (oil-lamp), and for the same reason—want of fuel. I believe that I am not original when I say that rice has ruined Bengal as the potato has ruined Ireland. Both countries are endowed by nature with soils of great fertility. In the Middle Ages, Ireland was celebrated for her herds

[2] Report on the Famine in Pooree, by Udoy Chund Dutt, Ind. An. Med. Sc., No. 23, p. 311.

[3] With regard to the great famine in Madras in 1877, my friend, Dr. Lewis, has kindly obtained for me the following data from the official returns:—In 1875, the population of the Madras Presidency was 29,299,586. In the six years 1875–80, excluding 1877, the death-rates from all causes, per 10,000, were 211, 233, ... 278, 189, 157; in the famine year, 1877, they rose to 532.

[4] "On the Climate and Fevers of India."

of cattle, which she exported in abundance to England and other countries. Bengal was, at about the same time, a land of great pastures, upon the rich grass of which the sacred herds fed in such multitudes that they were offered by ten thousands in sacrifices to Kalí.

I then contended, and still believe, that the only valid remedy for the *Morbus Bengalensis*, as well as the only means of enabling the Bengali to withstand the marsh-poison of his country, until he shall have driven out the malaria by bringing his rice swamps into dry cultivation, is *the introduction into Bengal of a* HIGHER STAPLE OF FOOD. I urged and still urge the necessity of mature deliberation and steady action upon the questions—(1) How far it may be possible to widen the pasturage of Bengal, and to extend the cultivation of wheat and legumes, of oil-producing plants, and of fruit trees, especially the mango, throughout the country; and (2) to what extent, in the meantime, the opening of ports along the sea-board, and the extension of railways through the most fertile tracts of India may allow of the importation of wheat into Bengal until the country can produce its own wheat. The poor Bengali gladly eats wheat-meal when he can get it, which is very rarely indeed. Whenever I asked a patient what diet he would prefer, the reply was "*Ek bala roti, ek bala bhat*," one daily portion of wheat-meal chupattees and one of rice. Within the last few days I have been informed that the cultivation of wheat in Upper India promises to enable Hindostan to supply the wants of the United Kingdom. I do not find an indication of such promise in the latest statement of moral and material progress and condition of India; but I do not think that the contemplation of such a result is absolutely Utopian; and I trust that, should Providence vouchsafe to ordain it, the benefit will be extended to the underfed multitudes of Lower Bengal.

Fayrer has shown that the registered deaths from *Fevers* in 1870, were 3,564,035 out of a population of 187,105,833. The very large majority of these fever deaths were due to marsh and jungle influence. Would any other nation have been as little active as we have been in reclaiming, with a view at once to enhance agricultural produce and to maintain public health, the waste and swamp lands of India? Although, as a Briton, I would hold them, as a sanitarian I should not be sorry to cede vast tracts in both India and the United Kingdom to those admirable land-reclaimers, the Dutch. I feel certain that, had they held rule for the last two centuries from Batavia to Cabul, India would have far less fever, and a great deal more wheat, beeves, and sheep than she now possesses. As I have just said, the spread of wheat cultivation ought to tend in some measure to the mitigation of the evil of marsh-fever engendered in irrigated rice fields. I cannot but look upon their want of action in reclaiming land which is the source of the most prevalent and the worst diseases of the country as the weakest point in the Indian sanitary system; but much improvement in this respect can hardly be anticipated as long as the men of the direly threatened city in which we now stand are willing to allow millions of acres of swamp-land to impest every breath of air which reaches them from their east and from their west. I believe that, when cholera next visits London, at least 90 per cent. of the mortality will be due to the fact that the Londoner is as insensible to the evil influence of his marshes (I speak as a Kentish man) as the animal that grazes there!

With regard to *the Prevention of Small-pox*, India has a well-organised and widely-spread system of vaccination. This succeeded a native system of small-pox inoculation, which was probably more widely spread, but of less preventive efficacy. When I first knew Bengal, 75 per cent. of the adult population had been inoculated, and therefore stood secure against small-pox. The excellent report which I have so often cited shows that the total number of vaccinations in India during 1881 was 4,414,342, with a percentage of success to primary operation of from 80 to 98·23.

The Government statement shows that the numbers of *patients treated in the Civil Medical Institutions, Hospitals and Dispensaries* of India were 7,397,095 in 1880, and 6,999,965 in 1881. In these years respectively, the numbers of in-patients were 216,298, and 218,376. In 1881 the cost of maintaining these institutions was 370,586*l*. In that year, 8,288 surgical operations of great importance were performed, with 5,758 recoveries, and 283 deaths. Cataract cases were operated upon in 2,801 persons, 1,803 of whom were restored to good sight. I have noted that, in the dispensary at Seharunpore, no less than 831 stone cases were operated upon in the eighteen years ending July, 1866.[5] There is a point of minor but still of vast importance to which I would just allude, as it at present excites a good deal of attention in charitable circles. Not many years before I went to India in 1848, women in that country trusted to midwives in the hour of their greatest trial; even English ladies were attended by native *daees*, whose ignorance was not so much absolute as horrible. Now, and for many years past, in India, as in Europe, all European ladies are attended by medical men. Within my own time, in England, the midwife has been changed from a professional person into a nurse. Unquestionably, the ignorant and absolutely unteachable *daee* still prevails in millions of native households, and there is on foot a movement to send professionally educated women to India, with a view to the abatement of this evil. Undoubtedly, the intention is prompted by benevolence, but I perceive clearly that, unless it be conducted with great tact and care by highly-qualified and judicious ladies, the measure will prove retrogressive, and will result in more harm than good. I would enquire of those excellent ladies who are earnest in promoting this mission—would they and the majority of their countrywomen advocate the introduction of this system at home? *They* possibly would, but no one else would entertain the idea for a moment—otherwise the project of educating medical women for home work would receive very much greater encouragement than it does at present. In every one of the many years of my Indian experience, the aid of English medical men in these cases was more and more sought for by the natives, and I believe that the number of those natives who would rather allow death to occur than call for the aid of a medical man, is yearly becoming more and more minute. Is it wise to check this advance in humane and saving enlightenment by sending out medical women, however highly-qualified they may be? I do not think that the oldest of the two lying-in hospitals in the city of Madras has been established more than thirty years, and yet, in the year 1882, no fewer than 1,904 confinements, chiefly native, took place in those admirably conducted institutions. Does true humanity demand that such progress should be discountenanced and checked in its present vigorous and most hopeful growth by this latest offspring of mistaken philanthropy?

In briefly considering the questions—*What are the present death-rates in India? How do they compare with English rates? and how far does Indian sanitation appear capable of reducing mortality?* I may as well say one or two words germane to my last observations. I have recently worked out the statistics of 808 married ladies, European and East Indian, who died *from all causes, not merely in child-bed*, between the ages of 14 and 50, in the time of midwife ascendency, up to 1848. Of these ladies 51, or 6·3 per cent., died in child-bed.

[5] Dr. A. Garden.

Dr McClintock[6] gives the death-rate of *parturient* women as one in the 100. In 1882, the death-rates of women in child-bed, in the two Madras lying-in hospitals (where many neglected and ill-managed native women were received in a dying state), were 2·94 and 3·13 per cent.

In 1858 I showed that from the commencement of the present century, the average annual rate of mortality in hospital, from all causes, among the men of H.M. and the H.E.I.C.'s. European Forces, in the Three Presidencies of India, had been

62·45 *in the thousand.*

Surgeon-General Hugh Macpherson found that, during the eight years ending 1853–54, the hospital death-rate of European Troops in the Bengal Presidency was

63·38 *in the thousand.*

During these eight years the total number of deaths *out of hospital* was 1,175—a large proportion, the occurrence of which was explained mainly by the fact that nearly the whole of this period was one of active and trying warfare.

The returns show that, during the last five years, the mortality rates of our European army throughout India, have been :—

1878—21·46
*1879—24·28
*1880—24·85
1881—16·86
1882—12·07

* Excluding troops serving in Afghanistan.

In comparing these rates with those given as prevailing shortly before the Great Mutiny of 1857, it is to be borne in mind that the early rates belong to a period in which the health of the troops suffered greatly in war, and from all the destructive influences attendant upon field service in enemy's country. The hitherto unexampled lightness of the death-rate of 1882, viz., 12·07, is in a large measure attributable to "the remarkable abeyance of cholera among the European troops." We can hardly expect again to have so low a death-rate within the next decennium. Still this exceptionally small Indian death-rate of a single year—12·07 per mille—is seen to be comparatively large when we find it shown, in the Army Medical Department Report for the year 1881, that, during the ten years 1871–80, the death-rate of the whole British Army, at home and abroad, only exceeded it by a fraction, being 12·59 per mille, while the rate in the West Indies was 11·02 ; in the United Kingdom 7·95 ; and in Canada 6·64.

The mortality of the *Native Army of India* is large. In the five years 1877–82, it ranged from 13·38 in 1877, to 37·79 and 41·12. In the last two years, in which there was much trying war service in Afghanistan, the death-rates in the regular native army of Bengal were so high as 53·61 and 53·15 per mille.

The *death-rates in the General Population of India*, as obtained in 1882, under a still admittedly imperfect system of registration, ranged from 13·61 in Assam, to 29·99 North Western Provinces and Oudh. In Bengal the rate was 15·40 ; in the Punjab 27·03 ; in the Central Provinces 29·10 ; in the Madras Presidency 15·7, and in the Bombay Presidency 20·25.

Knowing the people and their modes of living as I do, I cannot but think that these rates are underestimated and that, as the system of registration becomes more accurate, the rates will be found to be considerably higher. Still it is to be borne in mind that these are mainly *rural* rates.

Dr. Beddoe[7] in an article on "Mortality" gives the following *city* mortality rates for 1878—Calcutta 37·7 ; Madras 48·8 ; Bombay 41·8. Nothing that parallels these rates has occurred to me in reading the recent mortality rates of the principal cities of the United Kingdom, one of the highest of which has been 29 per mille.

The death-rates of *European Soldiers' Wives and Children* in India have always been deplorably high. Macpherson shows that, between the years 1838 and 1853, the mean death-rate of women in the three Presidencies was 35·47 per mille.

The Sanitary Commissioner gives the rates between 1875 and 1882 as ranging from 19·78 in 1882, to 29·20 in 1878. My friend Dr. Joseph Ewart who has written[8] with great power on the "Causes of the excessive mortality among the women and children of the European soldiers serving in India," says that, through the kindness of Surgeon-General Marston, he has been placed in a position to give, side by side, the death-rates of the women belonging to the European troops serving in India, and in the United Kingdom ; thus, one of the lowest Indian death-rates, that for 1882, being 19·78, the home rates for the four years 1877–80 were only 8·59, 8·65, 7·75, and 8·37.

The *Children's* death-rates, as given by the Sanitary Commissioner, are still more appallingly high. During the last eight years they ranged from 50·26 in 1882, to 79·73 in 1878. From the high authority cited above, Dr. Joseph Ewart shows that, in the four years 1877–80, the death-rates of soldiers' children in the United Kingdom were 24·08, 28·41, 26·86, and 30·28.

The outcome of this dreary array of figures, to which you have listened with so much forbearing patience and courtesy, but which you will find to be of the most vital importance and interest when you come to study them in print, is that—although wherever we are able to draw an accurate statistical parallel, Indian death-rates are now generally lighter than they were in the evil old times of ill-built and over-crowded barracks and hospitals, battle, famine, and long campaigns, bleeding, calomel and ignorant midwives—English men, women and children are at present subject to far higher death-rates in India than they are in any other large division of the British Empire.

The following questions deserve the deepest consideration from sanitarians and legislators.

Why should the last decennial death-rate of our European Soldiers in India—19·37—so vastly exceed that of their brethren in the West Indies, 11·02, even when it is admitted that the pestilential influences of the West Indies are less potent than those of the East.

Why should the mortality of Soldiers' Wives in India be at present, to use Dr. Joseph Ewart's words "about *three* times as heavy as in England?" We may well exclaim with him "the discrepancy is as enormous as it is appalling!"

Still again, why should the death-rate among Soldiers' Children in India, in the four years 1877–80, exceed, as Ewart has shown, the death-rate of barrack children in the United Kingdom by 26·25, 51·32, 50·20, and 30·28 per mille?

In placing these facts in the form of questions, I do not mean to leave it to be inferred that the causes of these terrible discrepancies are not to a considerable extent recognised ; or that the Government and their medical officers are not devoting the most earnest interest and very great ability to the work of amelioration, which recent statistics show is generally advancing. My plain object is to offer you a fair insight into the present state of public health in India, that you may compare it—by no means in a spirit of exulting self-sufficiency—with the better, but still vastly improvable, condition of living which is vouchsafed to us at home.

[6] As cited by Dr. Playfair.

ON A CASE OF PERI-NEPHRITIC ABSCESS CURED BY DRAINAGE.

By R. CLEMENT LUCAS, B.S, Lond., F.R.C.S.

Surgeon to the Evelina Hospital for Children, and Senior Assistant Surgeon to Guy's Hospital; Corresponding Member of the Société de Chirurgie of Paris.

I am indebted to my colleague, Dr. Goodhart, for permission to publish the following case, which was admitted into the Evelina Hospital under his care, and to Mr. Milligan, the registrar, for the care he took in reporting it. To our excellent House-Surgeon, Dr. Newnham, much of the success of the case is due.

The case is of interest from the rapidity with which the large abscess cavity closed after free drainage was established, and the great relief at once obtained by opening it. It illustrates also the value of cutting down through the muscles in the loin to find the abscess instead of waiting for it to make its way to the surface. Such procrastination may allow the abscess to form a communication with the colon, or to burst into the peritonæal cavity, complications which may almost certainly be avoided by an early operation.

A. M., aged 2, was admitted into the Evelina Hospital on February 1st, 1884. The parents were living and healthy, and there were two other children also well.

Previous history.—The child had had scarlet fever and whooping cough, but he had not suffered from measles. According to the mother, he was a strong and healthy boy up to the 9th of November, 1883, when he was knocked down by a boy and fell on the back of his head. Ever since that time he has been ailing. One day he would take his food and appear well, the next he would be fretful and his appetite would be bad. He has had no discharge from his ears.

History of present illness.—About a fortnight ago the child seemed drowsy, complained of pain when touched, and could not take his food. The mother took him to a medical man, but at the end of a week the child appearing no better, she brought him among the out-patients at the Evelina Hospital. He has not been kept in bed, but has sat in a chair by the fire. He has been very restless and thirsty at night, has vomited twice, and his bowels have been constipated.

Condition on admission.—A fairly well nourished child lying on its back, with its legs drawn up towards its abdomen. Lips of a good colour free from sordes. No dilatation of the alæ nasi. A slight flush on both cheeks. Skin warm and moist. The child appears lethargic and takes little notice of being examined. No swelling of any joint. No œdema anywhere. Temperature 100·4.° Tongue moist. The abdomen is full but not tender on pressure. Some gurgling over the right iliac region and also just above the umbilicus. Passing up in a curve from the right iliac region to above the umbilicus is felt, a firm band whose concavity is internal, probably the colon displaced forwards and distended with fæces. Over the right lumbar region there is more resistance than over the left. There is no increase in hepatic or splenic dulness. The heart sounds are normal. Pulse 120°, regular, soft, and rather weak. Chest well formed and resonant. Respiration thoracic, 39 per minute.

February 2nd.—Legs still drawn up. Pulse 126°. Very fretful. Resistance still felt on pressing on the right side of the abdomen.

February 3rd.—The case was examined by Dr. Goodhart. The bowels have acted freely and removed the band previously described (no doubt due to fæcal accumulation in the colon), and now, deeply seated in the right loin, can be felt a large firm mass running up under the ribs and bulging into the loin. It is a localised swelling accompanied by faint redness of the skin. The mass is tender on deep pressure, and the child cries when it is manipulated. There is no tenderness of the spine and no extension of the swelling into the psoas region. The left base is dull from the eighth rib downwards, and there is a coarse inspiratory murmur here of abnormal quality, but no tubular breathing. There is no apparent displacement of the heart.

February 4th.—The child is lying on its left side with legs drawn up. The swelling in the right lumbar region is now raised above the general level of the abdominal wall, and is easily seen and felt. Fluctuation is easily obtained all over the right side of the abdomen extending to the median line. The muscles are kept rigid over the tumour, and the boy cries when he is examined, the swelling at the hinder part being especially tender. There is no superficial redness. As the urine is passed into the bed very little could be collected, and it was questionable whether this contained a trace of albumen.

February 5th.—The tumour remains the same. There is no redness of the skin, and it is not very painful when examined. There is loss of resonance all over the right lumbar region, the note changing at a line drawn vertically through the anterior superior spine; and one inch further back towards the spine it is quite dull. The abdomen is full and rather distended but the right side is not rigid to-day. Urine without sediment; no albumen or sugar. There appears to be no loss of resonance of the left base now.

February 6th.—The condition of the tumour is the same as yesterday. The right thigh is flexed on the abdomen. Mr. Lucas examined the tumour and determined to operate. The patient having been placed under chloroform and the carbolic spray being directed over the lumbar region, Mr. Lucas made an incision, commencing about an inch and a half from the spine and running forward parallel with the last rib. The sac of an abscess was reached after cutting through the abdominal muscles, and on being opened, a large quantity of thick, curdy, but not offensive, pus escaped from the opening. The wound was then enlarged vertically so that Mr. Lucas could introduce his fingers and explore the relations of the abscess cavity. It was found that the abscess lay between the quadratus lumborum muscle and the kidney; this organ being displaced forwards and having posteriorly a somewhat irregular surface. The spine was felt with the finger, but no evidence of disease in it was discovered. The abscess cavity extended downwards towards the ilium, but its origin could not be traced to disease of this bone, which was covered with periosteum and muscle. Much thick pyogenic membrane was extracted by forceps from the cavity of the abscess, which was afterwards syringed out with carbolic lotion. A large drainage tube was inserted and the wound dressed antiseptically.

February 7th.—There is no albumen or blood in the urine. The boy is sitting up in bed and appears to be in no pain. Pulse 120°. The wound was dressed, as the discharge had soaked through the dressings.

February 8th.—The temperature since the operation has not risen above 99·2°, and the boy seems in no pain. He is eating and sleeping well. Pulse 132°.

February 15th.—Nothing has occurred since the 8th worthy of note. His progress has been uninterruptedly good. There is no pain and the discharge is small in amount. The drainage tube was removed to-day.

February 19th.—Still going on well. He eats and sleeps well, and his bowels are regular. Wound dressed every other day.

February 25th.—Dressed yesterday. Wound closing. Very little discharge. The boy's health is good.

*

March 4th.—Wound practically healed. He is up to-day.

March 6th.—He is running about the ward.

March 15th.—Discharged quite cured.

The boy was kept under observation, and on July 8th, was thoroughly examined. He was then fat and in perfect health. There was no evidence whatever of spinal disease. His back was not tender, and bent with ease into a rounded curve. There was no thickening left on the right side of his abdomen, and save the scar in the loin, nothing to point to his previous illness.

Remarks.—Difficult as it is to obtain satisfactory histories of disease in children, the peri-nephritic abscess in this case was, I have little doubt, correctly traced to an injury caused by another boy throwing the little patient down on his back. The child had previously suffered from scarlet fever and whooping cough, and his tissues were probably in a condition little able to resist injury, or to bring about repair. The injury happened about three months before he came under observation, and it had been noticed that he had been ailing, and often fretful, and that he had suffered from capricious appetite from the time of the accident. It is not improbable that when thrown down he may have fallen on some stone or other body which damaged his loin. It is often quite impossible to determine what injuries a child may have received after a fall, and the injury to the head appears in this case to have obscured any other. On the other hand, a history of injury may be deceptive, and lead one to suspect a peri-nephritic abscess when the tumour is purely renal. Thus, in the case of a patient from whom I removed a renal calculus last November, there was a history of his having been in a railway accident in the January previous, and a more definite history of his having fallen across a groin at the seaside in the month of July. He had retraction of the thigh, and a tumour in the lumbar region, whilst his urine was perfectly normal. Such a history, apart from other symptoms, would lead one to suspect peri-nephritic abscess rather than nephritic, but the tumour proved to be renal, and excited by an impacted stone. A history of injury must not, therefore, be allowed to obscure the possibility of other causes ; still, a definite history of a contusion in the loin would incline one to the diagnosis of a peri-nephritic abscess. In a case which came under my observation last year, there was a history of a kick by a horse under the ribs some months before, and I have little doubt that the abscess was attributable to that injury ; so, in the present case, a definite injury dates the onset of symptoms. It may be interesting to consider how far the kidney itself is responsible for the abscess in these cases. In other words, what relation does injury to the renal texture bear to the frequency of abscess after a contusion of the loin? The loose fat surrounding the kidney at first sight suggests a tissue that might be very prone to diffuse suppuration, while its depth from the surface is such as to give it a general protection. The liability of this fatty envelope to suppuration would follow the law as to suppuration elsewhere, in so far as it would increase after fevers or long depressing illnesses. Some suspicion of danger of exciting suppuration in this tissue was doubtless one of the notions which deterred surgeons till recently from operating upon the kidney. How far this view might be justified if old methods of dressing were employed I have no evidence to offer, but under strict antiseptic precautions it is certainly not a dangerous tissue to operate through, and large wounds made to introduce the hand for exploration of the kidney will generally heal by first intention. My own experience now extends to nine cases in which I have explored or performed some operation upon the kidney, and in no case has there been suppuration in this tissue of a kind to give me anxiety. I am therefore inclined to acquit the fatty envelope of any greater tendency to suppuration than exists in areolar tissue elsewhere. Bruising of the loin may excite deep-seated abscess here just as the cellular tissue elsewhere is excited to suppurate when injured, a result which is determined as much by the general health and constitution of the patient as by the severity of the injury.

Bruising of the kidney may be a complication of contusion of the loin or abdomen, and is usually indicated by a certain amount of blood in the urine. Such a case I was called to see at Guy's Hospital on July 9th, 1884. A sailor had fallen a distance of 25 feet into a ship's hold, striking against a beam in his descent. He was admitted in a state of great collapse, complaining of great pain in the abdomen, with a scalp wound on the left temple accompanied with contusion, and a fracture of the left radius. His urine was drawn off, and found to be slightly coloured with blood. The amount of blood, however, was not such as to indicate a severe lesion of the kidney, whereas his collapse and central abdominal pain were intense. He died seventeen hours after the injury from ruptured intestine. After death, a considerable amount of blood was found extravasated into the cellular tissue around the left kidney, and the cortex of that organ was bruised and ecchymosed, but there was no rupture of its surface. Had the man escaped the rupture of the intestine, would such an injury have excited an abscess in his lumbar region? I am inclined to think that in a healthy man, with good organs, such an injury is not frequently followed by suppuration, and with sufficient rest a good result may be anticipated. Nor when the cortex of the kidney is ruptured do I find, after an examination of the records of a great many cases, that suppuration is a frequent complication ; and it is, I believe, only when the rupture extends into the pelvis, or one of its calyces, the ill results of extravasated urine are likely to follow. Should suppuration follow, I have no doubt whatever that the earlier a free exit is established for the evacuation of the pus, the better for the patient ; and my principal object in publishing this case is to point out the safety with which this may be effected through the loin under antiseptic treatment. It will be noted that the highest temperature recorded after the operation was 99·2° ; the drainage-tube was removed on the ninth day, and the wound was closed within a month.

SOME OBSERVATIONS ON ENDEMIC FEVERS IN INDIA.

By Surgeon J. PEDLOW, M.D.
Army Medical Department.

(*Continued from page* 77.)

Now, coming to the year 1883, with the exception of a mild case of remittent fever admitted on the 16th January, in which the temperature was normal morning and evening on the thirteenth day, one case of febricula in February, and a second in March, there was no run of cases until April. In that month six cases were admitted and six in May. They to a great extent took the place of the simple continued and remittent fevers of the previous season, and many of them were indistinguishable from them in character. Some of them assumed gradually a more severe type until they resembled ill-defined enteric. Two more cases of this fever in June and two in July were also admitted. The first case of enteric fever in this year was admitted on 25th April, and the last on the 7th

November. They were distributed as follows: three in April, three in May, one in June, six in July, seven in August, three in September, and one very mild case in November. The only fatal cases this year were enteric; two died in May, two in July, two in August, and one in September. With regard to remittent fever, in addition to the case in January, there was one in July, two in August, and two in September. In this last month also a case of remittent was admitted with a sharp relapse which had been discharged ten days previously. There were only two cases of simple continued fever, both in April, and the last case of fever for this year, one of febricula, very mild in character, was admitted on the 11th December. It will thus be seen from this statement that in both years the period of greatest prevalence of simple continued, remittent and febricula was immediately before, and during the enteric fever period. A run of such cases foretold unerringly the arrival of the fatal form. It is also apparent that in 1883, enteric fever to some extent took the place of remittent. This was simply due to the fact, that if at any time during the course of a case there was evidence of intestinal complications, it was returned as enteric. The high mortality of 1882, compared with 1883, is thus partly explained. *Under any circumstances, it is highly probable that some climatic condition, showing its existence and growth by mild and severe cases of undefined fever, gradually attained its maximum virulence during the prevalence of the fatal enteric cases and attacked chiefly young soldiers under 26 years of age.*

With regard to ague it may be mentioned that twenty-seven cases were admitted in 1882, and about forty-three in 1883. They were pretty equally distributed throughout the year, except in January, February, and March, 1882, which were below the average of the other months. Seasoned soldiers who have periodic attacks of ague, prefer a dose of quinine to being taken into hospital, and consequently all the cases do not appear in the returns.

Coming to an analysis of the cases returned as enteric, I find that seven cases of the thirty-four had obstinate constipation throughout, and four, constipation followed by mild bilious diarrhœa of a few days' duration. Delirium was often absent in the mild cases. In all the severe cases which proved fatal at an early period the motions were very bilious at the outset and often until death. They were a bright green or yellow, very frothy, and often passed with violence. The periods under treatment and the character of the temperature varied much. In the cases which recovered, three were in hospital 72, 73, and 77 days, seven cases 61 to 69 days, six cases 40 to 46 days, three cases 32, 37, and 38 days, one case 51 days, and one case in which there were two relapses 128 days. As regards the temperature, dating from the estimated day of illness, usually one or two days before admission, in two cases it was normal morning and evening on or about the 22nd day, in two on the 23rd day, in two on the 27th day, in one on the 32nd day, two on the 36th and 40th days, and in the others on the 9th, 12th, 15th, 16th, 17th, 19th, 24th, 25th, 28th, 38th, 47th, and 99th day. With regard to symptoms they will be treated more in detail when the individual cases are recorded, but many of the fatal ones and those in which the temperature was high during the first week, differed much from typical cases. In many of the former, the patients stated on admission that the attack was sudden, and ushered in by severe pain in the head, and often by intense giddiness, with vomiting of green bilious matter; occasionally these symptoms passed away, and the patient felt better until the next day when they returned. With regard to those cases with normal temperatures under twenty days, four of them had high fever and persistent headache, diarrhœa with bilious motions and abdominal tenderness, one of these also had delirium at night and urinary retention; the fifth case had enteric motions, and the sixth, constipation throughout, headache followed by delirium and mild bronchitis, and in his case convalescence was much retarded by crops of boils.

The following is a record of one of the mildest of these cases. Private E. M., age 22, was detained in hospital on the 22nd August, and admitted on the following day. He complained of severe headache and pain in the back; his face was much flushed, his skin dry and hot, and his eyes suffused. There was some pain and gurgling in right iliac fossa, and the bowels were moved six times on the day of admission, the motions being bilious and frothy. He said he had had all these symptoms three days. On the 24th, his condition was unchanged, his tongue was thickly furred. He stated he had passed a restless night. There was some abdominal tenderness on pressure. On the following day the motions had the characters of those of enteric fever. There was a slight cough, and a few sibilant rales were heard over chest. There was no delirium, and the headache was less. On the 26th there was some improvement; tongue was somewhat cleaner. His condition from that time improved, and he was discharged on the 38th day of illness.

9th	99·6	103
10th	98	98·6
11th	98	99·2

Now this case much resembled some others in which, after the temperature had reached the normal, and symptoms of improvement were setting in, some unknown cause brought about a relapse. These relapses actually occurred in six cases. In two of these the temperature had been normal morning and evening for some days; in two normal only in the morning; in one normal morning and evening for one day, having been normal the morning of the previous day, and in the remaining case the patient had actually been discharged from the hospital. In five cases the original attack was mild, and of a doubtful nature as regards the enteric complications. The sixth case was more severe, and had two distinct relapses. It was of much interest, as showing that in a pretty sharp original attack abdominal pain and tenderness, characteristic stools, and severe delirium may be absent, and that in case of a relapse a slight increase in its severity may be followed by the appearance of these symptoms. In the absence of these in the original attack, the diagnosis naturally lies between simple continued, and remittent, so that this and some of the other relapses actually show the identity of these fevers in these cases, at least in this station. The following is a summary of this case. The patient, a boy, aged 15, was admitted to hospital on the 31st July, 1883, with a sharp attack of fever. He stated that two days previously he was attacked with giddiness and sickness, which subsided when he lay down. He had also aching pains in the limbs. The following day he had headache, and the sickness and giddy feeling returned on his rising up. On admission, his face was flushed, and his tongue covered with a white fur; his bowels acted three times in the 24 hours, and the motions were bilious. There was no abdominal pain or fulness, and no tenderness on pressure. He was restless at night. Diarrhœa

ceased on the fourth day of illness, and on the sixth day the motions were normal; headache also disappeared. He had very slight delirium on the seventh night, which subsided in a few days; tongue was then noted as brown in centre, and red at the sides. The bowels were constipated. Some improvement was evident on the twelfth day of illness; the tongue commenced to clean, and appetite improved. This improvement slowly continued, and his temperature was normal morning and evening on the twenty-eighth day of illness. The bowels were still obstinately constipated, and he frequently required enemata of soap and water. During the seven days preceding the second attack he was apparently doing well, and difficulty was experienced in keeping him in bed. On the afternoon of the thirty-fifth day of illness, he was seized with severe headache and vomiting, and his temperature, which was normal in the morning, rose suddenly in the evening to 102°. Bronchitic symptoms set in two days after, and delirium was present on the fortieth night. The bowels were constipated, but there was considerable abdominal tenderness. As the temperature at 4 o'clock p.m. rose high, and as a higher rise was anticipated, he was put in a bath daily, at a temperature of 85°, from the fortieth to the forty-fifth day, both inclusive, until the temperature fell to 99° or 100° in the mouth. This fall usually required half-an-hour. Characteristic diarrhœa set in on the forty-first day, and continued for eight days, and there was much abdominal pain and tenderness. On the forty-sixth day there was evident improvement, and his tongue commenced to clean; the stools lost their enteric character about the fiftieth day, and the temperature again reached the normal on the fifty-seventh day, and continued so for ten days. On the sixty-sixth day, when almost well, and sitting up in bed, there was a rise in the evening of over two degrees. The third attack came on gradually with complete morning remissions and evening exacerbations; there was no headache, and the appetite was good for some days, the fever became more continued on the seventy-second day, and the tongue furred and white. On the seventy-third day his abdomen was tumid and painful on pressure, and his skin was hot and dry, temperature at 10 o'clock a.m. was 104·8°, and he was put in bath at a temperature of 88° for three-quarters of an hour. Before bath, temperature 104·8°, pulse 132, respiration 18. After bath, temperature 101·4°, pulse, 130, respiration 16. Half-an-hour after it rose to 102·9°. The bath was repeated same evening at 5 o'clock; before bath, temperature 105°, pulse 128; after bath, temperature 102°, pulse 116. Next morning the motions were enteric in character; bath was again repeated, morning and evening, with the same result. He was occasionally delirious throughout the day. On the seventy-fifth day his temperature fell a little; there was then great abdominal tenderness and tumidity; the patient lay with his legs drawn up. Respiration was very hurried, and the motions, which were very fœtid, were passed in bed; teeth were covered with sordes, tongue was dry and dark brown; sibilant rales were heard over the lungs, and the base of both was also congested; urine was dark-coloured, but contained no albumen. There was some pain over kidneys. These symptoms continued with very little change from the seventy-fifth to the seventy-eighth day. There was a little delirium at night, but the patient lay in an apathetic condition, and disliked being disturbed. From the last date there was some improvement; abdominal pain and tenderness gradually subsided, and the stools lost their enteric character. The temperature fell to normal on the ninety-ninth day. Convalescence was rapid, and he was discharged hospital on the 128th day.

The temperature in this case was peculiar in the first attack; it only rose once above 103°, and varied between 101° and 103° until the fourteenth day of illness. After being normal from the twenty-eighth until the thirty-fourth day, the relapse showed a very sudden rise and the range was higher. In the third attack, on the contrary, the invasion was gradual, the temperature being normal in the morning for three days, and 101° and 102° in the evenings. Within the next four days it had run as high as 105° in the afternoons, and a higher temperature was prevented by baths.

Now the following case, in which there was a relapse, differed much from the one just recorded. In this one a mild attack of what, in the absence of any complication, was considered simple continued fever, was followed by a sharp attack of so-called enteric fever, in which there was abdominal pain and tenderness and bronchitis Private F., age 21, service in India two years and eight months, was detained in hospital on the 25th August, 1883, and admitted the following day. He complained of severe pains in the forehead and back. His face was flushed, and his eyes suffused, tongue was covered with a moist white fur, bowels were constipated. Pain disappeared from the head in four days, and his temperature fell to normal on the morning of the seventh day; tongue was then cleaning, and improvement was evident. On the fourteenth day temperature was normal morning and evening, and continued so until the twenty-seventh day, when there was a morning rise of 2·2°. His face was then flushed, and his tongue was moist and clean; headache returned that day, and was very severe; tongue became furred and white, and abdominal pain and tenderness with bronchitis followed in the next three days. His throat was congested, and pain was complained of over the spleen. His intellect was confused, and he answered questions apathetically, and with an effort. He continued in this condition for six days, the tongue becoming quite parched, and the temperature reaching 103° every evening. On the thirty-fifth day he looked somewhat better, and his tongue became moister. His temperature fell on this and the following day to 100°. His bowels were constipated throughout each attack. There was much debility afterwards, and he was not discharged from the hospital until the 72nd day. Urine was examined twice; it contained no albumen.

Estimated day of Illness.	TEMPERATURE.	
	Morning.	Evening.
	°	°

38th	99·6	101·6
39th	99	101·8
40th	normal	

Now a consideration of the characters of both these cases, I think, will show that these renewed attacks occurring when the patients were almost convalescent were *bonâ fide* relapses, but with characteristic symptoms added in proportion to their severity. The original attack in the first case was considered remittent in type, and in the second case, as stated before, febricula, or simple continued fever. The relapses, however, with their visceral complications, but one with and the second without diarrhœa, necessitated a change of diagnosis to enteric. *Each attack almost exactly represents the different types of fever met with here, and the varying characters of the same in different cases.*

In the next case, the original attack was mild and defervescence incomplete. The patient was admitted on the 15th July, 1883, with slight fever which lasted for six days. On the seventh and eighth days the temperature was normal in the morning, and on the tenth, eleventh, and twelfth days varied between that and 99°. The case appeared to be one of febricula. On the fourteenth day the temperature rose to 100° in morning and 103·2° at night, and in the following ten days varied between 102° and 104·2° at night. It then slowly fell, reaching the normal on the thirty-sixth day. Throughout, there was no delirium or abdominal pain. There was sharp headache in the relapse and obstinate constipation, and convalescence was much delayed by œdema of limbs and debility.

In the following case a well marked attack of fever, with visceral complications, followed a mild original attack. Private S., aged 23, service in India eight months, was admitted to hospital on the 22nd October, 1882, suffering from severe headache, fever, and diarrhœa, which he stated had gone on for seven days. This diarrhœa continued for three days after admission, the bowels on the third day being moved eight times. The motions were bilious. His tongue, however, cleaned, and the temperature reached the normal on the seventh day in hospital, or thirteenth day of illness. His condition then was apparently improving. Temperature continued normal in the morning for three days. On the fifteenth day of illness, symptoms of a relapse appeared, his tongue became furred and severe headache again set in. The following day, tongue became quite dry and rough; it was red, and had lost the white fur; the diarrhœa also was severe. On the nineteenth day, the stools were enteric in character. His throat also was much congested and very painful. Delirium set in on twentieth day and his lips became quite dry and brown, tongue was fissured and shrunken looking, and teeth covered with sordes. On the twenty-second day the diarrhœa subsided and the tongue lost its shrunken appearance; the delirium disappeared on the twenty-fourth day, but the patient lay in an apathetic condition, and spoke with an effort; bowels were then constipated. He commenced to improve slowly from that date, and was discharged from the hospital on the 28th December. The temperature in this case was peculiar, on the 16th, 17th, 18th, and 19th day it reached its highest point between three and four p.m. It was 104·4°, 104·2°, 104°, and 104·2°, on each of these days respectively. About that time many other cases were also similarly irregular as regards the temperature.

In the following case the diagnosis was somewhat doubtful, and the case irregular from the outset. It had a fatal issue. Private S., age 24, was admitted to hospital on the 17th of August, 1883, complaining of debility and looseness of the bowels. Diarrhœa he said had existed for two or three days previously. There was some abdominal pain; he had no headache or pain in back or limbs, face was not flushed. During the first four days in hospital, the bowels were moved six or eight times a day, the motions being dark-coloured, and very offensive, but passed without pain or straining. On the eighth day of illness his temperature fell to normal morning and evening, and beyond the continuance of slight diarrhœa he was much improved. This improvement continued for three days and his tongue became cleaner. On the evening of the twelfth day, temperature rose to 102·2° and the diarrhœa became severe; his tongue was furred and irritable. He continued without improvement until the twenty-second day, when his condition seemed somewhat better, and his appetite improved. On the thirty-seventh day of his illness, the diarrhœa returned, the stools became dark-coloured and very fœtid; delirium was present for the first time that night. He sank shortly afterwards into a state of collapse, and died in that condition on the forty-second day of total illness. He had two admissions for dysentery during his four months' service in India. On *post-mortem* examination there was passive congestion of brain membranes and increase of cerebro-spinal fluid. The respiratory organs and the liver were healthy, spleen was atrophied. Small intestines were healthy until within eight or nine inches of the ileo-cæcal valve, there the mucous membrane was congested; some inches further, it was thickened and a few patches of mucous membrane were eroded as if cleanly dissected off. There was no enlargement or ulceration of Peyer's patches or glands, and no apparent traces of them. The large intestines were very much congested as far as the rectum, which was healthy. Numerous patches of erosion in the mucous membrane of the ascending colon were found and the bowel was much inflamed there. The mesenteric glands were enlarged. The kidneys were healthy. This case had the characteristic morning remissions and evening exacerbations of a mild typhoid case. It is probable that the previous attacks of dysentery had destroyed the solitary and agminated glands.

(*To be continued.*)

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

GOVERNMENT CIVIL HOSPITAL, POINT DE GALLE, CEYLON.

CASE OF GUNSHOT WOUND OF THE COLON, AND BASE OF LEFT LUNG, WITH RECOVERY.

By. C. J. KRIEKENBECK, M.B., M.C., Edin.
Medical Officer in Charge.

Fred. L., a boy of 16, on his way out to China, was accidentally shot by the second steward of the ss. *Glencoe*, whilst carelessly handling an army revolver. He (the steward) had taken the revolver out of a drawer, not knowing it was loaded, and stated afterwards, that before he knew anything, he heard the report, felt the bullet go through the palm of his own left hand, saw the boy L., who was standing about three feet in front of him at the time, stagger, and cry out he was wounded. On being examined by the surgeon of the ship, the steward was found to have a wound going through the palm of the left hand, splintering the metacarpal bone of the middle finger.

The lad L. had a wound on the left hypochondriac region, the bullet going upwards and outwards, wounding the edge of the left lung, and lodging beneath the

skin of the back, from whence it was cut out by the ship's surgeon. All this happened on the 10th February, in the Red Sea, and nine days after, the surgeon wishing to have a consultation with a *confrère* on shore, the steamer put in at this port, and the cases were seen on board by my friend Surgeon Lloyd, of the A.M.D., stationed here. He advised and superintended their immediate removal to this hospital, where I took charge of them.

The following is a condensed statement from notes taken at the time by my house-surgeon, and my own entries day by day :—

Frederic L., admitted 1.30 p.m., 19th February, 1884. Has a hectic flush ; temperature 99·6°; pulse 148 ; respiration 54 ; great dyspnœa. Lies flat on his back. Breathing short and hurried. Emphysema all over left side of chest, the crackling under the fingers extending to Poupart's ligament on that side. Wound of entrance three inches to the left of the mesial line, between the cartilages of the eighth and ninth ribs, sucking in air with every inspiration. The wound of exit was closed up, and there was a strong fæcal odour about him.

Bowels not moved for several days. He was put to bed and the wounds dressed under the carbolic spray, with boracic acid and iodoform lint. Allowed brandy and ice, with quinine and opium pills, chicken broth, bread and milk, and beef-tea.

February 20th.—States he slept fairly well, and feels much easier. Bowels not moved. Takes nourishment well. Temperature 101°. Breathes easier.

February 21st.—In *statu quo*. Temperature 100·4°. To have a castor oil enema.

February 22nd.—Lies on his back still. Fæcal odour very marked in spite of carbolic spray and antiseptic dressings. No passage of fæces per anum. Enema alone came away. This made me suspect that not only had the lung been injured, but that some portion of the intestine was also involved, and that from the position and direction of the wound, and the circumstances stated above, the portion wounded was evidently the end of the transverse, or the upper portion of the descending colon. *This had never struck any of us before.*

I accordingly removed all dressings, and under the carbolic spray had him gently turned on to his left side, when there rushed out 64 ozs. of dark-coloured, foul-smelling fluid fæces, from the wound of entrance. The odour was most horrible in spite of the carbolic spray and the sea breeze blowing through the eight open windows and three doors of the large ward upstairs. He was then placed again on his back, and four syringes full of weak carbolic lotion (1 to 120) syringed in, then turned again on his left side to allow it to run out, and this was done till the lotion ran out clear, twice a day ; the wound was covered over then with lint squeezed out of boracic acid solution, and iodoform sprinkled between two folds. Under this treatment, the stuff that escaped every morning and evening, when he was turned on to his side, lost its marked fæcal odour, being, in fact, now nothing more than the digested food, &c., voided through this novel artificial anus, just before it could go lower down the gut, and assume the usual fæcal odour. The temperature, pulse, and respiration, became normal, the emphysema began to disappear gradually, and the wound of entrance contract and heal. I should have stated before that the wound of exit had closed and healed up a day or two after the bullet had been extracted, and before patient came into hospital.

He continued to do well, and now stated that "he felt inclined to go to stool, but couldn't." A simple castor oil enema was given him, bringing away a little fæcal matter in small lumps.

After this he began to pass dark-coloured stools per anum, and the escape of fæcal matter through the wound grew less every day, the wound itself contracting and healing rapidly ; *too* rapidly in fact, as the sequel showed ! On the 5th of March, seventeen days after admission, nothing came through the wound, which was now closed up by granulations. In 24 hours, however, his temperature, normal the previous days, went up at once to 103.6° ; he complained of "a feeling of tightness" on the left side, and pain. Under treatment he felt easier, but soon after commenced to retch. This forced out through the wound a small quantity of the same stuff he used to pass before. Suspecting what had occurred, I gently enlarged the opening and inserted a drainage tube, the carbolic spray playing all the time, and on turning him on to his left side, 24 ozs. of fluid, excrementitious matter, similar to that passed before, came away. Weak carbolic lotion was syringed in again till it ran out clear, and the drainage tube left in the wound, which was dressed as before with boracic acid and iodoform. The temperature went down to normal at once, the discharge through the drainage tube became less every day, and he passed his stools in the natural way. The wound commenced to contract and push out the drainage tube, and on the 15th March the last bit of tube was forced out. He had been rapidly gaining strength, and was found one day trying to stand up. By the 18th March he was able to walk to his chair, the wound being completely healed. By the 30th March he was quite well, and fit to leave hospital, but had to wait for a steamer to take him on to Hankow. On the 23rd April, an opportunity offering, he left for that port quite strong, and in great spirits.

In conclusion I may state that the steward had a very bad hand when admitted. The left hand and upper arm very much swollen and erysipelatous ; temperature 101°, and edges of wound sloughing. This case was also always dressed, under the carbolic spray, with boracic acid and iodoform, and quinine and opium pills internally. In a few days the pain was very much less, he slept well, the swelling and erysipelas disappeared, the temperature (according to the chart) became normal, and by the 15th March the wounds had healed. The middle finger was stiff and he could not bend it well, but with passive motion, in time, I am sure he will have his hand all right again. He also left on the 23rd April with his companion in misfortune, to rejoin his steamer in China.

Medical Times and Gazette.

SATURDAY, JULY 26, 1884.

Our Paris Correspondent writes :—The French are said to be fond of change, and apt to promote revolutions. It must, however, be acknowledged that a full compensation exists on the other side, and that we frequently meet with more than Celtic obstinacy in our great men. Dr. Fauvel has afforded ample proof of this. At the last meeting of the Academy of Medicine, a letter from the celebrated Inspector of Public Health was read, in which he distinctly states it as his opinion that the cholera at Toulon and Marseilles is a mere local outbreak, which will die out on the spot where it was born, without extending to other localities. Dr. Fauvel adds that as soon as his health is restored, he will return to his post and stand up in defence of his views, which remain unchanged, in spite of all that has been said to the contrary. Not only

does the Inspector-General resist the power of argument, but he goes straight against the testimony of facts. Cases of cholera have broken out at Arles, where ten fatal cases occurred in a single day; at Nimes, at Lyons, at Aix, and in various other southern localities. The number of deaths has slightly diminished at Marseilles, while it has certainly increased at Toulon, the highest figure on record being 49 deaths in a single day. A certain number of medical students have been sent to the afflicted city by the Faculty of Montpellier; they were accompanied by two of their professors. The meritorious devotion of these gentlemen is enhanced by the fact that several physicians, students, sisters, and attendants have already fallen victims to the epidemic. The Mayor of Toulon is still in a state of great prostration, but his life is said to be out of danger. He was (very properly) made a Knight of the Legion of Honour during the Ministerial visit. M. Alazard, a town councillor, after most praiseworthy exertions in favour of the sick, fell a victim to the epidemic. His widow and children retired to their country seat at La Cran, but the Mayor of the locality refused to receive them, and prevented them from entering their own house. His conduct has met with universal disapprobation, except in the south where the terror of the epidemic seems to have obliterated all feelings of justice. The prescriptions of the Board of Health are openly violated at Toulon, where choleraic dejections are thrown, as before, into the open streets, or kept in the houses without being disinfected. While this state of things persists, it seems difficult to predict the close of the epidemic.

According to the statement made by the Director-General of Public Assistance at Paris, no cases of true cholera have been observed in hospital, although diarrhœa is frequent enough. Some fatal cases of cholera nostras have occurred in the town, but as they are really limited, and do not spread, they may be referred to the ordinary state of public health during the summer months in Paris. It is well known, of course, that every year, in July and August, some cases of sporadic cholera break out in this city.

Two doctors of Marseilles have succeeded in discovering the morbid agent of Asiatic cholera, which, according to their statement, is a "*mucor*" entirely distinct from the "*comma*" of Dr. Koch. Considerable amusement was created at the Academy, when the perpetual secretary, Professor Beclard, exhibited the sealed box which contained preparations and specimens of the offending "*microbe*." Amidst a general burst of laughter, the president was requested "to keep the box sealed." Thus does the spirit of Comedy invade the ground of Tragedy, even in the most serious of human affairs.

Much disappointment has been expressed in Vienna and elsewhere that no official account has as yet been published of the results of Dr. Koch's visit to the South of France. This feeling, however, will soon be dispelled by the report of the next meeting of the Berliner Medicinische Gesellschaft, at which Dr. Koch is expected to make a valuable contribution to the stock of our knowledge of cholera and to present a summary of the results of his own labours on the subject.

The steamer *St. Dunstan*, with a cholera infected crew, arrived in the Mersey on the 18th inst. Some deaths had occurred during the voyage home from Marseilles and several of the survivors were in a condition described as a "want of tone." The Liverpool Medical Officer of Health immediately visited the ship and took active measures by disinfection and isolation to restore confidence to the frightened sailors. The convalescents and suspects were removed to the cholera hospital at Rock Ferry. The captain, officers, and crew, who remain on board in quarantine, are all quite well. The water ballast will be thoroughly disinfected with carbolic acid before being discharged.

A Ministerial Enactment issued by the Prussian Government contains a long series of orders and recommendations on the subject of the sanitary precautions necessary to be taken before and after the appearance of cholera in any given district. Among other instructions will be found an important order with respect to the medical inspection of all persons travelling by railway into Germany from any infected country. Suspicion on the part of the inspecting officer will warrant him in detaining the suspected passenger in quarters to be specially provided for such cases. The traffic along the great rivers is not subject to such severe restrictions. By way of ensuring due attention to the regulations laid down, a further extension of the system of sanitary commissions is to be carried out and applied to towns of less than 5,000 inhabitants. A long and minute series of instructions is appended for the guidance of these commissions, and to many of these excellent regulations the words "if possible" have somewhat naively been added, as they would appear to be as impracticable in effect as they are correct in theory. Instructions for disinfection of clothing and other matters are given in detail, steam being in almost every case the chosen disinfecting agent. The use of dry air at high temperature is not mentioned, and no stress is laid upon the paramount necessity of boiling all the water used for drinking or any domestic purpose whatever.

The chances that the Medical Act Amendment Bill will be passed this year, or will even be again brought before the present House of Commons, are rapidly reaching the vanishing point. Mr. Gladstone stated on Monday night that the Bill could not possibly be taken this week, but that during the week the Government would consider what course can be taken with regard to it.

The grievances of the Indian Medical Service were very ably and temperately brought before the House of Commons by Mr. Gibson and Sir Lyon Playfair on Friday sennight. The medical officers have been labouring under a sense of hard treatment and injustice

for some years ; and the questions that have from time to time during the last two or three Sessions been put to the Under-Secretary for India on the subject have shown that not a few Members of the House were assured of the reality of the grievances complained of, and sympathised with the Service. The Government, however, refused to recognise that any just ground of complaint existed ; and so the discontent spread and increased, and at last found full vent in the House of Commons on Friday. Mr. Gibson and Sir Lyon Playfair moved that the condition of the East Indian Medical Service called for the early attention of Her Majesty's Government ; and that the House trusted that steps would soon be taken to lessen the block in promotion, and the disappointment at the methods of employment existing in its ranks. The motion expresses very exactly the chief grievances of the Service ; and they most acutely and especially affect the junior officers. Nearly all the speakers confined their observations to these grievances, and we shall follow their example. We have not been able to assure ourselves that the senior officers have any great cause for complaint. There are still many very valuable appointments and prizes open to the seniors, though since the Service was divided into two branches, the Military and the Civil, fewer of the great prizes fall to the officers of the Military branch than was formerly the case ; and it may be that in both branches seniority in the Service is more often made to give way to selection on account of special merit. But the authorities must be allowed the power of selection for merit; and though this may give rise now and then to a charge of favouritism, that is a charge which it is very easy to make, and very difficult to either prove or disprove. The grievances of the junior officers are, on the contrary, solid and unquestionable, and we have dealt with them fully in another portion of this paper.

The Under-Secretary for India endeavoured in a laboured speech, bristling with statistics, to prove that there is no foundation whatever for the complaints made. The overmanning of the Service was one of those accidents that will happen now and then in every service, as deaths and resignations do not occur in constantly regular mathematical proportions, and, therefore, mistakes must be sometimes made in calculating year by year the number of officers to be added to the medical reserve ; and he defied any rational person to interpret the incriminated memorandum in the sense attributed to it by the medical officers. He explained the need there is, which no one denies, of retaining a reserve of surgeons in excess of the bare number required to fill all the necessary appointments in times of peace, and he stated that the nature and conditions of this reserve are fully explained in the Indian Medical Blue-Book of 1881 ; but it is difficult to suppose that Mr. Cross really means that any man who thinks of trying for the Indian Medical Service must obtain and study the Indian Medical Blue-Book for 1881, as well as the memorandum issued by the India Office. Mr. Cross was uncompromising in his attitude towards the Service through the greater part of his speech ; but at the end he softened, or affected to soften, a little. He asserted that his sympathy was with the juniors of the Medical Service, and that if, consistently with his duty, anything could be done for them, he should be delighted. The statements made by the various speakers during the debate should receive the utmost consideration, and the whole matter should be placed before the Government of India. Whether Mr. Cross's sympathy and consideration are likely to prove of any value, we have no means of judging ; but though the motion was not pressed to a division it was supported by Members from all quarters of the House, and the Government will do well to consider that a complaint receiving such support must be very real and urgent.

The President of the Local Government Board has had time to consider the report of the Select Committee on the scheme for the sewerage of the Lower Thames Valley, and in polite terms altogether condemns it. It is, he believes, a fact that the Committee decided to recommend that the existing combined district be broken up after they had heard the evidence of only two out of the eleven constituent authorities, and without taking any evidence whatever on the part of the Main Sewerage Board on the subject. He points out that the authorities of the districts included in the joint district had failed, one after another, in their efforts to provide proper schemes for the disposal of their sewage ; and that it was simply and expressly because they had so failed that the Main Sewerage Board was constituted after local conferences and enquiries, and that its constitution was confirmed by Parliament after full consideration by a Select Committee. The decision of the Committee precludes the Sewerage Board from carrying out a scheme unanimously adopted by that Board for the purpose of keeping unpurified sewage out of the river ; and at the same time the Committee have rejected an unopposed scheme that would have protected the Board and the ratepayers from the penalties to which they will be liable, under the Thames Conservancy Act, after September next, for the discharge of unpurified sewage into the Thames.

Sir Charles Dilke observes that should the recommendations of the Select Committee be accepted, and the proposed new groups of districts be formed, the earliest possible date at which any of the authorities can be in a position to commence works, unless suitable land can be purchased by agreement, will be in 1886. But according to past experience it would be hopeless to expect that the separate schemes of the new authorities would not meet with strong opposition. We observed last week that the scheme of the Select Committee appeared perilously like going back to the chaos of discordant authorities that preceded the Joint Board ; and Sir Charles agrees with us. He sums up his criticism of the report by saying, that the present decision of the Committee would appear to make it impracticable to prevent the pollution of the river by sewage passing into it in a crude condition.

We were quite prepared to hear that the Government had found it impracticable to carry out the promise given in March last, to bring in a Bill this

Session for the regulation of the sale of poisonous patent medicines. Such a measure, however, has been prepared, and will be introduced in the House of Peers next Session by the Lord Chancellor. In the meantime it may be hoped that the measure now in force may be applied in a somewhat more liberal spirit than has recently been the case.

Some important conferences have been held at the Health Exhibition during the week. On Monday the subject was Ambulance Organisation. The chair was occupied by Sir James Paget, and the audience included some of the most distinguished experts in this special subject. Dr. Crawford, the Director-General of our own Army Department, Dr. Billings, the well-known chief of the corresponding department in the United States, Baron Mundy, the representative of the Austrian Army Medical Department, and of the Vienna Volunteer Society for Saving Life, Sir Joseph Fayrer, Dr. Farquharson, M.P., and others helped, both by their presence and by their contributions to the discussion, to give importance to the gathering. The readers of papers were Mr. John Furley, who chose for his subject "The carriage and removal of the sick and wounded," and Mr. V. B. Barrington Kennett, who dealt with "the Ambulance organisation of the metropolis during epidemics." Mr. Furley dwelt with a pride that was fully justified on the completeness of our present arrangements for affording first aid to the sick and wounded, compared with the absence of organisation a few years ago, and he foretold a great increase in the demand for specially constructed ambulance carriages. He insisted that these ought to be arranged as far as possible on a uniform system. Mr. Barrington Kennett described the present ambulance system, by which "infected persons are being removed from the Metropolitan area at the rate of nearly 300 a week, with the result that nine-tenths of the small-pox patients, instead of filling the London hospitals, are being treated twenty miles away from the metropolis." Sir James Paget in opening the discussion urged on all present the duty of aiding to the best of their power the extension of the work of first help to the sick and wounded.

On Monday afternoon Mr. Ernest Hart gave a lecture on Smoke Abatement, and on Tuesday Dr. Poore held forth on Thrift in its Relation to Health. There were more points of similarity between the lectures than their titles would lead one to suppose. Both dealt with the disposal of refuse; both arraigned the systems at present in vogue; and both suggested complete combustion as a practical solution of the difficulties. As far as the titles went, Mr. Hart's paper might have been termed "Thrift in Relation to Health" just as properly as Dr. Poore's, a total combustion grate deserving to be called a thrifty appliance quite as much as a Moule's earth-closet. A London fog is matter in the wrong place, no less than sewage in a water-way; and if the effluent from our chimney-sewers and the effluent from our drains were as innocuous as they ought to be, the effect on the death-rate would be most marked. As Mr. Hart pointed out, the mortality in London in some foggy weeks was as great as it would have been during the prevalence of a heavy cholera epidemic.

On Tuesday the series of conferences, held by the Epidemiological Society, were inaugurated by Dr. Norman Chevers with the presidential address on Health in India, which we publish in full in another column. Subsequently, Dr. W. Squire read a paper on change in type of epidemic disease. Even when such supposed change in type was anything more than the effect of circumstances, he believed it did not go beyond the accidents of the disease, which re-appeared in other cases with all its old characters unchanged. There were, however, two well recognised variations of type in epidemic diseases, viz., their rise and decline, both as regards prevalence and severity at certain seasons, and their recurrence in the form of aggravated epidemics at longer intervals. Scarlatina was a striking example of this, being as Heberden said of the allied disease diphtheria, "sometimes so mild as to call for no treatment, at others so violent as to admit of no relief" and malignant forms of small-pox occurred at long and irregular intervals apparently quite independent of sanitary conditions. As to any change of type of a more essential and permanent nature, such as to explain and justify opposite modes of treatment, he believed that the change was really in the attitude of the observer only.

On Wednesday Surgeon-Major R. Pringle, M.D., gave a short account of leprosy in India, appealing to the public as he had repeatedly though fruitlessly appealed to Her Majesty's Indian Government for state aid on account of the leper asylum at Dehra Doon, founded by the late "Shikari Wilson" and the "Dehra Doctor Sahib" (Surgeon-Major G. G. McLaren), and hitherto supported on the most frugal scale by private charity. Here 70 poor lepers of different ages and sexes are maintained in content and comparative comfort at five shillings per month! The duty devolving on the English Government of providing such asylums is more urgent now that the law prohibits the practice which still prevails in the native states of preventing the perpetuation of the disease in families, through the marriage of cases in the earlier stages, by putting the sufferers out of the way, *removing* them from the districts, over a precipice or otherwise.

Inspector-General Lawson opened a discussion on Cholera by reproducing the views he has repeatedly put forward at the Epidemiological Society and elsewhere, maintaining that it is not conveyed by human intercourse, but appears wherever favourable conditions, as manifested by diarrhœal diseases, &c., which may be looked on as prodromata of an outbreak, are present. He again quoted the list of epidemics more or less local in which importation had not been proved, and apparently ignored the many instances in which the importation of the disease was clear. On the occasion of the debates already alluded to we expressed our dissent from the views held by him, and we have not,

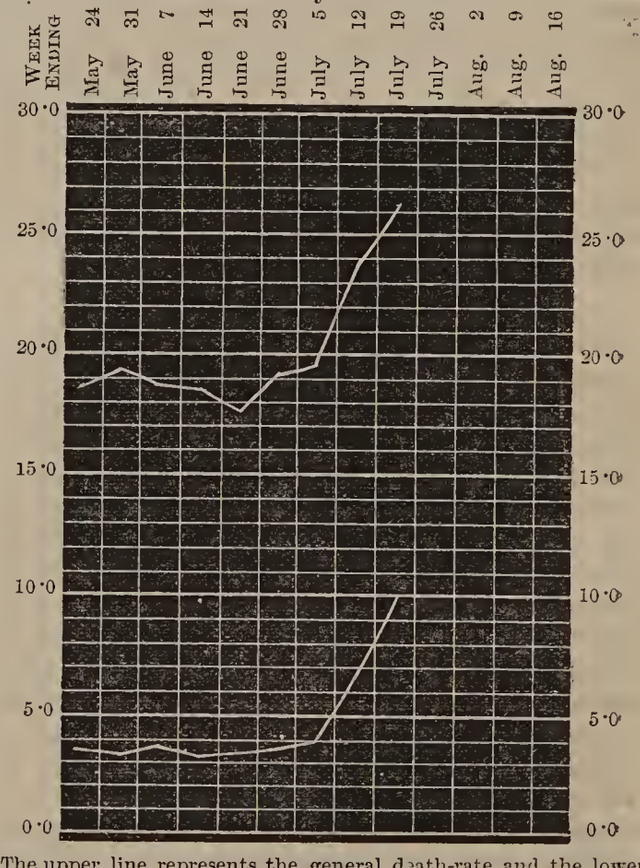
any more than he has, altered our opinions since. We heard, however, with surprise of the prevalence of epidemic cholera in England in 1867–8 !

On Tuesday evening at the Health Exhibition, Sir Francis Bolton explained the exhibit of the united London Water Supply Companies to a select number of medical men, representatives of the press, and others specially interested in the subject. As the Government Examiner, he was in a position to make an authoritative statement. It was interesting to hear him express his own belief that London is supplied with better water, and with a better quality of water than any other city in the world, a fact testified by the low death-rate, and especially the low death-rate from zymotic diseases. A visit to the water pavilion is calculated to afford both instruction and astonishment. The processes of filtration, storage, and supply are not a little wonderful and complicated. Sir Francis Bolton pointed out that one of the greatest difficulties the water companies had to contend with, was the apathy of the public, who neglected in an inconceivable manner their storage cisterns. He had inspected many houses both of the lowest and of the highest classes, and had found the cisterns choked with every kind of dirt and impurity; the water was thus contaminated after being delivered. It was to draw attention to this that he had specially invited a few of those who were interested in the subject, hoping that they could make known the importance of a clean storage cistern. We willingly draw the attention of our readers to this point. It is not improbable that we may have a visit from the cholera this autumn, and if so we ought to fight it tooth and nail. Few more effectual steps could be taken than the thorough cleansing of cisterns in the first place, and the subsequent adoption of means to keep out fresh contamination. Many cisterns in their present state would offer a very suitable cultivation liquid for the cholera germ, if such exists.

On Monday next, at 2 p.m., the important series of conferences on School Hygiene, convened by the Medical Society and the National Health Society, will be opened by Sir Andrew Clark, the chairman for the first day. The most important of the discussions, viz., that on Overpressure in Schools, will take place on Tuesday, under the chairmanship of Mr. Arthur Durham, and will be taken part in by many distinguished speakers, whose names, together with the subjects and speakers on the subsequent days, will be found in our Diary for the Week.

The Annual Meeting of the Medico-Psychological Association was held on Wednesday, 23rd July, at the Royal College of Physicians, London, Dr. Rayner, the President, in the chair. Among other business, Dr. J. A. Eames was elected to be president for the ensuing year, and it was agreed that the next annual meeting should be held in Ireland. The president, in his opening address, dwelt on the delays to treatment caused by the present system of certification of the insane, and asserted that loss of chance of recovery, suicide, and other lamentable occurrences, resulted directly or indirectly from it. He deprecated any increase of the obstructions to placing an insane person under treatment, and advocated that every patient should be examined by a State medical official as soon as possible afterwards. He took the view that to abolish private asylums would logically involve the abolition of the care of single patients, which was regarded by many authorities as the most satisfactory mode of treatment. He recommended the addition of at least four medical commissioners to the present Lunacy Board, and an increase in the pay of the Commissioners in Lunacy. After alluding to various causes which might tend to reduce the development of insanity, and giving a summary of recent progress in treatment, he suggested that any additional accommodation for the insane hereafter provided should be specially adapted to cases of recent insanity. In conclusion, he expressed the expectation that at no distant date an arrest would occur in the present rate of development of insanity. An interesting discussion followed, and the members of the association afterwards dined together at the "Ship," at Greenwich.

The last weekly return of the health of London is a most unfavourable one. The death-rate, 28 per 1,000, was higher than in any week since March twelvemonth, and more than a third of it, viz., 9·9, was due to zymotic mortality. The latter rate was only exceeded in two of the great towns, viz., Leicester, which is always notorious in the summer for its mortality from infantile diarrhœa, and Preston. In London during the week 533 persons, or 242 more than the average, died of diarrhœa and dysentery, all but 20 being children under five years of age. The deaths from all the other zymotic diseases but scarlet



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London in each of the past nine weeks.

fever exceeded the average; including scarlet fever, but excluding diarrhœa and dysentery, the deaths last week were 253 compared with an average total of 195. The result is, that if the upper line on our chart had represented the zymotic death-rate per 10,000, as heretofore, our column would not have been long enough to contain it. A change has, therefore, been made, and the lower line now represents the zymotic death-rate per 1,000. Even so it shows a rise which cannot be quite a satisfactory sight to sanitarians.

The favourable item in the week's return is the abatement of the small-pox epidemic. During the past five weeks the deaths have steadily declined from 59 to 25 per week, while in the same period the weekly admissions to hospital have fallen from 354 to 141. There were still, however, at the end of last week 1,152 cases under treatment. This mitigation of the epidemic may be attributed to the measures undertaken by the Metropolitan Asylums Board, and especially to the zeal and activity of Sir Edmund Currie.

Mr. Victor Horsley, B.S., F.R.C.S. Eng., Assistant Professor of Pathology in University College, was on Wednesday last elected by the Senate of the University of London, Professor Superintendent of the Brown Institution, in succession to Dr. Roy, who has been recently transferred to Cambridge. There were nine candidates for the post, from among whom Dr. Creighton, Dr. Theodore Cash, Dr. Wooldridge, and Dr. Heneage Gibbes were selected, besides Mr. Horsley. The candidate on whom the choice fell, we believe almost unanimously, has already done good original work. Moreover, he is an able surgeon as well as a pathologist, and we cannot but think that the aims of the founder of the institution will be better served by the election of such a man than by the choice of a pure pathologist or physiologist. We can thus congratulate both the institution and the new professor on the selection which the Senate has just made. Mr. Horsley will enter on his new duties at once, and thus a vacancy in the office of Surgical Registrar at University College Hospital will occur.

An interesting experiment took place at Aldershot last night, when, for the first time in England, the electric light was tested in connection with ambulance drill. Baron Mundy who conducted a similar experiment at Vienna in the autumn of last year had promised to give his valuable assistance, and an electric light wagon, manufactured for military purposes, had been brought over from France, at the expense of the National Society for Aid to Sick and Wounded in War. Surgeon H. R. O. Cross, A.M.D. instructor to the Army Hospital Corps' Training School at Aldershot, was detailed to direct the arrangements, and to report upon the demonstration, assisted by Surgeon B. B. Conolly, A.M.D.; and Messrs. Woodhouse and Rawson had been asked to take charge of the electrical part of the experiment. The programme included the application of the electric wagon in searching for, succouring, and transporting 100 men, acting as wounded, from the field to the dressing station on the night after a supposed battle, by a bearer column of the Army Hospital Corps, with mule, mountain and wheeled transport, complete in every detail.

The movement which has resulted in the formation of the Volunteer Hospital Corps, originated at Charing Cross Hospital in March, 1883, and was chiefly due to the enterprise of Mr. James Cantlie. Since that date six other Metropolitan hospitals have joined it, and now have trained corps. On Friday, the 18th, H.R.H. Princess Louise held a formal inspection at St. George's Barracks, when the corps was put through a series of evolutions by Sir Guyer Hunter, who is the battalion officer in command. The corps as it now exists, consists of medical students, and it is designed to be a hospital corps for the volunteer army, and on exactly the same footing to the volunteers as the hospital corps is to the regular army. As medical students will ultimately become the officers in command, it was felt that they were the most suitable body to be first trained in the exercises; but it is not intended to limit these volunteers to medical students; indeed, there are, we believe, already one or two companies of lay members. We had the opportunity of seeing them go through a variety of evolutions at the Health Exhibition the other day, and we can most cordially congratulate the corps on their efficiency, and the officers on the success with which their efforts have so far been crowned.

Cæsar Hawkins, the *doyen* of English surgery, and the last of a family of distinguished surgeons, died on Sunday within a few weeks of completing his 86th year. His health had been breaking for some time, and his death had been long expected. By it the profession loses one of the very few remaining links which connect the present race of surgeons with the great men who flourished before the invention of chloroform and the microscope. Cæsar Hawkins was a grandson of the first Sir Cæsar, who was sergeant-surgeon to the Second and Third Georges. He was a pupil and colleague, at St. George's Hospital, of Sir Benjamin Brodie, and a colleague at the Hunterian School of Sir Charles Bell. He was surgeon to St. George's Hospital from 1829 to 1861, delivered the Hunterian oration at the Royal College of Surgeons in the presence of the late Prince Consort, in 1849, and was President of the College in 1852 and again in 1861. In the year following his second Presidency, he was appointed sergeant-surgeon to the Queen, in which office he succeeded Sir Benjamin Brodie, and had for his colleagues successively Sir William Fergusson and Sir James Paget. In 1874 he published his collected writings, a book which might with advantage be studied by our younger surgeons more often than it is. As a surgeon, Mr. Cæsar Hawkins was an adherent of the conservative school, a school from which medicine is tardily learning to distrust and dispense with that gratuitous interference with the course of disease which was at one time incumbent on every practitioner. His aim and teaching was to avoid an operation wherever possible, but to perform it pluckily and thoroughly when it was called for. He and others of

the same school might have chosen for their motto without much twisting of its sense, the passage from Hamlet, which Mr. Gladstone lately used to describe his policy on the Franchise Bill.

Like the majority of those who have attained high rank in the profession of medicine, Mr. Hawkins was a man of character as well as ability. One who knew him for nearly fifty years writes of him :—"During all these years he was ever the same—most industrious and painstaking in all matters relating to his work—high minded and honourable in all that was connected with the interests of his profession—kind and liberal to a degree, that truly it may be said, his right hand knew not what his left gave away. All who had the privilege of his friendship will endorse this estimate of his character. He was one of the most accurate and clear-headed of men that I had ever anything to do with—no lover of ostentation—no seeker after personal advancement by show or talk—but true in every sense of the word, and a thorough high-minded gentleman."

With the view of uniting the members of the Universities of Oxford and Cambridge at present working in various capacities at Guy's Hospital, a very successful dinner was held on Wednesday, July 16th, at the Holborn Restaurant, under the Chairmanship of Mr. J. N. C. Davies-Colley. It was decided that the dinner should be established as an annual event.

The Woolton Convalescent Institution at Liverpool provides an example, financially as well as otherwise, which it would be well for many of our medical charities to endeavour to imitate. During the past year 924 patients were received within its walls. These contributed 945*l.* The garden attached to the place realized 110*l.*; subscriptions, donations, and Hospital Sunday, 835*l.*; interest of the Roger Lyon fund and bank interest, about 900*l.* The expenditure was so far within the income that the committee were able to carry 1,200*l.* to the building fund, and still leave a small credit balance of 50*l.* The ordinary rate of payment per patient is 10*s.* per week. The accommodation is now much increased, and an extension of the privileges of donors and subscribers is announced by which nominated patients can be received at 5*s.* per week. The institution is situated in a delightful suburb of Liverpool, and commands extensive views.

A dramatic performance, in aid of the Building Fund of the Great Northern Central Hospital, was given at St. George's Hall, Langham Place, on Tuesday, 22nd instant, under the personal patronage of the Baroness Burdett-Coutts and the Ladies' Association of the Hospital. A special interest attached to this performance on account of the production of a new afterpiece, by Messrs. Walter Besant, and W. H. Pollock, entitled "The Charm," for the first time on any stage. The new play, which was preceded by an adequate representation of W. S. Gilbert's "Tom Cobb," was received with indulgence by a fairly large audience, although rather trying to the patience of the majority, owing to the unskilful arrangement of its dramatic situations, and the wearisome iteration of its leading sentiments throughout the dialogue. The Band of the 1st Battalion Manchester Regiment performed a selection of music during the evening.

Dr. E. C. Stirling, lately an assistant surgeon to St. George's Hospital, but now Lecturer on Physiology at the Adelaide University, has been elected a member of the Legislative Assembly for North Adelaide.

A Correspondent writes to us from Exeter :—General practitioners are often sent by some one to a case of accident or emergency, when the patient is not able to pay the fee. They are then in this dilemna: either they attend, and get no fee, or they decline to attend without payment, and are then called mercenary and heartless. A case has just come before the Exeter County Court, in which the judge decided that "merely sending a man for a doctor was no contract to pay." In Exeter the police have lately been empowered to call medical men to cases of accident or emergency, the Town Council paying a fee of 3*s.* 6*d.* or 7*s.* for a day or night visit respectively; and sixteen or eighteen medical men have given in their names as willing so to attend. But in this instance, the surgeon was not called through the police; nor does the police arrangement meet the difficulty specified. If the County Court Judge's ruling be correct, our only protection, when called to a patient circumstanced as above, and not by the police, is, to refuse to attend without payment. For a medical man to go single-handed into court to try this or any other question affecting the rights of the profession, is occasionally proper and necessary, but the chances of success, or at any rate of making the proceedings tell to the advantage of the profession, would be much enhanced if the action taken were known to be that of an association of medical men. Union is strength, and union is very often the one thing wanting in medical action. Trade is powerful in Exeter, and meets with consideration, because tradesmen hang together. The medical profession would have more weight and influence if the common interests of all were more kept in view. The sanitary state of localities is just now of pressing importance. That of Exeter shows but little improvement of late; for, although the Medical Officers of Health fulfil their duties efficiently, their representations are not adequately carried out by those on whom the duty of doing so rests. Not that the reluctance to act is greater, or the back streets and alleys worse, than in some other towns; but this does not diminish the risk; for whether in one town or fifty, filth about human dwellings will produce its natural consequences.

On Monday, the 21st inst., Dr. Charles A. Cameron was elected Vice-President of the Royal College of Surgeons in Ireland, by the large majority of 54 votes out of the total poll of 88. The Vice-Presidency was vacant through the resignation of Dr. Anthony H. Corley, who is a candidate for the Chair of Surgery, rendered vacant by the death of Dr. James Stannus Hughes. Among the many official appointments held

by Dr. Cameron are those of City Analyst and Superintendent Medical Officer of Health for Dublin, Pathologist to the Coombe Lying-in Hospital, and Lecturer on Theoretical and Practical Chemistry in the School of Surgery, Royal College of Surgeons. On the same day an election was held to fill the vacancy caused on the Council of the College by the retirement of Dr. Edward Hamilton, who is also a candidate for the vacant Chair of Surgery. The following is the result of the poll :—For Mr. Austin Meldon, 40 votes ; Mr. Frederick Alcock Nixon, 33 votes ; Mr. Johu Benjamin Story, 12 votes ; Mr. James Good Curtis, 2 votes.

Another well known and respected teacher in the Medical School in Vienna has lately passed away at the early age of 39. Dr. Julius von Massari was for several years a most active and popular teacher of Gynæcology, especially amongst the numerous foreign students for whom the great Viennese School provides such abundant academic attraction. His death took place from an attack of acute endocarditis, on July 12th, and his funeral was made the occasion for a display of the universal regret felt at his loss by his many friends and colleagues.

The first number of the new *Centralblatt für Laryngologie, Rhinologie und verwandte Wissenschaften*, lately. published by Hirschwald, in Berlin, fully justifies the large measure of support which, as the Editor, Dr Felix Semon, informs us, has been already accorded to it. The use of the German language for an international journal edited in London, would appear at first to be somewhat of an anomaly, but a glance at the history of previous undertakings in England and America will sufficiently explain the reasons which have influenced the choice. The recent demise of the *Archives of Laryngology* in New York, from sheer inanition, will be in the recollection of all Laryngologists, and the fact that no journal specially devoted to this subject has succeeded in maintaining an independent existence in this country is equally well known. It is more than probable that a very large proportion of those interested in the progress of Laryngology, whether practising as specialists or not, have studied the subject in one of the great German schools and hence possess a knowledge of the language sufficient to enable them to read the new *Centralblatt* without difficulty. The object of the journal, as already noted, is to furnish a really trustworthy summary each month of the current publications in the region of medicine and surgery comprised in its title. As a guarantee of the character of the work, the signature of each contributor is appended to his article, review or abstract. The arrangement of subjects is for the most part anatomical, and under each heading will be found a reference of longer or shorter extent according to the importance, novelty or special interest, of the subject matter, of every published work which has appeared in any country within recent times. That the work is truly international in fact as well as in name may be gathered from the list of contributors to the present number, whose contributions are dated from most of the capital cities of Europe and also from the United States of America. Reviews of standard works appear amongst others from the pens of Drs. Gerhardt and Morell Mackenzie. The journal is clearly printed and furnished with a good index, and bears every evidence of skilful and painstaking editorship. It will undoubtedly take a prominent place in the ranks of first class medical journalism.

The numerous theories as to the proper treatment of enteric fever by calomel, by alcohol, by the cold bath, by quinine, by water, by wiue, by carbolic acid, by milk, by bread and butter, by corrosive sublimate, by salicin, by over-feeding, and by starvation, which have been from time to time flourished in the face of the medical world, might not unreasonably be supposed to have exhausted the subject of everything like novelty. A paper recently read before the American Medical Association, however, promulgates a theory which is not only ingenious in itself, but which also affords to the practitioner the grim satisfaction of, so to say, hoisting the typhoid bacillus with its own petard. According to Dr. J. K. Jackson, the microbe of enteric fever is a nitrogen-feeder ; and the nitrogenous wasting of typhoid-fever patients, the diminution of their fibrin, the deficiency of urea, and of all their nitrogenous excretions is due, not only to their inability to digest nitrogenous food, owing to the congested and inflamed condition of the peptic and other glands, but also to the consumption of nitrogen by the parasitic organism, which is "the acknowledged ætiological factor in the production of enteric fever." Thus feeding on the tissues of its host, the micro-organism breaks up their nitrogenous constituents into ammoniacal compounds, and hence the ammoniacal exhalations from the typhoid-fever patient, from his breath, his skin, and his urine. This pathological condition furnishes a two-fold indication for the treatment of the disease. Since the nitrogenous waste cannot be made good by the ingestion of nitrogenous food, ammonia should be administered freely, even to saturation. "Fortunately this nitrogenous base furnishes us with salts of such different therapeutic virtues that we can select one suited to any stage of the disease, and to any condition of the system." The nitrate of ammonium, in doses of ten or twelve grains every two hours, will reduce the typhoid-fever temperature to 102° F., and keep it there. As the disease progresses, and there is less need of a sedative, or if diarrhœa supervene, the acetate should be substituted for the nitrate, and acetate of lead and opium given at the same time. If nervous symptoms show themselves, with a failure of vital power, ammonic carbonate, combined with potassic chlorate should be resorted to ; but if coma develope, recourse is to be had to the chloride of ammonium in five grain doses every two hours. The effect of this is described as magical. Dr. Jackson looks on the delirium of typhoid fever as being due to deficient nourishment, a delirium of starvation, and finds that it usually yields in a few hours to the free administration of ammonia.

But the ammoniacal salts possess another and far-reaching effect, of which the *modus operandi* has

hitherto remained unrecognised. It is a law, we are told, that no organism can live in its own excreta. Hence the microbe of enteric fever, whose own life-processes comprise the conversion of the patient's nitrogenous tissue into ammonia, perishes if the system be saturated with ammoniacal salts. So that highly carbonaceous medicament, quinine—although it is the antidote *par excellence* to the carbon-feeding (and carbon excreting) parasite of malarial fever—has long been abandoned by Dr. Jackson as not being the appropriate germicide for typhoid fever. For a disease in which ammonia is the excretory product, ammonia is the most efficient germicide; for this nitrogenous base not only supplies the nitrogenous waste, but also destroys the vitality of the organism which causes it.

This theory has yet another development, not less attractive. It is usual to account for the protection of the system against a second attack of contagious zymotic diseases by supposing the immunity to depend upon an exhaustion of the pabulum necessary for the support of the parasite; but we are now asked why, in accordance with the law lately enunciated, we should not attribute it to an infusion into the system of some excretory product which forever acts as a poison to the parasitic organism? And in reply, we must frankly admit that "if this be the law," then this also "is the most probable explanation." Surely here is additional cause for abounding humility in the reflection that the human body, so fearfully and wonderfully made, the source of so much pride, the object of such care and adoration, is safe from an attack of typhus, or of small-pox, only so long as it continues a refuse-heap sodden with the excretion of by-gone generations of microscopic parasites! Unfortunately Dr. Jackson has declined to publish the results of the treatment which he pursues in accordance with his theory. We do not say the treatment founded upon it, because, from the length of time during which he has practised it, we may gather that it was begun long before the existence of bacilli as the causative factors in the production of zymotic disease was commonly suspected, much less regarded as fully established, even by our author. This at least is a more charitable inference than to believe that the practice was not empirical in origin, and that its originator has for so long refused to make known its worth in the treatment of suffering humanity. Dr. Jackson is "reluctant to state the result of this treatment," preferring that its value should be personally estimated by practitioners as the result of their own experience of its efficacy amongst their patients, unbiassed by any percentage statements in its favour, such as he more than hints he could, if necessary, supply. As, however, he professes to have been pursuing this one plan of treatment for 35 years, and has seen no reason to deviate from it during that period, we gather that the doctor himself, and presumably his patients also, are sufficiently satisfied with its results.

In the course of an excellent article on ovariotomy, contributed by Dr. J. B. Hunter to the *New York Medical Journal*, the writer states that instead of making the requisite solutions of corrosive sublimate and of carbolic acid with distilled water—the unsuspected impurity of which is often "a source of danger, and may easily invalidate all the other antiseptic precautions"—he now uses exclusively water taken from the boiler of a steam engine. In the boiler of a lower-pressure engine the temperature of the water will have been raised to about 50° F. above the boiling point; in that of a high-pressure engine the temperature of the water will be much higher; in either case it will have sufficed to destroy those organisms, some forms of which are known to survive a temperature of over 212° F. Water from the boiler of an engine, which can be obtained almost anywhere, is probably the purest that is available for such purposes.

"Rough on rats" is being largely advertised in this country as an effective means of ridding premises of these and other similar pests. Its mortal efficacy is, however, not less impartial than potent. The American Press has had frequent occasion of late to record its deadly effects upon human beings; and now, roused by its successful employment by a suicide, the question is asked as to whether the time has not come for some measures to be taken to check its indiscriminate sale? Something more than this is probably needed to arouse the British public to an adequate appreciation of the dangers attendant on general peddling in a "really reliable vermin-killer."

By his will the late Professor Gross directed that his medical library should be offered to one of certain medical institutions named at the choice of his executor; he left a sum of 5,000 dollars for the purpose of founding a prize, to be awarded every five years, to the writer of the best original essay illustrative of some subject in surgical pathology or surgical practice founded upon original investigation—the candidates to be American citizens. The executor of the will has offered both the library and the prize to the new Philadelphia Academy of Surgery, and this body has accepted the trust.

THE DEBATE ON THE INDIAN MEDICAL SERVICE.

The long-delayed discussion on the grievances of the junior officers of the Indian Medical Service at length came off on Friday last. It is hardly to be expected that the officers will derive much satisfaction from the tone of Mr. Cross's speech, or from the grudging promises with which it concluded; but it will be some consolation to them to feel that they can command such able championship and such general sympathy as was extended to them by the several speakers in the debate. There was very great risk that their prospects of securing such sympathy and support would have been prejudiced by the able, but impolitic, pamphlet which was issued a few months ago by some of their number. To bring a charge of wanton breach of faith against a Government department is not the best way of securing the favour of impartial judges, especially when it can be shown, as Mr. Cross succeeded in showing on

Friday, that there is no ground for such a charge. Happily, as it turned out, the pamphlet did not work the harm it might have done. Much is to be forgiven to men who have been put out of heart and temper by what they consider unjust treatment; and, doubtless, the many Members of Parliament who read the pamphlet had their sympathies stirred by the grievances it so tellingly unfolded and forgot its faults of taste.

It is not easy to understand the grievances of the junior officers without some little study; indeed, many seniors in the Service aver that they cannot themselves understand them. We have gone to some trouble in perusing the bulky blue-book issued a few years back, have carefully studied the various memoranda which have been issued, and have made many personal enquiries. As a result of these investigations we think that Mr. Cross can fairly claim to be exonerated from all charges of breaking faith. The memorandum which is accused of having misled the medical officers was first published in 1864, and was issued in an unaltered form until last year. It stated the rates of pay in the Indian Service, from which it appeared that that of surgeons of less than five years' service was Rs. 286 per mensem. It next stated the salaries of the principal appointments, showing that a surgeon of under five years' service would obtain Rs. 450 per mensem if in charge of a regiment. A subsequent paragraph, the wording of which has been the cause of all the misunderstanding, ran as follows :—"A medical officer will, however employed, be restricted to the rate of pay laid down in paragraph 14 (*i.e.*, in the case of surgeons of under five years' service, Rs. 286 per mensem), until he shall have passed the examination in Hindustani, known as the Lower Standard." The obvious intention of this proviso was to encourage officers to pass the examination at the earliest possible opportunity, and the way the India Office meant the whole series of paragraphs to be understood may be expressed in some such terms as the following :—"We promise you Rs. 286 as soon as you enter the Service, and Rs. 450 when you receive an appointment, provided you have passed the 'Lower Standard.'" The candidates read it quite differently, and thought the Government promised an appointment and Rs. 450 as soon as ever that examination had been passed. The writers of the pamphlet already referred to, in omitting the paragraph which detailed the lower rates of pay before an appointment was obtained, acted with more astuteness than candour, and no doubt fairly laid themselves open to Mr. Cross's charge that their statements were of a most misleading character.

Thus much is required to explain the position of the India Office, in whose reputation for fair dealing and honesty, as a Government department, everyone must be interested. We pass by all these unfortunate recriminations to come to the real points at issue. The Government may not have been—and in our view has not been—guilty of deceiving its subordinates; but there can be no doubt as to two points—first, that the officers who entered the Service a few years ago did enter it under a misconception; and secondly, that since they have been in the Service the conditions of pay and employment have been much more unfavourable than they were justified in expecting, even assuming them to have been under no misconception. As it was, they were the subject of a double misconception. Their information was derived from two sources, first from the Government memorandum, and secondly from what they gathered from friends and others as to the prospects open to them in India, and in both cases they were deceived. For reasons which could not have been foreseen, their entry into the Service nearly coincided with a block in promotion, as the result of which a very much larger number of officers were kept on the lower rate of pay than had been previously the case. Thus the memorandum, which had never before been regarded with discontent, because appointments were rapidly obtained, came in for a large share of vituperation when men found themselves kept for years on a scale of pay which was originally intended to apply to only the earliest period of service. It is obvious, of course, that in a service like the Indian Medical Department, where long furloughs are given from time to time to the officers in regular employment, there must be a certain number of men available to take their places when on leave. But it may be safely stated, that those who organised the department never calculated on having a hundred or more able young men, employed year after year in this *locum tenens* duty. Indeed, the fact that of recent years the India Office has considerably diminished the yearly number of vacancies, may be regarded as a confession that there had been a serious miscalculation as to the requirements of the Service.

We have been told by Mr. Cross that time will put everything straight, and that in a year or two all the men who complain of grievances will obtain permanent appointments. That, however, is but a barren consolation to those who have been working away through the best years of their life on the very inadequate stipend which goes by the name of "unemployed pay." Something more than the mere efflux of time is required to restore loyalty and content to the junior branch of the Service, and we sincerely hope that the Government will see its way to giving some solid recompense for the deferred hopes of the past, as well as ample promise for the future. The feeling which is prevalent among scores of young Indian surgeons is that they have been "done" by the Government. They think that the Indian authorities tried to get the best available medical talent without being willing to pay a fair price for it. All of us who have had anything to do with the medical schools during the past decade, can instance cases of men who were tempted away from the prospect of certain, if somewhat deferred, success at home, by the comparatively high pay promised them in India. They passed a brilliant examination and went away, believing that they would be earning nearly £500 a year the moment they set foot in India. These men, after serving five or six years in the East, after passing, some of them, through arduous campaigns, after being despatched from one unhealthy station to another, *at their own expense*, are still earning about £250 a year, or about half what they would be making at home if they had put a brass plate on their door and waited for patients. No wonder that they send home furious letters, cursing the day when they were tempted to India, and begging their friends

to do all they can to prevent others from falling into their mistake. Some few, by luck or interest, have been more fortunate; but the number of individual cases of hardship that one hears of, and the instances quoted in the course of Friday's debate, show that the complaints are not the mere outcry of a handful of grievance-mongers who would have been mutinous in the best-managed Service in the world. If the Indian authorities wish to retain the able services of the men they have caught—if it is still their policy to attract men of the same high stamp to the Service—if, above all, they are anxious to see in it that all-important condition of efficiency, content, they must do something more than act up to the letter of the memorandum as they themselves interpret it. A more liberal treatment in the matter of pay and promotion would, no doubt, do much to restore content to the Service; but to be fully efficacious it should be combined with a more generous display of sympathy and a more evident anxiety to see things from the standpoint of their discontented subordinates than the officials of the India Office have yet shown.

THE ARTIFICIAL FEEDING OF INFANTS FROM A NEW STANDPOINT.

The high rate of infantile mortality, and its very definite and sudden increase in that class of cases in which artificial feeding has to be resorted to, has long been recognised. The difficulties experienced in bringing children up by hand have led not only to the substitution of the milk of various domestic animals for that of the mother—and this in various degrees of dilution—but also to the production of a long list of artificially compounded "foods" which claim to take the place of the infant's natural aliment, many of which are positively unnatural, and therefore more or less injurious in character, while none of them can be considered in every way satisfactory. Even those whose composition agrees most exactly with the generally received analyses of the milk of the nursing woman, fail adequately to replace it; while their cost, and the trouble entailed in preparing them, are obstacles fatal to their adoption by a large section of the community. Some children—in the aggregate, a considerable number—there must always be, for whom artificial feeding is a necessity; and for these the desideratum is a food which shall, in its composition and digestibility, represent mother's milk with an exactitude sufficient for all the practical purposes of digestion and nutrition, and which shall at the same time be inexpensive and easily prepared from materials always at hand. It is not improbable that the efforts which have hitherto been made in the direction of the point first named—that of obtaining an artificial food comparable, in composition, with human milk—have been founded upon imperfect data, and have therefore naturally produced unsatisfactory results. Dr. Arthur Meigs[1] takes up the position that human milk normally contains no larger proportion of casein than about one per cent, and that it is of the first importance to the child that this proportion should not be exceeded in the composition of any substitute. He makes out a strong case in support of this view. With respect to the varying results of the analyses of woman's milk made by different chemists, he points out that as regards certain of its constituents there is very little discrepancy: the fat—which can be completely extracted by ether; the water—which can be accurately estimated by evaporation; and the inorganic matter—which can be easily and correctly determined by incineration, afford but little difficulty in estimation; and an almost exact uniformity of conclusion with regard to the relative quantities of these substances is revealed by an examination of the different analyses; nor is there any practical difference of opinion in regard to their amounts. If we take the estimates of casein and sugar, however, the case is very different, and it is noticeable that while, in regard to cow's milk, chemists have all arrived at conclusions which are practically identical, there exists the widest divergence of view as to the proportions in which these ingredients exist in human milk; the results vary from Dolan and Wood's estimate of casein at 7·005 per cent., to that of Henri and Chevallier who place it at 1·52 per cent.; Dr. Meigs' own experiments lead him to conclude that the real proportion is about one per cent. It is a striking fact that if, in any of these analyses, the amount of casein and sugar be added together, "the sums are found in every instance to be nearly the same." This is well shown in the subjoined table compiled by Dr. Meigs, which also

	Vernois & Becquerel.	Simon.	Henri & Chevallier.	Dolan & Wood.	Haidlen.	L'Heretier.	Doyere.	Clemm.	Tidy.	Meigs.	Payen.	Quevenne.	Regnault.
Casein	3·924	3·43	1·52	7·005	3·1	1·30	0·85	3·533	3·533	1·046	0·215	1·05	3·9
Sugar	4·364	1·82	6·50	1·921	4·3	7·80	7·31	4·118	4·624	7·407	8·805	7·32	4·9
Total	8·288	8·25	8·02	8·926	7·4	9·10	8·16	7·651	8·157	8·453	9·020	8·36	8·8

shows that, in each instance where the amount of casein is large, that of sugar is small, and *vice versâ*. It must, therefore, be concluded that human milk, the composition of which as regards water, fat, and inorganic matter, is practically constant, either varies continually and within very wide limits as regards the proportion of sugar and of casein which it contains; or else, that the methods employed by the majority of chemists for determining the quantities of these ingredients are faulty, and their conclusions incorrect.

The former inference can scarcely be admitted as the correct one. Wanklyn's statement that cow's milk is a substance exhibiting great uniformity of composition, is probably also true of human milk; we may very fairly argue by analogy that it is *primâ facie* very unlikely that human milk would vary in the relative proportion of its most important constituents to the extent which published analyses seem to indicate. Moreover, it is significant that the results attained by any one investigator—though they differ widely from those of another—are, for himself, practically always identical; and this, even though they include analyses of very many specimens derived from different women. So that the conclusion is unavoidable that these differ-

[1] *Proof that Human Milk contains only about one per cent. of Casein; with remarks upon Infant Feeding.* Philadelphia County Med. Soc., Dec. 22, 1883.

ences in the analyses published by different observers are due, not to variations in the quality and composition of the milk, but to the defective methods employed by most of the investigators. The problem is, however, one admitting of mathematical proof. As we have already indicated, there is no practical difference of opinion as to the percentage composition of human milk so far as regards water, fat, and inorganic material; moreover there is a general agreement that the total amount of casein *plus* sugar constitutes about eight per cent. If it can be shown, then, that of this eight per cent. the sugar accounts for seven per cent., it is obvious that the casein of human milk cannot be present in larger amount than the remaining one per cent. of the whole.

In the paper to which we have referred, and which is well worthy of attentive perusal, Dr. Meigs describes in detail the method of analysis which he has pursued for some years past, with the object of determining the amount of sugar present in human milk; he appears to have proceeded with great care, and the approximate accuracy of his results may be inferred from the fact that when the same method is applied to cow's milk, it gives the amount of sugar as about four or five per cent.—the quantity generally conceded to cow's milk. As the mean result of ten separate analyses of the milk of 43 women, Dr. Meigs gives the quantity of casein as 1·046 per cent., and the composition of human milk as follows:—water 87·163, fat 4·283, casein 1·046, sugar 7·407, ash 0·101. In this connection it is worth noticing that Bierdert, in an exhaustive article on the subject (Virchow's Archiv, Band 60, 1874) states that, as the result of numerous experiments conducted upon lines quite different from those above mentioned, he has "come to the conclusion that the amount of cow casein which an infant's food should contain is one per cent."; and this is the more remarkable since he arrives at this opinion from a reason wholly unconnected with the idea that human milk contains only one per cent. of casein

The milk of the cow is almost universally that which is taken as the basis of artificial foods for infants. It contains about four per cent. of casein; and when reduced by dilution with water so as to contain the ideal one per cent., the mixture becomes, of course, relatively poor in fat, sugar, and salts. The deficiency may, however, be remedied with sufficient exactitude by the addition of a proper quantity of cream, sugar of milk, and lime water, or, perhaps, of the phosphates of lime and soda: and this principle has found application in one of the most successful foods hitherto used in this country, the so-called artificial human milk devised by Dr. Frankland and introduced to the notice of the profession some years ago by Dr. Playfair. Bierdert and others, indeed, contend that there are absolute and important chemical differences between the casein of the cow and that of the human female; but this cannot be held to have been demonstrated with certainty. It is not possible to be certain as to all the chemical relations of a substance whose chemical composition has not yet been certainly determined; its solubility, for instance, varies greatly in accordance with the manner in which, and the agent by which, the original coagulation was effected, and the extent to which it has been dried; if thoroughly dried for several hours at 100° C., casein is rendered quite insoluble in water, and even in a strong solution of caustic soda. Cows' milk is usually, if not always, acid in reaction; that of women is alkaline. Lehmann says,[1] "I believe that the jelly-like coagula of woman's milk are more dependent on the alkaline state of the fluid than on any peculiarity in the casein; at all events, I have found that women's milk, when acid, yields a much thicker coagulum than when alkaline; and that cows' milk, when alkaline, a much looser coagulum than when acid." There would appear, therefore, to be certain obvious advantages to be gained by the use of lime-water in compounding such an artificial food as shall adequately replace the infant's natural aliment, since it secures the desired alkalinity of the mixture and furnishes certain useful mineral constituents; while long experience has empirically proved its value as a most useful adjuvant to the digestion of cow's milk by the human stomach.

When hand-feeding is desirable or necessary, Dr. Meigs recommends the following plan:—From a reliable druggist packets of pure milk-sugar containing 17¾ drachms each are to be obtained. The contents of one of these is to be dissolved in a pint bottle filled with hot water; this solution (which will not remain good for more than a day or two in hot weather) must be kept in a cool place; if it becomes sour—as is easily known by smell and taste—it must be thrown away, the bottle scalded out, and a fresh solution prepared. When the child is to be fed, the nurse should mix together two tablespoonfuls of good cream, one of milk, two of lime-water, and three of the sugar-water; as soon as this mixture has been warmed, it may be poured into the bottle and given to the child. After the first few weeks, the child will require a larger quantity, and twice as many tablespoonfuls of each of the ingredients (making about half-a-pint in all) may be mingled for each meal. It is an easy matter—minimising trouble and expense—to have the lime-water made at home.

Assuming that the milk used is of average good quality, and that the cream contains about seventeen per cent. of fat (analyses of seventeen specimens gave an average of 16·398), the percentage composition of such a mixture is as follows:—Water, 87·639; fat, 4·765; casein, 1·115; sugar, 6·264; ash, 0·217, which corresponds very fairly with the analysis of average human milk already given. If some of it be agitated with ether and alcohol the coagulation "takes place in the form of a very fine network, which remains permanently distributed throughout the lower stratum of the liquid, no sediment forming at the bottom." If the lime-water have been omitted, the coagula are thick and heavy, sinking at once. The still common rule of obtaining the child's milk from a single cow is certainly one more honoured in the breach than in the observance. Apart from the fact that slight variations in diet, &c., affect the milk of the individual cow much more than the general average of the mixed milk obtained from a herd of a dozen or twenty animals, there is the more important fact that the cow is, during lactation, subject to periodical returns of œstral excite-

[1] *Physiological Chemistry*, Vol. I, p. 378.

ment, during which the quality of her milk is liable to be injuriously modified. The infant's stomach affords delicate indications of these changes in its food, as must often have been noticed in the case of children brought up under these conditions ; and breeders have observed similar results to follow in the case of the sucking calf. The admixture of the milk of one or two cows in this state with that of many others in their usual condition minimises the effect, if it does not entirely neutralise it. In other words, cows', not a cow's, milk should be employed. If then the child exhibit symptoms of a dyspeptic character at intervals of every three or four weeks, the milk of the single cow should always be discarded ; and if other milk of good quality is not easily obtainable, it is better to resort to condensed milk—although most of the varieties now in the market contain an enormous excess of sugar and too little fat, and it is difficult to believe that "any article which has been canned and kept for weeks and months, and perhaps for longer, can be so good as the same thing when fresh." To the families of the poor, who frequently possess ample grazing ground in the form of common land, hedge-rows, and roadside stretches of turf, a goat or two would prove the source of both health and profit.

Authorities are apt to vary a good deal as to the extent and manner in which the strength and amount of the infant's food should be increased from time to time. It is usually advised that the food should be gradually increased in concentration, until finally, pure cow's milk is given. Dr. Meigs incidentally points out the interesting and suggestive fact that, after the colostrum has once disappeared and the nursing process has settled down into its even course, the increase in the solid ingredients of human milk is so slight that it may be disregarded. "Analyses show that the milk of a woman whose child is two months old, does not differ materially from that of one whose child is twelve or fifteen months old. It is best, therefore, if the infant thrives and grows as it should, not to make any change in the [artificial] food until after six to nine months of age have been attained." If the child be a robust and healthy one, it may take as much of the food as it wants (and a healthy child will often take three pints, or even more, in the twenty-four hours), but always of the same strength.

Towards the construction of an ideal food for infants deprived of their natural sustenance, numerous investigators, starting from various points and travelling by different roads, have been for long advancing. The article to which we have made full reference, is a valuable contribution to our knowledge on this subject, and Dr. Meigs' conclusions deserve careful and respectful consideration. Many an infant, thanks to its "inherent powers of adaptation to the environment," has doubtless "pulled through" rather in spite of than because of the well-meant but mistaken efforts which were made to supply the place of nature. There is something akin to a novel satisfaction in the consolatory suggestion, that at least the weak stomach of the puny town-bred babe may even have benefited by the sophistication of the milk which should have been supplied to its elder brothers and sisters *pur et simple.*

THE SOURCE OF THE LIQUOR AMNII.

It is generally believed that the liquor amnii is partly made up by fœtal urine. The main argument in favour of this view is that in cases of congenital occlusion of the urethra, the bladder, ureters and kidneys are found greatly distended with fluid, showing that urine is secreted during fœtal life, and if this be so, the secretion can only escape into the liquor amnii. Our laborious German brethren, however, are not satisfied with this inference, and have sought to strengthen or refute it by direct experiment. In a paper by Dr. G. Krukenberg, of Bonn, recently published in the *Archiv für Gynäkologie*, these researches are summarised and critically examined. We cannot afford space to condense the very elaborate arguments as to the source of the amniotic fluid upon which the author enters ; but we may briefly quote the facts which, after searching examination, he regards as experimentally proved. First, substances capable of easy chemical identification (*e.g.*, iodide of potassium) have been administered to the mother during gestation, in order to see whether they found their way into the liquor amnii. No such substances, even when given in large and frequent doses, have, however, been constantly found in that fluid, although it may be expected that with improved methods of experiment they will be found more frequently. In every case in which the chemical used was present in the liquor amnii, it was present also in the urine first passed by the fœtus after birth. This is the only statement as to which there is general agreement in the results of different observers. Dr. Krukenberg's own experiments lead him to a different conclusion. He has never failed to find iodide of potassium in the liquor amnii if it had been given to the mother *some hours* previously. He criticises carefully the experiments upon animals which have been made ; and his remarks, which are very cautious, point to the general inference that what is true of animals does not always apply to the human species. He thinks, however, that there is reason to believe that, both in animals and in the human species, the membranes permit transudation more readily towards the end of pregnancy than at an earlier period. It follows that experiments on the liquor amnii at the end of pregnancy do not throw light on the mode of its production during the earlier months. He thinks it has not been experimentally demonstrated that the fœtus passes urine into the liquor amnii, although the absence of such demonstration does not negative the fact. He considers at great length the causes of the increase in the amount of urea excreted which takes place after birth, and its diminution after the first four or five days of life. But he makes no mention of the researches of Parrot, who brought forward evidence that the diminution in urea is only relative ; the urine contains a smaller percentage of urea, but more urine is passed ; so that the quantity of urea in proportion to the weight of the child steadily increases. If Parrot's view be correct, Dr. Krukenberg's reasoning is superfluous, seeing that what he wants to explain is not a fact. He then considers the qualities of the liquor amnii, and comes to the conclusion that the physical and chemical examination of

this fluid gives us no information as to its source. The next point for discussion is the hypothesis of Fehling, that the liquor amnii is exuded from the umbilical cord. Fehling supported his view by a table showing the more the liquor amnii, the longer the umbilical cord, and inferred that the longer the cord, the more the fluid. Dr. Krukenberg has re-arranged the table, grouping the cases so as to show whether the longer the cord, the more the liquor amnii, and he finds that, grouped in this way, the two sets of figures do not vary coincidently. He concludes that the production of liquor amnii by exudation through the umbilical cord is neither experimentally proved nor probable. Dr. Krukenberg's paper is a very laborious one, and for that reason we have thought it worth attention; but it does not seem to us that it much advances our knowledge of the subject.

REVIEWS AND NOTICES OF BOOKS.

SOMNAMBULISM AND HYPNOTISM.[1]

The choice of somnambulism as one of the subjects to be taken up by the Committee for the Collective Investigation of Disease gives a special interest to some recent publications dealing with this hitherto neglected and perhaps unnecessarily obscure chapter of nervous pathology. Dr. Tuke has for many years made this and some allied subjects specially his own, and has perhaps as much right to speak on them as any observer of these phenomena. Those who have paid attention to the question of hypnotism, apart from the imposture and credulity by which the matter is generally confused and obscured, are perhaps all ready to admit with Dr. Tuke that the state which is genuinely produced in so-called hypnotism is closely allied to, if not identical with, natural or spontaneous somnambulism. It is mainly this point which is illustrated in the book before us. The first chapter describes what is denoted by the term somnambulism; and the phenomena are referred to a suspension or inhibition of certain parts of the brain while others are in full activity. This partial explanation is not very new, although from time to time it is stated afresh with an air of originality, and Dr. Tuke's account shows us that there is but little greater difference between the views held a century ago by Unzer and Prochaska, in Germany (and later by Laycock), and those most recently enunciated by Heidenhain and others, than can be accounted for by the alterations in terminology necessitated by a fuller knowledge of nervous physiology. It matters but little whether we say with the older observers that the cerebral centres are reflex no less than the spinal, and that consciousness is not essential to the acts performed under their guidance, or speak with more modern writers of the inhibition of the ganglion cells of certain regions of the cerebral cortex, or even bring the phenomena in question under the Spencerian formula of "dissolution," as applied by Dr. Jackson to the nervous system. But, doubtless, much light is thrown upon the subject of somnambulism by any or all of these figures of speech.

While somnambulism in its simplest forms is closely allied to dreaming, it is, as Dr. Tuke points out, to be regarded practically as pathological, and "in its severest forms approaches perilously near to nocturnal epilepsy." There would seem to be strong reasons for regarding these conditions as not entirely dissociated, though it may be difficult to prove statistically their concomitance in individuals. It is not unknown to medical men that sufferers from epileptic attacks, or obscure nervous symptoms, probably epileptic in character, have been subject to somnambulism during their childhood; and it is certainly sometimes very difficult to distinguish between the actions of a somnambulist and a victim of what is known as epileptic "vertigo," or "insanity." Dr. Tuke gives some very telling examples of this difficulty; and the case of one Treadaway, who not many years ago was tried for murder, but was shown to be epileptic by the medical enquiry instituted on his behalf, is an additional instance in point. An interesting account is given towards the end of the same chapter, occupying, too, the whole of the next, of a case of a girl, aged 16, under the care of Dr. Wilks, in Guy's Hospital, who was a valuable example of the close connection of somnambulism and hypnotism, for she both spontaneously walked in her sleep and was easily hypnotised (or "mesmerised"); the main difference noticed between these two conditions being that she appeared when sleep-walking to be less amenable to directions, and somewhat obstinate.

The third chapter deals with the physical and mental conditions in hypnotism, as far as they can be ascertained from observation and the description given by the hypnotised person of what he can remember after having been in the hypnotic state. One of the most noteworthy statements with respect to the physical condition of the hypnotised is that the respirations are much quickened, and M. Richer's belief is quoted, that the tracing taken with a pneumograph is a very useful test of simulated hypnotism. With the cataleptic subject, he says, the tracing is uniform in character from beginning to end; with the simulator it soon becomes irregular, through the disturbance of the respiration caused by muscular effort and fatigue.

The "subjective" symptoms of the hypnotised are treated in an interesting manner, being largely gathered from the description given by Mr. W. North, a physiological expert, who was frequently hypnotised in the presence of Dr. Tuke. The whole chapter is of some importance, as, though stating nothing new, it contains at least an original set of observations of a condition whose study is somewhat unduly neglected by the physicians of the day. The work ends with an account of the experiments in artificial somnambulism at the *Salpêtrière*, where, by the way, the various nervous phenomena, which erewhile were apparently referred by some of the observers there to the direct influence of metals, magnets, and solenoids, seem now to be relegated to their more proper ætiological sphere

[1] "Sleep-walking and Hypnotism." By D. Hack Tuke, M.D., LL.D. London: J. and A. Churchill, 1884.
"Der Hypnotismus." Von Dr. Conrad Rieger. Jena: Gustav Fischer, 1884.

of nervous impressionability, including "hypnotism" and "suggestion," a view which has been held from the first by a majority of English observers and students of these phenomena.

The German publication which treats of hypnotism is an interesting contribution to our knowledge of this condition. The conclusions arrived at by Dr. Rieger are in the main the same as are now generally held by physiologists. His work is based on observations both on animals and men and women. Dr. Rieger holds the view, and gives good reasons and examples for so doing, that those who are most easily hypnotised are certainly those who are recognisable as being more or less disposed to nervous and mental disturbances of various kinds. Although there are apparent exceptions to this rule, we are strongly in accord with this view, which indeed is now most generally held, and only eagerly repudiated by those who refuse to regard the subject of hypnotism from an unprejudiced standpoint, and prefer to speak, in psychical terminology of the condition being due to some unknown effluence proceeding from the agent to the patient.

EDINBURGH OBSTETRICAL TRANSACTIONS.[1]

This volume, though a thin one, is very rich in good matter. A wise editorial supervision appears to have been exercised, and we find less space than usual wasted in the description of commonplace specimens. The first paper of importance is "Some observations on the Bladder during the early Puerperium," by Dr. Halliday Croom. It is written in the true scientific spirit, and helps us a step forward in the comprehension of the puerperal process. It will advance Dr. Croom's reputation, and should be read by everyone interested in scientific midwifery. Dr. Peter Young contributes a good practical paper on "Hæmorrhage from the External Genitals during and after Labour." Dr. Brock writes "On Obstinate Vomiting in Pregnancy," and criticizes the theories advanced to account for it. He relates three cases under his own care, in each of which albuminuria was present, and was, in his opinion, the cause of the vomiting. The paper at least shows how much we have yet to learn as to the natural history of this condition. Professor Simpson contributes a paper "On the Prophylaxis of Ophthalmia Neonatorum." The greater part of it is compiled from German sources, but at the end is an account of the use during three months of Credé's method of prevention, in the Edinburgh Maternity Hospital. He also publishes a sort of clinical lecture, mainly compiled from the writings of others, on "Superinvolution of the Uterus." He describes the treatment of the condition in question, but does not discuss the most important point in that respect, viz., should it be treated at all? In addition to these papers he writes on the basilyst, and on axis traction forceps. Dr. David Berry Hart furnishes what is perhaps the most important paper in the volume, viz., a study of the anatomical conditions which lead to rupture of the vagina during labour. Like all Dr. Hart's work, it is able, original, and thoroughly scientific in spirit and in method. Professor Freund, of Strasburg, contributes a paper on "Extra-Uterine Gestation," but its value is not great, because in several of the cases the diagnosis was unverified. We have not exhausted the list of papers, but we have mentioned the chief. We congratulate the Society upon the production of so good a volume. Papers like those of Croom and Hart show that the teaching of Matthews Duncan is still not without influence on the younger obstetricians of Edinburgh.

ABSTRACTS AND EXTRACTS.

ARTIFICIAL ATTENUATION OF THE BACILLUS OF SPLENIC FEVER.[1]

By Drs. Koch, Gaffky and Loeffler.

Great discoveries in science, like great innovations in operative surgery, which are only successful in the hands of one discoverer or of one operator, are apt to be accepted with something more than the proverbial grain of salt. The great results which were expected to be obtained by M. Pasteur's method of artificial diminution of the infective powers of the milzbrand bacillus were somewhat dashed by the fact that certain competent observers had been unable to bring about any such diminution, although they had followed out M. Pasteur's plan with accuracy.

In order then to remove the uncertainty which such a want of agreement must entail, a series of "experimental studies" were undertaken by the three authors of the above article, with the results mentioned in the following abstract. The experiments having to be made, for the most part, upon large animals, a special building was erected having two divisions. In one of these the dissections were carried on, and in the other, arrangements were made for the accommodation of the animals to be experimented on. The floors were cemented and drained into a cistern, so that the accumulated fluids could be conveniently disinfected. The bodies, after dissection, were subjected to the action of steam at a very high temperature and so rendered innocuous. The apparatus employed as an incubator was that of d'Arsonval, of Paris, the capsules of Erlenmayer being used for the cultivation fluid, each capsule containing 20 cubic centimetres of chicken broth, neutralised with carbonate of soda.

The primary infective material consisted of dried blood, five years old, from an ordinary case of splenic fever.

An inoculation was made with this into a healthy mouse, which rapidly succumbed. A portion of its spleen was removed with antiseptic precautions and placed in the cultivation fluid. On the eighteenth day experimental injections were begun, two mice being inoculated every two days; portions of the virus being at the same time transplanted into preparations of peptone gelatine. Microscopic examination of the latter proved that the growth of the bacilli continued with unabated vigour; the effect upon the inoculated mice, however, became less and less from day to day, and after the twenty-second day no interference with their health could be observed. Although all these proceedings were conducted in exactly the same way, it was found that in the earlier inoculations the mice were affected in very different degree, some being immediately destroyed and others remaining but little injured by the process.

On further cultivation it was found that the attenuated virus remained as innocuous as heretofore, although no difference could be detected in the appearance of the bacilli. Some of the animals thus unaffected by inoculation were then re-infected with the original virus. In every case the animals died within three days, proving that no immunity whatever had been obtained. On making further investigations upon animals which had been

[1] Reports of the Imperial Board of Health in Germany, Edited by Dr. Struck, Vol. ii., 1884.

inoculated with the earlier and more active cultivations, a curious difference was found between the effect of the virus upon mice and guinea-pigs respectively. Even in cases where the mice were rapidly destroyed, the guinea-pigs remained wholly unaffected. With so marked a difference between small animals, it might well be assumed that the results in the case of sheep would present still greater variety.

Four sheep were inoculated with the attenuated virus, without being apparently affected thereby. Three weeks later they were very freely infected with virus, cultivated for twelve days, from a mouse which had died of milzbrand; guinea-pigs and mice being inoculated at the same time. The mice died, the other animals showed nothing more than slight febrile disturbance.

These animals were then infected with the original material and they all died, without exception, on the second day. Here also the previous inoculations proved of no avail in diminishing the effect of the poison. In M. Pasteur's experiments the cultivated virus was assumed to lose its active properties in proportion to the length of time that it was preserved at a constant temperature of 106° to 108° F., but in none of his communications was any indication given as to the means by which the degree of attenuation could be estimated at any given time. Two degrees called the first and second vaccine were employed in his inoculation experiments, and these have been understood to represent cultivations of twenty-four and of twelve days' duration respectively. A third degree was instituted in Koch's experiments consisting of a six days' cultivation. Inoculation of the twelve days' virus (second vaccine) was made into three sheep which had already been infected with the twenty-four days' virus (first vaccine). Of these, one died on the eighth day. The remaining two were inoculated with the six days' virus (third vaccine) and remained unaffected, some unprotected guinea-pigs being destroyed by it. After an interval of fourteen days these sheep were inoculated with the original virus and at the same time a control inoculation was made into one healthy unprotected sheep. The latter died at once of milzbrand, but one of the original sheep, already infected with the first, second and third vaccines, died also. The remaining sheep appeared ill, but recovered.

Thus only one in three of the sheep experimented upon can be said to have gained immunity by the inoculation of the attenuated virus—a result by no means in accord with the experience of M. Pasteur.

As the result of a second series of experiments upon mice, guinea-pigs and sheep, a marked variation was observed in the virulence of cultivations of different dates; thus, the virus which was very fatal on one day was found to be innocuous the next. This fact led to the supposition that in some of the specimens there might be a growth of spores taking place among the bacilli. Microscopic examination proved this to be the case.

A further series of experiments was then undertaken, the virus being daily transferred to a fresh glass of chicken broth instead of being left continuously in the same, so that the danger of any impurities gaining access to the fluid was lessened.

Four preliminary inoculations were made into the animals selected, the first being after a fifteen days' cultivation; the second after eleven days; the third after nine days, and the fourth after five days. A fortnight after the last of these inoculations the surviving animals were infected with the original material, and of seven sheep, eleven guinea-pigs and seven rabbits, only three sheep remained alive. These results, so different from those obtained by Pasteur, can only be explained by the assumption that the virulence of the infective material in his cases must have been considerably less than in the present instance.

The actual cause at work in the artificial attenuation of the virus has been assumed by M. Pasteur to be the oxygen present in the air.

The authors, disagreeing with this view, believe that the cause is to be found in the temperature under which the cultivation is carried on. Even with so slight a difference as one-fifth of a degree centigrade, they found that the infective power of the bacilli was materially affected. It was further proved that under some circumstances the attenuated virus may be made to recover its infective power; this point however will be made the subject of further investigation in the future.

The main fact that a certain degree of immunity is conferred upon sheep by means of inoculation, may be considered as proved by these experiments, in which a very virulent poison was used for the final infection. The amount of immunity against natural infection has yet to be considered. That a great difference may exist between natural and artificial infection is seen in the case of the bovine animals which are but little affected by inoculation of virus whilst they are peculiarly susceptible to natural infection.

Experiments upon this point were instituted by Professor Koch and his fellow workers. In order to avoid the possibility of abrasions of the mucous surfaces by prickly forms of fodder, they caused the animals to be fed upon slices of potato into which the virus, in various degrees of cultivation, was inoculated. The first series of experiments was made upon sheep, but in every case the virus consisted of bacilli alone in which no development of spores had taken place. Notwithstanding the very large doses of infective material thus introduced the sheep remained unaffected. A second series of experiments in which the virus contained spores in active development, proved fatal within two days to every one of the infected animals.

The *post-mortem* examination showed that, amongst other changes, severe œdema of the larynx had been induced. The three first stomachs were found intact, but very severe lesions had been set up in the small intestine, similar in appearance to those described by Waldeyer and others as Mycosis Intestinalis.

These changes were never found in the cases which died from inoculated virus, and the position in which they were discovered proves that the spores of the milzbrand are not destroyed by the acid contents of the stomach but that they are capable of further development in the intestine, through the unabraded mucous membrane of which they may find their way into the tissues.

As the result of a long series of investigations the following deductions were obtained. The natural form of milzbrand occurs by infection of the small intestine with small quantities of spores ingested with the food. The greater the number of these the more rapidly fatal is the disease; their action is as rapid as that of the bacilli when injected subcutaneously. Animals which have obtained immunity from the inoculated disease are not thereby protected from the action of the spores introduced by the mouth. M. Pasteur's views upon this matter cannot therefore be corroborated. A safe and practical method of protective inoculation has yet to be discovered.

SURGERY.

Professor Cheever on Etherisation.—Dr. Cheever, Professor of Surgery in Harvard University, read a very interesting paper at the last meeting of the American Surgical Association, which is reported in full in the *Boston Medical Journal* for May 29th. It was entitled "Some of the Dangers and Disadvantages of Anæsthesia," by which Professor Cheever means etherisation, as no other anæsthetic than ether is ever used in Boston. This he has employed for 26 years without ever having met with a death in consequence, and the largest statistics he is acquainted with only give one death in 23,204 cases. Still, as he observes, the vast advantages attendant on the use of ether and its wonted safety have obscured the dangers that may arise. Ether can kill, and there are operations which can be better done without it; and the object of this paper is to point out where are the dangers and disadvantages. (1) The danger in breathing ether is chiefly due to impeded or failing respiration. Temporary paralysis of the palatine muscles causes stertor, and the *falling back of the tongue* carries with it the epiglottis and closes the larynx. This may be met by drawing out the tongue; but when the operator believes that all is safe when he sees its tip at the incisors, he may be mistaken, for in this position it still blocks the entrance of air through the falling of the palate, and a sufficient passage for this can only be obtained by forcibly drawing the tongue out of the

mouth. "The larynx can also be opened by placing from behind the two thumbs under the angles of the lower jaw, and pressing forwards. The muscles being relaxed the jaw subluxates over the *eminentia articularis* or, rather, on to it, and carries forward the tongue, and with it the epiglottis, and thus opens the larynx, the mouth being already open." (2) Some persons are very sensitive to the irritating fumes of the ether, which give rise to a croupy respiration, a spasmodic stridor, followed by an incessant dry cough. Letting in more air relieves the spasm of the glottis, and the deeper etherisation quiets the tickling cough. In many, however, a new peril soon follows from a *great secretion of frothy mucus*, which overloads the air passages until a state like capillary bronchitis is produced, the livid patient being on the verge of suffocation, drowned in his own secretions. This is a very troublesome complication, requiring etherisation to be suspended for a considerable time. (3) Tetanic symptoms are often annoying and become dangerous if not relieved. Obstinate pronation of the forearm and wrist, inversion of the thumbs, opisthotonos, boring the head back in the pillow—these are evidences of suffocation, and are relieved by removing the ether and allowing a few inspirations of air. A most dangerous symptom is a *tetanic setting of the inspiratory muscles of the chest.* No air enters, respiration by the diaphragm fails to fill the lungs, and the patient will die, as in true tetanus, unless relieved by artificial respiration. This condition must not be confounded with that where the diaphragm is seen laboriously pumping a collapsed lung, the glottis being closed by the tongue or by spasm. (4) *Simple exhaustion* is another source of danger, the respiration failing so gradually as not to attract notice. In two cases cited death was obviated by recourse to artificial respiration; and a moment's inattention on the part of the surgeon might have led to fatal results. (5) *Disease of the heart* may cause death, "and yet I have repeatedly etherised patients with valvular disease with safety, by using caution, and giving them plenty of time. Ether is a stimulant to the circulation, and if given slowly, well mixed with air, and not pushed either to lividity or exhaustion, may be given safely in many cases of heart disease. (6) *Apoplexy*, sanguineous or serous, may follow the coma of etherisation in the old, or in drunkards. Atheromatous vessels may give way under the great congestion produced by full anæsthesia; and the "wet brain" of alcoholism may succeed the stupor of ether. (7) Passing from the dangers to the disadvantages of anæsthesia, and first in regard to its relation to *shock*. Although it lessens primary shock, it does not remove the secondary shock which follows an operation, and if long continued it adds to this. Long etherisation prostrates the patient. A frequent pulse, lowered temperature, drenching sweats, and nausea, are the sequences of an anæsthesia which lasts more than from half-an-hour to one hour. (8) A disadvantage is that anæsthesia *decoys the operator into delay and slowness in his work*. Formerly, celerity was the great object in view; and although the great change which has taken place in this respect adds greatly to the surgeon's comfort, and to his care and deliberation, it sometimes renders execution too cautious. The patient may benefit by greater skill and conservatism, but he suffers from prolonged exposure, tedious narcotism, and greater secondary shock. (9) *Drunkards* and steady drinkers yield slowly to the narcotism of ether. They pass through a long period of excitement and delirium before they get to sleep, and have an equally long and violent delirium on coming to. During etherisation they are subject to persistent or recurring tremors, which delay an operation, or jeopardise its safe execution. It is frequently not until the surgeon has finished, that they become quiet, and narcotised. (10) *Vomiting* and *lasting nausea*. Most patients vomit during or after anæsthesia, or both, and this is especially disastrous in abdominal sections, operations for hernia and upon the eye. After amputation, too, it may lead to hæmorrhage under the flaps of a stump. Nausea may last a couple of days, and may turn the scale against successful rallying from secondary shock. We know of no agent to arrest it. (11) "Intoxication and delirium on coming out of ether, are especially injurious after a fracture has been set; and except in a child, or to settle a diagnosis, the setting of broken bones is better done without ether. In nervous women the delirium assumes the form called hysterical. I have seen it last for 24 hours." Professor Cheever advises that extraction of cataract, tracheotomy for disease and paracentesis thoracis should be performed without anæsthetics; and he observes that it is a noteworthy fact that most of the fatal cases from ether have occurred during operations on the rectum, perinæum or vagina, this probably arising from the surgeon being at too great a distance to observe the mouth, the tongue, and the respiration, and the person administering the anæsthetic being incompetent. In such cases, "the operator should observe the levator ani, which moves with the diaphragm. This may be called perineal or pelvic respiration." When stertor occurs, the patient should be tipped forward, the cheek opened with two fingers, the tongue drawn out, and the fauces swabbed. To *ensure* safety, the surgeon should hear every respiration of the patient. "If you would avoid asphyxia, nausea, and headache, and *be safe*, use only the best and the purest anhydrous sulphuric ether.

Narcosis per Rectum.—The idea of producing narcosis by etherisation of the rectum would appear to have originated with Professor Pirogoff, in St. Petersburgh, in the year 1874. The subject has lately come to the front again in a description given by Dr. Molliere, of Lyons, of the method which he has employed with this object. He used the ether either cold, in the form of spray, or warm, by plunging the vessel containing it into hot water and allowing the vapour to pass into the bowel through an elastic tube. Ten minutes, at least, appear to have been necessary to produce insensibility. An interesting account of a recent case under his own care is given by Professor Starcke, of Berlin, in the current number of the *Berliner Klinische Wochenschrift*. For the operation of removal of the sub-maxillary gland, a male patient was etherised by means of the vapour conducted into the rectum through a long tube. About 30 grammes of the drug were used, an injection of morphia being given just previously. The patient bore the ether very well, and in about four minutes appeared to fall into a quiet sleep. In a few minutes more, however, he suddenly cried out, "I am bursting," and then for the first time it was observed that the abdomen was intensely distended. The insufflation of ether vapour was at once discontinued, but as the patient was completely insensible, the operation was proceeded with and concluded satisfactorily. For several hours the man remained in a state of absolute coma, but eventually recovered without any signs of rectal or other injury. A striking feature of this case was the complete absence of any cardiac disturbance, notwithstanding the fact that a very profound degree of narcosis had been reached, and Dr. Starcke notes this point as proving the fallacy of the prevalent idea that the subcutaneous injection of ether in cases of syncope, acts as a powerful cardiac stimulant. The exact quantity of ether required for complete rectal narcosis is not as yet determined. A vigorous and healthy sphincter is an essential element in the success of this proceeding; in a case treated in a similar manner to the above, the attempt failed signally from this cause alone, that the rectum was quite unable to retain the vapour for the necessary length of time to permit of its absorption. It is also of vital importance to guard against the possible condensation of the vapour within the bowel. The subject will probably be fully discussed at the forthcoming Congress at Copenhagen, where it will be introduced by Dr. Molliere himself. Meanwhile, Dr. A. Poncet, of Lyons, as the result of his observations made on cases and experiments upon animals (*Lyon Médical* 22nd and 29th June), observes that the alleged advantages attributed to the procedure, which, he thinks, are somewhat prematurely advanced, are too inconsiderable to be set against the accidents which may be induced by its employment. It is easy enough to regulate the quantity of ether that may gain admission; but the great point is that insensibility may be induced before all the ether is absorbed, and the withdrawal of the cannula has nothing to do with the action of the as yet unabsorbed ether. The surgeon is in fact placed in a dilemma. Either too little ether enters the rectum and anæsthesia is not obtained, or desiring to have complete

anæsthesia of a certain duration, he prolongs the administration and exposes the patient to a danger, the cause of which he cannot immediately suppress. This mode of anæsthesia, in M. Poncet's opinion, should be abandoned, failing as it often does in its production, and giving rise to more danger than attends the ordinary procedure.

NEUROLOGY.

Chorea.—In the *Bristol Medico-Chirurgical Journal* for June, Dr. E. Long Fox contributes an article on this subject, dealing with the aspects of its pathology and treatment only. As regards the former, we do not find ourselves by any means in accord with the views enunciated, for he treats of hemichorea and rhythmical chorea as both belonging to the same category as ordinary chorea. He very truly points out that various psychical phenomena are apt to appear, which, taken together with the motor phenomena, indicate very clearly the cerebral origin of the affection. He refers to cases of post-hemiplegic hemichorea in which lesions in, or in the neighbourhood of, the internal capsule have been found, and quotes three cases of his own in which young adults about the time of puberty had died of chorea, in one of which minute emboli were found in the vessels of the corpus striatum. The chorea of pregnant women he regards as reflex, and mentions rythmical chorea as an instance of reflex chorea from pelvic irritation, though he afterwards says that it is perhaps more nearly allied to hysteria than to chorea. He then goes on to speak of the milder forms, and of all cases in which there is no lesion, as chorea minor, a functional disorder. A functional disease he defines to be one where the lesions cannot be recognised easily or at all *post-mortem*, where the lesions are transitory or concerned with alterations between the relation of the blood supply to the tissues, whether dependent upon variation in the quantity or quality of the blood, changes from which perfect recovery is possible. Fright and mental worry act by producing an impression on certain regions leading to an impairment in their nutrition, insufficient food acts in the same way practically, the weakened heart failing to keep the nerve centres sufficiently supplied with blood. The feebleness and deficient quality of the blood supply resulting from rheumatism would explain the frequent appearance of chorea after that disorder. His conclusions, then, as regards chorea minor might be summed up in the proposition that it is a disorder due to debility producing an impairment in the nutrition of the co-ordinating centres of the brain corresponding to the part affected.

Enteric Paraplegia.—In a paper recently published in the *Boston Medical and Surgical Journal*, Dr. Roberts Bartholow revives the doctrine of reflex paraplegia, secondary to intestinal, renal and genital disease. As regards pathogenesis, he adopts the thesis put forward in 1861 by Brown-Séquard, who maintained that a strong contraction of the vessels of the cord, induced by reflex stimulation, is the essential condition of reflex paraplegia. A moderate degree of intestinal irritation suffices; for irritation of the end organs of the sensory nerves, not too violent and long continued, stimulates the vaso-motor centre in the medulla, and causes a general contraction of the arterioles; but excessive and protracted irritation depresses the vaso-motor centre and relaxes the vessels. Mere loss of blood in sufficient quantity will cause paraplegia (Kussmaul and Tenner); tying the abdominal aorta, and its obstruction by disease (Gull); embolism of the spinal vessels (Panum); large uterine hæmorrhage (Moutard-Martin)—have alike "stopped the spinal cord functioning." In other words, an insufficient blood-supply—an anæmia—is a cause of paraplegia. Dr. Bartholow gives cases of digestive disturbance, complicated with paraplegic symptoms, in which the latter disappeared under treatment successfully directed to the gastro-enteric troubles; and maintains "that there is a reflex paraplegia due to a functional disturbance of the intestine—enteric paraplegia." One of the means of determining whether a given paraplegia is functional—*i.e.*, due to a mere anæmia—or is dependent on a myelitis, is said to be the subcutaneous injection of strychnine. Dr. Bartholow also contends that there is another paraplegia, very different as regards origin and prognosis, which succeeds to certain cases of enteric, renal, or genital disease, but which is due to an ascending neuritis. The differentiation between reflex and secondary paraplegia is made by attention to the following points:—Reflex paraplegia is sudden, or at least rapid, in its development; secondary paraplegia develops gradually; the former is soon complete in all its symptoms; the latter attacks one spinal function at a time. Reflex paraplegia follows the fortunes of the producing malady; secondary paraplegia pursues an independent course, and when the alterations begin in the spinal elements, they proceed in their own way. Reflex paraplegia, of and by itself, never proves fatal, nor does it inflict permanent damage; secondary paraplegia may be the cause of death, and, if not fatal, effects lasting mischief.

A Premonitory Symptom of Locomotor Ataxy.—Another crisis has put forth a claim to recognition as caused by, and as a forerunner of disease of the spinal cord resulting in locomotor ataxy. For a long time we were content with gastric crises, then the various forms of pains proved their claim to recognition, then intestinal crises clamoured for a place, quickly followed by vesical, renal and laryngeal crises. And now (*Progrès Médical*, July) M. Pitres introduces us to crises of muscular stiffness (*courbature*) as an early symptom, and one owning the same cause as the other crises. In the three cases which he has recorded, these crises preceded all other symptoms of ataxy by a considerable period, varying in each case. The attacks were sometimes daily, sometimes occurring several times a day, sometimes absent for a few days; they were always transient, and they finally disappeared when the signs of ataxy became well developed. The affected regions were the sacro-lumbar region mostly and the limbs, the patient during the attack feeling as if he had had a long ride, or had over-exerted himself in swimming. Relief was generally obtained by sitting or lying down, there was no pain at all. M. Pitres considers that the attacks are due to affection of the sensory nerves of the muscles, and regards them as analogous to the gastric and other crises.

Epilepsy.—At the meeting of the American Medical Association in May, Dr. William Pepper read a paper on this subject, in the medical section. Epilepsy, he contended, depended upon a supremely unstable condition of one or more areas of grey matter, rendering them liable to sudden and violent discharges. The causes of this were numerous and varied, including heredity, nervous exhaustion, shock, sunstroke, impaired circulation, as in heart disease, and prolonged peripheral irritation. Epilepsy then was not a single definite disease, but merely a state of impaired nutrition and morbid instability of the grey matter, rendering it liable to sudden and violent discharges varying greatly in different cases. The degree of instability was the all-important point. Everyone was liable to convulsions, it was merely a question of the provoking cause required. The principles of treatment were to relieve anæmia, neurasthenia, and morbid sensibility by diet, change of occupation, change of residence, and rest. An absolute milk diet long continued was recommended in some forms. Nitrate of silver was good where there was gastro-intestinal irritation. The value of the bromides was recognised, but their use had some disadvantages, and required caution.—*Philadelphia Medical Times.*

The Knee-phenomenon in Children. — Pelizacus examined 2,403 children between the ages of six and thirteen, with respect to the presence or absence of the patella reflex. Out of all these children there was only one boy in whom he was never able to obtain the patella reflex, in a few others in whom it was not present at the first examination it was always found on subsequent trials. The boy in whom it was absent was apparently in perfect health. These results are very different from those obtained by Eulenburg and Berger, who found an absence of patella reflex in 4·8 and 1·56 per cent. of the children examined.—*Archiv für Psychiatrie, &c., Bd. XIV., Hft. 2.*

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, July 2nd, 1884.

H. Gervis, M.D., F.R.C.P., President, in the Chair.

The following specimens were shown :—

Dr. Godson. Phosphatic calculus, which caused a vesico-vaginal fistula.

Dr. Walter (Manchester). Transfusion apparatus. Double uterus with single cervix, and a deciduous substance expelled after labour for the fifth time. Pedunculated fibroid removed from a prolapsed uterus.

Spondylolisthesis.

A report of the Committee on Dr. Neugebauer's specimens of spondylolisthesis was read. They consider that the specimens bear out Dr. Neugebauer's views, which are essentially that the anterior half of the vertebra (typically the fifth lumbar) glides away from the posterior half, owing to congenital deficiency or fracture. Such predisposing causes may not result in spondylolisthesis without the operation of overweighting. Dr. Neugebauer states that Professor Lambl has withdrawn his theory of hydrorachis as a cause of spondylolisthesis.

Mr. Noble Smith's appendix to the report was read. He described specimens showing caries as probably a consequence of displacement.

On Fibro-cystic Myoma of Uterus—Septicæmia.

Dr. H. A. Lediard (Carlisle), read a paper on the above subject. The symptoms dated 12 months back, and included pain, bleeding, vomiting, and anæmia. The tumour felt cystic in parts and a bruit was heard over it. It reached 2½ inches above the navel. Afterwards diarrhœa set in and the temperature rose. After an examination by the sound, severe symptoms began, including the usual signs of peritonitis, and death occurred on the ninth day. The tumour grew chiefly from the posterior wall, and was partly cystic, as were both ovaries. The kidneys contained miliary abscesses ; the spleen was enlarged and soft, containing several recent infarcts. Liver fatty, lungs œdematous and congested. No trace of peritonitis was found, but no examination of the veins was made. The uterine mucous membrane was nowhere abraded. The case was brought forward chiefly to ascertain the opinion of the Society as to the cause of death.

The President said that Dr. Lediard was not singular in his experience. A small abrasion was sometimes fatal.

Note on a Condition observed in the Navel-cord of a young Infant.

Dr. John Williams read the above paper. The cord at birth appeared natural, on the second day the distal two inches had dried, while the proximal inch was succulent as at birth. In the next few days it broke down and became stinking. There was some bleeding on the fifth day ; the cord did not fall off till the ninth day, when it left a somewhat conical stump with an ash-grey surface, and a small red central depression. A thin sheath sloughed off the stump. Sir J. Paget, who saw the child, advised its removal (if it remained) by ligature, as in the case of common wart of the umbilicus. It disappeared altogether on the fourteenth day. The early appearance of the wart was remarkable, it had not been observed before the eighth day.

Remarks were made by the President. Drs. Edis, Williams and Herman.

Note on the Involution of the Puerperal Uterus in the Absence of the Ovaries.

This paper was also read by Dr. John Williams. The patient had had her left ovary removed in 1879, and her right was removed during labour in 1883 for cystic disease. Recovery uninterrupted. The involution was decidedly delayed, and on the twenty-eighth day it was still above the brim, the sound passing four inches. Seven weeks after delivery the uterus was of the usual size in the fourth week. Seven months after delivery it was smaller than the virgin organ, sharply anteflexed and the cavity was only two inches long. In this case the immediate effect of removal of the ovaries was retardation of involution, but the changes in the peritonæum caused by ovariotomy must be remembered. The ultimate result was exaggeration of the uterine involution, like senile atrophy.

The President endorsed Dr. Williams' view of the case.

Dr. Carter remarked on the rarity of super-involution. There exists without doubt a condition of atrophy of the ovaries in such cases, and their removal produced the effect which he should have expected.

On Fœtal Extensions or Retroflexions during Pregnancy.

Drs. Matthews Duncan and Hurry read a paper on the above. The authors have collected all examples of extension of the limbs or body of the fœtus occurring during pregnancy, and have tried to throw light on their causation. These extensions may be of a leg or of both legs, or of the whole body. They may be caused by malformation, goitre, amniotic bands, exomphalos, shortness of cord, and morbid conditions of the mother.

The President remarked on the special value of the paper, as throwing light on some of the causes of face presentations.

Dr. Champneys said that the only variety that he had himself observed was the *siège decomplété* (Lefour). In this, when primary, the legs after birth at once resume the fœtal attitude, and fly up over the shoulders in a most striking manner.

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Saturday, June 7th, 1884.

Dr. Thudichum, President, M.D., F.R.C.P., in the Chair.

Littré's Operation.

Dr. H. Campbell Pope read a case of Littré's operation of inguinal colotomy for congenital deficiency of rectum. The child when first seen, two days after birth, was vomiting a greenish coloured watery fluid ; it was dusky in appearance and the abdomen was immensely distended with flatus, especially in the course of the colon. On examination per anum, the finger entered a cul-de-sac, about one inch in depth and of the ordinary calibre of an infant's bowel. No upper sac or protrusion could be felt, but when the child strained a general bulging could be distinguished. *Operation.*—Fifty hours after birth a trochar was passed from the extremity of the cul-de-sac into the pelvis in the usual direction of the rectum. This proceeding was followed by the escape of about two drachms of straw-coloured odourless fluid, and on introducing the trochar still further a little meconium escaped. As the fluid was apparently from the peritonæal cavity, it was decided to open the sigmoid flexure of the colon after Littré's method. An incision, about 1½ inches in length was made above and parallel to Poupart's ligament, and on opening the peritonæal cavity six drachms of straw-coloured fluid escaped. The large bowel was seen to end in a free floating extremity. It was opened by an incision in its long axis and fastened to the external opening by four sutures. No further vomiting occurred after the operation. The child did well for the first fortnight, and the wound healed, but after this time the gut began to evert and a large portion, three inches long, became constricted and ultimately sloughed off. This process again recurred, and a further portion, two inches in length, sloughed off. After this the progress was entirely satisfactory, and twelve months after birth a perfect artificial anus, capable of retaining fæces, resulted. Ultimately the child died of hæmorrhagic measles when thirteen months old.

Dr. Pope recommended in cases where the bowel could not be satisfactorily reached from the anal cul-de-sac that an exploratory abdominal incision should be made (as for inguinal colotomy) and the end of the bowel examined. If feasible it should be brought down to the anal cul-de-sac and fastened to it, an incision having been made in the

upper extremity of the cul-de-sac. If this could not be done, Littré's operation might be concluded.

Dr. TRAVERS did not advocate the use of the trochar, but careful dissection from the anus, keeping close to the sacrum. Where the gut could not be reached thus, he would perform Littré's operation.

Dr. THUDICHUM agreed with the suggestion as to an exploratory abdominal incision.

Dr. ALDERSON had a case in which, after a prolonged operation from the anus, the child died from collapse two hours after.

Dr. POPE in reply agreed with avoiding the use of the trochar, and condemned very prolonged operations from the anus.

The Rysselberghe Meteorograph.

Surgeon-Major T. H. HENDLEY read a paper on the above subject, which had been installed under his superintendence in the Meteorological Observatory of H.H. The Maharaja of Jeypore, in India. He thought a description would be interesting, as the study of meteorology was so intimately connected with the science of medicine, and as the instrument under notice was the most complete and perfect of its kind. The meteorograph, by means of a diamond point attached to the armature of an electro-magnet, engraves, at intervals of ten minutes, a series of graduated curves, easily convertible into figures, which represent the indications of all the ordinary meteorological instruments. The traces are made on a thin metallic plate stretched on a cylinder which revolves before the electro-magnet, and after the plate has been removed, and the lines deepened in an etching fluid, copies can be made of the record in any number in a copper plate press. M. Van Rysselberghe, the inventor, has moreover succeeded in making an arrangement by which he records automatically in Brussels, by means of the meteorograph, the readings of instruments which are kept at Ostend. The meteorograph is divided into several parts, (1) A battery of 20 meidinger elements; (2) A clock which sets free every ten minutes; (3) The motor, which controls the mechanical movements, viz., A, the revolution of the cylinder, and B, the up and down movements of a series of bars, which carry "automatic observers" for each of the instruments, the whole (or recording portions) of which are arranged on one plane; (4) The cabinet, which is fastened in a window before the motor. In this cabinet is also placed the commutator or distributor of the electric current. It will be sufficient to describe in full how the readings of one instrument, the dry bulb thermometer, are effected. A platinum probe, which is supported on one of the moveable bars in the cabinet, and is in connection with one pole of the battery, descends into the open stem of the thermometer, and as soon as it touches the mercury, which is in connection with the other pole, an electric circuit is completed, the probe remains suspended on a ratchet claw attached to the armature of a "relay," and the current passes into the engraving electro-magnet; its armature bearing the diamond point is pulled away from the cylinder against which it has been hitherto kept in contact by a spring, and the trace is broken. This trace is not re-established until a second probe touches the mercury in the wet bulb thermometer, and in this way, one after the other, all the readings are recorded by interruptions in a single line drawn round the cylinder. The trace for a second series of observations is made below the first by the descent of the engraving magnet which on an endless screw is easily affected as it ascends and descends. The rain-gauge is placed at some distance from the main instrument and the wind cups and vane are at the top of the building.

Surgeon-Major HENDLEY, in reply to Dr. Thudichum, said that there was a special department in India, under Mr. Blandford, F.R.S., meteorological reporter to the Government of India, which tabulated and utilised the observations made at all the principal towns in the country; issued weather forecasts that were every year becoming increasingly useful to agriculturists, sailors, and others; and exchanged publications with, or furnished copies of records to, foreign Governments and societies, and especially to the Signal Office in New York. The relation of meteorology to medicine was not lost sight of, but it would of course require time and labour to obtain valuable results, but that special importance would be given to the observations obtained by automatic instruments, such as the meteorograph, the only one he believed now in actual use in India, though a second obtained at the same time would probably be shortly installed. He added that many other automatic instruments were in use in the country, and in response to the query whether there were observations in the higher Himalayas, said that there was one at Leh which had been recently established.

Peripheral Lesions as the Exciting Cause of Chorea.

Dr. KILNER read a paper on the above subject. After a few preliminary remarks, seven successive cases were quoted in support of the theory. The lesions in these cases being rheumatism, dentition, ovarian, uterine, masturbation in the male, and various causes in one case. Afterwards it was stated that it was extremely probable that in nearly every instance an exciting peripheral lesion could be found as well as a central derangement. For shortness sake, the central derangement, whatever it may be, was called hyperkinesis, and the peripheral lesion excitor. It was considered that if the hyperkinesis was not very great, the excitor must necessarily be powerful, and, on the other hand, if the hyperkinesis be intense, the excitor need only be mild, and when both the hyperkinesis and the excitor were intense, a severe attack of chorea may be expected. It is also extremely unlikely that the hyperkinesis of itself produces chorea because before it becomes sufficiently great to cause an attack an excitor will arise, as the system can hardly be considered in a perfect state of health; but this excitor may be so slight as to be easily overlooked. In one of the cases quoted the natural function of menstruation was sufficient to determine an attack. The removal of the excitor is in many cases followed by a cure when the hyperkinesis is not very strongly developed, but when this is intense, the removal of the excitor is generally insufficient to produce a cure, as such slight causes are necessary to renew the attack these are likely to arise. If the dual theory be correct, the treatment of chorea must be directed to the removal of the excitor as well as of the hyperkinesis. No special treatment of the former, the only one coming into the scope of the paper, could be given, because it would include the whole range of medicine and surgery.

Dr. ALDERSON generally noticed rheumatism in connection with chorea.

Dr. THUDICHUM said the commonest cause of irritability was some chemical change in the nervous system; he instanced cases of injury causing chemical change.

Dr. KILNER said, in answer to a question from Dr. Alderson, the coarse changes occurring in the brain in hemiplegia furnished an excitor. It was still an undecided point whether athetosis occurred independently of a coarse cerebral disease. He had never met a case of chorea with the movements on one side and the loss of power on the other, and could not localize the seat of hyperkinesis in such a case.

Mr. H. H. TAYLOR showed two kidneys affected with cystic disease. They each weighed about 4 lbs. They consisted of congeries of cysts varying from the size of a marble to an orange; none of the cysts were within other cysts. They contained, some a clear fluid, others milky, some dark but clear, others dark and thick. No renal tissue could be found.

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE XI.

AMBULANCE.

WE regret we cannot congratulate the Executive Council on any special excellence in this department. With scarlet fever and small-pox more or less endemic among us, with the promise of an outbreak of cholera prophesied from last year, and with considerable prospect of its being realised, it is disappointing to find an exhibition which is supposed to be devoted to the furtherance of the public health, so meagrely supplied with exhibits which can at all strictly

be described under the head of "Ambulance." This very meagreness, however, will have the advantage of demonstrating how ill prepared we are to meet any severe or unexpected strain on this part of our social system, should epidemic or war break out on any large scale. The Executive Council issued some memoranda for the guidance of exhibitors: under the head of "Ambulance" indicating "the articles and appliances which the Committee are anxious may be shown by the Army Medical Departments of various countries, the societies established to render aid to the sick and wounded in war, and other organisations which may be able and willing to contribute." First, as regards the Army Medical Departments, our own exhibits a more or less complete equipment, suitable for various circumstances and climates. Belgium sends a four-wheeled ambulance wagon and a four-wheeled pharmacy wagon, besides a few minor articles. It is not, of course, possible to speak offhand as to the relative merits of these exhibits without a more careful examination than is possible under the circumstances, but we incline to think that the Belgian ambulance wagon is better than the English one; while the English pharmacy wagon is much superior to the Belgian one. Speaking of the latter, however, neither the one nor the other can be considered sufficient without a convoy of *fourgons* to carry lint, bandages, splints plaster of Paris, and the like. The wagons are splendidly built, and suitable for the rough usage to which they will be liable in warfare. No other countries are represented in this department. Neither are there any exhibits from "Societies established to render aid to the sick and wounded in war." This we much regret. Both Germany and Russia have splendidly organised Societies, which could take the field within a few days' notice; and we believe France, Austria, and Italy are also not without their organised "Red Cross" Societies. An exhibit from Germany would have been very interesting and instructive on the one hand, and it would have made our own deficiency in this respect the more glaring and suggestive on the other. It is well known that a "National Aid Society" was founded in 1870 to render aid to the sick and wounded; an immense sum of money was subscribed, and a large balance remained in hand at the close of the Franco-German War (which called the Society into existence). A small portion of this balance was spent during the Turco-Servian War, but a considerable sum is still in hand. Under the circumstances, we think it very deplorable that the managers of this fund should make no sign on an occasion like this, when they have been appealed to by the Executive of a Health Exhibition so well and widely patronised as the present one. It is probably no exaggeration to say that this country is as ill provided in this respect at the present moment as when, fourteen years ago, surgeons, nurses, and hospital material were first sent to France and Germany, and when, thanks to a complete want of organisation, the proffered help was a trouble and nuisance, rather than of any real service to those to whom it was sent. We are very doubtful indeed whether in case of need we should find ourselves better prepared in these respects than we were at the time of the Crimean war, when so much mortality was due to the want of the most ordinary medical help and appliances.

St. John's Ambulance Association, which chiefly concerns itself with the care of accidents in civil life, makes a good show of various models of stretchers, for hand use, and on wheels. Many of these are very ingenious, and they are adapted to every variety of purpose. Mr. John Furley, who appears to be the active worker in this association, shows also under his own name a very light and inexpensive ambulance carriage for "use in small towns or villages." It is lightly built, has a canvas covering, runs easily, and is very suitable for the transport of accident cases. A stronger carriage, we hear, with wooden panels and sliding windows, is made on a similar pattern. A third carriage, somewhat more pretentious and of greater cost, is likewise exhibited. It possesses a very ingenious and useful method of swinging the couch on which the patient reclines, permitting of its being withdrawn to the foot of the carriage, thus saving much labour and jolting. None of these ambulances are built for infectious cases—though some might easily be adapted.

The Metropolitan Asylums Board make a very good show. There is their new ambulance wagon for infectious diseases, and this is really the class of ambulances that we most need in this city of London at the present moment. It is admirably constructed, in every way suitable for its special purpose, and is capable, with little trouble or cost, of being thoroughly disinfected after each time of using. The present theoretical arrangements of the Board appear as nearly perfect as they well can be, provided in actual practice they can be faithfully carried out. On page 7 of a little *brochure* issued by the Board—which ought to be in the possession of every medical man in London—it is stated that "within *five minutes*" of telegraphing to the Central Office, "an ambulance carriage, fully equipped and with an attendant nurse, is on the road to remove the case." This may be so, but we happen to know that it required two days a few weeks ago before the managers of a children's hospital in East London were able to get a case of small-pox moved from their hospital; and that a good deal of telegraphing backwards and forwards, and of going from pillar to post, had to be gone through. We just mention this, for it would be fatal to efficiency if the weak points of their organisation are not brought to light. In the *brochure* we are told that "application is made to the relieving officer, who gives an order for admission." It cannot be too well known that in certain parishes the relieving officer *dare* not give such an order without consulting his chairman; and that for the sake of saving a few shillings every kind of obstacle will occasionally be placed in the way of granting such an order. In other respects the arrangements appear to us admirable. An order having been granted, a telegram is sent to the Central Office; this office telephones to the nearest ambulance station to despatch an ambulance, and take the patient off to one of the hospital ships. Here the patient remains until the disease is over, and he is then sent to Darenth to recruit and get back his strength. In this way the risks of infection are reduced to a minimum. Mr. Norton exhibits a very handsome brougham ambulance, built for the London Fever Hospital; it appears to be well adapted to its purpose.

All these ambulance carriages are of a very expensive type, heavy, and highly finished. We think that something lighter and less expensive might be devised. There is no need of so much finish nor of such expensive wood, in view of the large numbers which are actually needed. If built somewhat more lightly, in the American fashion, and on india-rubber tiers, ambulance wagons might be made, we should think, equally well suited to their special requirements and at much less expense.

In this section are also found all kinds of sick-room appliances. They figure for eight-tenths of the entire show, and include sedan chairs of every conceivable shape; couches with and without internal machinery for turning them over and about, each one superior to every other, if we may believe the inventors; head rests, leg rests, sanitary mattresses, parlour-bed couches, mechanical easy chairs, self-propelling chairs, bed pans, bronchitis kettles, hammocks, and a thousand and one other things, such as we have described again and again. Not that we are insensible to the vast amount of inventive energy which all these things represent, or unmindful of the value of many of the inventions to the bed-ridden patient. We advise those who can to go and see for themselves; they will find much to admire and to wonder at, and not a little that may one day prove very useful.

MEDICAL NEWS.

Royal College of Surgeons of England. — The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 21st instant, viz:—

C. G. Grimmer, L.R.C.P., Edin., Bungay, Suffolk; A. L. H. Dixon, L.R.C.P., Edin., Ashford, Brecon; Coniston Spackman, L.R.C.P., Edin., Faringdon, Berks; A. W. Graham, L.S.A., Cambridge Street, S.W.; E. K. Campbell, M.B., Edin., Wimpole Street and H. J. Hewer, L.S.A., Highbury New Park, students of St. Bartholomew's Hospital; A. C. Purchas, M.B., Edin., Auckland, New Zealand; David Hepburn, M.B., Edin., Milnathort, N.B.; L. G. Mallam, M.B., Edin., Armidale, N.S.W. and F. A. Pockley, M.B., Edin., Sydney, N.S.W., of the Edinburgh School; Herbert Child, L.S.A., Headingley; John Welpton, Leeds and Ambrose Atkinson, Leeds, of the Leeds School of Medicine; H. W. McConnel, B.A., Cantab, Girvan, N.B.; F. J. Warwick, B.A., Cantab, Loughborough Junction, S.E. and Edwin Greenough, M.B., Edin., Wibsey, Bradford, of the Cambridge School; Henry Mason, Ullesthorpe and Alfred Williams, M.B., Glas., Glasgow, of the Glasgow School; Alfred Hanson, L.R.C.P., Edin., Launceston and A. J. Stiles, M.B., Edin., Spalding, of University College Hospital; H. S. Jones, L.S.A., Bromsgrove and Henry Simms, Stourbridge, of the Birmingham School of Medicine, and Robert Lawson, L.S.A., St. Andrews, Fife, N.B., of St. Thomas's Hospital.

Two gentlemen were approved in Surgery, and when qualified in Medicine will be admitted members of the College. Two candidates having failed to acquit themselves to the satisfaction of the Court of Examiners were referred to their professional studies for six months, and one for three months.

The following gentlemen passed on the 22nd inst., viz.:

D. M. Brown, M.B., Edin., Edinburgh; T. G. Churcher, M.B., Edin., Walworth Road, S.E.; Edward Walker, M.B., Edin., Huddersfield; J. C. Taylor, M.B., Edin., Windermere and R. H. A. Whitelocke, M.B., Edin., Jamaica, of the University of Edinburgh; J. E. Crisp, L.S.A., Lacock, Wilts; J. R. Heele, L.R.C.P., Lond., Southampton, and A. B. Blacker, L.S.A., St. George's Road, S.W., of St. Thomas's Hospital; Horace Jeffries, L.S.A., Bromsgrove, of the Birmingham School of Medicine; J. F. Mirza, L.R.C.P., Lond., Bombay, of the Bombay Medical School; A. W. Collins, L.R.C.P., Lond., Rainhill, Lancashire, of the Liverpool School of Medicine; H. M. Hughes, M.B., Durham, Harrowgate, of the Newcastle School of Medicine; W. W. F. Fletcher, M.B., Cantab., Argyle Square, of St. Bartholomew's Hospital; R. N. Jones, L.R.C.P., Lond., Swansea, of King's College Hospital; G. F. Welsford, M.B., Cantab., Winterbourne, Isle of Wight, of the Cambridge School, and H. C. Thurston, L.R.C.P., Lond., Thornbury, Bristol School of Medicine.

Three gentlemen were approved in Surgery, and when qualified in Medicine will be admitted members of the College. Eight candidates were referred for six months, and two for three months.

The following gentlemen passed on the 23rd inst., viz.:

Edwin Roberts, Leeds, student of the Leeds School of Medicine; J. H. Ferguson, M.B., Ed., student of the University of Edinburgh; Frederick Bryan, M.B., Durh., Melbourne, of St. Thomas' Hospital; R. T. Williamson, L.S.A., Burnley, Lancashire; James Mc F. Clarke, L.R.C.P., Lond., Bolton, and C. S. Earle, L.R.C.P. Ed., Manchester, of the Manchester School of Medicine; G. R. Beardmore, L.S.A., Islington, N., of the Sheffield School of Medicine; G. S. Gent, L.S.A., Bristol, of University College Hospital, and Robert Trevor, L.R.C.S., Lond., Halsey Street, S.W., of St. George's Hospital.

Six candidates who passed in Surgery at previous meetings of the Court, having subsequently obtained Medical Qualifications, were also admitted Members of the College, viz.:—

J. E. McDougall, L.R.C.P. Edin., Walton, Liverpool, Student of the Liverpool School of Medicine; C. J. Sharp, L.R.C.P., Lond., Liverpool, of St. Mary's Hospital; G. H. Weston, L.S.A., Bognor, and G. A. Shackel, L.S.A., Reading, of St. Thomas's Hospital; R. T. Bowden, L.S.A., Tenbury, Worcestershire, and R. W. Quennell, L.R.C.P. Ed., Brentwood, of St. Bartholomew's Hospital.

Six candidates passed the examination in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College. One candidate was referred for three months, six for six months, and one for nine months.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, July 17th, 1884:—

Philip Henry Nutting, Hasely Hall, Warwickshire; Thomas Whitworth Sewell Morgan, Roupell Park, Streatham Hill; Francis Harrison Preston, 11, Ampton Street, Gray's Inn Road; George Arthur Shakel, Erleigh Court, near Reading; Thomas Armand Bourne-Soden, Newcastle-on-Tyne; James Dibble Staple, 99, Hereford Road, Bayswater; Sydney Charles Ernest Wright, 153, Upper Kennington Lane, Vauxhall.

The following gentlemen also on the same day passed the primary professional examination:—

Ralph Holyoake, London Hospital; Bernard Volckman, London Hospital.

Naval Medical Service.—Staff-Surgeon William Middleton Power, has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

New Hospital at Rugby.—A new hospital, built at the cost of about 20,000*l.* and presented to Rugby by Mr. and Mrs. R. H. Wood, Penrhose House, Rugby, who have also endowed it with a further sum of 10,000*l.*, was opened by the founders on the 17th instant. It stands in grounds 10 acres in extent, on the south side of the town, facing the open country.

Social Science Association.—At the annual business meeting of members held on Tuesday last, the Right Hon. G. J. Shaw Lefevre, M.P., was elected President for the year 1884-85, while in the Department of Health, Dr. Norman Chevers, C.I.E., was elected President, and Mr. H. H. Collins and Dr. Edward Seaton, Hon. Secretaries.

Professor Langer.—The Emperor of Austria has just conferred upon Hofrath Dr. Carl Langer, Professor of Anatomy in the University of Vienna, the *Ritterkreuz* of the Order of Leopold. This high distinction, in acknowledgment of the merits of this learned savant, indefatigable teacher, and able referee of the Minister of Public Instruction, has given great satisfaction in professional circles.

Subcutaneous Injections in Cholera.—Dr. Roussell, the inventor of direct transfusion, has, we are informed from Paris, resumed his former experiments on the hypodermic injection of the salts of copper which he regards as a prophylactic against cholera. He has also constructed a new apparatus by means of which large quantities of albuminous fluids may be applied hypodermically in the algid stage of cholera.

London School of Medicine for Women.—Surgeon-General Evatt, M.D., Army Medical Department, delivered a lecture on the 15th instant to the students of the London School of Medicine for Women. He pointed out the shortcomings of the present system of field hospitals, and desired to rouse the attention of the public, and especially the medical profession, to the necessity of organising in time of peace a system that would bear the test of war. He made suggestions as to the manner in which the women students could co-operate in such a plan.

"Facts Concerning Vaccination."—At a meeting of the Vaccination Officers' Association, held on Saturday last, a cordial vote of thanks was given to the National Health Society for issuing their pamphlet entitled "Facts Concerning Vaccination." The association expressed their appreciation of the "thoughtful kindness which prompted the society to assist the vaccination officers of the Metropolis in the discharge of their often difficult duties." We are informed that the pamphlet in question has now been distributed from house to house in most of the districts in the Metropolis where small-pox is epidemic, and that the demand for it still continues. Something like 150,000 copies have already been issued since the present epidemic began.

Royal College of Surgeons.—From the last annual report of the receipts and expenditure of the Royal College of Surgeons, which has just been published, it appears that the former amounted to 20,024*l.* 0*s.* 5*d.* derived principally from fees paid by candidates on examination, viz., 16,917*l.* 7*s.* Fees paid on admission to the Council, Court of Examiners, and Fellowship amounted to 94*l.* 10*s.* Rent of Chambers adjoining the College, 1,530*l.* 18*s.* Dividends on Stock, 1,182*l.* 19*s.* 3*d.* The expenditure amounted to 20,046*l.* 7*s.* 4*d.*, the largest item of course being in fees paid to Council and Members of the Court and Boards of Examiners, viz., 7,674*l.* 4*s.* The next largest in amount was for salaries and wages for the three departments, Office, Museum, and Library, viz., 3,784*l.* 14*s.* In the extraordinary expenditure, 700*l.* appears in honoraria to Mr. Trimmer, Dr. Goodhart, and Mr. Doran, and taxes, stamps, &c., 1,469*l.* 9*s.* 3*d.*

The Prevention of Cholera in Dublin.—A special meeting of the Public Health Committee of the Corporation of Dublin was held on Monday, the 21st instant. The meeting was convened for the purpose of taking into consideration a letter, dated the 19th instant, from the Local Government Board for Ireland, requesting the observations of the Corporation of Dublin on the subject of its appointment to superintend and see to the execution of any regulations which it may be necessary to make under the 149th section of the Public Health (Ireland) Act for the prevention of the spread of disease in the City of Dublin, should the city be threatened with or affected by cholera. The following resolution was adopted:—"Resolved that, having considered the letter of the Local Government Board of the 19th instant, should the Board select this Committee as the Urban Sanitary Authority, the sole authority for administering the provisions of the Public Health Act and the Epidemic and other Diseases Prevention Act, 1883, the Committee recommend the Municipal Council to accept the responsibility of carrying out the regulations of the Local Government Board, believing that a divided responsibility would militate against the efficient supervision and conduct of the duties required under them. The Committee make this recommendation in the full assurance that the Council will have the cordial co-operation of the Guardians of the North and South Dublin Unions, by affording us every facility for carrying out the regulations made under the Act, and placing at our disposal their machinery, provided that the Local Government Board makes arrangements for the expense to be incurred being distributed over the North and South Dublin Union areas."

Professor Rutherford on the Medical Bill.—Professor Rutherford concludes a long letter to the *Scotsman*, chiefly devoted to the castigation of Professor Struthers, with the following remarks on the Medical Bill: "It was manifestly drawn up on the line of removing all medical licensing powers from universities and corporations, and transferring them to a single medical board in each division of the kingdom. The medical and surgical corporations would ultimately have been ruined, and the universities seriously injured, by the Bill as it first appeared last year. No doubt some of its dangerous clauses have been removed, and if Sir Lyon Playfair's amendment regarding coadjutor examiners is carried, it will be very much improved. But the principle of practically superseding the present medical authorities by the proposed medical boards will still be shown, even if the Playfair amendments are carried, in the method of electing the members of the general council, which is to be no longer by the medical authorities themselves, but by the medical boards, and I have shown how it may come about that the largest medical educating authority in Scotland may come not to be represented at all on the medical council. Surely such a contingency was never contemplated by the framers of the Bill. The whole machinery of the medical boards will be cumbersome, expensive, and not conducive to harmony. Additional examiners, or assessors appointed by the General Medical Council to attend examinations by the various authorities, would have attained the necessary object of keeping the examinations up to a proper standard perfectly well; and other necessary reforms could have been attained by a Bill much simpler than the present one." It is very curious that the champions of the examining bodies cannot be got to understand that one of the main virtues of the Medical Bill is, that it puts an end to direct representation of corporations on the medical council.

St. Thomas's Hospital Volunteer Ambulance Bearer Company.—On Wednesday last the Company was inspected by Major-General Elkington, C.B., Deputy-Adjutant General, Dr. Crawford, Director-General of the Army Medical Department, and his staff. A large company witnessed the proceedings, among whom were Lord Morley, Under-Secretary of State for War, Mr. Brand, Surveyor of Ordnance, Surgeon-General Hanbury, K.C.B., Baron Mundy, Dr. Billings, of the Surgeon-General's Department, Washington, Sir Frederick Pollock, Professor Longmore, Mr. Ellissen, of the French Red Cross Society, Mr. Furley, Mr. Archibald Forbes, Brigade-Surgeon Nash, Surgeon-Major Roe, Surgeon-Major Evatt, Surgeon Cross, Mr. Cantlie, Sir William MacCormac, President of the St. Thomas' Ambulance Association, and Dr. Ord, Dean of the Medical School. The company numbers about 90 members, of whom 64 were present on parade, dressed in default of a regulation uniform in white shirts, white flannel caps and trousers, and a Geneva badge on the right arm. By kind permission of the Archbishop of Canterbury the drills have taken place in the grounds of Lambeth Palace, and here the inspection was held. The company, under the command of Mr. Makins and Mr. Piggott, marched past with stretchers, and the stretcher drill was then proceeded with. After some preliminary marching each stretcher detachment was sent out independently to search for wounded, the latter being scattered in pairs about the grounds labelled with the injury supposed to have been received. Dressings were applied, the severely wounded placed upon the stretchers and carried back to the hospital tents in the rear, those with slight injuries marching back by the side of the stretcher. The dressings on the wounded men were then inspected by General Elkington and Dr. Crawford, the stretchers were refolded and the men reformed in close order. At the close of the drill, which lasted an hour, General Elkington addressed the company in terms of high praise and commendation. He congratulated them on their numerical strength, appearance, and excellent performance. He trusted that by next summer the corps would have increased and the movement extended, so that an efficient ambulance department would be added to that important organisation, the Volunteer Force of this country. Dr. Crawford added some valuable remarks from the medical point of view, and Lord Morley spoke in praise and encouragement, pointing out that such beginnings of ambulance work in a hospital among young men, who would in a few years become qualified to practice, would be the means ultimately of extending the instruction throughout the country.

South London School of Pharmacy.—The following is the list of the successful competitors at the school examinations, held from the 26th June to the 5th July, 1884:—Senior Chemistry, Medal, R. Wilkinson, Certificates (equal), D. Arnott and F. Jackson; Junior Chemistry, Medal, W. Rushton, Certificate, W. Holme; Botany, Medal, T. J. Clark, Certificate, R. Atkinson; Materia Medica, Medal, W. Holme, Certificate, T. J. Clark; Pharmacy and Practical Dispensing, Medal, J. E. Brown, Certificate, W. Rushton; Extra Certificates of Merit, Messrs. Coleman, Cooper, H. Jackson, King, Matthews, Taylor, Ward, and Williams.

Professor Hoffmann. — Several American chemists recently had a large gold medal of Geheimrath A. W. Hoffmann, of Berlin, struck at Philadelphia, in remembrance of his visit to the United States last year, and in recognition of the great services he has rendered to science and industry in the province of organic chemistry. On one side of the medal there is a well executed portrait of the professor; and on the obverse the inscription "To A. W. Hoffmann, from his friends and admirers in the United States of America."

APPOINTMENTS.

Anderson, James, M.D., M.R.C.P. Lond.—Medical Registrar to the London Hospital, *vice* C. F. Coxwell, M.B., M.R.C.P. Lond., resigned.

Carroll, E. R. W., M.R.C.S., L.R.C.P.—House Surgeon to the Royal Westminster Ophthalmic Hospital.

Champ, J. H., M.B., Lond.—House Physician to Guy's Hospital.

Clegg, W. T., M.R.C.S., L.R.C.P.—Registrar to the St. Paul's Eye and Ear Infirmary, Liverpool.

Davies, John, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the First District, Bath Union.

Davies, W. T. F., M.B., Lond.—House Surgeon to Guy's Hospital.

Fort, J. W., L.D.S.R.C.S.—Honorary Dental Surgeon to the Lancaster Infirmary.

Henry, R., M.D.—Medical Officer of Health to Comber Dispensary District.

Hill, J. Higham, M.D., F.R.C.S.E.—Government Medical Inspector for the United States of America at the Port of London.

Jones, M. P., M.B. Lond.—Resident Obstetric Physician to Guy's Hospital.

Macindoe, Alexander, M.B. and M.C. Glas.—Medical Officer to the Ashley District, Drayton Union.
Manley, J. H. H., M.B., B.C. Cantab.—Resident Obstetric Physician to Guy's Hospital.
Meyer, C. H. L., M.B., B.S., Lond.—House Surgeon to Guy's Hospital.
Phillips, F. B. W., M.R.C.S.—Resident Obstetric Physician to Guy's Hospital.
Piggot Allen, M.R.C.S. Eng. and L.R.C.P. Edin.—Medical Officer to the Fifth District Bromley Union, in succession to Mr. J. H. Booth, resigned.
Ryle, R. J., M.B., Oxon.—House Surgeon to Guy's Hospital.
Scott, T. H., M.B., B.S., Univ. Dub.—Assistant Surgeon to the Adelaide Hospital, Dublin.
Spurgin, W. H., M.R.C.S.—Medical Officer of Health for the District of Maryport, *vice* Dr. Pearson, resigned.
Targett, J. H., M.B., Lond.—House Physician to Guy's Hospital.
Worthington, S., M.B., Lond.—House Physician to Guy's Hospital.

VACANCIES.

Bristol Dispensary.—Surgeon. Candidates must possess a diploma in surgery from the Royal College of Surgeons of England, Scotland or Ireland, or from the Faculty of Physicians and Surgeons of Glasgow, and in addition to such diplomas in surgery, must possess a legal qualification to practise Medicine in Great Britain and Ireland, and be duly registered according to the regulations of the Medical Act. For salary and other particulars, apply to Mr. E. Stock, 57, Queen Square, Bristol, to whom testimonials must be sent on or before July 31st.
City of Liverpool Temporary Small-Pox Hospital.—Resident Medical Officer. (*For particulars see Advertisement.*)
Gravesend Hospital.—House Surgeon. Salary, £80 per annum, with board, lodging and washing. Candidates must be members of one of the Royal Colleges of Surgeons of the United Kingdom. Applications, with testimonials must be sent to the Honorary Secretary, on or before August 12th.
Houghton-le-Spring Union.—Medical Officer to the Newbottle District, in succession to Mr. George Chalmers, resigned. Area, 5,380 acres. Population, 7,883. Salary, £30 per annum.
London Hospital Medical College, Turner Street, Mile End, E.—Two Assistant Demonstrators of Anatomy. (*For particulars see Advertisement.*)
Martley Union.—Medical Officer to the Witley District, in succession to Mr. J. N. Greensill, resigned. Area, 12,798 acres. Population, 2,697. Salary, £70 per annum.
Martley Union.—Medical Officer to the Martley District and the Workhouse, in succession to Mr. Edward S. Greensill, resigned. Area, 10,816 acres. Population, 2,166. Salary, £60 per annum. Salary for Workhouse, £30 per annum.
Paddington Green Children's Hospital, London.—House Surgeon. Salary, £80 per annum, with lodging. Applications to be sent to the Secretary before July 28th.
Royal Hants County Hospital, Winchester.—House Surgeon. Salary, £100 per annum, with board and lodging. Candidates must possess a diploma from the Royal College of Surgeons in England, or the surgical diploma of a Royal College or a University in England, Scotland, or Ireland, and also a degree in Medicine from one of the said Universities, or a licence from the Royal College of Physicians in London, or a licence from the Society of Apothecaries. Candidates shall not be eligible for the office without unexceptional testimonials of moral character. Applications with testimonials, to be addressed to the Secretary at the hospital, on or before August 2nd.
Scarborough Hospital and Dispensary.—Assistant House Surgeon and Dispenser. Salary, £50 per annum, with board and lodging. Testimonials to be addressed to the Secretary not later than July 26th.
Stronsay Parochial Board.—Medical Officer and Vaccinator. (*For particulars see Advertisement.*)

DEATHS.

Godfrey, R., M.R.C.S., formerly of Bath, at Epsom, on July 12th, in his 92nd year.
Hawkins, C. H., F.R.S., F.R.C.S., at 26, Grosvenor Street, on July 20th, in his 86th year.
Knaggs, Henry, M.R.C.S., &c., at 189, Camden Road, N.W., on July 17th, in his 86th year.
Morris, Henry, F.R.C.P., L.R.C.P., of Fern Bank, Glossop Road, Sheffield, on July 11th, aged 45.
Searle, J. L., M.D., at Ashton House, Steeple Ashton, on July 17th, aged 83.
Taylor, A. A., M.R.C.S., at Bradbourne House, Acton, on July 18th, aged 28.

NOTES, QUERIES, AND REPLIES.

WHEATLEY MEMORIAL FUND.

[TO THE EDITOR OF THE MEDICAL TIMES.]

Sir,—The Committee of the Wheatley Memorial Fund have now closed the subscription list, and desire me to announce a final list of donors, which I shall be obliged if you will insert in your next issue.

The Committee also authorises me to beg leave to publish the balance sheet of the Treasurer of the Fund, and to inform the Subscribers that the Treasurer has handed over £804 6*s.* 1*d.*, after payment of expenses, to the beneficiaries of the Fund, in the proportion of two-thirds to Miss Maria Wheatley, the sister, and one-third to Miss Mary Caroline Wheatley, the niece of the late Mr. B. R. Wheatley.

Balance Sheet.

(Signed) J. Cooper Forster,
July 21st, 1884. Treasurer.

I am, Sir, yours &c.,
Berkeley Hill, Hon. Secretary.

Royal Medical and Chirurgical Society.
53, *Berners Street, W.*
July 21st, 1884.

Final List of Subscriptions.

Mr. J. Moncrieff Arnott, £10 10*s.*; Dr. Bigelow (Boston, U.S.A.), £10 10*s.*; Dr. Hare, £7 7*s.*; Dr. Wilson Fox (additional for postage), £6 9*s.* 7*d.*

The following have sent five guineas each:—Dr. George Johnson (2nd donation), Dr. Wickham Legg, Dr. Ord, Mr. Richard Quain, Dr. Russell Reynolds, and Dr. Walshe.

The following has sent five pounds:—Dr. Garrod.

The following have sent three guineas each:—Dr. Blandford, Mr. Thomas Bryant, Mr. MacCarthy, and Dr. Ringer.

The following have sent two guineas each:—Dr. Graham Balfour, Mr. Richard Barwell, Sir William Bowman, Bart. (2nd donation), Dr. Broadbent, Dr. Lauder Brunton, Mr. W. O. Chalk, Dr. Sydney Coupland, Mr. C. C. Dent, Dr. Dickinson, Dr. Fenwick, Dr. Fish, Sir William Gull, Bart. (2nd donation), Dr. Hawksley, Mr. Timothy Holmes, Dr. Marcet, Mr. John Marshall (2nd donation), Dr. John Ogle, Sir James Paget, Bart., Dr. Parken, Dr. Reed, Dr. Roper, Dr. Burdon Sanderson, Dr. Sankey, Mr. W. S. Savory (2nd donation), Dr. Shepherd, Sir Spencer Wells, Bart. (2nd donation), Dr. Wilks, and Sir Erasmus Wilson (2nd donation).

The following have sent one guinea each:—Dr. Althaus, Dr. Barratt, Dr. Ballard, Dr. F. Beach, Mr. E. U. Bury, Dr. Biss, Dr. Mitchell Bruce, Mr. George Eastes, Dr. de Fonmartin, Mr. Cooper Forster (additional Treasurer's postage), Mr. John Gay, Dr. Goodhart, Mr. W. H. A. Jacobson, Mr. Kiallmark, Sir William Mac Cormac, Mr. H. Page, Dr. T. Niven (Fife), Mr. Laidlaw Purves, Dr. Savage, Dr. Semple, Dr. Spitta, Mr. Waren Tay, Dr. Frederic Taylor, Mr. Thomas Taylor, Mr. C. S. Tomes, Mr. Edgcumbe Venning Dr. Hermann Weber, and Dr. Samuel West.

Royal College of Surgeons, Examination Papers.—At the final or pass examination for the diploma of membership of the Royal College of Surgeons of England, the written portion of which was commenced on Friday the 18th instant, the unprecedented large number of three hundred and fifty-two candidates presented themselves, to whom the following questions on Surgical Anatomy, and the principles and practice of Surgery were submitted, when they were required to answer at least four out of the six questions, including one of the first two, between 1.30 and 4.30, viz.—1. Mention the several structures which must be divided in removal of one half of the Inferior Maxilla. 2. Describe the Ligaments of the Hip-Joint, and state how they are affected in Dislocation upon the Dorsum Ilii. 3. Describe the treatment you would adopt in a case of extensive Lacerated Wound of the Scalp, and mention the evil consequences which may follow this injury. 4. Describe the varieties of Keratitis. 5. State the various complications of Fracture of the Ribs and their treatment. 6. Mention the complications that may occur in the course of Gonorrhœa in the male and female respectively. Explain their modes of origin.

On the following day, the 19th instant, the following questions on Midwifery and the Diseases of Women were submitted to the candidates when they were required to answer three out of the four questions between 12.30 and 2 o'clock, viz.—1. Describe the Mechanism of Labour with the child in abdomino-anterior position and the breech presenting. 2. What means would you adopt with a view to prevent Hæmorrhage after Labour? 3. What is meant by concealed accidental Hæmorrhage? What are its symptoms, and how would you treat it? 4. What conditions produce enlargement of the Cervix Uteri? How would you distinguish between them?

The following were the questions on the principles and practice of Medicine, when candidates were required to answer three out of the four questions, including No. 4., between 2.30 and 4.30 o'clock, viz.—1. Discuss the symptoms and production of General Dropsy, indicating the causes on which it may depend, the manner in which the several varieties can be distinguished, and the treatment called for in different circumstances. 2. What are

the causes and symptoms of Bell's Paralysis, or Paralysis of the Portio Dura? Point out the distinctions between this condition and the paralysis observed in Hemiplegia. 3. What are the causes, signs, and symptoms of Pneumothorax? 4. State the therapeutical effects of the following drugs; and mention their officinal preparations, and their doses when for internal administration :—Silver, Lead, Zinc, Antimony, Digitalis, Colchicum, Belladonna, and Stramonium.

M., St. George's Hospital.—The late Mr. Cæsar Henry Hawkins was admitted a member of the Royal College of Surgeons, December 7th, 1821, made one of the honorary fellows of the College in the first batch, December 11th, 1843, a member of the Council in 1846, a member of the Court of Examiners and Hunterian Orator in 1849. Twice President of the College, viz., in 1852 and 1861. Dr. Francis Hawkins, the first Registrar of the General Medical Council, was his brother.

COMMUNICATIONS RECEIVED—

Dr. W. Alexander, Liverpool; Mr. Edmund Owen, London; Mr. Berkeley Hill, London; Dr. H. Donkin, London; Dr. Clifford Beale, London; Dr. Willoughby, London; Mr. Lawson Tait, Birmingham; Mr. Pridgin Teale, Leeds; The Hon. Secretary of the Obstetrical Society, London; Messrs. Kingsbury & Co., London; Mr. Cowell, London; Mr. W. Hay, Hull; The Secretary of the International Health Exhibition, London; Mr. Alex. Meighan, Glasgow; The Hon. APPOINTMENTS FOR THE WEEK.

Friday, July 25 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday, July 26.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, July 28.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

International Health Exhibition (Conference on School Hygiene).—Prof. De Chaumont, "School Dietaries."

Tuesday, July 29.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

International Health Exhibition (Conference on School Hygiene).—"Over-pressure in Schools." Communications by T. Pridgin Teale, F.R.C.S., C. Kegan Paul, M.A., R. Brudenell Carter, F.R.C.S., Sir Joseph Fayrer, F.R.S., Langdon Down, M.D., J. Crichton Browne, F.R.S., J. Marchant Williams, Richard Greenwood, Prof. Michael Foster, F.R.S., Spencer Watson, F.R.C.S., and C. E. Shelly, M.B.

Wednesday, July 30.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

International Health Exhibition (Conference on School Hygiene).—"Infectious Diseases in relation to Schools." Communications by T. J. Dyke, F.R.C.S., and H. Alder Smith, F.R.C.S.

Thursday, July 31.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

International Health Exhibition (Conference on School Hygiene).—"School Construction and Arrangements." Communications by J. Murgatroyd, F.R.I.B.A., Clement Dukes, M.D., and E. Noble Smith.

Friday, August 1.

International Health Exhibition (Conference on School Hygiene).—"Recreations and Gymnastics." Communications by Rev. E. Warre, M.A., Hon. E. Lyttelton, and R. von Schweitzer.

ON OLD AND MODERN POISON LORE.[1]

By A. WYNTER BLYTH, M.R.C.S.,

Medical Officer of Health for Marylebone.

The modern word toxicology has a deep significance, it can be traced back to an ancient root, meaning "bow" or "arrow," or in a wider sense some "tool" used for slaying. The oldest poison lore was that of primitive races in various parts of the world, who, in remote unhistoric time, took a lesson from the snake, and remedied the imperfection of their weapons by steeping them in venom.

The arrow poison of the Gauls is said to have been hellebore; that used by certain American Indians is curarine, a vegetable extract from plants of the Strychnos order. Some races adopted snake poison, and others putrid blood; this last producing a disease termed in our day septicæmia, or blood poisoning. In this way the septic poisons may have been very early known.

Weapons soiled with the blood of former wounds would be found more deadly than clean, freshly-made weapons; and starting from this empirical fact, the arrows or spears would be steeped in all manner of offensive pastes and smeared with the vegetable juices of those plants which were deemed noxious; and as the effects were mysterious, they would be ascribed to the supernatural powers, and covered with a veil of superstition. The poisonous properties of arsenic, opium, henbane, aconite, and a few others were known to the ancients and handed down by oral tradition as a part of priestcraft, long before they were reduced to writing; the exact amount of knowledge thus transmitted in this way can only now be a matter of inference. On an Egyptian papyrus preserved at the Louvre, M. Duteuil read, "Pronounce not the name of I. A. O. under the penalty of the peach." Now peaches, as peaches, are perfectly harmless, but prussic acid can be distilled from them; the Egyptians were the first known to have practised distillation, hence under the dread threat of the peach it is clear enough that they meant prussic acid; this is probably the earliest evidence extant of the actual separation of a poison in a more or less pure state by a chemical operation. No mention is made of prussic acid among the early Roman writers, yet there is good reason to believe that a knowledge of the deadly Egyptian distillate of peaches passed to the Romans. A knight in the reign of Tiberius, accused of high treason, swallowed poison and fell dead at the feet of the senators; no poison but prussic acid, and that in a tolerably concentrated form, would have this effect.

The early treatise of Nicander of Colophon (204–138 B.C.), to which followed Dioscorides, however, shows that whatever use or abuse might be made of a few

[1] A Lecture delivered at the International Health Exhibition on July 15th, 1884.

violent poisons, Greek and Roman knowledge of toxic substances was stationary, primitive and incomplete.

The Asiatic races used poison more than the Northern or Western nations; the ancient practice of the Hindoo widow—self-immolation on the burning pile of her husband—is ascribed to the necessity the Brahmins were under of putting a stop to the crime of domestic poisoning. Every little conjugal quarrel was liable to be settled by this form of secret assassination, but the law seems to have effectually stopped the practice. The Asiatics knew the properties of arsenic, aconite, opium, and various solanaceous plants, but were not acquainted with prussic acid.

The part that poison has played in history is considerable. The pharmaceutical knowledge of the ancients is more graphically and terribly shown in the deaths of Socrates, Demosthenes, Hannibal, and Cleopatra, than in the pages of the old writers on poisons. In the early part of the Christian era, professional poisoners arose, and for a long time exercised their trade with impunity. In A.D. 26 poisoning was so much in use as a political engine that Agrippina refused to eat of some apples offered to her at table by her father-in-law, Tiberius. It was at this time that the infamous Locusta flourished. She is said to have supplied, with suitable directions, the poison by which Agrippina got rid of Claudius; and the same woman was the principal agent in the preparation of the poison that was administered to Britannicus by order of his brother Nero.

It was the custom of the Romans to drink hot water, and as no two men's tastes are alike, great skill was shown by the slaves in bringing the water to exactly that degree of heat which their respective masters found agreeable.

The children of the Imperial house, with others of the great Roman families, sat at the banquets at a smaller side table, while their parents reclined at the larger. A slave brings hot water to Britannicus, it is too hot; Britannicus refuses it. The slave adds cold water, and it is this cold water that is supposed to have been poisoned; in any case, Britannicus had no sooner drunk of it than he lost voice and respiration. Agrippina, his mother, was struck with terror as well as Octavia his sister. Nero, the author of the crime, looks coldly on, saying that such fits often happened to him in infancy without evil result; and after a few moments' silence, the banquet goes on as before. If this were not sudden death from heart or brain disease, the poison must have been either a cyanide or prussic acid.

In those times no autopsy was possible; although the Alexandrian school, some 300 years before Christ, had dissected both the living and the dead, the work of Herophilus and Erasistratus had not been pursued, the rudiments of human anatomy were only known, while as to pathological changes and their true interpretation, such knowledge had no existence. It was not, indeed, until the fifteenth century that the popes, silencing ancient scruples, authorised dissections; and it was not until the sixteenth century that Vesalius, the first great anatomist, arose.

In default of pathological knowledge, the ancients attached great importance to mere outward marks and discolorations. They noted with special attention spots and lividity, and supposed that poisons singled out the heart for some quite peculiar action, altering its substance in such a manner that it resisted the action of the funeral pyre and remained unconsumed. It may, then, fairly be presumed that many people must have died from poison without suspicion, and still more from the sudden effects of latent disease, ascribed wrongfully to poisons. For example, the death of Alexander the Great has been confidently ascribed to poison, but "Littré" has fairly proved that the great emperor, debilitated by his drinking habits, caught a malarious fever in the marshes around Babylon, and died after eleven days' illness. If, added to sudden death, the body, from any cause, entered into rapid putrefaction, such signs were considered by the people absolutely conclusive of poisoning—this belief prevailed up to the middle of the seventeenth century, and lingers still among the uneducated at the present day. Thus, when Britannicus died, an extraordinary lividity spread over the face of the corpse, which they attempted to conceal by painting the face. When Pope Alexander VI. died, probably enough from poison, the rapid *post-mortem* change was noted, and considerable stress is laid upon it by the historian Guicciardini—but we know that such changes are utterly untrustworthy, some poisons indeed, such as arsenic, retarding putrefaction.

An essay might be written entitled Royal Poisoners. Charles le Mauvais, King of Navarre, gave a commission of murder to Woudreton, to poison Charles VI., the Duke of Valois, brother of the king, and his uncles the Dukes of Berry, Burgundy and Bourbon; the infamous document is still extant; it directs Woudreton to purchase sublimed arsenic, to sneak into the kitchen, larder, or anywhere else, and drop the powder into the soups or meats.

Charles IX. figures in the annals of human vivisection. There was a question whether bezoar was an antidote or not. The king decided the question by giving a cook convicted of some slight theft a lethal dose of corrosive sublimate, following it up with bezoar; but the man dies in seven hours, although Paré gives him oil—a grim business. Our own King John, of memory far from spotless, is said to have shut Maud Fitzwalter the Fair, in the highest, chilliest den of the Tower, and when neither cold, nor hunger, nor solitude broke her strength, when she still disdained his shameful suit, he foisted on her a poisoned egg, of which she ate and died.

The part that dynamite is playing in this age was played between the fifteenth and seventeenth centuries in Venice and Italy by poison—the criminal dynamite school of the nineteenth and the criminal arsenic school of the fifteenth in political basis—in reckless disregard of human life—are similar. The Council of Ten sat in Venice, decreeing the removal of this or that man. Curiously enough, the proceedings of the infamous oligarchy were recorded in writing with the utmost fidelity and candour; and in the strangest minutes ever penned, we may read now the reasons for and against the proposed assassination, the number of votes on either side, the sum paid, and the success. I will give one example and only one. On the 15th December, 1513, a Franciscan brother, John of Ragubo, appeared before the Council of Ten, and offered his services to remove any objectionable person out of the way. For the first successful case he required a pension of 1,500 ducats yearly, which was to be increased on the execution of future services. The Presidents, Girolando Duoda and Pietro Guiarini, placed the matter before the "Ten" on the 4th of January, 1514, and on a division, ten against five, it was resolved to accept so patriotic an offer, and to experiment first on the Emperor Maximilian. The bond laid before the "Ten" contained a regular tariff, appraising the value of the lives of most of the men of note of the day, and concludes—"The further the journey, the more eminent the man, the more it is necessary to reward the toils and hardships undertaken, and the heavier must be the payment." In the seventeenth century there arose a band of poisoners in Italy; the most notorious of whom was a certain Toffana. She used arsenic in solutions of various degrees of concentration; her solution was called Acquetta di Napoli. She is on fairly good grounds suspected of

having removed by means of Naples water, more than 600 persons, among whom were two popes. With the Acqua Toffana, the Acquetta di Perugia played at the same time its part. It is said to have been prepared by killing a hog, disjointing the same, salting it as it were with arsenic, and then collecting the juice which dropped from the meat. The juice was considered far more poisonous than an ordinary solution of arsenic; and recent researches on certain compounds which arsenic forms with organic matters lend countenance to this view. Toffana had disciples; Hieronyma Spara formed an association of young married women, one of the objects of which was the assassination of their husbands.

Italian and Venetian annals are not alone stained with these detestable crimes. The curious may read in Voltaire's History of Louis XIV.'s reign, the crimes of the Chambre ardente, of St. Croix, de Brinvilliers, the priest Le Sage, and the women La Voisin and La Vigourcux—of these Madame de Brinvilliers was specially infamous. She is said to be the inventor of "les poudres de succession," and essayed their strength on the patients at the Hotel Dieu. She poisoned her father, brothers, sisters, and others of her family, but a terrible fate overtook both her and her instructor and master in villainy, St. Croix. St. Croix was suffocated by deleterious vapours from his own chemicals. Madame de Brinvilliers' crimes being known, she fled and took refuge in a convent, from which she was lured by a detective, who disguised himself as an amorous abbé. She was beheaded and her body burnt near Notre Dame, in the middle of the reign of Louis XIV.

The old poison lore, mixed up with legend, myth and superstition, culminated in the use of arsenic. Arsenic, white, tasteless, and deadly, capable of introduction into the human frame in all manner of subtle ways, of killing slowly or quickly, and of simulating the effects of disease, was at one time almost synonymous with poison. For more than a century, after the properties of arsenic were to some extent popularised, there was no certain method known for its detection; and as late as 1836, whatever evidence of arsenical poisoning might be afforded by collateral circumstances, the risk of detection by chemical analysis was not great; hence the invention of a certain test for arsenic is so important, that the date of its discovery marks a toxicological epoch, from whence we may fairly date the rise of the modern poison lore. The great chemist, Scheele, in the eighteenth century, observed that arsenic united with hydrogen made a very peculiar and fœtid gas. After him Proust also studied the gas, and observed that when arsenical tin was dissolved in hydrochloric acid, that the gas could be lit, and then when allowed to play upon a cold surface, stains of the metal arsenicum were deposited.

Trommsdorf next announced, in 1803, that when arsenical zinc was introduced into an ordinary flask with water and sulphuric acid, an arsenical hydrogen was disengaged, and if the tube was sufficiently long, arsenicum was deposited on its walls. Stromeyer, Guy Lussac, Thenard, Gehlen and Davy later studied this gas, and Serullas, in 1821, proposed this reaction as a toxicological test. Lastly, in 1836, Marsh, a chemist at Woolwich, published a memoir in the *Edinburgh New Philosophical Journal*, entitled "Description of a new process of separating small quantities of arsenic from substances with which it is mixed." On the basis of the work done by the pioneers already enumerated, Marsh arranged an apparatus of great simplicity, which is known under the name of Marsh's test. The method is now in use, and will separate, with certainty, a millionth of a grain of arsenic—thus the most tasteless and the easiest administered poison in the whole world is also the one which it is easiest to detect.

Modern poison lore is distinguished from ancient poison lore by its extent, by its exactness, by the laborious compilation and verification of its facts, by the application of various instruments of precision, both at the bedside and in the laboratory. In modern times the throbs of the pulse, the respiratory waves, and even the functional enlargements of internal organs, are made to record their own movements on strips of paper, moved by clockwork, and adjusted by mechanism of an ingenious character. The number of degrees of temperature gained or lost is registered by thermometers. The channel by which the poisons leave the body is determined by chemical analysis, and by the same means we know much relative to the localisation of a poison in different tissues.

It is just about as difficult for the toxicologist to say how many poisons there are at present known, as for the botanist to enumerate existing species. By varying methods of classification all kinds of numbers could be obtained in either case. In the following statement, I have counted such substances as lead, copper, arsenic, antimony, and the like, as single units. Each of the metals named enter into a very large number of combinations, all of which are more or less poisonous, and which, if each compound were enumerated, would swell the total to a big figure. In like manner, although in the common foxglove (digitalis) there are several poisonous principles, yet they are so nearly allied that they may be all included under one head, and so on with other cases, proceeding in this way.

Inorganic solid poisons	19
Liquids, more or less volatile, and many anæsthetic, such as ether, chloroform, methylene, benzene, alcohol, &c.	18
Acids, both organic and inorganic	10
Alkaloids	51
Glucosides	20
Organic anhydrides	2
Complicated animal and vegetable poisons not yet fully classed	26
Gases	14
	160

I get a total of 160 poisons, as about the number at present known to science; but not more than 40 of these ever figure in the Registrar-General's reports as a cause of death, and over 60 are chemical rarities, not existing in ordinary commerce.

Previous to the nineteenth century, more than seventy of these poisons were either unknown, or only known as vegetable extracts; it is the glory of modern chemistry to have separated from plants most of the active principles in a perfectly pure state, and to have shown that what was formerly considered simple is really complex. Take, for example, opium; it has been known as a narcotic from the earliest times; before 1803 no one ever imagined that it contained more than one active principle, but in 1803 Derosne separated from it morphine and narcotine, and at the present time no less than twenty-one definite principles, all having different physical, chemical, and physiological properties, some, indeed, antagonistic, have been separated from this wonderful drug; or take aconite, that has been from the most remote times the favourite poison in India. Aconite, or the common monkshood, contains six alkaloids, two of which alone seem to be physiologically active. Digitalis, the common foxglove, contains at least seven closely related and yet not identical principles; and, in short, it is now evident that poisonous plants generally contain a family group of poisons.

Life mainly rests on a tripod, heart, brain, and lung, Some poisons act specially on the heart, others concentrate themselves on the lungs, and others ascend to the brain, but a great majority irritate and inflame the fine velvet lining of the great convoluted tube of the

body, and only act indirectly on the cardiac, nervous, and pulmonary systems. I have calculated that about 19 per cent. of the 160 known poisons act directly on the brain and spinal cord, either lulling to preternatural sleep, or exciting to preternatural activity; 5½ per cent. affect the respiration, a little over 4 per cent. affect the heart primarily, while no less than 39 per cent. are irritants; as for the remainder, their action is so mixed that they seem to affect various organs at one and the same time.

I have no intention of describing to you the symptoms produced by toxic substances, but take the opportunity of pointing out in a general manner the wonderful mimicry of disease produced by certain poisons.

The fatal bite of the Cobra di Capello not unfrequently produces all the effects of a somewhat rare malady known as glosso-pharyngeal paralysis, or, in plainer English, palsy of the tongue and throat.

Atropine, the active principle of belladonna, will produce a dry sore throat, a vivid rash on the skin, a quick pulse, a high temperature, with delirium: the resemblance to scarlet fever is completed by a slight desquamation, or subsequent peeling of the skin.

A large fatal dose of arsenic mimics cholera; there is the same excessive depletion of all the fluids of the body by one channel, the vomiting, the collapse, and rapid death. Phosphorus produces jaundice; strychnine simulates tetanus, and the symptoms have been mistaken many times for hysterical convulsions.

Madness has been produced by lead. Last year I saw in Dr. Rayner's clinic at Hanwell some remarkable examples of this; in nearly all cases there were illusions of sight, one patient saw round him wind bags blown out to look like men. These apparitions floated after him and very much worried and alarmed him.

A more terrible form of brain disease has been produced by an artificial poison. Some years ago mercuric methide was prepared in a London laboratory, and two young chemists, engaged day after day in its manufacture, became ill from breathing the vapour; complicated symptoms of brain disease appeared, which culminated in idiocy, and they both died.

Mercuric methide is not, however, the only poison which may produce insanity or idiocy. The dhatoora of the Hindoos, which is identical with belladonna, has in Indian history played the peculiar *rôle* of a State agent, and has been used to produce imbecility in persons of high rank whose mental integrity was considered dangerous by the despot in power. It usually, however, produces but a temporary insanity: in one case after a toxic dose a tailor sat for four hours moving his hands and arms as if sewing, and his lips as if talking, but without uttering a word. The "insane root that takes the reason prisoner" may be found among the solanaceous plants. In an ancient cloister the monks ate in error henbane root, and in the night were all taken with hallucinations, so that the pious convent was like a madhouse. One monk sounded at midnight the matins; some who thereupon thinking it was morn, came into chapel, opened their books, but could not read; others declaimed; some sang drinking songs of a character not befitting the place; and the greatest disorder prevailed.

Several poisons produce ulcerations and skin diseases. The remarkable malady, first described by Dr. B. W. Richardson, under the name of the bichromate disease, is another example of similarity between an artificially induced affection, and one which seems to occur spontaneously. Potassic bichromate is made on a large scale, and the workmen who inspire the dust through the nose suffer from an inflammation of the septum, which ultimately may be destroyed by ulceration. It also causes painful skin affections—eruptions like eczema and psoriasis, and very deep and intractable ulcerations. The effects of the bichromate are not confined to men; the dust gets in any crack the horses at the factories may have about their hoofs, and causes an ulceration from the effects of which even the hoofs may be shed.

If glosso-pharyngeal paralysis, scarlatina, affections of the skin, tetanus, insanity, and idiocy may be either simulated or produced by drugs, on the other hand, certain diseases simulate the symptoms of poisoning, and the most rational explanation of these cases is that the body itself manufactures its own poison. One of the best examples is that known as "diabetic coma." In diabetic coma, there is first mental confusion, in which the person may wander aimlessly about the streets, and have somewhat the appearance of ordinary intoxication; then follows irresistible drowsiness, and ultimately death,—altogether a series of phenomena which might be well mistaken for the narcosis of opium or alcohol.

The establishment of almost perfect antagonism between certain vegetable poisons belongs to modern poison lore; for example, atropine is antagonistic to pilocarpine; atropine makes the skin dry, pilocarpine causes in five minutes a profuse perspiration; atropine dilates the pupil, pilocarpine contracts it. The heart of an animal arrested by atropine can have its tick-tick restored by the direct application of pilocarpine. Poisoning by pilocarpine is relieved and cured by atropine; poisoning by atropine is relieved and cured by pilocarpine.

The relationship between chemical composition and the direction of toxic activity also belongs to modern poison lore; the alkaloid strychnine, which causes powerful tetanus, may be changed by the chemist into another alkaloid which produces the opposite effect—paralysis; morphine, a drug producing sleep, may also be transformed by a very slight chemical metamorphosis into an emetic.

In being obliged to avoid any detailed account of the symptoms of poisoning, I cannot omit to point out the errors of most of the popular descriptions. Few dramatists have been happy in the description of death from poison; the death of Cleopatra, described by Shakespeare as resulting from the bite of a venomous snake, is like no clinical description of fatal illness from bites of any class of snakes.

In Philip Massinger's play—"The Duke of Milan," Francisco dusts over a plant with a poisonous powder; this plant Eugenia holds; Ludovico Sforza kisses her hand twice, and from this slight contact very rapidly dies—why, it is doubtful whether pure aconitine itself, the most powerful of all known substances, and only separated within the last few years, could be inhaled under these conditions in sufficient quantity to do harm.

Beverley, in Edward Moore's "Gamester," takes poison in the fifth act, after which he makes several pretty long speeches, and ultimately dies suddenly, but, so far as we can learn, with considerable calmness. Nathaniel Lee, in his tragedy, "Alexander the Great," provides a poison for the destruction of the emperor, which is described as of "exalted force."

> "* * mixed with his wine a single drop gives death,
> And sends him howling to the shades below."

Nevertheless, after taking the poison, Alexander walks about, declaims much, kills Clytus, and goes through the latter part of the fourth act, and most of the fifth, comfortably enough; then raves in delirium, regains his senses, and dies after a very fine speech. There was no poison known to the writers of the plays alluded to which would produce symptoms in any way similar. At the present day there is, however, a liquid made by artificial means, the effects of which are stranger than those imagined by play-writers—after it is swallowed, the person walks about for an interval of time varying

from a quarter of an hour to two hours. His skin, and even the whites of the eyes, become of a strange purplish livid colour, but he may feel fairly well, then the fatal symptoms set in with appalling suddenness, and he dies in a few minutes. For anyone who delights in constructing stories of sensation, these occasional effects of nitrobenzene, just described—the weird blue colour, the interval allowing of acts and rhapsodies, and the abrupt termination, afford considerable, although perhaps not commendable scope.

If progress has been made in the discovery of new poisons, and new methods of detection, so also progress has been made in the treatment of poisoned persons. Take, for example, the modern treatment of a patient suffering from a toxic dose of strychnine. In chloroform we have not a chemical but a physiological antidote. Death takes place from the terrific spasms affecting the breathing. If chloroform be inhaled, and the nervous system lulled to sleep, time is afforded for the elimination of the alkaloid by the natural channels, and a chance is given to an otherwise hopeless case, In turpentine we have a most wonderful antidote for poisoning by phosphorus; and the more complete, for it seems to follow and catch up as it were the phosphorus, even when circulating in the blood.

Few of us contemplate the possibility of accidental poisoning in our own households; yet among the daily necessities of civilized life, very active poisons hold their place. Bleaching powder, carbolic acid, salts of sorrel and even some forms of washing blue are deadly enough, and from time to time are the cause of accidents. The proper antidote for these ought to be in every house, and the elementary knowledge of the proper treatment of such accidents should be known by all.

There was an ancient myth, long believed, that certain stones changed their colour at the approach of poison, and that there was also a substance which would neutralise every poison. This is no longer thought probable or possible. Nevertheless, attempts have been made with some success to compound a liquid which plays the *rôle* of a multiple antidote. One of the best consists of a saturated solution of sulphate of iron, 100 parts; magnesia, 80; animal charcoal, 44 parts; water, 800. It is preferable to have the animal charcoal and magnesia mixed together in the dry state and kept in a well corked bottle; and when required for use, the saturated solution of sulphate of iron is mixed with eight times its bulk of water, and the mixture of charcoal and magnesia added, with constant stirring.

The multiple antidote may be taken in wine-glassfuls once every ten or twenty minutes in recent poisoning by arsenic, zinc, opium, digitalis, mercury, or strychnine.

As to immediate treatment of other common poisons.—In poisoning by acids use calcined magnesia, or carbonate of soda, or any bland oil. In poisoning by caustic soda vinegar should be given. A good domestic emetic is sulphate of zinc, which now may be bought of most chemists in the form of convenient tablets. With the simple remedies named, that is, multiple antidote, calcined magnesia, vinegar, sulphate of zinc tablets, and let us add, for phosphorus, a small bottle of French turpentine, a cupboard may be stocked, and thus, for a few shillings, precautions taken against an emergency which may arise at any moment.

The use of poison by man I have thus first traced to the barb of the arrow envenomed by vegetable extracts; later, poisons were used in a more subtle manner; the stroke in daylight was replaced by the poisoned chalice; but at the same time it was found that poisons were also medicines, and able, when used legitimately, to preserve as well as destroy life. Later still the very essences of the plant world were separated as pure crystalline forms, and, aided by instruments of precision, their properties studied in all manner of ways. Rays of light, from the development of physiological and other sciences, were brought to converge upon the general subject; and modern toxicology, though far from perfect, has rendered the crime of secret poisoning a dangerous game to the player. An important part of modern poison lore has been built up by experiments on animals. All that has been done in the past in this direction I cannot justify; but these experiments have for the most part been undertaken by noble and humane men, for noble and humane purposes. If these experiments have increased the ways of death, they have multiplied the means of recovery; they have given to the physician many a potent elixir, charming away pain and restoring health. They have enlarged our knowledge of the action and nature of remedies, and have proved safeguards against illicit criminal practices. These experiments have shown that certain poisons are so potent and subtle in their action as to almost equal the wonders in tales told of charms condensed in necromancers' phials. The animal body can be played upon as if it were a machine. The strokes of the central pump can be slowed or quickened; the vital heat lowered or increased; the pupil of the eye expanded or narrowed; the limbs paralysed or convulsed; the blood sent to the surface or withdrawn to the interior; even the natural hue and colour of the body can be changed. If it be asked, cannot this strange science become, in the hands of an unscrupulous, abandoned, and yet learned man, a power of destruction fearful to contemplate? The answer is, the risk of this is small. The higher kind of brain is a moral brain; the highest scientists are the most religious, it may not be a religion of special creeds, it may not even be a Deistical religion; but no one who has observed the phases of thought of the nineteenth century can with truth deny, that side by side with the evolution of physical and natural science, there has also been an evolution and practice of the purest doctrines of Krishna and Buddha; if indeed it were not so, and the most exalted intellects abandoned themselves to the secret destruction of their fellow creatures, the results would be disastrous. As for the ordinary criminal mind, like that of the Comte le Pommerais, who specially prepared a then almost unknown alkaloid, or the surgeon Palmer, or still more recent semi-scientific murderers whose names I pass over in silence, there is absolutely no ground for believing that they could escape detection; however cunning they may think themselves, however rare the agent they may employ, the toxicologist has weapons and means at his command to diagnose the sickness of nature from that of malignant art, and to separate and identify the poison.

SOME OBSERVATIONS ON ENDEMIC FEVERS IN INDIA.

By Surgeon J. PEDLOW, M.D.
Army Medical Department.

(*Continued from page* 113.)

Returning to a consideration of the other cases, in all except two there was abdominal pain and tenderness in a greater or less degree. In four cases, all of them fatal, there was hepatization of one or both lungs, and in five others some hypostatic congestion; three of these latter also ended fatally, bronchitis alone was present in nine cases, one of them fatal. In four fatal cases the liver alone, and in two the kidneys alone, were congested. The urine was tested for albumen in

*

twenty-one cases. This was present in seven cases, five of which were fatal. It was present, as a rule, in those cases in which the liver and kidneys were both congested. In four of the fatal cases both these organs were in that condition, and in the fifth case the kidneys were much inflamed. With regard to the duration of the illness in fatal cases, one died on 6th day, one on 7th day, two on 14th day, two on 17th day, and the others on the 10th, 15th, 16th, 21st, 26th, 38th, and 42nd days. Intestinal ulceration was present in all these cases of enteric proper, with the exception of the one just recorded. In five cases, in addition the solitary glands of the large intestine were enlarged and congested. In some cases these glands were closely set together and looked exactly like the pustules of small-pox. In eleven cases the colon was also very much congested, and in two cases the rectum. In four cases the mucous membrane of the large intestine was eroded. The spleen, except in one case, was enlarged and congested. It varied from 10 to 28 ozs. in weight. The mesenteric glands were enlarged in all except two cases. The condition of the membranes of the brain has been previously alluded to as causing cerebral disturbance of a marked nature, and early death. Some of these cases in the first few days of illness had convulsions, and in two cases these attacks counterfeited typical epileptic fits with tonic and clonic spasms. Coma, as a rule, supervened at an early period in these cases. The virulence of the poison whether of climatic or pythogenic origin was tested by the extent of the lesions found on *post-mortem* examination. In many cases the bladder was much inflamed, and the whole intestinal tract, from the mouth to the anus, more or less congested.

The following is a record of one of these acute cases. Private J. M., age 23, service in India three months, was admitted to hospital on the 18th June, 1883, with diarrhœa and severe headache, which he stated had attacked him suddenly the previous day. The tongue was moist and furred, the face was flushed, and the eyes suffused. There was some tenderness over the abdomen; temperature 101°. He was frequently purged throughout the day the motions being frothy and feculent. Next day, the third day of the illness, the motions were bilious and there was some straining; the tongue was brown in centre; temperature 103°; delirium set in the same night and the patient was very violent. He had sharp convulsions and the efforts of three men hardly succeeded in keeping him in bed. The tongue became quite dry and parched, with bright red round spots sharply defined on the rough brown surface. When not in one of these paroxysms there was constant twitching of hands and feet. He was then quite unconscious, urine and motions passed in bed. On the 22nd urine was tested, specific gravity 1028, acid, loaded with albumen. He was now quite comatose. There was a profuse fœtid sweat from the arms and upper portion of the body, while the skin of the legs and abdomen was quite dry. He died at 11.30, noon, on the fifth morning after admission, the temperature having risen to nearly 106° an hour before death. On *post-mortem* examination the sub-arachnoid space was found full of fluid, and a large quantity of recently formed lymph, semi-consistent, was thrown over the surface of the frontal convolutions. The liver and kidneys were congested and the spleen also. The latter weighed 14 ozs. There were some spots of congestion in the upper portion of the ileum. The first diseased Peyer's patch was met with about nine feet from ileo-cæcal valve. This patch was two inches in length, and half an inch broad. It was a slender oval in shape, and its surface was raised above the mucous membrane, its substance was soft and lymphy and eroded in one or two places. Its long axis corresponded to that of bowel, and its margins were well-defined. The second patch was ten inches below this one, and others were met with at intervals of four or five inches, they became larger, thicker, and broader as the valve was neared. Within three feet of the ileo-cæcal valve the solitary glands were found enlarged and closely packed together, as many as ten or twelve to the square inch. Peyer's patches were here fully a quarter of an inch thick and were stained with bile. A mass of ulcerated patches surrounded the valve. The bowel on section through one of them was fully half an inch thick. The colon was congested throughout and its upper portion thickly studded with enlarged solitary glands, the rectum also was much congested.

The second acute case, which ended fatally on the seventh day, was in a young soldier only a few weeks landed in India. The symptoms were similar to the one just recorded, but a few rose-coloured spots were seen on chest and abdomen. He was admitted to hospital on the 12th May, 1883, and died on the 16th. On admission he had severe headache and diarrhœa with dark offensive motions; delirium set in early. He had clonic convulsions frequently; both lungs became congested early, and he died comatose. The *post-mortem* lesions were very similar to those of previous cases. Spleen weighed 28 ozs., and the liver was very much congested.

Estimated day of Illness.	TEMPERATURE.	
	Morning.	Evening.
	°	°
3rd	103	105
4th	104	105
5th	104·2	104·6
6th	103·8	103·8
7th	104·8	

Now contrast the severity of these two cases with the following one, which they somewhat resembled on admission. In this case the original attack was considered simple continued fever, and the patient was discharged after 23 days' treatment apparently well. Private L., age 21, service in India five weeks, was admitted to hospital on the 21st April, 1883, with bilious diarrhœa, which he stated had lasted for two days; he also had sharp pain in the bowels before admission; an acute pain was complained of in the head chiefly on the vertex, his skin was hot and dry, his face suffused. The tongue on third day, in hospital, became quite dry and brown except at the edges, and intestinal complications were expected. The diarrhœa, however, ceased the following day, and the motions became normal in character; the pain also disappeared from the head. He improved rapidly, the temperature became normal on the ninth day of his illness, and he was discharged on 23rd day of hospital treatment. He was re-admitted a fortnight afterwards and then stated that shortly after discharge the diarrhœa returned and that he became feverish in the evenings. On re-admission the temperature was 104·4° first evening, and there was abdominal pain and tenderness with some tympanites; diarrhœa had then ceased, temperature reached the normal on the ninth day of hospital treatment, and he was discharged well on the 32nd day.

Allusion has been made previously to frequent irregularities in the temperature, not common at home in enteric fever. It is usually stated that a temperature of 104° within the first 24 hours, as a rule, excludes it. In an insidious attack the patient would rarely report himeslf sick before the lapse of that time. In some of my cases, in which the patient described his illness as coming on suddenly with rigors and severe headache the previous day, I have found the temperature over 104° on the evening of second day, and very high temperatures are constantly seen in these severe cases

in the first two or three days. A normal temperature at any time during the first week, is also said to exclude enteric. In the second case given in this paper, the last relapse commenced with a series of evening exacerbations, the temperature being normal in the morning for three days; and in all the cases of relapse but one, the temperature had reached the normal in the original attack at some time in the first seven days. I give below a few details of two cases returned as enteric, in which the temperature was also irregular. One patient was 27 years old, the second 28. Both these cases, while under treatment in hospital for gonorrhœa in August and September last, were attacked with diarrhœa and headache. The first case was very mild at the outset, and the patient said nothing about his illness for some days. In each case there was much sleeplessness and nervous prostration, and the stools, which were feculent at the outset, afterwards assumed enteric characters. There was great debility in both cases, and the first case was re-admitted after discharge with œdema of the legs, and diarrhœa.

13th	98·6	102·6	3
14th	99·4	103·4	4
15th	99·4	101·4	3
16th	normal	103·2	3

From the latter date the temperature gradually fell to normal in the evenings, and diarrhœa subsided on the nineteenth day.

In the second case the rise was more sudden, and the daily range less.

15th	98·4	100·8	3
16th	98·6	99·8	3

In this case a normal evening temperature was reached on the twenty-fifth day.

Cases with temperatures similar to both these cases were common enough, but in many there was constipation throughout, and they were therefore considered remittent in type.

The following case was also peculiar as regards the temperature at the outset, though in other respects well marked. Private B., age 21, service in India six months, was admitted to hospital on the 29th September, 1883. The day previous to admission he stated he was suddenly attacked with dizziness, and severe bilious vomiting, which was followed by a shivering fit. He then lay down and felt better in the evening; the next day the shivering returned and he came to hospital. On admission his tongue was quite clean and moist, but headache he stated was very severe. He also complained of pain down the back and over the liver. Bowels were constipated. There was no abdominal tenderness. On the following morning the temperature fell to normal. There was little change during the next two days, tongue became furred, and the headache was still severe on the fifth day; temperature at 4 o'clock, was 103·6°, and he was put in a bath at a temperature of 86°; it rose in bath to 104°, but fell in one hour to 103°. Delirium was present that and the previous night, tongue became brown in centre, and the eyes were much suffused. There was but little change during the next six days. There was much nervous prostration, and the limbs were constantly jerking. Bowels constipated. The baths were repeated every day until the fourteenth day, sometimes twice a day. He was rolled up in a blanket and made comfortable in the bath by pillows. After the first bath the fall in temperature was usually from 2° to 3° in the hour, and it rarely rose again to within 2° of the original height after the evening bath. The evening temperatures were usually taken before 4 o'clock, and consequently did not represent the highest temperatures which would have been reached. On two occasions the administration of the bath was delayed for half an hour to see if the temperature would fall naturally, but it kept steadily rising till it was over 105°. On the thirteenth day of illness there was some bronchitis, and diarrhœa with enteric stools, set in. The diarrhœa was mild in character. There was some tympanites and abdominal uneasiness, not amounting to pain. The delirium was kept in check by the bath, and the tongue, though brown, was moist throughout. On the seventeenth day there was some improvement, diarrhœa ceased, and the delirium disappeared. On the thirty-second day there was evidence of a tendency to relapse, which passed away and the patient was discharged from hospital on the 16th December.

Now these cases of so-called enteric fever thus briefly recorded, and selected from a large number of others equally irregular, will show, even to one who has not seen and treated them, how different are the types of fever in India with visceral complications from those met with at home.

(To be continued.)

ON SOME CASES OF TREPHINING.

By WM. ALEXANDER, M.D., F.R.C.S.,

Visiting Surgeon, Liverpool Workhouse Hospital.

The operation of trephining was looked upon in the earlier days of surgery as the most interesting, the most delicate, and the most serious of operations. More delicate operations have sprung up since that time, abdominal surgery has now usurped the interest that then belonged to cranial surgery, whilst the seriousness of the ordinary operation of trephining has to a large extent disappeared.

The diagnosis of brain disease, and our knowledge of the functions of the healthy brain have made rapid advances within the past few years, but surgery has not been able to keep pace with them and chronicle the removal of tumours, or the frequent evacuation of abscesses during life. *Post-mortems* alone are still the criteria of diagnostic precision in cerebral disease. Cases of compression from depressed bone, meningeal hæmorrhage, or pus, and a few cases of epilepsy are still trephined; but the indications are much the same as in the days of Percival Pott.

The bony covering of the cranial cavity is a formidable obstacle to operative proceedings, and the small apertures that we have hitherto dared to make give room neither for those operative nor diagnostic purposes to which, through exploration, we can have recourse elsewhere. Besides, the object of all operation is to preserve the *conscious spirit*, the *ego*, of the individual, and limbs and organs, and senses must give way in order that it may be retained. In operations in the cranial cavity there is a danger of destroying the conscious individual and leaving behind an automatic arrangement of muscles and bones and nerves and viscera, that will require the sacrifice of another life to keep right for even a limited period.

A patient cured of a cerebral tumour that threatened his life is worse than dead if he can only follow his nose till he comes to a wall to which he stands "glued" until someone turns his face elsewhere. The most loving friends would soon wish such a one buried, nor could they be found fault with. The automaton is not their relative, and his mummy preserved in a glass case would be as interesting and much less troublesome. For this reason, as well as from the inherent surgical difficulties of such operations, removal of brain tumours will probably never become a common operation. But tumours of the dura mater, vascular derangements and fluid collections, both internal and external, may be more successfully treated than now. My cases will be best followed by remarks on their most useful and salient points, and hence, with these brief prefatory remarks, I will proceed to describe them in order.

Case I.—*General Paresis, especially of left side, with stupidity—Signs of old injury to right side of head—Trephining—Great improvement both mentally and physically.*

Geo. P., æt. 18. Came into hospital originally on May 18th, 1881, suffering from fever. Since that time he has been living in the workhouse. His father died in gaol. His mother deserted him, and he has been a vagrant and a beggar all his life, except occasionally when he worked as a farm labourer. At the age of fourteen years, through excessive drinking he was sent to Rainhill Asylum and remained there four years.

On September 3rd, 1883, I first saw him in the infirm wards of the hospital, with general loss of power, most marked on the left side without any very distinct loss of sensation. His lower lip hung down and saliva dribbled from his mouth. There was no facial palsy. Everything was passed beneath him, and he was so stupid that nothing could be got out of him. A cicatrix existed on the skin over the right parietal bone, just behind its centre, beneath which was an irregular depression.

On September 26th I trephined over the inequality and found the skull to be enormously thick. The dura mater was healthy looking, although the ring of bone was somewhat irregular on the inner side. Operation performed under the spray.

27th.—Temperature, morning and evening, 99° and 98·4°. Complains of pain in head. Can move left arm much better. On the 28th the evening temperature reached 103°; 29th, morning and evening temperature, 99·8° and 101·2°; 30th, 99·8° and 101·2.°

October 1st, 98° and 100·4° Can speak much better. Temperature afterwards normal. Wound quite healed up by the 14th. On October 15th he got up and was able to walk about with crutches; 29th, fell and hurt his arm. In a few days it was well and he was able to go about again. Since that time he has had occasional attacks of powerlessness, but they are very slight and of short duration. His mind is much improved, and he can talk and answer questions well. He is still in the workhouse under observation.

Remarks.—In this case the ostensible cause of operation was based on well-recognised principles of science and of surgery. Marks of injury on the right side of the head, with some paralysis of motion on the opposite side of the body, naturally led to the suspicion of a cortical lesion, probably connected with the injured bone. However, my real reason for operating was to bring atmospheric pressure to bear upon the fluid that probably saturated the atrophied convolutions and so allow them to resume their functions. In numerous *post-mortem* examinations of old people who suffered from stupidity and paresis, such as this patient was the subject of, I had often noticed the atrophied convolutions swamped in fluid that was sometimes of a jelly-like consistency and appearance. The benefit of removing this œdema seemed to me very apparent were it not that all the individuals in whom I noticed the symptoms had already reached the natural span of human existence, and except it were possible to rejuvenate them at the same time it would be worse than useless to operate. This patient, however, was a young man, with an atrophied brain, who was now little better than a vegetable. Indeed he was much worse than a vegetable, as a dirty animal always is. When the large trephine circle of bone was removed, the dura mater collapsed very decidedly, and the healing wound was drawn very decidedly inwards. Atmospheric pressure was brought to bear to that extent upon the cerebral contents, and a proportionate diminution of the cerebral fluid was thus effected. The man has been cleanly since and has been nearly always able to go about. To attempt to generalise from a single case would be unwise; I will therefore content myself with putting the case thus briefly before the profession.

Case II.—*Painful Traumatic Otorrhea, with symptoms of central and ophthalmic disease—Partial relief from trephining—Complete relief from free opening of mastoid cells.*

Wm. B., æt. 33, a dock-labourer, and who describes himself as a very sober, hard working, single man, fell fifteen months ago from the top of a pile of bags and knocked the left side of his head against a gate. There was no visible wound and only slight pain and swelling. After a few days had passed a discharge began to come from the ear of that side.

About a fortnight after the first injury the patient again fell to a depth of 17 feet, and again hurt the left side of his head, close to the ear. The discharge had continued for nearly three months when he became an out-patient at the Eye and Ear Infirmary. He did not attend long there, but during his attendance he had what he calls an operation performed. He does not know anything of the nature of the operation. It was done without pain and relieved him slightly for a time. He had nothing else done to him until he entered hospital under my care on February 20th, 1884.

He came into hospital not so much for the deafness and discharge, as for other symptoms that alarmed him. For some time past the left eye becomes occasionally queer; sight sometimes completely disappears, especially when "the gas is lighted"; at other times it seems as if things were passing quickly before it. The pains in the side of the head and over the orbit are intense, and nearly always present. Giddiness, loss of memory, vomiting and abdominal pains are getting more and more frequent. These symptoms during the last few months had alarmed him greatly. The eye was examined ophthalmoscopically but no record of the examination has been retained.

On admission no swelling could be felt or seen over the mastoid process, a scanty discharge came from the ear; the membrana tympani was thickened and entire.

On April 2nd I trephined the mastoid process. The mastoid cells were very hard and it took a long time before the circle of bones could be removed. When it

was lifted out, the lateral sinus could be plainly seen posteriorly. The mastoid cells in front were filled with what seemed to be inspissated pus. The wound was closed under the same antiseptic precautions that had hitherto characterised the conditions of the operation. Next day the temperature was 100°, the only time it rose above the normal. On May 2nd he was discharged with the trephine wound closed, the discharge from the ear cured, the pain and other symptoms abated but occasionally troubling him.

He was re-admitted on June 4th, 1884, seeking further relief, as the old symptoms had returned.

On June 24th I cut down upon the anterior wall of the trephine aperture, which was now filled by dense cicatricial tissue, and with bone forceps I thoroughly opened up the mastoid cells in front and below the wound. The bone removed was hard and had its interstices completely filled with thick white curdy looking material. The deep hole thus made was plugged with boracic lint.

Towards the evening of the day of operation he was rather dull and complained of pain in ear and buzzing in head. No increase of temperature was experienced; the wound suppurated freely and was kept open by plugging with a piece of boracic lint.

July 3rd. Very much improved, operation wound healing rapidly, deafness much less, no pain in temple, nor any return of the old symptoms.

July 21st. Discharged quite well.

CASE III.—*Abscess of Mastoid Cells.—Trephining —Cure.*

Michael D., æt. 41 years, admitted to hospital February 11th, 1884; married; six children, all healthy.

About three months before Christmas the patient received a blow on the head with an iron bar which fell from its place and struck him a little above the left ear. A lump formed but was not accompanied with much pain, and in a few days the swelling disappeared.

About a fortnight after the injury a strange sensation was felt in the left ear. He became partially deaf and subject to a constant drumming noise on the affected side. These symptoms continued for a fortnight, when pain set in rather suddenly and a dark coloured discharge began to come from the ear, and has continued up to his admission. A swelling was then visible and palpable behind the ear. Under medical advice this was poulticed. The swelling gradually disappeared, but the pain continued. He gave up work and soon after came under my care.

The mastoid swelling behind the affected ear is more diffused than normal, but not much more prominent. It is not very tender to touch and gives no indication of matter beneath. A foul discharge of dark yellow pus exudes from the large auditory meatus. The membrana tympani is imperfect and the posterior wall of the meatus is felt by the probe to be stripped of its periosteal lining. The patient seems to be almost deaf on this side, and complains of severe diffused pain over the side of the head radiating from the ear, in consequence of which his countenance has an anxious worn expression. Until March 19th the treatment consisted in gently syringing the meatus with boracic acid lotion and afterwards dusting it with powdered boracic acid. During this time the swelling behind the ear became larger and more and more painful. The discharge from the ear continued the same.

On March 19th I trephined the enlarged mastoid process behind and on a level with the meatus. When the trephine groove had been sunk to a depth of a quarter of an inch, the circle of bone came away and a large irregular cavity filled with dark-coloured bad smelling pus was exposed. The pus was cleared out and the cavity plugged with lint steeped in carbolic oil. The symptoms completely disappeared with the exception of the deafness, and on April 15th he was discharged to town with the trephine wound quite healed, the cavity in the bone obliterated, the discharge from the ear stopped and all the pain gone. He felt quite well and hardly knows that he is still almost deaf on that side.

These two cases illustrate the advantages of trephining in that very common disease inflammation of the mastoid cells which is mostly secondary to ear disease. Death from such a cause is by no means rarely met with, and I can lay my hand on several specimens of dried bone showing mastoid excavations made by imprisoned abscesses, that killed through the induction of meningitis and cerebritis or cerebral abscess.

The second case was a very satisfactory one to the operator in that he found a deep abscess whose odorous contents testified to the accuracy of the diagnosis and the danger to life. The only regret was that the operation had not been performed sooner, and some weeks of suffering saved.

The first case was more obscure, no swelling could be distinctly recognised, the symptoms were more cerebral than auricular, and it was only the history of the case and the urgent need of the patient that led me to explore. In the first operation the mastoid cells were not sufficiently open to relieve the tension of the more active area of disease situated probably beneath the dura mater, whence meningeal inflammation and nerve disturbance of a chronic kind had already spread, occasionally exciting vaso-motor disturbances, the direct mechanism of which we may guess at but need not waste space in describing until it becomes more than a guess.

POST-MORTEM EXAMINATION OF A CASE IN WHICH REMOVAL OF THE UTERINE APPENDAGES FOR MYOMA HAD BEEN PERFORMED THREE YEARS BEFORE DEATH.

By LAWSON TAIT, F.R.C.S.

In the brief paper by Sir Spencer Wells, in the *Medical Times and Gazette* for July 5th, that writer says: "We have still to learn much as to the effect upon uterine growths and out-growths of the removal of the ovaries. Vague unsupported assertions have little influence upon the opinion of a thoughtful or sceptical profession." For my own part I was under the belief that so much that was definite and thoroughly well supported had been written on this subject by many besides myself that it was a matter beyond the range of scepticism. The following small contribution may, however, help the unbelieving into a better frame of mind.

I have just received from Dr. Saundby a jar containing the uterus of a woman, aged 47, from whom I removed the uterine appendages for a large myoma on June 21st, 1881. At that time she was under the joint care of Mr. M. Hallwright and myself, for profuse menorrhagia, accompanied by intense pain. All other efforts having failed to relieve her, her health being completely destroyed and the tumour growing rapidly, I advised the operation. The tumour reached about an inch above the umbilicus, and the upper end of the incision necessary to reach the appendages was almost at that land-mark. Dr. George Fyfe, Dr. Savage, and Mr. Raffles Harmar were present at the operation. She made an easy recovery, and never lost a drop of

blood from the uterus after her convalescence, which was completed within a month. She rapidly gained strength and health and, as she said upon my frequent visits to her, had neither ache nor ail. She happened to live close to my house, and was therefore frequently exhibited to visitors. She has been seen and examined by Dr. Marion Sims, Dr. Battey, and Dr. T. A. Emmett. Ten days ago she suddenly began to suffer from symptoms of intestinal obstruction, and as this resisted all ordinary measures, I opened her abdomen for the second time last Wednesday, July 23rd. Dr. P. Sydney Jones, of Sydney, Dr. Vanderwar, of Albany, and Mr. J. W. Taylor were present. I feared, of course, that the obstruction was due to some adhesion of intestine to the stumps of the former operation, but I am glad to say that my fears had no foundation. I performed enterotomy, but she survived the operation only some fifteen hours. Dr. Saundby made the *post-mortem* examination, and removed the uterus entire. The myoma has shrivelled to the size of a small orange, certainly less than a tenth of its size three years ago, and there is no trace of ovaries, or tubes, or stumps, or ligatures. I have sent the preparation to the Museum of the Royal College of Surgeons, where Sir Spencer Wells can see it for himself.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ROYAL FREE HOSPITAL.

CASE WITH SYMPTOMS RESEMBLING THOSE OF LARYNGEAL PHTHISIS—LATER, TWO ATTACKS OF LOSS OF CONSCIOUSNESS IN QUICK SUCCESSION, THE LAST FATAL—LATENT HEPATIC ABSCESS OF CONSIDERABLE DIMENSIONS.

(Under the care of Dr. COCKLE.)

(From notes by Mr. M. N. Banerjea, M.R.C.S., L.S.A., House Physician.)

William H. Fowler, aged 35, a clerk by occupation, was admitted into the Royal Free Hospital, under the care of Dr. Cockle, on March 12th, 1884. Previous to admission he was under the treatment of a neighbouring practitioner, who sent him to the hospital as suffering from pneumonia. He had been abroad, and spent seven years in the United States, but lived the rest of his life in London. He returned from America eight years ago. Never had any illness till May, 1883, when he suffered from what was supposed to be "inflammation of the bowels," and remained ill until August.

The family history good. The present illness began four weeks ago with cough and pain in the chest, the cough gradually getting worse. On admission he appeared to be somewhat emaciated, was quite hoarse; complained of cough, pain in the chest, and night-sweats. He had clubbed fingers, and over the apex of his left lung there was impaired resonance, with crepitation. Heart sounds normal. The liver extended three inches below the ribs in the mammary line, but was normal in shape and consistence, smooth on the surface, and quite free from tenderness on pressure. There was some splenic dulness. Temperature 101·6°, pulse 100. Urine acid, sp. gr. 1,015, no albumen, normal in respect to quantity and colour.

From the 12th to the 15th not much change; the temperature keeps up between 101·4° and 102·4°. On the morning of the 15th the patient felt somewhat better, but in the evening, at 10 p.m., had a severe rigor, followed by profuse perspiration, the temperature running up to 104·6°, and coming down below the normal within a few hours.

On the 16th temperature below 99° till 6 p.m., when it began to rise, and was 103° at 12 p.m., when he had profuse diaphoresis without any rigor. 17th to 21st, temperature oscillating between 100° (morning) and 103·4° (evening). Night-sweats, but no rigor. On the 22nd, looking very pale, getting thinner, more hoarse. On the 29th, dulness at the base and lateral aspect of the left lung, especially in the axillary line; expansion less, breath sounds feeble, and harsh friction on the same side.

April 2nd, conjunctivæ slightly yellow; no change in the condition of the liver. On 3rd and 4th, conjunctivæ more yellow, skin not jaundiced, no hepatic tenderness. Between March 26th and April 5th the evening rise of temperature did not take place every day, but regularly every other day. During this period the temperature ranged between 100° and 103°. On the 5th, at 2 p.m., had a "fit" while in bed, lasting about seven minutes, during which time he lay unconscious and perfectly quiet, with occasional twitchings of the face. On recovery he did not know that there had been anything wrong, and no trace was left of the fit. On the 6th, felt as usual in the morning; at 5 p.m. had another fit similar to the one he had yesterday, and died within five minutes.

Autopsy.—Pleuræ adherent to the chest-wall, the adhesions on the left side being recent. Lungs—right lung normal, base slightly œdematous. Some consolidation of the base, and lateral aspect of the left lung. No tubercle or cavity in either. Heart and pericardium normal. Larynx—there was a small ulcer on the left vocal cord. Brain—nothing abnormal. Peritonæum—a little straw-coloured fluid was found in the peritonæal cavity, with a few flakes of lymph floating in it. No recent lymph on the coils of intestine. Around the bladder, the coils were matted together with old adhesions, but there was nothing abnormal on the mucous surface of the intestines—no cicatrix indicative of dysentery. Spleen enlarged and pulpy. Kidneys large, pale, slightly fatty. Liver—nearly the whole of the upper surface was adherent to the diaphragm by firm bands of old adhesions. The organ was uniformly enlarged without any bulging, and weighed 6½ lbs. It was of nutmeg appearance, and tough in consistence. The gall-bladder contained no calculi. On section a long anfractuous cavity, lined with a very thin but firm and semi-transparent membrane, with no inflammatory thickening around, was found to extend from the junction of the posterior and external borders of the right lobe to the transverse fissure, then taking a course parallel to the fissure, and finally terminating near the margin of the left lobe. The cavity, about three inches wide and one inch deep, was situated posteriorly in relation to the thickness of the liver, a thin layer of liver-tissue intervening between it and the transverse fissure; it contained a thick creamy substance of the consistence of treacle, which, on microscopic examination, was found to consist of pus cells. Two round and circumscribed growths, each about two inches in diameter, and several pea-sized granulations of the same structure were embedded in the substance of the liver, one of the two large growths being soft, disintegrated, and apparently undergoing cheesy degeneration. Sections of the nodules were examined by Mr. Eve, who has kindly furnished us with the following notes:—

"The greater part of the sections submitted to me for examination consisted of loose fibrous or connective

tissues having an areolar arrangement, and containing very few nuclei. But in portions it passed by gradual stages of transition into a tissue composed of small inflammatory cells, intermixed with granular material. The mutual relations of these structures teuded to show that fibrous tissue had been in process of formation by the small-celled inflammatory tissue, which (as could be seen at one part of a section) had invaded the surrounding liver substance. It was observed that the inflammatory cells occasionally were aggregatcd into rounded masses or clumps resembling giant-cells of moderate size, but the giant-cells were not continuous with a reticular stroma, nor was any other evidence of tubercle present. The microscopic appearances lead to the conclusion that the nodules (from which the sections were taken) were inflammatory new formations, either owing their origin to the same exciting causes as that producing the abscess, or perhaps occupying the sites of small necroses of the liver substance which had not suppurated."

Remarks (by Dr. Cockle).—The case detailed presents points of much interest, both as regards the possible duration and, until towards the close of the case, the entire latency of hepatic abscess, so far as regards any subjective phenomena. Physical examination revealed great increase in size of the liver, a firm and uniformly smooth coudition of the surface of the viscus, but without the slightest pain or tenderness either spontaneously arising or elicited upon firm pressure. Indeed, such condition seemed somewhat suggestive of amyloid change, associatcd as it was with splenic enlargement. The chest symptoms were alone promiuent, and apparently pointed to laryngeal phthisis. They would seem to have arisen as a more or less independent affection. How long the hepatic abscess may have existed is matter of opinion; also, whether it could have resulted from the "inflammation of the bowels," or had an earlier origin in malarious disorder. Looking to the great weight and size of the liver—its tough texture and nutmeg aspect, the inspissated pus, and the condition of the cyst-membrane—I hazard the conjecture that the abscess originated in malarious poison imbibed long ago, and probably giving rise to hepatic symptoms so little accentuated as to have left no record in the memory.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

(Under the care of Mr. EDMUND OWEN.)

(From notes taken by Dr. CHAFFEY.)

Cleft Palate.

J. M., a healthy-looking boy of eight years, was admitted on April 28th, for a wide cleft, extending through the whole length of the hard and soft palate; the hare-lip with which the cleft had been originally associated had been closed several years previously by Mr. Pollock. Chloroform was administered on a piece of lint, and a strip of mucous membrane was liberally removed from each side of the cleft from behind the incisor teeth to the tip of the uvula. The hard palate having a high arch, the flaps of muco-periosteum came well together after being detached by the raspatory. About twelve sutures of fine silver wire were introduced, and the approximated edges were set frec of all tension and muscular strain by an incision made through the tissues of the soft palate. Just behind the incisor teeth one horse-hair suture was inscrted, the tissues there being too thin and friable to stand the strain of the tubular needle and wire. When the operation was nearly finished a delay occurred on account of a collection of mucus and clot having caused serious impediment to respiration. The administration of a subcutaneous injection of ether roused the boy and brought about a clearing of the larynx so that the operation could be completed. After the lapse of a week, during which time the boy was fed on fluid diet, the mouth was examined, when it was found that primary union had resulted everywhere except at the junction of the hard and soft palate, where a granulating aperture of the size of a pea remained. This steadily diminished in size, and when the boy was last seen was all but closed.

After the operation Mr. Owen remarked that success depended very much on having perfectly raw surfaces in close apposition throughout the entire extent of the fissurc, and that if an error be committcd in the removal of the mucous edge of the clcft it is probably that too little is removed, not too much. A few years ago he was in the habit of dealing with the cleft in the soft palate first, leaving that of the hard for a subsequent opcration, now he invariably dealt with the entire cleft at a single operation.

Fæcal Umbilical Fistula.

There have recently been two cases of this chronic affection in the Louise Ward, and in each instance a cure was permanently established. The treatment consisted in thoroughly clearing out the alimentary canal by purgative and enema, and then in keeping it in a state of absolute rest by the continuous administration of small doses of opium. At the same time cod-liver oil was prescribed, and the wouud was left undisturbed under a pad of dry wool.

Medical Times and Gazette.

SATURDAY, AUGUST 2, 1884.

THE Medical Act Amendment Bill reccived its *coup de grace* from the Prime Minister on Friday, last week. Mr. Gladstone did not affect any great regret at having to send the Bill to join the majority of the Government measures, but was content to say, that having regard to the convenieuce of hon. members and to the circumstances of the Session, the Government did not intend to proceed any further with the Bill during the present Session. Two causes not mentioned by Mr. Gladstone combined, however, to kill it, and those causes were the real indifference of the Ministry, as a whole, and of our legislators to the measure; and the quarrels of the medical licensing bodies. No doubt Lord Carlingford and Mr. Mundella greatly and honestly desired that the Bill should become law. They have worked very hard to make the measure a valuable one from the point of view of the public, and to disarm the opposition of the Univcrsities and Corporations; and they earnestly wished to be rid of a very troublesome task. The existing Government would also have been pleased to have had the credit of carrying medical reforms which successive Governments and a Royal Commission have declared to be of immense importance to the public welfare; aud it can hardly be doubtcd that they could have carried the Bill this year had they determined to do so, for it had reached the Committee stage and could have been pressed forward at any hour of the day or night. But that was just

what they did not care to do. They felt no very strong or intelligent interest in the matter, and they knew that the vast majority of the members of the House are Gallios as regards matters medical; and just when the fate of the Bill was trembling in the balance, just when the House had been informed that it was hoped the chief opponents to the measure had been satisfied, and its way been made smooth, opposition burst out on new as well as old grounds, and provided Government with an excuse for dropping the Bill. The Ministers in charge of it, in their anxiety to succeed, accepted from Sir Lyon Playfair an amendment affecting what had seemed to be one of the essential points of the measure—the management of the final examinations—but while this was so arranged as to satisfy the Scottish Universities, it did not please all the English bodies; and the weakness shown in adopting also, we believe, some urged changes in the constitution of the Medical Board for Scotland, only changed the form of, instead of appeasing, the hostility to it. It was clear that the measure would still be sturdily opposed, and that the most determined opposition would come from the tenacious Scotch; and may it not be suspected that while the Prime Minister for the time being represents Midlothian, no Scottish University or Corporation will be seriously harried or worried? Be that as it may, the final determining cause of the withdrawal of the Medical Act Amendment Bill was the opposition excited by jealousies between the Scottish licensing bodies.

Is the loss of the Bill to be much regretted? The answer to that will depend largely on the degree of belief held in the self-reforming tendencies or intentions of the licensing bodies. We are very sorry to lose the proposed re-organisation of the Medical Council, and the provision prohibiting the registration of half-qualifications. We are inclined to believe that the new Medical Council would have shown itself strong enough to put down examinations made attractive by too tender a consideration for weak candidates; and would have exercised generally a useful and not meddlesome supervision over the qualifying bodies. But we confess to grave doubts whether the amended Playfair Amendment would have been workable; and it seemed to us to have taken away one of the chief reasons for the creation of the Medical Boards. One of the greatest evils, however, that can follow the loss of the Bill will be the renewal next year of the agitation for legislation; and, whether that will happen or not, and to what extent it may recur will very much depend on the use that the various licensing bodies in the three divisions of the kingdom make of the time again given them to reform any weak points in their proceedings. No doubt the English Colleges will proceed to carry out their conjoint scheme; and it is much to be desired that they should lower the fee for their conjoint qualifications, which if we remember right is at present fixed at thirty guineas. The Apothecaries' Societies will, it is to be supposed, strengthen their position by including surgery in the subjects of their examinations, and they will have to make these generally so good that the awakened Medical Council will be able to consider that they afford a fair though not a high test of fitness for general practice. And some of the Scottish Corporations need to reform their examinations in some way. The last list that we published of candidates, twenty-five in number, who had passed the final examination for the licence of the Royal College of Physicians of Edinburgh, does not contain the name of a single Scottish student. Is it to be believed that the candidates were not attracted there by a belief that the examination was less severe than that of the English College? We will at present say no more on this subject, but we feel sure that if the licensing bodies act wisely now they may to a large extent disarm any future agitation for a Medical Act Amendment Bill.

On Monday last, when the House of Commons went into Committee of Supply on the Army Estimates, a long discussion arose on the Contagious Diseases Acts. Mr. Puleston, Mr. Cavendish Bentinck, Dr. Farquharson, Major-General Fitzwygram, the Commanding Officer at Aldershot, Mr. Acland, and some other members complained of the results that have followed the suspension of the compulsory clauses of the Acts. Nothing new was perhaps said with regard to this; but ample evidence was adduced in proof of the evil effects, moral and physical, of the change made last year in the administration of the Acts; and there was a consensus of opinion that it has resulted in a large increase of moral and physical evils in the districts to which the Acts had previously been applied. The Secretary of State for War admitted that the health of the Army had suffered, though slightly he said, from the change; but he maintained that the effects in this respect had been exaggerated, and he contended that the Acts were not passed for moral but solely for sanitary purposes; and Mr. Campbell-Bannerman spoke in a like strain with respect to the effects produced upon our sailors, so far as concerns the Royal Navy. But this must surely be felt to be a very lame and sorry reply to the unquestionable proofs that the abolition of the compulsory clauses of the Acts has resulted in marked increase of general and especially of juvenile immorality, and of physical evil? It cannot but be that the subject will be brought forward again and again till some fresh, large, and well considered measure is adopted to protect the public as well as our soldiers and sailors from all the evils arising from the spread of the diseases with which the Contagious Diseases Acts were intended to deal. The social morality of the public at large must be cared for as well as that of the Army and Navy.

On Monday evening, Mr. Hopwood asked the Secretary to the Local Government Board whether it was a fact that a child had lately died, in Hull, from erysipelas which had appeared soon after vaccination; and whether there was any cause of the erysipelas but the vaccination. The case merits a brief notice, because, as stated by Mr. Hopwood, it affords much more plausible ground for the allegation of "death from vaccination" than can be found in the great majority of such accusations. Mr. Russell's reply, however, made it quite clear that vaccination had no

share in causing the death in this case. The child (a boy named Best) was vaccinated on June 9th, and in the second week after vaccination contracted erysipelas from which he died on June 30th. He was attended by a medical man, Mr. Cooper, who certified that he died from "general erysipelas," and even in communicating this information to the public vaccinator, stated that the erysipelatous affection began on the child's neck; that it next extended down the unvaccinated arm and the same side; and that the vaccinated arm was affected last and least. Mr. Cooper had stated that he saw no special connection between the erysipelas and the vaccination. The Board had learned that the other children who were vaccinated from the same source as the child Best, had had nothing the matter with them beyond the ordinary phenomena of vaccination.

The National Health Society have, as is well known, done very good service to the public by publishing, and of late broadly distributing a well-written and sound pamphlet, entitled "Facts Concerning Vaccination," and the value of the pamphlet was enhanced by the fact that it had been revised by the Medical Officer to the Local Government Board, and had been recommended by the Board as likely to prove of good service in house to house visitation. These things disturbed the peace of Mr. Hopwood, one of our most ardent anti-vaccination legislators, and he tried, on Thursday sennight, to get the Parliamentary Secretary to the Board to admit that certain statements contained in the pamphlet as to the safety and harmlessness of vaccination had been disproved by Dr. Cory's experiments upon himself. But Mr. G. Russell said that the Committee of Medical Experts appointed to report, had expressly stated that "the infants from whom Dr. Cory took lymph for his experiments upon himself were in such a condition of obvious syphilitic disease as would certainly have precluded their use as vaccinifers by even an inconsiderate and reckless vaccinator. Indeed, they were selected by Dr. Cory for his self-vaccination because they were unquestionable syphilitic cases." The rule of practice with the profession is not to take lymph from a child suspected in any degree whatever of being syphilitic, or of having any skin disease; and the Local Government Board strictly enjoin the observance of this practice upon all public vaccinators. Consequently the Board could not see that the result of Dr. Cory's unhappy experiments had made it necessary to alter in any way the statements objected to by Mr. Hopwood. They still hold that "with due care in the performance of vaccination, no risk of any injurious effects from it need be feared," and that such mischief as the communication of a foul disease by vaccination can only happen through gross and culpable carelessness.

Our Paris Correspondent writes:—The cholera was again the theme of discussion in the Academy of Medicine on Tuesday, but it must be confessed that the subject is growing rather stale. The venerable Dr. Guérin, who in spite of his age (he is upwards of 84) still retains his wonted impetuosity and spirit, had at the previous meeting delivered an able speech in favour of the spontaneous growth of cholera, and the identity of cholera nostras and Asiatic cholera. In a long and substantial reply, Dr. Proust traced back the epidemic both at Toulon and Marseilles to importation, and exonerated the official scientific bodies from the reproach of inertia, which has been urged against them from different quarters. Dr. Besnier followed Dr. Proust and defended similar views with somewhat different arguments. He ended by expressing the wish that a chair of epidemiology should be founded in all the medical faculties of the Republic. The public at large are getting tired of this protracted discussion, which has done little except bring into more distinct evidence the discrepancies between the opinions of scientific men upon this interesting but obscure subject.

The appearance of cholera has by a most natural consequence brought forward a crowd of communications, laid before the Academy of Science and the Academy of Medicine, for the prevention and cure of the disease. The "Prix Bréant," in favour of those who contribute to the knowledge of the origin or treatment of cholera, has elicited this year no less than 360 communications; while at the Academy of Medicine Professor Beclard read a teeming list of proposed remedies, some of which are of a rather extraordinary nature. One gentleman proposes to dispel the miasmatic influence by firing guns in unlimited numbers, it being well known that this military proceeding has the effect of purifying the atmosphere. Another proposes to create an artificial winter, by disposing over all France a system of mirrors, so arranged as to reflect back the sun's beams as fast as they come, a method which might perhaps meet with some opposition from the agriculturists.

Professor Hoyen has just published an elaborate lecture in the *Revue Scientifique* on the treatment of cholera, in which he chiefly advocates ipecacuanha and opium in the earlier stages, and black sulphide of mercury, with salicylate of bismuth, in the more advanced periods. When the patient falls into the state of algidity and collapse, the professor recommends the intravenous injection of the following solution:—

Aq. Simpl.	1,000	parts.
Chloride of Sodium,	5	„
Hydrate of Sodium,	1	„
Sulphate of Sodium.	25	„

At Marseilles and Toulon the cholera seems to be gradually subsiding. The deaths from the epidemic at Marseilles, since its outbreak, amounted to 1,000 on the 25th instant. But while the disease is dying out in the two above-mentioned ports, it spreads unquestionably in Provence. A very serious epidemic prevails at Arles, where out of 25,000 inhabitants, 20,000 have emigrated. There exists also a serious visitation at Aix, and smaller places are also contaminated. No cases of Asiatic cholera have been hitherto recorded in Paris. All the necessary precautions in case of an outbreak have been taken beforehand.

The Government have very wisely reprinted some extracts from the reports of the Medical Officer and Medical Inspectors of the Privy Council, dealing with previous outbreaks of cholera. These have been bound up with a preliminary report by Dr. Buchanan, and with the memorandum of precautions recently issued by the Local Government Board, and the whole may be purchased for the small sum of fourpence.[1] The reprints, says Dr. Buchanan in his preliminary report, are intended to serve a double purpose. "The extracts from the reports of the medical officer exhibit, at greater length than in a memorandum, the doctrines concerning cholera in Europe which have been continuously held by the principal medical advisers of the English Government. We may believe that they are commanding more and always more adherents among sanitary authorities on the Continent, though hitherto they have not obtained sufficient recognition in practical effort. The extracts from reports of Medical Inspectors on the other hand are primarily intended for the assistance of those who may have to deal with local conditions provocative of cholera or with any outbreak of the disease in England. It is hoped that both series of extracts may at the present moment be of service as indicating the true lines of preventive action against the disease which is now threatening Europe."

At the Health Exhibition on Friday evening Dr. de Chaumont delivered a lecture on the Prevention of Cholera to a numerous audience. The most important point in the advice he gave was, in our opinion, his warning about disinfectants. Fire, he said, was the only true disinfectant, most so-called disinfectants being simply deodorants. If there existed a system of drains properly flushed and properly protected, there would be no need for disinfectants. Unfortunately, the use of disinfectants was often only an excuse for uncleanliness and insanitation. As to the prospects of an outbreak of cholera in England, Dr. de Chaumont observed that, although it was unsafe to prophesy, yet he felt pretty confident that if cholera did reach British shores it would obtain no foothold. He did not say that it would not come, but he did say that there was every reason to hope that the English people would escape it. If they did escape, he thought he might say that it would be entirely due to the improvements in sanitation which had taken place, especially in the large centres of population in recent years. This, however should not lead to the relaxation of precautions, but rather to greater care in enforcing them, so as to make assurance doubly sure.

The first of the Autumn Congresses—that of the British Medical Association—opened on Tuesday last, when the President, Dr. Cuming, of Belfast, was introduced by his predecessor, Dr. Waters, of Liverpool, and delivered his presidential address to an audience well representing the medical profession in the three kingdoms. We have sufficiently commented on this address in another column, as also on the able address in medicine, delivered by Dr. Ord on the succeeding morning. After Dr. Ord's address, the President announced that Dr. Foster had been elected President of the Council, in room of Mr. Wheelhouse, of Leeds, and Dr. Foster in his new capacity announced that the Council had agreed to accept the invitation of Cardiff next year, and that they had elected Dr. Edwards of that town President. On Wednesday afternoon the work of the sections commenced, and there was considerable crowding to the Section of Surgery to hear Sir William MacCormac's opening address. Unusual interest attached to this oration; in the first place because there was this year no general address in surgery, and in the second place, because the speaker is himself a Belfast man, a great favourite with the profession, and celebrated as a congress-caterer. Sir William MacCormac did not disappoint expectation. His address was long, thoughtful, and business-like, and astonished even his admirers. Dr. Savage opened the proceedings in the Psychological Section with a long address on which we have expressed our views elsewhere. In the other sections the presidential addresses were shorter. In the Section of Obstetrics, Dr. Godson, with excellent taste, refrained from putting himself in competition with Dr. George Kidd, who is to deliver the address in Obstetric Medicine this (Friday) morning. In the Section of Pharmacology and Therapeutics, Dr. Maclagan chose for the subject of his address "Methods of Therapeutic Research," while in the Section of Public Medicine, presided over by Dr. Cameron, M.P., papers were read on the "Prevention of Epidemics," "Quarantine," and "Cholera."

The Section of Ophthalmology was opened with a short address from the President, Dr. McKeown, and subsequently Dr. Wolfe, of Glasgow, brought forward some subjects of great practical interest. He showed two cases in which adhesion of the lids to the eyeball caused by burns had been cured by transplanting conjunctiva from the rabbit. By this contrivance vision and mobility are restored to a class of cases which must otherwise be regarded as beyond the reach of remedy. This operation, which was introduced by him some years ago, has proved successful in the hands of American and Continental Surgeons, and we presume that even anti-vivisectionists will find no fault with the procedure. We have previously referred to Dr. Wolfe's operation for separation of the retina as a real advance in eye surgery. The case which he showed to the Glasgow Medico-Chirurgical Society, in April last, was again shown at Belfast, on Wednesday. The patient can now tell the time on the seconds pointer of a watch, and thread a needle, so that the recovery from absolute blindness thus effected may now be looked upon as not evanescent. In opening a discussion on cataract, Dr. Wolfe stated that during the last twenty years he had operated in 975 cases of cataract, in which corneal section was made, and that out of so many he had only six in which corneal suppuration supervened. His method for extraction of cataract, in which every cause of failure is eliminated,

---

[1] Sold by Knight & Co., 90, Fleet Street; Shaw & Sons, Fetter Lane; Hadden, Best, & Co., West Harding Street, Fetter Lane; and P. S. King & Son, Canada Buildings, King Street, S.W.

was first published, he said, in the *Lancet* in 1868, and its advantages were now beginning to be recognised and adopted by surgeons of repute in this and other countries. To demonstrate the applicability of his operation to local and constitutional complications, he showed a patient in an advanced state of diabetes on whom he had operated for cataract successfully a fortnight previously. On Wednesday evening the President and Council gave a most successful *conversazione* in the rooms of Queen's College.

On Thursday morning Professor Redfern delivered the address in Physiology, which was chiefly devoted to the consideration of the lymphatic system, a subject which is also to be introduced for discussion in the section by Professor Charles, of Cork. The sectional meetings were resumed in the afternoon, and in the evening the Annual Public Dinner of the Association was held in the Examination Hall of Queen's College.

The Imperial Carolinische Leopoldinische Academy of German Naturalists has just presented its highest mark of consideration, the gold Cothenius medal, to Dr. Heidenhain, of Breslau, on account of his researches on the Secretion of Glands and the Physiology of Muscles, which are of abiding value in physiology.

The Conferences at the Health Exhibition have been continued almost daily since our last issue. On Thursday week the Society of Arts held the conference on Water Supply, which, but for the death of the Duke of Albany, would have been opened as the first of a series by the Prince of Wales, but which was now held under the presidency of Sir Frederick Abel. The consideration of the subject was limited mainly to its geological, medical and chemical aspects, legal and financial difficulties being put on one side. Several papers dealing with the sources of water supply were read on the first day, but the papers which were of most interest to the medical profession were taken on Friday. The first of these was by Professor Sorby, F.R.S., who dealt with the much-vexed question of the purifying action of minute animals and plants on water contaminated by sewage. The author had proved by experiment that the entomostraca in particular might be kept alive for months by feeding them on excrementitious matter, and there was no doubt that an immense amount of sewage material was consumed by these animals. It could not be supposed, however, that these comparatively large animals removed, except incidentally, such minute objects as disease germs, but it was well worthy investigation whether the more minute infusoria consumed such germs as a portion of their food. He had not been able to examine this question critically, but was inclined to think that even particles the size of germs might be consumed by beings only 1-1,000 inch in diameter. The influence of minute plants was also very great in purifying and oxygenating water. Professor Odling read a paper, in which he attempted to show that there is no presumption of the presence in river waters of disease-producing organisms, and what little was known of their life history, and the evidence from what had been observed of the effects on the health of populations would lead to the inference that they do not develop, propagate, or exist in such water so as to be capable of acting prejudicially. Mr. Mitchell, commenting on Professor Sorby's paper, drew attention to the recent method of detecting the presence of bacteria in water by cultivating the spore in the way followed by Dr. Koch. He mentioned that for the last two years the process had been adopted in the examination of the water supply of Berlin.

The conference on School Hygiene convened by the National Health and Medical Societies of London, was opened on Monday, July 28. The chair was taken by Dr. F. J. Mouat, in the absence of Sir A. Clark, and Professor de Chaumont delivered an address on "School Dietaries," bristling with facts and figures. Approaching his subject from the scientific standpoint of the potential energy contained in each form of food and the work done by the boys or other persons in question, including of course the vital processes within the body, he criticised severely nearly all the fixed dietaries that had come under his notice as being either insufficient to supply energy for the work required, or as presenting an actual or a relative deficiency of one or other of the food stuffs. The effects of a continued insufficient supply of food were, he said, first that the organism was compelled to consume its own materials, and later a general reduction of the bulk of the tissues by a process of fatty degeneration which could never be repaired when it once reached a certain point. Ill-fed children grew up stunted and feeble in body and mind, with little resisting power. Any increase of work called for an increase of food to supply the necessary force, a fact too often ignored. Variety too was essential, and men or children, sooner or later, loathed and rejected a monotonous diet however good in itself, and, what was more remarkable, even an insufficient supply. In proof of this the speaker instanced the experience of the Duke of York's School at Chelsea. He then went on to consider what practical diet would fulfil the required conditions, and recommended milk, meat, cheese, whole meal bread, fresh vegetables and fat in some form or other, the last often being a matter of some difficulty. To diminish the indigestibility of the albuminates of cheese and beans, he recommended the softening of these by a small quantity of bicarbonate of potash as recently suggested by Mr. Mattien Williams. Dr. Pringle, who followed, quoted his experience of the Indian prisons where the prisoners, compelled to work hard on a diet calculated on that of the indolent free population, lost weight rapidly; and also of the great Indian famines in which the natives of Orissa, though able to obtain an unlimited supply of fish, died of starvation as rapidly as did those of the interior on their scanty allowance of rice, both diets being alike deficient in one or other of the food stuffs. Mr. Bousfield gave an interesting account of the penny dinners now being given to Board School children and Dr. Alder Smith, Medical Officer of Christ's Hospital,

gave a history of the improvements effected in the school diet during the fourteen years he had held that position, especially in an unlimited supply of bread, and an increased allowance of milk. A special breakfast was provided for delicate boys, and a second supper for those who have to study late. Several medical officers to workhouse schools contributed their experiences, and Dr. Mouat referred to facts which he had gathered in India and at home.

On Tuesday the most important subject of the week came on for consideration—over-pressure in schools. We have considered the discussion more fully elsewhere but may state here that it was most ably opened by Mr. Pridgin Teale, who thus summarised his experience :—That examinations are powerful agents, capable of doing harm as well as good. That work for examination is essentially work done under pressure and with anxiety, and is physically exhausting. That, whereas, in view of the physical well-being of the community, examinations ought to be as few as possible and at long intervals, they are being multiplied with a recklessness which can be explained only on the supposition that the physical and medical aspect of education has been entirely left out of consideration. That the element of competition greatly intensifies the physical strain of examinations ; that a further aggravation of the physical strain is produced by the imperfection of examinations which test, and, by testing, enforce in education a loading of the memory rather than a training of the faculties. That the multiplication of subjects to be studied for examination is a growing evil, and deserves condemnation both from a physical and educational point of view, and that the arrangements for higher education ingeniously provide a constantly increasing pressure upon the rising generation.

Mr. Brudenell Carter, who followed, brought forward evidence to prove "that the long hours of confinement in what is too often a vitiated atmosphere, coupled with other ordinary conditions of school-work and discipline, exert a hurtful influence upon the physical development of the frame, especially upon the heart and lungs and upon the organs of vision, and that this influence is so considerable that it must already be regarded as a matter of national importance." Mr. Carter stated among other facts, that in one of the London Board-schools defective vision was found in one-fourth of the scholars. Dr. Shelly next read a paper in which he condemned the modern system of punishment by "imposition" which he considered much more cruel and prejudicial to health than moderate corporal punishment. The discussion was continued by Sir Joseph Fayrer and Dr. Crichton Browne, the latter making a very powerful speech, and was subsequently joined in by many others. Mr. C. Kegan Paul bore the chief onus of defending the Code, but his contention that the evils of over-pressure are exaggerated and unreal did not meet with any general acceptance.

On Wednesday the Conference considered the question of the prevention and treatment of outbreaks of epidemics in elementary and in public schools, Dr. George Buchanan, F.R.S., occupying the chair. The first paper was read by Mr. T. J. Dyke, Medical Officer of Health for Merthyr Tydfil, who advocated the closure of schools during outbreaks of scarlatina and measles, in place of excluding infected and infective children. He quoted several instances in his own district, which he conceived to lend support to his recommendation, but his statistics seem to us open to criticism, as being in some cases fallacious, or wanting in precision as regards dates, &c., and in others capable of very different interpretation. Dr. Alder Smith followed with a masterly paper "On the Preventive Treatment of Infectious Diseases in Public and High Schools." He insisted on the necessity of undivided medical responsibility. One medical man, and one only, should, he said, have the entire school under his daily supervision, and he should be responsible to the governors only. In large schools he would have the younger and older children in separate establishments, in order that epidemics, to which the former are more liable, should not interfere with the more important work of the latter. He recommended a primary certificate on entrance, stating the diseases a child had already had, that the number susceptible of any particular disease might be known, as well as certificates on the return of boys to school of any risk they may have run of infection. He discussed the isolation of cases for febrile symptoms which might indicate the invasion of disease, the arrangements for separation of such as were actually attacked, and the difficulties introduced by the mixture of day scholars with boarders. A disinfecting oven he held to be an indispensable adjunct to every school, and expressed his utter want of reliance on any assurances of disinfection performed at home. He described the precautions taken, and the procedure followed in his school, the periods of incubation, and the quarantine accordingly observed, as well as the periods at which he believed convalescents from each disease might be allowed to return. As evidence of the soundness of these views and practices, he stated that during his term of office there had been 25 outbreaks of scarlatina in Christ's Hospital, of which 23 had been immediately suppressed. These 23 included 17 isolated cases, four sets of two cases, and two of three cases. The other two were of 23 and 33 cases respectively, but the last, which hung about the place for three months, was the only one in which the efforts at arresting it could be considered unsuccessful, for the former consisted of two batches of almost simultaneous cases ; ten occurring within five days, and 13 more derived from these just five days later ; the second batch were isolated, and no further case appeared. Mr. Pridgin Teale, Mr. Ed. Chadwick, and other gentlemen took part in the discussion.

The Paris Faculty of Medicine has been called upon, according to the traditional rules, to present a list of three candidates for the vacant chairs of the late Professor Wurtz, and of Professor Gosselin, who has lately resigned. It is invariably the custom for the Ministers to nominate the first on the list. For the chair of surgical pathology, the list bore the

names of Drs. Lannelongue, Tillaux, and Le Dentu. For the chair of chemistry, the names were those of Drs. Gautier, Bouchardat (son of the venerable professor of hygiene), and Henninger. Drs. Lannelongue and Gautier may therefore be considered as virtually nominated. Drs. Campenon and Za Paguier have just been nominated surgeons to the hospitals of Paris, after a long and serious competition.

Baron Mundy's paper at the United Service Institution, on Tuesday, was one in which just at the present moment no one can help feeling some interest. The object of it was to consider the best means of affording aid to the injured after a railway accident. His proposal, and it seems to us a very sensible one, is that at intervals along the great railway thoroughfares, ambulance waggons should be kept in readiness with supplies of surgical instruments, bandages, and other things likely to be wanted. Better apparatus ought, he thinks, to be devised for extricating the injured from beneath the carriages, and a register should be kept at every railway station of the name and address of medical men in the district, bearing in mind (and this is the only point on which we are disposed to quarrel with the distinguished lecturer), he says, that the least capable surgeon would be more useful than the ablest physician. As regards London at any rate many of our leading physicians have seen a good deal of surgery as dressers and house surgeons, and could if need be, we doubt not, prove that their hands had not forgotten all their cunning.

The electric-light ambulance drill at Aldershot on Thursday se'nnight, on which we had a brief note last week, was a distinct success, the only failure apparently being in occasional aberrations on the part of the illuminating agent. The arrangements, under the direction of Mr. H. R. O. Cross, A.M.D., were well carried out, and it was seen that not only were the members of the bearer column well up to their work, but that the illumination was such as to enable them to apply the necessary dressings to the presumed wounds with all accuracy and despatch. The demonstration was witnessed by many distinguished authorities, including Sir Joseph Fayrer, Surgeon-General Gilborne, Surgeon-General Mackinnon, Dr. Crawford (Director-General of the Army Medical Department), Dr. Farquharson, M.P., Dr. Don, Professor Longmore, C.B., Mr. Cantlie, and M. Ellissen, of the French Red Cross Society, all of whom expressed themselves satisfied that the application of the electric-light would be an important innovation in the surgery of the battle-field.

The first ordinary meeting of the Medical Officers of Schools' Association was held in the rooms of the Medical Society on last Thursday week, and was well attended. In the course of a brief Presidential address, Surgeon-Major Evatt congratulated the members upon the fact that the association had already been joined by the medical officers of two-thirds of the principal English schools, and indicated some of the many ways in which mutual and general advantage should accrue from their work in the wide field thus opened out to them. Dr. Andrew read a paper on "The Prevention and Treatment of Epidemic Disease in large schools." He pointed out that, in connection with the so-called specific febrile diseases, there were still many questions shrouded in obscurity, and that the members of such an association were placed in an exceptionally favourable position for working towards their elucidation. Special mention was made of such points as the incubative period of the specific fevers, which Dr. Andrew considered to be not nearly so uniform as is stated in the text-books; the possibility of establishing the existence of symptoms during the period of incubation, and thus rendering possible an earlier recognition of the malady, and an earlier, and so more effectual isolation of the patient; the recognition of those conditions which determine the production of different types of the same disease — of scarlatina, of enteric fever, and of diphtheria, for example; the relation of the different forms of disease to one another—as of scarlet fever to rheumatism; and their influence upon each other—with especial reference to those cases quoted by Professor Paget, in which the occurrence of enteric fever appeared to produce an increased susceptibility to the action of the vaccine virus—and presumably to that of small-pox itself. Dr. Andrew observed that such an association possessed special opportunities for tracing the development of inherited peculiarities, and for determining the best modes of correcting hereditary diatheses; as well as for collecting and formulating opinions as to the best practical plan for the construction of school buildings, especially in connection with the important question of readily providing for the early and complete isolation of infectious cases; and he asked the opinion of members as to the desirability of providing separate establishments for pupils under 12 or 13, and for those above that age—a plan which, in the case of Christ's Hospital for instance, has conferred upon the school appropriated to the older boys a noticeable comparative immunity from the specific maladies of adolescence.

Several speakers took part in the discussion which followed. Amongst them, Dr. Alder Smith referred to the first piece of Collective Investigation yet undertaken by the association, viz., the series of questions as to their usual methods of dealing with the different phrases of the three common specific exanthemata which was lately issued to the principal schools in the country. The answers to these questions had been laboriously analysed by Dr. Cronk, of Repton School; but the replies in most instances varied within such extraordinarily wide limits as to render their classification almost impossible. This fact alone might be held to justify the formation of such an association, while it demonstrated the need for wider investigation and fuller enlightenment. The time of isolation, and of quarantine, the necessity for securing the thorough disinfection of the patient and of his clothing, &c., and the means by which this was to be accomplished, were matters as to which school doctors were proved to differ to an extent almost inconceivable. To these and kindred questions Dr. Alder Smith also drew attention at the conference held on Wednesday at the Health Exhibition.

Some of the speakers admitted that they would have spoken more freely on certain of the points which arose in the course of the discussion, but for the presence of a short-hand reporter. It was pointed out, however, that no medical officer was bound to jeopardise his own position by the specific denunciation of any obstacle with which he had been obliged hitherto to contend in vain. At the same time, it was most undesirable, and would place the association in quite a false position and greatly cramp its capacity for good, if the sense of its general meetings were to go forth to the public as an expression of satisfaction with scholastic management in general, coupled perhaps with a unanimous resolution against an equally general abuse, while the real state of things, the nature of the evil, the method of its harmfulness, and the means by which it is to be avoided or done away, were only to be discussed *in camerâ*.

Publicity can only do harm to such a movement if it be shunned. The general public is becoming remarkably alive to its interest in hygiene, and is ripe for instruction in its principles; those who will honestly and fearlessly lead and direct it towards the truth in these matters need not fear its frown. The great majority of the masters and governing bodies of schools (and the rest may be trusted to follow the popular lead in such matters) feel that it is important to their own interests that they should be abreast of the health-science of the day; not a few of them have a genuine appreciation of its importance. We believe that, so long as it is true to itself, the Association of Medical Officers of Schools—speaking with the voice of a special collective and unanimous authority—will find its hands greatly strengthened for the introduction of reforms where reforms are needed, and for the correction of abuse where such exists. Such school authorities as may at first feel inclined to doubt the necessity of a hygienic reformation will at least realize the impolicy of endeavouring to check its progress.

On Thursday, July 24th, Dr. Edward Hamilton was elected Joint Professor of Surgery in the School of the Royal College of Surgeons in Ireland, in room of the late Dr. James Stannus Hughes. The voting was very close, Dr. Hamilton receiving ten votes, and Dr. Anthony H. Corley, eight. Dr. Hamilton is an Ex-President of the College, and Surgeon to Dr. Steevens' Hospital, Dublin. He is an able surgeon and a fluent speaker.

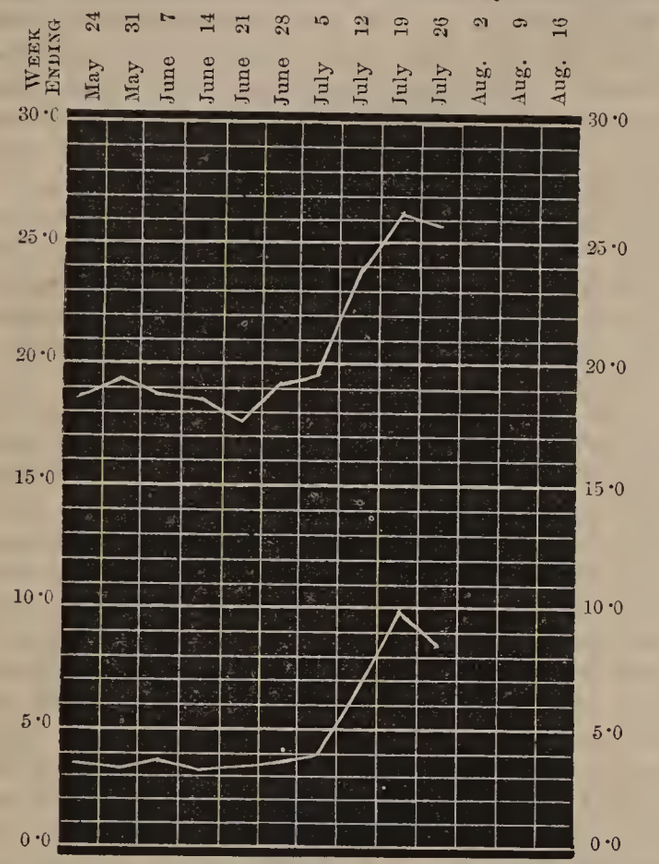
At Londonderry Assizes, on Saturday, July 26th, before Baron Dowse and a special jury, an action for libel, which cannot fail to interest all members of the profession, came on for hearing. The plaintiff, Mr. Edmund Murphy, is a medical practitioner residing at Dunfanaghy, co. Donegal, and the defendant, Mr. Daniel McSweeney, ex-suspect, Falcarragh, co. Donegal is a Poor Law Guardian for the Union of Dunfanaghy. The action was brought in consequence of a report which appeared in the *Londonderry Journal*, and which was supplied by the defendant, giving an account of certain proceedings that took place at a meeting of the Poor Law Board concerning the plaintiff. T report contained allegations made before the Board by the defendant himself of Mr. Murphy's incompetency, he being Medical Officer of the Dunfanaghy Dispensary District, and imputing to him improper treatment of a patient who had died while under his care, and also accusing him of having introduced to the Union a contagious fever. Damages were laid at 500*l*. The plea for the defence was a formal denial of having written or published the report, or that it was published in a defamatory sense, or was a libel. There was also a plea of privilege as a guardian that it was published without malice, and was a fair comment on the proceedings. At the conclusion of the pleadings and evidence, the judge charged. The jury then retired, and after a short absence returned into court with a verdict for the plaintiff, damages 100*l*.

The West-End Hospital for Diseases of the Nervous System has just lost the services of Dr. Broadbent, Dr. Crichton Browne, F.R.S., Mr. Brudenell Carter, Dr. Heron, Dr. Dawson Williams, Dr. Wolfenden, and Dr. Huggard. Their resignation, we understand, is owing to their disapproval of the resolutions passed a few days ago at the annual meeting. This is the third occurrence of the kind within the last two months. The only radical cure that suggests itself to our minds is, that means should be adopted amongst the leaders of the profession to discourage the establishment of small hospitals, especially in London. Of course we know that this is much easier said than done. At any rate we think that medical men will have to be careful to ascertain something about the lay members of the committee, in future, before deciding to join a hospital.

A letter which we saw in the *Times* a few days ago must clearly have been destined for the columns of Mr. Punch, unless we are much mistaken. The writer proposes that in order to dezymotize (we could hardly bring ourselves to quote such a word) drinking water, the services of electricity should be called in, and that everybody should provide himself with a battery, with which to set free nascent oxygen in his water. Putting the scientific value (!) of the proposal on one side, what excellent use Mr. Du Maurier would have made of the idea if it had been entrusted to him!

The Registrar-General's current weekly return of the health of London is better, but only slightly better, than that of last week. The general death-rate was lower by two decimal points, 25·9 compared with 26·1 per 1,000, and the zymotic death-rate was 8·3 compared with 9·9. The total number of zymotic deaths, viz., 661, was only 145 above the average, instead of exceeding it by 299, as was the case in the previous week. Diarrhœa and dysentery caused 466 deaths, 396 of which occurred in infants under one year of age. In the case of every zymotic disease, except diphtheria, the mortality was less than in the previous week, but only in the case of measles and scarlet fever was it below the average. The deaths from small-pox numbered 17, and were only six in excess of the cor-

rected average. The weekly number of cases admitted to hospital is still steadily declining, and the number of cases under treatment in hospital has fallen in three weeks from 1,368 to 1,011. The twenty deaths that



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London in each of the past ten weeks.

occurred from diphtheria were double the average, a fact which furnishes very conclusive evidence of defects in sanitation somewhere. The health of the other twenty-seven towns was not nearly so good last week as in the preceding week. The deaths from zymotic disease, viz. 603, showed an increase of 108, all of which increase is to be laid at the door of diarrhœa. Only eleven towns out of the twenty-seven had a zymotic death-rate of less than 5·0 per 1,000. Leicester distinguished itself by a zymotic rate of 16·9, or exactly half its general death-rate; while Huddersfield, at the other end of the scale, registered only one death from zymotic disease, and consequently can boast of a zymotic death-rate of only 0·6.

With a view of perpetuating the name of Samuel Gross in close association with medical tuition, the Alumni Association of Jefferson Medical College has inaugurated a movement to secure, in some medical school, the endowment of a memorial professorship to be designated the S. D. Gross Professorship of Pathological Anatomy. The movement has obtained influential support, and a numerously signed circular has been issued, in which "the profession at large, the personal friends of the late Professor Gross, and others interested in elevating the standard of medical education, are cordially invited to participate in this graceful recognition of conduct and services which have largely helped to establish the high standard of excellence to which surgery has attained throughout the United States, and served so much to dignify the repute of American medicine." We are requested to state that contributions may be sent to Dr. R. J. Dunglison, treasurer, Lock Box 1274, Philadelphia Post Office, and will be acknowledged in the columns of the *Medical News* of Philadelphia.

Dr. Billings has just transmitted to the Surgeon-General of the United States Army the last corrected proof of Vol. V. of the "Index Catalogue of Medical Books." This volume, which begins with "Flaccus" and ends with "Heart," numbers 1,055 pages, and includes 15,555 author-titles, representing 5,755 volumes and 12,596 pamphlets. It also includes 8,069 subject-titles of separate books and pamphlets, and 34,127 titles of articles in periodicals, making a total in the five volumes of 50,986 author-titles, which represent 30,722 volumes of books and 40,075 pamphlets, 49,552 subject-titles of separate books and pamphlets, and 183,864 articles in medical journals and transactions of societies, together with 4,335 portraits of medical men.

A very decided difference of opinion would appear to exist with respect to the exact identity and properties of the various bacilli which have been associated hitherto with several of the infective diseases. The experiments of Pasteur on the bacillus anthracis have been repeated by Koch and others with directly contradictory results, and Dr. Klein has now published (*Centralblatt für die Med. Wissenschaften*, No. 30) a series of observations which he has made upon the micro-organism which has been found by Friedländer and others in the sputa and tissues in acute pneumonia Following out a similar line of investigation to that taken by other observers, he infected small animals mice and rabbits, with typical pneumonic sputa. Some of these were quite unaffected thereby, others were killed within three or four days, with symptoms of septicæmia. There seemed to be two distinct forms of septicæmia, however, one of which was characterised by remarkable changes in the intestinal tract, severe diarrhœa during life and marked signs of peritonitis after death accompanying the other symptoms and *post-mortem* appearances which are indicative of profound blood-poisoning. Blood taken from these animals and injected into others produced a similar series of pathological changes. In the second form of septicæmia no diarrhœa or peritonæal effusion took place. Both lungs were hyperæmic, but no signs of croupous pneumonia could be discovered. Numerous micrococci were found in the vessels of the lungs and also in the blood of the heart. These were mostly oval in shape, somewhat pointed, and surrounded with a distinct hyaline capsule. Injections made with blood from these cases also, were found to set up corresponding changes in healthy animals. It is remarkable that in neither form of blood-poisoning was there any reproduction of the croupous pneumonia from which the infective material was derived. Whatever poison, therefore, may have been instrumental in setting up the septicæmia, it is clear that it must have been present in the pneumonic sputa independently of the poison proper to the disease itself. The hyaline capsule, which Friedländer considered to be characteristic of the pneumococcus, has

been observed by Klein and others in the micrococci found in pyæmia.

By stimulating the sympathetic, Gaskell has shown that the rate of cardiac rhythm is most markedly accelerated, the strength of auricular and ventricular contractions increased, and the ventricle can be made to beat again in sequence with the auricles when the normal sequence has been impaired. By stimulating the intracranial vagus both the rate of the rhythm and strength of the contractions is permanently diminished. The course of these sympathetic nerves in the frog corresponds in every respect to the accelerators of mammals. The action of the sympathetic upon the heart is only like its action on blood-vessels, of which the heart is but a modification. The vagus and sympathetic functions are quite independent of each other, the vagus being purely inhibitory and the sympathetic purely augmentor. Gaskell had previously shown that stimulation of the vagus nerve in the frog could produce two opposing effects—(1) Slowing or acceleration of the heart; (2) increase or decrease of the *force* of auricular or ventricular contraction; (3) heightened or lessened excitability of cardiac muscle; (4) diminished or improved conducting power of the tissue; these varied effects being evidently due to joint stimulation of nerves belonging to two different series, one inhibitory, the other augmentor; or to the stimulation of nerves now able to augment, now to inhibit the heart, either because of the condition of the muscle or the nerves. While stimulation of a vagus trunk diminishes the strength of auricular contractions and slows the rhythm, the stimulation of the sympathetic is followed by quite opposite effects. Following out these researches in the frog, Gaskell has clearly shown that the vagus nerve outside the head is really a mixed vago-sympathetic trunk, but within the cranium the two nerves are separate, and stimulation of either is followed by its own peculiar effects, while stimulation of the mixed vago-sympathetic trunk is followed by those mixed results which have hitherto been so difficult of explanation. The further instalment, of which this is only a preliminary, will be looked for with great interest, Gaskell's former researches being so full of suggestions new to cardiac physiology.

In his report on the Borough of Huddersfield for the past quarter, Dr. J. Spottiswoode Cameron, the Medical Officer of Health, is able to give a very favourable account of his district. None of the zymotic diseases have been prevalent, thus there were only two deaths from measles, and one from scarlatina. Diphtheria only accounts for two deaths, but twenty-six are attributed to whooping cough, constituting the only exception to the otherwise low mortality from the infectious diseases. Dr. Cameron lays great stress on the necessity for precautions against cholera, and urges the importance of more thorough flushing of the house drains, and more frequent emptying of the closet tubs during the warm weather.

In the competition that is arising amongst towns which depend for prosperity on their sanitary reputation, Sevenoaks is taking a high place. The average death-rate for the past eight years has been 16·8 per 1,000, but last year a death-rate of only 13·8 was obtained. Only six deaths occurred in the year from zymotic disease, of which four were due to whooping cough, and one each to diphtheria and diarrhœa. This excellent return may be safely attributed to the good sewerage and water supply provided by the Local Board. Complaints had been made from time to time that the surface ventilators of the sewers gave out unpleasant odours, but this has been obviated by the erection of air shafts, and Mr. Butterfield, the Medical Officer of Health for West Kent, finds that of the twelve districts under his care the four lowest death-rates are met with in those very localities where sewers exist and ventilators are most abundant. And yet some authorities still sigh for the cesspool.

Dr. Koeberle recently related to the Société Medicale de Strasbourg, his second case of splenotomy, performed on a woman, 46 years old, for an hypertrophied spleen, the result of intermittent fever. Both this and his first case were examples of the largest spleens that had ever been removed, the organ in both cases resting on the pubis, while there was also great enlargement of the liver. The spleen in the present case measured 40 centimetres in length, being only five centimetres less than in the other case, in which the organ, when emptied of its blood, weighed 6,800 grammes. The affection had run a rapid course of less than a year and a half, and at last there was effusion into the pleura, pericardium and peritonæum, the patient being much emaciated and cachectic, passing but a small quantity of urine and exhibiting a temperature of from 102° to 104° F. As in the former case, there was great adhesion to the diaphragm. In that case fatal hæmorrhage had taken place from the vessels of the adhesions, but in the present case this was prevented by three ligatures on the splenic vessels. As a consequence of the constriction caused by these, arterial hæmorrhage took place from a large number of cutaneous vessels along the line of incision, where complete hæmostasis had prevailed for more than hour. A great deal of blood (which was very plastic and rich in coagulable fibrin), was in this way lost; but in spite of this the patient rallied well for a while after the operation, which lasted nearly three hours; but in in about an hour after its completion she was seized with convulsions and died. This case is another example of the danger of removing large spleens; but the operation was only performed at the woman's insistance, after its danger had been completely explained to her.

At the Ordinary Meeting of the Royal College of Physicians, held on the last day of July, the greater part of the business was simply formal. Three gentlemen who have passed the examination by the Board of Censors were elected and admitted to the membership of the College; and licences were granted to 65 candidates who had been approved by the College Examiners. The censors, treasurer, registrar, assistant registrar, librarian, the Curators of the Museum, the Finance Committee, and the examiners for the ensuing year were elected; the censors being now Dr. J. W. Ogle, Dr. Wilson Fox, Dr. W. H. Stone, and Dr. J. E.

Pollock. The by-laws providing for the annual appointment of two Vice-Presidents of the College were enacted for the second time; and became effective by-laws. The Cholera Committee presented for the approval of the College a paper of instructions to be issued for the information and guidance of the public in case of an outbreak of cholera in this country,

THE BELFAST ADDRESSES.

The addresses given at the meeting of the British Medical Association this week will strike all who read them as affording ample material for reflection and future work; and cannot fail to be instructive to practitioners of medicine in every branch. It is quite clear that both Dr. Ord and Sir William MacCormac have spoken because they had something to say, and have not treated their audience to a perfunctory recital of inferior thoughts and insignificant work; nor is the president's address wanting in comments and criticisms on the medicine of the day which are not yet hackneyed enough to be pointless. Dr. Cuming began his presidential address with a reference to the generally satisfactory state of Belfast as regards sanitary matters, expressing, however, a well-timed hope that the present imperfect method of dealing with the town sewage might possibly be improved after the visit of the distinguished sanitarians connected with the Public Health Section of the Association. Going on to speak of the importance of the study of minute organisms in relation to disease, Dr. Cuming laid due stress on the equally great importance of bearing in mind that there must be an appropriate soil for the development of the morbific parasites, and stated his belief that there was a great field open here for collective investigation. In touching on the difficult question of the part played by functional disturbance in the production of disease, the speaker was on debatable ground, but, in spite of the liability to misrepresentation of a few passing remarks on such a wide subject, there can be no doubt that his warning against an entirely anatomical view of disease was not superfluous. In the exclusive sense of what is discoverable by *post-mortem* examination alone, an attempted anatomical explanation of disease must obviously be often inadequate or at fault, as destructive lesions are frequently all that can be thereby demonstrated; but it remains true nevertheless—and this, perhaps, was not fully brought out by Dr. Cuming, owing to exigencies of time—that all explanation of morbid symptoms must be based on a reference primarily to what we at least think we know of anatomy and physiology, and ultimately, indeed, of all the sciences which underlie our pathological studies. It is one thing to teach with no uncertain voice that we cannot hope to explain many well-marked nervous phenomena by *post-mortem* examination, but must rely on more indirect methods for enlightenment, and quite another to venture to formulate our belief on the statement that "the symptom sometimes causes the lesion rather than that the lesion causes the symptom." There is truth in this paradox, but to many—perhaps to most—it will be a hard saying, and open to misconstruction. All, however, will probably agree with Dr. Cuming as to the importance, in the present day especially, of remembering the value of clinical observation, not as opposed to, but in conjunction with, anatomical study; and in maintaining that the direct observation of morbid processes during life must never be warped or strained by theories exclusively based on *post-mortem* pathology.

The address on medicine, by Dr. Ord, is a worthy example of the result of such clinical observation as was insisted on by the president; and certainly goes far to emphasize the contention that we must look elsewhere for the causes of many diseases than to what we are accustomed to call structural lesions. Following out the views which have been gradually gaining ground amongst pathologists as to the great part played by what is called nervous irritation in the production of grave disorders of nutrition in various structures, Dr. Ord gives valuable support to this hypothesis by pointed quotations from his own experience. We were glad that at the close of his address the lecturer called attention to the observations of Weir Mitchell on the nutritive disorders excited by surgical injuries of nerves. For a large part of the well-known researches of Charcot and others on the question of trophic disturbances, both direct and reflex, caused by irritation of nerve-centres and nerves, are undoubtedly the offspring and development of the work of the American observers, Weir Mitchell, Morehouse, and Keen, which was based on cases occurring during the American Civil War, and published under the title of "Gun-shot wounds and other injuries of nerves." Dr. Ord put before his audience, to use his own words, "the result of observation and thought set going by the reading of the works of predecessors and contemporaries." None the less, however, is Dr. Ord to be credited with originality of observation, and the lucidity of expression evinced in this lecture renders his teaching of the greatest value. Perhaps the most important point insisted on by the lecturer was the probable dependence of rheumatic arthritis on nerve-influence. The arthropathies of *tabes dorsalis* throw much light on this subject; and, whether we regard *tabes dorsalis* as depending primarily on central or peripheral nervous disturbance, we cannot refuse to extend our views, with Dr. Ord and others, and entertain the likelihood of similar trophic disorders taking place in a reflex manner from irritation of distant parts, and conveyed along nervous paths. The series of cases detailed by Dr. Ord of that form of chronic arthritis so common in women and known under the name, among many others, of "nodosity of the joints," gives especial point to the theory which he espouses; and should further observation confirm this explanation, it must be said that Dr. Ord has made a distinct advance in clinical medicine by his carefully and richly supported hypothesis of the reflex causation of arthritis by uterine irritation. Very interesting remarks, too, were made by Dr. Ord on the probable agency of gonorrhœa and sexual excitement in the production of certain joint troubles, sometimes amounting to distinct arthritis; remarks which, besides relating closely to the main text of the lecture, may be regarded also as favouring the hypothesis of peripheral disturbance playing an important part in the causation of some of the system-diseases of the spinal cord.

The thoughtful and light-giving observations of Dr. Ord on the nervous relations of diabetes, gout, and the affection called "myxœdema," a subject which the lecturer has made especially his own, are none the less worthy of careful study than the points to which we have already called attention. It is Dr. Ord's opinion with respect to the last named disease that "the great tendency of existing observations is to class it among neurotic dystrophies." So far this opinion seems an exceedingly probable one, and for this reason, among others, we will hope that Dr. Ord may use his well-earned authority on this subject to popularise a more appropriate name than "myxœdema" for such a well marked clinical "symptom-complex" as is presented to us by this affection.

Sir William MacCormac's address in the Section of Surgery has a wider interest and application than concerns practical surgeons alone. His remarks on the radical cure of hernia by excision of the whole or part of the sac are of great practical weight, being based on a goodly series of cases. He concludes that this method should be employed in all instances of strangulated hernia, and may also be used, with little serious risk, in cases where an ordinary hernia is continuously troublesome to the patient, and cannot be kept in position by a truss. But it is the lecturer's treatment of the subject of gastrotomy and thyroidectomy that will appeal to a larger class than those to whom his remarks were addressed. Good reasons are stated for believing that the operation of gastrotomy, if performed early enough, in cases of malignant stricture of the œsophagus will undoubtedly give striking relief to the patient, and often tend to prolong life for a considerable time. It is the prevailing opinion that the field of this operation is mainly confined to non-malignant and traumatic cases; but we are inclined to believe with Sir William MacCormac that the early performance of gastrotomy will often be a useful example of palliative surgery, even in obviously cancerous cases. Under the head of thyroidectomy Sir William Mac Cormac touches on the supposed connection there is between ablation of the thyroid gland and the occurrence of the cretinoid symptoms known generally under the title of "myxœdema." The question cannot be regarded as settled as to whether these cretinoid symptoms are the result of the excision of the gland or whether both the diseased gland and the supervening symptoms are part and parcel of one underlying morbid state, and independent of the operation; but as it seems clear that it is mainly in young persons that this connection is observed, the practical conclusion is drawn by the lecturer, after a full discussion of the question, that in adults the operation may be undertaken with as much safety as any of the great operations of surgery. However this may be, the question raised by the surgical procedure under consideration has an obvious bearing on the pathology of the affection called myxœdema.

Dr. Savage's address to the Section of Psychology was a somewhat curious one. Speaking to an audience of superintendents of lunatic asylums, he was naturally obliged to say something civil, so he spoke in vague and general terms of "signs that collections of facts concerning the insane are being vigorously made." What these signs are and where they are to be discerned we know not, nor did Dr. Savage give us even a hint. Case-books, as kept in asylums, he was forced to confess are not satisfactory productions. Well, no. It is difficult to suppose that the robust and energetic mind of Dr. Savage could be satisfied with case-books "as kept in asylums." Such entries as "about the same," "going on favourably," "no change," and the like, do not attain a very high value as scientific records; and if Dr. Savage had added, as he might have added, that in the ordinary case-book "as kept in asylums" even such entries as these are made only once, twice or, at the outside, four times a year, the practice of keeping case-books could hardly be regarded by him as one of the "signs that collections of facts concerning insanity are being vigorously made." The addresses in the other sections are usually largely occupied in recapitulating or referring to the advances that have been made in knowledge and in practice during the past year. In the address to the Section of Psychology references of this kind are absent. They were absent last year. They are usually absent. Why is this? "Records" said Dr. Savage, "are rarely of any value, because they are so defective." Have we any real pathology for insanity as a whole? Emphatically Dr. Savage answered no. He might have returned an equally emphatic answer to a more restricted enquiry. Have we any real pathology for any form of insanity? for any case of insanity? Emphatically no. As the moth tends to the flame, and the pansy to the sun, so Dr. Savage to the subject of general paralysis. The longer he lives and the more cases he sees, the more convinced is he that at present we have not got the clue to the true division of this disease, nor are we much nearer solving the problem of its causation. "Asylums have not contributed the amount of knowledge which they ought" to the localisation of function. The portion of the address which was not occupied in the unhopeful attempt to infuse a little life into the British school of psychiatry was like all that Dr. Savage writes, interesting and suggestive. It was far from being a mere "fact-heap," but still the connections among the facts were doled out in driblets. The address was like the *débris* of a broken chain. There were a few facts linked together here, and a few more there, and a number of couples and solitary facts lying about indiscriminately. But there was no connecting principle running through the whole. We are convinced that Dr. Savage can produce something much better than he has yet given to the world, and we wait with impatience for some work that shall be worthy of him.

OVERPRESSURE IN SCHOOLS.

Although unanimity of opinion is apt to lessen the interest of debate, it at least implies a pretty general belief that the subject deserves discussion. At the meeting of the Conference on School Hygiene held at South Kensington on Tuesday last, both speakers and audience were practically at one as to the fact that an unnatural forcing process of some

kind—conveniently termed "overpressure"—is going on in schools; and it was admitted that this overpressure appears to obtain, or, at least, that it has hitherto been most commonly and most carefully noted, in those schools which are under the control of the Educational Department. But amongst those who took part in the discussion there was much difference of opinion as to what overpressure consisted in, as well as to what extent, and upon what class of scholars it was particularly incident. Equally striking was it to observe that, while those who most confidently alleged the existence of the evil and emphasized its dangers, comprised all the medical men (but not the medical men only) on the platform, and all of the men whose knowledge of children and of school-life was extensive — those who expressed an opposite opinion were laymen, mostly possessed of exceptionally wide experience in their own sphere of educational work; and further, that the latter, while admitting generally the existence of some degree of overpressure in certain cases, or in certain strata of the trained material, for the most part professed that such cases had not come under their personal observation. To some such, indeed, the reply was obvious; and Mr. Kegan Paul's statement that during his eight years' experience amongst Eton collegers he had found no instances of break-down from over-work, was fairly met by the reply that he had looked for it in the wrong place—that the preliminary work at the preparatory schools and of the entrance examinations was something more than a mere filtering process, and that it had given him boys who were able to endure the ordeal of education at high pressure without apparent detriment, just because it consisted in the elimination of the weaker candidates—but that it afforded no indication of the extent to which the latter had suffered in the process.

It is much to be regretted that the subject is one which, directly it rises to the surface, seems to excite antagonism between the medical and the lay authorities on the matter. As soon as a medical man begins to criticise any of the provisions of the Educational Code, or declares that harm is produced by some of its operations, it is taken up by some Educational authority as though it were an imputation on the efficiency of a really perfect system: and the question is too often argued, on one side at all events, as though it were the honour of the Educational Department, rather than the well-being of the children that is at stake. Doctors are not enemies of education, few men appreciate more fully than they the transcendent value of that deep mental culture, that power of acquiring and of dealing with acquired knowledge, that strength of self-control, that noble humility, which is implied in the full meaning of education as contrasted with mere schooling; but the best of them are, and it is well for the people that they should be, strenuously opposed to such spurious education as consists mainly in an overloading of the memory and a simultaneous weakening of the body. When Mr. Kegan Paul expresses his wish that doctors would be more precise in their charges and in instancing cases of over pressure, humanity forbids us to agree with him: firstly, because the possibility of greater precision in such a case would necessarily imply the existence—and the already long-continued existence — of a very wide-spread evil; secondly, because the value of a warning is in great measure proportionate to its timeliness. Instances of children and of adolescents breaking down under the combined effects of the overwork and worry entailed by education at high-pressure—not by any means in Board Schools only—have been at least sufficiently numerous to demand attention; but because the sufferers are necessarily individuals, and because they constitute, therefore, "isolated cases," it is too much the fashion to disregard their significance—and this even amongst people who are in other matters shrewd enough from the first few pattering rain-drops, to presage the coming storm. To be told that, in claiming fair treatment for the body under any educational system, we are "overvaluing health" is at least surprising. If health still means—as it did a thousand years ago, and, for the matter of that, as it meant yesterday—the condition of being "whole," it must surely be impossible to overvalue that ideal health which is a perfect mind in a perfect body.

In refusing to appoint a committee to investigate this question of overpressure, the London School Board has not acted wisely. The abolition of payment by results, the improvements which are being gradually, almost stealthily, made in the position of the pupil-teachers (and it was admitted on all hands that they have been great and general sufferers, that, in the words of a prominent lay member of the London School Board "the pupil-teacher system implies much overpressure which must be got rid of"), and other similar modifications, may, as is asserted, be now in process of introduction only because now, after some years spent in considering and elaborating them, it is considered possible or advisable to make such alterations. The public, however, will be apt to couple these changes with the cry which has been raised as to the existence of a wide-spread evil, and the refusal of a great educational body to enquire into the truth or otherwise of the allegation. We repeat that the question which has been raised is not as to the value of education, or the efficiency of any particular educational system, but as to the existence of an evil which, if it do exist, can only be cured by a modification of the special conditions, whatever they may be, which give rise to it. It is not unreasonable to ask for a searching enquiry into such a matter; the refusal to grant such a request may easily be made to bear a sinister significance.

Mr. Marchant Williams, while joining issue with such authorities as Mr. Pridgin Teale, Mr. Brudenell Carter, and Dr. Crichton Browne, and denying the existence of educational overpressure in the sense in which they applied the term, asserted that there was overpressure in the London Schools, but that it was "the overpressure of hunger, of poverty, and of drink." The distinction is one which we are unable to appreciate. Because, as the result of the poverty and drunken habits of their parents, these children come to the Board Schools without any breakfast, or remain there through the day without any dinner, the Board is not thereby exonerated from the charge of subjecting them to overpressure if it imposes on them the mental

tasks which even well-nourished children of the same age find sufficient difficulty in mastering. We never heard that the hardships of making bricks in Egypt was rendered less arduous by the admission that no straw had been provided. Medical men are not blind to the evils produced by drink, and they cannot fairly be accused of keeping silence on the matter. We are tempted to wonder whether Mr. Williams was serious in saying that the doctors would do far more good by preaching to the parents against drink, than by warning school authoritics against that overpressure in which the parents' drunkenness, no doubt, also has its share.

The real position of this subject, however, has been all along lost sight of. After all, overpressure in schools is not *the* question, and to treat it as though it were so is to miss the lessons derivable from a broad view of the whole situation ; it is, in fact, but one aspect—prominent indeed, perhaps menacing—of that general tendency to overpressure and over-stimulation observable in modern life. Go into the nurseries, examine the toys, attend the parties, read the books of the children of to-day, and on every hand there is evidence of a preeocious stimulation of their faculties. Left to itself the child would enjoy its mud pie or its sawdust doll ; but even its nursery "education" is carried on at high pressure, and long before it has learnt to spell the word, it has begun unconsciously to realise what *blasé* means. Some neglect or ignorance of the value of relative proportion is at the root of much popular misconception on this subject of overpressure. Simply to decline to admit the existence, or to guard against the evils of, overpressure in schools, is a course likely to be attended with disastrous results ; but that the public should be lulled into the belief that overpressure in schools is the only overpressure from which the children of this generation are suffering, and from which they need relief, would be more lamentable still.

WELDON *v.* SEMPLE.

This most important case has been tried at great length and has at last been decided. The judge left no fewer than seventeen questions to the jury, every one of which was answered by them in a sense favourable to the plaintiff, to whom they awarded damages amounting to 1,020*l*. The significance and importance of this finding can scarcely be exaggerated, especially as it has been weightily corroborated by the decision of Tuesday last against Dr. Winslow by the Master of the Rolls and his colleagues in the Court of Appeal ; and it is requisite that its bearings and consequences which are unusually wide and far-reaching, should be examined with great care and at some length. The purely personal questions involved may be dismissed in a few words. Mrs. Weldon undoubtedly suffered inconvenience, anxiety and worry from the action of the defendant ; and the compensation awarded to her cannot be considered inadequate. She has had to wait a long time for redress, but justice has in her case vindicated its character as much for sureness as for sloth ; and her grievance may be regarded as having been laid out at compound interest. For Dr. Semple we are unable to feel much sympathy. Without endorsing all the findings of the jury, we think there was yet in his conduct enough of haste ; of indifference to, or unconsciousness of, the gravity of his action ; of readiness to be satisfied with unsupported, unverified evidence ; of want of ordinary caution, such as but for his own admission would be incredible, not only to justify but to necessitate an adverse verdict. The fact too that Dr. Semple was a friend of Dr. Winslow, and had previously signed many certificates on his behalf, rendered the transaction open to suspicion as being contrary to the spirit, if not to the letter of the law.

Beyond the personal question, however, the bearings of this verdict are of the greatest moment from several points of view. It is of importance to the public at large, to the insane, and to the medical profession, especially that portion of it which is engaged in the practice of lunacy. To the public at large the trial is of great importance, but its true significance appears to have altogether escaped the attention of the journals to which we are accustomed to look for the expression of public opinion. It provides them one and all with an occasion to rail against the Lunacy Laws, and to clamour for their alteration. To us the indications appear to point in a diametrically opposite direction. Apart from the very few medical men who are proprietors of private asylums, the medical profession has no interest whatever in the maintenance of the Lunacy Laws as they are. So that our responsibility in the matter is not increased, it is to us, as medical men, a matter of perfect indifference by what steps a patient is to be consigned to an asylum. Looking at the matter then from the point of view of the citizen, whose chief concern is the possibility of being wrongfully imprisoned in an asylum, the lesson that this trial conveys to us is that the present law of lunacy offers us a thoroughly efficient safeguard against any such danger. Here is a woman who offers fairly strong *primâ facie* evidence of insanity—evidence that is no doubt open to be rebutted, but still evidence of such a nature that the patient's own witness admits that she may have been "crazy." She is visited by two physicians who, apparently, comply with the letter of the statute, and who, it is presumable, eomply with what they believe to be its spirit. They sign certificates of her insanity. The order and statements are drawn up and signed, and all the documents are in such form as to satisfy at least one judge of their validity. It is safe to say that in very few instances indeed of persons really sane are the preliminaries necessary for their incarceration likely to be so complete, in such good form, or so apparently in accordance with the law. Yet what is the result ? The patient brings an action against one of the certifying physicians and gains £1,000 damages. So far from being "detestable," "monstrous," or even insufficient, this appears to us the best possible proof that the present law of lunacy offers amply sufficient safeguards against such wrong-doing as is often read of in works of fiction, but almost never met with as an actual occurrence. It must be remembered that these points —of separate examinations, &c.—had never been tried before. The law on this subject will in future be clear without any additional statute ; and is it to be supposed that any medical man, however reckless, unprin-

cipled, or greedy of gain, will ever render himself liable to a penalty of £1,000 and the costs of such an action as that of Weldon *v.* Semple, by giving a certificate without making very certain indeed of his patient's insanity? The probability is just the opposite, and there is considerable danger now that no medical man will, under any circumstances, take the responsibility of certifying a private lunatic; and that the interests of these unfortunate people may suffer considerably in consequence.

The safety as well as the practicability of the present law appears favourably in contrast with the alternative proposals. Mr. Justice Hawkins is impressed with the importance of the certificates being made on oath. But what is the additional safeguard of an oath, as taken by a careless or unprincipled person, over that offered by a certificate? Surely none beyond that afforded by the fear of a prosecution for perjury. And what prosecution for perjury could threaten more dire consequences than that of the verdict in Weldon *v.* Semple? Another suggestion is, that no one shall be committed to an asylum save on the verdict of a jury after open trial. When it is remembered that between twelve and thirteen thousand persons are committed to lunatic asylums every year, the practicability of this arrangement becomes more than doubtful; nor would the publicity be by any means welcomed by the patients whom it is intended to benefit. To the insane themselves the present laws regulating admission to asylums are probably as beneficial as any that could be desired. In the vast majority of cases it is of the greatest importance that if a patient is to be sent to an asylum he should be sent without delay and without any exciting preliminaries. The chance of recovery is, as is well known, greater the earlier the case comes under asylum treatment; and any delay that is interposed between the positive diagnosis of insanity and the submission to asylum treatment diminishes the patient's chance of recovery. To the medical profession a change in the mode of admitting patients to asylums would be by no means ungrateful. The responsibility at present resting on certifying medical men is very heavy, and the remuneration by no means correspondingly great. The method of committal by trial would relieve them of all responsibility and probably increase the remuneration. The method of committal by affidavit would probably be more remunerative, and the responsibility certainly not greater. By no change would the profession be likely to be placed in a worse position than it is at present.

From the point of view of the medical men who practise lunacy, a change in the mode of committing patients to asylums would not be unwelcome. Whatever the change it could not but take the direction of throwing more business into the hands of the specialists, and if it compelled greater lucidity, greater detail, and more precision in the drawing of certificates, it could not fail to benefit those who have the care of lunatics in asylums. While, therefore, looking at the matter from the point of view of the medical man and the specialist, we see no reason whatever to deprecate a change in that part of the Lunacy Laws which concerns the mode of committing patients to asylum treatment, but rather are biassed in the direction of desiring a change; yet as citizens desiring every safeguard against improper incarceration, and as friends of the insane themselves, we fail to see that the principle of the present method of committal need be or should be departed from. Improvements in detail are doubtless possible, and if the verdict in Weldon *v.* Semple impresses, as it must impress, every medical man with the absolute necessity of construing the law in a liberal spirit and of taking the utmost pains to secure important evidence, and to verify it thoroughly before putting it in a certificate, the trial will have a very important and a very beneficial result in clarifying the law and improving procedure.

REVIEWS AND NOTICES OF BOOKS.

SOME OLD FRIENDS.[1]

We have before us a pile of new editions of well-known medical classics, the reissue of which we greet with satisfaction. It is pleasant to retreat for a moment before the battalions of new books which the medical publishers of France, England, Germany and America are hurling against us, with a certain contempt of consequences, and to take refuge with these old friends of ours, whose acquaintance we first cultivated as students, and whose help we have learnt to look for in the difficulties of practice. A new edition of an old and successful work, if it only keep fair pace with the times, has many advantages over an entirely new book on the same subject. It is more or less familiar to those who have studied previous editions; however much it may have suffered addition and change, the old familiar landmarks are there, and one has not to study its plan before one can find one's way about in it. Of the volumes which we are about to review, a large percentage, we should say, will be sold to men who have borrowed and read earlier editions in their student days. Then a new edition of an old book is much less likely to reflect unduly the prevailing fashion of the day. A certain deference to it may be expected of it, but not a servile or extravagant one. Again, the fact that a new edition is called for is, to some extent, a guarantee that it is wanted, that it fills a gap in medical literature—a statement which could not be predicated of more than a very small proportion of new books. On the whole then in the case of all works founded on clinical observation we are inclined as readers to favour new editions of old and tried books in preference to entirely new ones. As reviewers of course we have no right to *à priori* prefcrences. We have to judge every book

[1] 1. A Treatise on the Continued Fevers of Great Britain, by Charles Murchison, M.D., LL.D., F.R.S. Third Edition. Edited by W. Cayley, M.D., F.R.C.P. London: Longmans, Green & Co., 1884.

2. Lectures on the Diseases of Infancy and Childhood, by Charles West, M.D. Seventh Edition. London: Longmans, Green & Co., 1884.

3. A Treatise on the Theory and Practice of Medicine, by John Syer Bristowe, M.D., LL.D., F.R.S. Fifth Edition. London: Smith, Elder & Co., 1884.

4. A Treatise on Surgery, its Principles and Practice, by T. Holmes, M.A. Cantab. Fourth Edition. London: Smith, Elder & Co., 1884.

5. Injuries and Diseases of the Jaws, by Christopher Heath, F.R.C.S. Third Edition. London: J. & A. Churchill.

6. Henfrey's Elementary Course of Botany. Fourth Edition, by Maxwell Masters, M.D., F.R.S. London: Van Voorst, 1881.

on its own merits, taking care that, so far as our influence reaches, no old book shall go on living undeservedly on its old reputation and no new one be denied praise when it has fairly earned it.

These remarks apply especially to the new edition of Murchison's "Continued Fevers," which has been edited with singular discretion by Dr. Cayley. No work published within the last generation has done more to maintain the reputation of the English School of Medical writers than Murchison's "Fevers," and any new book on the subject which could expect to compete with it would have to be of extremely exceptional merit. Dr. Murchison was not a very great physician, but he had powers of careful and accurate observation, infinite industry both in the study and the ward, and a remarkably methodical mind. If he had one fault as a medical writer, it lay in his disposition to impress upon clinical facts a greater orderliness than they actually present. This is perhaps less seen in his "Fevers" than in that favourite of the examination candidate, his work on "Diseases of the Liver." Indeed the former is altogether of a much higher order of medical literature than the latter, and it is upon it that Murchison's future reputation will rest. Our comparative immunity in England during recent years from two of the continued fevers deprives much of the present work of the intense practical interest it had for the physician when it first appeared. But it would be rash to assume that neither typhus nor relapsing fever will ever again renew their ravages amongst us, or that we shall never more be driven by necessity to take down Murchison from the shelf and study what he has to say about them. The opportunities of observing these two fevers have fortunately been limited of late, and Dr. Cayley has found little to add to or to alter in Murchison's text. In the introduction under the heading of "Causes of Continued Fevers," he has expressed the opinion that the notion that contagious fevers are due to parasitic organisms must now be regarded as in all probability correct; and he accepts the researches of Pasteur and others as showing the modifiability of these organisms. As Dr. Klein however has recently shown in his Interim Report, it is a little premature to believe in the conversion of harmless into pathogenic germs, except as a pure hypothesis, and the whole question of the proximate cause of the continued fevers must be regarded as still *sub judice*. In respect to typhus, the fact of its being caused by a specific microbe, is only supported by the analogy of other contagious diseases. In the case of relapsing fever the evidence of its being dependent on a micro-organism is fairly complete, and Dr. Cayley has given a very good account and illustration of the spirochæte which is invariably found in the blood, in quantities varying concomitantly with the degree of the fever. In respect to the treatment of typhus, Dr. Cayley cannot speak with any certainty as to the effect of cold bathing in reducing the mortality, but he has found it more efficacious in relieving distressing symptoms than any other remedies.

It is to the chapters on Enteric Fever that readers of this new edition will turn with most interest. Here there are three important points which have called for special attention on the part of the new Editor, viz., first the questions of direct contagion, which has again been brought to the front, by the facts published by Dr. Collie and others; secondly, the question of micro-organisms; and thirdly, the question of anti-pyretic treatment. The first question is, we think, dismissed by Dr. Cayley in fewer words than its importance demands. The facts which Dr. Collie has added, in the *Sanitary Record* for July 15th, to those previously published, are very striking and call for serious and detailed consideration. As to the question of micro-organisms, our knowledge of which has been ably summarised for this edition by Dr. Heneage Gibbes, Dr. Cayley thinks there are strong grounds for believing the poison of enteric fever to be constituted by one of these organisms, it being "highly probable that putrefactive change is one of the conditions necessary for their development from the germs contained in the stools of cases of enteric fever." Under the head of "Treatment" the Editor deals at length with cold bathing and the administration of kairin. His praise of the former is unqualified; of the latter he speaks with more hesitation. In conclusion we may reiterate our opinion that Dr. Cayley has performed his difficult task admirably. It would have been easy to spoil the book by too much emendation and we think the new Editor has acted most wisely in confining his revision to such alterations as the progress of knowledge had rendered absolutely necessary.

Dr. West's "Lectures on the Diseases of Infancy and Childhood," of which a new edition has recently appeared, is another work which has deservedly won a world-wide reputation and has done much to maintain the credit of the English School. It would have been a thousand pities if it had been allowed to pass out of vogue because it had fallen behind our present knowledge. In his new edition Dr. West has done his best to retain the confidence of the reader. No one can read the chapters on meningitis or convulsions, without feeling that he is in the presence of one who is really a master of the subject, as Dr. West may well claim to be seeing that he can speak from an observation of 70,000 cases extending over a period of well-nigh fifty years. His description of the morbid anatomy of infantile paralysis shows that he has thoroughly followed the revolution that has taken place in our knowledge in this direction in the last few years, whilst his advocacy of the use of the hypodermic syringe in a doubtful case of pleurisy, and his regulations for the treatment of empyema are sufficient evidence that in matters of diagnosis and treatment he is as well posted up as if he had but just been up for his degree. Dr. West's views on the identity of croup and diphtheria are we hope and believe perfectly well known to all our readers, and they will be found here couched in that elegant diction of which he is one of the very few living masters. His rules too for establishing the points of difference between diphtheria and scarlatina are admirably conceived. Dr. West has shown caution in his attitude towards some of the latest views, but he has introduced sufficient emendations in the text of his "Lectures" to make them still far and away the best book that we have on the subject. The references to recent works scattered throughout the volume, and the numerous allusions to the work done in the children's section of the International Medical Congress in 1881, over which he presided with such marked success, show that the author has not relaxed his study of contemporary literature. In regard to the new problems suggested by the discoveries of bacteriologists, Dr. West takes up a more philosophic position than Dr. Cayley has done in the work we have just reviewed. He admits, with most reasoning physicians, that the new discoveries "do not furnish data such as can govern the course of the ordinary enquirer in the study of disease or as can control his practice." He does not, nor do we, underestimate their value, or the work of those who are striving to give them greater scientific certainty, but in this matter "they also serve who only stand and wait."

Dr. Bristowe's "Treatise on the Theory and Practice of Medicine" first appeared so recently, and the alterations that it has been found requisite to make in the new edition are so slight that it may be dismissed in a few words. As in the case of the two previous works some important additions have been necessitated by

recent advances in bacterial pathology. This study, however, is progressing with such rapid strides, that in some respects even this last edition of Bristowe is already out of date. Thus in describing the attenuation of the bacilli of Splenic Fever (p. 141), Dr. Bristowe gives Pasteur's results, without having been able to modify them in accordance with those more recently obtained by Koch, Gaffky and Loeffler, a summary of which was published in our last issue. Again, the pages dealing with the cause of cholera were probably through the press before Dr. Koch had made known his discovery of the "comma" bacillus, as they contain no mention of it. It is interesting, however, to observe how closely the views arrived at *à priori* by the author (p. 237) have been realised in the behaviour of the bacillus as described by Dr. Koch. Under "tubercle," Dr. Bristowe quotes the early experiments of Dr. Wilson Fox without having been able to notice the newer researches which have shown the first results to have been unreliable. Dr. Bristowe believes that the evidence in favour of the view that the bacilli discovered in tubercle are its cause, is very strong, but even accepting it he does not think that it necessarily follows that tubercle is infectious any more than that ague is infectious. Several other alterations have been made in the new edition which we have not space to enumerate. It suffices to say Dr. Bristowe has done everything in his power to maintain the reputation of his book, as being one of the best, if not the best, complete treatise on medicine in the English language that can be placed in the hands of the reader, be he student or practitioner.

We must pass very briefly over the remaining books on our list. Mr. Holmes' "Treatise on Surgery," and Dr. Bristowe's "Treatise on Medicine" were first issued within a few months of each other by the same publishers. Both have taken a recognised place in their respective branches, both have fully deserved the success they have won, and the authors of both have conscientiously striven to bring their new editions up to date. Very few changes have been made in the present edition of Mr. Holmes' work; but on referring to the subjects in which most distinct progress has been made since the publication of the last edition, we find that the points which have been omitted are few and unimportant. Mr. Holmes is quite justified in claiming that his work is a faithful reflection of the advance of surgery.

In recording the issue of a new edition of Mr. Heath's standard work on "Injuries and Diseases of the Jaws," it is sufficient to say that the author has made very considerable additions and alterations, rendered necessary by pathological advance and by increase in his own experience. The volume thus embodies all that is known on the complex and difficult subjects of which it treats. The additional woodcuts are admirable.

A few lines will be sufficient to record the publication of a new edition of "Henfrey's Botany," edited by Dr. Masters. The general plan of the work has not been altered, but much new matter has been added in the chapters on the Histology and Physiology of Plants. We come again on our old friends the bacteria; indeed the fact that in five out of the chance company of books we have here reviewed important alterations have been necessitated by discoveries in the field of bacterial pathology, makes one freshly realise in how many scientific pies the omnipresent bacterium has a finger.

The Library of the Royal Medical and Chirurgical Society will be closed on Monday, August 11th, and re-opened on Monday, September 15th.

ABSTRACTS AND EXTRACTS.

WELDON *v.* SEMPLE.—THE PRESS ON THE VERDICT.

The *Times* says that it admits of little doubt that a verdict adverse to the defendant was perfectly justifiable, that the jury might well come to the conclusion that there had been a lamentable lack of care, and that it would be scandalous if each case of suspected lunacy were sifted with no more intelligence than was displayed with regard to Mrs. Weldon. Unsatisfactory though the present law was, and calculated, as the judge said, to fill everybody who contemplated it with terror and alarm, it did not seem in this instance to have been genuinely observed, and it was a serious flaw in the defendant's case that the selection of the certifying doctors was entrusted to the proprietor of the asylum to which the plaintiff was to be consigned.

The *Standard* thinks that there is ground for great satisfaction in the verdict of the jury, and that the overwhelming majority of the public will be of opinion that if to have been treated with excessive and unjustifiable harshness can entitle Mrs. Weldon to damages, the finding is amply warranted. In future, members of the medical profession will be more careful to act independently of one another, and of the proprietor of the asylum, whose interests are concerned.

The *Daily News* points out that it is a matter of congratulation for the public to be assured that the treatment which Mrs. Weldon received is unauthorised, even by the very elastic regulations of the Lunacy Acts, and concurs with the finding of the jury that Dr. Semple did not *bonâ fide* and honestly, separate from Dr. Rudderforth, personally examine the plaintiff. With a little more caution, however, Dr. Semple might easily have kept within the statute, and though Mrs. Weldon has been triumphant, her triumph does not justify the law.

The *Morning Post* is of opinion that the language from the judicial bench on the state of the Lunacy Laws was strong, but certainly not stronger than is deserved. It is not necessary to assume that the law is habitually or frequently abused to pronounce its condemnation; but it is sufficient, as Mr. Justice Hawkins put it, "that the law opens a door of easy access to abuse, and persons who were wicked-minded would find it easy of abuse, and in that way a great deal of mischief might be done." When the next Lunacy Act is passed, it should provide for the examination of an alleged lunatic before a Justice of the Peace, and all private lunatic asylums should be suppressed. There should be no motive operating in the minds of those who have charge of asylums to detain their patients a single day longer than is absolutely necessary for their protection.

The *Guardian* considers the verdict a natural protest of common justice and common sense against the existing state of the Lunacy Laws. The jury held that Dr. Semple had not kept within the limits of this bad law; but he might have kept well within them and still inflicted unjust suffering on Mrs. Weldon. There will be no proper security for personal liberty until the order for detention as a lunatic shall in all cases be signed by official persons, or the detention itself shall in all cases be in a public asylum.

Truth contends that the verdict of the jury is confirmed by public opinion. The examination in Mrs. Weldon's case was only colourable. Mr. Justice Hawkins is to be congratulated for having so directed the enquiry as to show that if the Lunacy Laws are to remain as they are, the liberty of no man or woman in the United Kingdom is safe.

COLOUR BLINDNESS.

After discussing the various theories of colour perception, as propounded by Newton, by Young, and by Hering, and pointing out how they all fail to afford a satisfactory explanation of the phenomena of congenital colour blindness, whether partial or complete, Dr. Swan Burnett (*American Journal of Medical Sciences* for July) proceeds to detail his own views which have on a previous occasion been brought forward in a less complete form. He starts with the proposition that an

abnormality in the retina, optic nerve, or centre of vision in the brain would cause some alteration in the normal sensation. He supposes that the reason that the possibility of the defect being in the brain in cases of colour blindness has not received more consideration is perhaps the use of this word blindness, which is clearly a misnomer. The patients thus affected are not really blind; a red-blind man sees the colour, but is not able to separate the impression made by it from that made by some other colour. The mistakes of the colour blind are errors in judgment. Abnormal colour perception may be of two kinds, central and peripheral; in the first of these the difficulty lies in the brain. To this class would belong all congenital cases in which the spectrum is not shortened, and even some in which it is. The other variety would include cases where the defect was the result of inflammatory changes in the optic nerve or retina, and perhaps some of the cases in which the spectrum appears shortened. As there are no physical, anatomical, or physiological grounds for regarding the retina as a differentiating organ, he proposes to give up that notion altogether, and consider it "to be a substance whose ultimate structure is such as to allow it to respond at one and the same time to a large number of ethereal vibrations, at least such a number as shall be represented by the clearly-distinguishable colours of the spectrum." The impressions thus received by the retina are transmitted by the optic nerve to the brain, and there converted into sensations. The term colour blindness he would restrict to those cases where everything appears black, or white, or a dull shade of grey; all other forms he would prefer to call cases of abnormal colour perception. In the central cases, that is, where the defect is due to error of judgment, the retina may be in an absolutely perfect condition. Most of those who are the subject of this condition see the spectrum dichromic, the dividing line being about the blue. In such a case the person cannot differentiate between the vibrations corresponding to those colours which lie on either side of the line, it does not follow that the vibrations are the same, but they are so nearly alike that he is likely to confuse them. When there is shortening, it may be that the vibrations corresponding to the missing part of the spectrum fail to excite the cerebral molecules. The peripheral forms would depend upon the optic nerve being unable to transmit, or the retina to receive, these particular impressions. In the normal eye they seem to be unaffected by the ultra-red or ultra-violet rays, and it seems therefore perfectly justifiable to assume that under certain conditions they might be unable to pass on to the brain other colour waves. Embryology confirms this view by showing that it is probable that the optic nerve is a highly specialised nerve of common sensation, and the retina a modification of the integument in which the nerve terminates. As to the part of the retina which is specially concerned in the transmission of these impressions, Dr. Burnett is of opinion that as far as his theory is concerned it is a matter of indifference which layer receives them. The rods and cones alone are not the only parts affected, as was proved by the fact that in a tiger which had good visual power this layer was completely absent. Nor is the pigmentary layer essential, otherwise albinos would all be colour blind. In order to determine the relative power of the different waves to affect the retina, Dr. Burnett adopted the following plan. A piece of white paper was placed with a black ground in the sunlight, and the retina was exposed to it for a certain length of time; the eye was then covered up so that all light was excluded, and he then studied the changes that took place in the after-image. As a result of these experiments he inferred that the shorter waves (blue) affected the retina most easily and most strongly at first, but that they were sooner exhausted than others which did not act quite so speedily at first. The order of disappearance followed the colours of the spectrum from the blue to the red end. He could not, however, feel certain that these results related solely to the retina, as the brain might have had some effect. Lastly, he asks whether a certain portion of the brain presides over the function of the colour sense, or whether one centre serves for light, form, and colour vision. The sense of form would depend upon the number of retinal elements affected, and their relation to each other in space. Colour would be the result of a discrimination between the changes produced by other waves of different lengths, while the sense of light (white) would be the sum of all these wave impressions occurring at the same time. If one cerebral atom corresponds to each retinal element, then the cerebral mass concerned in the reception and perception of impressions made on the retina need not be greater than that of the retina itself. It would not be necessary that in this mass different portions should be set apart for the perception of the different colours, for the variations in the vibrations in the retina, or in the luminous body itself, would be able to take place just as well in the cerebral mass. Cases of hemiachromatopsia of cerebral origin he would account for by the supposition that the cerebral molecules of one side were rendered incapable of responding to the missing colours, or the lesion might be in the optic tract, preventing the fibres from carrying the wave motion representing that colour from the retinæ to the brain. We have to thank Dr. Burnett for a most able, interesting, and thoughtful article, dealing in a masterly manner with a great problem. His division of cases into central and peripheral, and placing the congenital cases in the former group will, we believe, prove to be the correct solution.

REPORTS OF SOCIETIES.

ACADEMY OF MEDICINE IN IRELAND.

Sub-section of Public Health.

Dr. Grimshaw, President, in the Chair.

Increase of Insanity.—Suggested Reform of the Lunacy Laws and Practice.

Dr. T. More Madden having recently read a paper, in another Section of the Academy, on certain mental and nervous disorders, now called attention to other aspects of the subject, offering further evidence of the general prevalence and increase of insanity in all classes, and more especially amongst women, in whom it was frequently traceable to cerebro-nervous disorders originating in reflex irritation from utero-ovarian causes. These disorders, however, were very frequently unrecognised and neglected in lunatic asylums, the result being, that many women were needlessly confined or improperly detained in such institutions. The present administration of lunatic asylums and the laws by which it is directed, afford scope for the possible occurrence of abuses. He made suggestions for the improvement of the administration, and some needed reforms in the lunacy laws. Although the recent increase of insanity had been disputed as a popular fallacy, even by psychological authorities, including the Lunacy Commissioners, the statistical evidence of the fact was incontrovertible. At present, one in every 414 of the population of England and Wales is a registered lunatic; while in 1800, there was only one lunatic in 7,300 of the population. In 1806, there were 2,248 lunatics in England and Wales; in 1819, 6,000; in 1823, 8,000; and in 1826, 14,000. In 1845, there was one in 800 of the population insane, and thirty-seven years later, one in 414, or 76,765 lunatics, comprising 42,482 females, being an increase on the preceding year of 1,182 females and 676 males. In Ireland, since 1851, the population decreased 12 per cent., and there has been an increase of 41 per cent. in the number of lunatics. In 1851 the number was 9,980, or one in every 1,291; but last year it had risen to 13,820, or one in 369. The increase of lunacy had been greater amongst women than men, owing to the influence of uterine or peri-uterine causes of reflex cerebro-nervous irritation. There were also general moral and social causes. The facility with which any person can be legally confined as a lunatic is indefensible, seeing that any two of the most inexperienced of the 24,000 practitioners on the medical register can virtually consign any man or woman to a lunatic asylum. That this power was liable to abuse he illustrated by cases in his own experience.

He therefore suggested that the power of signing certificates should be restricted to certain officially appointed medical inspectors of lunatics; and that in the case of alleged female lunatics, one of the inspectors should be a physician with some experience of the special functional disorders, the reflex consequences of which may either simulate or eventuate in insanity. The lunacy laws differ in England, Scotland, and Ireland; and the pauper lunatic asylums in England and Wales involve an expenditure of upwards of a million, while those in Ireland cost 200,000*l*., according to last year's accounts. The reform of abuses and the improvement of curative treatment could be attained with diminished cost to the public. Let all the lunatic asylums become public property, and placed under one central official administration in each country. The compensation of proprietors of private asylums would not be a serious consideration, considering the profits that would arise from continuing those institutions as first and second-class State asylums, and ultimately these profits would relieve the cost of the general public lunacy system. He suggested the abolition of the office of resident medical superintendent of public asylums, whose functions he would transfer to lay governors or masters, leaving the resident physician free to devote himself entirely to strictly professional functions, in which he should be assisted by a staff of extern or visiting medical officers. A large number of the chronic and harmless patients of the weak-minded or imbecile class would be cared for with greater comfort to themselves and less cost to the public, outside the walls of lunatic asylums. As an amendment of the laws relating to so-called criminal lunacy, he suggested the adoption of a law similar to the 64th Article of the French Penal Code, and the appointment of medical assessors in all trials in which the plea of insanity is advanced.

Dr. Doyle hoped the gentlemen connected with private lunatic asylums would state their views. Human nature was weak, and those who had private asylums could not be blamed for trying to keep good-paying patients as long as possible. He knew of a case pronounced by the keeper of a private aristocratic institution as incurable; but the patient being unable to pay, was placed in a public institution, and in six weeks' time was discharged. Within the past year, four or five cases of lunacy came under his care, in three of which he detected uterine disorder, but he could not lay too much stress on it as the exciting cause. Females got into a nervous state frequently; but in the majority of cases where their lunacy was not due to hereditary predisposition, it was traceable to some local cause, the same as in *delirium tremens*. From what he knew of them, he hoped private asylums would be abolished.

Dr. Neville took considerable interest in lunacy since his first professional appointment as *locum tenens* in one of the large county asylums. The effect the diseases of the female genital organs might have in the causation of mental trouble was apt to be exaggerated by gynæcological specialists, and the question of lunacy was somewhat looked at through gynæcological spectacles. Where it was a case of one specialist attacking another, he discounted a good deal of the criticism. He knew some of the gentlemen who gave attention to diseases of the mind to have studied these diseases as earnestly as specialists did in any other branch of medicine or surgery. The great trouble taken, both in public and female asylums, could not be excelled by any specialist. As to the increase in lunacy, shown by the figures quoted, it should be remembered that the causes of lunacy had greatly increased, *e.g.*, the wear and tear of modern life. On the other hand, the struggle for existence made it the more necessary to get rid of the drones of society, and certainly lunatics, being of no use to themselves or their families, were drones in society, and their families would be anxious to put them under restraint. Nowadays medical education had advanced, and with it the diagnosis of insanity. Specialists in diseases of the mind would say there had been just as much improvement in the treatment of insanity as in obstetrics. Indeed, he saw a complaint made in connection with the meeting of the British Medical Association in Belfast, that there had been no advance made in obstetrics for several years. But he did not admit the truth of either allegation. On the contrary, he believed there had been an advance. The use of opium in melancholia had a remarkably beneficial result. Dr. More Madden had adduced the statistics of Bethlem 100 years ago, and, contrasted with those of the present, the cures were then two out of three, while now the proportion was much more unfavourable. But he did not believe in the statistics of 100 years ago, or in the treatment either. Could any sane man believe that the exhibition of the patients to the public, at 2*d*. or 3*d*. each, was better treatment than that resorted to at the present day? In the majority of cases where disease of the female genital organs gave rise to insanity, there had been hereditary tendency to insanity, and that would come out just as if she had disease of the liver or the lung. Disease of the genitals was, no doubt, an exciting cause, but it required the back-ground of an hereditary predisposing cause. He did not agree with Dr. More Madden and Dr. Doyle about doing away with private asylums, believing as he did that in those establishments the insane were as safe and as well cared for as they would be if confided to a corporation or the government. Nor did he agree with Dr. More Madden's idea in reference to the Medical Superintendents of County Lunatic Asylums. As the head of the institution, the Superintendent was properly a medical man, having a medical assistant and a crowd of officials under him to carry out the details. He was well paid for his work and gave his whole time to it, and if in the task of supervision he missed the discharge of some of his medical functions, it was not greatly to be regretted. As a rule, consulting physicians who resided outside the institution knew nothing whatever about lunacy, being general practitioners without any special knowledge. In his own experience a ridiculous illustration of this occurred where the consulting physician in three different cases—one of asthma, one of acute mania, and the third of injury to the knee-joint—ordered a blue pill and a black draught for each.

Dr. Henry Kennedy had not the same experience as Dr. More Madden of the enormous increase of lunacy. Registration had the effect of bringing out cases which 25 or 50 years ago would not have been noticed at all. He did not see why private asylums should not be continued. That abuses might exist would be allowed, but there were competent inspectors to visit private asylums and investigate their management. As to treatment, cod-liver oil had become almost a specific where there was a tendency to insanity indicated by such symptoms as restlessness and refusal of food on the part of persons advanced in life. In all those cases death almost invariably ensued from tubercular phthisis. Dr. More Madden was in some respects right regarding the stress he laid on uterine irritation.

The Chairman did not think the statistics justified the extreme conclusion drawn with regard to the increase of lunacy. The statistics of 100 years ago were not of much weight. Independently of that fact, it was only recently lunatics had been brought in considerable numbers into a position in which they could be tabulated. The great asylums did not exist, though the lunatics may have existed. In Ireland the statistics improved with the development of the system of collecting the information, so that each decennial census was superior to the preceding. In 1851 the difficulties to be overcome were so great that an enormous number of errors were committed. Since then the population had been prevented from increasing chiefly by emigration; and the lunatics did not emigrate, neither did the old nor the very young. Consequently considerable allowance must be made for these in the calculation. He thought Dr. More Madden had taken too severe a view of the mode of conducting asylums. The functions of the superintendent were various. But the director of any great establishment for the treatment of disease should be a medical man, even if he had to abdicate his medical functions. No doubt the function of hotel-keeping performed by the owners of private lunatic asylums was derogatory to the profession, but all the same, he was strongly in favour of private asylums. A lunatic able to pay for his support should not be treated at the public expense. There were wealthy lunatics, and their being unfortunate enough to be mad was no reason why they should be deprived of the advantages of people of wealth. It was only in private asylums they could have those advantages.

MEDICAL NEWS.

Royal College of Physicians of London. — The following gentlemen having passed the required examination were admitted as Members, July 31st, 1884 : —

George Newton Pitt. M.D. Camb., 9, St. Thomas Street, S.E.; Richard Sisley, M.B. Lond., 1, Park Row, S.W.; Edward George Younger, M.D. Brussels, Hanwell.

Royal College of Surgeons of England. — The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 24th ult., viz :—

Julius Coronel, M.D. Amsterdam, W. Indies; C. E. Gooding, M.D. McGill, Barbadoes, W.I.; J. B. Loring, M.D. McGill, Montreal; G. B. Rowell, M.D. McGill, San Francisco; H. C. C. Shaw, L.R.C.P. Lond., Kingston-on-Thames; S. E. Craddock, L.S.A., Milman Street, W.C.; Francis Penny, L.S.A., Crewkerne; George Morgan, L.S.A., Brewer Street; J. R. Watson, L.S.A., Moore Street, S. W.; Hyde Marriott, L.S.A., Stockport; A. W. Aikins, M.D. Toronto; G. C. Macdonald, L.R.C.P. Edin., Craven Street; T. H. Miller, L.R.C.P. Lond., Clapham; R. F. T. Perkin, Warwick; W. T. Rees, L.S.A. Llanboidy, Carmarthenshire; T. G. Parrott, L.R.C.P. Lond., Aylesbury; J. U. Bolton, L.R.C.P. Edin., Wimbledon; C. W. Biden, L.R.C.P. Loud, Peckham; and C. R. Riley, L.R.C.P. Lond.

Five gentlemen passed in Surgery, and when qualified in Medicine will be admitted Members of the College. Four candidates, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for six months, and one for three months.

The following gentlemen passed on the 25th ult., viz.':—

A. M. Watkins, L.R.C.P. Lond., Newton-le-Willows; E. Webster Hulme, Manchester; E. O'R. Somers, Salford; J. Stevenson, L.R.C.P. Lond., Stretford, Manchester; P. W. Williams, Bristol; C. E. Purslow, Wolverhampton; E. P. P. Macloghlin, Wigan; G. S. Wild, Liverpool; T. G. Laslett, L.R.C.P. Lond., Bootle; William Spry, Southsea; L. Drage, Hatfield; C. B. Innes, Hampstead; W. C. G. Collins, L.R.C.P. Edin., Holford Square; A. J. G. Barker, Finsbury Park; and Alexander Harper, Hertford Street, W.

Five gentlemen passed in Surgery. Six candidates were referred for six months, and one for three months.

The following gentlemen passed on the 28th ult., viz. :—

P. L. de Montbrun, L.R.C.P. Lond., Trinidad; J. H. E. Brock, Bartholomew Road, N.W.; A. F. Voelcker, Argyle Road, W.; J. R. Adie, Brixton; P. D. Turner, Tulse Hill; F. S. Barber, Claremont Square; J. E. Ruck, Devizes; W. H. W. Stacey, Norwich; A. S. G. C. Reid, Chatham; W. A. Aikin, Clifton Place, W.; R. W. Brogden, L.R.C.P. Lond., Clapham Road; R. H. Castor, L.R.C.P. Lond., Primrose Hill; and J. R. Roberts, L.R.C.P. Lond., Suez, Egypt.

Seven gentlemen passed in Surgery. Five candidates were referred for six months, and two for three months.

The following gentlemen passed on the 29th ult., viz. :—

J. J. D. Vernon, Newcastle-under-Lyne; A. H. Tubby, Kennington; A. E. Taylor, Acton; T. G. Lavie, Queen Anne's Gate, S.W.; E. A. C. Smith, L.R.C.P., Lond., Woolwich; John Elliott, Whitchurch, Salop; W. M. Gabriel, Gloucester Gardens, W.; S. H. Habershon, Brook Street, W.; T. G. Penrose, Gower Street, W.C.; W. T. Cocking, Sheffield; John James, Llangwyryfon; A. R. Hall, Stranraer Place, W.; A. H. Fowler, L.R.C.P., Lond., Sharsted Street, S.E.; O. W. Roberts, L.R.C.P., Edin., Cambridge Gardens, W.; A. T. Field, L.S.A., Shepherd's Bush, and T. W. S. Morgan, L.S.A., Roupell Park, S.W.

Three gentlemen were approved in Surgery. Three candidates were referred for as many months, four for six months, one for nine months, and one for twelve months.

The following gentlemen passed on the 30th ult., viz. :—

F. A. Spreat, Belsize Square, N.W.; A. G. R. Foulerton, Norland Square; Sydney J. Palmer, Seaton, Devon; Charles Gayford, Brecknock Road; C. D. Muspratt, Clapham, S. W.; R. M. H. Randel, Sydenham; T. E. Hornbuy, Mile End; P. V. Jackson, Ballina, co. Mayo; William Washbourn, Blackfriars, Gloucester; Charles Andrews, Hammersmith Road; and Frank Pearse, L.R.C.P. Edin., Exeter.

One candidate passed the examination in Surgery. Four candidates were referred for three months, eight for six months, and one for nine months.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, July 24th, 1884 :—

Adolphus Theodore Field, Sunnyside, Shepherd's Bush, W.; William Hall, 30, Cumberland Park, W.; James King Lewis, 101, Old Woolwich Road, Greenwich; George Frederick Pollard, 103, Earl's Court Road, Kensington, W.; Richard Greenhill Silverlock, Northwold, Norfolk; Ernest Vallance, The Deanery, Stratford, E.; Francis James Warwick, 40, Vaughan Road, Loughborough, S.E.

University of Edinburgh. — The following are the candidates who have passed the second professional and final examinations. Those marked thus * have passed with distinction :—

A. M. Adams, M. S. P. Aganoor, N. E. Aldridge, J. H. L. Allott, M. Altounian, S. Arnold, E. H. Banister, J. Barrie, G. B. Batten, J. B. Bawden, T. W. Bell, D. Berry, *A. Bissett, J. A. Blair, F. M. Blumer, B.A.; T. Bonar, F. F. Bond, J. E. Bottomley, *P. Bowes, H. Bramwell, H. R. Bramwell, R. A. Brewis, *D. M. Brown, *R. M'D. Brown, T. A. Brown, S. B. Burns, J. M. Cadell, E. K. Campbell, *E. Carmichael, W. R. Carter, L. M. F. Christian, T. G. Churcher, R. L. Clark, D. Cloete, J. G. Cossins, R. S. Coulthard, A. H. Croucher, W. L. Cullen, A. S. Cumming, T. B. Darling, H. H. Davies, T. L. K. Davies, J. D. Davies, T. W. Dewar, *D. G. Donaldson, D. R. Dow, M.A.; T. Easton, M.A.; E. Eckersley, T. Edwards, H. S. Fairbank, J. E. A. Ferguson, J. H. Ferguson, T. Ferrier, G. Fisher, W. S. Flett, A. Fraser, T. Fraser, M.A.; T. A. W. Fulton, C. H. Gage-Brown, W. G. Galletly, D. J. Galloway, D. F. Gardiner, L. R. Gray, F. G. Greenbury, E. Greenough, B. Griffiths, C. D. G. Hailes, *W. W. Hall, J. R. Henderson, T. M. Hodgson, W. A. Holmes, T. A. F. Hood, *R. Howden, R. S. Hubbersty, Dirk de Vos Hugo, J. Hume, B. E. Iastrzebski, J. O. Jones, G. H. Kenyon, M. A Ker, D. O. Kerr, J. Kerr, W. V. M. Koch, D. Laing, W. Laing, C. A. Lane, *W. S. Lang, A. E. G. Langschmidt, C. N. Lee, A. W. M. Leicester, L. H. Le Merle, C. L. Lempriere, W. G. Little, M.A.; G. S. P. Loubser, W. W. R. Love, C. J. Macalister, B. F. P. M'Donald, A. G. Macdonald, W. C. M'Ewan, M.A.; J. M'Gibbon, A. Mac Gregor, D. MacGregor, M.A.; H. J. Mackay, W. B. Mackay, J. C. Mackenzie, *J. H. Mackenzie, M.A.; M. MacLaren, B.A.; A. Maclennan, J. M'Leod, B.A.; J. M'Myn, A. Macqueen, G. D. Malan, L. G. Mallam, A. Matheson, A. Menzies, W. J. van der Merwe, G. Michael, R. Mitchell, M.A.; D. Morgan, A. E. Morison, D. Mowat, W. J. Munro, B.A.; F. Murray, B.A.; B. H. Nicholson, J. Noble, F. B. O'Flaherty, *A. G. Paterson, M.A.; C. E. Paterson, *F. A. Pockley, J. M. S. Preston, E. F. T. Price, W. T. Prout, A. C. Purchas, T. R. Rait, *F. M. Reynolds, T. Rhodes, W. Richards, J. Rigg, A. L. F. Robertson, J. Robertson, J. C. Robertson, R. M. Robertson, A. J. T. Roux, J. Rutter, Y. S. Sanitwongse, T. S. Shaw. *F. H. Simmons, G. R. Smuts, W. Sneddon, J. S. Stephen, H. F. D. Stephens, S. H. A. Stephenson, *J. Stevens, M.A.; C. H. Stewart, B.Sc.; J. W. Stirling, J. Stuart, G. H. H. Symonds, J. C. Taylor, G. Thomson, R. S. Thornton, C. G. Thorp, J. Tod, Cecil G. Traill, George A. Tullis, J. W. O. Underhill, E. Walker, N. H. Walker, N. P. Walker, D. Wallace, T. A. Watson, S. F. Wernich, A. Westlake, R. H. A. Whitelocke, W. J. Will, *C. Wilson, A. B. Winder, J. E. Wolfhagen, J. C. Young, B.Sc.

The following is a list of candidates who have passed the second professional examination :—

W. A. Anderson, J. S. Archibald, J. W. Astles, A. G. Baschet, S. Beattie, C. N. Bensley, J. W. Black, R. Bone, W. F. Boycott, J. Brown, W. J. Cameron, C. Charleton, S. F. Clark, J. Cram, A. E. Curtis, D. N. P. Datta, J. W. Dawes, H. G. Dickman, A. Fisher, R. S. H. Freeborn, J. W. Gainer, J. Garvie, T. H. Gibson, A. E. Grant, J. W. Grant, A. E. L. Gray, D. M. Greig, A. C. Guthrie, S. P. Hallows, J. T. Harvey, F. W. Hennessy, J. R. Hill, J. J. Hoffman, R. E. Horsley, R. Howden, W. H. M. Ingham, H. Jamieson, J. P. Johnston, E. C. Kingdon, J. H. A. Laing, D. J. Lawson, E. L. Lees, *R. F. C. Leith, Æ. D. M. Macintyre, A. C. Mackenzie, C. J. R. M'Lean, R. H. Maclean, R. MacLelland, P. B. M'Nicol, C. C. Manifold, C. G. Matthew, *H. B. Melville, W. F. Menzies, D. M. Moir, *E. J. B. du Moulin, J. K. Murray, W. R. Nasmyth, W. B. Nisbet, E. S. Nutting, J. W. Pare, M. Paterson, T. J. Paton, J. H. Pringle, J. T. Richards, G. B. Ritchie, E. T. Roberts, F. C. Roberts, R. Robinson, A. M. Ross, J. R. H. Ross, D. W. Scotland, W. E. S. Scott, H. Scurfield, G. P. Smith, *J. W. Smith, R. Stewart, W. J. Thomas, F. C. Thorp, J. W. Travell, H. Ware, *C. H. Waters, A. B. Whitton, R. A. Wilson.

University of Glasgow.—The following candidates have passed the final professional examinations for M.B. and C.M. :—

Alexander G. Auld, Harry Bamber, John Beveridge, William T. Blakely, William Brown (Wigtown), William Brown (Kilmarnock), William M. Brown, John Innes Brownlee, George Clark, James Cowie, James Crawford, William Cullen, J. B. Cumming, John Cunningham, Henry E. N. Dobie, Robert Eaglesham, James D. Farquharson, James Findlay, David Finlay, Alexander Frew, Andrew B. Fulton, William Lewis Gray, Michael H. Greener, Henry Mason, Ernest Mackenzie, C. O. Hawthorne, James Hinshelwood, M.A., Alexander Jack, Hugh Kelly, Francis E. Kendall, Arthur G. Keogh, John A. Kerr, Matthew Killoch, Alexander M. Kinghorn, Alexander Kirkpatrick, Robert Livingstone, Hugh Logan, Duncan Marquis, W. Gray Marshall, M.A., Robert G. Miller, David Moffat, Archibald N. Montgomery, Andrew Murdoch, James William A. Murdoch, Benjamin W. MacArthur, Duncan Macartney, M.A., and William M'Creadie.

Royal College of Surgeons in Ireland.—At a meeting of the Court of Examiners, held on the 14th of July and following days, the undernamed gentlemen, having passed their final examinations for the Letters Testimonial, and taken the declaration and signed the roll, were admitted Licentiates of the College, viz. :—

Arthur J. Barlow, Henry T. Baylor, George Brown, William G. Connor, John J. A. Costello, Samuel A. Crotty, Robert Cross, George Davidson, Henry G. G. Day, Ulysses C. H. De Burgh, William Dillon, Joseph E. Dormer, Andrew A. Doyle, Alexander

T. Drake, Fitzwilliam Evans, Charles J. Falkner, Martin Fennelly, Richard H. J. Fetherston, Robert Gloster, William E. Grandy, John Hobbs, Samuel Hornock, William G. F. Johnston, Cornelius J. Kelly, Patrick J. Kiernan, Alexander D. La Touche, Edmund D. La Touche, Richard R. Leeper, Kenneth Mackay. Michael J. Magan, Barcroft Manly, Robert F. M'Ardle, Arthur R. F. M'Cutcheon, John J. M'Donnell, John M'Fadden, Arthur M'Gauran, John M'Grane, Henry V. M'Loughlin, William M'Manus, Hugh Morrison, Timothy A. Mulcahy, Ed. G. Newell, John J. Norton, James Oakly, Alfred Ross, James L. Rowlette, Francis H. Sinclair, Alfred J. Smith, James H. Stewart, Augustus J. O. W. Tabuteau, Hamilton J. Thornbury, Launcelot A. Whitcroft.

Twenty were stopped. At the examination held on the 30th June and following days for the first half of the Letters Testimonial, 74 candidates presented themselves, 48 of whom were stopped.

Victoria University, Manchester.—The following have satisfied the Examiners in the intermediate examination for the degree of M.B. :—

Division I.—F. C. Bury. Division II. (in alphabetical order)—J. M. Johnson, J. Kauffmann, and W. K. Wills.

The following have satisfied the Examiners in the preliminary examination in Science (Faculty of Medicine) :—

Division I.—G. Braide, W. A. Hooton, E. A. Shaw, and J. C. Thresh. Division II.—H. Merrall and H. Sidebotham.

Cholera Precautions in Dublin.—At a special meeting of the Municipal Council, held on Monday last, the following resolution was—after considerable discussion—finally adopted :—"Resolved, that in the event of the Local Government Board (for Ireland) deciding to constitute the Corporation sole authority to give effect to Clauses 149 and 150 of the Public Health (Ireland) Act, together with the provisions of the Epidemic and Infectious Diseases Act (1883), the Council hereby declares its willingness to accept the responsibility, and authorises the Public Health Committee to make suitable arrangements for the efficient discharge of the duties, subject to the proviso that the expenses of the execution and superintendence of such regulations shall be paid by the sanitary authority, which would be liable for the same under the Public Health (Ireland) Act, 1878, had such direction not been made by the Local Government Board." At a special meeting of the Board of Governors of Sir Patrick Drew's Hospital, Dublin, held on Friday, July 25th, the following resolutions were adopted :—"Resolved, that with a view of affording local accommodation in case of the arrival of cholera, a communication be made to the proper authorities suggesting the immediate erection of sheds on the hospital premises for the reception and treatment of male and female patients under the control of the governors of the hospital." "That arrangements (if possible) be at once made with such authorities (under the 149th and 155th Sections of the Public Health (Ireland) Act) for the provision of aid and accommodation, and to defray the expenses attendant on the reception of cholera patients." "That copies of these resolutions be forthwith forwarded to the Local Government Board (for Ireland), the Corporation of Dublin, and the Commissioners of Pembroke township, and that the Committee of Economy be instructed to carry out the details of the arrangements."

Sanitary Congress.—The arrangements for the Congress and Exhibition to be held under the auspices of the Sanitary Institute at Dublin, in the autumn, are approaching completion. The Exhibition will be opened from September 30th to October 18th, and the Congress will take place in Trinity College, where the Examination Hall and four rooms in the new buildings have been very kindly placed at the disposal of the Institute by the Board of Trinity College. The Royal Dublin Society have granted the use of their lecture theatre for the president's address, &c. The following papers have been promised. In Section I. (Sanitary Science and Preventive Medicine—special question, housing of the poor). Papers by Professor De Chaumont, Professor Cameron, Dr. Ringrose Atkins, Mr. Barrington Kennett, and Mr. E. Spencer. In Section II. (Engineering and Architecture—special question, disposal of sewage and town refuse). Papers by Mr. Percy Boulnois, Mr. W. Eassie, Mr. Henry Robinson, Mr. Parke Neville, Mr. J. Young, Mr. W. R. Maguire, and Mr. J. A. Fahie. In Section III. (Chemistry, Geology, and Meteorology—special question, effect of various water supplies and of site and climate on health). Papers by Professor Tichborne, Rev. M. H. Close, Dr. J. Byrne Power, and Professor Hull.

The Dwellings of the Poor.—The Royal Commission on the better housing of the poor, which is presided over by Sir Charles Dilke, will, it is understood, present an interim report to the autumn session of Parliament in October. This report will embody the evidence and the recommendations of the Commission, with regard to the metropolis and England and Wales generally, both in respect to the urban and rural populations. The Commission will afterwards proceed to take evidence concerning the state of matters in Scotland, and then with regard to the towns of Ireland.

Epidemic in France.—A despatch from Moussey, in the Department of the Vosges, states that an epidemic, supposed to be purple typhus, is raging there. Ten persons have succumbed and 30 others are said to have been attacked.

The Plague.—Dr. Batorsky, a surgeon attached to the Department for Foreign Affairs, has left St. Petersburgh for Bagdad, in order to join a medical board deputed to investigate the outbreak of plague in that district.

Small-pox in South Africa.—It is reported that small-pox is increasing to an alarming extent at the Diamond Fields.

"Dreadnought" Seamen's Hospital, Greenwich.—A quarterly general court of the governors was held on Friday last, at 39, Fenchurch Street, E.C., Joseph Moore, Esq., in the chair. Three hundred and ninety-six seamen had been admitted to the hospital as in-patients during the past quarter from British and Foreign ships, of which number 84 came from the Port of London, 34 from Liverpool, 25 from Glasgow, 13 from Hull, and 12 from Newcastle. In addition to the British seamen 124 sailors of different nationalities were benefited, including 24 from Norway, 19 from Sweden, 12 from Germany, 11 Fins, 5 from the United States, besides representatives from France, Holland, Russia, Arabia, and amongst the Colonial possessions of the Empire from Australia, Canada and the West Indies, while one patient is entered as "Born at sea." The committee reported that the system of drainage at the hospital, which had been in operation since the erection the building in 1763, was inadequate for the sanitary requirements of the present day, and that the engineer whom they had professionally consulted on the subject, reported it as being so radically defective that nothing short of its entire reconstruction would place the hospital in a safe sanitary condition. The works consequently to be undertaken were very extensive, and were estimated to cost 7,370*l*. They also said that while the drainage works were in progress they deemed it a favourable opportunity for enlarging the insufficient accommodation hitherto provided for divine worship. The present chapel (a converted ward) has at the best of times been but barely sufficient for the wants of the hospital, and now without doubt it is too small for its purpose. This is mainly due to the increased number of patients treated, and the committee in inviting contributions towards the drainage expenses, and for the erection of an entirely new chapel (estimated to cost 1,281*l*.) hope they are making ample provision, in both these respects, for many years to come.

The Fiske Prizes.—The *Boston Medical Journal* is of opinion that the subjects of the Fiske Prizes are not sufficiently made known. They were established by a Dr. Caleb Fiske, once President of the Rhode Island Medical Society, to which body the adjudication is entrusted. On more than one occasion they have been awarded to Englishmen. There are four prizes, of 200 dollars each, offered for 1885, viz. :—(1) Original Investigations in Household Hygiene. (2) The Present State of the Germ Theory of Disease. (3) Physiological and Pathological Effects of the Use of Tobacco. (4) Migraine—its Nature and Treatment. Essays (with mottoes written thereon, with sealed packets having the same mottoes on the outside, with their author's name and residence within) to be forwarded, post-free, to Charles W. Parsons, M.D., Secretary to the Trustees of the Fiske Fund, Providence, Rhode Island, on or before May 1st, 1885.

Foreign Graduates' Association.—Dr. W. C. Daniel, of Epsom, has been elected President for the ensuing year, *vice* Dr. H. J. Hardwicke, of Sheffield, who becomes a Vice-President. Dr. K. N. Macdonald, a former president, has also been elected vice-president, and Dr. J. J. Bailey, of Marple, Hon. Secretary. The Council consists of twelve London and Provincial foreign graduates.

At the Examination in Diseases of Women, held at the Hospital for Women, in July, the first prize was awarded to Mr. J. R. Jones, of University College Hospital, the second prize to Mr. Barber, of St. Bartholomew's Hospital.

New Eye Hospital at Birmingham.—On Thursday week Lady Leigh formally opened a new eye hospital, which has been erected in Edmund Street, Birmingham, and which will take the place of the old institution in Temple Row, which has long proved inadequate to meet the numerous demands made upon it. The cost of the new hospital and appliances is estimated at 20,000*l*.

Charitable Bequests.—The late Mr. James Carthew Quick, of 82, Marine Parade, Brighton, has bequeathed 1,000*l*. each to the London Hospital, Whitechapel, and the Sussex County Hospital, Brighton.

The Lunacy Laws.—In consequence of recent legal proceedings which have attracted public attention, Sir Henry Holland has placed before the Government a suggestion that reports, for presentation to Parliament, shall be called for from the secretaries of the different embassies as to the working of the lunacy laws on the Continent, and especially on the following points:—Whether there are private as well as public asylums; what are the checks against improper admission or detention of persons in an asylum; what supervision and inspection, if any, is exercised, by any public and recognised authority; and the nature and powers of such authority.

Post-Mortem Introduction of Arsenic into the Body.—The *Boston Medical Journal*, July 10th, states that experiments have been carried on in the chemical laboratory of the University of Michigan, with the view of determining whether or not white arsenic can be diffused through the body after it has been mixed with water and injected into the rectum or mouth after death; this having been the most important question in a murder case tried in Michigan recently. Drs. Vaughan and Dawson concluded from their experiments on dead bodies that arsenic is widely diffused through the body when introduced after death, and that, therefore, in a case of suspected arsenical poisoning, if arsenic had been introduced into the body after death, the finding the poison in the various organs would be no proof that the arsenic was introduced during life, and was the cause of death. Arsenical embalming fluids may, according to the above, be used as a means of covering up crime, and this fact should be borne in mind in cases of suspected poisoning by arsenic.

Observations on a Decapitated Head.—We transcribe from the *Revue Scientifique*, July 5th, the principal part of a paper by Dr. Petitgrand, giving an account of the observations he had the opportunity of making upon an Annamite who was decapitated, at Saigon, in 1875, an account characterised by the editor of the *Revue* as highly important, as furnishing the most precise evidence of the presence of consciousness after decapitation that exists. The man executed was a pirate of robust frame and brave demeanour, and M. Petitgrand concentrated his whole attention upon him. He was placed in a kneeling posture, strongly attached to a solid post in front of him, with the head and neck voluntarily and strongly flexed. The place for the blow having been marked with betel-juice, the head was struck off at one blow by means of a long sword having a broad blade,—the procedure to be properly carried out requiring great address on the part of the executioner, and much *sang-froid* on that of the culprit. When this is the case there is of course far less contusion and concussion of the spinal cord than with the guillotine; and, therefore, so far a greater possibility of an ulterior manifestation of the functions of the encephalon. During the preparations, Dr. Petitgrand never withdrew his eyes from the culprit, placed at two metres distance only, and with whom he more than once exchanged looks. The head fell within a metre and a half from him, without, as ordinarily, rolling away, and, the divided part of the neck resting on the sand, the hæmorrhage which ensued was very slight. At this instant he was startled at finding the eyes of the head steadily fixed on his own, and not believing that this could be an act of consciousness, he rapidly described a quarter of a circle around the head which lay at his feet, and saw plainly the eyes following this movement. He now returned to his former position but more slowly, and the eyes followed him for "a very short instant," and then suddenly ceased to do so. At this moment the face expressed manifest anguish, the poignant anguish of a person in a state of acute asphyxia. The mouth opened violently, as if to take a last gasp of respirable air, and the head, thus displaced in its equilibrium, rolled on its side. This contraction of the maxillary muscles was the last manifestation of life, a period of from fifteen to twenty seconds having elapsed since decapitation. From these facts Dr. Petitgrand draws these conclusions:—(1) That the head separated from the body is in possession of all its faculties as long as the hæmorrhage is restrained within certain limits, and that the proportion of oxygen dissolved in the blood is sufficient for the maintenance of the nervous function, that is for a short period, which, in any case, would not exceed half a minute. (2) That the repeated convulsive movements of the lower jaw, after the head has become detached—movements which, without doubt, have given rise to the expression, "biting the dust"—are nothing else than the habitual reflex movements of the face in acute asphyxia. These cannot be absent when the little blood contained in the decapitated head flows away or becomes disoxygenated; and are caused by the sensation (probably conscious) of the want of necessary oxygen in the blood remaining in the encephalon. On the present occasion Dr. Petitgrand had no opportunity of observing the trunk of this beheaded man; but he has had opportunities of observing it on other occasions, and has always noted the following circumstances. The head once detached, the trunk (the body being attached by cords to the post is unable to fall) suddenly assumes the vertical position, columns of arterial blood springing up a metre or more in height. This straightening of the trunk, and the jets of blood being simultaneous, are in fact related to each other as cause and effect; for at each new systole, manifested by the projection of a column of blood, the trunk is raised, to bend again immediately. The jets soon do not ascend to more than a few centimetres, and the movements of the trunk are reduced to mere oscillations. After from twelve to fifteen systoles, all the blood is evacuated and the trunk remains motionless, and as it were suspended to the post, which prevents it falling on the ground. Dr. Petitgrand has never noticed any elevation of the ribs or sinking of the epigastrium, or any other sign of an attempt at respiration. The heart seems to continue to live awhile its own proper life, as is shown by its violent systoles, which are capable of effecting the stretching of the trunk.

Female Circus-riders and Gymnasts.—Dr. S. E. Post, in an interesting letter to the *New York Medical Record*, for May 17, communicates the results of observations, which he had the opportunity of making during several weeks upon the leading women-performers of a circus. His attention was directed to the influence of their work on the general health, and on the menstrual and child-bearing functions. He found that the riding, jumping, and leaping did not influence pregnancy unfavourably. Temporary suppression of the menstrual fluid sometimes occurs during these exercises, and its duration tends to be prolonged; but an excessive loss was not found in any case. The non-existence of uterine disease could not certainly be ascertained; but it appeared probable, from the absence of pelvic discomfort and leucorrhœa, and from the excellent general health. Their faces did not exhibit any evidence of especial fatigue, and they all ate and slept well. Dr. Post furnishes particulars concerning five of these women: three being foremost riders, and two gymnasts. Their histories differed mainly in the fact that the gymnasts had early abortions without extraordinary cause, while the riders never miscarried, except as the result of a fall, their routine work not producing this effect. The routine life of

the gymnast obviously much favours the dislodgment and expulsion of the ovum at an early stage. But it must be observed that her costume furnishes much less facility for concealing pregnancy, and, therefore, a greater temptation for provoking abortion than is the case with the rider, who can exhibit throughout the eighth month without detection. The fact that pregnant women can undergo the violent exertion they have to sustain while in the ring, and yet bring forth healthy children at term, and suckle them, is most remarkable. The explanation in part lies in their having pursued this habit of life from childhood, the muscular attachments of the uterus being probably rendered unusually firm by the training that has been pursued. Menstruation, however, is more injuriously affected, dysmenorrhœa of some kind being the rule among these women. The menstrual discharge often becomes suppressed during performance, to appear afterwards in excess. The influence of the work on involution of the uterus seems good, for some of these women returned to their occupation in from four to six weeks after confinement, without injury. In some of these women the chest-development was very fine, measuring under the clothing 34, 36, and 38 inches in individuals weighing less than 130 lbs. With a superb bust curve, in none of them were the breasts large, the effect being obtained by the "ribbing out" of the thorax, which renders even a small breast prominent.

A Child with a Tail.—A correspondent of *Science*, June 6th, describes a tailed child which was recently born at Louisville. "We found" says one of a party which visited the child, "that it was a female negro child, eight weeks old, normally formed in all respects, except that slightly to the left of the median line, and about an inch above the lower end of the spine was a fleshy, pedunculated protuberance about 2½ inches long. At the base it measured 1¼ inch in circumference. A quarter of an inch from the base it was somewhat larger, and from thence it tapered gradually to a small blunt point. It closely resembled a pig's tail in shape, but showed no sign of bone or cartilage. The appendage had grown about a quarter of an inch since the child's birth. The parents are both normally formed. In Darwin's "Descent of Man," Vol. I., p. 28, he speaks of a similar case, and refers to the *Revue des Cours Scientifique*, 1867–68, p. 625. A more complete article is that by Dr. Max Bartels, in the *Archiv für Anthropologie* for 1880. He describes 21 cases of persons born with tails, most of these being fleshy protuberances like the one just described."

Dental Caries in Normandy.—Several departments in Normandy furnish a considerable number of rejections among the recruits drawn for military service. The Seine Inférieure for example, furnishes a mean of 50 per cent. of rejected conscripts. This singular fact in so wealthy a department, in which the population seems strong and prosperous, has excited the attention of Dr. Chervin. He finds that the most frequent malady giving rise to rejection, after cases of "general weakness," which preponderate, is dental caries, which, taking the department altogether, furnishes 15 per cent. If the different cantons in the department are examined, a great difference among them is discovered, varying from 80 per 1,000 the lowest, to 229 the highest number. Pursuing his investigation of the department for 20 years, M. Chervin arrives at the conclusion that race is the chief cause of the predominance of caries. Examining one of the ethnic elements which is the most persistent, and which furnishes most information on the subject of race-stature, he finds that the department is inhabited by two different races, the shorter in the east, and the taller in the west. In the population of the higher stature, dental caries is far more frequent than in that of the lower stature; and this fact is not peculiar to the Seine Inférieure, but is observed also in other departments.

APPOINTMENTS.

Boulter, Walter Ernest, M.R.C.S., Eng., L.R.C.P., and L.M., Edin.—Medical Officer to the Infirmary and the Workhouse, Woolwich Union, *vice* Dr. Riee, resigned.

Emmison, Luther, L.F.P. & S., Glas., L.S.A., Lond.—Medical Officer to the Haxey District, Gainsborough Union.

Lediard, H. A.—Surgeon to H. M. Prison, Carlisle, *vice* J. A. Macdougall, resigned.

VACANCIES.

Battle Union.—Medical Officer to the Sixth District, in succession to Mr. Roger Duke, resigned. Area, 11,282 acres. Population, 2,697. Salary, £80 per annum.

Conway Union.—Medical Officer to the Conway District and the Workhouse, in succession to Dr. Robert Jones, resigned. Area, 18,475 acres. Population, 6,702. Salary, £80 per annum. Salary for Workhouse, £35 per annum.

Lancaster Infirmary and Dispensary.—House Surgeon. (*For particulars see Advertisement.*)

Queen's College, Birmingham.—Medical Tutor. Salary, £100 per annum. Application by August 7th.

West London Hospital, Hammersmith, W.—Surgeon Dentist. Application by August 21st.

DEATHS.

Bell, Alexander Montgomerie, M.D., F.R.C.S.E., at 43, Manor Place, Edinburgh, on July 28.

Riordan, Thomas Travers, M.D., Formerly of Castleconnell, county Limerick, at Marksbury, Somerset, on July 10, aged 80 years.

NOTES, QUERIES, AND REPLIES.

CHOLERA AND ITS TREATMENT.

[TO THE EDITOR OF THE MEDICAL TIMES.]

Sir,—The cholera is making sad havoc in France, and may any day break out in this country.

There are many young medical gentlemen who will be perplexed to know as to the treatment.

In 1848 and 1849 many different modes of treatment were tried, and notwithstanding all the researches that have been made since, there is no fixed plan of treatment adopted by the Profession. Many eminent medical men have placed their valuable lives in danger, and worked hard to find a remedy; but the only means known of preventing the disease and checking it are those adopted by Sir Guyer Hunter and his Staff in Egypt. Isolation and cleanliness, pure air and good water, and especially early medical attention and good nursing. We have been taught by sad experience that impure water and filth favour all epidemic, endemic, and contagious diseases, and increase their virulence.

During the epidemic of 1849 I was requested to take charge of those suffering from cholera and diarrhœa in the townships of Westhoughton, Over Hulton and Lostock. These townships were very free from stagnant and filthy water, and although I was kept busy night and day for six weeks, I had only two deaths from cholera; whereas in the adjoining township of Hindley, the water was very deficient, and a brook which *took in the sewage* from houses on both sides passed through the village. The disease in this village was very virulent, and many deaths took place. Isolated cases occurred near this spot. A committee of gentlemen sat here night and day to give out blankets, food, and other necessaries. Five medical men were stationed in the village. Isolated cases of death took place in the immediate neighbourhood of the village. Other cases were treated successfully in the more healthy portions of the township where pure air, good water and proper attention could be had. I found the most favourable symptom was the secretion of bile in the motions, and I adopted with success the calomel and opium treatment in doses of two grains to one grain, or two grains to half a grain for an adult, together with a saline mixture. Properly prepared sago-gruel and brandy, toast water, coffee or cocoa, or milk and water in equal parts, boiled and allowed to go cool. Hygiene is too much neglected. The food and drink are quite as important, and require quite as much attention as the medicine, also the immediate removal of all discharges. I believe I was instrumental in saving many lives by advice as to preparing and administering food and drink. I am convinced that good nursing is quite as necessary in cholera as medicine. I have seen patients almost pulseless for hours, the legs and arms cold blue with violent cramps, who after many hours rubbing with warm flannels, and giving gruel and brandy in small quantities, recovered, and some are now living who were in that state in 1849. It has been stated that many of the deaths which take place at Toulon, are from the subsequent fever. No doubt some of these cases are attributable to giving opium without calomel, thus checking the natural secretion from the liver. The acid treatment recommended by the College of Physicians of Dublin, was used in many cases in 1849 by some of my colleagues, but was abandoned and the treatment adopted by me resorted to with greater success.

I am, Sir, yours &c.,

Johnson Martin.

Hope Gate, Bolton,
July 22nd, 1884.

The Provident Surgical Appliance Society.—The recent Floral Fête and Fair, held at the Duke of Wellington's Riding School, in aid of the Provident Surgical Appliance Society for the Relief of the Crippled Poor, has done much to make the useful institution more widely known. The fête was uot so well attended as it deserved to be, considering the many attractions provided, including the leading dramatic and musical artistes, but we are glad to learn it was a success. Mrs. John Wood, the celebrated actress, purchased one of the Beaufort artificial legs, which this society provides, and gave it to the Surgeon on the understanding that it was to be applied to the first deserving case. The leg was exhibited at the fête with Mrs. John Wood's card attached to it. The society carries on its work at 28, Finsbury Circus.

COMMUNICATIONS RECEIVED—

Mr. CUMBERBATCH, London; Mr. LAWSON TAIT, Birmingham; Sir SPENCER WELLS, Bart., London; Mr. JORDAN LLOYD, Birmingham; Mr. C. LOWTHER KEMP, London; THE SECRETARY OF THE FOREIGN GRADUATES' ASSOCIATION, Sheffield; THE REGISTRAR-GENERAL, Edinburgh; THE GENERAL HOSPITAL, Vienna; THE SECRETARY OF THE LOCAL GOVERNMENT BOARD, London; THE EXPRESS DAIRY COMPANY, London; Dr. LEDIARD, Carlisle; Dr. BANHAM, Sheffield; Mr. MITCHELL BANKS, Liverpool; Mrs. LANKESTER, London; Dr. CLIFFORD BEALE, London; THE SANITARY COMMISSIONER FOR THE PUNJAB, Lahore; OUR DUBLIN CORRESPONDENT; OUR EDINBURGH CORRESPONDENT; THE SECRETARY OF THE SANITARY INSTITUTE OF GREAT BRITAIN, London; Mr. THOS. ON THE MEDICAL CHARGE OF THE POOR.[1]

By TIMOTHY HOLMES, M.A., F.R.C.S.,

Surgeon to St. George's Hospital, &c.

GENTLEMEN,—Having been honoured by an invitation from your secretary to give this evening's address, I thought it better to choose some subject which, while it would interest us all, whether consulting or domestic practitioners, would be a little away from the ordinary round of purely medical topics. I was inclined, also, to bring my present subject—"The Medical Charge of the London Poor"—under your notice by the fact that I have long been associated in the movement for founding provident dispensaries, and for reforming the out-patient departments of our hospitals and our dispensaries, and my opinions on these subjects have not always been accurately understood—very probably, by my own fault.

The subject is an enormous one. To treat it adequately would require far more than the time at my disposal; and it could not be treated with any approach to fulness without a free discussion in which opposite ideas could be expressed, and long-standing prejudices combatted. There is no possibility of arriving at any satisfactory solution of the question without some such discussion, in which both classes of practitioners, the family and the hospital medical men, shall take part.

I hardly think it necessary to spend time in proving that the present system of medical attendance on the London poor is bad. No one that I have met with denies this; and I fear that instead of getting better it is getting worse. The chief abuses of which we complain are the inordinate numbers of the patients; the absence of all care in the selection both of patients and of cases for the out-patient departments; the disappointment and detriment which is caused to the out-patients by hasty routine treatment; and the damage to private practitioners caused by the competition of gratuitous institutions. The steps recently taken (and especially the opening of a 3*d.* pay department by one of our chief hospitals) all tend to aggravate every one of these evils; yet, as far as I see, the medical profession make no stir in a matter so vitally important both to the public and themselves, while ready to embark in various medico-political schemes and speculations which, whether right or wrong, are of infinitely minor importance.

It is on this aspect of the question that I want you to think seriously this evening. I have often been represented as urging out-patient reform or provident dispensaries as a panacea for the abuses of which we have abundant reason to complain. I hope I am not so foolish. I have done my best to recommend to the profession such steps as I thought most advisable under present circumstances; but I know as well as any one else that a long pre-existing and gradually increasing

[1] The Cavendish Lecture. Delivered before the West London Medico-Chirurgical Society, on July 11th, 1884.

system like the present can only be gradually amended; and I hold most firmly that it never will be amended until the general opinion of the medical profession is strongly enlisted in its reform, and until the great body of the general practitioners of the kingdom are prepared to take personal trouble in effecting its reform.

The poor of London under medical care naturally divide themselves into three classes: Those under the Poor-law; the out-patients of the various gratuitous hospitals and dispensaries; and those who pay for medical attendance, members of clubs or otherwise.

In all these kinds of medical attendance I contend that there are defects which act injuriously both to the patients and to their medical attendants; and I further contend that there is no chance of the remedy of these defects except by the vigorous and united action of the medical profession, an action which again necessitates an enlightenment of the public sentiment of the profession on the subject. So long as we go on under the assumption that some change in the regulation of hospitals, or some Act of Parliament, or some plan devised by a society or an individual, will remedy the evils of the present system, so long the system will continue and its evils will increase. It grew up gradually in consequence of the negligent action of the profession; its reform can only be expected to come about gradually, as a consequence of our awakening to a sense of its evils and applying those gradual remedies which alone can effect a change in so inveterate an abuse.

Let us not overlook the fact that the first great opportunity for the introduction of a sounder state of things was given by the enactment of Gathorne Hardy's Act, which established efficient Poor-law hospitals in all parts of the metropolis and out-patient dispensaries, which, if not equally efficient, can at any time be made so. Before that period, it might fairly be argued that the medical charge of the poorest class of our population was almost avowedly thrown by the State on the charity of the medical profession. Now the condition of things is almost reversed. The State has made arrangements for the supply of medical assistance to all persons of the lowest class who require it, and it is the medical profession through whose persistence in miscalled charity it is in a great measure due that these arrangements are not completed. It must be recollected that the acceptance of medical relief from the Poor-law institutions does not make a man a pauper. The existence, then, of these institutions takes away all pretence of actual necessity for the numerous charitable foundations which, under the name of free dispensaries and institutions for special classes of persons or of maladies, swarm in every part of the town, to the impoverishment of the great subscription hospitals, but to the benefit, no doubt, of many persons besides those who resort to them as patients.

My first contention, then, is that a great improvement would be at once made in the medical care of the poor if all possible attention were given to render the existing Poor-law dispensaries more efficient for their purpose. At present, if I am not mistaken, they are considered by the poor as much inferior to the out-patient departments of hospitals and to the free dispensaries as medical institutions, and are chiefly resorted to with a view to get the doles of food, &c., which the Poor-law medical officers are allowed to prescribe. But, of course, in order to their being brought into full use, they must be made thoroughly efficient in all respects as medical institutions, and we must face the question whether the view which I have above attributed to the poor of the medical inferiority of these dispensaries to the out-patient departments of hospitals is true or no. Now I am strongly impressed with a view of the Poor-law medical service which, if it is not true, is at any rate widely prevalent, and which is so simple that it can easily be refuted by facts if it be erroneous. I mean that it is so underpaid that it cannot be efficiently served. The answer which the public authorities would give to any such assertion is a simple one, and one which, from their point of view, is conclusive, viz., that they have no difficulty in obtaining qualified candidates at the rates which they fix, and therefore are not justified in wasting the money of the ratepayers by giving more. And it is perhaps hopeless to expect any other answer from them. Is it any less hopeless to say that the common opinion of the profession ought to prevent men from applying for appointments which are inadequately paid, and which are only sought for as a means of keeping some one else out of the district or for some other indirect object? I do not know; but this I am sure of, that the main reason why so enormous a weight of unpaid labour is saddled on the medical profession is the existence in that profession of so large a number of persons always ready in vulgar phrase to "undersell" their competitors. Meanwhile, in default of such a healthy corporate feeling, or in expectation of its growth, can nothing be done by the great corporations of the profession? I am amused to see at the present time the excitement in the medical journals and in public about giving the members of the profession votes for representatives in the Medical Council, votes for the election of the President of the College of Surgeons, a share in the management of the College, &c. What practical good to any one of us would the obtaining of any or all these objects be? In homely phrase, who would be a penny the better for them? But if we could make either College an organ through which the general body of its members might approach the Government on public questions, such as that under discussion, with some prospect of negotiating on fair terms, it would be a matter of direct importance to every practitioner to obtain adequate representation in that College, and the College itself might obtain an influence over its members far beyond what it now exercises, limited as that is by all sorts of formalities, and hardly efficient even for the repression of the grossest forms of charlatanism. I would commend this hint to our medical politicians, and pass away from this first part of my subject with the mere assertion that the first step, or the most essential condition, of reform in the medical care of the London poor is the completion of the Poor-law dispensary system; and that this is intimately connected with the reform of the whole system of electing, paying, and regulating the medical service of the Poor-law.

Our next topic is one on which so much has been written and said that it is unnecessary for me to discuss it as if it were new to any one here. Large figures have been produced to state the enormous numbers of persons who are in attendance on our hospital out-patient departments and dispensaries. These figures have been questioned, though never disproved; but I do not care to go into such a barren dispute. No one who knows anything about it, certainly no one who has been an officer of one of these institutions, can deny either of these two assertions—that the out-patients are far more in number than can possibly be fairly attended to in the time, and what is perhaps even more important, that a very large proportion of them are suffering from affections which cannot be cured by the method employed of giving them a bottle of physic and sending them away in the smallest number of seconds possible. To remedy these evils, the plan I have suggested is one to which I invite your serious attention. It is intended to compass three main objects:—1. To limit the number to a point at which each individual can be fairly attended to by the appointed officer. 2. To direct the out-patient department to its proper function—that of giving advice in cases likely to derive benefit from that advice, instead of wasting its energies in dealing out medicine to a miscellaneous crowd, half of whom probably either do not take the physic or do not get any good from it. And 3. To

put the out-patient department in its proper place as one of the main engines of teaching medicine to the students.

In the first place, I would abolish all the existing free dispensaries, or convert them into provident dispensaries. They were founded before the Poor-law improvements already alluded to, and these have rendered them now quite superfluous. The out-patient departments ought then to be consultative merely, except for those who would have been in-patients of the hospital. And no one should be admitted to consultation unless sent by some medical authority in the neighbourhood of, or affiliated to, the hospital. Such medical authorities would be the provident dispensaries and medical men of the district, and they might attend the consultation. The numbers would of course be limited, and the letters would be obtained previously.

I submitted this suggestion to a meeting of the Hospitals Association at which I was unluckily not able to be present, and was surprised to see afterwards that it was criticised as intended to abolish out-patient practice. On the contrary, it would render such practice far more effective both for the cure of the patient and the instruction of the student. We may usefully take a lesson in this particular from the Scotch hospitals. In Edinburgh the foolish system (or no system) which has grown up in London of late years has no existence; but it is a regular part of the visit of the physician or surgeon to give an out-patient consultation after he has seen his in-patients, and it is, to the student, one of the most useful parts of the visit. An hour spent in listening to such consultations would do more towards teaching a student the ordinary routine of professional business than a month spent in watching a jaded medical officer scratching prescriptions or letters in hot haste on successive bits of paper and struggling to get rid of patients whose cases he has no time to study, far less to describe.

Another criticism on this scheme comes from certain hospital medical officers who think that it would diminish the utility of the out-patient department as a supply of cases for the wards. This I believe is an entire mistake. If the out-patient department is limited to consultations there would be no temptation to the dispensary officers or private practitioners to send their chronic cases to the hospitals, and surely out of the interesting or obstinate affections requiring consultation more valuable cases could be selected for admission than from the present higgledy-piggledy.

The other objection, that the above plan would limit the opportunities of the hospital out-patient officers for observing the effects of treatment is met by the consideration that they have all the former in-patients to treat, and can thus by concert with their seniors obtain as many examples of any disease which they may wish to study as they may desire. Besides, there is no reason why the effects of the treatment suggested to any dispensary or private patient should not be verified as often as is judged necessary. The advice given at the out-patient consultation might easily include the recommendation, so often given to a private patient, to come again at a certain date in order to observe the effects of the treatment suggested.

But the limitation of the numbers of out-patients is a primary condition of any really efficient treatment or teaching, and this diminution cannot be effected unless there are other institutions to take the place of the free dispensaries which are to be abolished, and the curtailed out-patient departments. As I have said, an enlarged and reconstituted Poor-law department will do this to some extent. But to undertake the medical charge of all these vast crowds at the public expense would be to substitute a worse evil for that which now exists. Most of them are able, perfectly, to pay for themselves, under the provident system, and most of them besides are suffering from ailments which can only be treated by domestic medical care, not by the hospital prescription and physic bottle, and it is here that the system of provident dispensaries and clubs comes in, and to some system of this kind I am sure we must come at last. A provident dispensary is really only a sick club; but it has the great advantage over an ordinary club that it can be made part of a large system, extending over the whole country (if the scheme succeeds), so that a member would not lose his former contributions by change of domicile, but would register as a member of the nearest branch which he might find in his new home. During the many years I have been connected with this subject I have not yet heard any better plan proposed. But I am by no means a fanatic on the point, nor blind to the defects of the scheme which has been put forth by the Society with which I am myself connected. Its main defects (I speak of those which are avoidable defects) are two, viz.: that the fees are too low, and that there are no certain means of keeping out persons whose income is too high. Let me not be thought wanting in courtesy if I say that the first defect is the fault of the medical profession itself. We could have fixed higher fees, but for two objections that seemed to us unanswerable—first, that these fees are already as high as those paid by the clubs whose members we invite to join; and second, that one of the great difficulties which provident dispensaries have to face is that they are sure to be undersold by the neighbouring medical men. This applies even to present rates. When medical men equal to all appearance in titles and standing to the officers of the provident dispensary will give medicine and advice for 6*d.*, and are not deterred by any medical opinion from starting sham provident dispensaries of their own, it is evident that we cannot fix such fees as I in my own opinion would judge satisfactory. Here, as in the case of Poor-law appointments, the only effectual aid which can be given must come from the profession itself.

With regard to the absence of a preliminary inquiry before admission as a member, it is in my opinion a matter of slight consequence. No working population, in the present day, would tolerate an enquiry that would really be effectual, and as we invite the great friendly societies to join in the movement, it is clear that no enquiry into the circumstances of those already members could be instituted. But the matter is really of no great importance. Flagrant abuses can be remedied by complaint to the Committee of the dispensary (of which the medical officers are members), and if a few persons thus obtain admission into a dispensary who ought to be private patients, the price is a small one to pay for the certainty of a fixed, though moderate, income without bad debts or cost of collection out of a class who now pay nothing.

Anyhow, we have done our best to start a system under which we hoped to improve the medical care of the poor, and at the same time to benefit the medical practitioners. Our success up to the present time has not corresponded with our hopes, and this I think depends on two main causes, the competition of gratuitous institutions and the indifference or hostility of the bulk of the medical profession to our scheme. Perhaps the two may be reduced to one, for I think if the medical profession were heartily in favour of the scheme they would soon find means to enforce a reform of the gratuitous institutions.

And this it is which induces me to avail myself of this opportunity of bringing the matter before you to-night. If private practitioners were satisfied with our hospital and dispensary system as it is, there would be no more to be said; but you meet no one who thinks that it is not in want of reform; if a better scheme were anywhere proposed, I for one am in no way bigoted to my own, but I have never met with even any other scheme better

or worse, which has been practically thought out, and put in working order. And really the matter presses. Lately we have seen with amazement a great hospital (Guy's) doing, I presume, under high legal sanction, that which we would consider disgraceful if done by a struggling young medical speculator, I mean offering advice and medicine to all and sundry for threepence. This strange proceeding has been still more strangely represented in some quarters as a development of the provident principle. Now, it cannot be too clearly understood or too frequently repeated, that the essence of the provident principle is to induce a man to make provision *in health* for the sickness which is sure some day to fall upon him, and such provision as will give a reasonable remuneration to his medical attendant. If this be so, I need hardly say that a plan which says to the poor man "take no thought for the day of sickness, for when it comes you may surely hope to have 3*d.* in your pocket, and this is all that the authorities of Guy's Hospital think the opinion of their medical men and their own medicine is worth," is even more destructive of providence than the gratuitous plan; since it gives the patient the satisfaction of paying for what he has, and therefore encourages people to apply who know they are not objects of charity. You and I know that the price charged is below the value of the article; but I doubt much whether the patients think so. The plan if it became universal would no doubt do more than anything else to perpetuate all the evils of the present system in their most aggravated form. It appears to me, as an ignorant layman, directly contrary to the eleemosynary principle on which the hospital was founded, and which its Act of Parliament must express, and it deserves, I think, the strongest disapproval and the most active opposition that the profession is capable of giving to it.

The same opinion, I am afraid, must be expressed on the admission of paying patients into hospitals, as now practised at Guy's and St. Thomas's. I have always asserted the necessity of pay hospitals in London; but we must recollect that there are two classes of hospitals in this city, those which, like the one in which we are now assembled, are founded for the cure of the sick only, and those which also undertake the function of teaching medicine. I am myself disposed to reckon the latter function as even superior in public importance to the former. At any rate it is a most important matter, and the present supply of material for clinical teaching is by no means too great for its purpose, more particularly in the hospitals connected with our largest schools. To withdraw any part of the existing beds from clinical instruction, and thus to turn a part of the hospital into a sort of sick hotel, is, in my opinion, a distinct breach of trust. It is true that the scheme is represented at both hospitals as only a temporary and experimental one, but such experiments require most jealous watching; and here, again, the profession should make its voice heard, and should insist that no such innovations as those which I have mentioned should be introduced at our great hospitals without the sanction of the medical staff, and, I think, without consultation with other hospitals. The newly founded Hospitals Association will, if successful, furnish a ready means by which such important public topics can be ventilated; and I hope that it will soon excite the attention and secure the co-operation of medical officers and governors of all the hospitals in London. The necessity for some common action can hardly be denied in the face of changes so radical and so dangerous being made without, so far as we know, any attempt to ascertain the feeling of the profession on the question of their desirability. But I must not detain you longer; my paper will have amply answered its purpose if it has convinced you that the medical care of the poor of London is at present very defective, that many of its defects are matters of urgent importance to ourselves, and that for their reform we must look not to the action of other persons, or of public authorities, but to our own personal vigilance, and our own personal efforts.

VICTORIA AND TASMANIA AS RESORTS FOR CONSUMPTIVES AND PERSONS AFFLICTED WITH LUNG DISEASE.

By J. W. BARRETT, M.B. (Melbourne University.)
Demonstrator of Physiology in King's College, London.

The number of persons suffering from lung disease (chiefly phthisis) who are sent to the colonies for the benefit of their health is and has been for some time past on the increase.

The results ensuing are exceedingly distressing in the main, not so much from any fault of the climate, or rather climates (for there are many in Australia), as from an absence of information on the part of the invalids and their advisers as to the place to go to, and the occupation to be followed when they reach it.

Seeing so many lives, as I believe, sacrificed in this way, I have endeavoured in this paper to give briefly and accurately the necessary information, for the benefit of patients ordered to that country.

Taking, then, as the climate required for persons suffering from lung disease *one not liable to sudden changes; equable to a high degree; not necessarily hot or cold, but preferably temperate*, it remains to be seen to what extent these considerations are satisfied by any of the numerous Australian climates.

For this purpose a brief allusion to geographical and meteorological conditions is necessary.

Of those Colonies which are to the north of the Victorian part of the river Murray, which lies between latitude 36° S. and 34° S., little need be said; for although the inland climates are equable, they are altogether too hot during the long summer to be desirable residences for delicate people. The heat, however, though intense, is throughout almost the whole of Australia very dry, and free evaporation is allowed, otherwise it would be unbearable.

It will then be necessary only to consider the climates of Victoria, Tasmania, and New Zealand, which are all south of the 34th parallel of latitude. Of the last named colony, the information I possess is not based on personal experience, but accounts tend to show that the climate is rather similar to that of Great Britain, and if that be so, it is certainly not a desirable residence for this class of invalids.

Victoria, situated as it is between the 34th and 39th parallels of latitude, possesses unique geographical and meteorological characters. It is the most southern part of the Australian continent, and is irregularly oval in shape, the long dimension running from east to west. It is bounded on the north by a large river, the Murray, and on the south by the Southern Ocean, and is completely divided by a chain of mountains into a northern and a southern area. The northern area, that situated between this great dividing range and the Murray, is practically a wooded plain, traversed by great rivers which run to the Murray. The southern area, that between the dividing range and the ocean, is an irregular slope to the sea.

Now there is a constant heating of the interior of Australia by the sun, and as the ocean stretches from the southern coast to the South Pole in almost unbroken extent, it is easily understood why southerly winds prevail almost constantly along this coast.

These winds are laden with water, which is deposited on the southern area, and on the dividing range, whilst but little reaches the northern area, which is comparatively dry. From time to time, however, either from compensatory or cyclonic causes, fierce northerly winds prevail, blowing therefore from the land to sea. These hot winds are of excessive temperature, and correspond probably to the sirocco. During their continuance, from one to five days, the evaporation is enormous, but sooner or later the cool southerly wind rushes in, and a fall of temperature of as much as 50° Fahr. occurs in a few hours, whilst along the line of neutralisation, rain is often deposited in a tropical manner.

and often damp. *The northern*, equable and dry; in fact, to agriculturists unpleasantly so.

It will then be seen that the one climate is the exact antithesis of the other. In the southern I have known the temperature in the sun fall from 140° Fahr. to 90° Fahr. in two hours. It need hardly be added that such changes usually occur in the summer, when people are wearing light summer clothes, so that the results to them are intensified. Melbourne, which is in the southern climate, corresponds in mean temperature to Nice and Mentone, but in no other climatic conditions is there much correspondence.

In this southern area, and on the range, live the

Sketch Map of Victoria.
The dotted circle shows the limits of the region suitable for consumptive patients.

But this line of neutralisation is neither mathematical nor fixed, and is a broad area which travels from the sea to the range with some velocity, *but it rarely or never crosses the range.*

Thus in Victoria are two distinct climates. *The southern*, variable in the extreme, especially in summer

greater part of the population of Victoria in the cities of Melbourne (population 300,000), Ballarat (population 40,000), Geelong (population 12,000), and other smaller towns with districts. The only city in the northern area is Sandhurst (population 36,000). But there is a large population on the plain,

*

particularly along the Goulburn River, in the so-called Goulburn Valley; Shepparton, Mooroopna, Murchison, Numurkah, and Echuca being towns so situated. But of all the cities in the southern area, none experience such sudden changes as Melbourne, and it will therefore be of use to contrast the relative mortality from phthisis in Melbourne and in the rest of the colony, of which the total population is 800,000.

The Government statist, Mr. Hayter, has been kind enough to furnish me with the following returns, which give *the necessary information.*

Deaths from Phthisis per 10,000 Persons Living In and Outside Melbourne 1861–82.

Year.	Melbourne.	Extra Metropolitan Districts.
1861	23·44	10·63
1862	24·64	8·71
1863	23·71	8·79
1864	20·08	8·70
1865	22·11	8·57
1866	20·42	9·53
1867	21·56	8·87
1868	20·83	7·63
1869	23·87	8·83
1870	22·49	8·56
1871	22·08	7·20
1872	18·69	8·62
1873	20·51	8·77
1874	22·04	8·94
1875	21·46	9·25
1876	22·46	8·28
1877	22·74	9·29
1878	22·62	9·63
1879	21·77	8·45
1880	23·95	8·92
1881	22·71	9·45
1882	23·09	10·03
Means ...	22·15	8·88

That is, the mean mortality from phthisis in Melbourne is 22·15, in the rest of Victoria 8·88.

It has been urged that importations from abroad have swelled the list. But the results are too uniform to be affected by such a comparatively small and variable element. So that evidence from this source is strong as to the influence of the climate of Melbourne in producing phthisis, and in assisting its progress when present, probably by promoting pneumonic attacks. It may be of interest to notice also that phthisis in Victoria is actually increasing amongst males from 20 to 55 years of age, although their numbers have decreased thus—

Year.	Males Living between 20 and 55 years of age.	Deaths.
1861	178,695	337
1871	174,076	384
1881	154,290	433

In England and Wales the death-rate from phthisis from 1866 to 1880 was 22·81 per 10,000 persons living, and is therefore nearly the same as that in Melbourne, but very much greater than that of the rest of Victoria, and, judging from my own experience, infinitely greater than that in the northern area of Victoria.

Further, the death-rate from phthisis in Melbourne is much higher than that in any of the other Australian colonies. But the death-rate from phthisis in the other parts of Victoria is less than the total results of any other colony, save New Zealand, thus—

	Mean No. of Deaths from Phthisis per 10,000 Persons Living.
Melbourne	22·15
Rest of Victoria..	8·88
South Australia..	9·73
New Zealand	8·48
Tasmania	10·21
New South Wales	10·31
Queensland	12·48

All these figures then prove more or less conclusively that the climate of Melbourne has a powerful influence in producing phthisis, and conversely that the climate of the extra-metropolitan districts have a less powerful influence.

The death-rate from phthisis in the northern area has never yet been obtained, but, as has been shown, even when combined with part of that of the southern area (extra-metropolitan) it is only 8·88. If alone it would be in all probability very much smaller, and it seems to me to be in every respect a suitable and desirable climate for consumptives, in fact to all appearance the most perfect existing.

Climate of Tasmania.—Tasmania is an island situated about 250 miles south of Melbourne. It is smaller than Ireland and almost uniformly mountainous. Whilst the climate is warm during parts of the year, still, owing to its situation, the hot winds and the sudden changes which are characteristic of the climate of Melbourne never occur. But, on the other hand, in winter the climate is decidedly cold, and snow, which is quite unknown in Melbourne, falls frequently. Whilst the summer is equable and in every way adapted for consumptives, the winter is decidedly unsuited.

Tasmania, in fact, possesses a bracing climate, better adapted for Indian invalids than any other class, and a sanatorium for soldiers of the Indian army has been established there. The mildness and beauty of the summer induce the Melbourne people to flock over in thousands during the height of the Melbourne summer.

From this sketch it will be seen that all evidence tends to show that the climate of Melbourne is favourable, not only to the production, but to the fatal termination of phthisis cases, and that the most suitable climate for persons affected with lung complaint is that of the northern area of Victoria for the whole year or of Tasmania for the summer.

The low rate of mortality from phthisis in the other colonies simply shows that their climates do not tend to produce phthisis to the same extent that the Melbourne climate does, but it does not follow that they are equally suitable for such sufferers as that of the northern area of Victoria. And, as a matter of fact, they are not; north of about the 35th parallel the temperature is very great and the climate is very trying.

The first part of the question may be regarded as answered, viz., a determination of the most suitable place of resort.

The second, as to the occupation to be followed, can be very shortly and definitely stated.

It is a very great mistake (where possible to avoid it) to exchange sedentary life in England for a similar one in Victoria. The object should be to seek manual or outdoor employment in one of their very varied forms on the sheep or cattle stations.

Such employment is easily forthcoming to the willing, and is both beneficial and agreeable.

The influence on phthisical patients of some mild but purposive occupation is too well known to require comment, and this found is doubly beneficial.

If the summer should prove too severe for an

invalid, he can in 36 hours reach Tasmania and stay there till the heat of midsummer has passed.

It cannot be too strongly insisted that no patients should be sent out who are suffering from advanced phthisis ; they should remain near home. It is for patients in the early stages that the climate of the northern area holds out such advantages.

To recapitulate. The following advice should be given to patients in the early stage of phthisis who wish to try the climate of the colonies of Australia.

(1) That they should, if possible, go out by the fastest and best equipped steamers.

(2) That they should go to Melbourne and at once travel north of the Dividing Range to such places as Sandhurst or anywhere in the Valleys of the Goulburn or Murray.

(3) That they should obtain outdoor employment on a sheep or cattle station, or some similar place.

(4) That, should the summer try them, and the practice of midday rest fail to relieve, they should go to Tasmania for January and February.

That, however, in all cases they must remember that their place of safety lies north of the Great Dividing Range.

POSTURES IN SCHOOL: THEIR INFLUENCE UPON PHYSICAL DEVELOPMENT.[1]

By NOBLE SMITH, F.R.C.S., Ed.

It is an important fact that a large number of individuals become deformed during their growth. In the streets, in schools, and in every public gathering of people we may observe instances of such occurrence. Doubtless some of these deformities may be produced by accidents and by disease, but posture has considerable influence as an exciting cause, and even strong children may grow up crookedly if kept for long periods of time in bad positions. The formation of the skeleton favours the production of deformity when constrained postures are maintained for long periods. The skeleton, although a framework, is unlike the framework of a house or ship, because the latter is a fixture in itself, whereas the former can be moved, one bone upon another, such movement being limited by ligaments, which bind the bones together, and by the muscles. The human framework thus constructed would allow the body to collapse were not the muscles ever ready to control its action, and to maintain its varied postures. The erratic movements of a drunken man show well how much the upright form depends upon control which he should exercise upon his muscles.

To understand how physical development may be influenced by postures, we must consider how the body grows, or rather, how the bones increase in length. If we examine the skeleton of a new-born child, we find the bones but partly ossified. At birth the ends of all the long bones of the limbs remain in their original cartilaginous state, the shafts alone are ossified. It may be realised how readily these ends of bone are moulded by unequal pressure, how growth in one direction may be checked while it proceeds unhindered in another. In early life ossific particles develop in these cartilage ends of bones and gradually grow, but it is not till puberty, or later, that the bones become complete. For instance, in the thigh bone the head is not united to the shaft until the eighteenth year of life ; the lower end until the twentieth. In the leg bones the heads are not united to the shafts until the twenty-fifth year of life ; the lower ends until the twentieth. The spine, which in respect to our subject is the most important part of the human skeleton, is formed of twenty-six bones placed one above another, but each is separated from its neighbours by elastic discs of permanent fibro-cartilage. Each of these bones, which together form the spine, are in the first place, like the other bones, but cartilage, and they develop by the growth of several osseous points, which gradually unite, but do not terminate their full development until about the thirtieth year of life. The ligaments which join the bones together in the skeleton are weak in childhood. The muscles also are less able to support the joints in early life than later. Thus it is seen that during youth the frame is fitted for free movement, for the activity so natural to the young, but is not suited for sustaining long the body weight in any one position. In active movements pressure of one bone upon another in any one direction is but of short duration, and this activity is natural to the young. Young children lounge about, and play, and crawl upon the floor, and when in health are seldom quiet, except in sleep.

If natural activity is checked—for instance, if a child is made to walk or sit, when it would rather play upon the floor—irregularities of growth may be produced. Walking, though movement, is not natural activity, the body weight is thrown too much upon the legs. The arches of the feet give way, and flat feet are produced ; the ankle joints get weak ; the knees succumb to frequent pressure, and bend towards the centre of the body, knock-knees resulting. Later in life the child may suffer from attempts on the part of the anxious mother, nurse, or governess at making it "sit up." Now this enforced "sitting up" is probably the commonest cause of spinal curvatures. The child when left alone will rest itself in various positions, either by leaning back or to one side, or, best of all, when working at a desk, will rest its head upon its hands with elbows on the desk, and thus relieve the back from undue strain. How many governesses or school-mistresses would tolerate such so-called "careless" habits? Probably none. They try to keep their pupils straight, but then their plan defeats its object, and they produce the very evils that they are attempting to avoid. Let me explain the facts on which I base these views. When sitting upright, and without a back rest, the spine is held erect by means of dorsal muscles ; these cannot act for long, they soon get tired, and then the spine subsides upon itself.

Let any one attempt to hold his arm erect above his head for long ; he will soon tire, the arm will fall, because its muscles get exhausted. The muscles of the back are also soon fatigued, and the result is that the spine is either bowed out backwards or subsides laterally. If the child is weak or careless the spine will bulge out backwards, and a "round back" will be produced. The back, however, may be held apparently upright with a very small amount of muscular exertion by allowing the column to subside laterally, until the joints between the spinal bones limit their further flexion. Under such circumstances the equilibrium of the body is maintained by a double curvature, and the spine assumes the form of an attenuated S. Whether the spine is bowed out backwards or bent in lateral curves, it happens that at the concavity of the bends, where there is excess of pressure, the growth is much restricted, whereas at the convexity, where the pressure is less than natural, development takes place quite freely. Growth thus occurs unequally, and in course of time each bone which helps to make the curves assumes a wedge-like form.

It is a well-known fact that girls are more often affected with crooked spines than boys, the proportion of the former to the latter being six or seven to one. In considering the reasons for this preponder-

[1] Read at the Conference at the International Health Exhibition, on Thursday, July 31st, 1884.

ance of the deformity among girls, it is necessary to study the differences in the lives of the young of the two sexes. From their infancy upwards girls are discouraged from playing and romping. The games they *are* allowed to play do not require so much freedom of action as do those of boys. As girls grow up more attention is given to their deportment, greater attempts are made to induce them to "sit up," whether at lessons or at meals. In short, all the factors in the formation of curvatures of the spine occur to a much greater extent with girls than they do with boys.

It is a false system to attempt to refine young girls by restraining their natural freedom of movement. It is this false process which does so much to encourage the production of deformity. Long walks in precise and stately file produce a harmful strain upon the spine and legs, whereas free movement in such games as cricket and lawn tennis afford most healthful exercise. After a long, uninteresting, formal walk, the girl returns to work, the muscles of the back are then fatigued from prolonged use in one direction, and when she sits she soon allows her back to fall into a curved position. Marching in file is very necessary work for soldiers, it may be suitable work for convicts, but it is not a proper routine exercise for girls. Overwork, by causing general fatigue, impairs the pupil's health, so that her muscles and other tissues become less able than in health to sustain the body weight. Girls seem to be very easily induced to do a large amount of sedentary work, and they readily fall into the habit of neglecting physical exercise. It is therefore most important that their studies should be carefully arranged, so that a due amount of active recreation is ensured. Girls are said to be more restless as regards their postures than boys; but is it not that the natural restlessness of young people is more noticed in the case of girls, and more often checked?

We have seen that if any one posture is maintained repeatedly for long periods of time without the body being perfectly at rest, the normal development of the skeleton will be interfered with. The periods which may be called long vary in accordance with the particular posture adopted. That which is a long period for one position is a short time for another. Then again, the periods which may be termed long, depend upon the health and natural strength of the child. A feeling of fatigue is a certain indication that a change of posture is required. I will now analyse a few typical postures. *Standing upright* for too long fatigues and exhausts the muscles, and they are thus weakened. The result is a gradually lessened ability to prevent the body falling into bad postures at other times. Standing with both feet close together is a very fatiguing attitude. *Standing upon one leg* places the base of the back in an oblique position, and thus causes lateral curvature of the spine. *Standing and supporting the body with the hands* upon a chair or with the back against a wall, is better than not having any extraneous support at all, but it is likely to produce roundness of the back. *Standing with the arms crossed* also makes the back round. *Standing* may produce flat feet and also knock-knees. In the latter case the weight falls chiefly on the outer side of the joints, and they gradually give way towards the central line of the body. *Sitting with the arms resting upon too low a table* produces a round back, and if the right hand is used for writing, drawing, &c., the shoulder of the right side is raised more than that of the left, and the spine is placed in a laterally curved position. *Sitting with the arms evenly supported on a desk*, or with the elbows upon a sufficiently high desk, and the head resting upon the hands, are fairly good postures. *Sitting in a chair with a suitable back rest* is a very good position, but it is quite possible for the back to be made "round" while in this posture by the pupil bending forwards frequently, and thus contracting the chest. *Sitting with the knees close side by side* is a very fatiguing attitude, but I believe it is not considered elegant for a young lady to sit otherwise, unless she crosses the knees, and crossing the knees is also a bad position, and necessitates the spine being placed crookedly. *Recumbency in bed* even may involve the assumption of bad postures. The body may be bent, the knees and head approximated, causing a rounded back. The pillow may be too high so that the spine is curved laterally in sleeping on the side, or posteriorly in sleeping on the back.

The above remarks may be easily applied to other positions than those described, but it is perhaps desirable to refer to playing upon the piano. This is necessarily a very fatiguing posture, even when the pupil uses a well-constructed seat which supports the back, and therefore the time devoted to this practice should for weak children be of but short duration. I have mentioned that round backs are produced by several positions. The appearance of the figure thus caused is perhaps the least of the bad results of this deformity. A round back involves the production of a flattened chest, and a constricted space for the lungs, heart, and stomach. A long paper might be written upon this subject alone, regarding the indigestion, the impeded circulation, and the lessened capacity for respiration thus engendered. I will here only refer to the lessened capacity for respiration. We are indebted to the late Dr. Hutchinson for almost exhaustive researches upon the movements of the chest, and the relation between the breathing powers and the health. Among a host of valuable facts which he published was that which showed a certain standard of what he called VITAL CAPACITY for every individual of a similar height, weight, age, and sex. The VITAL CAPACITY of an individual is indicated by the volume of air which he is able to expel forcibly from his lungs after a full inspiration. At the middle period of life the vital capacity *necessary for health* of a man measuring 5 feet high, is 174 cubic inches, while for a man 5 feet 10 inches, it is 254 cubic inches. These measurements never vary in perfect health, and, therefore, when the amount of respiratory power as thus indicated is diminished, it proves the existence of either distinct disease, or, to say the least, it shows a lessened vitality. Dr. Hutchinson also proved, and in fact it is a matter of general observation among medical men, that in people with round backs, the vital capacity is very much lessened, and it seems probable that individuals thus afflicted are more liable to become consumptive than others, and have less power to resist an attack of ordinary lung disease. We, therefore, have excellent reasons for doing all we can to prevent the development of round backs. I have found that by improving the posture an increase in the circumference of the chest in expansion of from 1 to 2 inches has taken place in a few months.

Standing upon one leg is likely to cause curvature of the spine by placing the pelvis in an oblique position, but I must mention that even standing with both legs upright may have a similar effect in many individuals. I refer to people in whom one of the legs is shorter than the other. It seems that such a condition exists much more often than was formerly believed. The researches of Drs. Hunt, Cox, Wright, and Roberts in America, and of Dr. Garson in London, show that equality in length of the lower limbs is an exceptional condition. In fifty-four persons examined by Dr. Cox, only six possessed limbs of equal length—the variations ranging from $\frac{1}{8}$th to $\frac{7}{8}$ths of an inch. Dr. Garson carefully measured seventy skeletons at the Royal College of Surgeons, and in only 10 per cent. of these cases were the limbs equal in length. The left limb

was found longer than the right in thirty-eight cases (54·3 per cent.). The right was the longest in twenty-five cases (35·8 per cent.). The amount of inequality varied from $\frac{1}{25}$th to half an inch. I may mention that of fifty-four cases of curvature of the spine ; in twenty-four, one or other leg was found to be shorter than the other ; and I have observed an important fact which probably shows that in these twenty-four cases the deformity was dependent upon the postures produced by the inequality in the length of the legs. This fact is, that in twenty-one out of the twenty-four the short leg was the left, causing a lumbar curve to the left ; whereas, in the three cases in which the short leg was the right, the lumbar curve was also to the right ; in all cases, there was a compensating dorsal curve. In the other thirty cases (in which no inequality of the legs existed) the exciting causes seem to have been bad postures long continued, and frequently repeated.

And now let me add a few words with regard to the *avoidance* of bad postures. In the first place, I must urge most emphatically, that in respect to girls, and they are girls who chiefly suffer, it will be utterly useless to attempt to remedy or prevent the evils I have referred to simply by laying down rules regarding postures. Rules may be devised, and they have their value, but so long as parents and guardians entertain the idea that energetic action in play, and the adoption of easy postures at work, are unladylike and unbecoming in a girl, so long will weak and deformed backs, legs, and feet, and the want of good health, which are thereby engendered, remain as common as they are in the present day. Ladies who have the management of schools and collegiate establishments, seem generally to be inclined to entertain more liberal views upon these matters now than formerly, but their endeavours to improve the physical condition of their pupils are often disapproved of by the parents. At a large establishment at Ealing, where the advantages of free exercise are fully appreciated by the lady who has the immediate direction of the pupils, stately walks have been almost entirely abolished, and out-door games substituted. Of all these games, cricket is approved of by the girls above the others, and the enthusiasm with regard to this excellent game is very great. However, in some cases, the parents have raised objections to cricket, as being too unladylike for their daughters, and stool-ball has been recommended as a substitute. But such a game is far less beneficial than cricket ; in fact, it is the very freedom and variety of movement, the energy displayed at one moment, the temporary easy repose at another ; and also the interest which it excites among the players, which constitutes alike its excellency as an exercise from a hygienic point of view, and its unladylike nature from the point of view of the fashionable mother. Tennis, and fives, and many other games may have their place among the recreations of girls. Swimming has a great influence in developing the muscles of the spine, and in straightening a round back, providing, of course, that there is no lateral curvature. Drill and gymnastics have their advantages, but they should be carried out in moderation, and be more carefully supervised than ordinary games. They are very useful in bad weather, when out-door games are less practicable. The Swedish systems of drill and gymnastics have become rather popular of late, and are valuable as means of exercise, but should not take the place of games.

With regard to postures in school. It is very desirable that children should be allowed much freedom of choice regarding their change of position. Standing in class should be avoided as much as possible, in some schools it is entirely abandoned. If the pupils are to stand at all they should not be obliged to place their feet close together, because, by so doing the basis of support is made too small, and a greater effort has to be made to maintain the equilibrium of the body than if the feet are slightly separated. Standing upon one leg may be permitted, but each leg should be used alternately to support the body. We find in this exhibition many specimens of seats and desks specially made to allow school work to be done by the pupils in good postures. The fault which I have chiefly noticed in schools where these special desks and seats are used is, that the desks are too low, and that consequently the children are obliged to stoop to do their work. The seat should be sufficiently high to allow room for the legs to move freely or rest naturally on a foot-board. The back should be upright with a projection to fit the back of the pupil above the hips. It is best that the back of the seat should rest the shoulders whilst the pupil is sitting up reading. The seat should support nearly the whole thigh. The edge of the desk should reach to within an inch of the body of the pupil when he is sitting upright. It should be sufficiently high to allow the pupil to write without or with a minimum of stooping, the eyes being about 14 inches from the work. The desks should slope 20° for writing and 40° for reading. The light should come from the left hand of the pupil, so that it falls upon his work while he remains in a good posture. Writing as usually taught is the occupation at which probably the body is most frequently placed in bad positions, but if upright writing were substituted for the present plan of sloped writing, the body might very easily be kept also in an upright posture. This plan of upright writing is most valuable, and its adoption in schools would do much to prevent the formation of curved spines. I might describe the influence of posture in other occupations of school life, but time forbids.

In conclusion, I will only add that if any one entertains a doubt as to the influence of the bad postures I have referred to in the production of deformity, let him consider the well established fact, that even in later life, when the bones are entirely ossified, the posture of the body has a material influence upon the form. Those who must stand for many hours together become flat-footed and knock-kneed, waiters in public restaurants are good examples of this fact. The seamstress, the clerk, the writer and engraver show by their rounded backs and narrow chests, how long-continued posture acts on *them*, and many trades show similar results ; upon the other hand we find the country yokel with drooping shoulders and slouching gait drilled to become a well formed man. Much may be done to change the form, even in adult life, but if the body is deformed in childhood by injudicious postures, and the health ruined by overwork, then are produced effects which no amount of care in after life can quite remove.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL.

SO-CALLED "HOSPITAL GANGRENE" OCCURRING IN A PRIVATE DWELLING BEFORE ADMISSION INTO HOSPITAL.

(Under the care of Mr. BARKER.)

(For the notes of this case we are indebted to Messrs. A. Drew, and J. Maughan, House Surgeons.)

The subjoined case as an instance of a bad and fatal attack of so-called "hospital gangrene" in a private dwelling, and which had made extensive ravages before admission into hospital, seems to claim some special notice. The origin of the disease, without any crowding

together of persons suffering from wounds, and where, if the patient is to be credited, the surrounding conditions were not peculiarly bad, is also noteworthy.

J. J. R., æt. 38, was admitted into University College Hospital last April with an ulcer of the left leg. His past history included long standing alcoholism, chancres, without secondary symptoms, several attacks of gonorrhœa and privation. Ten years ago a small scab appeared on his left leg, and this, when scratched, discharged and dried up again. Gradually it got bigger, but improvement followed and it had ceased to trouble him twelve months ago.

In April, 1883, the leg was struck by a cricket ball; ulceration was re-awakened and this continued till the day of his death. He has been in the habit of dressing the ulcer with "purified lard."

On April 3rd, 1884, he felt a burning pain in the leg and when he looked at it was astonished to see the ulcer twice as big as it had been twelve hours previously, when he had last dressed it with the lard. The skin around it was red, hot, and tender, and he also observed a bad smell and a covering over the sore "just like mud."

Two days afterwards he got "the shivers," and remained in bed until admitted under the care of Mr. Barker on the 12th of April, the ulcer having increased enormously in the meantime. The left hip and knee joints were then flexed and the foot everted, a condition maintained throughout his illness. The ulcer was found occupying the lower third of the leg, and measuring seven inches in both diameters. A black border surrounded it and the skin beyond this margin was red and tender. The edges were irregular, thick, and indurated at one spot, thin and overlapping at another. The floor was covered entirely by black and adherent or dirty greenish-yellow sloughs overlying the muscles which could be seen to move below.

Patient was admitted into a private ward and a few hours afterwards (the case being clearly one of hospital gangrene) was etherised with a view to thorough cauterisation of the wound. Mr. Barker then, with the Paquelin cautery, cut a groove about half-an-inch deep all round the margin, and cauterised the floor, detaching the sloughs and charring the underlying tissues. The leg was dressed with iodoform and salicylic wool. He was put on spoon diet, and extra strong beef tea, and he was ordered four grains of ammon. carb. three times a day.

Next day the discharge was profuse, and very fœtid; he was ordered six ounces of brandy per diem.

On the 15th his foot became œdematous. Two days afterwards the muscles of his face began to twitch, and his hands were unsteady when extended. He complained of pain while the leg was being dressed on the 19th. The inflamed skin around the ulcer was painted with glycerine and belladonna.

Late in the evening of the 21st he had a morphia injection, on account of his restlessness and wandering delirium at nights.

On the 27th there was clearly mapped out an area of œdematous granulation tissue five inches by three inches on the outer part of the ulcer. This was covered by a dull grey, opaque film, firmly adherent to the substrata, the rest of the ulcer being much improved.

During the preceding week his temperature had assumed somewhat of the hectic type, never, however, rising above 102·8°. He was ordered two grains of quinine every four hours and a bottle of Burgundy a day.

On the 28th this grey elevated area was dabbed over with a (gr. v. ad ℥ i.) solution of corrosive sublimate, and iodoform was dusted over the whole ulcer, iodoform wool being applied well round the leg.

Two hours afterwards the pain was so severe that he was ordered a full dose of opium, and this was repeated during the night.

Next day his pulse was 120, small and compressible, his temperature 102·8°, and his leg apparently unimproved by the corrosive solution. Mr. Barker again thoroughly cauterised the whole ulcer with the actual cautery. A dry antiseptic dressing was applied, and ♏ x. Tinct. of Opii ordered every six hours.

On the next day the discharge was abundant, purulent, and extremely disagreeable.

On the 2nd of May the tibia could be felt by a probe passed through a cleft in the floor, and the tissues exposed by the removal of sloughs presented a dusky bluish red colour.

On the 3rd his brandy was increased to eight ounces and Mr. Barker again cauterised the leg. This time it was dressed with carbolic oil and salicylic wool. It was on this day, just before the operation, that some dippings were taken from the dirty yellow pus, and Mr. Barker was successful in staining them, and demonstrating bacilli and micrococci in abundance. The prevailing bacillus closely resembled the bacillus tuberculosis.

On the 6th the patient's temperature rose to 103°, but soon fell again. He was ordered ten ounces of special port per diem. His nocturnal delirium increased, until it became necessary to tie him down to the bed.

On May 8th sordes appeared on the lips and teeth, the tongue was dry, and the breath offensive. He sighed frequently, and passed his urine unconsciously. On the same day a large quantity of sloughs came away from the ulcer, exposing a considerable area of bare bone at the upper part. Thick, curdled pus welled up when pressure was directed to the upper and outer border. He was ordered one-sixteenth of a grain of Hydrarg. Perchlor. three times a day. The same evening his temperature rose to 103·4°, and the following morning to 104·2°. In four hours it had fallen to 100°. The quinine was discontinued when the perchloride of mercury was ordered.

On the 10th some of the discharge was examined and bacilli again found. Blood taken from the unhealthy granulations also contained bacilli. The leg was again cauterised, after being well washed in (1 in 20) carbolic lotion. The burrowing abscess on the outer side of the tibia was opened up. The parts were then bathed with (1 in 1,000) solution of corrosive sublimate, and afterwards with (1 in 20) carbolic. A Listerian dressing was then applied.

On the 11th and 12th patient was almost constantly delirious, and on the 13th he exhibited the following symptoms:—Marked subsultus, picking at the bedclothes; tongue dry, fissured, and brown; breath very offensive; pulse 136, weak and irregular, and anorexia. Nutrient enemata were ordered every four hours. On the same day the leg was dressed, owing to the discharge coming through. The pus was profuse, dark yellow, and horribly stinking. The ulcer was washed in (1 in 20) carbolic, and a boracic fomentation applied.

Patient gradually sank, and on the morning of the 15th he died.

Autopsy.—No visceral disease was found, except a little fatty degeneration of the cortex of each kidney.

On turning up the soft parts of the leg the tissues were found separated from the tibia for one-quarter of the length of the shaft above the edge of the ulcer. These tissues immediately surrounding the bone were converted into a dirty green gelatinous slough, and this extended into the surrounding muscle for about one-third of an inch. There was slight formation of new bone on the periosteum of the posterior surface of the tibia, just above the internal malleolus, also on the inner border of the fibula, which, however, the gangrene did not reach.

The knee-joint was normal.

The glands in the groin were small and reddish on section.

Medical Times and Gazette.

SATURDAY, AUGUST 9, 1884.

THE cholera is abating—by lysis, like the third week of a typhoid temperature—at Marseilles and Toulon, and it shows no signs as yet of making a rapid advance northwards, but it still prevails to a considerable extent in many towns in the South of France. Deaths are daily occurring at Arles, at Aix en Provence—not Aix-les-Bains, which is hundreds of miles away, as the doctors of that popular resort of rheumatics have anxiously pointed out—at Voguè, in Ardèche, and in several towns in Italy. Fears are expressed that a recrudescence of the epidemic may be caused by the premature return of *emigrés* to Toulon and Marseilles, both of which, according to the testimony of recent visitors, are still in a very unsatisfactory hygienic condition. M. Clémenceau, who has recently been on a tour of inspection, detailed his experiences in the infected towns to the French Chamber on Saturday. Drains, he said, were in many cases defective; water was scarce; the sewage was not carried to a sufficient distance; and at Toulon the state of the crowded and unhealthy dwellings surpassed anything in London or Paris. Legislation on this point was urgent, and he only wished that the Republican Cabinet were as Radical as were Her Majesty's Ministers in England. Marseilles was being ruined by marine quarantines, which were a form of panic; and there were prefects who even quarantined furniture. M. Clémenceau sharply criticised the inaction of the Government, and laughed at the three Ministers who, when they left Toulon, had two eucalyptus trees placed in the train. He urged that the funds devoted to colonial aggrandisement might be better employed in sanitary measures in French ports, which otherwise might lose their trade. M. Paul Bert concurred in M. Clémenceau's criticisms, and moved a resolution condemning the inaction of the Government, which, however, was not carried.

THE London Correspondent of the *New York Times*, who has just returned after visiting Marseilles and Toulon, has painted the sanitary state of these ports in colours far darker than those of M. Clémenceau. Every one who reads his statement, as published in Wednesday's *Pall Mall Gazette*, will wonder that the death-roll, which according to the latest official report has numbered 2,200 since the beginning of the epidemic, has not been thrice as long. This sanitary neglect seems all the more unpardonable now that it has come out that there was a case of undoubted cholera in Marseilles last year, the existence of which was hushed up by the Mayor. Meanwhile there has as yet been no relaxation of the futile quarantine arrangements on the Spanish and Italian frontiers. The Italians appear to be coming to their senses, and the papers are drawing attention to the uselessness of quarantine and cordons. But the Spaniards are congratulating themselves that their immunity thus far has been entirely due to their precautions on the frontier, and they are still persevering in the most ridiculous observances even where—as at Gibraltar—no foe threatens. All the North of Europe is still open and likely to remain so, though if you are going to stay in Holland, you must leave your dirty linen at the frontier to be washed and disinfected, and sent on to you at the earliest opportunity.

IN addition to Dr. Koch, M. Clémenceau and the correspondent of the *New York Times*, Marseilles and Toulon have attracted to them for the purposes of investigation two well-known authorities, Baron Mundy, of Vienna, and Dr. Dutrieux Bey, of Alexandria. The latter will be remembered for the able report that he drew up on the Egyptian epidemic of last year, and the account of his present investigations, which he intends to lay before the Paris Academy of Medicine and the International Congress at Copenhagen, will be looked forward to with great interest. In the case of the Egyptian outbreak, Dr. Dutrieux concurred in the views arrived at by Sir Guyer Hunter, that cholera had been endemic in the country for a considerable period before it took on an epidemic character, and his present object is to discover whether the same is true of the epidemic in the South of France. It is said that he has already hunted up cases in which choleraic symptoms occurred so long ago as January last.

THERE has been as yet no case of true Asiatic cholera in England, though it is said that a case occurred last week in Lambeth which was seen by a well-known Indian authority and declared indistinguishable from it. The College of Physicians has published a somewhat colourless memorandum on the subject, which we print elsewhere, and active measures of precautions have been taken at all the ports. Dr. de Chaumont, after setting things in order at Portsmouth and Southampton, has paid a visit of inspection to the Port of London, under an order from the Local Government Board, and is making an exhaustive enquiry into the arrangements for preventing the ingress of cholera by means of the Thames shipping. Two vessels have in the course of the week appeared off Cardiff, and one has arrived in the Mersey, flying the yellow flag. All were ordered to the quarantine station for observation and disinfection, and so far there has been no sign of any infection having spread from them.

THE British Medical Association has just completed one of the most successful annual meetings ever held in its history. Belfast has been visited for the first time, and the *éclat* with which everything connected with the meeting has passed off has astonished those who had expected most, and even taken by surprise some of the oldest congress-trotters in the association. In last week's issue we gave a brief review of the most important addresses, which were certainly up to the level of, if not above, those of former years. The sections, with one exception, displayed no very marked departure from the routine of other years; though the amount and character of the work, and the standing and

ability of the speakers were certainly such as to do credit to the association as one of the chief medical organisations of the world. The weather, except for the evening of Wednesday, was everything hat could be desired, and this, though an apparently trivial consideration, is of great importance, when we consider that many at least of those taking part in this annual gathering have educated themselves into regarding it as one of the holidays of their busy professional life, a statement especially true of the more active and restless brains in the association. Amongst our profession, as amongst all bodies of intellectual men, it will be found that—

> Some place their bliss in action, some in ease ;
> *Those* call it pleasure, and contentment *these*.

It is in the former class almost exclusively that the men who take their holiday at the British Medical Association Annual Meeting will be found. Those who seek for contentment in their holiday change do not trouble themselves with the ceaseless activity and unrest of the annual reunion and its accompanying festivities. The profession is, however, always represented well otherwise ; and to the student of character it can be safely said that no collection of men affords such splendid scope for study, all classes being present, from the listless pleasure seeker to the eager searcher after truth. At the Belfast Meeting there may have been the usual percentage, and we are happy to say it is a small one, of young men who invariably make the most of some shallow little knowledge to gain notoriety and satiate their appetite for being reckoned amongst the lions of the moment. The solid lasting work done by the association proves that such men are the rare exceptions, and the reverence and respect universally paid to those leaders of the profession who visit the assembly, speaks volumes for the good sense of the profession at large.

It has been often said that the weakest point in connection with the meeting of the British Medical Association has been the meagre supply of the fruits of pure scientific research ; we are happy to be able to chronicle a new departure in this direction. In reviewing the career of scientific medicine during the last quarter of a century, perhaps there is nothing which strikes one so much as the backwardness of the department which one would expect to receive the greatest attention and elucidation. We speak of the knowledge, or rather of the ignorance, of the physiological and therapeutic actions of remedies. This unprogressive condition of pharmacology and therapeutics, when contrasted with the rapid strides recently made in the departments of Pathology, Medicine, and Surgery, is evidently due to a number of constantly acting forces, not the least of which is the difficulty caused by the operations of the Vivisection Act, which has so unmistakably embarrassed original work in this country. The impetus which improved implements have given to the study of microscopic anatomy and physical diagnosis has not been an altogether unmixed good. How often can we trace the death-knell to all impartial scientific use of time-honoured remedies from the moment that an observer has looked down a microscope and realised the existence of a gross lesion such as is seen in locomotor ataxy or tuberculosis! The teaching in many of our large schools when viewed from this standpoint is as eminently unscientific as it is productive of scepticism of the worst kind. Such unbelief is no doubt preferable to the blind faith which accepts therapeutic statements on the flimsiest evidence, but it is carried too far by some of the most *popular* teachers of our time, who will spend a couple of hours in the wards with the practitioners of the next generation discussing the causation, diagnosis, and pathology of some complicated case, and dismissing the treatment in a single sentence. The profession doubtless will hail with delight the first signs of the pendulum swinging in the opposite direction, and the president's address affords ample food for reflection to those who have neglected the study of rational treatment and screened their ignorance behind a learned pathology.

Hence it is that we welcome the creation of the new Section of Pharmacology and Therapeutics as one of the happy signs of a brighter and more earnest attempt to make this department keep pace with the swift advancement of our knowledge in other directions. Those who are for the time answerable for the management of the affairs of the association have shown a wise discretion in establishing a department which will not be presided over or directed by those whose daily duty is the interpretation of anatomical or pathological facts, or whose *sole* training and experience has been derived from the action of remedies upon diseased organisms, a result which has hitherto flowed from the custom of consigning all pharmacological or therapeutic contributions to the Sections of Anatomy or Medicine. It is true that the number of workers in this special department is small, and there may be some difficulty in keeping up, year by year, a continuously increasing supply of results such as will do credit to the association, but that is only a reason why the greatest machine of our professional day, or any other day, should try and consolidate its ranks by inducing scientific workers from every province of the great region of pure medicine to enter and labour within its circle. The success of the new section proves that a growing need is being felt, and that there is an ardent desire for a more enlightened system of therapeutics ; and while we congratulate the association upon keeping in advance of the time, we hope that the work done to lift treatment out of the slough of empiricism and neglect will always maintain the high standard which has so markedly characterised the opening of the department.

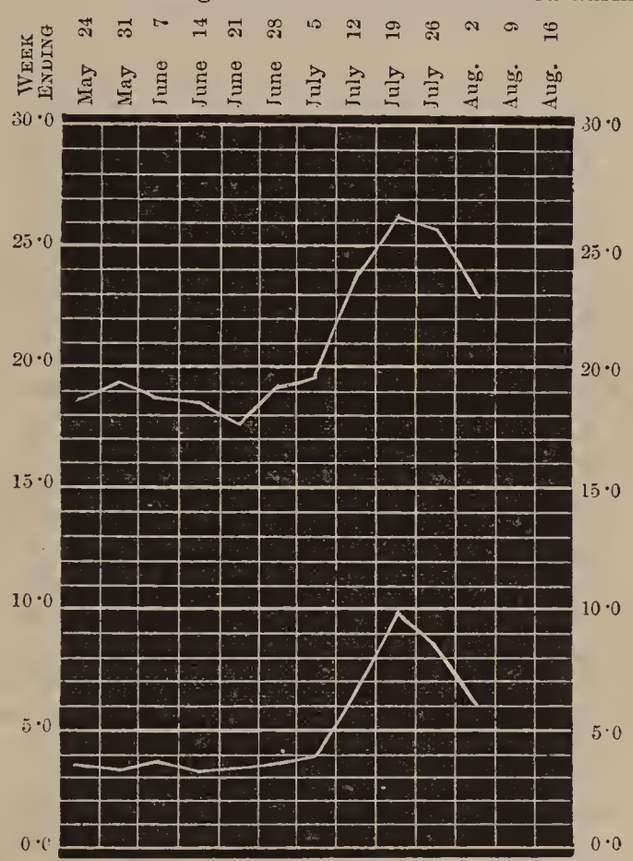
It was high time for the association to think of taking some steps to stamp out one of the greatest anomalies in connection with medicines—the Patent Medicines Act, which too often has been used by unscrupulous impostors to deceive their dupes by the presence of an apparent Government sanction to their dishonest nostrums. The anomaly of a new Pharmacopœia being produced for the use of practitioners of this country without their even having a voice in its revision, is, we hope, one of the things of the past, and

we cannot see a more useful or necessary direction in which to turn the great power of the organisation than in claiming a right to have the general profession represented upon the Pharmacopœia Committee. These matters engrossed the attention of the new section, and steps were taken to refer them to the central executive body, who, we hope, will not allow them to be lost sight of.

While there is hardly any subject in medicine, surgery, or the allied branches which would not give rise to considerable difference of opinion upon its discussion, we think that if we turn from the scientific and practical questions submitted at the association to the general features of the purely pleasurable aspect of the meeting, there we shall find only one idea prevailing amongst every class of members visiting Belfast. The universal verdict was one of complete and whole-hearted appreciation of the success of every undertaking provided for the comfort and pleasure of the visitors. The *conversazione* was one of the most enjoyable reunions ever witnessed by the members; the annual dinner was a very decided success, and the reception given by the mayor of the town was not allowed to fall behind in any detail. Saturday, devoted to excursions, found about 300 members of the association winding up the hard week's work by an examination of the wonderful geological formation of the Giant's Causeway. This excursion afforded a rare day's pleasure, and fitly brought to a close a meeting which will long remain green in the memory of every member of the profession who visited the commercial capital of Ireland.

Dr. Cameron's address in the Section of Public Medicine, at Belfast, on "The Cholera Microbe, and how to meet it," contained a very clear statement of how much, or rather how little, our ideas concerning cholera should be modified by Dr. Koch's recent discovery. Very little, says Dr. Cameron, of a definite or satisfactory character is known about the so-called cholera-bacillus. Dr. Klein has discovered a similar bacillus in an epidemic of diarrhœa in England; and it appears certain that it is unsafe to establish practical conclusions, and especially, as Dr. Cameron points out, *negative* practical conclusions, on the unsupported premisses arrived at by Dr. Koch's investigations. We are obviously, therefore, not justified in acting on Koch's conclusion that the cholera poison can only harm us when it reaches us moist through the channel of the stomach. Dr. Cameron insisted that in order to establish the microbic origin of a disease as a scientific fact, four things were necessary:—(1) Something that may be a microbe must be found in the blood or tissues in every case of the disease; (2) it must be shown by artificial cultivation to be a microbe, possessing its vitality apart from the organism of the animal in which it lives; (3) when purified by such cultivation, it must be capable, if introduced into the systems of animals in which it can develop, of reproducing the particular disease; (4) before the results can be admitted as scientific facts they must be corroborated by independent observers. These are admitted to be stringent tests; but they have been complied with in the case of cattle anthrax, fowl cholera, and tubercle. In the case of cholera, however, not one of the four requirements has as yet been met, and we agree with Dr. Cameron that, while admitting the importance of the discoveries, we are bound, in the interests of scientific medicine, to reserve our judgment, and to refuse to act upon them as if they were established facts. Dr. Cameron's lecture is a very wholesome protest against the premature acceptance and popularisation of an inchoate investigation as a finished and fruitful scientific conquest.

The death-rate of London fell last week, from 25·9 to 22·9 per 1,000, but the number of deaths registered was as many as 83 above the average. Of this excess only 26 are accounted for by the unusual mortality of zymotic diseases, the death-roll from this class of disease amounting last week to 484, whereas the average is 458. The mortality from diarrhœa, which caused such a high death-rate to be recorded during



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London in each of the past eleven weeks.

the two preceding weeks, has fallen considerably for the time, the deaths from this disease last week being only 30 above the average. Both the deaths from, and the admissions to hospital for, small-pox have shown a very satisfactory falling off, the former last week numbering 11, and the latter 66. Seven weeks ago these numbers were respectively 59 and 354. In many of the provincial towns diarrhœa is still very fatal, the annual death-rate per 1,000 from this cause alone being 12·6 in Preston, 11·0 in Leicester, 7·1 in Salford, 6·9 in Norwich, and 6·1 in Nottingham.

The Conference on School Hygiene was continued at the Health Exhibition on Thursday, the 31st ult., the subject for that day being the Construction and Arrange-

ments of School Buildings. Mr. Murgatroyd, of Manchester, who has had considerable experience in the erection of large middle-class and high schools, contributed a most admirable paper describing the plans he has usually followed. Dr. Clement Dukes, of Rugby School, next discussed the question of School Dormitories. He complained that in many schools the space allowed was actually less than that fixed by law for convicts and paupers. The cubicle system he condemned in the strongest terms on every consideration of health and morality. Mr. Noble Smith, in a paper on the influence of Posture on the Development of the Body, which we publish in full in another column, attributed the largest proportion of deformities and of cases of defective eyesight to the faulty attitudes induced by badly constructed seats and desks, together with want of sufficient and proper exercise, especially among girls. In his own practice he found the number of girls suffering from one or other form of curvature of the spine to be to that of boys as eight to one.

On Friday the subject of Games and Athletics was to have been opened by the Rev. E. Warre and the Hon. E. Lyttelton, but unforeseen circumstances prevented the attendance of either. Dr. Walter Fergus, of Marlborough College, read a paper on the Development of Boys, with special reference to games, among which he gave the place of honour to football, maintaining that the few accidents that did occur were mostly attributable to breach of the rules. Mr. Noble Smith preferred cricket, and stated that in some high schools the girls entered into this game with fully as much enthusiasm as boys. Indeed, he maintained that there was no game, with the exception perhaps of football, now played by boys which might not be practised by girls with unmixed benefit to body, mind, and manners. Mr. Roman von Schweitzer, the veteran Director of the German Turnverein in London, which has done so much to popularise systematic gymnastics in this country, traced, in a wonderfully clever and amusing manner, the progress of gymnastics from the earliest period of Greek history to the present day, and maintained the value of the methodical exercise on scientific principles of every group of muscles. The aim of gymnastics was, he said, the attainment of the highest possible development of every part in perfect symmetry and harmony, and so potent a means demanded intelligent supervision and direction in the care of the young, not to drive the learners to their task, but to check their incautious zeal and ambition. He was far from wishing to disparage games, for until he had passed his sixteenth year he was an enthusiastic football player; but each had its use, and gymnastics could be followed by the young men of our large cities at seasons and hours when outdoor games could not. He described the uses of each kind of exercise, and their adaptation to the capabilities of men, boys, and girls respectively. The gymnast, he said, was less liable to accidents than other men, and, conscious of his powers, was self-possessed and fearless in the hour of danger. The inability of most women to swim, and of all to climb, rendered them helpless in shipwrecks and fires.

Sir James Paget, Mr. Noble Smith, Dr. Roth, Mr. Holmes, and others joined in the discussion, the two last-named urging the claims of Ling's system with few or no apparatus. These comparisons Mr. von Schweitzer deprecated. Every system was good, he believed, if conscientiously and intelligently carried out; but he maintained that the German included all that was really valuable in the Swedish, and it had in every essential feature been adopted in almost all the armies of Europe, not excepting that of France. Dr. Willoughby read a paper describing the Ferien Colonies, or Holiday Colonies for the children of the poor, which are now formed in all the principal towns of Germany and Switzerland. The weakly children, recommended by the teachers and selected by a medical examination, are sent out for a whole month into the country during the summer holidays, in parties not exceeding fifteen or twenty, in charge of a picked teacher of the same sex, to a farmhouse or other healthy locality in the mountains or forests, where, under the influence of life in the open air, liberal diet, and association with a genial and sympathetic teacher, they rapidly exhibit an improvement in bodily health, intelligence, and manners, which is not lost even after the end of a year or two spent amid the unfavourable surroundings of their homes. He considered this plan very superior to that of boarding children, one or two, in the families of respectable country people, which, practised to a small extent here, is carried out on an enormous scale in Denmark, and he believed that the money thus spent in securing palpable benefits for a selected few would be better laid out than in giving to a larger number the equivocal privilege of "a day in the country," with its consequent excitement and fatigue.

The Conference closed on Saturday with papers by Dr. G. E. Shuttleworth, of the Royal Albert Asylum at Lancaster, and Dr. Fletcher Beach, of the Darenth Asylum, on the "Health, Bodily Development, and Mortality of Imbeciles, as compared with children of sound mind." Dr. Shuttleworth showed that the defective development was not confined to the mental faculties, but that their bodies were no less feeble, even the hands being often characteristically malformed. A large proportion, perhaps 40 per cent., were subjects of some form of scrofula, and as many suffered from epilepsy, chorea, &c., even when epilepsy was not the immediate cause of the idiocy. They belonged also in most cases to families in which scrofula or nervous diseases were frequent, or were the children of drunkards. The mortality between the ages of 5 and 20 was in each quinquennium from 8 to 10 times as great as in the general population of the same age; while at Darenth, where only younger children were admitted, Dr. Beach found the death-rate twice as high as it was at Lancaster. Dr. Langdon Down occupied the chair, and confirmed the observations of the preceding speakers from his own experience. The Conference then broke up. We trust that the many able papers which were presented to it, and which will no doubt be published, will have the result of calling the attention of the public to questions of national importance which affect

not fewer than five millions of individuals—*i.e.*, the entire juvenile population of each succeeding generation.

Curiosity tempted me on Bank Holiday afternoon, writes a correspondent, to mount to the top of the Guilds' Institute, where Mr. Watson Cheyne has recently opened a pathological laboratory in connection with the Health Exhibition, in order to see what interest was shown by the British public in that newest of studies, bacteriology. Except for the attendant and myself, the room was empty, the only empty room, I will make bold to say, in the whole Exhibition. This may perhaps be in part accounted for by its inaccessibility, in part also perhaps by a feeling amongst the public that germs are uncanny things and not to be run after. But the chief reason no doubt lies in the general ignorance on the part of most people outside the profession (and on the part of some within it) that this very study of germs is one of the most fascinating that exists, and that a few words of explanation are enough to make it interest any intelligent being. It touches so many matters of common every day experience. The child who has picked gum off a cherry tree, the dairymaid who cannot keep her milk sweet, the housewife troubled by the growth of mould on her jams, the epicure who loves his blue Stilton and Camembert, the man who has seen his friend die of decaying lungs, or has himself suffered from a zymotic disease, has had an object lesson in bacterial pathology which ought to give to Mr. Cheyne's demonstrations an interest above that of anything else in the whole Exhibition. All that is needed is a few words of intelligible explanation.

The arrangements of the laboratory are not yet complete—the cholera germ, for instance, is not yet on view—but there is already much worth seeing. The way in which the different germs grow in or upon their gelatine pabulum is admirably shown, while the microscopic preparations and microphotographs of the germs of anthrax, glanders, tubercle, &c., though familiar to most visitors to medical *soirées*, will be a revelation to the intelligent layman. Other exhibits worth attention are the mode of examining water by cultivation, as regularly practised at Berlin, the method of testing the relative value of disinfectants by their influence as germicides, and the processes for examining air, water, and earth for the presence of germs. The specimens of plants infested with microscopic growths and the graphic representations on the walls of the mortality from zymotic diseases are also well worth studying. At one end of the room are several tables fitted up for the use of different workers, a sign, it is to be hoped, that this laboratory is not intended only as a passing show for the public, but will be made a permanent institution where the study of bacteria can be systematically carried out under competent guidance. Mr. Watson Cheyne should be made Germ-Inspector in Ordinary to the Queen, with an adequate salary.

The profession in general and St. George's men in particular will cordially approve of the promotion of Sir Prescott Hewett, from the post of Sergeant-Surgeon Extraordinary to that of Sergeant-Surgeon to the Queen. It was thought by some that as Sir Prescott Hewett had retired from the active practice of his profession before having the good fortune to attain to that quaint dignity, which has come down to us from the days of Crecy and Agincourt, the post would be bestowed on another surgical baronet. By ignoring this imaginary disqualification, however, the advisers of Her Majesty have been able to reward one who has set the best possible example to his successors—that of making room for younger men while still in the full tide of practice. All who have seen Sir Prescott Hewett in his frequent visits to town since his retirement, will be inclined to admit that he has found another reward for his self-denial. He has grown young again.

On Wednesday week, "Founder's day," Sir Joseph Fayrer presided at the annual distribution of prizes at Epsom College. There was the usual reading of honours gained elsewhere by the pupils of the school, and the customary recitations, followed by the distribution of prizes. Subsequently Dr. West, the head master, announced that the Governors of St. Mary's Hospital, and the Staff of St. Thomas's had resolved to offer scholarships to their medical schools, to be competed for by pupils of the College; and then Sir Joseph Fayrer, as chairman, "said whot a owt to 'a said an' a coom'd awaäy."

Members of the medical profession who have with reason made frequent complaints in our columns of the unprofessional advertisements appearing in the daily newspapers, will be glad to learn that, so far as the Royal College of Surgeons of England is concerned, an important step has just been taken calculated to check these practices by the removal, by resolution of the Council of that College, at a meeting on the 5th instant, of one of its Members, viz., Mr. George Washington Evans, who has, after careful enquiry and due deliberation, been judged by the Council to have been guilty of an offence against the by-laws of the College by the issue of advertisements and pamphlets declared to be "prejudicial to the interest,' and "derogatory to the honour of the College," and "disgraceful to the profession of Surgery." The effect of this resolution will be that the name of George Washington Evans will also be erased from the Medical Register.

The pass-lists of the summer matriculation, and of the annual preliminary scientific examinations of the London University have just been published. For the former examination there were 972 candidates, of whom 536, or 55 per cent., were successful. In the honours division there were 81 candidates, eight of them ladies; in the first division, 407 candidates, 67 of them ladies; and in the second division, 48 candidates, four of them ladies. From the small proportion of ladies in the honours and second divisions, it is evident that they fully realise the truth of the saying, *In medio tutissimus*. At the preliminary scientific (M.B.) examination there were 254 candidates, of

whom 134 passed (or 52·8 per cent.), 14 in the first and 120 in the second division. Six ladies appear to have entered for this examination, but only one passed, and she was placed in the second division. The intermediate examination in medicine is still in progress; 150 candidates have entered, of whom only one is a woman.

The Medical Graduation Ceremony, writes our Edinburgh correspondent, took place on Friday, the 1st instant. Previous to the ordinary graduation, the honorary degree of LL.D. was conferred on Professor Asser, of Amsterdam, and on Sir Joseph Hooker, of Kew. Both gentlemen were very heartily received. The same degree was also conferred *in absentiâ* on Dr. Ludwig A. Wiese, who would have received the degree at the Tercentenary Ceremonial, but was unable to be present. Thereafter thirty-seven gentlemen received the degree of M.D., Drs. George Frederick Crooke and William Russel taking gold medals for their theses. One hundred and seventy-one candidates were then presented for the degrees of M.B. and C.M. The Ettles Prize—the blue ribbon of the year—was awarded to John Stevens, M.A., M.B., C.M., who also received the Hark Scholarship. The Beaney Prize and Scott Scholarship were gained by Francis Antill Pockley, M.B., C.M.; the Buchanan Scholarship by Fourness Henry Simmons, M.B., C.M.; and the Tyne Surgical Fellowship by Ernest Edmund Maddox, M.B., C.M.

Professor Cossar Ewart, the Promoter of the year, who rose amid loud applause, then addressed the graduates. After some advice as to the course they should adopt in order to promote their present knowledge, more especially with reference to residence for a period at some other school, Professor Ewart referred to the great disadvantage under which the pursuit of science lay in this country from the almost total absence of anything in the form of fellowships which might enable graduates to prosecute the study of the various departments of scientific work. He contrasted the liberality of Germany in this matter with the state of things here. He offered various suggestions as to the mode of improving matters by the appointment of Assistant-Professors, at reasonable salaries, the establishment of elective fellowships, &c. In dealing with the question of ways and means, the speaker said that he could see two sources of help. One was that the Professors themselves would liberally contribute to such a scheme, and, in the second place, he felt sure that when the want was known help would come from without.

The suggestions made are well worthy of attention, and we cordially commend them to the best consideration of the Professors in the Medical Faculty. If report speaks true, the recent action on the part of the present Assistants, to call attention to their somewhat unsatisfactory status, by means of a memorial to the Lord Advocate, has not been viewed with that favour on the part of the Professors which one would have expected from men eager to move in the direction indicated by Professor Ewart. Perhaps it may be that they themselves were preparing to do so, and are annoyed at having been anticipated in the matter; but if such is the case, the matter has been kept a profound secret. If the course suggested by Professor Ewart is to be followed, the first step is most assuredly that of establishing a number of assistantships, whose emoluments and status will be sufficient to induce well trained and able men to devote themselves to the work of research and higher teaching. As matters stand at present, the position is one in which the continued drudgery of elementary practical teaching is rewarded by the most miserable of salaries. Is it to be wondered that almost any appointment in the other schools, offering, as many of them do, leisure for research and a reasonable remuneration, is sought after by the best men of the Edinburgh School? Thus do we lose, year after year, our best teachers and workers; and of what purpose are our palatial buildings and sumptuous laboratories, if they contain materials in abundance but no men to use them?

The usual graduation ceremony in connection with Glasgow University, took place in the Bute Hall, on Thursday, the 31st ultimo, when the graduates, whose names we give in another column, were duly capped. Professor Young subsequently delivered an address on "the aims and duties of the medical practitioner," in which he lauded dispensary work amongst the poor as a valuable means of education for the future practitioner. He then made some very rational remarks on intemperance, and passed on to consider another form of enforced intemperance—over-pressure in schools. It was not, he thought, overwork so much as ill-directed work that was to blame. There were two errors at work jointly or combined. The one was that children were allowed to waste time, and were then compelled to atone by severe toil; this was the parent's error. The other was, that, even if their work hours were properly managed, they had too much to do; this was the error of the teachers, and one often thrust on them in public as well as voluntary schools. After pointing out dietetics, studies, occupations, and amusements as directions in which preventive medicine had ample field, Professor Young concluded by addressing some words of advice and warning to his hearers. It was for them to show, he said, that from those halls were sent out, not well-drilled tradesmen, but cultivated, thoughtful men, worthy to follow a noble art. (*Hear! Hear!*) [The italics are our own.]

At an inquest held on Tuesday last the Bethnal Green Board of Guardians did not appear to much advantage. An inmate of the workhouse availed himself of the opportunity afforded by the absence of any one in charge to cut his throat with a table knife in one of the wards after dinner. It appeared from the evidence that for the past two years there had been only one attendant on duty in the ward, and that during his necessary absence at dinner and on other occasions, the inmates of the ward took care of themselves as best they might. The guardians have received

a good fright, and we doubt not that for the present they will not push their parsimony to quite such an extreme point. It might be asked how a man with such a history of homicidal tendency as this man had came to be in the general ward ; possibly the fear of subsequent legal proceedings had deterred the doctor from signing his certificate.

The celebrated naturalist Carl Theodor von Siebold having retired from his professorship of Zoology at Munich, a "call" to supply his place has been sent to Professor Weissmann of Freiburg.

THE COPENHAGEN LEECHMOTE.

It may be taken for granted that it never occurred to Thorwaldsen, when he modelled his figures of Æsculapius and Hygeia for the bas-reliefs over the entrance to the royal palace of Christiansborg, that within a century the modern representatives of those divinities, gathered from all parts of the civilised world, would be standing in Copenhagen streets, and admiring his handiwork. Still less, probably, did it enter into the minds of our Viking ancestors, when they crossed the North Sea in search of plunder, that the return journey would one day be made so peacefully by their degenerate descendants. Could they have foreseen it what laughter would have gone round the board at this modern witenagemote,—this meeting of wise men who cross the sea, prepared to pay for board and lodging, and to take nothing home with them but new ideas and pleasant memories. The name of the meeting-place—Copenhagen, Chapman's haven, Buying haven (cf. German *Kaufen*=to buy)—might perhaps be deemed prophetic of some such mercantile proceeding ; but when the last of the Vikings put off into the German Ocean, Copenhagen was probably not even a fishing village, and certainly had not acquired the name which its position subsequently won for it. All these details, however, we may leave to the guide-books to tell ; just as confidently as we may leave to our contemporaries all moralisings on the interesting event of next week. There is nothing new to be said about International Medical Congresses in general.

It is not to be expected that the Congress at Copenhagen will be as big or as brilliant an affair as the London Congress. To match that, or to "whip" it, we must wait another three years, until the United States are given an opportunity of showing what they can do at Washington. Still, size and lavish expenditure are not necessary to make a Congress successful from a scientific point of view ; possibly they interfere with such success. At any rate the list of subjects and the names of the contributors who are to engage attention at Copenhagen warrant one in believing that quite as good work will be done in the Section rooms there as was done at Burlington House three years ago. The United Kingdom will be well represented at the Danish capital. Sir William Gull, Sir Joseph Lister, Sir Spencer Wells, Sir W. MacCormac, Sir Joseph Fayrer, Dr. Burdon Sanderson, Dr. Ferrier, Dr. de Chaumont, Mr. Bryant, and their younger colleagues, may be safely trusted to worthily uphold the reputation of the English School against the many redoubtable champions of Continental science—Virchow, Pasteur, Paul Bert, Koch, Ranvier, His, Panum, Tommasi-Crudeli, Esmarch, &c.—whom they will meet.

In one respect the Copenhagen Congress seems likely to surpass previous meetings of the same nature. It will be remembered in years to come, it is to be hoped, as having witnessed the successful inauguration of a movement which is the necessary complement of these international gatherings, and which will, no doubt, have an important influence on the scientific progress of the future. It is gratifying to think that England is taking the leading part in organising the proposed "International Collective Investigation of Disease," and certainly the task could not have been entrusted to better hands than those which are to carry it out. Sir William Gull will stand sponsor for the new-born scheme at one of the General Meetings, while the active work required to set it upon its legs will be undertaken by Professor Humphry, Dr. Mahomed, and Dr. Isambard Owen. Sir William Gull may be confidently expected to rise to the occasion, and his address on the subject will be marked by that philosophic breadth of thought and happy suggestiveness of speech which he always has at his command. The idea is a big one, and it is a credit not only to England, as we said before, to have been the earliest to propose it, but it is a credit also to Medicine that she should be the first of the sciences to organise and gather up the research of the nations. Such, however, is only in accord with her proud title, "*Mater Scientiarum.*"

ANTI-VACCINATION ARGUMENTS AND FIGURES.

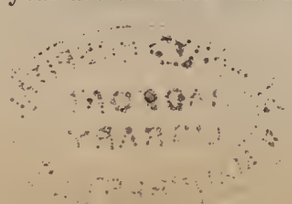
We can understand the motives which actuate the most rabid teetotallers, opponents of the Contagious Diseases Acts or anti-vivisectionists, so-called ; and however much we may differ from them in their conclusions, we can make some allowance for the exaggerations, if not misrepresentations, into which they are led by their mistaken zeal in what they suppose to be a crusade against cruelty, immorality, or vice. But it is quite otherwise with the promoters of the agitation against vaccination, with whom it is impossible for any reasonable man to feel the smallest sympathy. No questions of morals or religion are involved, but simply those of scientific facts to be approached and solved like any others in the domain of public health ; in short, they are these : Does vaccination confer any real protection against attacks of small-pox, or diminish the mortality of the disease? Is it attended by any appreciable danger to life, or risk of communicating other diseases? And, supposing both questions answered in the affirmative, do the certain benefits of vaccination so outweigh the contingent dangers as to justify its compulsory performance? This is the real point at issue, which demands a fair and full examination, for the mass of statistical and experimental evidence in support of vaccination is so overwhelming and so consistent with itself that to discredit it necessitates the monstrous assumption that, with the exception of a few obscure individuals, so few indeed that in each country they may be counted on

the fingers of one hand, the whole medical profession throughout the world is involved in a huge conspiracy, agreeing in their mis-statement of facts and manipulation of figures, in order that certain of their brethren may profit by the fees paid for vaccinating infants at 1*s.* 6*d.* each—*Credat Judæus non ego*—and yet these very men who would remorselessly sacrifice the health of future generations to the Moloch of trade interests are everywhere indefatigable in promoting, too often thanklessly, those sanitary measures which tend to reduce the total amount of disease, and to which alone, the anti-vaccinationists would have us believe, any diminution in the mortality from small-pox is to be ascribed. Surely it is at once more probable, and more charitable to believe that the leading opponents of compulsory vaccination are, like those who formerly resisted the factory and adulteration acts, so possessed by a feeling of repugnance to any interference with the so-called liberty of the subject as to be incapable of distinguishing truth from falsehood, or of seeing anything that is contrary to their pre-conceived ideas, if, indeed, prejudice have not blunted or effaced their moral sense; while their following is composed of persons who, whether from sheer ignorance, credulity, or an innate aversion to compulsion, are easily deceived by reckless assertions into the accuracy of which they have neither the means of enquiring nor the disposition to do so.

To refute the undigested mass of shameless mis-statements, gratuitous assumptions, statistical jugglery, and fallacies of every kind which constitute the literature of these people would be a veritable Sisyphean labour, or like cutting off the heads of the Lernean monster. No credit whatever can be reposed in their figures; Dr. C. J. Pearce, for example, in several parts of his book asserts that the death-rate from small-pox for the five years 1875–79 was in England and Wales no less than 344 per million, whereas the correct figure is 82, and that the mortality has not diminished since the passing of the Vaccination Acts, whereas the mean annual mortality for the whole preceding period for which statistics are available was 420, and for the twenty-eight years 1854 to 1881 only 196 per million. But still more fallacious because more plausible is their mode of manipulating accurate statistics so as to deduce false conclusions from true premisses. Dr. Boing, their champion in Germany, says truly that in the ten years preceding the first Vaccination Act of 1867 there were in England and Wales 41,606 deaths from small-pox, and in the eight years following, which included the epidemic of 1871–72, the heaviest of which we have complete records, 53,933. Very well, but if we classify the deaths according to age we shall find that the great majority of these were born before vaccination was made obligatory, and that their deaths should be credited to the want of compulsion in their infancy. Again, they persistently refuse to distinguish between the deaths, if any, of vaccinated children under one year of age, and of those who have not yet been vaccinated, assuming that because vaccination at some period, three, six, or twelve months in different countries, is obligatory, every infant born into the world is from that moment a sharer in the alleged benefits of the operation. Whereas, the vast majority of deaths under one year are of those who have for some reason or other not been vaccinated, for a large number, in some London parishes 15 to 20 per cent., escape vaccination altogether. These fallacies might be ascribed to thoughtlessness, but we could expose others so gross that they must have been intended to deceive others since it is impossible to believe that they could have deceived their authors.

Much harm has been done to the cause of vaccination by the propagation, which its opponents are inclined to view with complacency, of absurdly exaggerated notions as to its efficacy, *e.g.*, that the protection afforded is, or ought to be, absolute, and bears no relation to the number or size of the vesicles, and that want of success in vaccination or re-vaccination is evidence of insusceptibility to small-pox infection. It is of the highest importance that the public should be provided with correct information as to what is and what is not vaccination; what it does and what it does not claim to do. To begin at the beginning: there is probably no such thing as an infant insusceptible of successful vaccination; at least, Dr. Cory has vaccinated 15,000 without meeting with one such; there may be degrees of susceptibility, but we know well that there are degrees of operative skill. The insusceptibility to the infection of small-pox imparted by successive vaccination is at first almost absolute, irrespectively of the degree of success attained, but it is otherwise with the duration of this immunity which is directly proportional to the efficiency of the vaccination, as is also the modifying influence exerted by the vaccination on any subsequent attack of small-pox. In the case of a child in whom only one insertion has taken the protection is probably lost after the lapse of a year, whereas in one with four or five good vesicles it lasts for ten or more years. But whatever permanent influence a thorough primary vaccination may exert over the remainder of life, re-vaccination, best performed when the effect of the primary operation has begun to fade, *i.e.*, soon after the tenth or twelfth year, if that were satisfactory, or earlier if it were not, is absolutely necessary for future protection. The immunity conferred by re-vaccination is equal to that given by an attack of small-pox itself; thus of the 14,000 patients admitted into the Homerton Hospital in 1871, only four had been re-vaccinated, and the only cases among the attendants in the hospitals of the Metropolitan Asylums Board were those of persons who had not been re-vaccinated. It is unreasonable to expect absolute and permanent immunity when we know that small-pox itself does not infallibly protect from a second attack. Dr. Neuretter found among 1,133 children under 14 years of age treated for small-pox in the Children's Hospital at Prague between 1870 and 1873, no fewer than thirteen, or more than one per cent., had suffered previously, nine of them within seven months. Yet no one doubts that small-pox is one of those diseases which occur, as a rule, but once.

The most complete statistics as to small-pox and vaccination are to be had from Germany, where nearly all medical men are in some sense servants of the State, where the profession is more organised than it is here, and where the military system involves the examination of every man on his attaining his twentieth year. Thus Staff-Surgeon Evers in 1882 found among



2,291 men, the entire surviving male population born in the battalion districts of Chemnitz, in the year 1862, 1,946 who showed marks of vaccination and 345 who did not; of the former 26, and of the latter 73 had had small-pox, *i.e.*, 1·3 of the one, and 78·8 of the other; no account being taken of those who had died of the disease during the severe epidemic of 1871-2 which had intervened. Of that epidemic Dr. Flinzer, of Chemnitz, has left us records unexampled for their completeness. The population was a little over 64,000; the cases of small-pox were 3,596 and the deaths 249. Analysing these he shows that 2,643 cases and 242 deaths occurred among 5,712 unvaccinated, and 953 cases with 7 deaths among 53,891 vaccinated persons; 4,652 who had already had small-pox escaping altogether. No death occurred among the vaccinated under 14 years, while 220 (or 88 per cent. of the total mortality) were of unvaccinated children. The period 1870–3 was one during which small-pox raged throughout Europe with a severity unknown since 1838, and it is interesting to compare the mortality in Bavaria, where vaccination was compulsory at some time *during the first two years* of life, with that of Holland where it was optional. For every 100,000 living at each of the ages 0 to 1, 1 to 5, 5 to 10, and 10 to 20 years, the deaths in Bavaria were 232 (most if not all of them unvaccinated) 10, 3, and 2. In Holland 767, 455, 145 and 72. Thus, of every 1,000 children born 593 (!) in that country died of small-pox within the year! No statistics which do not take account of ages and distinguish between vaccinated and unvaccinated infants, are of the smallest value for, as we have seen from Dr. Flinzer's figures, showing that nine-tenths of the deaths occurred among the latter. Vaccination may be strictly enforced and yet, the disease being once introduced, a heavy mortality occur among the children on whom the operation has not yet been performed, the vaccinated population enjoying immunity. It was so in pre-Jennerian days, when the mortality was almost confined to infancy and childhood, as was clearly shown by the tables laid before the Epidemiological Society at their last meeting. The reason why so many adults at present are attacked by, and die of, small-pox is that they were protected during early life by vaccination, but neglecting to be re-vaccinated they become susceptible again after puberty.

The anti-vaccinators are never weary of appealing to the small-pox statistics of Berlin of 1871-2, but it should be generally known that the more stringent vaccination laws of some of the smaller states were not adopted by Prussia until after the lesson taught by that epidemic. Dr. Voigt tells us that in Hamburg vaccination was rarely performed until the fifth year, when the school regulations made it necessary, and in Berlin it was far from general. Both towns suffered heavily, but since that time the number of deaths in Hamburg, with its 500,000 inhabitants and the great thoroughfare of emigration, has averaged 5 per annum, and in Berlin, with a population of 1,225,000, they have, with the exception of one year when they amounted to 50, been but from 2 to 8 annually. But even in the great epidemic years during the Franco-German war, the French Army lost 23,232 men, and the Germans, vaccinated for the most part, though, as we have reason to know, not universally on enlistment, lost only 223! With the present prevalence of small-pox in England it is interesting to observe that for a long time past the total deaths from this cause in the whole German Empire have averaged from 2 to 4 per week and that a large proportion of these have occurred in Metz, which has been a German town only since 1871, though in Prague, which politically is outside the Empire they range from 10 to 20 weekly. In Frankfort not a single death has been recorded for we know not how many years.

The strongest, indeed the only plausible, objection that can be urged against vaccination, is the possibility of the communication of syphilis, the production of erysipelas or blood-poisoning, and it is alleged of other skin diseases. As to the latter we may state positively that their appearance after vaccination is a mere coincidence, or at most that it may have been accelerated by the febrile irritation set up. We have seen several instances of eruptions, as eczema, occurring at the the third or fourth month in children whose vaccination had been deferred for some reason or other, but which would otherwise most surely have been attributed to the operation. Erysipelas will follow the inoculation of septic matter or exposure to sewer gases after vaccination as after a scratch with a pin, and we have seen cases of erysipelas in the vaccinated infant side by side with diphtheritic sore throats, and other results of blood-poisoning in other members of the family attributable to the same cause.

Lastly, with regard to syphilis, no one can deny that it has been communicated by vaccination; but such an accident cannot occur without gross negligence on the part of the operator. However desirable it may be, it is not necessary to know the pedigree of the vaccinifer; a child whose skin is perfectly clear, and whose vesicles are of typical form, may be safely used as a source of lymph; but we would advise our medical friends never to vaccinate even from unimpeachable sources a child who has the slightest evidence of congenital syphilis, lest he be made a scapegoat for the sins of its father. Such cases have not unfrequently occurred, and no Local Government Board enquiry will remove the obloquy incurred by previous misrepresentation. The employment of calf lymph, though it has no advantage over human as regards efficacy, has the merit of precluding such an allegation.

CIVILISATION AND THE TEETH.

If the fully-evolved man of the future is to be, as has been prophesied, a hairless individual, he is only too likely to be—excepting his indebtedness to the manufacturing dentist—a toothless mortal also; for which result a persistent preference for ornament over use must be mainly held responsible. If Helen of Troy possessed teeth as good as those of her Britannic contemporaries, she had probably as square a jaw, and a mouth of equally capable dimensions. One item in the civilised ideal of female beauty, the rose-bud mouth to wit, is undoubtedly accountable for a great deal of the crowding and consequent injury of the

teeth especially observable in patients of the upper and middle classes, while the frequent decay of the back teeth even before the marriageable age is reached, and the persistence of the visible front teeth till shortly after that age would seem to show that natural selection has some of the infirmities not usually associated with abstractions, and that "out of sight" is even for it "out of mind." Certain of the luxuries of modern life, and the operation of some of its so-called duties, aid in completing that destructive effect against which, curiously enough, another outcome of the civilising process—inherited gout—alone seems able to oppose its recognised attributes of large, regular, strong, and well-enamelled teeth. In the case of the negroes of the Southern States of America, a remarkable dental degeneration seems to have attended the changes in food and habits which followed the abolition of slavery. Formerly the slaves lived chiefly on corn-meal and meat: at breakfast, coffee, and with dinner, vegetables were taken in addition. Occasionally wheat-flour took the place of corn (maize), but it was ground on the plantation and not bolted. This food, served at regular hours, and combined with plenty of fresh air, exercise, and sleep, made the teeth strong and hard. Now the negroes eat fine wheat-flour bread, spend a large part of their wages in sweetmeats, eat at irregular times, and sleep too little.

The other side of the story is presented in a paper recently published by Dr. Kirk, who has under his care, in the Pennsylvania Institute for Deaf and Dumb, the teeth of some 400 children. By the time that the children have been a year in this institution an entire change is noticed in the character of their teeth; they have become so hard that the instruments must be re-tempered in order to cut the dentine in preparing the cavities for filling; they become more firmly implanted in their sockets, and extraction is thus rendered difficult; several cases of the spontaneous arrest of caries, and of new formation of dentine have been observed. These favourable changes are attributed to the dietary, which consists largely of various preparations rich in bone-forming material, such as maize, oats, and wheat, from which the layer just beneath the siliceous coating has not been removed in milling, together with a liberal supply of milk and a limited amount of sugar.

Another important, but only lately recognised, cause of dental decay, is the undue exaction of nervous energy—probably often combined with insufficient or improper alimentation. Recent observations have shown that carious teeth are common in modern schools in proportion to the educational standard adopted; and that the children in the higher forms have—out of all proportion to their more advanced age—worse teeth than those below them; while caries has not infrequently been noticed to commence suddenly, or to extend rapidly, during the period of examination strain. The greater work imposed upon the cerebral and other nervous centres is supposed to divert a portion of the phosphates and other mineral constituents which ought, by rights, to be devoted to the nourishment and growth of the dental structures; and it is not improbable that the secretion of the buccal glands and mucous membrane is modified under the influence of mental exertion, to the deterioration of the teeth.

A newly-awakened affection for certain hygienic reforms promises to accomplish much for us and for our descendants; but fashion and folly are doing even more in other directions. If it be true that the spread of a dietetic love of water is the real reason why the increase in the medical profession has not exceeded three per cent., something less innocent, surely, is responsible for an addition of 43 per cent. to the ranks of the dentists during the same period. Altogether, although the means of securing present comfort, and of avoiding an otherwise not distant era of toothlessness appears quite within our reach, the prospect is not reassuring. A few generations will pass and a posterity which may be learned in the application of "atmospheric suction," and in celluloid and gold plates, will universally sleep without its dental tools; it will miss the point of many allusions in the writings of its ancestors; and the figures which are now stereotyped in our handbooks of anatomy as representative of the infantile, the adult, and the edentulous jaw, will be regarded in the light of an anatomico-archæological puzzle. Teeth—in the sense in which we still use the word—will then remain only to such animals as are too stupid or too wise to be civilised and educated.

REVIEWS AND NOTICES OF BOOKS.

LARYNGOLOGY IN PRACTICE.[1]

A VAST number of works on the special subjects which now form no inconsiderable part of the average doctor's every day requirements are published for the nominal benefit of "students and practitioners." To what extent they are successful in hitting the mark at which they aim, the publishers and booksellers alone can tell; the measure of success which they merit may, however, be judged by anyone who will take the trouble to peruse them. Such a perusal of Dr. Gottstein's work will probably lead the reader to the conclusion that to him at least the credit of having produced a work at once comprehensive, clear, and practical may fairly be conceded. The study of Laryngology has of late years received far more attention at the hands of teachers and students than was ever the case in former times, and the value of a practical knowledge of laryngoscopy has become well recognised in the daily routine of work, and is no longer the exclusive privilege of a limited number of specialists. An essentially practical work upon the subject is therefore fully justified in its appearance, and may fitly supplement the standard works of Mackenzie, Stoerk, Tobold, and others of established reputation.

In dealing with the subject, Dr. Gottstein has divided his work into three main divisions, in the first of which he discusses laryngeal disease in general, its ætiology, diagnosis, and treatment, entering with sufficient detail into each. In his second division

[1] *Die Krankheiten des Kehlkopfs* (Diseases of the Larynx). By Dr. J. Gottstein, Docent in the University of Breslau. Vienna: Toeplitz and Deuticke; 1884; pp. 261.

he treats of the primary affections of the larynx, inflammatory, traumatic, and nervous, and of the new growths which may occur within it. The third part relates to those affections of the organ which are secondary to some form of general disease. The early chapters dealing with the technical part of the subject are written in a very practical tone, and evidently embody the teachings of a wide experience. The rule that no laryngoscopic examination can be regarded as complete unless the anterior commissure of the vocal cords be clearly seen may possibly sound severe, but it is a rule that ought always to be borne in mind, if only as a stimulus to the zeal of laryngoscopists who find it difficult of fulfilment. Although bound, as the writer of a text-book, to make mention of all the divers methods of introducing remedies into the larynx, the author gives very clear indications of his own preference for certain modes of treatment. Thus he is by no means enthusiastic about the use of medicated spray, believing that so little of the medicine reaches its destination by this means that for all practical purposes plain steam would be just as useful. The direct introduction of the remedy by means of the brush or the insufflator he regards as far more effective, always provided that it be introduced under the guidance of the mirror. The use of the galvano-cautery is but lightly touched upon, preference being given to the forceps or the guillotine in cases of endo-laryngeal tumour. The advantages of the galvano-caustic apparatus of Voltolini and of Bruns would appear to deserve something more than passing mention. The difficulties attending the introduction of instruments into the larynx are of themselves considerable, and the substitution of the light thin wire for the thick and heavy handle of the forceps or the guillotine is no small gain where absolute accuracy of touch is required. The freedom from hæmorrhage and the diminished pain and laryngeal spasm which follow its application ought also to be regarded.

In dealing with the subject of acute laryngitis the author draws especial attention to the nocturnal spasm of the glottis which is prone to attend the affection in young children. The occurrence of isolated "croupy attacks" in children who otherwise enjoy good health is familiar to most practitioners, but its true nature is frequently left undecided. The importance of recognising the premonitory symptoms and instituting the appropriate treatment, which is in the main prophylactic, is here fully insisted on. In the diagnosis of chronic laryngitis due importance is attached to the necessity of making a thorough examination of the general condition of the patient, and especially of the thoracic viscera, before coming to a conclusion. In the simple forms of this condition local applications must be recognised as the appropriate treatment, and in expressing this opinion, Dr. Gottstein stands in complete accord with all previous writers upon the subject. This truth, perhaps, is but too little regarded in this country where it must be confessed that gargles and inhalations are too often resorted to for indefinite periods with results as unsatisfactory as the treatment is unscientific. In dealing with the various forms of laryngitis, much stress is laid by the author upon the condition which he terms submucous laryngitis, and which is, in effect, inflammation of the submucous cellular tissue, analogous both in its course and its causation to the corresponding condition in the subcutaneous tissues. In many respects the laryngeal changes which it induces may resemble the alterations set up by perichondritis or by œdema. It is generally local at first, and not of necessity symmetrical, but usually attacks the loose folds of submucous tissue, as in the ary-epiglottic folds or the inter-arytænoid mucous membrane. The condition has been described and figured by previous writers, but not differentiated with sufficient clearness from the affections which it resembles. The processes of ulceration as seen in the larynx are described concisely and clearly, and a wholesome caution is given against over-readiness to diagnose the condition from the laryngoscopic signs alone. Morbid growths and their operative treatment are described and discussed somewhat summarily. The author expresses dissent from the frequent use of the galvano-cautery in such cases, but gives no reasons for his adverse opinion. He would in all cases prefer the removal of growths *per vias naturales* where possible, and would reserve the extra-laryngeal treatment for the remainder, or for cases where extreme dyspnœa, dysphagia, or aphonia are present. Amongst the most valuable, if not the most original, sections of the book is that relating to the neuroses of the larynx. A good description is given of the disturbances of co-ordination of the movements of the vocal cords, many instances of which have of late been put on record. The law which has now become established with respect to paralysis of the recurrent laryngeal nerve, that the abductor muscles supplied by it are the first to lose their function is here accepted as the opinion of "all authors." It may not be out of place to note that the discovery of this law, mainly due to the labours of Dr. Felix Semon, is of very recent date, and but few authors have as yet found the opportunity of expressing their opinions upon it. Of the concluding chapter upon the secondary affections of the larynx, space will not permit of any detailed notice. The book as a whole is a practical treatise of real value to practical workers, and may be accepted as a trustworthy guide by those "students and practitioners" to whom it is especially addressed.

Transactions of the American Gynæcological Society. Vol. VII., for 1882. Philadelphia: Henry C. Lea, Son and Co.; pp. 485.—This volume is perfect as usual in paper, type, and binding. As to its contents, although it contains plenty of matter for study, yet better volumes, in our opinion, have appeared in the series. The first paper is by Dr. Emmet, on "a new method of exploration, with the pathology and treatment pertaining to certain lesions of the female urethra." This new method is the making of a urethro-vaginal fistula. According to Dr. Emmet, this is "the only method within our knowledge to-day which fulfils every indication; is safe, simple, and within the scope of any one possessing the least degree of surgical dexterity." We are inclined, until the subject is better understood, to put this along with Dr. Emmet's astonishing assertion, that women never become pregnant after the cervix has been torn. We cannot always tell whether Dr. Emmet is joking or not. He seems aware that some of his dicta excite surprise, for he prefaces the statement quoted by saying, "I have been told by my friends that I hold a fair reputation with the profession, for being reliable and moderate in my statements." We need not criticise

the paper, because the bubble was pricked by Dr. Skene, who in an excellent speech corrected Dr. Emmet's exaggerations, and put a reasonable, perhaps somewhat too favourable, view of the new method before the association. We would advise those who read Emmet's paper, to read also Skene's criticism of it. As Dr. Skene says, "honesty of purpose does not always secure accuracy of observation or soundness of judgment." The next paper, on "the proper use of ergot in obstetrics," by Dr. Joseph Taber Johnson, is also characterised by absurd exaggeration, and was also effectively and rationally criticised. Dr. Fordyce Barker's speech will serve as the antidote to Dr. Johnson's extravagance. Dr. Drysdale describes at length his views on the "ovarian cell;" but it was apparent in the discussion that he has not yet convinced the profession of the diagnostic value of these bodies. Dr. Stansbury Sutton writes on "the treatment of the pedicle in ovariotomy," and Dr. Parvin on "the cure of the perinæum," but neither of these papers contains anything novel. Dr. Fordyce Barker, in a paper on "leucorrhœa," reminds his readers of the fact, which some might think has been almost forgotten in America, that leucorrhœa sometimes depends upon constitutional causes, and that in such cases local treatment is neither necessary nor beneficial. Mr. Knowsley Thornton states his opinion, which will be well known to readers of this journal, as to "the relative value of hysterectomy, and removal of uterine appendages for the cure of uterine fibroids." Then follow two very unsatisfactory papers on the subject of "extra-uterine pregnancy." The first is by Dr. Garrigues, on the treatment of this condition by electricity. He thinks this measure curative; but in most of the cases he relates, the diagnosis is open to doubt. Dr. Thomas gives the history of 21 cases coming under his own observation. But the diagnosis was unverified in too many of them for the paper to be of scientific value. Dr. S. C. Busey writes on "the influence of the constant use of high-heeled French shoes upon the health and form of the female, and upon the relation of the pelvic organs." Dr. Busey's writings upon the diseases of the lymphatic system are so good, that we read with respect anything coming from his pen. The present paper, however, is purely theoretical. Dr. Busey simply points out what might be expected to follow; he does not adduce any evidence that these consequences actually are produced. In the discussion which followed, several speakers remarked that numbers of women wear these shoes without suffering from any evident ill effect. The next paper is a really extraordinary one. It is by Dr. Ely van de Warker, on "the mechanical therapeutics of versions and flexions of the uterus." The author fervently believes in mechanical gynæcology, and his paper is illustrated with no less than 138 pictures of pessaries! What is also remarkable is, that it is put forward as a "pioneer paper." The author describes the lever action of Hodge's pessary in pulling up the posterior vaginal attachment of the uterus. This explanation was first advanced by Schultze. It was brought to the notice of the Obstetrical Society of London, in 1876, by Dr. John Williams, who gave due credit to Schultze. Dr. Williams's paper, on "the mechanical action of pessaries," was appropriated without acknowledgment by Dr. Frank P. Foster, who read a paper identical with it, both in title and in substance, before the American Gynæcological Society, in 1881. And now, in 1882, we have it again reproduced, without mention of any previous writer, in this "pioneer paper!" Which almost forces one to believe that in America a pioneer must mean a person who comes last! Dr. Collins Warren describes a modification of the operation for ruptured perinæum, but it does not seem to us an improvement. Dr. W. L. Richardson, of Boston, comes next, with a valuable contribution to scientific obstetrics, in the shape of a further series of those measurements of the uterine cavity in childbed, by which he has done so much to advance our knowledge of the process of puerperal involution. Dr. Mann furnishes a laborious and useful paper on "surgical operations on the pelvic organs of pregnant women." Dr. Baker writes on "hyperæmia of the vesico-uterine membrane" detailing a number of cases in which, to cure irritable bladder, he submitted the patients for several months to the inconvenience and suffering of a vesico-vaginal fistula. There seems to us no evidence to show what was the morbid condition present in the cases described; and it may well have been that the patients professed themselves well, simply to avoid further treatment. The volume concludes with a memoir of Professor James Platt White, written, in a somewhat inflated style, by Dr. T. Gaillard Thomas.

Although we have criticised freely some of the papers in the volume, yet we are glad to say that both in some of the papers and in most of the discussions, we think we perceive a less tendency to exaggeration, more hesitation before jumping to conclusions, some increase of scientific scepticism—in short, a little swing of the pendulum towards conservatism, caution, and moderation. Whether we are right in this, whether the re-action against excessive local meddling that is felt in England has yet spread to America, time will show.

Mittheilungen aus der Chirurgischen Klinik zu Tübingen; von Dr. Paul Bruns. 1. und 2. Heft. Tübingen: H. Laupp, 1884, pp. 380.—These "contributions from the surgical clinic" of the Würtemburg university may best be compared to our volumes of Hospital Reports, of which those that proceed from Guy's form one of the oldest and best examples. Situate on the borders of the Black Forest, Tübingen is a little out of the ordinary track of students visiting the Continent. Yet its university, founded in the latter half of the 15th century, is very highly and justly esteemed. The volume is dedicated to the memory of Victor Bruns, who was chief surgeon from 1842 to 1881, and well known for his many contributions to practical surgery. The papers are by different authors, either past or present "assistants" in the Hospital, and embrace the whole range of surgical cases, which will be found discussed from the latest and most advanced scientific standpoints. Thus, Dr. Bruns (now Chief Surgeon, and editor of the volumes) among other papers contributes one on the operative treatment of irreducible separation of the epiphyses. In cases without external wound, he suggests boldly cutting down on the injury, and removing the extremity of the diaphysis, and then reduction of the epiphysis to its normal position; his suggestion is supported by two successful cases. If the subsequent volumes maintain the standard of the present ones, they will prove a most interesting addition to this periodic class of literature. They are well illustrated, and as regards type and general finish, do credit to the publishing firm from which they issue.

Index of Surgery; by C. B. Keetley, F.R.C.S. London: Smith, Elder and Co., 1884. Second edition, pp. 494.—This book is for the senior student; it is intended by the author that it should be read just before the final examination, after he has carefully studied a complete text book of surgery. By going over the various diseases systematically and giving himself a mental examination on each point as it turns up, the student is able to test his knowledge; if he is unable to follow the index, he must read up the subject at greater length in his text book, and try again. Used in this manner the book will prove very useful. We must congratulate the author on the rapid sale of his first edition.

On the Treatment of Spinal Curvatures by Extension and Jacket; by H. Macnaughton Jones, M.D. London: J. and A. Churchill, 1884.—We hope that every one who has adopted Sayre's treatment of spine disease will not think it necessary to write a book and say so. Excepting to announce this fact, we do not quite see what object Dr. Jones has had in view in the present publication. Having, however, said this much, we readily admit that the treatment followed, both in regard to the spine and also to the hip and knee joints, commends itself to us as being based on rational principles, and the descriptions of the various apparatus recommended are well written. The book has a sufficient profusion of illustrations.

The Retrospect of Medicine; by Drs. W. and James Braithwaite. Vols. 88 & 89.—This well-known work continues to maintain its place among professional literature. Its

size is convenient, and though closely printed, the text is clear and easily read. For the practitioner, too busy to wade through the piles of periodical literature now published, and yet anxious to keep himself fairly posted in what is new and good, we can confidently recommend the work before us; he will find it an engaging and useful carriage companion during his rounds; there are few subjects of any importance which are not referred to at greater or less length. A copious index brings every article within easy reach of the reader.

ABSTRACTS AND EXTRACTS.

RICKETS IN WILD ANIMALS.

Although we have from time to time reported in our notice of the doings of the Pathological Society the many excellent papers on this subject by Mr. J. B. Sutton, we need make no apology for going over some of the same ground again in summarising his communication on the subject in the July number of the *Journal of Anatomy and Physiology*. For purposes of convenience he divides the life of a mammal into three stages, viz., infancy, during which the chief centres of the long bones are developed; puberty, at which the cartilages at the extremities of the long bones, though still separate from the shafts, become ossified; and maturity.

Rickets of Infancy.—The investigations, it should be mentioned, have been conducted almost entirely with regard to monkeys. The first symptom is that the monkey is less lively than usual, grovels about on the floor, and seems to be in pain. Paralysis in the lower extremities and with it incontinence of urine and fæces and priapism follow; the monkey swings himself along using his arms as crutches. Deformity of the chest and curvature of the spine make their appearance about this time, and if the animal is exposed to a chill he gets a cough which soon carries him off. At the autopsy the chief internal lesions are: the lungs show a certain amount of collapse, dependent on the diminished capacity of the thorax by reason of the falling in of the chest walls, to be alluded to directly; the heart generally shows a milk-white patch somewhere on its surface, a consequence of the friction also set up by the deformity in the shape of the thorax; fatty liver is very common, on only two occasions, however, was the spleen found enlarged, the stomach was often dilated; the spinal cord, in cases in which there had been paraplegia, was found compressed, and on microscopical examination it was found that the medullary sheaths, and axis cylinders also, in many places were destroyed, and that the nerve cells had either disappeared or undergone disorganising changes. Of more importance, however, were the changes in the bones. The thorax was pigeon-breasted, sometimes to an extreme degree; the ribs were beaded, a second row of beads being sometimes present near the angles, due really to sub-periosteal fractures. The bones of the skull were often so soft that they could be cut with a knife, those at the base exhibiting a marked degree of craniotabes, whilst those at the vault were somewhat thickened and spongy, and often presented on their inner aspects a worm-eaten appearance, that is to say, the cartilage-formed bones were thinned, whilst the membrane-formed bones had undergone thickening. A high degree of kyphosis was often present, but in addition the vertebræ were frequently very soft, and it is owing to this softness that, when the animal is in the erect position, the weight of the body compresses the vertebræ, thus causing them to encroach upon the spinal canal; to this may be added the fact that a layer of ossific matter is deposited upon the inner side of the vertebræ, and thus the compression of the cord and resulting paraplegia are fully explained. The clavicle is usually thickened, especially at the sternal end, the scapula is soft, the epiphyses of the humerus, radius and ulna are much enlarged owing to the deposit there of a spongioid tissue; the carpal and metacarpal bones are affected similarly, but to a less degree, the long bones tend to be curved, and their periosteum is thick. The long bones of the lower limb show precisely the same change; the pelvis shows a narrowing, especially in the antero-posterior diameter. On microscopical examination of one of the rickety epiphyses three zones may be recognised, viz., (1) A layer of normal cartilage exceeding many times its healthy thickness. (2) The layer of cells arranged in vertical columns, but consisting not of ten or twelve super-imposed cells, but in severe cases of rickets as many as fifty or sixty may be counted in a single column. (3) Beyond these a layer of irregular calcareous trabeculæ enclosing here and there "islets of spongioid tissue" and tracts of hyaline cartilage. The trabeculæ from the thickened periosteum pass into the bone as in health, but do not undergo ossification, which accounts for the softness of the bones.

Rickets of Puberty.—Baboons, bears, lions, and tigers were the animals chiefly studied in this respect. The symptoms are rather vague, paralysis and defective deutition being the commonest, the animal being destroyed on account of his paraplegia. In such cases the spinal cord is found nipped, the liver usually fatty, and often albumen in the urine. The disease may be general, or it may be limited to the axial skeleton alone or to the skull alone. When general the ribs are beaded, but there is not the same amount of deformity of the thorax as in the early form. The skull is immensely thickened, but not the base, only the vault; occasionally the bones of the face are affected, the permanent teeth are late in appearing. In the vertebræ proliferation of the cartilage between the centra and the epiphysial plates occurs causing a swelling, which encroaches upon and compresses the spinal cord. The long bones are not often much affected, they show the same changes as in the early disease, but to a less degree. When the skull is alone affected the thickening may reach a very high degree. Thus in the early form the limbs are chiefly affected, and in the later the skull and trunk almost exclusively.

Rickets of Maturity.—This is much less common. The disease attacks every part of the skeleton, and is evidenced by paraplegia, loss of teeth, and fracture of the bones of the limbs. The skull is light and porous, the alveolar margins of the jaw are absorbed, allowing the teeth to fall out; when fresh the bones are soft and may be cut with a knife, but when dried they are easily crumbled. The chest is often deformed, and the long bones are readily curved during life.

The causes of rickets in animals are probably the same as in the human subject, improper feeding being placed in the front rank. Mr. Sutton concludes his very interesting paper with a few remarks on the so-called fœtal rickets. He is entirely in accord with our best authorities in this country in regarding the affection as of the same nature as cretinism, and as having no real affinity with rickets.

MALE HYSTERIA.

The subject of hysteria in males has lately been brought prominently before the Berliner Medicinische Gesellschaft. A prolonged discussion upon some of the points raised served to show very clearly that the nature and origin of the phenomena so frequently grouped together under that convenient title, are as far as ever from any clear and comprehensible definition. The constant association of hysteria with affections of the uterus or indeed of any single organ has long since been disproved, but its frequent association with disease or disordered function of some of the viscera, is clearly shown by many recorded cases. It is only of recent years that the occurrence of hysteria in males has been fully recognised, and the proportion of male to female cases formerly given by Briquet as 1 to 20, is probably somewhat below the mark.

Heredity is a marked feature in these cases and there is usually a history of nervous irritability in childhood. The period of youth and puberty is the most common time for hysterical phenomena in males, whereas in women there is no period of life exempt from the liability. In his paper on the subject Herr Mendel relates some typical cases and points out that in some instances a kind of dual existence appears to be present in which the patient may be in perfect health with intervals of hysterical disturbance of the

nervous system, the memory in each state retaining no impressions of the events taking place in the other. He draws a marked distinction between hysteria and hypochondriasis. In cases of the latter class, the patient seeks out a cause for his discomforts, and fixing his mind upon the one point, cannot be reasoned or persuaded out of the truth of it, no matter how absurd and inconsistent it may be. The hysterical patient on the other hand exhibits a greater variety of functional disorders, is much influenced by his surroundings and gives every evidence of nervous instability. Hence the rapidity with which hysterical cases may be cured when entirely removed from old associations and the sympathy of relatives. Among the complex symptoms characteristic of hysteria, is that of local pain. Until recent years this local pain has generally been believed to be pelvic and to be associated with the ovaries.

Many cases however were cited in the debate on Herr Mendel's paper in illustration of the fact that such painful spots may also be found elsewhere. Pain localised in the right ovarian region was found to persist unaltered in a case in which the ovary and a tumour connected with it had been removed by Herr Landau, and hence it could not be due to direct local causes. In his remarks upon the case, however, the operator expressed belief that the pains are essentially to be regarded as forms of visceral neuralgia, having some peripheral origin, most probably in the genital apparatus. In an interesting case related by Herr Senator, two painful spots were discovered, symmetrically situated over the parietal bones, in a boy who exhibited very marked hysterical symptoms. Pressure on these spots, even during sleep, at once set up violent crying and struggling. The case was rapidly cured by isolation. The relation of these painful spots to the condition of hemi-anæsthesia in women is not as yet determined, but a few cases have been recorded by Remak and Landau, in which a bimanual examination of the ovary of the affected side proved the organ to be exquisitely tender. In one instance with similar symptoms, the painful spot was localised in a movable kidney.

OBSTETRICS.

Tearing of the Muscular Floor of the Pelvis during Delivery.—A recent number (Band xxii., Heft ii.) of the *Archiv für Gynäkologie* contains a paper which is important from the scientific reputation of the author on the above subject. He commences with a luminous description of the muscular floor of the pelvis, and this to our mind is the most valuable part of the communication. First he considers, for the purpose of refuting them, the absurd exaggerations current in certain American books as to the functions and importance of the perinæum. He points out that the so-called "perinæal body" is really a very small thing, and not at all the gigantic structure displayed in certain diagrams; that it may remain torn through for years, without any prolapse resulting; and that the most extreme degree of prolapse may occur in patients in whom the perinæum is intact. These are facts familiar to every observant gynæcologist, and insisted on by Dr. Matthews Duncan in his work on the perinæum and in his clinical lectures. Dr. Schatz then studies the structure and functions of the "pelvic diaphragm." Here his work is upon the same lines as that of Dr. D. B. Hart, of Edinburgh. The pelvic floor is composed, he says, of three muscular systems. The hindermost consists of the muscular and ligamentous bundles going from the coccyx to the ischial spines. The middle system is formed by muscles running from the ischial tuberosity to the coccygo-anal ligament. The anterior system is composed of the fibres of the levator ani. The anterior part of the diaphragm is thus purely muscular, the middle partly ligamentous, while the posterior has an osseous support. The posterior stretches the least, the anterior the most, during labour. Therefore when the muscular floor of the pelvis is torn, it is most often the levator ani which suffers, less often the more posterior muscular systems. When such tearing has occurred, it can be ascertained by the finger in the vagina, which will feel the gaps in the tissue made by the giving way of the muscle. These may be at the posterior, or lateral parts, the former being the more common. They may, or may not, be combined with lacerations of skin or mucous membrane. When they are so combined Dr. Schatz recommends sewing them up. He thinks that they occur most often in women with rigid unyielding soft parts, and are best to be prevented by the use of hot irrigation and warm baths. In describing these clinical phenomena Dr. Schatz does not detail any observations verified by dissection, or by especially carefully made and exactly recorded observations in the living. It appears as if he had rather thought it enough to apply his theoretical deductions to the explanation of familiar clinical facts. The practical part of the paper, therefore, seems to us the weakest, but the prefatory description of the pelvic floor we think, as we have said, most luminous and instructive.

The Use and Abuse of the Forceps.—Professor Goodell made the following observations in a recent clinical lecture:—"Tears of the perinæum will occur whether the physician uses the forceps or not, but in the majority of cases they come from the use of the forceps, or rather from the abuse of the forceps. Let me give a piece of advice to you as young men. When the proper time comes, put on the forceps and boldly bring down the head, but when it begins to bulge the perinæum, take off the forceps. I do not think that any of you are competent to deliver the head over the perinæum with forceps. The temptation is to turn the head out too quickly. If you take off the forceps you will rarely have a bad tear, and if it does occur you will not get the blame for it. It is a very rare thing for me to end a labour with the forceps on. When the perinæum begins to bulge, I support the handles to see whether the pains are strong enough to end the labour. If so, I remove the forceps. There is such an abuse of this instrument that I sometimes think that Baudelocque was right when he said that the forceps had done more harm than good. It requires great skill and judgment to end a labour with the forceps. A physician from inexperience, or being demoralised by a long and tedious labour, is liable to use undue violence and deliver the head too quickly, or to make traction in the wrong direction. I have myself torn the perinæum, and seen many good physicians do the same. From this experience I should recommend that, unless there be an excellent reason for contrary action, the forceps be taken off when the head reaches the perinæum. Occasionally one blade will catch over an ear and you cannot get it off; but in the majority of cases it can be removed, and that is the proper thing to do."—*Philadelphia Medical Reporter*, June 14.

Craniotomy in Germany.—Dr. Adolph Merkel contributes to a recent number of the *Archiv für Gynäkologie* an analysis of 100 cases of craniotomy occurring in the Leipzig clinic. Statistics are of very little use in determining questions relating to this operation, because its results depend almost entirely upon the personal dexterity of the operator, the cases in which the operation is done, and the time at which it is done. An obstetrician who recognises the necessity for the operation early, and therefore does not waste time in fruitlessly attempting delivery by other methods, and who handles his instruments skilfully, ought to get a mortality, so far as the mother is concerned, not larger than that of ordinary labour. There are, however, two points in Dr. Merkel's communication worth noting. One is, that his results of craniotomy followed by cephalotripsy are better than those in which the latter operation was not done. The other is, that the author finds the scissor-shaped perforator (Levret's is the form he uses) better than the trephine, which is so commonly used in Germany, and recommended in German books. The latter discovery, English practitioners have long since made; and we doubt not, that if they will try the English perforators, German obstetricians will come to agree with Dr. Merkel.

"Endometritis Dissecans."—Dr. P. Kubassow, of St. Petersburgh, contributes a paper to a recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie*, in which he describes three cases of an unusual kind, to which the above name has been given. They are cases in which the lining membrane of the uterus was separated and cast off

entire, in an unbroken sac. They thus seem analogous to, if not identical with, the morbid condition known as membranous dysmenorrhœa; but they differ from it in that the membranous sac, instead of being regularly passed every month, was only discharged once, in the course of an acute illness. The thought occurs to the reader at once, that they are possibly only cases of early abortion. In one of them a dilated and ruptured Fallopian tube, with a considerable extravasation of blood in the pelvis, was found *post-mortem;* a state of things which, on the face of it, looks as if there had been extra-uterine gestation, and the membranous sac passed had been the uterine decidua. Dr. Kubassow thinks that the exfoliated membranes were not products of pregnancy, either intra- or extra-uterine, for these reasons. (1) The history was not that of pregnancy. (2) The histological structure of the membranes was not that of decidua, the giant cells characteristic of the latter being absent. (3) No ovum, nor any trace of ovular attachment was found. Dr. Kubassow has not been able to find this disease described by any author except a compatriot of his own, Dr. Siromjatnikoff, who has published two cases. These two, with Dr. Kubassow's three, are the only cases as yet published of the disease "endometritis dissecans, vel exfoliativa." For the name Dr. Siromjatnikoff is responsible.

Dermoid Cyst. — Dr. Baker (*Boston Medical and Surgical Journal*, January, 1884) reports the case of a hospital patient who was considered to be suffering from pelvic abscess. The aspirator-needle, carried up behind the uterus, gave a fluid like pus; a free incision opened the peritonæal cavity, into which the air entered with a good deal of noise. The fluid proved to be not pus, but fat, and upon this circumstance was founded the diagnosis of dermoid cyst. An incision, about an inch long, was made into the cyst, and its edges united with those of a corresponding incision in Douglas's pouch. Injections into the cyst were repeatedly made; at one time a mass of hair presented and was removed, and later tissue containing teeth and bone came away. Knowing the difficulty of destroying the interior of these cysts, Dr. Baker passed a Sims' speculum *into* it, and applied the thermo-cautery to the whole surface. This was done four years ago, and the patient has remained well since, with no appearance of any return of the cyst.

Unusual Effect of Ergot.—A correspondent of the *New York Medical Journal*, June 14th, relates the case of a healthy woman, aged 25, to whom Squibb's fluid extract of ergot in twenty drop doses three times daily was ordered on account of uterine hæmorrhage. Four days later the dose was increased to one drachm thrice a-day; the first teaspoonful was taken on Saturday evening, and repeated on Sunday morning, noon, and evening. On Sunday morning the patient's forearms and hands, legs and feet became very red and swollen. She was nervous and restless, and her lower limbs felt sore, tender, and heavy. She rose from a chair with difficulty, and could walk with ease only after half-an-hour's exertion. Fleeting pains passed through the shoulders; whenever she closed her eyes "she saw lightning"; formication was experienced in the arms and legs; she was drowsy, and slept nearly all the day. She felt very cold, exchanged her summer clothing for winter attire and slept under warm and heavy bedclothes. On Monday morning the unusual condition had passed off, and she took another teaspoonful of the ergot; in less than one hour all the symptoms of the previous day had returned. The extremities were red and œdematous; she had become cold and uncontrollably sleepy. All the phenomena, subjective and objective, had passed away by the afternoon of that day. It is not stated whether the teaspoon employed was of pharmaceutic or of domestic capacity.

The Battey-Tait Operation.—Dr. Thallon terminates a very elaborate examination of this operation (Seguin's *Archives of Medicine*, April), with the following conclusions. "1. The operation is not justifiable for purely nervous symptoms, independent of clearly marked evidence of organic ovarian disease. 2. It is not justifiable in cases of uterine disease or hydro-salpinx. 3. It is not justifiable—in the light of our present knowledge—for the relief of uterine hæmorrhage, or the arrest of the growth of uterine tumours. 4. It is justifiable as a last resource—all other rational methods of treatment having failed. (1) In certain malformations and injuries of the utero-vaginal canal, rendering menstruation impossible. (2) In incurable disease of the ovaries. (3) In pyo-salpinx. The cure which the Battey-Tait operation offers to the large number of sufferers who constitute the fourth class, is one of the most glorious achievements of the surgery of our age."

Vaginal Injections in the Puerperal State.—Dr. Fordyce Barker is reported to have said that for two years he has directed his nurses never to give a vaginal injection, unless especially ordered, in the puerperal state. Experience has taught him that patients did better than when antiseptic vaginal injections were used in a routine manner.—*Boston Medical Journal*, July 3.

PHARMACOLOGY AND THERAPEUTICS.

Poisoning by the Fumes of Nitric Acid and of Ammonia.—The *Boston Medical and Surgical Journal* for May 22nd contains a report of four cases resulting from the accidental emptying of a carboy of commercial nitric acid. Three of the patients escaped with weakness, slight cough, and general mucous *râles*, lasting for a few days, slight hæmoptysis and a "severe cold" lasting a fortnight, and an attack of pneumonia respectively. In the fourth case, exposure to the acid fumes was more free and prolonged; discomfort was experienced — weakness, pain on coughing, &c.—four hours after the accident, but, with the exception of incessant coughing during the night, no marked symptoms showed themselves until death occurred at 6.15 p.m on the following day. Both lungs were found to be reddened and œdematous; the mucous membrane of the larynx, the trachea, and the epiglottis was injected, and presented several minute ecchymoses; kidneys and liver injected; the other organs were normal. Cases reported by Christison and by Taylor are referred to; and it is suggested that death is due to poisoning by nitrous acid, with which commercial nitric acid is contaminated. The fumes appear to excite an immediate local action—irritating the lungs, and directly affecting the heart and the muscular coat of the arterioles, and a later central action on the cord, with bronchial irritation, hyperæmia and œdema of the lungs, and later pneumonia; further, in the most serious cases there is often a marked but temporary and delusive improvement in all the symptoms (as in one form of poisoning by phosphorous). In contrast with the above, Dr. Swan reports the case of a man, aged 63, in whose arms a pound bottle of strong liquor ammoniæ exploded. The immediate distress for breath was great; the inside of the mouth and the tongue were much burnt and covered with white patches; the fauces were less red; burning pain at the epigastrium and severe frontal pain were complained of. There was loss of speech and of appetite, and sonorous *râles* were heard. The symptoms began to decline in a week's time, when œdema of the lungs appeared. Recovery was fairly complete at the end of a month or six weeks.

Poisoned Arrows.—*The Union Médicale* for April 20th contains an extract from a report of a commission, appointed by the Governor of New Caledonia, for the purpose of examining into the nature of the arrow poison said to be employed by the natives of the Pacific Islands, and how its effects may be best counteracted. The conclusion that the commission came to is (while admitting the reality of poisoned arrows on the West Coast of Africa and those employed by the Indians of South America), that these arrows are not poisoned at all, the fatal effects which they sometimes produce being generally due to tetanus, an affection of frequent occurrence in those climates. The arrows were obtained with difficulty, but various experiments were performed with thirty-five procured from various islands, with entirely negative results. The wounds produced in the engagements of the natives with each other are never immediately fatal, days or even sometimes weeks passing before they induce tetanus, which is the usual cause of death.

Slow Elimination of Hydrocyanic Acid. — Dr. Moser, of Parsons, Kan., records the history of a young man, 27 years of age, who drank at 9 a.m. of a preparation of hydrocyanic acid. He then took some salt and water, vomited freely, and became very weak. Dr. Moser saw him two hours later, when he was retching, cyanotic, weak, pulse only 60, apparently about to become collapsed, and with dilated pupils. Stimulants and iron were given, and he improved, but sank again. From 6 to 8 p.m. he was unconscious, and had at times spasms of all the flexors. Next day he was up and dressed, but suffered from frequent and painful micturition, and complained of the taste of bitter almonds in his mouth. "For several days I distinctly got the odour of the acid in the breath. But all the text-books say that it is very rapidly eliminated, *i.e.*, in two or three hours. What I would like to understand is, whether the teaching of our text-books regarding the elimination of hydrocyanic acid is correct."—*New York Medical Record*, June 21.

Poisoning by Belladonna.—In the *Bulletin de Thérapeutique* for May 15, Professor Masse relates in considerable detail a case of poisoning by a decoction of 3½ grammes of belladonna leaves taken by mistake. As he observes, it is truly a typical case, resembling in its simplicity a physiological experiment, in which the symptoms were successively developed, and accurately observed. We have not space for the details, but the perusal of the original paper will certainly interest some of our readers. Professor Pécholier, of Montpellier, communicates to the same journal for June 30th, an interesting case in which 10 grammes of extract of belladonna were administered as an enema to a young lady 18 years of age. This arose from a mistake, the belladonna which had been ordered to be used, mixed with 20 grammes of lard for frictions on the abdomen, having been mixed with milk and given as an enema. A full half hour elapsed before Professor Pécholier reached the patient, and although he found no serious symptoms of poisoning besides some dryness and constriction of the throat, and marked dilatation of the pupil, he set vigorously to work. Throwing a very large handful of salt into about 200 grammes of water, he at once gave this as an injection, and on its being returned, a notable portion of the poisoned milk came with it. A second enema was given directly afterwards, and as soon as they could be prepared 30 grammes of castor oil with 2 drops of croton oil were given by the mouth, and an enema made with a decoction of 20 grammes of senna and 30 of sulphate of soda. In less than an hour abundant evacuations had taken place, the last of which contained no traces of the milk. We need not pursue the subsequent details of the case, as all serious symptoms were cut short, and next day the patient might be considered as having quite recovered. The fact that in this case the belladonna had been incorporated with lard, and was suspended rather than dissolved in the milk, necessarily rendered its absorption more slow, and gave time for the effect of the purgative remedies.

Local Application of Ether in Neuralgia of the Bladder.—Dr. Parmenter, of Buffalo, writing to the *New York Medical Record* for July 5th, states that in two cases of severe neuralgia of the bladder, in which the usual remedies had been used in vain, he injected into the viscus ten drops of ether in two drachms of water. Within one minute the ether was perceptible in the breath in both instances, and within five minutes there was perfect relief from pain, which previously had been most severe. The observation was verified a number of times. The mucous coat of the bladder being non-absorbing, as some authorities claim, how could the ether pass so quickly into the circulation?

Dr. J. Boeckel on Iodoform.—At a meeting of the Société de Méd. de Strasbourg, Dr. J. Boeckel gave an account of the results of the iodoform dressings which he had employed since 1882. In a total of 240 operations he obtained 220 cures against 20 deaths. In this number of cases he does not include autoplasties, the removal of small tumours, or operations on the toes and fingers. All the operations of the least importance were cured under its influence, most of them by the first intention; and the dressing had shown its good influence in all the cases by absence of complications and the rapidity of the cure.—*Compte-Rendu Général*, July 23rd.

Chloroform for Tape-worm.—A correspondent of the *Philadelphia Medical Reporter* states that he has found the following formula highly successful in the treatment of tape-worm:—Chloroform, Ext. Fil. Maris, aa ʒ i, Emuls. Ol. Ricin. (50 per cent.) ʒ iii. To be taken at once after a fast of 24 hours. The tape-worm was expelled entire in all cases, and in two, even when the extract of male fern was omitted.

Removal of Stains of Nitrate of Silver from the Hands.—M. Liesegang recommends that the stains should be rubbed with the following solution: Iodine 1, iodide of potassium, 10; water, 100; and ammonia, 1.—*Journal de Médicine de Bruxelles.*

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE XII.

Cookery.

But little that is new in this department is to be seen in the Exhibition. Restaurants are much the same as elsewhere, only perhaps rather worse, through being overcrowded, and the supply is often not equal to the demand. Some few lectures have been delivered on the subject of cookery, and some demonstrations given as to economical cooking, workmen's dinners, &c. The raw material of which food is composed is well illustrated, and there are almost innumerable cases containing prepared, and therefore cooked, foods of various sorts, such as those displayed in the South Gallery: potted meats, and fish, biscuits, sweetmeats, jams, &c. In Case 69, Mr. Van Abbott exhibits his special preparations for the needs of invalids and infants, and his bread, biscuits and flour adapted for diabetic patients. In Case 68 we see a very nutritious and pleasant biscuit, shown by Alexander Grant, which possesses the advantage of great portability, and contains, in combination with meal, various sorts of meat, poultry, and cheese, specially adapted for travellers or sportsmen. Such preparations as this are not confined to the food galleries, for in the Western Gallery, devoted to "Machinery in Motion," the modes in which certain articles of food are prepared or cooked are fully illustrated. Jam is made from fresh fruit before one's eyes in Stall 1,144; though in Class II., South Gallery, Case 48 contains the most delicious whole fruit jams in the Exhibition, made by Messrs. Beach, of Ealing; and in Case 51, Messrs. Barnes & Co. exhibit their well known preparations of boiled fruit. Possibly these ready prepared articles of diet do not exactly come under the head of cookery; but as man is a cooking animal, it is certain that any specimens of progress in this art must be a gauge of his advancement in refinement and civilisation, whether the action of heat, which is the primary factor in cookery, be applied for the preservation of perishable articles of food, or for the purpose of rendering them more palatable, and of easier digestion at the moment of consumption. The word "cookery" comprises the preservation of food otherwise than by the action of fire, as for instance where fish, beef or fruit is dried by the heat of the sun, which is probably the earliest and most primitive form of cookery. Over and above the application of heat to food in order to render it easily digestible, and pleasant to consume, the combination of different materials in due proportion, and the well chosen and skilfully imparted flavour to such combinations are essentially included under "cookery." Readers of "Pickwick" may recall the original definition of the varieties of meat pies, all made out of one unrecognised form of animal food, that being the mythical "eat" of the pie-man of the district. "'Tis the seasoning as does it," said Mr. Weller, whether they be "weal and ham, mutton, beef or kidney pies!" There is much to be said for this view of the question, and it is certain that good and proper cookery does a great deal to render unpromising food nutritious and appetising, just as ignorant and careless cookery

destroys and wastes much valuable material, and often must be blamed for producing dyspepsia and ill temper. The simplest cookery to be successful must be based on certain principles, and all who attempt any one of the processes of cooking should be well acquainted with the differences between them, and should not be liable to confuse boiling and simmering, frying and broiling, roasting and baking, and so on. When certain articles of food are eaten raw, as is the case with oysters, with fruit, or with salads, no process of fire cooking is necessary; but the preparation and dressing of a salad is an art which requires as much attention as many other more elaborate processes. The examples served in the restaurants of the Exhibition of this form of cookery are rarely to be commended, for the mixing of a salad which appears so simple, in reality demands attention to so many small details that but few cooks are equal to it. It is difficult to induce British cooks or landlords to believe that a salad cannot be prepared with wet vegetables, or without a sufficiently roomy salad bowl. Water, oil and vinegar do not mix well together, and the first essential of a good salad is to have the lettuce, or green substance of which it is to be made, perfectly dry and fresh. A lettuce should be divided and carefully washed in pure water, then thrown into a clean cloth and well shaken, until all the moisture is absorbed. The leaves should then be broken with the hand into fragments, and placed in the bowl. Three table-spoonfuls of the finest and purest salad oil may now be poured over the leaves, which should be carefully turned and mixed till the oil is all taken up by them. A little salt sprinkled from a salt dredger, and a few grains of black pepper carefully ground over the mixture from a table pepper mill, and the salad awaits the vinegar as a final addition, which must be applied with discretion and very moderately. When allowed to come well in contact with the lettuce leaves, on the top of the salt and pepper, and thoroughly mixed, so that every particle of green is saturated with this combination of oil, acid, and condiment, without one particle of sediment or moisture having settled at the bottom of the bowl, the salad is ready to serve.

Probably the cheap rate at which coal has long been attainable in this country has produced carelessness in the use of it as a cooking agent, and accounts for the low condition of that art which generally exists. In France and other countries where the difficulties of fuel have to be contended with, and economy in its consumption observed, more attention is paid to the art itself, and a great national school of cookery has taken root amongst the people.

The restaurants or dinners at the Exhibition are of the most ordinary kind. The only variations from the stereotyped dinners are to be met with at the vegetarian dining-room, and at the Chinese restaurant. Of the first, notice has already been taken, and it does not deteriorate; the frying is excellent, and all is done that is possible to make food tasty and appetising which lacks the savory element of meat in any form. It is well to observe that the practice of those who direct this establishment, and indeed of most vegetarian kitchens, is to use cotton seed oil for the purposes of frying with great success. This oil is largely imported into Liverpool, and has long been used in Jewish cookery. It is far less expensive than butter or lard, and much finer and purer than the ordinary fat of middle-class kitchens. The slight smell of oil, which is evident when it boils, is obviated by placing a piece of bread in the pan during the heating process. Every good cook knows that fat of any sort should be allowed to boil well, and get rid of all the little particles of water, which splutter and crack as they pass off, before putting anything into the frying-pan to be cooked.

The National Training School for Cookery roused public attention some years ago to the miserable condition of the art of cookery in this country, and so far it did good service to the community; but it has not fully carried out its promises, and it is to be feared that the poor have not derived much benefit from its teachings. Nevertheless a large number of competent teachers have been trained in this school, who are now in various parts of the country giving lectures and demonstrations in cheap cookery to special classes of persons. Cooks of the upper and middle classes benefit by these lectures, for some improvement can be traced in the ordinary dinners of this section of society, and teachers can be secured in country districts on certain terms. Lately, a class for the teaching of good cheap cookery has been established at Netley, for the soldiers who are quartered there, and who have leisure during convalescence from illness to learn much that may be useful to them afterwards, either in foreign countries where the commissariat is often the most scanty, or at home when thrown on their own resources. The lady who gives these lessons says that soldiers are the best and most interested pupils she ever had. Her experience amongst the artisans of the North of England, where she previously taught, was not nearly so encouraging.

It is scarcely to be expected that purveyors of food will lay themselves out to make their bills of fare instructive as well as appetising, and it must be confessed that there is no advance or improvement to be seen in the dinner tables of the Exhibition of this year, beyond what all are accustomed to find in the hotels and restaurants of London. The only interesting feature in this direction, is the introduction of certain Chinese dishes into the menu, served in an annexe of the Chinese court, and this deserves description.

The Chinese dinner is served in a room decorated in an appropriate fashion by a native artist. A wisteria and a bamboo tree, with birds flying about among the leaves, cover the walls. Gay and somewhat brilliant and barbarously stiff artificial flowers in bunches ornament the tables, lotus blossoms, pinks, androses with unnaturally green leaves being the favourites. In a gallery at the end of the room sits a band of Chinese musicians, whose frantic noises and grotesque attitudes are certain to provoke the laughter which is said to be so great an aid to digestion, if they do not startle and agonise the visitor beyond the point of amusement. Around the central artificial bouquet on the dinner-table, several little dishes are placed, containing Chinese confections, sugared potato chips, lotus seeds, and almonds, which are intended to be casually eaten during the repast. These seeds of the sacred lotus, never before seen in London, are soft, white, and about the size of a bean, and though about as pleasant as the seeds of a sunflower to eat are not, we fancy, attractive enough to induce many who taste them to become "lotus eaters" in the sense usually attached to that term. Every guest is supplied with chopsticks and a little two-pronged instrument, with which to catch and transfix any tiny dainty. An attentive Chinaman, with a countenance which encourages confidence, volunteers lessons in the art of using the chopsticks, but in deference to European awkwardness the ordinary knife, fork, and spoon are also supplied.

Dinner commences with the usual *Hors d'œuvres* of dried and tasty meats, fish, olives, &c. Bird's nest soup is then served in tiny basins, and is very good indeed, but as this restaurant is directed by a French *chef* who only introduces Chinese dishes suited to European tastes, it may be but a symbol of what is common in China. The so-called birds' nests of which this soup is made, consist only of gelatine, much like the constituents of the Iceland, or Carrageen Moss, and so form a very good basis for excellent soup, which will bear any amount of flavouring. As old traditions fade rapidly away, and are replaced by scientific discoveries, we are now told that the masses of glutinous material used by the Chinese as birds' nests are no birds' nests at all, but natural growths on the rocks where they are found, and are of purely vegetable origin, much like lichens or fungi. Be this as it may, they have long been supposed to be the habitations and work of certain swallow-like birds, and the illusion is difficult to dispel. With the bird's nest soup is handed in little cups the hot wine called "Shaohsing wine." It is made from rice, and to English taste is indescribably unpleasant. All sorts of little dishes follow this very distinctive soup, such as "*Saumon à la Nankin*," "*Filet de Sole à la Ravigote*," "*Crême d'Amande Pralinée*," &c., all of which suggest the French element of the repast. But besides the bird's nest soup, the Chinese eat several things that we do not, and we recognise them under the Franco-Chinese jargon, "*Bêche de mer aux Truffes*," and "*Shark's Fin à la Bagration*." The first of these dishes is in reality the sea slug, or sea cucumber—Helianthus of the naturalist, "Hi sung" of the Chinese. It lies at the bottom of the deep seas off the coast

of China, and measures about 2½ inches long by three-quarters of an inch thick. When dried it looks like a piece of india-rubber from which protrude rows of short spikes. It keeps well in this state and is cut open when cooked, having somewhat the consistency and taste of turtle, though much less attractive in every way. The "Shark's fins" are entirely cartilaginous, and depend on the sauce in which they are stewed for flavour.

A very peculiar and distinctive Chinese dish was absent from this restaurant, owing to misadventure on the voyage; but we have been privileged to taste it at a private dinner given by a friend who is interested in national peculiarities of diet. Eggs that have been encased in clay and buried in a dry soil for many years, are esteemed great luxuries by the Chinese and are by no means to be despised. No trace of decomposition can be discovered in these ancient eggs, which, by their encasement and burial, are excluded from the attacks of bacteria and the production of objectionable changes; but a chemical modification appears to take place in the constitution of the egg, both yolk and white become transparent, and when eaten are soft, and creamy, and almost delicious, by no means resembling an ordinary egg; but as some of these eggs have been buried for half a century, time and isolation have mellowed and refined away any original roughness of character. It was intended that the English dinner eater should, for the first time, have been initiated into the mysteries of these celestial delicacies, but a whole consignment of them came to grief in their friable cases on their way hither, so that at present we feel no temptation to bury our eggs for the benefit of the next generation. Native beverages seem to be very limited in the Chinese commissariat, we were only offered the "Shaohsing" wine, but were told that champagne was largely consumed in China; the pleasant waiter, with a smile that was "child-like and bland," told us that it was sent from England! Our repast was brought to a conclusion with a cup of "Imperial tea," served in the balcony overlooking the illuminated gardens, which might have been celebrating the Feast of Lanterns, so brilliant and beautiful were they. In Pekin this tea is said to cost eight shillings a pound. It is never sent to Europe, probably because our custom of adding sugar and milk to an infusion of tea prevents any appreciation of the very delicate and delicious flavour of these choicest of leaves, which are dried in the sun instead of over a fire. Each person's infusion of tea is made in a separate little china cup covered with a saucer, and this is poured gently into another cup, with the saucer slightly tilted, so as to prevent the escape of the leaves, by the attentive Chinaman, who volunteered pleasant remarks and explanations of the customs of his country in broken English. Towards the conclusion of the feast the musicians outdid themselves in noise, but their efforts are so excruciating that they play only for two minutes at a time by a sand-glass. A sort of mimic opera is also introduced, in which the chief actor, who gesticulates and writhes about in an extraordinary manner, never utters a sound, but follows the noises and speeches made by a person behind him partly hidden from view. The finale of this unique performance was even more alarming than the commencement, and sounded as if every plate and dish in the establishment were suddenly smashed, ending in a great flourish and whistle as of a terrific railway accident. Chinese applause does not consist in any of the ordinary demonstrations of satisfaction such as clapping of hands or stamping of feet, but in a sort of cynical and rapid ejaculation of the sounds "Hi Haw," "Hi Haw," on the part of an appreciative audience. A visit to this unique restaurant is quite worth making, and the repast is not more expensive and far more curious than that served under the name of the club dinner in the rooms over the conservatory which is thought to be the *chef d'œuvre* of the contractors.

In conclusion it may be well to say that three little handbooks on cookery are the outcome of the Exhibition. An excellent little book "On the Principles of Cooking," by Sept. Berdmore, published by Clowes & Co., contains many valuable suggestions and much interesting and useful information. "Food and Cookery for Infants and Invalids," by Catherine Jane Wood, is full of useful hints, but there are some errors, and far too much preaching to make it an acceptable teacher to the majority of those who have the care either of infants or invalids. Some of the advice given would come better from the doctor than the nurse. The simple recipes for soups, broths, jellies, &c., at the end are quite reliable and good. Then there is a collection of "recipes for cheap dinners," as served in the dining-rooms of the Exhibition by Mrs. C. Clark, the Lady Superintendent, which represents dishes served at the sixpenny dinners to be had there daily. They are wholesome and satisfying, though not, of course, luxurious.

GENERAL CORRESPONDENCE.

REMOVAL OF UTERINE APPENDAGES FOR MYOMA.

[To the Editor of the Medical Times.]

SIR,—Sir Spencer Wells has remarked that "vague unsupported assertions have little influence upon the opinion of a thoughtful or sceptical profession." By way of supplying something so definite as to be "beyond the reach of scepticism," Mr. Lawson Tait relates the case of a woman, aged 47, from whom he removed the uterine appendages in June, 1881, to relieve profuse menorrhagia and intense pain associated with a large uterine tumour. The woman died last month, and the myoma had shrivelled to "less than a tenth of its size three years ago." But who can say how far this was a change frequently seen in such cases in women between 47 and 50 years of age, who have undergone no operation? Again, he says, "this woman suffered for ten days from symptoms of intestinal obstruction," adding, "I performed enterotomy, but she survived the operation only some fifteen hours." Can anything be more vague? What part of the intestine did he cut into? Did he close the opening by suture, or form an artificial anus? What was the cause of obstruction, and was it removed by enterotomy? And might not the woman have been alive now if she had been treated by opiates and her abdomen not opened?

Yours, &c.,
F.R.C.S.

[To the Editor of the Medical Times.]

SIR,—Mr. Lawson Tait has sent to the College of Surgeons a preparation which, he says, proves that after removal of the uterine appendages, a uterine tumour has shrunk, in the three years between the operation and the death of the patient, to a tenth of its former size. He describes it as now the size of a small orange. At the time of operation he says it was just above the umbilicus. The tumour has contracted under the action of the spirit in which it is preserved, but it is now as large as a full-sized orange—and it measures three inches in one diameter, by four inches in the other. Of what size must the abdomen of the woman have been, if a tumour measuring 40 inches by 30 only reached two inches above her umbilicus? Is Mr. Tait's statement "vague,"—or can he suggest a more appropriate designation?

I am, Sir, Yours, &c.,
AN ANATOMIST.

INVENTIONS AND IMPROVEMENTS.

A NEW ANTISEPTIC VAPORISER.

By R. FITZROY BENHAM, M.R.C.S., &c.

SOME twenty years since, when a lad, it occurred to me that in order to render the atmosphere pure in the sick and other apartments, certain disinfectant agents should be mingled with water, and vaporised by raising the temperature to a little above the boiling point of the latter. I accordingly constructed an apparatus after various artistic designs, which was made to contain the solution in a closed chamber, with a vent-hole of only just sufficient size to allow the steam to escape at such a pressure as would cause both the disinfectant and the water to be equally diffused—the boiling point of the former, for instance, carbolic acid, being in excess of that of water. Being acquainted with

the theory upon which "Nero's engine" was constructed, it also occurred to me that by balancing a small tube on a pin projecting from the top of the apparatus, the steam after leaving the vent-hole might, in its effort to escape, tend to form a vacuum and force its way, with the air, into the tube, when the latter would revolve with considerable rapidity, and in doing so would diffuse or spread the steam in a way no other means could effect compared with the size and portability of the apparatus.

Not being at the time a member of the Medical Profession, it did not occur to me to direct the attention of the Medical Journals to my invention, though many scientific men who saw it pronounced it to be an admirable apparatus for disinfecting sick chambers and the like. As an amusing scientific contrivance, it met with incredible success, thousands of gross being sold at prices varying according to the quality and beauty of the design. I may add that, besides other large areas, the Agricultural Hall at Islington, was disinfected and perfumed in this manner, namely, when the Messrs. Sanger produced their equestrian and other entertainments, a fact which was noticed in all the leading daily papers.

Now that the germ theory is fully established, as regards pulmonary and other diseases, and it has been clearly demonstrated, times without number, that it is possible with appropriate means to abate or modify the development of such organisms by means of suitable antiseptics—spread, so to speak, in the atmosphere in an effectual manner, I am induced to bring before the profession an inexpensive apparatus which will, I hope, fully carry out the most sanguine expectations of those who advocate this

method for the diffusion of such antiseptic agents. Before, however, describing the details of the apparatus, to which I have just referred, it may be as well to note, that some antiseptic agents, carbolic acid foremost, do not become converted into vapour at ordinary temperatures—hence the objection, so far as my experience goes, of using the various forms of inhalers; but even apart from this, the invalid cannot constantly wear an inhaler, no matter how comfortable it may be, and during this period he ceases to breathe air rendered antiseptic. So also by burning the antiseptic we do not render it volatile, hence we do not render it antiseptic, except to the extent that a certain amount escapes unburnt and is thus diffused. Again, by vaporising a solution in the form of spray it does not volatilise to any great extent, since the dew settles quickly on the nearest surfaces, and does not rise and diffuse itself as the vapour of steam does, nor does the sprinkling of solutions on clothes cause diffusion of the agent for the same reason. Recently, however, I have read several articles in the various medical journals, written by gentlemen who advocate the mixture of disinfectants, in various ways, with the steam issuing from an ordinary bronchitic kettle, and though this somewhat carries out the principles of which I advocate, it is not always convenient to have a fire burning, in order to keep the water boiling, in the room of the invalid, especially in hot weather.

Remove the balance-tube and feeder-screw, and charge the boiler about three-fourths full of a solution of Calvert's pure phenol, 1 in 50, then replace the former. About three-fourths fill the lamp with methylated spirit and light it, which will cause, when the steam is generated, the balance tube to revolve with great rapidity for a considerable time, and thus most effectually spread the vapour over the entire apartment. Other disinfectants and perfumes may be used in a similar manner, but as most of them are more volatile, especially the latter, they will be more rapidly vaporised than the water, hence it is preferable to add only the essential oils of perfumes instead of with spirit to the water to make the solution.

In conclusion I may state that Messrs. C. Wright & Co., of 108, New Bond Street, are the makers of the apparatus in various sizes.

FLETCHER'S SYRUPS OF THE BROMIDES.

The syrups of the bromides (Syrupus Ferri et Quiniæ hydrobrom., and Syrupus Ferri et Quiniæ et Strychniæ hydrobrom.), which have been introduced by Messrs. Fletcher, Fletcher, & Stevenson, of Holloway, N., have only to be made known to the profession to secure a large sale. They are well-prepared, keep well, and are as palatable as any combination of bromine and quinine can be expected to be.

HARTMANN'S WOOD WOOL AND HYGIENIC WOOD WOOL DIAPERS.

The wood wool prepared by Paul Hartmann, of Heidenheim, Germany, has been known for some years on the Continent as an excellent material for dressing wounds. The value of prepared wood as a dressing material was discovered by Dr. Walcher, assistant in Professor Bruns' clinic at Tübingen, and the discovery was turned to account by M. Hartmann, who succeeded in producing a soft and pliable substance to which he gave the name of sublimate wood wool. This material has been used extensively by Professor Bruns who employs it as a substitute for the gauze of the typical Listerian dressing. It is so flexible that it can be tightly bound on to the wound without danger, it rapidly absorbs and gives off moisture, thus fulfilling, according to Dr. Bruns, "the two great essentials of a good dressing material—that it should be dry and seldom need changing."

Recently this material has been utilized for the purpose of the so-called hygienic diapers, which consist of a pad containing 90 per cent. of wood wool mixed with 10 per cent. of cotton wool and impregnated with 0·3 per cent. of corrosive sublimate. It will be found that they absorb discharges readily, and prevent any offensive odour; but their great merit is that they can be burnt immediately after use, a custom which we venture to say will one day become universal. They will be found a great comfort by ladies suffering from excessive or offensive losses.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.

The ordinary meeting of the Council was held at the College on Tuesday last, August 5th. The Council confirmed their resolution of the previous meeting for removing Washington Evans from the roll of Members of the College under Clause 2, Section XVII, of the By-Laws, for unprofessional advertising and publication. The honorary medal of the College was presented to Sir Erasmus Wilson. An *honorarium* of 50*l*. was voted to Dr. Garson for his services in the museum in the interval between Professor Flower's resignation and the appointment of his successor, during which time he (Dr. Garson) took charge. The vacancy which will occur in the Court of Examiners by the expiration of Mr. John Wood's term of office, was announced. Mr. Wood is eligible, and will most probably apply for re-election. The vacancy will be filled at the next meeting of the Council, which will not take place until the third Thursday in October (the 16th). The Council then adjourned.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following have been admitted Licentiates :—

George Leslie Airth, M.D. Toronto, 59, St. Peter Street, E.; William Wilfred Banham, Worsborough Dale, Barnsley; Gilbert Lacy Barritt, Waterside, Todmorden; Frederick Augustus Newton Bateman, 62, Pall Mall, S.W.; George Russell Beardmore, 328, Upper Street, N.; Edgar Beaumont, 30, Gipsy Hill, S.E.; James Francis Bell, 12, Vicar's Road, N.W.; Charles Walter Biden, 11, St. Mary's Road, S.E.; Albert Bowhay, Gunnislake, Tavistock; Richard William Brogden, 2, Grove, Clapham Road, S.W.; Ernest Ebenezer Bronstorph, M.D. Montreal, 19, Philpot Street, E.; William McEnery Brown, M.D. Toronto, 59, St. Peter Street, E.; Richard Henderson Castor, 44, Ainger Road, N.W.; Herbert William Chambers, Lowestoft; Arthur Ward Collins, Rainhill, Prescot; George William Collins, 66, Adelaide Road, N.W.; James Ralph Collyer, Enfield; Sidney Ernest Chaddock, 9, Milman Street, W.C.; John Charles Davies, Rhos, Ruabon; Pedro Louis De Montbrun, 19, Porteus Road, W.; Cadwallader Edwards Evans, Westbury-on-Trym; Thomas Frederick Forster, 88, Guilford Street, W.C.; Henry Arthur Fotherby, St. George's Infirmary, Fulham Road, S.W.; Alfred Henderson Fowler, Guy's Hospital, S.E.; Thomas Preston Gostling, University Hospital, W.C; Edward Campbell Greene, 29, Rowan Road, W.; Charles Henry Hale, 14, Elgin Road, W.; James Harvey, 9, Larkhall Lane, S.W.; Arthur Hillaby, 59, Manor Road, S.E.; Thomas Johns Hitchins, Broadfield, Crawley.; Francis Rowland Humphreys, Guy's Hospital, S.E.; Edwin Guy Hunt, 46, Guilford Street, W.C.; Richard Nelson Jones, 1, Baron Court Chambers, S.W.; John Rushworth Keele, Southampton; Herbert Arthur Kent, Salisbury; Jamsetjee Framjee Kolapurvala, 11, Malpas Road, S.E.; Cawas Lalcaca, 3, Whitehall Gardens, S.W.; James William Lichfield, 16, Talgarth Road, W.; John Marriott, 22, Percy Circus, W.C.; Jafarkuli Faredunbeg Mirza, 84, Richmond Road, W.; Robert Everard Molesworth, 12, Belmont Road, S.W.; George Alfred Everitt Murray, St. Bartholomew's Hospital, E.C; Thomas Horrocks Openshaw, Poplar Hospital, E.; Percy Sprague Oram, 315, Amhurst Road, N.; Thomas Godfrey Parrott, Aylesbury; John Dudley Price, Waddam's Pool, Dudley; Charles Cooper Reilly, 76, Denbigh Street, S.W.; James Reid Roberts, 3, Vernon Chambers, W.C.; Owen William Roberts, 60, Cambridge Gardens, W.; John Valentine Salvage, 2, Lancaster Road, S.E.; Charles John Sharp, 9, Normanby Place, Liverpool; Harry Charles Costello Shaw, Kingston-on-Thames; Edward Arnold Cloete Smith, Shooters Hill; Howard Lyon Smith, 80, Tollington Park, N.; Arthur George Southcombe, St. Bartholomew's Hospital, E.C.; John Stevenson, 141, Tachbrook Street, S.W.; Andrew Stewart, M.D. Montreal, 31, Great Coram Street, W.C.; Hugh Champneys Thurston, 7, Nicholas Street, E; Frederick Adolphus Trevan, Melville Hospital, Chatham.; Robert Trevor, 42, Halsey Street, S.W.; Arthur Muriel Watkins, 61, Guilford Street, W.C.; John Arthur West, Bickley Park; Ezra Herbert Williams, M.D. Toronto, 54, St. Peter's Road, E.; Arthur Henry Wilson, 11, Abercromby Square, Liverpool.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 31st ult., viz. :—

Messrs. Frank Fratman, Bristol; W. L. Blight, Sladesbridge, Cornwall; A. L. Scott, L.S.A., Dunmow, Essex; H. C. Chapman, St. Mary's Terrace; W. H. Tomlins, L.S.A., Rutland Street, N.W.; C. H. Mayer, L.K.Q.C.P.I., Sydney, N.S.W.; W. H. Pinches, L.R.C.P. Edinb., Fulham; Alexander Harper, Hertford Street, Mayfair; J. A. P. Smith, Granville Square; C. J. Heath, Cromwell Road, W.; Edward France, Sheffield; W. H. Hiddingh, Balham; Frank Percival, Leinster Square; R. A. Baillie, Blackheath; G. C. Wilkin, Hyde Park Street; and A. H. Stewart, Colville Terrace.

The following passed on the 1st inst., viz. :—

Messrs. N. G. Gilkes, L.S.A., Leominster; E. J. David, L.S.A., Pontypridd; L. J. Kidd, Cambridge Street, W.; F. A. Priug, L.S.A., Exeter; Rowland Hill, Beeralston, Devon; C. J. Arkle, L.S.A., West Derby, Liverpool; C. C. Caleb, M.B. Dush., Allahabad; and W. H. Wright, L.K.Q.C.P.I., Liverpool.

The following passed on the 4th inst., viz. :—

Messrs. W. P. Squire, Torquay; W. L. Livermore, L.S.A., Finsbury Park; E. J. Penny, L.S.A., Dorchester; C. S. Sherrington, L.R.C.P. Lond., Ipswich; Harry Appleton, L.S.A., Granville Square; John Marriott, L.R.C.P. Lond., Leicester; and W. H. Haw, L.S.A., Cape of Good Hope.

The following passed on the 5th inst., viz. :—

Messrs. J. S. H. Roberts, L.S.A., Swansea; E. H. Phillips, L.S.A., Brighton; L. M. Guilding, L.S.A., Reading; A. C. Wey, L.S.A., Plymouth; J. P. W. Gray, L.S.A., Barnsbury Park, N.; William Windley, L.S.A., Nottingham; G. A. Bolton, Surbiton, and W. L. W. Marshall, L.S.A., Brixton Rise.

The following passed on the 6th inst., viz. :—

Messrs. E. J. Foot, L.S.A., Bigbury, Devon; Henry Cropley, L.S.A., Swaton, Lincolnshire; H. W. G. Mackenzie, M.B., Cantab, St. Stephen's Terrace, W.; W. G. Weaver, L.S.A., Hereford; and T. P. Beddoes, Church Stretton.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, 31st ult. :

Samuel Brookfield, Dresden, Staffordshire; William Henry Carrington, 15, St. Thomas Street, S.E.; Thomas Webb Fowler, 381, Summer Lane, Birmingham; Gilbert Capel Hall, 44, Bath Row, Birmingham; Walter Herbert Haw, 3, Mecklenburgh Street, W.C.; Frank Lane, 11, Bedford Road, Tottenham; William Lawrence Wright Marshall, Brixton Rise, S.W.; Charles Lever Pinniger, 17, Bennett Park, Blackheath; William Skilbeck Stables, 19, Alfred Street, Bath; Frank Marsh Wright, Bottesford, Nottingham.

The following gentleman also on the same day passed the Primary Professional Examination :—

Harry Brandreth Lavies, King's College Hospital.

UNIVERSITY OF ABERDEEN.—During the past year the following candidates received Degrees in Medicine and Surgery :—

The Degree of M.D. :

Alexander Theodore Brand, M.B., C.M., Driffield, Yorkshire; William Carnegie Brown, M.B., C.M., Penang; Morgan Davies, M.B., C.M., Llangwyryfon, Cardiganshire; Frederick John Fehrsen, M.B., C.M., Kingston, Jamaica; Sylvester Williamson Findlater, M.B., C.M., Dufftown; Edward Footner, M.B., C.M., Brigade Surgeon; Joseph Willoughby Hodgson, M.B., C.M., Exmouth, Devon; Timothy Siddall Jones, M.B., C.M., Swansea; Edward Knowles, M.B., C.M., Birkenhead; George Herbert Le Motteé, M.B., C.M., Army Medical Department' Chatham; Charles Low, M.B., C.M., Arbroath; James Millar, M.B., C.M., Arbroath; John Hay Moir, M.B., C.M., Burton-on-Trent; John Murray, M.B., C.M., Surgeon Major, Ipswich; Alexander Nicol, M.B., C.M., Inverurie; Henry Astley Phillips, M.B., C.M., Waterbeach; James Bernhardt Klingner Robb, M.A., M.B., C.M., Montrose; Charles Lloyd Tuckey, M.B., C.M., London; James Hutchinson Walker, M.A., M.B., C.M., North Borneo; Percy Roberts Wilde, M.B., C.M., Bath.

The Degrees of M.B. and C.M.:

Henry M'Kenzie Adamson, Morphie, Montrose; George Henry Allden, Southampton; John Hector Anderson, Aberdeen; Joseph Anderson, Preston; Albert Henry Barrett, Wallingford, Berks; Christopher George Battiscombe, Blackheath; Francis Alexander Bennet, M.A., Cullen; James Wilson Bett, Dundee; William Ronaldson Clark, M.A., Edinburgh; James Will Cook, Allness; Alexander Mitchell Cowie, Mortlach; James Forsyth Craig, M.A., Leslie, Insch; George Burnett Currie, M.A., Aberdeen; Heury Moger Cyril Dalton, Newcastle, New South Wales; Alexander Gordon Davidson, M.A., Wartle, Aberdeenshire; George Duffus, Cullen; Alexander Gray Duguid, Longside, Aberdeenshire; Walter Angus Elmslie, Resthwet, Chapel of Garioch; Charles Albert Falkner, Rajahmundry; John Andrew Fehrsen, Graaf Reinet, South Africa; William Revely Forster, Blyth, Northumberland; Thomas Best Gibson, M.A., Aberdeen; John Gordon, Keith; Thomas Bell Graham, Ecclefechan; Andrew Grant, Balmoral; John William Harrisson, Sandwich, Kent; Charles Robert Lyall, Aberdeen; Stuart Macdonald, Elgin; Frank Innes Mackintosh, M.A., Deskford, Cullen; Alexander Maclean, F.R.C.S. Edin., Thurso, Caithness; Andrew Anderson Maclennan, Nairn; George Milne, Methlic; James Mitchell, Aberdeen; James Mitchell Munro, Inverurie; Alexander Murchison, Lochcarron; Eapen Poonen, B.A., India; Robert Dowell Presslie, Aberdeen; Alexander Reid, Auchindoir; Irvine Kempt Reid, Aberdeen; Alfred Ernest Roberts, London; William Robertson, M.A., Rathen; John Russell, Longhope, Orkney; William Ledingham Ruxton, West Riding Asylum, Wakefield; James Savege, Montrose; Patrick George Simpson, Aberdeen; William Leith Ireland Sutherland, Aberdeen; Herman Thiele, Bermuda; Leslie Fyfe Walker, Aberdeen; John Eustace Webb, Windsor; James Will, Ellon; John Thomas Windle, Burnley; James Martin Young, Boyndlie, Fraserburgh.

Of the above candidates,

George Henry Alden; William Ronaldson Clark, M.A.; Thomas Best Gibson, M.A.; John Gordon; Alfred Ernest Roberts; James Wills

received their Degrees in Medicine and Surgery with Honourable Distinction.

The John Murray Medal and Scholarship was awarded to

Arthur Greatorex Smith,

and will be presented to him along with his Diplomas on his attaining the necessary age. At the same time

Charles Gordon Bennett, Arthur Stephen Inglis, John Charles Davidson Irvine

were certified as having passed all the Examinations, but did not Graduate.

UNIVERSITY OF GLASGOW.—The degree of Doctor of Medicine has been conferred on the following :—

*Robert Allan, M.B., Scotland; James Dunlop Boyd, M.B., Australia; David Donald, M.B., Scotland; Mark Kippax Hargreaves, M.B., England; John Goff, M.B., Scotland; John Robertson Lewis, M.B., Scotland; †George S. Middleton, M.A., M.D., Scotland; Robert Miller, M.B., Scotland; William Morrison, M.B., Scotland; Angus Macphee, M.B., Scotland; Peter Caldwell Smith, M.A., M.B., Scotland; †John Lindsay Steven, M.B., Scotland; James Thompson, M.B., Scotland; James Wills, M.B., Scotland.

* Commended for Thesis.
† Highly commended for Thesis.

The degrees of Bachelor of Medicine and Master in Surgery have been conferred on the following, in addition to the list published in our last issue :—

William M'Crackeu, Scotland; Thomas C. M'Culloch, Scotland; Roderick Macdonald, Scotland; Alexander MacDougall, Scotland; Duncan MacGilvray, Scotland; Ernest MacKenzie, England; Charles Mackinnon, M.A., Scotland; Donald J. Mackintosh,

Scotland; Digby M. Macphail, Jamaica; Alexander M. Macrae, Scotland; Alexander B. Paterson, India; Alexander Peacock, Scotland; William G. Pretsell, Scotland; James Ralley, Scotland; William Rankin, Ireland; John O. Reddie, Scotland; John Ritchie, England; Alexander Robertson, Scotland; Frank Russell, Scotland; Henry Rutherfurd, M.A., Scotland; Gavin S. Scott, Scotland; Robert Scott, Australia; Miller Semple, Scotland; Robert M. Service, Scotland; Mark Sharman, England; James Shaw, Scotland; John Sinclair, Scotland; William Muir Smith, Scotland; Wm. F. Somerville, M.A., B.Sc., Scotland; Walter W. Spence, Scotland; Francis Taylor, Scotland; Wm. C. Taylor, Australia; Joseph Thornley, England; George B. Todd, Scotland; Allan Watt, Scotland; John White, Scotland; George Wilson, Scotland; James Wilson, M.A., B.Sc., Scotland.

Faculty of Physicians and Surgeons of Glasgow.—The following candidates passed the final examination at the July sittings of the Examiners, and were admitted Licentiates of the Faculty:—

Frank S. Barnett, Stoke Newington; D. M. Barry, West Drayton; Alex. C. Boothman, Glasgow; Samuel B. Fairley, Birmingham; A. G. Goodwin, Glasgow; David Jameson, Newtonards; John G. Margenont, Ceylon; Alfred Taylor, Bolton; Ernest W. C. Wilkinson, Glasgow.

The following passed the final examination for the double qualification and were admitted Licentiates of the Faculty and of the Royal College of Physicians of Edinburgh:—

John George Anderson, William Drysdale, J. S. Forrest, J. Jones, W. Jones, Rees Morgan, J. T. Necon, John H. Owen, all of Glasgow; S. Hallock, and O. Johnson, of Edinburgh.

King and Queen's College of Physicians in Ireland.—The following Licentiate in Medicine having complied with the by-laws relating to Membership, pursuant to the provisions of the Supplemental Charter of December 12, 1878, has been duly enrolled a Member of the College:—

John Bellew Kelly, Lic. Med., Drogheda.

At the Quarterly Examination for the certificate in Sanitary Science granted by the College, held on Thursday and Friday, July 10th and 11th, the undermentioned candidate was successful:—

Thomas Robert Judson, M.R.C.S., Eng.

At the Quarterly First Professional Examination, held on Monday, July 7th and following days, the undermentioned candidates were successful:—

Julia Maria Brinck, London; Emma Littlewood, London: Izset Mead, London.

At the usual Monthly Examinations for the Licences of the College, held on Monday, Tuesday, Wednesday, and Thursday, July 7th, 8th, 9th, and 10th, the successful candidates were the following:—

For the Licence to Practise Medicine:

George Stamer Browning, Croome, county Limerick; Alexander Edward Carte, Dublin; William Henry Clarke, Manchester; James Vance Collins, Dublin; George Patrick Cope, Dublin; Thomas Joseph Daly, Mullingar, county Westmeath; Vernon Kitchen Dearden, Manchester; Thomas Francis Griffin, Buenos Ayres, South America; Hudson Hairsine, Howden, Yorkshire; Richard A. Hayes, M.D., Univ. Dub., Dublin; Thomas Francis Higgins, Manchester; John Colclough Hoey, Kingstown, county Dublin; Denis Kennedy, Rathmines, Dublin; Frederick Duncan Lawson, Rathmines, Dublin; Patrick William Maxwell, M.B., Univ. Edin., Dublin; Michael Alcock Ottley, Sheffield; Robert Chambers Owen, Liverpool; James Robinson Phillips, Aughnacloy, county Tyrone; William Henry Banner Robinson, Dublin; Agnes Russell, Brighton; John Richard Rygate, Cambridge; Francis William Sullivan, Navan, county Meath; John Williams, Bodedery, Anglesey.

For the Licence to Practise Midwifery:

George Stamer Browning; Alexander Edward Carte; William Henry Clarke; James Vance Collings; Thomas Joseph Daly; Vernon Kitchen Dearden; Thomas Francis Griffin; Thomas Francis Higgins; Denis Kennedy; Frederick Duncan Lawson; John Joseph Lyons, Kilkenny; Thomas Joseph McGrath, Golden County, Tipperary; Michael Alcock Ottley; Robert Chambers Owen; William Henry Banner Robinson; Agnes Russell; John Richard Rygate; Henry Shackleton, M.D., Univ. Dub., Dublin; Francis William Sullivan; John Williams.

Naval Medical Department.—The following appointments have been made at the Admiralty:—W. J. Eames, Fleet-Surgeon, additional, to the *President*; and T. L. Horner, Staff-Surgeon, additional, to the *President*.

Army Medical Department.—Brigade-Surgeon Randolph Webb to be Deputy Surgeon-General, *vice* W. Stewart, M.D., granted retired pay; Brigade-Surgeon Richard Chapman Lofthouse, M.D., is granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major Albert Stanley Knight Prescott to be Brigade-Surgeon, *vice* R. O. Hayden, retired upon temporary half-pay; Surgeon-Major John Colahan, M.D., to be Brigade-Surgeon, *vice* R. Webb, promoted; Surgeon-Major Thomas Walsh to be Brigade-Surgeon, *vice* J. H. Whittaker, granted retired pay; Surgeon-Major David Arthur Leslie, M.D., is granted retired pay, with the honorary rank of Brigade-Surgeon.

British Medical Service.—The following Surgeons on probation in the Medical Department of the British Army were successful at both the London and Netley Examinations. The marks shown are those which were gained at the London Examination; the order of position not being affected by the marks gained at the Netley Examination:—J. R. Barefoot, 2,440; R. H. Clement, 2,420; G. D. Hunter, 2,335; W. C. Beevor, 2,300; L. E. Anderson, 2,275; G. B. Russell, 2,250 (gained the Montefiore Second Prize); A. E. C. Spence, 2,220; J. R. Mallins, 2,200; R. J. McCormack, 2,180; H. N. Thompson, 2,169; J. I. P. Doyle, 2,145; N. Manders, 2,120; L. R. Colledge, 2,110; S. F. Freyer, 2,075; C. Birt, 2,070 (gained the Parkes Memorial Bronze Medal); R. S. F. Henderson, 2,020; H. Mitchell, 2,000; S. Butterworth, 1,990; C. J. Holmes, 1,930; I. R. Lane, 1,920.

Indian Medical Service.—The following Surgeons on probation in Her Majesty's Indian Medical Service were successful at both the London and Netley Examinations. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:—J. H. T. Walsh, 5,517 (gained the Herbert Prize of 20*l.*, with the Montefiore Medal and Prize of 20 guineas, and the Martin Memorial Gold Medal); H. Hendley, 4,879 (gained the Director-General's Prize in Pathology); H. E. Banatvala, 4,606; G. H. Fink, 4,423; W. G. P. Alpin, 4,146.

Army Medical School, Netley.—The forty-eighth session of the Army Medical School terminated on the 4th instant, when the results of the final examinations for commissions in the Medical Departments of the British and Indian Services were declared, the prizes awarded, and the business of the term concluded. Lieutenant-General Sir George Willis, K.C.B., Commanding the Southern District, attended by his Staff and the Principal Medical Officer of the District, arrived at Netley from Southsea at 12.30 p.m., and immediately proceeded to the Lecture Hall, where the staff of Netley Hospital and their guests, with the Professors of the school and other visitors were assembled. The Director-General of the Medical Department and the Physician to the Council of India were unable to attend, and we regret to say that Surgeon-General Murray, Principal Medical Officer of the Royal Victoria Hospital, was also absent from indisposition. The usual official documents reporting the work of the session were read, with the names of the surgeons on probation for both services, reported fit to receive commissions according to the subjoined list. It will be seen that the Herbert Prize of 20*l.*, the Montefiore Medal, with the same sum in money for military surgery, and the Martin Memorial Gold Medal for military medicine were won by Mr. J. H. T. Walsh, of H.M.'s Indian Service. The Second Montefiore Prize for military surgery was gained by Mr. G. B. Russell, of the Army Medical Department. The Parkes Memorial Bronze Medal for hygiene was awarded to Mr. C. Birt, of the British Medical Service. Mr. H. Hendley, of H.M.'s Indian Medical Service, was the successful competitor for the Director-General's Prize for Pathology. Sir George Willis, after presenting the prizes, addressed the gentlemen whose course of study at Netley had been successfully ended. The general offered them his hearty congratulations, and in the kindest manner gave them some useful hints as to their future career in the Service, the result of much experience in peace and war, urging them never to relax their efforts to keep abreast of a constantly advancing profession, reminding them that, like officers in other branches of the Service, their efforts in this direction would, under recently published regulations, be tested before promotion. Sir George hoped they would cultivate good relations with other branches of the Service, by whom their skilful services would be appreciated, and wished them one and all a successful and honourable career. Professor Longmore repeated the good wishes and congratulations of himself and his colleagues, and in their name bade them a hearty farewell, declaring the business of the

session ended. The company then adjourned to the handsome mess-room of the Department, where a sumptuous luncheon was served. Among the guests were some of the officers of two ships of the United States Navy, one, the *Lancaster*, bearing the flag of Rear Admiral Commander Nicoll Ludlow.

The Royal College of Physicians and the Cholera.—The following Memorandum on Cholera has been drawn up by the Committee recently appointed for the purpose, and has been issued by the College: "The Royal College of Physicians of London, feeling that in the event of the occurrence of Epidemic Cholera in England, the public may properly look to them for advice and guidance, deem it to be their duty to issue the following instructions. These instructions are not intended to supersede the necessity of immediate medical assistance, or to impose any authoritative restrictions on medical practitioners. The College would, above all things, earnestly impress upon every person the extreme value and importance of sanitary measures in preventing the invasion and limiting the spread of the epidemic. Large experience has shown that nothing is of more importance than to secure a due supply of pure water, and to prevent all possibility of its contamination with sewage, or impurities derived from other sources. Free ventilation, avoidance of overcrowding, great cleanliness, and thorough drainage in towns, villages, and dwellings, are also of urgent necessity. The local sanitary authorities or their medical officer should be consulted on such questions. Excess in eating or drinking, or long fasting should be avoided. The moderate use of cooked vegetables, as well as of animal food, is recommended, and, in general, such a plan of diet as each individual has learnt by experience to be most conducive to his health; for any considerable change in the diet to which a person has been accustomed is seldom advisable during the prevalence of an epidemic. Milk and also drinking water should be boiled. The vessels used for the storage of food or drink should be cleansed with boiling water. Raw vegetables and unripe or unsound fruit should not be eaten. Exhaustion from fatigue, long watching, or deficiency of food, and exposure to cold and damp, render persons especially liable to cholera. The College would therefore urge the necessity of supplying those in need with food, fuel and clothing. Persons engaged about those affected with cholera are not, with proper precautions, more liable than others to the disease. The fear of direct infection may, therefore, be practically disregarded; but it is absolutely necessary that some one or other of the ordinary disinfectants, such as carbolic acid, should be applied abundantly to the excretions, soiled linen, and utensils, before these are removed from the apartments of the sick. Extreme cleanliness and disinfection of the discharges from the stomach and bowels cannot be too much insisted upon, as it is generally believed that the disease is disseminated through these. The College would earnestly insist upon the importance of organizing, in any district infected by cholera, the system of house to house visitation, and of establishing temporary hospitals for the reception of patients who cannot be properly treated in their own homes. The College would further suggest that such temporary hospitals should be numerous rather than large, and so distributed as to make it unnecessary to convey to any great distance those who are stricken by the disease. Ambulances and stretchers for the removal of the sick should be provided. During the prevalence of cholera, any unusual degree of looseness of the bowels, though painless, should not be neglected, and on its occurrence, the patient should immediately go to bed, be kept warm, and medical advice should be at once obtained. Previously to the arrival of a medical attendant, any of the medicines used at other times for checking common diarrhœa may be taken, such as the chalk mixture, or the compound cinnamon powder."

Association Française pour l'Avancement des Sciences.—This body will hold its next meeting at Blois from the 4th to the 11th of September.

Paris Academy of Medicine.—Professor Macleod, of Glasgow, has just been elected a foreign corresponding member of this body. He obtained the votes of 41 of the 54 members who were present, the other candidates being M. Deroubaix, of Brussels, and M. Krassowski, of St Petersburgh.

The Paris Night Service.—Dr. Passant reports that the number of calls for medical aid, during the quarter ending June 30, amounted to 1,730, being a mean of 19·10 per night, in place of 17·55 per night of the corresponding quarter of last year. Of these 1,730 calls, men formed 32 per cent., women 53 per cent., and children under 3 years of age, 15 per cent.

Improved Dwellings Company.—According to the last half-yearly report, just issued, of the Improved Dwellings Company, the mortality in the Company's dwellings had been 15·5 per 1,000, against 20·4 in the metropolis, in face of the fact that the birth-rate has been 37·34 against 33·09 in the metropolis.

An Exhibition of Lepers held in Terrorem.—A unique variety of the moral show has been devised by a Californian, calling himself Dr. O'Donnell. He has secured two Chinese lepers, with a large portfolio of photographs of other cases, and proposes to travel and exhibit them. The show is in the interest of anti-Chinese immigration. Dr. O'Donnell states that there are between 200 and 250 lepers in San Francisco already, and that the disease is increasing.

Water and Constipation.—Dr. Squibb, in his last *Ephemeris*, has a suggestive article on constipation, which he believes in most cases is due to insufficient water in the fæcal mass. The individual does not ingest water enough to supply the blood with its 79 per cent., and therefore the blood absorbs it from the intestinal contents. "Drink water," is Dr. Squibb's motto. It is a good one, but water, as everyone knows, will not cure habitual constipation in a very large percentage of cases.

High Fees in Dentistry.—The *New York Medical Record*, July 12th, refers to a case that is likely to come before the law courts. A dentist had made a charge of 7,000 dollars for four days' work, the patients being three wealthy ladies of one family. The operators were a father and three sons, and the time consumed was four days, with some extra work after hours. The value of the time was fifty dollars per hour for each dentist. The gentleman, who is a foreigner, to whom the bill had been sent, believed that a mistake had been made, and on being assured that this was not so refused payment.

The Pyrennees and the Cholera.—At the suggestion of Dr. Garrigou, of Luchon, Editor of the *Revue d' Hydrologie et de Climatologie Pyrénéennes*, the medical men of the French Pyrennean thermal stations have signed the following protest:—"In the presence of malevolent reports which persons, doubtless interested, have thought proper to spread concerning the Pyrennean thermal stations; the medical men of those stations regard it in the interest of all to protest in mass, and to declare that the sanitary condition of these Pyrennean thermal towns is as perfect as possible. There is no indication of any epidemic whatever." Then follow nearly 100 signatures.

Sir Erasmus Wilson.—Our readers will be glad to learn that at a meeting of the Council of the Royal College of Surgeons of England on Tuesday last, the 5th inst, the honorary gold medal of the College was awarded to Sir William James Erasmus Wilson, a past President of the College, in recognition of his great liberality in his contributions to the museum, in the endowment of the pathological curatorship and in the foundation of the professorship with which his name will always be associated and held in honour. This medal was founded in 1800, when, curiously enough, it was awarded to another Professor James Wilson; in 1822, Mr. James Parkinson obtained it; in 1825, Mr. Joseph Swan, a late member of the Council, won it by his valuable contributions on the nervous system; in 1834, Professor George Bennett, of the University of Sydney, obtained it for his many donations to the museum, as did Dr. W. L. Crowther, of Hobart Town, in 1869; in 1876 it was awarded to Dr. T. B. Peacock.

Bolingbroke House Pay Hospital.—At a special meeting held on August 2nd, with the double object of

improving the finances of the Bolingbroke House Pay Hospital, Wandsworth Common, and of giving it a less local character by extending its sphere of usefulness, it was resolved to open its wards and private rooms for patients sent in under the care of any registered medical practitioner. Hitherto the patients have been attended by an honorary visiting staff, which has given for three years past a constant and efficient attendance at the hospital. At the meeting referred to these gentlemen very kindly facilitated the trial of the new experiment by placing their resignation in the hands of the managing committee.

Hospital Sunday Fund.—A meeting of the Council of the Hospital Sunday Fund was held at the Mansion House on the 31st ultimo to approve the awards for the present year. A report from the committee of distribution was presented, stating that the total sum available for distribution, after allowing sufficiently for liabilities and the usual current expenses, was 31,283*l.* Of that total 29,026*l.* was now recommended to 98 hospitals, and 2,257*l.* to 50 dispensaries. The awards for 18 general hospitals were as follows:—Charing Cross, 700*l.*; French, 200*l*; German, 700*l.*; Great Northern, 200*l.*; King's College, 1,200*l.*; London, 2,900*l.*; Metropolitan Free, 225*l.*; Poplar, 285*l.*; Royal Free, 875*l.*; St. George's, 1,600*l.*: SS. John and Elizabeth, Great Ormond Street, 120*l.*; St. Mary's, 1,050*l.*; Seamen's, 600*l.*; Middlesex, 1,700*l.*; Tottenham Training Hospital, 215*l.*; University College, 1,200*l.*; West London, 310*l.*; and Westminster, 900*l.* Of the special hospitals the City of London Hospital for Diseases of the Chest, Victoria Park, was awarded 820*l.*, and the Hospital for Consumption, Brompton, 1,320*l.* Mr. Custance, the secretary, stated that the fund was at present about 200*l.* in excess of the amount collected in any previous year, and that was quite irrespective of any sum which might be sent to them, according to public announcement, as the proceeds of the recent *fête* at the Health Exhibition. The Rev. R. J. Simpson moved, and Mr. R. Moreland seconded, the adoption of the report and the payment of the various awards, excepting, for the present, that to the North-West London Hospital, where a dispute is now going on as to its management. This was carried unanimously.

The Library of the Obstetrical Society will be closed from August 18th to September 18th.

The Library of Guy's Hospital will be closed on Monday, August 11th, and reopened on Monday, September 1st.

Proving a Will before Death.—"There has been a good deal of discussion," the *Philadelphia Medical Times*, June 14th, observes, "over the bill before the New York Legislature allowing a person to prove his will before his death. It is conceded that it is very desirable to prevent the disgraceful scenes now frequently enacted in the law courts upon the probate of a rich man's will; but there is a great difference of opinion as to the advisability of permitting the contents of a will to be made known prior to the testator's death. The present bill seems to require this to be done, and it is quite likely that a disinclination to have the nature of the distribution known will be as strong in influencing the action of testators as the desire to prevent unseemly wrangles over the will. The most practical proposition seems to be to allow a person to get the decision of a court as to his testamentary capacity, while directing that the will shall not be opened until after the death of the testator."

Branny Foods.—Drs. Randolph and Roussel read at the Philadelphia College of Physicians (*Philadelphia Medical News*, July 12), an important paper derived from an exhaustive examination of what has been written in old and modern times concerning the importance of the bran constituent of wheat as an article of diet, and they arrive at the following conclusions, which, it will be seen, differ much from the views generally entertained:—(1) The carbohydrates of bran are digested by man to but a slight degree. (2) The nutritive salts of the wheat grain are contained chiefly in the bran, and therefore, when bread is eaten to the exclusion of other food, the kinds of bread which contain these elements are the most valuable. When, however, as is usually the case, bread is used as an adjunct to other foods which contain the inorganic nutritive elements, a white-bread offers, weight for weight, more available food than does one containing bran. (3) By far the greater portion of the gluten of wheat exists in the central four-fifths of the grain, entirely independent of the cells of the fourth bran layer (the so-called gluten-cells). Further, the last-named cells, even when thoroughly cooked, are little, if at all, affected by passage through the digestive tract of the healthy adult. (4) In an ordinary mixed diet, the retention of bran in flour is a false economy, as its presence so quickens peristaltic action as to prevent the complete digestion and absorption, not only of the proteids present in branny foods, but also of other food stuffs ingested at the same time. (5) Inasmuch as in the bran of wheat, as ordinarily roughly removed, there is adherent a noteworthy amount of the true gluten of the endosperm, any process which, in the production of wheaten flour, should remove simply the three cortical protective layers of the grain, would yield a flour at once cheaper and more nutritious than that ordinarily used.

APPOINTMENTS.

Baker, Albert de Winter, M.R.C.S. Eng., and L.R.C.P. Lond.—Medical Officer to the Dawlish District, Newton Abbot Union, *vice* Mr. Arthur D. Parsons, deceased.

Biden, Charles, W., M.R.C.S., L.R.C.P. Lond.—House Surgeon to the Children's Hospital, Paddington Green, *vice* F. T. Hebb, resigned.

Hadden, Walter Baugh, M.D. Lond., M.R.C.P.—Physician to the Royal Hospital for Children and Women.

Haines, Alfred Henry, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the Tydd District, Holbeach Union, *vice* Dr. O. Meara.

Hough, C. H., M.R.C.S.—Surgeon to the Derbyshire General Infirmary, *vice* J. Wright Baker, resigned.

Humphry, Lawrence, M.B.—Assistant Physician to the Addenbrooke's Hospital, Cambridge.

MacAlister, D. M.D.—Physician to the Addenbrooke's Hospital, Cambridge, *vice* Dr. Paget, resigned.

Newman, Arthur Joshua, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to Farncombe District, Guildford Union.

Pitt, George Newton, M.A. M.D. Cantab., M.R.C.P.—Assistant Physician to the East London Hospital for Children, and Dispensary for Women, Shadwell, E., *vice* Fras. Warner, M.D., resigned.

Popplewell, Thomas William, M.R.C.S. Eng., and L.S.A., Lond.—Medical Officer to the Blisworth District, Towcester Union.

Wood, William, L.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the Cranswick District, Driffield Union, *vice* Dr. Richard Wood, resigned.

VACANCIES.

Bradford Friendly Societies' Medical Aid Association.—Assistant Medical Officer and Dispenser. Salary, £120 per annum. Applications by August 14th.

General Hospital for Sick Children, Pendlebury, Manchester.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

Hospital for Consumption and Diseases of the Chest.—Resident Clinical Assistant. Applications by August 16th.

Luton Union.—Medical Officer to the Markyate Street District, *vice* Mr. S. W. Mackey, resigned. Area, 11,274 acres. Population, 3,871. Salary, £87 per annum.

Oundle Union.—Medical Officer for the Weedon District, *vice* Mr. S. Stokes, resigned. Area, 8,980 acres. Population, 1,497. Salary, £40 per annum.

Royal United Hospital, Bath.—House Surgeon. (*For particulars see Advertisement.*)

St. Asaph Union.—Medical Officer to the St. Asaph District and the Workhouse, *vice* Mr. Llewelyn Lodge, resigned. Area, 19,260 acres. Population, 4,241. Salary, £67 per annum. Salary for Workhouse £50 per annum.

St. Bartholomew's Hospital.—Dental Surgeon. Applications with Testimonials must be left, on or before September 4th, at the Clerk's office. Further particulars from Wm. Henry Cross, Clerk.

South Molton Union.—Medical Officer to the Second District and the Workhouse, *vice* Mr. James Flexman, resigned. Area, 17,288 acres. Population, 1,752. Salary, £38 per annum. Salary for Workhouse £40 per annum.

The General Hospital, Birmingham.—Resident Registrar and Pathologist. (*For particulars see Advertisement.*)

University College, London.—The office of Surgical Registrar in the University College Hospital will shortly be vacant. Applications and Testimonials to the Secretary, Talfourd Ely, M.A., on or before September 30th.

West London Hospital, Hammersmith.—Registrar and Pathologist. Honorarium of £25 per annum. Applications by Aug. 21st.

DEATHS.

Gregory, Bradley, Fleet Surgeon, R.N. (retired), at 5, Northernhay Place, Exeter, on August 1st, aged 47.

Jenkins, Robert Walker, M.R.C.S. Eng., and L.S.A., Medical Officer of Health, New Forest Rural District, at Fawley, Hants, on July 31st.

Marshall, George Henry, M.D., F.R.C.S., at 28, Tisbury Road, West Brighton, on July 31st, in his 71st year.

Renton, Robert, M.D., F.R.C.P.E., at 15, Rothesay Place, Edinburgh, on July 31st, in his 91st year.

NOTES, QUERIES, AND REPLIES.

MEDICAL DIRECTORIES.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—As the time is approaching for the preparation of the new edition of the Medical Directory, I desire to call the attention of the Editors to the desirability of omitting the information contained in the announcement that Mr. A. or Dr. B. is a member of the "Reading Pathological Society," or the "Nottingham Medico-Chirurgical Society." Every respectable member of the profession can be admitted a member of our Local Medical Societies on payment of a guinea; it implies no distinction or compliment whatever, and merely, unnecessarily, increases the bulk of the volume. The absurdity of introducing this kind of information is apparent, and it would be equally appropriate to inform the profession that Mr. A. or Dr. B. is a subscriber to the "Barchester Public Library" or to "Mudie's." In no other country is a Medical Directory encumbered with such irrelevant information.

I am, Sir, yours &c.,
F. R. C. P.

CHEMICALS AND SONG. "THE MARVELS OF THE AMMONIAPHONE."

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR.—Recently was copied into my daily paper an article from the *Pall Mall Gazette*, under the above heading, which I am puzzled to class whether as philosophic bosh emanating from some Philosopher of the University of Laputa, described in the travels of the veracious "Captain Lemuel Gulliver," or whether there is a substratum of fact in the article. How an atmosphere charged with peroxyde of hydrogen and ammonia, with a *soupçon* of some essential oils, will have a potent effect on the larynx, and increase the register of the voice from an imperfect octave, or so, to three octaves, improving also timbre and tone, I am at a loss to conceive. Is it fact or fiction?

I am, Sir, yours &c.,
Plymouth. O.

COMMUNICATIONS RECEIVED—

DR. STEPHEN MACKENZIE, London; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; Mr. J. GREENWOOD, Norwich; THE SECRETARY OF THE FACULTY OF PHYSICIANS AND SURGEONS, Glasgow; THE LIBRARIAN OF THE OBSTETRICAL SOCIETY, London; THE REGISTRAR-GENERAL, Edinburgh; THE SANITARY COMMISSIONER FOR THE PUNJAB, Lahore; THE REGISTRAR OF THE ROYAL COLLEGE OF PHYSICIANS, London; THE SECRETARY OF THE ROYAL COLLEGE OF SURGEONS, Edinburgh; THE SECRETARY OF THE ARMY MEDICAL SCHOOL, Netley; Mr. NOBLE SMITH, London; Mr. H. Contents.

ON THE INTERNATIONAL COLLECTIVE INVESTIGATION OF DISEASE.[1]

By SIR WILLIAM W. GULL, Bart., M.D., F.R.S.

Gentlemen, Friends, and Colleagues,—I esteem it a great honour to be deputed to address you on this occasion, and on a matter which promises to contribute to the advancement of medical knowledge by a wider and fuller method than has yet been sufficiently attempted.

The subject of my address is the institution of an International Collective Investigation of Disease. This object, I need not say, is intimately connected with the main purpose of these Congresses, if not indeed in the natural course of things an integral part of them. At present we come together as individual cultivators and practitioners of medical science; each contributing his quota to our knowledge on this or that subject which may or may not have been selected for thesis and discussion beforehand. Nor are our labours, even under these conditions, without excellent results. But a feeling is growing and already wide-spread, that by a more organised combination, a more intimate and better coöperation, not only the members of these Congresses, but all the working members of our profession throughout the civilised world, might sooner or later be organised into a body of fellow-workers, associated for collecting information on medical questions over the widest area.

There is perhaps no profession which enforces upon its individual members so strongly as does Medicine, the necessity of continued observation and intellectual cultivation; and there is no means by which this cultivation can be so well promoted as by meetings like the present, and by the active organisations in the form of committees or sub-committees which we hope and anticipate may spring from them.

The human intellect in its single and separate operation may produce wonderful results. Yet isolated as a man may seem to be in the intellectual labour which occupies him, he makes but little progress apart from the aid and coöperation of other minds which have worked and are working in the same direction. And though doubtless it will always be the privilege of the highest intelligences to clear the boundaries of knowledge, and to throw the rays of their genius into

[1] An Address delivered at the International Medical Congress, Copenhagen, August, 1884.

the surrounding darkness, yet all must be agreed on the great and almost supreme value of the intellectual coöperation of less gifted minds in the simple observation of facts, and especially when the needed facts are scattered over a wide field.

However much apart, as I say, a man may seem in the work of his intellect, he is really much less so than he seems to be; for as we cannot refer the strength of our bodies to any particular food that we have taken, so neither can we track the thoughts of our minds to the sources whence they may have been fed; and if our social nature has been raised from savagery to civilisation by social combinations, it is even more necessary that our intellectual nature should be helped in its growth and nurture by such intercourse and association as are here presented, and which we now propose further to advance.

Our great countryman, Bacon, has not generally been well received in the school of German philosophy, so that I must use some caution in citing him in favour of intellectual combinations in pursuit of the sciences. Still, on thinking over the bearings of Collective Investigation of Disease, I could not but feel that although three centuries have elapsed since he broached this question, and little has been done in it since, we might be about to realise his idea of a Novum Organon, the formation of a New Intellectual Machine for removing and overcoming the obstacles to our medical progress.

The purpose we have before us is no less than this, to enlarge and methodise intellectual coöperation, whereby, not only the active, but the at present inactive, faculties of observation of the wide-spread members of our profession may be combined into one or more lines of energy. I am not unmindful how much this presupposes; how it assumes the combination of exact observation and record, with refined criticism and analysis; how it demands the highest scientific perception, with the humble collection of the meanest facts; how, in fine, it means the development of intellectual combination into many forms of organisation which should be not one but *many instruments of research*. Such a forecast may perhaps lead us to exclaim—"Who is sufficient for these things?" Yet happily the answer is near—time, though short for the individual, is inexhaustible in the race—the intellect is in its infancy—its powers of growth unexhausted; and to these in their evolution there appears to be no limit. The work to be done is unchangeable; and there are eager and willing workers in all lands, who only need the encouragement and direction of the master-minds of medical science to set them to work.

Happily, the phenomena which demand our investigation, though complicated and transient, are, it need not be said, the result of unchangeable laws. The capriciousness of Nature, as we speak of it, is but the weakness of our own sense and understanding; and its so-called mystery and obscurity, but the darkness in ourselves.

The physiologist and the pathologist have to admit that not even in the caprices of man is there capriciousness; that mental caprices have their organic basis; that the whims, the fancies, and the prejudices of the human mind, not less than the changing activities of the functions of his body, or the revolution of the earth on which he lives, are but the resultants of unvarying laws, unchangeable as the fixity of the stars on which he gazes with wonder and admiration.

We may therefore have this encouragement, that when any of our work is done, however small and trifling it may seem, it is done and settled for all time, or at least so long as the laws of organisation remain what they are; that the clearing of a fact in respect of disease will remain an imperishable inheritance of knowledge to those who follow us, so long as there is disease in the world. We may support our labours, therefore, with a feeling of surety that the problem before us is a settled problem, however difficult its solution. Nature will not delude us, however much we may delude ourselves.

A superficial survey of the Sections of this Congress shows that the student of Medicine occupies an unique position in the pursuit of knowledge. For instance, if I turn the leaves of the programme, I find that the Section of Anatomy invites attention to cell nucleus and cell-division, the lowest unit of organisation; and the Section of Psychiatria to the Psychic-Epileptic equivalent, which, as no one will deny, stretches to the other pole of knowledge; hence, surely no man more needs to lay hold of the unchanging idea of law than the student of Medicine, as he ranges from one extreme of observation to another.

In the International Investigation of Disease, the prevalence of mental disorders in different nations will be a subject of enquiry. Also the forms which these maladies take, according to nationality, occupation, stratum of society in which they occur, &c.; the use of stimulants—alcohol, opium, hemp, tobacco, &c. This work obviously lies not only in the physical and physiological conditions of life, but in their intimate correlatives, the facts of psychology. The thoughts of the student of Medicine must, therefore, range from the atoms that build up the textures to the hopes that make the man. And even perhaps further than this, for in most of us the unsatisfied mind cannot answer itself with the measurables and ponderables of physical science, however much it may admit that all else is dependent upon them, but will strive to go behind appearances and feelings to the substratum of their existence, and cannot find rest for its foot until it traces their relation to an unchangeable first cause.

Du Bois Raymond might well remark that the problem of organisation would be comparatively easy if it were unattended with feeling and thought. That it would then, as it were, present us only with an astronomical problem, in which the atoms of things would, after the manner of the heavenly bodies, move on in their several orbits in lines which science might hope to deal with. For it is within the scope of science, even as we now understand it, to track an atom of oxygen, nitrogen, hydrogen, or carbon through its synthesis in a plant to its combination in the elements of brain or muscle, and still on to its resolution and return into its original form, with corresponding evolution of force. But when this shall have been done, we have learnt nothing of pain, nothing of emotion, nothing, indeed, of the science of many of the common facts with which

medicine has to deal every day. How different would be the problem for the physician if disease were unattended by pain or emotion, if the patient were indeed patient as unorganised materials are ; if there were no hopes or fears on the part of the object to be dealt with, and no embarrassment on the part of the practitioner from desire to please as well as to heal ! Quacks would then be banished to limbo. The course of nature could be watched until the equilibrium of health was attained, and the temptations to polypharmacy would be no more. But then, on the other hand, we should have nothing to do with life in its higher form, which is our ever-abiding problem, and we should miss the stimulus of affection, which, like a constant trade wind, carries us forward—at least the majority of us.

If for these preliminary remarks I need any apology, might I not say that I have come from the country of Newton and Harvey, that I have travelled by the home of Spinoza, and that I am speaking in the presence of the countrymen of Descartes and Leibnitz.

Gentlemen, I do not appear here to-day on my own behalf, but on behalf of the Collective Investigation Committee of the British Medical Association.

The British Medical Association is an Association of most of the medical practitioners in the Kingdom of Great Britain and Ireland ; and it has, I believe, affiliated Associations in our Colonies.

It numbers from ten to twelve thousand members, all, or almost all of them, actively engaged in the practice of Medicine.

It is organised into over fifty branches, with their presidents and committees.

These branches have weekly or monthly meetings for the purposes of professional intercourse, and for reading and discussing papers on medical subjects. It has, moreover, a weekly journal of very extensive circulation, which records the transactions of the different branches, and supplies to its members lectures and communications on the most important current subjects in medical science.

This Association has been founded over fifty years.

For some years past, and especially during the last four years, it has been felt that the aims of this great Association might be advanced to a higher point by establishing an organised plan of medical observation amongst its members, and, already, sub-committees to the number of fifty, comprising as many as a thousand members, have been established to carry forward this proposition. I am deputed by the Central Committee of this Association to ask you to-day to extend this combination by establishing an International Committee for the Collective Investigation of Disease, and I trust this may commend itself to the Congress.

Such an International Committee would have objects entirely germane to the recognised purposes of the Congress itself. Probably one might go even further, and say that such an International Committee should form an integral part of these International Medical Congresses, and that their operation would in time become one of the most fertile sources of International Medical Advancement. I am happy to think that but little argument will be required in this assembly to commend this proposition to your favour. Already in Berlin the Verein für innere Medicin has adopted the principle, and has established a committee, after the pattern of the British committee, to carry forward the work. The President of the Society, Professor Frerichs, has given his entire adhesion to the movement, and Professor Leyden has accepted the presidentship of the committee itself, which includes also very distinguished names ; and I hope that one or more of our colleagues from Berlin will to-day add a few words in favour of the proposition I am called upon to make.

In putting arguments forward for the establishment of a National Collective Investigation in its more limited form, it was permissible to insist upon minor advantages to be expected from such association—I refer to its educational value, since it could not but happen that every coöperating member would learn much from the investigations proposed ; and that whilst he promoted science, he would no less promote his own intellectual status.

Again, I pointed out in my Address in London, that the family physician or practitioner has a sphere of observation specially favourable to the study of ætiology, and modes of extension of communicable diseases. He has also special advantages for pathological study, which are not so much afforded to the professor in an university or hospital. It is his privilege to see the earliest beginnings of disease, and to have the opportunity of tracing its evolution and decline, or when so favourable a course does not happen, the steps of pathological progress are before him, whereas at the end of life when the whole organism crushes downwards into a chaos of pathological forms by the advance of disease it is often impossible on the *post-mortem* table to say where the failure began, and how it has advanced. The family physician's observations should thus supply a corrective to a too exclusive mechanical pathology.

Amongst the subjects suggesting themselves to us in England in near relation to this matter, was the formation of life-histories and family-histories in respect of disease, and these could only be obtained through the family physician. If such histories could be widely and accurately recorded, the natural associations of different forms of disease in individuals and families would be made evident, and might afford suggestions as to pathological relations not now suspected—relations between diseases which are separated in Nosological Treatises, but associated in Nature. This mode of enquiry, through family-history, would open a wide page for the record of the *pathology of ailments* ; a page than which there is none more interesting to the practitioner of medicine, since seven-tenths of his work, and perhaps more than this, lie in efforts to correct physiological deficiencies, and to maintain some near approach to the equilibrium of health, which a feeble organism unaided cannot reach. On this part of the field it is that we can study the relations between functional and organic diseases, especially in the range of nervous affections, where the degenerative tissue-changes in one individual of a family may be compared with the physiological disturbances in another. It is also in these family-histories that we might hope to have elucidated the difficulties of *correlated pathologies*. Why, for instance,

in a numerous family, whose members are living under the same conditions, one or two should become the subjects of pulmonary phthisis, one or two the victims of rheumatism, another of epilepsy, whilst the others maintain a healthy equilibrium. If such a history should be repeated in ten thousand families or in a hundred thousand, we surely might hope, by careful collation of the facts, to come to the groundwork of these differences, and to determine the rule which separates the epileptic and the rheumatic from the inroads of phthisis.

So much for the more limited though not less important advantages of National Collective Investigation, but in an International Collective Investigation, the ground widens very much, not only from the different intellectual characters of its working members but also from the greater variety under which disease presents itself.

The first gain, no doubt, will be from the intercourse and reaction of different national modes of thought, with and upon each other. It need not be said that the ways in which any subject may be viewed do not depend upon the subject itself, but upon the varied capacity of the minds brought into relation to it. Minds evolved during ages under special local and national conditions, and educated in lines of their own cannot fail to give new direction and shape to the questions proposed for solution.

Each national mind will feel a different mental necessity. This view might be much further enlarged, if this were the occasion for it. At the Congress in London I endeavoured to show that each nationality produces its own scientific school, and not least in respect of the Science of Medicine. One nationality is more distinguished by its powers of Analysis ; another by its powers of Synthesis ; one is critical, another historical ; one characteristically anatomical, another physiological. Even if this occurred to only a limited degree, there must follow an interchange and fertilization of ideas. And let no one believe that this is a dream. We have reached no more than the threshold of intellectual evolution.

International Associations like this will serve to nurse and nourish these powers in the future. But however this may be, these movements and combinations are in accordance with the spirit of the age. It is on all hands felt and acknowledged that the individual worker, apart from his colleagues, cannot hope to do much in any department of science, and that it is only by combination of members and subdivision of labour that scientific observation can be carried on successfully. The establishment of an International Collective Investigation of Disease, appeals to us from every side ; personally, as through its influence our energies are stimulated, and our intellectual activity varied ; socially, since observations made in one country cannot but correct or support those made in another ; collectively, since science is cosmopolitan, and can only grow well when fed from all sources. It has been objected that the results of Collective Investigation must, from the nature of the case, be inaccurate, superficial, and so far useless : that they are more likely to confirm prejudice than to extend knowledge, and as regards their scientific value, science is made up of quite other stuff. Now to this it may be answered that knowledge advances in many ways ; not only by the investigations of the gifted workers of science, but by the casual observation of an isolated fact. Indeed it has hitherto been objected, at least against the science of therapeutics, that more has been gained by accident than by methodical pursuit. The truth is, one step of knowledge, however gained, leads to another. The accidental infection of a milkmaid's hand, casually brought to the notice of Jenner in a country surgery, has not only contributed more than any other discovery to the limitation or suppression of a loathsome disease, but it has opened up pathological speculations of a far-reaching character, and which to-day, in the hands of Pasteur and his colleagues, reveals the hope that we have the key to many if not all infective diseases.

All will admit that in the daily routine of practice facts are occurring that are worthy of record, and that Medical Science loses much by the want of such record. By the combinations proposed, what are now casual and wasted observations would be methodised and stored for arrangement, comparison, and deduction.

The English Committee has proceeded as follows : having first determined certain subjects for Collective Investigation, cards of queries have been framed and distributed through the different Sections, leaving each member to select such subject or subjects as he might prefer.

As regards those life-histories of which I have spoken, patients and practitioners are advised to apply to the Association for blank books for these records. The head of the family or other person is directed to request the medical attendant, after each illness, to write a brief account of it, with any note he may be pleased to add ; so that, after the manner of genealogical trees —which show the distinctions of a family through the heroic deeds of its ancestors—there should be a genealogical history in time to come of all the diseases to which its members have been subject from generation to generation. Such books might also become a record of health as well as of disease, and so show not only how families, and from them nations, decay, but how they grow. No doubt such records even of a thousand families would contain singular revelations, and place many of our pathological ideas in quite a new light. We might learn that with tendencies to organic disease, there was less tendency to epidemic influences ; that if diseases were prone to change their form and multiply, they were equally, if not more, prone to lose their forms in a reversion to health ; that the occurrence of one disease might confer an immunity from another.

These life-histories might perhaps seem to have a more national than international value, but if they could be obtained, they would supply material for probably the widest inductions. But there is this difficulty about them. Fear, as the wise man said, is a bad counsellor, and, unfortunately, the construction of these life-histories is beset with fear. There is a lurking dread in every man, and in every family, of exposing their frailties. This presents an almost impenetrable barrier to gaining the facts upon which

life-histories are built. There is a fear also in the minds of the inquirers themselves, since there is a natural disinclination to intrude into secrets which are so anxiously guarded. But whilst we bear in mind the wise man's dogma, and remember that fear is a bad counsellor, we may resist its counsels as far as we can, where so much is at stake.

The clinical subjects which at present have been selected are acute pneumonia, chorea, acute rheumatism, diphtheria, and inherited syphilis. Cards of queries have been issued on each of these subjects, and each card is accompanied by a memorandum stating the object of the particular enquiry, and directing the attention of the observer to the queries proposed. These memoranda are of the first importance in this movement. It is on them that our hopes of success must be grounded. It is intended that they should indicate the defective state of our knowledge in the subjects brought forward for investigation. In doing this their value to the profession, and to the progress of our knowledge, is almost incalculable. It is no small matter to have set before us in a simple manner what the present state of our knowledge is, the defects which have to be made good, and the enquiries likely to lead to such a result. Text-books on medicine will hereafter have to follow something of this leading. Hitherto, and for the most part, they have aimed too much at satisfying the reader, and, in order to make the treatises complete, have assumed a knowledge both in pathology and therapeutics too little justified by fact, and so have hindered, rather than promoted, our progress.

These memoranda are intended to be critical suggestions and suggestive criticisms on the state of knowledge respecting the subjects brought forward. They are the centre of the proposed system. It may fairly be expected that each issue of them will be more exact and incisive. The successful framing of them is the one important object to be attained. Through them the influence of the more advanced intellects in the profession will extend through the whole of it, and will reach its most scattered and distant members. Nor can we doubt but that there will be a reaction from the periphery to the centre, maintaining a living cycle of active mental coöperation. Who can limit the effect of such action and reaction? or deny that there will thus arise new energy and new genius? for, happily, the cultivation of science need not remain the privilege of professors and teachers, but may become the common inheritance of all.

The volumes I hold in my hand are the first published records of the Collective Investigation in England. They contain Reports and Memoranda on the communicability of Phthisis, Acute Pneumonia, Chorea, Acute Rheumatism, and Diphtheria.

I would refer, by way of illustration of my remarks on Memoranda to the Memorandum on Acute Rheumatism. This recites our deficiencies on the ætiology of this disease, and might also include its pathology; the exceptional ways in which Rheumatism occasionally developes; its probable relation to the state of the nervous system; the new aspect of the pathology of joint-affections in relation to the spinal cord; the relation of the intensity of the rheumatic affection to anæmia; its clinical relation to tonsillitis; the intercurrent affections of the skin; and last, but, unhappily, not least, the treatment. I might add, however—not as a criticism, but as a suggestion—that an exhaustive Memorandum on Acute Rheumatism, showing the real state of our knowledge respecting this disease in all its relations, and the more than vagueness of our treatment of it, would have a value which I should find it difficult to express. Long-standing prejudices, which for the most part are entertained and fostered as if they were established and confirmed experience, would go down before the exposition of such a Memorandum, and its results in International Collective Investigation, as dry leaves before an autumn wind.

When enquirers on a given subject agree at the outset what are the imperfections of their knowledge respecting it, they naturally combine the more heartily in its further investigation.

The aspect of an enquiry from a personal standpoint, and that from a collective investigation standpoint, present the most important contrast. In the one, the Ego, however subordinated, is not lost. It lurks at the centre of the operations, and the results or supposed results of personal enquiry are too apt to be regarded as property, to be defended against all inroads, whether this property be worth defending or not. The observations and experience of any one man, however gifted, cannot be considered more than suggestive, and cannot have any authoritative value until confirmed by the repeated observations of others.

In a collective investigation, whether national or international, the individual and the results of his enquiry are obviously less open to distortion from personal favour or prejudice. This freedom from undue influence gives a greatly preponderating advantage to such associations as we are here met to establish.

Here the observer has no selfish interest in the result of the enquiry. His work will be equally good, whether immediately fruitful in positive results or not. The isolated observer, on the other hand, is apt to have interest in little else than positive results. In therapeutics the truth of this is too abundantly evident, to the confusion of medical practice, and to the vaunting of remedies and methods which are mostly of no value, or may be even worse than useless. It has not escaped the remark of the master of the logic of facts, that "Habet enim unusquisque præter aberrationes naturæ humanæ in genere, specum sive cavernam quandam individuam, quæ lumen naturæ frangit et corrumpit—ut plane spiritus humanus (pro ut disponitur in hominibus singulis) sit res varia et omnino perturbata et quasi fortuita. Unde bene Heraclitus homines scientias quærere in minoribus mundis, et non in majore sive communi;" not in the common world, but in the world of themselves.

One can hardly forecast the amount of good influence on therapeutics, if, instead of individual assertions respecting the value and success of this or of that drug or method, we had the teaching of calm and impersonal results deduced from an international area of enquiry, so large that the individual observer would be lost in the result.

Whilst our English Association has, as I have described, put forward several subjects for collective

enquiry with the memoranda and questions I have named, our German colleagues have determined upon a somewhat different method. They have selected but one subject for investigation, thinking it better to exhaust that before taking up a second or third; and they have naturally selected a subject which at the moment prominently occupies the attention of the profession in all lands, I mean pulmonary phthisis. Upon this they have proposed four points for solution:—(1) The heredity of the disease; (2) The communicability of the disease; (3) The cure of the disease; (4) The transition of pneumonia into phthisis.

These propositions are accompanied with many questions of detail which I will mention presently. The English Committee, at the beginning of last year, also proposed as a question for Collective Investigation the communicability of phthisis, and have reported upon it. The German enquiry is not yet reported upon. The important discovery of Koch that there is a specific organism associated with pulmonary tubercle, and his infection experiments, have naturally excited the greatest interest respecting the communicability of the disease. It is well known that at different times and in different countries the contagiousness of phthisis has been confidently believed in; and as Professor Ewald remarked at a meeting of the Verein für innere Medicin, observers in America, in England, and in Germany, have supported the belief in the contagiousness of phthisis by important records respecting it. Still, until Koch's discovery, the professional mind was very much asleep about it, or with only now and then a half waking-dream.

The English Collective Investigation Committee have put forward the question of communicability in the simplest form—"yes" or "no;" as follows: "Have you observed any case or cases in which pulmonary phthisis appeared to be communicated from one to another? Please answer Yes or No." It will be observed that this is not a mere voting question as to a man's belief, but whether he has observed any case or cases of the apparent communicability of the disease. "Out of the 1,078 members of the Association who returned answers to the questions issued on this subject, at least 261 believed they had seen cases of phthisis which have originated in communication from one person to another; about 39 more have seen cases which have made them doubtful whether phthisis may not be so communicated; while 105 have offered facts and arguments which seem to them to negative such a view. One hundred and fifty-eight of the affirmative returns refer exclusively to cases observed between husband and wife. Communication between husband and wife is mentioned, together with other cases, in 34 of the remaining returns. So that 192 observers report cases of supposed communication of phthisis occurring between husband and wife."

There are also a number of special returns where the disease seems to have spread from patient to nurse, and from friend to friend. I am not here of course to discuss the pathology of phthisis or of its communicability from person to person, but to argue for the advantages of collective research. And, perhaps, no subject could be selected better to demonstrate these advantages than the supposed contagiousness of phthisis. By extending the enquiry over a wide area, the recurrence of striking cases of apparent communicability are repeated over and over again, and must naturally impress the mind more than a case or two occurring in individual experience. The Committee, therefore, justly remark in their report, that they hope that this first step in Collective Investigation into one of the most important questions connected with the ætiology of phthisis, will be of value in leading to more open-mindedness in the discussion of disputed questions of experience and observation.

We shall await with interest the report of the Berlin Committee, for its Card and Queries is much beyond that of "Yes" or "No." It presents seven sections—(1) General questions as to the history of the family of the patient, the subject of phthisis; (2) Antecedents of the family; (3) Previous diseases of the patient, as, for instance, whether of phthisical habit or not, what diseases preceded the development of phthisis, as scrofula, measles, whooping-cough, chlorosis, &c.; (4) On the question of heredity follow queries on health of parents? either dead of phthisis? and when? have they suffered from scrofula? disease of the bones? lung diseases not phthisical? as pneumonia? pleurisy? gangrene? bronchitis? &c., were the grandparents or parents related in blood? age of father or mother at the birth of the patient? were they sober or not? &c.; (5) On contagiousness or communicability—was the disease taken from husband by wife? or from wife by husband? when the malady began? was the communicability between brothers and sisters or relatives or servants? was the contagion from residence in prisons, establishments for the insane, barracks, or infirmaries, &c.? was the infection by residence, clothing, or beds? by nourishment as through the milk of scrofulous animals, or consumptive nurses, &c.? (6) On the curability, including only such cases where at least two years had elapsed from the beginning of the disease—where did the arrest or cure seem to begin? did this come from the improvement of the general condition? are cough and expectoration gone? have the physical conditions altered, and in what way, &c.? (7) On the transition of pneumonia into phthisis—the day of the beginning of the pneumonia? its seat, as at base, apex, or middle of lung, &c.? right or left lung? expectoration—sanguineous? rusty? grass-green, &c.? signs of re-convalescence? when the first signs of tubercle occurred? &c., &c.

I have stated just now that I appear here on behalf of the British Medical Association for Collective Investigation; but I have to add that it is my duty to lay before you further what has been done by the Collective Investigation in Berlin. Within the short time that the Berlin Association has been in operation (spring, 1883), its activity and success have been remarkable. The Berlin Association had already, in February, 1884, nine months after its establishment, fifty-five branches; and Herr Leyden reported to the February meeting of the Verein für innere Medicin a communication he had received from Professor Rauchfuss, in St. Petersburg, informing him that they would establish there a separate Association for Collective Research, after the plan of that of the Verein für innere Medicin, and in relation with it. In Paris also,

in the Société des Hôpitaux, there had been negotiations respecting the collective investigation of the Verein für innere Medicin, and a similar one would be there arranged.

In the June sitting of the committee, under the presidency of Herr Fraentzel and Herr Leyden, Herr S. Guttman, the secretary reports that the German Association is daily making progress and exciting great interest; that on all sides, from Denmark, Sweden, Switzerland, Italy, Spain, and America, there were communications asking for information respecting this collective investigation, and with a request for the cards which had been issued.

With the Vercin für innere Medicin, there are associated of the Berlin Institutions the "Königstadt-Verein," the "West-Verein," the "Südwest-Verein;" and for the Associated Societies out of Berlin, there are correspondents for the Medical Societies in Rostock, Schwerin, Güstrow, Münster, Minden, Arnsberg, Regensburg, Paderborn, Aurich, Thüringen, Holland, Meran, Hagenau, Salzbrunn, Frankfurt (am Main), Köslin, Freiburg, Prag, Elbing, Mainz, Hannover, Graetz, Bochum, Frankfurt (am Oder), Hessen, Wiesbaden, Danzig, Memel, Marienwerder, Friedeberg, Lübeck, Chemnitz, Nürnberg, Bremen, Pommern, Breslau, Giessen, Dresden, Posen, Essen, Halle, Kiel, Basel, Göttingen, Liegnitz, Riga, Davos, and Marburg.

Further, there is an Association for Collective Research of the Institutions for the Insane, and already Herr Jastrowitz reports a combination of twelve of these institutions in different parts of the country. There is also a similar movement for enquiry into the health and the diseases of the inmates of prisons and infirmaries. In fact, our German friends have in many lines outrun us. Their exertions and their success in promoting this organisation make it superfluous for me to add arguments in favour of the proposition before this meeting.

I hope I may congratulate this sitting of the International Medical Congress in Copenhagen, upon the happy incident that we are to-day called upon to centralise these operations which have begun in England and Germany, into an International Committee of this Congress, whose function will be to promote them in all lands; and, by the continued coöperation of these Congresses, carry forward a movement, the fruits of which, as I have already said, it will be impossible to over-estimate; whether we limit our view to the results on our members, on the profession as a whole, on the public good, or on the brotherhood of nations.

There is but one caution, and that lies against our attempting too much at first. In our scientific ambition, it would not be difficult to o'erleap ourselves. It is by a little well done that we shall do much; whereas, if our deductions are hasty, incomplete, and unfounded, the authority which will naturally attach to these researches will be much more obstructive to the cause of science than the fallacious dogmas of separate individuals. If our hopes and prospects are encouraging, the steps we take cannot be too wary. The purpose of our association could only lead to failure, and, perhaps, even a gigantic failure, if the movement were not waited upon by strict caution and exact criticism. If the work proceeds at the present rate, a few years will witness one of the greatest and most useful movements in modern times. The founding of an International Collective Investigation of Disease will promote the national movements of the same kind in all countries, and will give a stimulus to international emulation under the happiest form.

In the time at my disposal it is impossible to sketch even in outline the number of subjects which claim attention. The Committees of the different Sections, as the work progresses, will select their subjects from their own point of view, some with a broader purpose will take the more common maladies, and the more curious the rarer ones. One of our English colleagues would have concise descriptions of rare maladies prepared as an entomologist would have them prepared, of newly-discovered insects; printing distinguishing features in italics. He instances Rhinoscleroma, Hebra's Prurigo, Morphœa, Alibert's Keloid of Scars, Addison's Disease, Hodgkin's Disease.

Cretinoid State in the Adult (Myxœdema).

Congenital absence of special bones (such as radius and tibia, with associated portions of carpus or tarsus).

Cases of Spina Bifida, illustrating either results of treatment or survival without it.

Cases of Sacral Tumour.

Cases of "the Recurring Iritis in young persons."

Aneurysms in the orbit.

The Osteitis Deformans of Paget.

Disease of joints in Ataxy ("Charcot's joint-disease").

Non-malignant growths in the tongue.

Hemiglossitis.

Kaposi's Disease.

The arguments for these more curious enquiries are not far to seek, since diseases which are rare in some countries may be frequent in others, and by their frequency afford the required ground for the study of their pathology. I might instance the glandular and elephantoid diseases of China, and the successful labours of Manson and Mayers, which have traced them to the presence of the *filaria sanguinis hominis*, producing lymphatic obstructions and filarial thromboses. The elucidation of such a piece of pathology, though the disease be limited to China, must have a good influence on the whole medical mind in breaking down pre-conceived opinions, and in showing that we cannot go too far a-field for our knowledge. It supplies moreover, a further argument for the International Collective Investigation of Disease.

Gentlemen, whilst I thank you for the favour with which you have received this Address, I cannot but express my deep sense of the imperfect way in which I have set forth the greatness and importance of my subject. I can now but commend the matter to your good efforts, assured that, through them, success will not be wanting.

Medical Charities.—Under the will of Mr. Hanson Freeman, of Knaresborough, 1,000*l.* each is bequeathed to the Halifax Infirmary, and the Harrogate Bath Hospital; Mrs. J. B. Grieve, of Berwick-on-Tweed, bequeaths 1,000*l.* to the Catholic Hospital of St. John and St. Joseph, Great Ormond Street.

CONSENSUAL MOVEMENTS AS AIDS IN DIAGNOSIS OF DISEASE OF THE CORTEX CEREBRI.

By VICTOR HORSLEY, B.S., M.B. Lond. F.R.C.S.

Assistant Professor of Pathology in University College, London, and Surgical Registrar to University College Hospital.

In the following case[1] of tubercular meningitis, which affords an example of the application of knowledge gained by experimental pathology to the diagnosis of disease of the brain, the somewhat uncommon phenomenon was observed of movement of one limb when the opposite one (previously rigid) was fully flexed. On further analysis of this and correlated symptoms, it became evident that here was a ready means of localising, at any rate, some of the disease in the encephalon. Briefly summing up the case it amounted to this: that a boy, aged 7 years, who had been treated some time for hip disease, was sent down to a convalescent home, where, from pressure of splint, &c., he unfortunately got a bed sore. On his re-admission to the hospital, he was suffering from chronic septicæmia due to the condition of the sore. This passed off under treatment, but about a fortnight after re-admission he was attacked by tubercular meningitis and general tuberculosis. As will be seen from the subjoined account, the onset of the disease was perfectly characteristic, and requires no further notice. On the tenth day of the meningitis, when the patient was examined, it was found that the left upper limb was rigid in the proximal segment, the arm. For the previous forty-eight hours it had been noticed that the patient never moved the *left* upper limb, and very rarely the lower limbs, but that the right upper limb he occasionally carried to the head, while at other times it lay perfectly lax. The child was completely unconscious, took no notice of anything happening around him, and when roused only moved his body sluggishly from side to side after a considerable interval of time. It is perfectly clear, then, that the cortex cerebri was very greatly inhibited, but its function not totally arrested. This point is of great importance, of course, in considering the diagnostic value of the above-mentioned symptom since it can but rarely occur that such a degree of cortical inhibition (or mental hebetude) should be reached in which a slightly painful, or at any rate uncomfortable, stimulus does not evoke a defensive reflex movement, and at the same time arouse an emotional disturbance of greater or less degree, while it does call forth, after a constant interval of time, a perfectly definite movement, obviously regulated by the excito-motor region of the cortex cerebri. The justification of this mode of explaining the consensual movement is to be found in the following clinical facts. In examining the degree of rigidity noticed in the left arm muscles, I found that when the elbow was rapidly and forcibly flexed, the right upper limb moved forwards and inwards after the constant and distinct interval in time of one second. For the first two or three times the interval between the flexion of the left arm and the movement of the right was two seconds, but this rapidly became shorter, until about the sixth time it was one second, at which point it remained constant. This is interesting when we remember how soon the personal equation can be reduced by a little practice. In further detail, the movement of the right upper limb began by flexion with adduction of the shoulder, the elbow being kept extended, and the wrist slightly flexed. The movement only followed *complete* flexion of the left elbow. For starting with the limb fully extended at 180°, if the elbow were steadily flexed through 120° there was no movement of the right arm, but this began as soon as the flexion of the joint was carried beyond that point; in short, as soon as over-flexion was produced. It is obvious, therefore, that the stretching of the previously rigid muscle formed the stimulus for movement of corresponding muscles on the opposite side of the body. The question at once arose whether the movement was produced by the stimulus simply passing across in the spinal cord, or whether it passed up to the highest centres in the cortex. That the right cortical excito-motor region was the seat of an irritative lesion was perfectly obvious, since, in addition to the rigidity with paralysis (voluntary) of the left upper limb muscles, there was slight nystagmus, with marked internal strabismus of the left eye, together with abolition of both superficial and deep reflexes. Taking this into consideration, with the relatively enormous length of time[2] (one second) that elapsed between the flexion of the left arm and the consequent movement of the right arm, I considered myself justified in assuming that the impulse passed from the right cortical centres (already in a state of high irritability) to those of the left side, and that the associated centres there "discharged," with the movement of the right arm as a result. Consequently, there was diagnosed a patch of discrete tubercular foci scattered over the right ascending frontal and the posterior third of the middle frontal gyri at least, while the left excito-motor area was healthy. This will be found from the report given below to have been the case.

As might be expected, flexion of the right elbow had no effect on any other joint.

Summary of Clinical Report.

J. C., No. 853. Re-admitted into University College Hospital, April 7th, 1884; aged 7 years.

Personal History.—Health always good. Circumcised for incontinence of urine.

Family History.—Maternal aunt died of phthisis.

History of Present Illness.—Began at the end of 1882 from a fall, in which the left hip was said to have been "sprained." The disease then ran a steady sub-acute course.

Present State.—On re-admission patient's temperature was 104·6°; he was considerably emaciated, and there was a foul sore over the right posterior superior iliac spine, and a small sore over the middle of the upper part of the dorsal spine. Around the left hip were the sinuses of previous operations, there was frec discharge of pus from the same, and the joint was loose and grated. Sores were treated with boracic acid, &c., and commenced to heal. Temperature gradually fell to normal on the 18th.

April 19th.—Patient complained of severe headache, and was very constipated.

April 21st.—Last night patient became very irritable, continued uttering a shrill cry, so loud as to wake the patients in the opposite ward. Towards morning he became drowsy and insensible; took no notice. This morning says he has no headache, but is irritable and peevish.

April 22nd.—Patient vomited last night. Constipation still very marked.

April 24th.—Patient seemed considerably better. Took notice of what was going on in ward. Did not cry out so much.

April 26th.—Patient quieter and weaker, did not cry out as usual when dressed, nor answer to his name. The face and chest occasionally flushed bright scarlet.

[1] I am indebted to Mr. Barker for permission to publish the notes I made on the patient while under his care.

[2] The child was intelligent and his personal equation in health was probably quite up to the average.

April 28th.—All reflexes greatly exaggerated ; ankle and knee clonus well marked.

Ophthalmoscopic Examination.—The right optic disc is distinctly swollen and the edge blurred, the veins being engorged ; the same condition noted also on the left side. Eyes.—The eyeballs did not move in unison ; the left eye turned inwards with nystagmus, while the right remained fixed.

April 30th.—The facts noted above with respect to the movement of the arms were observed this day, and moreover it was found that all the reflexes, superficial and deep, were abolished.

May 1st.—Patient died gradually early this morning.

Note.—The temperature throughout the course of the meningitis was subnormal, but the last two days rose to 102·8°. It was slightly higher on the left side.

Autopsy.—Thirteen hours after death. Rigor mortis well marked, and equal in the limbs. Head : Calvarium—Thin and translucent in patches even close to the centres of ossification. Dura mater smooth, bluish and transparent. Longitudinal sinus filled with ordinary *post-mortem* blood clot. Arachnoid : Right hemisphere—Whole arachnoid absolutely dry. All the sulci on the outer and inner surface are obliterated, excepting the anterior two-thirds of the superior frontal sulcus, the anterior half of the middle and inferior ditto and the intraparietal. The right hemisphere appeared fuller and more swollen than the left. Left hemisphere—The whole of the arachnoid on the left side is almost dry, but with the exception of the Sylvian fissure the sulci are all wide open and filled with cerebro-spinal fluid, especially those of the frontal and upper parietal region. Pia mater : Right hemisphere—Opaque and thickened over the whole hemisphere. Scattered over the whole of the pia mater are numerous grey granulations, in the sulci especially, while in the fronto-parietal region there are large yellow patches of tubercle as enumerated below. Left hemisphere—In the meshes of the pia mater are scattered a few discrete granulations none more than 2 mm. in diameter and none situated in the excito-motor area. There was well marked opacity along the middle cerebral vein. All the veins were over-filled and the hyperæmia could not be removed by pressure. Cerebrum—In removing the brain, there escaped nearly three ounces of fluid (℥ xxii). It did not contain sugar. Arachnoid and pia mater—As far back as the sixth nerve the membranes are white, opaque and matted together, this condition being most marked around the right optic nerve where it is about a quarter of an inch thick as far forwards as the front of the optic foramen. Right hemisphere—The yellow nodules of tubercle, noted above, most thickly cover the following convolutions and sulci between them, viz., the posterior half of the superior frontal, the middle frontal and the upper half of the ascending frontal. In the middle frontal gyrus they form a rather whitish mass divided posteriorly by the præcentral sulcus. Part of the inferior frontal sulcus, just opposite the anterior limit of the fissure of Sylvius, is also filled with large masses of tubercle. The posterior two-fifths of the superior frontal gyrus is covered with an almost continuous mass of tubercle which dips over into the longitudinal fissure covering the upper half of the marginal convolution to an extent equal to that on the outer surface. There were found several patches scattered along the fissure of Rolando, the anterior extremity of the intra-parietal sulcus, and also in the fissure of Sylvius, but the rest of the disease in this hemisphere (the right) was confined to small indiscriminate grey granulations, which were most numerous around the quadrate lobule. The softening of the fornix had extended a short distance into the caudate and lenticular nuclei of the corpus striatum. Left hemisphere—Beyond the few grey granulations noted above, there was only a small focus of tubercle one-sixteenth of an inch in diameter situated on the upper surface of the optic-thalamus. Cerebellum—On the lower surface of the left lobe at the anterior margin, there was a small tubercular nodule about one-fourth of an inch in diameter adherent to the dura mater, and pressing inwards into the cerebellum. Medulla oblongata and pons varolii—In the centre of the pons, just behind and above the left pyramidal tract, was a small tubercular nodule one-fourth of an inch in diameter. Rest of medulla, &c., normal. Cranial nerves—The sheaths of the optic nerves were greatly distended with fluid, giving them a translucent appearance. Commissures—The fornix is greatly softened and also the corpus callorum, especially in the anterior two-thirds of the posterior half. Spinal cord—Beyond a little opacity of the membranes in the dorsal region, the cord appears healthy. Eyes—Both optic discs showed usual swollen appearance, especially the right. Trunk : Serous membranes—Normal, except the right pleura which was adherent all over. Circulatory system—Heart distended with *p. m.* clot, muscle substance pale and soft. Respiratory system—Trachea and bronchi contain a quantity of frothy muco-pus. Lungs—Both riddled with grey granulations. Digestive system—Liver normal size, infiltrated throughout with minute grey granulations, slightly congested. Spleen—Adhesions on outer surface pale on section. Pancreas normal. Whole intestinal tract appeared normal except the large intestine which was congested in patches, and here and there the surface was covered with gelatinous mucus. Mesenteric glands were enlarged. Urinary system : Kidneys—In the upper end of the left kidney, there is a tubercular patch extending to the whole depth of the kidney substance in breadth equal to half a pyramid. In the lower end there is a small patch in a pyramid. In the lower end of the right kidney, there was a similar patch. Bladder, &c., normal—Urine in the bladder was pale, and contained a trace of albumen but no sugar. Genital system—Normal. Left hip—The head of the femur was found lying just outside, and behind the anterior inferior iliac spine forming a projection on the bottom of a granulating sinus opening. Head of the bone totally carious.

SOME OBSERVATIONS ON ENDEMIC FEVERS IN INDIA.

By Surgeon J. PEDLOW, M.D.
Army Medical Department.

(*Concluded from page* 145.)

Turning next to remittent fever, the distinction between it and the enteric form was a very artificial one. Cases in which the temperature was high, and irregular at the outset, and in which there was insufficient evidence of intestinal complications, were considered to belong to this class. Many of them, however, developed such complications suddenly in the course of the disease, and a change to enteric was often necessary. In nineteen cases four of them had relapses similar as regards temperature and general symptoms, excluding visceral lesions, to the relapses in the enteric cases. In eight cases there was sharp bilious diarrhœa at the outset, which usually ceased in two or three days. Their period of prevalence broadly corresponded to that of the enteric cases, and on admission there was, as a rule, the severe headache, the flushed face, and the furred tongue common to all the fevers. Some of them had vomiting and rigors previous to admission, and in three cases constipation was followed by diar-

rhœa, which was characteristic of intestinal congestion, if not of ulceration. The following figures give the number of days of each individual case in hospital which recovered, 86, 36, 11, 47, 27, 45, 90, 36, 15, 72, 29, 66, 39, 60, 42, 38, 57, 41, 37, the last a re-admission. With the exception of two cases, the third and seventeenth, the normal temperature in each case respectively given above was reached on the 31st, 14th, 23rd, 15th, 18th, 20th, 16th, 6th, 33rd, 10th, 30th, 14th, 33rd, 12th, 31st, 21st, 20th day of illness. It will thus be seen that, as in enteric, the date of these periods was very irregular, as we would expect in remittent, but not to the same extent in enteric. In severe cases there was bronchitis and delirium at night.

The following is a record of the only fatal case. Private W. M., age 24, service in India one year and ten months, was admitted to hospital on the 4th November, 1882. He stated that two days previous to admission he was attacked with severe pain in the head, and dizziness, and severe pain in back, which lasted for two days, and then subsided. On admission his face was flushed, and his eyes suffused; his tongue was furred. He spoke nervously, and his hands were tremulous; bowels were constipated. The day after admission he passed two natural motions. He was then unable to pass water, which was drawn off. There was no tympanites or abdominal pain. On the ninth day his temperature fell to 99°, and he appeared somewhat better, but on the tenth day there was a sudden evening rise and delirium set in. His tongue the following morning was quite dry and brown, and rough to the touch. There was much irritability of the bladder, teeth were covered with sordes, and he could hardly speak; throat also was much congested. Bronchitis set in on the twelfth day, and the bowels, which were constipated, were opened by calomel. He was delirious throughout the day, and the muscles of face and arms had frequent spasms. On the fourteenth day of illness he passed three very fœtid motions in bed. He sank into a state of coma, and died early the following morning. The fever was high, but irregular, on the eighth and ninth days, the morning temperature was 99·4° and 99° respectively. At the time of death it was 105·6°. On *post-mortem* examination, the membranes of the brain were found much congested; the spleen also was much congested; weight, ten ounces. The last four inches of the ileum were inflamed and thickened slightly, but the mucous membrane over Peyer's patches was quite anæmic, and there was no evidence of any change in the patches themselves. The colon was congested throughout. In the ascending colon there were a number of patches of erosion, irregularly circular, in size about a sixpence. They looked as if small pieces of the membrane had been dissected off. The bowel itself was much inflamed, and some ounces of inflammatory exudation were lying in the rectum.

The following is a record of another very severe case. It was peculiar inasmuch as, although the fever ran very high during the first three days of illness, the tongue, as in two or three other cases, was quite clean and moist. Its condition was probably an index to the state of the bowels, and showed that at that period there was no intestinal congestion or other complication. Private N, age 22, service in India two years and seven months, was admitted to hospital on the 25th November, 1882. He complained of severe headache and sleeplessness, which he stated had existed for two days; bowels were constipated. On the evening of the fourth day of illness his tongue became slightly furred along the centre, but was moist and clean at the sides. Bowels were opened freely by calomel. Mild diarrhœa, with enteric-looking stools, commenced on the sixth day of illness, and lasted for five days, when the bowels again became constipated, tongue was then quite dry, and fissured and brown. Delirium was severe on night of fifth, and on the seventh day he was very nervous and tremulous, and spoke with difficulty. He was delirious throughout the eighth and ninth days. During the next few days there was little change; urine was tested on the eleventh day, and was found to be full of albumen. The tongue was most peculiar; it was quite parched and withered-looking, and one deep fissure ran diagonally across it, from which blood constantly oozed. Improvement began almost suddenly on the twelfth day of illness, delirium subsided, and the tongue became moister. Debility was very great, and he was not discharged from hospital until the sixty-sixth day. On his discharge there was the scar of the fissure on the tongue. The fever, which was high at first, subsided suddenly on the fifteenth day, after which date the morning temperature was practically normal, but the evening temperature continued high for another twelve days.

In both these cases there can be little doubt that visceral complications did not commence for some time after the patient's admission. In the first case the patient, on the day after admission, passed two natural motions, and in the second case the tongue was clean and moist for three days. In both cases the abdominal symptoms were very mild, compared with the intense cerebral disturbance. In the fatal case the intestinal lesions were small, and gave but little evidence of its severity. This I have frequently seen in severe cases in other parts of India, especially in soldiers over 26 years of age.

The following is a record of a very irregular case in which, after recovery and discharge from hospital, the patient had a relapse. Private Page, 27, service in India two years and six months, was admitted to hospital on the 10th August, 1883, complaining of headache and sickness which he stated had existed for two days. His face was flushed, and tongue furred. The bowels were regular but subsequently became constipated. Headache disappeared in a few days, and he improved somewhat. There was some abdominal pain and marked tenderness over the liver. Ultimately, he was discharged on the 20th September. He reported himself sick nine days after and stated that two days previously he had an attack of ague, and severe headache. On admission, his tongue was furred but moist, bowels were purged six times in the twenty-four hours, the motions were bilious. During the next five days his eyes became jaundiced, and the bowels obstinately constipated. A few râles were heard in both lungs, tongue became dry, brown and fissured, and debility was great. He was very restless at night, and during the day apathetic. His condition was similar to many of the other cases, but tenderness over the liver, and the jaundice denoted that there was hepatic congestion; also, on the thirteenth day of illness there was some improvement; debility, however, was extreme. He was discharged hospital on the thirty-seventh day, but re-admitted a few days afterwards for debility. In the first attack, the temperature became normal on the fourth day, but rose again the next day to 101·6°, and did not reach the normal again until the twelfth day. In the relapse the fever continued, with one intermission on the fourteenth day, till the eighteenth day.

In the following case, a partial improvement was followed by a relapse. The temperature and the case itself resembled some of the enteric fever cases which had relapses. The patient was admitted on the 30th June, 1882, with severe headache and pains in the limbs and general malaise. On the 2nd July his temperature rose in the evening to 103·2°, and his face became flushed and eyes suffused. Pain was complained of over the bowels, which were constipated. His tongue became furred. He remained in that

condition until the 6th July, when signs of improvement set in; the bowels acted naturally, and his tongue commenced to clean; headache also disappeared. On the 9th July, twelfth day of illness, temperature rose high in evening, and headache returned. He passed a sleepless night, and his tongue again became furred and brown. He complained of pain over liver. Headache continued for two days; on the 11th July he again commenced to improve and made a quick recovery. The temperature came down to normal on the eleventh day, but at once rose to 104°, and continued high, with marked morning remission, for the next six days.

The irregular course of these and many other cases of remittent fever, was due, I believe, to the fact that the determination of blood was more to the liver and spleen than the intestines. As mentioned before, the intestinal glands were probably atrophied, and there were consequently no structures in the bowel susceptible of severe ulcerations.

Turning next to the consideration of simple continued fever and febricula, the cases of both met with in this station were essentially of the same nature as the enteric and remittent fevers, though milder in character. In them, as a rule, the fever subsided without evidence of any serious intestinal complications of any duration. There was in many cases bilious diarrhœa at the outset and severe headache, high temperature and furred tongue. In others there was constipation throughout. *The original attacks, as stated before, in many of the cases of enteric and remittent, which subsequently relapsed, were considered to be of this nature.* The average period in hospital of twenty-one cases of febricula was thirteen days, and of nine cases of simple continued fever twenty-two days, but the usual period in each was from fifteen to twenty-five days. The following is a record of one of these cases of febricula.

Private B., age 22, service in India two months, was admitted to hospital on 19th April, 1883. On admission his tongue was moist, but covered with a soft, white fur; the eyes were suffused, and the skin over face and body was flushed and hot. Headache, he stated, was very severe. These symptoms had existed for two days before admission. There was some pain in bowels, but no tenderness on pressure. He was restless at night. He continued in this condition for five days, when the headache disappeared. The following day the tongue commenced to clean, and his condition improved, and he was discharged on the 5th of following month. On admission his bowels were slightly relaxed, but constipation followed.

Subjoined is the record of the temperature :—

Estimated day of Illness.	TEMPERATURE.	
	Morning.	Evening.
	°	°
3rd	102·2	103·4
4th	100·4	104·4
5th	101·6	102·2
6th	100·4	103·2
7th	100·6	103·2
8th	99·4	102
9th	99·4	99·4
10th	98·2	98·8

Imperceptibly cases such as these passed into the remittent or enteric type as the intestinal complications were obscure or marked. The following case was for the first week considered a case of febricula, but it subsequently assumed the characters of an irregular remittent fever. Private R., age 22, service in India three years and six months, was admitted to hospital on the 1st July, 1883, with headache and fever, which he stated was caused by exposure of the head to the sun, when playing some games without a helmet. There was some diarrhœa on admission, the stools being very yellow. He complained also of severe pain in the abdomen. The diarrhœa subsided in a few days, and he improved. On the 13th July, this diarrhœa returned, and there was some straining with a little mucus. Pain also in abdomen returned. He was restless and sleepless at night. There was little change for the next week, the purgation continued in a mild form. On the twenty-fourth day of disease the diarrhœa ceased, and though the temperature still ran high, he commenced to improve. The attack left great debility, and he was not discharged hospital until the 29th August.

The following is a record of the temperature from about the fifth or sixth day of illness.

Estimated day of Illness.	TEMPERATURE.	
	Morning.	Evening.
	°	°
6th	98·4	103·8
7th	99	104·2
8th	98	99·2

The temperature continued normal until the 14th day.

Estimated day of Illness.	TEMPERATURE.	
	Morning.	Evening.
	°	°
14th	98·4	102·8
15th	99·4	104·2
16th	98·4	104·2

31st	99	99·4
32nd	99	99·2
33rd	98·4	99·2
33rd	normal	

This case might be looked upon as a sort of link between intermittent fever and the more severe forms, and the temperature throughout shows the tendency to the irregular relapses which characterised some of the enteric cases.

So much has been written from time to time on treatment of Indian fevers, that little can be added by me to that subject. The systematic use of the bath at as early a period as possible gave the best results here. It was used in six very severe cases here during last autumn (1883), all of which recovered. In these cases there was continuous high temperature at the outset, which would have (according to our previous experience) ended in cerebral mischief, and early death. A special bath of large dimensions, made for the purpose, was used, and the patients were made quite comfortable in it with pillows and blankets. They were kept as quiet as possible, and the temperature was occasionally taken in the mouth. Many of the cases in which this was difficult to do before immersion, owing to delirium, quieted down in the bath, and it was taken without difficulty. The shock to the system was

minimised by having the water at a temperature between 85° and 90°, and the tendency to chill was avoided by pouring some warm water round the hands and feet occasionally. Considering the early period at which inflammatory symptoms appear, it is of vital importance to resort to the bath as soon as possible before there is disorganisation or inflammatory change, and it should be continued systematically as long as the temperature rises high, especially in the mornings. We used it in some cases when the disease had made considerable progress, and its good effects were then doubtful. When the disease is declining, it will usually be found that the evening temperature, though probably high, falls rapidly in the bath. I have rarely seen a marked fall of temperature in the bath at the outset of a case under three-quarters of an hour in a full-grown man. The headache at the outset, usually very severe, was much relieved, as a rule, by drop doses of aconite given in the manner Ringer recommends. After prolonged immersion in the bath, a few doses of it and liquor ammoniæ acetatis usually keeps the skin acting, and prevents a rise of temperature for some time. It should be borne in mind that in many cases a very high temperature is reached early in the afternoon. In such cases the bath must be again resorted to. The necessity for frequent observation is thus shown. We cannot rely on morning and evening temperatures alone as to its necessity.

Summing up the various points in connection with all these fevers, we find—

(1) That their periods of prevalence were nearly and practically the same, and that they all commonly attacked new arrivals from 20 to 25 years of age, although more than half the strength of the regiment was above that age.

(2) That cases above that age were, as a rule, mild, and the visceral complications undefined and trivial.

(3) That relapses were common to both the so-called enteric and remittent cases, and that intestinal complications, though absent in the original attack, as far as could be judged, were often marked in the relapse.

(4) That the temperature was rarely typical, and frequently high at the outset of the attack, and—

(5) That the course of both mild and severe cases was often very irregular, and the average duration of fatal cases much less than in the home type, owing to the early development of cerebral mischief.

ON OPERATION FOR CATARACT.[1]

By J. R. WOLFE. M.D., F.R.C.S.E.

Mr. President and Gentlemen,—I have been asked to open a discussion on the following subject, namely, "Does the Position of the Section in Cataract Operations influence Suppuration of the Cornea; if so, what part is played in Septic Infection?" I have the more readily consented to do so, because my views, which I shall thus have an opportunity of stating, differ in many respects from those generally adopted, and because it will be a satisfaction to me to ascertain how far my experience coincides with that of other members of the Section.

In the first place, then, there is the question, how far the position of the corneal section in cataract operations contributes towards suppuration of the flap? This is a subject which I have carefully studied for upwards of twenty years, watching the results of not only my own operations for cataract, but also those of surgeons of repute in this and other countries. During this period, the number of my operations in which corneal section has been made, is, as far as I have been able to collect: idiopathic cataract 545, traumatic 430, total 975. As in all these I had only six cases of primary suppuration of the cornea, I infer that the position of the corneal section cannot be regarded as an important factor in the suppurating process.

At the very commencement of my career I was impressed with the conviction, which I recorded in the *Lancet*, that in the cornea we have a membrane almost resembling cartilage in respect to its slight tendency to proliferation. The case there referred to was that of an old lady upwards of 80 years of age, upon whom I successfully operated for cataract by Daviel's method, although during the treatment her foot began to show symptoms of gangrene, to which she ultimately succumbed. The conviction just mentioned has since then been confirmed in the course of my labours in connection with transplantation of the cornea, in which corneal and conjunctival bands are removed from the eye of one person to that of another. We see this also in our daily experience in removing iron splinters from deep layers of the cornea; we notice how, if the splinters are clean and free from rust, the cornea heals without cicatrization. When, for opening the lens-capsule or for evacuating the aqueous humour, you pierce the cornea with a needle or with a lance, no trace of the entrance of the instrument remains visible after the lapse of a few minutes. Indeed, we shall best be able to repair lesions, whether produced by traumatism or by pathological processes, if we carefully watch how nature effects her remedies. I have recently had two cases which illustrate that point. The first is that of a young man, aged 19, admitted to the Glasgow Ophthalmic Institution. His eye had been lacerated by a piece of iron through the greater part of the cornea nearly at the centre. The eye recovered with an adhesion of the iris and leucoma, involving more than the lower half of the cornea, but is otherwise reparable. Another young man, employed in a ship-building yard in Barrow, was brought, in June 1884, to the institution. A piece of iron had struck the centre of the cornea and penetrated partly into the lens. The foreign body had been extracted immediately on the occurrence of the accident, but suppuration had set in, and the eye had to be removed. These cases illustrate a general principle, that the cornea may undergo a great deal of injury and yet easily recover; and that injury to the cornea, when complicated with that of other structures, proves disastrous. These facts all seem to point to the conclusion that we must seek the cause of suppuration in cataract extraction elsewhere than in the cornea itself, namely, in the deeper structures. Suppuration takes place when, during the removal of the lens, violence has been done to the iris and ciliary body. So also, when lens fragments have been left behind in the interior of the eye, these, acting like foreign bodies, give rise to inflammation, which begins in the iris, ciliary circle and vitreous, proceeds to suppuration, and then the cornea participates in the suppurating process.

I remember when we used to operate by Daviel's method, and were accustomed to boast of the charming results produced by it. In the years 1859 and 1860 I attended the clinique of M. Desmarres, a man of great originality and dexterity, who revolutionized ophthalmic science, and to whom we are indebted for many modern improvements. In his clinique of that period we had, as nearly as I can recollect, 200 extractions of cataract, and I cannot remember a single case of suppuration of the cornea. It is only since the spooning out of the lens, and the squeezing with instruments have been adopted, that we have begun to hear of suppuration of the cornea. Von Graefe was a man of genius, an illustrious pupil of M. Desmarres, whose

[1] Remarks addressed to the Ophthalmological Section of the Meeting of the British Medical Association at Belfast.

teaching he utilized, enriching ophthalmology by his own inherent ingenuity also; but his operation for cataract, I regret to say, has not been an advance. When he first published his operation, it was somewhat rudely criticised by Prof. Hasner, of Prague. I then disapproved of the attack, but in looking back now to subsequent history, I am sure that if Von Graefe had been spared a few years longer, he would have withdrawn from currency the operation which bears his name. Everybody has been practising Graefe's operation for cataract. A linear incision is made at the extreme corneal periphery, and the lens is violently squeezed out with a gutta-percha spoon. What can you expect but that, in many cases, the nucleus passes through, leaving behind large cortical masses which set up mischief by the third, fourth, or sixth day? Not to mention loss of vitreous, sympathetic inflammation, and other mishaps to which the operation is liable. And then we make the cornea the scapegoat. Of course I do not refer to the great artists of our profession; men of experience and resource may practise Graefe's or any other method, because they can change their plan during the operation and overcome inconveniences; but I refer to the junior members of our calling, who imagine that they do the right thing in practising Graefe's operation and come to grief.

As a rule, it is better to terminate the corneal section at the conjunctival limbus, for then the lens can slide out without a hitch; but when the vitreous is soft, the incision should terminate in the cornea. The corneal bridge is then more conveniently divided with a pair of scissors, without any dragging upon the wound. It will not be out of place here to mention another point connected with cataract extraction. I refer, namely, to the preparatory iridectomy a fortnight or so before the extraction of the lens. This was first suggested by Mooren as an adjuvant to Daviel's flap extraction. I have shown, however, that with preliminary iridectomy we can limit the corneal incision to a curve extending little more than the third part of the corneal circumference, thus avoiding many of the risks to which Daviel's method is exposed, and so making it applicable to cases even in which the flap-operation is contra-indicated. My views have been before the profession for the last sixteen years, have also recently been brought forward at the meeting of the Association at Cork, and published in my work on "Diseases and Injuries of the Eye," 1882. I cannot help expressing here my great satisfaction at finding that some men of standing in our profession have now adopted this method. The late Mr. Critchett, whose death is a great loss to our circle of earnest workers, told me that in difficult cases in which he was very anxious to ensure success, he resorted to my method; and I know that he carried it out successfully in cases in which one eye had already been lost under a different operative plan. And so, after the lapse of sixteen years, the profession has come round to my views.

Now, Mr. President, after dealing at such great length with what I consider to be the real cause of corneal suppuration, you will be prepared to hear my views on septic agencies. Septicism, when applied to diseases of the eye, I consider altogether out of place, and regard it simply as another scapegoat for defective methods. When the lids are closed, the eye is placed within a shut cavity which is inaccessible to septic agents. Any irritating appliance during an operation on the eye can only do harm; and when I see ophthalmic surgeons taking their instruments for operation out of carbolic solution, I look upon it as an artistic mistake. In short, I think it would be more in conformity with scientific principles, if, instead of going in search of causes of suppuration, we tried to eliminate the elements of failure which are staring us in the face.

In confirmation of the safety of my operative procedure, and its applicability to the most critical cases of local and constitutional complications, I will show you a patient far advanced and emaciated from diabetes, on whom I operated for cataract a fortnight ago. You will see that I have terminated the section in the cornea, owing to the extreme softening of all the ocular tissues, and you will satisfy yourselves of the safety of my method.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

LONDON HOSPITAL.

PREGNANCY WITH EXTREME RICKETY DEFORMITY OF PELVIS, AND ALBUMINURIA — PORRO'S OPERATION — DEATH ON TENTH DAY.

(Under the care of Dr. HERMAN.)

(Reported by Mr. J. JAMES, Clinical Clerk, and Dr. A. J. RICHARDSON, Resident Accoucheur).

L. M., aged 29, admitted into the London Hospital, 2 p.m., February 14, 1884. Before admission she was attended by Dr. J. W. Fordham, who furnished the following particulars. Dr. Fordham was first sent for about 48 hours before the patient's admission into hospital. Dr. Hanna attended for him, and found the os uteri the size of a shilling, and the pains coming on regularly every ten minutes. She was seen again about twelve hours later, and the os found about the same size, the pains less frequent and not so strong. About eight hours after this, Dr. Fordham saw the patient, and found the os uteri high up, about the size of a five-shilling piece, soft and dilatable. He ruptured the membranes, and found that the fœtal head was about an inch above the external os, being prevented from descending by the projecting sacral promontory. Dr. Herman was then sent for, and after his visit the patient was with as little delay as possible admitted into the London Hospital.

State on Admission.—Patient flushed and excited, breathing hurried. Heart sounds normal. Abundant coarse *râles* all over chest: expectoration muco-purulent. (Patient said she had had a cough for four months before admission.) Urine acid, sp. gr. 1015, containing one-third albumen. Arteries hard and cord-like. Uterus reaching to ensiform cartilage, contracting regularly. Head presenting, position transverse, occiput to right, sinciput to left. Fœtal heart 148 per minute. Conjugate diameter, estimated by internal measurement with the fingers placed side by side, $1\frac{1}{4}$ inches. Diagonal conjugate, $1\frac{3}{4}$ inches. Distance between anterior superior iliac spines, 9 inches; that between iliac crests not greater. The patient was a dwarf, with rickety curvatures of legs.

At 6 p.m. Porro's operation was performed by Dr. Herman, Mr. Rivington and Mr. McCarthy being present. The abdominal incision was made in the middle line, beginning about 2 inches below the umbilicus, and was about 4 inches in length. The uterus was opened by a small transverse incision a little above the presumed situation of the internal os; and this wound was extended upwards by tearing. In this manner a sufficient opening was easily and quickly made, with but little hæmorrhage. An attempt was made to extract the child by the head, but as this could not be quickly done, a foot was seized and the child

thus delivered.[1] The uterus was then expressed from the abdomen, and the intestines at the same time kept back, by pressure on the lateral parietes. Lawson Tait's clamp was applied to the cervix, and screwed tight. While this was being done, the uterus partly expelled the placenta through the wound, which did not involve the placental site. The uterus was then cut away above the clamp. After the clamp had been tightened there was some free hæmorrhage coming from a vein apparently situated in the left broad ligament. This was stopped by ligature of the bleeding point. The peritonæum was then cleansed. A guarded pin was put through the stump above the clamp, and a strong whipcord ligature put round it below the pin. The abdominal incision was closed with four silk sutures, and dressed after the Listerian method. A 1 in 40 carbolic spray was used during the operation, which lasted in all 40 minutes.

About four hours after the operation it was found that hæmorrhage from the stump had soaked through the dressings. It was checked by tightening the clamp, and the wound was redressed.

February 15th.—Patient had at night $\frac{1}{4}$ gr. of morphia hypodermically, and has had a good night; not much pain. No vomiting. Pulse 120; Respirations 36; temperature normal. In the evening she vomited her food; the urine passed at 11 p.m. was very dark in colour, and there was considerable tympanites. Feeding by the mouth was discontinued, nutrient enemata being substituted.

February 16th.—Each quantity of urine passed has been successively darker in colour. Cough troublesome. Tympanites less. Occasional vomiting which causes pain, relieved by morphia and atropine. The clamp was again tightened. The wound was dressed in the morning, thymol being substituted for carbolic acid. In the evening it was again dressed, the stump being powdered with iodoform, and covered with dry salicylic wool. The temperature had then risen to 100·4°.

February 17th.—Patient had a very restless night. Severe pain in right side and groin. Breathing difficult, loud loose bubbling *râles* all over chest. At about 2 p.m. patient seemed very prostrate, and was for two or three hours only half conscious. An enema of brandy roused her and made her cough, after which she improved. In the morning the discharges were found offensive. Therefore in the evening an attempt was made to again make the wound aseptic by washing the stump with a solution of chloride of zinc, gr. xxx ad. $\overline{3}$j.; and it was again dressed with carbolic acid. Temperature rose in the afternoon to 101·4°.

February 18th.—A fair night. Discharges less offensive; pain better. A catheter passed up the rectum allowed some flatus to escape, and somewhat relieved patient. Temperature reached 101° in the afternoon. Urine for the first time free from albumen.

February 19th.—Temperature in afternoon reached 101·6°. Trace of albumen in urine. Progress otherwise apparently favourable.

February 20th.—Temperature in forenoon 101·8°. Still some pain, which is relieved by belladonna suppositories. In the afternoon the two upper stitches, upon which there appeared to be little strain, were removed. In the evening patient had a violent attack of coughing, and felt something give way, and a gush of fluid take place. The dressing was removed and it was found that the edges of the wound had separated.

February 21st.—Delirious last night. Temperature in forenoon 101°. Seems brighter and breathing better. Wound dressed, edges being brought together with strapping and silver sutures, and well irrigated with water, especially around the stump.

February 22nd.—Takes nourishment well. Delirious; pulse 160. Temperature in afternoon rose to 103·5°.

[1] The child survived and thrived.

February 23rd.—Died 7 p.m.

The *autopsy* was made on the following day by Dr. F. Charlewood Turner. The abdominal wound was gaping. The transverse colon was much distended, and immediately underneath the wound, presenting, as it were, at it. There was some purulent fluid in the pelvis, behind the pedicle, but no general peritonitis, the peritonæal cavity being shut off by adhesions between the intestines and parietal peritonæum, from the wound and the neighbourhood of the pedicle. Vagina and cervix uteri much congested. The pedicle was almost completely separated. Some cystic dilatation of veins at orifice of vagina. Lungs emphysematous and œdematous. Heart firmly contracted. Kidney surface smooth, pale, and opaque, with venous congestion, and presenting, in Dr. Turner's opinion, the appearances of tubular nephritis. Spleen and liver normal. Extreme rickety bending of humeri, femora, tibiæ and fibulæ. Pelvis, true conjugate, measured between the bones, soft parts not being included, $1\frac{1}{2}$ inches. Transverse diameter at brim $4\frac{1}{4}$ inches. Right oblique diameter $3\frac{15}{16}$ inches. Left oblique $3\frac{14}{16}$ inches.

Remarks by Dr. Herman.—Porro's modification of the Cæsarean section, by the removal of the great source of danger which is quite beyond the control of the surgeon, viz., the subsequent relaxation of the uterus, leading first to hæmorrhage, and later on to the escape of lochia into the peritonæum, offers such great advantage over the old Cæsarean section, that the last-named operation will probably become recognised as one which ought only to be performed when the cervix uteri is so diseased that a stump cannot be formed from it. The only points in the operation which call for remark are, first, the mode of opening the uterus, which was by making a small incision and extending it by tearing: a method suggested by Tarnier, adopted by Porro, and also by Godson, in his recently published case. By this method the amount of blood lost during the performance of the operation is lessened. Second, the occurrence of hæmorrhage from a vein in the broad ligament. The cause of this was not clear; but it deserves mention, as a complication which may occur in other cases. Death appeared to result in this case from the combined effects of three causes:—(1) bronchitis and œdema of lungs; dependent on (2) kidney disease; and (3) local peritonitis. The facts that the peritonitis was quite local, and that the patient survived nine days, form grounds for thinking that had the lungs and kidneys been healthy the patient would probably have recovered. The peritonitis seemed to have arisen in the manner in which Mr. Lawson Tait has pointed out that it usually is set up in cases in which a pedicle is secured outside the abdomen by a clamp, viz., by the trickling of secretions into the abdomen through a little opening left between the pedicle and the margins of the wound which embrace it; and when the pedicle is composed of muscular tissue which shrinks, it seems very difficult to devise any way of closing the abdominal wound around the pedicle so accurately as to make certain of preventing this.

The "John Reid" Prize.—The prize founded by the sister of the late John Reid, surgeon, Glasgow, in memory of her brother, is awarded for the best original research bearing on any of the departments of medical science, conducted in one of the hospitals or laboratories of Glasgow. The prize, which is of the annual value of 25*l.*, was, at a meeting of the trustees held on the 5th instant, awarded to Mr. H. Lyon Smith for two years, who, in the Pathological Laboratory of the Royal Infirmary, conducted an investigation as to the changes found in the circulation through the kidney in certain pathological conditions. Mr. Leonard Williams was awarded 10*l.* by the trustees in recognition for his paper on "The bacillus of tubercle." This investigation was conducted in the Western Infirmary.

VIENNA GENERAL HOSPITAL.

REMARKS ON A CASE OF THE SO-CALLED "SKRLJEVO" DISEASE.

By Prof. NEUMANN.

The patient, a native of Dalmatia, aged 24, states that four years ago he had intercourse with a woman who suffered from skrljevo, and that since that time he had suffered from a disease which began with an ulceration on the penis, and was followed at an interval of some weeks by ulcers and nodules on the skin, which appeared and disappeared. He also calls his disease skrljevo. The patient now presents the following symptoms:—On the upper and lower extremities are to be seen round and oval cicatrices varying in size, denuded of their pigment in the centre, but containing some pigment at their periphery. These cicatrices are especially marked on the extensor muscles of the extremities, in several places they run into each other and present a bilobate or trilobate outline. The forehead, the ridge of the nose, the zygomatic processes, and the upper-jaw are covered with white cicatrices of the size of a lentil, the space between these cicatrices presenting several nodules. Similar cicatrices and nodules are also present on those parts of the head which are denuded of hair; the two alæ nasi are converted into thin cicatrices, and stand at a higher level than usual, so that the septum is quite uncovered. Taking all these symptoms into consideration it is evident that this affection is syphilitic disease in the tertiary stage, in fact tertiary syphilis. The process must be considered an acute and malignant one, such severe symptoms having developed in such a proportionally short time.

The reason why the disease has taken on this acute course is to be sought in the bad conditions under which the patient has been living. He has been in want of proper nourishment, and moreover, he has not been submitted to specific treatment during the four years that he has been diseased; but has always tried to heal his sores by means of domestic remedies, by drinking different sorts of tisanes and so on. In this way it is to be explained how a disease of such a malignant type has developed in so short a time. If a disease of this kind is not treated in the proper manner, if, moreover, it is complicated with other diseases, there take place aberrations in the course of the syphilitic process, giving rise to symptoms which deviate very often from those we are accustomed to see, and which we recognise as syphilis only with difficulty and after long and careful examination. Other chronic diseases such as lupus, psoriasis, elephantiasis Arabum, and the ulcerative processes, are also due, in a certain degree, to differences produced by irrational treatment, and by the bad conditions under which the patient is living. The layman as well as the inexperienced physician are inclined to refer such cases to a local cause quite unknown, and as the latter does not recognise the disease, and as the cases are frequently limited to a small district of the country in which he lives, he calls them endemic. Hence names have been invented for different endemic forms of disease, as skrljevo in the Fiume littoral, radesyge in Norway, fibbens in Scotland, morbus dittmarsicus in the marshy regions of Germany, falcadine in Italy, pian and yaws in Africa, all of which are believed to be endemic diseases with an independent existence. But if we examine the diseases which are called by such different names, we find that they represent a series of chronic diseases, which are to be found also with us, and among which syphilis, lupus, scabies, psoriasis, and chronic skin-ulcerations are the most common and play the chief part. These diseases develop themselves in different ways under different local conditions, and so present symptoms which deviate from those we are usually accustomed to meet. For instance, an exact and precise enquiry into the character of the disease which is called "skrljevo," shows it to be simply the same affection which we call syphilis. The disease in such a case first runs its regular course; then, owing to unhealthy conditions, as the living of many families in a patriarchal manner, uncleanliness, want of education and so on, the affection develops itself rapidly. Such symptoms as papulæ on the sexual organs and the mouth, ulcerations and bone-diseases are not prevented from developing; they appear in a severe degree and persist for a long time, so that the different stages run into each other, and in this way produce morbid changes of a quite different type from those ordinarily met with.

Further, we often have the opportunity of convincing ourselves of the fact that other non-syphilitic diseases, as especially lupus, scabies, psoriasis, benign and malignant growths, are comprised in the name of skrljevo. In such cases the physician must first make the diagnosis of the disease, must separate the syphilitic forms from the non-syphilitic, and as to the first an anti-luetical treatment has to be observed. The syphilitic cases of skrljevo are characterised by the fact that an anti-syphilitic treatment, especially a mercurial one, is followed by rapid cure.

Medical Times and Gazette.

SATURDAY, AUGUST 16, 1884.

The Eighth International Medical Congress was opened with much ceremony by the King and Queen of Denmark, at Copenhagen, on Sunday last. Notwithstanding the dismal forebodings uttered in many quarters that the cholera would ruin it, it is a splendid success, and the false prophets must hide their diminished heads. Fine weather and a warm welcome are rendering the visit to Copenhagen thoroughly enjoyable to all the members of the Congress. If any complaint were possible under such circumstances, the heat alone would receive a small modicum of abuse, but the occurrence of an almost tropical thunderstorm has cleared the air and freshened the aspect of the city. The extreme cleanliness of the streets, and the rough but regular granite pavement are a marked feature of Copenhagen by day, and render the passage of traffic by night a source of decided annoyance to the Congressionists who vainly endeavour to sleep through the continuous roar which begins soon after 5 o'clock. The sections which sit from ten till twelve, and again from one till three, are being most zealously attended, and in the interval the Committee of the Congress have organised a public luncheon on the "Help yourself" principle, which has proved itself a most popular innovation. About 1,700 names have already been inscribed, a number far exceeding the estimate. The surgical section is the most numerously attended, but medicine and pathology are also attracting large audiences. On Wednesday an excursion was made on a gigantic scale to Cronborg Castle, where luncheon was provided, the excursionists afterwards visiting Hamlet's Tomb and Frederiksburg Castle. A friendly rivalry

exists between America and Germany as to whether the next Congress shall take place in Washington or Berlin. The point will be decided on Saturday.

The number of deaths from cholera at Marseilles and Toulon shows that the epidemic is certainly diminishing in severity in those towns, but the suburbs of the former are reported to be suffering considerably in proportion to their numbers. At Arles the death-rate from cholera is still very high, and forty deaths have been reported in two days at Les Omergues, a little village in the Department of the Basses-Alpes. At Toulon, a Reuter's telegram informs us, there have been 8,000 cases in all with 800 deaths, and the number of sick persons is still considerable though the death-rate is much lower. As we surmised last week, a considerable number of the most recent cases have been amongst the returning refugees. Up to the present, 32 towns or villages in France have suffered, and no authenticated case has occurred in Paris. Cases continue to occur in the province of Turin, but the epidemic does not seem to be gaining ground there. The rumour that there had been a case of cholera in Switzerland has been officially contradicted.

The cholera has not yet reached us, though infected ships continue to cause some temporary anxiety by their arrival at one or other of our ports. Our Port Officers of Health are, however, all on the look-out, and a case of cholera will not be easily smuggled past them just at present. The latest verdict on the subject on the part of the Local Government Board is a prohibition against the landing of rags from France until September 15th. It will be remembered that a similar step with regard to rags coming from the East was taken during the outbreak in Egypt, and the propriety of it was fully recognised at the time. At the meeting of the Association of Public Sanitary Inspectors, on Monday evening, Mr. Chadwick, the President, read a paper on "Preparations for meeting the cholera," and pointed out how entirely the experience gained in this country during the epidemic of 1848-49 in reference to the mode of propagation of cholera had been verified by the outbreak at Toulon. If the cholera did not come the labours of all the sanitary inspectors during the last few weeks would not by any means be thrown away, a vast amount of good, in the shape of the prevention of the other foul air diseases would have been wrought. The practice of quarantine he denounced as useless and mischievous, effectual cleansing of persons and places being the only reliable preventive measures.

Miss Florence Nightingale has been interviewed, so to speak, by correspondence, on the subject of cholera prevention, by an American paper. Her reply is vigorous and to the point. She considers it as proved that cholera is not communicable from one person to another, but that it is a local disease, an epidemic affecting localities, and there depending on pollution of earth, air, water and buildings. Isolation of the sick, quarantine and cordons are powerless to check the disease, and may indeed be positively harmful by directing attention away from measures that might be useful. To trust for protection to stopping intercourse she believes would be just as rational as to try to sweep back an incoming flood, instead of getting out of its way. The lesson to be learnt and the motto for every one to adopt is—"Set your house in order."

Our Vienna correspondent has favoured us with some valuable remarks by Professor Neumann on a case of that unpronounceable disease Skrljevo, which we publish in our Hospital Report column. In connection with this case our correspondent writes :—In the spring of this year this curious disease formed the subject of a discussion in the Austrian Parliament. The Government proposed that thirty thousand florins (2,500*l.*) should be granted for the suppression of the disease, which was extremely prevalent in the maritime districts of Croatia and Dalmatia, and which, according to the opinion of the chief sanitary authority, and of the Professors Hebra and Sigmund, was nothing else than syphilis. Persons suffering from this disease, or suspected of suffering from it, were to be compelled to undergo regular treatment. Dr. Roser opposed the motion, and proposed that a committee of specialists should be appointed to again enquire into the character of "skrljevo," and that the necessary measures should be taken after they had reported. Professor Schneider, the adviser of the ministers, took the side of the Government, and referred to the opinions already pronounced by the authorities mentioned above, upon which the motion of Dr. Roser was thrown out, and the proposal of the Government accepted.

Dr. Julius Ritter v. Massari, Privat-Docent for Gynæcology and Obstetrics, and son-in-law to Professor Braun v. Fernwald, died on the 12th July, at Dornbach, near Vienna, at the age of 39 years. He had for several years been the assistant of Professor Spaeth, in the clinic of gynæcology, and was known as a skilful operator and a good teacher.

The Medical Faculty of Innsbruck have proposed Dr. Gustavus Gärtner, assistant to Dr. Stricker (Professor of General and Experimental Pathology at Vienna), for the Extraordinary Professorship of those subjects at Innsbruck. The vacancy was caused by the retirement of Dr. Dietl, who was obliged to resign his chair owing to his state of health. Dr. Gustavus Gärtner was proposed *unico loco*, Dr. M. Löwit, assistant to Professor Knoll, in Prague, obtaining only "honorable mention."

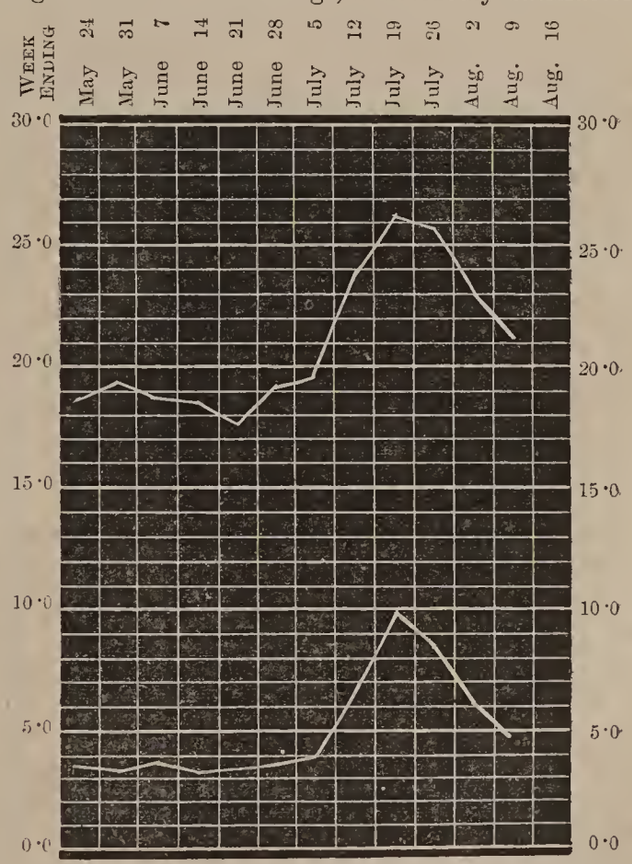
At a recent meeting of the Professoren Collegium of the Vienna Medical Faculty on the 19th July, it was resolved to recommend to the Government the Privat-Docents Wölfler, Englisch, Hofmokl, Mauthner, and Ultmann, for extraordinary professorships, as they have already been admitted by the committee appointed to consider their claims. At the same meeting two new proposals were made : Professor Bamberger proposed Primarius Dr. Oser, and Professor Nothnagel recommended Primarius Dr. Charles Bettelheim, for extraordinary professorships. It was resolved at the

same meeting not to proceed to the election of an ordinary professor in the second clinic of Ophthalmology, which has become vacant by the death of Professor Jäger, till the winter semester ; in the meanwhile Dr. v. Reuss has been entrusted with the office to deliver lectures in that clinic for the next semester. The general opinion is, that the ordinary professorship will be conferred on Professor Mauthner, as he had already been proposed *secundo loco* after the retirement of Professor Arlt. The Minister of Education has confirmed the election of Dr. Maximilian Herz as Privat-Docent in Children's Diseases, and that of Dr. Edward Zillner as Privat-Docent in Forensic Medicine in the Medical Faculty of Vienna.

The fifty-seventh annual meeting of German Naturalists and Physicians will take place at Magdeburg, from the 18th to the 23rd of September next.

The death of Sir Erasmus Wilson on Friday last has deprived the medical profession of this country of one of its most prominent men. It is more than half a century ago since Sir Erasmus, after studying at Aberdeen and St. Bartholomew's Hospital, commenced his professional career. Though he afterwards confined his attention entirely to a special subject, he began life as a surgeon, and early showed a marked leaning towards conservative surgery. His appointment to the Middlesex Hospital, as Lecturer on Anatomy, gave him the opportunity of showing what a thorough anatomist he was, a fact evidenced by his "Anatomist's *Vade Mecum*," which passed through many editions, and the beautiful plates which he brought out conjointly with Dr. Jones Quain. It was at the Middlesex Hospital, too, that he first showed that interest in and grasp of skin diseases, the subject to which a few years later he gave his whole attention. His *magnum opus* on Diseases of the Skin was one result of this exclusive study, and although it is not perhaps up to date in regard to the latest histological discoveries, it is a book which the general practitioner will always be very glad to make room for on his shelves. It would take a long time to enumerate all the writings of Sir Erasmus Wilson, for his pen was for many years a very busy one; several of them will be found scattered through our periodicals of a quarter of a century ago. We have said that one result of his devoting himself to skin diseases especially, was the production of a book on the subject; another result was the acquisition of considerable wealth, which he turned to better account than most successful practitioners are in the habit of doing. In 1869 he offered the sum of 10,000*l.* to the College of Surgeons to found a Chair of Dermatology, and for several years he held the professorship himself. On his resignation of it, not many years since, it was felt that the interests of science would be better served by a Chair in Pathology, and accordingly the Chair of Dermatology was given up and the present Professorship of Pathology established in its place. More recently he showed that he had not forgotten his old *alma mater*, and founded the Chair of Pathology in the University of Aberdeen, which, in the hands of its present occupant, has already borne good fruit. For the Infirmary at Margate he always had an affection, and not long ago he greatly increased the usefulness of that excellent institution by building a new wing, and on the occasion of the International Medical Congress meeting in London, in 1881, he took the members of the Skin Section, of which he was the President, down to Margate to inspect it. The Medical College at Epsom, too, has good cause to remember his generosity. In 1881 he became President of the College of Surgeons, and at the end of his year of office, being in somewhat weak health, he gave up practice, and left London altogether. A short time since the College of Surgeons voted him an honorary gold medal, in recognition of his services to the college and of his valuable presents to the museum; and as we announced in our last issue, the medal was presented just three days before his death.

The fall in the death-rate of London has continued, the rate for the past week being 21·1 per 1,000, exactly 5 per 1,000 less than it was four weeks ago. The actual number of deaths was however 29 above the average for the past ten years. The deaths from zymotic diseases numbered 379 as against 484 during the preceding week. Diarrhœa accounted for but 219, being ten below the average, a decidedly satisfactory



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London in each of the past twelve weeks.

state of affairs when we bear in mind the intense heat experienced at the latter part of the week. The deaths from small-pox rose from 11 to 16, and the number of admissions into the small-pox hospitals from 66 to 110, so that it is to be feared that we are not quite so near the end of the epidemic as last week's statistics might have led us to hope. Bolton heads the list of the chief towns with a general death-rate of 30·2 per 1,000,

whilst Salford occupies the unenviable position of having scored the highest death-rate, 10·1 per 1,000, during the week, from diarrhœa.

The International Congress of Hygiene which is to be held at the Hague, under the presidency of M. Heemskerk, the Dutch Minister for the Interior, will tread close upon the heels of the Copenhagen meeting, many of the visitors to which will, no doubt, take it on their way back from Scandinavia. It opens on Thursday, August 21st, and closes on the following Wednesday. Specially favourable terms are offered by the railways leading to the Hague to members of the Congress, a reduction of fifty per cent. on the fare being allowed by the State railways of Holland and Belgium, and by the "Nord" of France. To obtain this reduction it is necessary to produce a "carte d'inscription," which may be obtained from the general Secretary, Professor Van Overbeck de Meijer, of Utrecht, for the sum of ten florins, equal to something under seventeen shillings. The arrangements of the Congress do not differ from those which obtain at other congresses. There will be general meetings, at which papers and communications of general interest or superior merit will be read, while the hard work of the Congress will be distributed over five sections, viz., (1) General and International Hygiene; (2) Urban and Rural Hygiene; (3) Personal Hygiene; (4) Professional Hygiene; and (5) Demography. In the first section, Dr. Koch will hold forth on a subject not yet announced, and the report of the able committee chosen at last year's Inter-Colonial Medical Congress, to consider the proposed foundation of an international league for the collective investigation of epidemics, will be presented and discussed. In the second section two somewhat cognate subjects—*déboisement*, or the destruction of forests, and cremation—will come on for discussion. In the third section Professor Brouardel will introduce the subject of adulteration, and M. E. Vallin, of Paris, will speak of the danger of feeding on the flesh and milk of tuberculous animals. Other interesting subjects will be discussed, including educational over-pressure. In the fourth section the prevention of industrial diseases, and the influence of burial societies will be discussed; while in the fifth section several important statistical subjects will engage attention. We are sorry to see that our country is so meagrely represented amongst the contributors to the Congress. Possibly the favourable terms offered by the railway companies may induce some to go, at any rate in the guise of listeners. They could not find a better place to spend a holiday than in the shady streets of the Hague and on the sand dunes of Scheveningen.

The transactions of the Inter-Colonial Congress held at Amsterdam last autumn have just reached us. The most important debate was that on Quarantine, introduced by a paper by Professor de Chaumont, followed by papers from Dr. F. J. Van Leent and Mons. M. Kruyt. The discussion was continued by several members, including Prof. T. R. Lewis and Dr. Joseph Ewart, both of whose speeches appear in full in English, a compliment thoroughly well earned. Our representatives on this occasion have deserved well of their country, for besides the above, papers were read, or communications made, by Sir Joseph Fayrer, Dr. Norman Chevers, Dr. Dyce Duckworth, and Dr. Waring.

It will be remembered that some two months ago public attention was called to the subject of over-pressure by a death certificate in which the medical man had appended the remark, "This is the second death in my practice within a week, the cause of which was produced from pressure at a Board school." There was a good deal of correspondence about it at the time, and the London School Board referred the matter to a committee of two of their number for investigation, laying before them also a letter addressed by Dr. Borham, the practitioner in question, to the Education Department. It will surprise no one to learn that that committee have reported in effect that the case is not proven. To establish the true relation of cause and effect in these cases is one of the most difficult medical problems of the day, and in our opinion could only be attempted, with any prospect of success, by medical men accustomed to examine and deal with large numbers of children during the school days of early childhood. Absolute proof in any given case that cerebral symptoms were due to overwork will always be difficult, if not impossible, to obtain; but when dealing with large numbers the objections that might be raised in an individual case would have little if any weight.

We have been much interested in some remarks made at a recent trial in Glasgow, by Sheriff Guthrie, on the right of parents to remove their children from a hospital when warned that such a proceeding would be likely to cause the death of the child. The case which was the occasion of the observations was an excellent one for the purpose. A little child had been run over by a tramcar and taken into the infirmary. Whilst there tetanus set in, and the child was removed by his mother contrary to the opinion and advice of the medical authorities. The child died within an hour of his removal, and the parents brought an action against the tramway company for causing the death of their child. The parents lost the case, there being no evidence of carelessness on the part of the defendants. In giving his decision the sheriff is reported to have said: "The infirmary authorities seem to think they are bound to hand over children, whatever their state may be, on the demand of their parents. I entirely demur to that opinion. I think it is the duty of the infirmary authorities to refuse to permit unnecessary risk to life, and no Court of Law would for a moment sanction the doctrine that the parent was legally entitled to cause his child's death, when it is patent to medical authorities that such would be the necessary result of removing the patient." And he went on to say that even if the defendants had been found not to have used all due care, he would have had some difficulty in holding them liable in damages and awarding solatium for the death of the child to the parents who possibly by the removal of the child from the infirmary had caused its death.

In this last opinion there can be no doubt that the sheriff, for whom we have great respect as a man of common sense, and what is even more, as one who has the courage of his convictions, is in error. It has been laid down in the law courts over and over again, with perfect justice, that it is no defence to a charge of murder or manslaughter to say that the person might have recovered with more skilful treatment. You cannot compel a wounded person to call in medical aid at all, or to follow the advice that is given him when he does place himself in the hands of a doctor, and to this part of the sheriff's argument we must therefore demur. On the general question as to the right of parents to remove their children from a hospital whenever they choose, there is a good deal to be said. At first sight one would be inclined to say, that undoubtedly a parent must have a perfect right to remove his child from a hospital or institution if he wishes to do so. In the case of adults, we never insist on keeping a patient in a hospital against his will, provided we are satisfied that he is sufficiently in possession of his mental faculties to understand what is told him and be responsible for his actions. Were the rule otherwise, a hospital would tend to become a prison, having once entered which a man surrendered his personal liberty for the time being. This is not the case, and it is not to be desired that it ever should be; and, therefore, when the consequences of the step he proposes to take have been fully explained to the patient and his friends, he must be left to do as he pleases. We recollect an instance where a patient, with intra-thoracic aneurysm, who insisted on going out after being warned in the most positive manner of the great risk such a step involved, fell dead on the door-mat outside the ward. Even the Glasgow sheriff could not have censured the hospital authorities in such a case.

But with children the case is a little different. We can quite understand and appreciate the feeling which would make a parent take his child out to die at home when assured that his recovery was hopeless, even though such removal would in all probability shorten the few remaining hours of life yet left. But when a parent is distinctly told that to remove his child is to make his death certain, whereas if left in the hospital there is a possibility of his recovery, the man who, under such circumstances, persists in taking his child away is not to our mind adequately punished by the censure of a coroner's jury. It will perhaps be objected that there are no diseases where such an alternative could be laid before the parent with perfect confidence and truth. To this we would reply that there certainly are such instances; in the case of typhoid fever for example, late on in the disease, when the patient has had some hæmorrhage from the bowel, or there are signs of peritonitis, recovery is still possible, though, of course, we could give no positive assurance of it; and the same would apply to a child on whom tracheotomy had been performed but a short time for diphtheritic laryngitis. Surely the parent who would remove his child under either of these circumstances is just as guilty of manslaughter as the shaker who, from ignorance and superstition, refuses to have medical advice for his child at all.

There are many other ways in which a parent may neglect to do the best he can for his child, or rather may refuse to allow someone else to do it for him. How often do we hear the expression—I would rather follow him to his grave than have him operated upon. The wish in such a case is usually gratified, for very few men care to operate in direct opposition to the parents, knowing that failure, which of course is always possible, may expose them to a persecution of which no one can foretell the termination. There is probably not a physician in London in hospital practice who has not lost a case of typhoid fever through a grape or an orange surreptitiously given, and we recollect one instance in which a woman, who had already caused the death of one of her children by giving him an orange when suffering from typhoid fever, was caught in the act of trying to do the same kind turn for another of her children. If that woman could have been prosecuted and convicted of intent to do grievous bodily harm, if not indeed actually to kill, hospital authorities would have been supplied with the material for a most useful placard, and one which we venture to think might prove the means of saving many lives.

Our Philadelphian namesake is much exercised that the members of the Massachusetts Medical Society should have agreed to admit women within their portals. It admits the justice of treating legally qualified practitioners on equal grounds, but fears that in an old established community the admission of women into the medical societies on equal terms with men will encourage a class of *dilettante* doctors, "women who enter at medical schools as a relief from china-painting and South Kensington art work, and other like serious pursuits, and who receive a diploma in due course, without having any real appreciation of the dignity or the duties and responsibilities of the medical degree." If these things be so, surely the fault consists in admitting them into the profession, not in allowing them to join the medical societies. To a woman who has been admitted into the profession it seems to us to be our bounden duty to hold out the right hand of friendship instead of putting obstacles in the way of her increasing her slender stock of professional knowledge. We fail to see the expediency of our contemporary's proposal to require that candidates for admission into their medical societies shall have been at least five years in practice, and shall have attained the age of thirty. In this country, at any rate, such a restriction would not conduce to the scientific value of the papers read at the meetings of our societies.

The *Boston Medical and Surgical Journal*, commenting on the same decision, opines that while the question, in this particular instance, has been settled, that of the wisdom or profit of women attempting the practice of medicine, save in very exceptional cases or under very exceptional circumstances, remains entirely open. "We are aware that we are not on the *popular* side of the question, that our views are called ungenerous by those

who believe there must be a selfish motive, and narrow by those with whom novelty is synonymous wisdom. But we dislike demagogism, whether in politics, in society, or in the professions, and do not think improvements necessarily result from change. We believe that women in this particular community are already aided and abetted in too many foolish fads and fancies. There is too much bad piano playing and too little good cooking, and sewing taught them. They, more than men, are too much encouraged already to *attempt* uncommon things rather than to find an interest and profit in doing ordinary things thoroughly well. In regard to this particular fad of encouraging them to practice medicine, we know that some of those who have been in favour of it, and have even now voted to admit women to the examination by the Massachusetts Medical Society, but who are candid, acknowledge that their experience derived from consultations with our best female practitioners, and from cases sent to such for treatment, tends to convince them it is a mistaken movement. If the sum total of human happiness can be increased by the pursuit by women of what have hitherto been regarded as virile occupations, so much the better; but both theory and practice lead us to believe it as little in regard to medicine as to law, theology, or politics. No action of medical societies or of legislatures can alter the male and female physiology, and the experience of ages is the best index of the mental, moral and physical fitness of each sex for the profitable exercise of certain functions. If we desire to prove these problems over again for ourselves in this age and community, there will undoubtedly be a limit to the amount of harm which will result, and it may keep us out of worse mischief." Such an expression of opinion is noteworthy as coming from a country where the "equality of the sexes" is more loudly proclaimed and more generally allowed than in our own; but it contains truths to which we in England should not be blind, and which have an application much wider than that involved merely in the admission of women to the profession and practice of medicine. That is after all a comparatively small question, and every year that passes shows the more forcibly how little it justified the frantic feelings it excited amongst some members of the profession, feelings which, it is whispered, still smoulder on in certain elevated regions.

The result of the trial at Liverpool, Good *v.* Whittle, reported elsewhere in our pages, is satisfactory, not only to the defendants, but to the profession at large, since it indicates clearly that, even in very difficult cases, medical men have only to act straightforwardly and with reasonable care, in order to secure themselves against any legal after-consequences of giving a certificate of lunacy. Cases similar to that of Mrs. Good are very common and very difficult to deal with. The patient is an intelligent woman, capable of withstanding a rather severe cross-examination, of giving smart answers, displaying an ordinarily good memory, and reasoning fairly well. Insanity could not, or could scarcely, as it appears, be detected in her conversation. But it showed itself in her acts. The difficulty of certifying in such cases as this is often extreme. The conversation of these patients is often rational, intelligent and shrewd. Their acts may be a little eccentric, but for any single act they have a most plausible explanation ready. A casual observer would repudiate with warmth the notion that they are insane. But on longer acquaintance it is found that explanations are continually being required. Each explanation may be quite valid for each particular act, but then the eccentricities are so numerous and so diverse that the explanations become inconsistent with each other. Even then, however, it may be extremely difficult to lay a finger on any one act or expression and write it down in such form as to convey to a stranger unquestionable proof of insanity. Often it is only the gradual accumulation of small indications repeated again and again that at length carries conviction to the mind, and enables the observer to arrive at the positive conclusion that the patient is insane. And no one of these indications is of itself of sufficient cogency to be adduced as a proof of insanity. It is only their sum that convinces, and it is precisely this aggregate that cannot be introduced into a certificate. Bearing in mind the difficulties that beset the certifier in cases of this class, the verdict of the jury is eminently satisfactory. Had Mrs. Good been sent to a private asylum, it is doubtful whether the verdict would have been as favourable to the defendants as it is; and had Dr. Mold been the proprietor of the asylum, and the certifying doctors been his intimate friends, the conditions would have been still less favourable for such a verdict. The result of the trial supplies another argument to those who would abolish private asylums altogether.

In a preliminary statement of Dr. Sordes, Inspecting Physician for the Protection of Infants out at Nurse, published in the *Lyon Médical*, a most satisfactory account is given of the operations of the "Loi Roussel" in the Department of the Rhone during the last five years. This law was passed by the French parliament at the instigation, and in consequence of the perseverance, of Dr. Roussel, its chief provision being the submission of all hired nurses in France, and their charges, to regular official medical inspection. Dr. Sordes has held the post of inspector since 1879, and the figures he reports are as gratifying as they are surprising. Prior to the institution of the inspectorate, the mortality of children put out to nurse was computed at 40 or 50 per cent., and in 1879 and 1880 the deaths still reached 46 and 22 per cent. respectively; but this arose from the difficulty there was found at first in bringing the parents and nurses under the operation of the new law. In 1881, however, the mortality fell to 8·50 per cent., in 1882 to 5·50 per cent., and it is anticipated that in 1883 it will not be found to be higher than 3 or 4 per cent.—and that, notwithstanding that $\frac{19}{20}$ths of the infants are brought up by hand. The mortality of these inspected infants is indeed very sensibly less than that of infants brought up at their own homes. For, as the inspector's visits cost nothing, they are summoned even

unnecessarily for the most trifling ailments; while amongst the peasantry, fear of expense and want of confidence in doctors lead to dangerous delays. Dr. Sordes has had under his charge since 1879 about 1,200 infants, who at the mean mortality of 40 per cent. would have furnished 480 deaths, while he lost only 83 of the children, notwithstanding the great mortality of the two first years; while the success of his colleagues in other parts of the Department is equally great. Never was money better spent, Dr. Sordes concludes, than in paying for this successful organisation under the "Loi Roussel."

So far the Committee appointed to enquire into the reality of the protection afforded against hydrophobia by the recent experiments of M. Pasteur, have entirely verified his conclusions. All the 23 dogs which M. Pasteur submitted as protected have been found proof against inoculation with the virus of rabies, whilst eight unprotected dogs on whom intra-venous inoculation was performed, and five unprotected ones which underwent trepanning and inoculation, all became mad, and three out of six dogs experimented on by being bitten by mad dogs met with the same fate. The Committee are now going to see if they can obtain the same success with the inoculation of the protective material that M. Pasteur has had, and further to investigate whether, after a dog has been bitten, the effects can be modified or prevented by inoculation.

SIR WILLIAM GULL ON THE NEW MACHINE.

The profession has seldom had placed before it an address which at once suggests and deserves such deep reflection as that which Sir William Gull delivered at Copenhagen on Thursday, and which we publish in full in another column. There are, indeed, few men in our ranks, either here or abroad, who could have brought to the treatment of the subject of International Collective Research at once such steadiness of judgment and such sweep of thought. The medical mind is exposed to two dangers in relation to this topic. Those on the one hand who fully realize the extreme difficulties of scientific research, and the limitations of the average practitioner, are tempted to think very lightly of collective investigation as a means of medical progress. Those on the other hand who do not adequately appreciate either those difficulties or those limitations, and who fall readily under the sway of large ideas, are apt to think and to write too enthusiastically of the movement, and to expect of it results which it can never achieve. Sir William Gull steers clear of both these tendencies. He admits that collective research "assumes the combination of exact observation and record, with refined criticism and analysis; that it demands the highest scientific perception, with the humble collection of the meanest facts." And yet he believes that it may bear fruits which it is "impossible to over-estimate, whether we limit our view to the results on our members, on the profession as a whole, on the public good, or on the brotherhood of nations." And further, believing this, he is tempted into no exaggeration of language or statement, but propounds his argument with studied moderation. Whatever else there may be in his address, there is certainly no "schwärmerei." When Sir William Gull—who, so far as his influence on medical thought is concerned, is nothing if not sceptical—can see reason to expect useful results from what is more or less amateur investigation, it would be affectation on the part of younger believers in scepticism to set their face against it.

It will be a new idea to those who are not read in philosophy to learn that collective scientific investigation is not a modern project, but that it suggested itself nearly three centuries ago to Francis Bacon as the new machine, the "Novum Organon," whereby the facts of nature might be observed, arranged and treated in such a way as to come within the mastery of man. Bacon's magnificent idea, and with it his reputation as a philosopher, fell into undeserved disrepute, because it was found in effect that the discovery of natural laws did not follow the lines he had laid down; but that instead of observing a multiplicity of facts, and then proceeding mechanically by comparison and elimination to arrive at general truths, the process adopted by born investigators was to hazard an hypothesis on the warrant of a few facts, and then to verify it by more extensive observation and experiment. Only by this means, it has been maintained, is the necessary stimulus and direction obtained for the devising of new experiments and the search after new facts. It is evident, however, that this is true only of certain sciences and certain forms of research. Where an investigation depends entirely on experimental research, or is directed to the discovery of hidden general laws, it is obvious that the Baconian method is inapplicable. For it leaves no room for that use of the scientific imagination which can alone suggest a fruitful line of enquiry. Where, however, an investigation does not depend on direct experiment so much as on the observation of facts scattered over a wide area, and on the study of those experiments which Nature herself makes when, where and how she may, it is obvious that the work of the professional investigator may and must be supplemented by that of less skilled enquirers who, in proportion to their numbers and distribution, have better opportunities of observation than he can command. The promoters of the Collective Investigation movement propose to combine the two methods of research, supplementing the scientific insight and imagination of the skilled and picked investigator, with the powers and opportunities of observation of the rank and file of the profession. The memoranda stating the object of particular enquiries and turning the attention of the observers in the required direction, will form the link between the one class of mind and the other. Through these, says Sir W. Gull, the influence of the more advanced intellects of the profession will extend through the whole of it, and will reach its most scattered and distant members.

As medicine is to be the first science to which this new modification of the Baconian method is to be

applied, so, it may be pointed out, it is almost the only one in which it would be practicable. In no other branch of natural science are there so many observers more or less efficiently trained, and enjoying, from the very nature of their daily work, so many hourly opportunities of registering important facts. Even as it is, medicine, like botany and zoology, has been in great measure built up of facts observed by, so to speak, amateur observers, that is, observers with whom observation has been the secondary and not the primary business of their lives. The only matter for surprise and regret is that the valuable work of these observers has not already long ago been systematised, directed and stimulated by some central organization. Hereafter, let us hope, the present generation and the present year will be looked back upon as forming as important an era in the progress of medicine as the publication of Bacon's great work formed in the history of scientific enquiry in general. After the forcible and closely reasoned address of Sir William Gull, we do not think that there will be many who will have the courage to laugh down the new movement. Difficulties of course there will be. The average man is not to be turned into a trustworthy observer, because his observations are collected and published. The "idola" of which Bacon warned us will still distract and disturb the search after truth, but as Sir William Gull has shown, the very magnitude of the operations of the Collective Investigation Committee will tend to neutralize and eliminate these sources of error. The "idola tribûs," the errors to which minds are liable from their national constitution, will be naturally reduced when many nations share in the work; while the "idola specûs," the errors arising from egoism and individual bias will be eliminated when the observer is only an impersonal unit in a vast multitude of fellow-workers. It may be calculated that those who only work for personal renown will not enter enthusiastically into the new movement, but that it will be left to such as are actuated mainly by love of truth and an ardent desire for human welfare—the motives which the author of the "Novum Organon" put forward as the main incentives to scientific research.

THE ELEMENTS OF HYGIENE IN SCHOOLS.

Despite our boasted educational facilities and the rapidity with which so many new buds on the tree of knowledge are expanding under the fostering or forcing influence of a culture which is almost hothouse in its character, the medical practitioner is still only too familiar with what he can but regard as the woeful ignorance or stupid defiance of sanitary principles amongst the people. If he be young, it startles him; should he be careless, it will baffle him; and, in any case, it may sometimes well dishearten him. The soundest diagnosis and the most careful nursing and the most appropriate pharmacopœial treatment may avail nothing to the patient who continues the victim of a stupid oversight or of a perverse misapplication of the fundamental laws of sanitary construction. Even in those cases which seem at first sight less serious, the ultimate result may be, for that very reason, even more disastrous. The evil is not so marked, perhaps, as to arrest attention, but it is as effective as it is insidious; and because he is not at once prostrated by its influence, and does not therefore credit its existence or believe in its malignity, the patient continues to live placidly under the shadow of the upas tree, to whose deadly influence his bodily health does not, indeed—to use the language of extremes—immediately succumb, but from which it none the less continuously suffers. And, after all, in the vast majority of cases, the *fons et origo* of all the mischief is merely a simple something done in the way it should not have been done, or not done when it ought to have been done; an obvious sin of commission or of omission in construction or in application, which benefited nobody in the doing of it, which saved neither time nor money, which may even have entailed needless expenditure of both; the necessary outcome, in short, of blind ignorance or carelessness which would be criminal only that it is so common. It is needless to specify instances; every practitioner can from his own experience recall examples where the patient has suffered from faults for which he was not responsible and which he may have lacked either training or intelligence to detect, or from his personal neglect of such simple rules and precautions as he would readily and easily have carried out, had he but been acquainted with them. It is more to the purpose to ask where the remedy for these evils is to be found. Obviously, they can be cured only by attacking them at the fountain head. There is no advantage in inverting the pyramid, and but little is gained by becoming learned in prophylaxis after avoidable but irremediable mischief has been done. In other words, if men and women are to be educated in the proper culture and development of their bodies as well as of their minds, if it is well for them to possess a *corpus sanum* as the fit temple and instrument of those higher faculties which can best exert their powers only when duly housed and fitly served, the requisite training must, in both cases, begin in childhood.

There can be no doubt that at least the elements of personal and public hygiene should have a recognised place amongst the subjects of every school curriculum. It is not desirable to produce a generation of juvenile sanitary prigs or pedants; but, while stopping far short of such a result, much might be done in this way towards ensuring that the men and women of the future shall not exhibit that crass ignorance of and indifference to the very essentials of sanitation which are now so lamentably common. Teachers would find little difficulty in following out some such suggestions as those which were put before the American Public Health Association, in November of last year, and in impressing on their pupils that the diseases which kill them in greatest numbers have been classed by wise men as *filth diseases*; "that small-pox is easily preventible by vaccination; that scarlet fever, diphtheria, typhoid fever, yellow fever, cholera, and even pulmonary consumption, are preventible by cleanliness and correct habits of life"; that such diseases, in short, are not the inalienable birthright of mortality, but that they are the result of persistent violations of the laws of health; that there are houses and whole groups of houses in the country as well as in the town

"where slovenliness and filth so much abound that sickness in some form is present at all seasons of the year"; and that filth not only infects the atmosphere in the immediate neighbourhood of its accumulation, but that it can and does transmit its germs afar. In order the more surely to fix the memory of these truths upon the mind, the teacher should "employ sketches on the black-board to illustrate dangerous proximity of the family residence, the stable and barn-yard, the pig-stye, the duck-pond, the privy vault, and the kitchen sink-drain, to the water supply in the well or cistern; to show how the milk supply may become contaminated . . . . . and dangerous"; the principles to be followed in building houses, workshops, and factories so that they may be healthy to live in and occupy; and how necessary to the maintenance of good health are fresh air, pure water, and plenty of well-cooked wholesome food. It would also be easy to indicate, by simple appropriate diagrams, the system of sewerage usually adopted in towns; the importance of traps and proper disconnections; and the danger to health from imperfect ventilation, etc., etc. Novel instruction in matters dealing so directly and obviously with their own every day life would come to all school children as a pleasant interlude in their ordinary routine of work. They would thus imbibe, without effort and almost unconsciously, a knowledge of those broad and fundamental principles which it would be almost impossible for them to forget, and which, however much the mere *fashion* of sanitation may change from time to time, it would never be necessary for them to unlearn. To the many boys who evince a natural fondness for mechanical and constructive occupations, the practical character of such instruction would particularly commend it; and it would appeal to that natural preference for the concrete exhibited by nearly all of them. Similar knowledge is not less requisite for girls; and an acquirement of clear ideas on the principles of sanitation as applied to their own persons, to general household arrangements, to the care and treatment of children and of the sick, to the hygiene of the bedroom and of the nursery, would be as interesting in their earlier years as it would prove valuable to them in the capacity of mother, wife, or nurse. There is no need to overload the mental digestion of the child, already hardly taxed, with knowledge of this kind; what is wanted is breadth and quality of foundation rather than bulk and heterogeneity of superstructure. Much of it might be learnt without any approach to intellectual strain, by means of simple illustrations such as Dr. Reeves advises, and the "object lessons" which the phenomena of modern life constantly display. Once started on this path of knowledge, the growing mind would be continually discovering fresh occasions for increasing its store of information and exercising its powers of observation, until these processes became more or less automatic, but none the less practically useful to their owner and his race. It is not necessary to raise the question as to whether instruction in the rudiments of sanitary science might not advantageously supplant other branches of knowledge whose acquirement may be a useful mental exercise, but which have, for the vast majority of their students, no practical application whatsoever. At any rate it must be admitted that if men and women would give to the study of their own bodies, of their surroundings, of the management and maintenance of their own health and vigour, a care and interest equal to that which so many bestow upon such matters in relation to their dogs and horses, their poultry, and their household pets, they would gain immensely; gain not merely by a vast increase in the health and happiness of themselves and of their households, but gain the new pleasure of some intelligent appreciation of the construction and methods of the human body—that wonderful vital machinery which is too often treated as though it were made of boiler-iron and endowed with perpetual motion.

THE INTERNATIONAL MEDICAL CONGRESS.

Opening of the Congress.

The International Congress at Copenhagen bears every prospect of success. An essential element in the success of any great gathering must always be found in the number of members who attend it, and even before the opening of the session the numbers registered have far exceeded the expectations of the Reception Committee. The English contingent is fairly representative, including nearly all the leaders of the well-remembered Congress of 1881. The various routes indicated for the guidance of the medical pilgrims appear to have been all employed, although the shortest of them has naturally conveyed by far the greater number. A large party, pioneered by Sir W. MacCormac, and including Sir W. Gull, Sir Risdon Bennett, and many others, travelling *viâ* Flushing, Hamburg, and Korsoer, crossed from Kiel on Saturday.

Most of the members of the party will bear a lively recollection of this short but singularly uncomfortable voyage. Crowded together on a small steamer, which would afford only moderate accommodation for about fifty persons, were more than two hundred and fifty human beings, male and female, the former mostly medical. A persistent head wind and consequent chopping sea, the impossibility of obtaining sufficient food or even sufficient space to sit down, produced a state of things, after a few hours' lively tossing, neither pleasant to recollect nor edifying to record. Well-known faces from America, Berlin, Vienna, Paris, and London became, from the one all-conquering cause of sea-sickness, tinged with hues and altered by distortions neither picturesque nor becoming. More than one authority on gastric nervous disturbances might be seen obviously the subject of those remarkable phenomena so easy to speculate about, and so difficult to deal with; and many will doubtless feel that nothing less than a crown of martyrdom is due to them for such sacrifices in the cause of the medical sciences.

Arrived at Copenhagen, evidences are afforded on every hand of the determination on the part of the city to render the reception of its guests a worthy one in every sense. The demand for accommodation having become so far greater than was anticipated, the resources of the city have been taxed somewhat severely, but the courtesy of all persons concerned has withstood the strain which such a demand involves. The general meetings, which are held in the Palais de l'Industrie, have been fitly inaugurated by a general recep-

tion, in the presence of the Royal Families of Denmark and Greece, at which an address of welcome was delivered by the President, Professor Panum. Referring in most eulogistic terms to the brilliant success of the London Congress, he claimed for the Executive of the present meeting the credit of having attempted, however imperfectly, to reproduce, according to their means, the best features of the great gathering of 1881. He was followed by Sir James Paget, who, in a few sentences framed in his own inimitable style, made a graceful reference to the lasting debt which England owes to the Royal Family of Denmark for its gift of the Princess of whom all Englishmen are proud. In wishing success to the present Congress he made allusions to the advantage which had accrued to the study of medical science in England from the international gathering over which he had presided. Although "insular in position," we were thereby led to become "cosmopolitan in mind." The problems of science cannot be settled by this or that nation alone, and this international comparison of theory and practice forms the safest means of arriving at the truth.

As the representative of Germany, Professor Virchow next delivered a characteristic speech, especially bearing upon the subject of experimental research, and his remarks in advocacy of the principle involved were received with general applause. He congratulated Denmark on its freedom from legislative interference in this respect, and concluded with a comparison of the old system, founded on the Hippocratic teachings, with the essentially modern views in vogue in Northern Europe at the present day. A short speech from Professor Pasteur, who was received with much enthusiasm, was followed by a general statement by Dr. C. Lange, the Secretary-General. The President then delivered his inaugural address.

The French language was used by the Danish speakers, and unfortunately the difficulties presented thereby were added to by the bad acoustic properties of the hall, which, although most tastefully decorated for the occasion, did not permit of all of the large audience, numbering over one thousand, obtaining either a clear view or a distinct hearing of the several speakers. At the close of the proceedings a general conversation took place, all the leaders of the various nationalities being presented to the King of Denmark and his son, the King of Greece, who passed from one to another in the crowd with evident enjoyment of the scene. Three faces were conspicuously absent from the circle of medical celebrities, viz., those of Lister, of Charcot, and of Pantaleone. The first of these, however, will not be absent from the whole of the meeting.

Of the various nations present, the German, French, and Scandinavian are far more largely represented than the English and Italian; few nations, however, are represented by so many acknowledged leaders as our own. With Paget, Gull, Spencer Wells, Risdon Bennett, Marshall, and Acland for our sponsors, we may safely challenge comparison in this respect with any of the nations present.

The sectional meetings are held in three different buildings, somewhat inconveniently distant one from another, and the programmes of each day are to be duly announced. At present, however, the valuable volume of "Abstracts," so useful to the members of the last Congress, has not made its appearance; it is, however, promised. The Committee of the Congress have arranged a series of entertainments, including a general excursion to Elsinore, which will doubtless attract large numbers of members. The meeting will be wound up with a *fête d'adieux* on Saturday, the 16th.

First General Meeting.

The first General Meeting of the Congress was held in the large hall of the University, which was filled to overflowing. Professor Pasteur, who was most warmly received, delivered an address on the progress of our knowledge of the part played in the causation and spread of contagious diseases in men and animals, by the various microbes, with especial references to his recent researches on hydrophobia. The virus of the latter disease is always developed in the nervous tissues and in the salivary glands; the incubation may be very long and is always variable. Injection of virus into the membranes of the medulla by means of trephining invariably produced hydrophobia. The disease is never spontaneous but is always derived from the original disease of the dog. The symptoms depend essentially upon the part of the nervous system in which the virus is situated, and their virulence is in direct proportion to the length of the incubation, while the latter in itself depends upon the quantity of poison present. He related particulars of several experiments in illustration of this. For all these investigations the necessity of trephining in order to obtain accuracy must be insisted on. By injections made with virus derived from animals successively inoculated from one another, he found that the period of incubation became regularly shorter with each successive attenuation of the virus. The whole process of inoculating his rabbits was accomplished in nine minutes and a half. A further series of experiments made upon monkeys gave different results, the period of incubation becoming longer instead of shorter. Most of the inoculations were made from a rabbit which died after an incubation of fourteen weeks. The artificial cultivation of the virus is still unaccomplished.

Pathological Section.

In the Pathological Section, Professor Virchow was unanimously called to the chair, and the business opened at once with a paper by Professor Weigert, of Leipzig, on Coagulation Necrosis. His views upon the subject have already been made known, his chief contention being that certain forms of necrosis in internal organs are preceded by and are directly due to an active process of coagulation. The parts especially liable to this form of necrosis are those in which a very free circulation of coagulable material can take place, it being the epithelial elements especially which are the first to suffer. The fact of certain cells losing their nuclei does not permit at present of precise explanation. Professor Virchow, whose views upon the subject are diametrically opposed to those of Professor Weigert, entered at some length into the pathology of necrosis, which he considers to be essentially due in the first instance to loss of fluid. The presence of fluid in animal tissues is a vital condition, and its loss is a feature of partial tissue death, both in the vegetable and in the animal kingdom. He would prefer to regard the process as one of inspissation of the tissues rather than look to any active process of coagulation.

A paper interesting to the ophthalmologist as well as to the general pathologist, was read by Dr. Salomonsen, on the Active Elements in Jequirity Infusions, which he believes to consist essentially in an active principle, jequiritine, and not in the presence of specific bacteria. Although the latter were always present in fatal cases, it was clearly proved that, when unaccompanied by jequiritine, they showed no specific action whatever. The injection of carefully sterilised jequirity infusion, however, was quite as active a poison as that prepared in the ordinary way, and

contained abundance of micrococci. A further series of experiments described by M. Cornil, consisting of filtration of the infusion through porcelain, had been successful in separating the bacilli from the fluid containing them, but both the precipitate and the filtrate still possessed active poisonous properties. The bacilli retained these properties at a temperature of 150°. His views upon the disease were in opposition to those of others who deny the activity of a special bacillus of jequirity. Dr. Salomonsen in reply was inclined to explain M. Cornil's results as due to simple septicæmia.

REVIEWS AND NOTICES OF BOOKS.

Manual of Pathological Anatomy; by Cornil and Ranvier. Second edition, re-edited and enlarged. Translated, with the approval of the authors, by A. M. Hart. Volume II., Part I. — In this the first part of the second volume are some fine specimens of the pure abstraction or sweeping proposition, such as (v. p. 7), "the pathological anatomy of the lung is reduced essentially to that of the pulmonary alveolus." This seems very much like saying that the world is an epitome of the universe. Another similar proposition is to be found at page 131, "it is a general law that the tubercle always causes inflammation round itself, which varies according to the organ affected, pursues a special course and tends to end in a caseous condition." This appears to be a roundabout way of saying that tubercle is the cause of its own existence, progress and death, and that all tubercles are as like as so many peas. We do not care much for such abstract propositions, for they may be made to mean anything or nothing. Now, as compared with the edition of 1869, the main feature of this volume is the increase in the amount of space devoted to disease of the lungs. The authors have much enlarged their disquisition on pulmonary tubercle, they have renewed with increased force their attacks on the dualism of phthisis, and show themselves firmer partisans than ever of the unitary doctrine. We do not propose to enter into any discussion as to the relative merits of either of these views, but will just mention the fact that the adherents of unity are divided among themselves as to what they exactly understand by this comprehensive abstraction. We are quite at one with the authors in their views, promulgated first in 1869, as to "tubercular granulations originating in the pulmonary alveoli, occupying the infundibala, and filling a patch of the lung with similar cells." Yet it is unsatisfactory to note further on that they themselves seem somewhat diffident on this point: for until it is proved to the contrary, we shall see no reason why the endothelium of the lung should not be susceptible of the tubercular inflammation. Indeed, we cannot see how it could be otherwise; for whatever theory as to the contagium be adopted, the endothelial lining of the air cells will be one of the first parts of the lung tissue to be attacked. It is because observations are made too late, *i.e.*, too long after the disease has been set up, that this effect has been overlooked: and with regard to the secondary developments from the original focus or foci of infection, we regard them very much in the same light as the secondary developments of a malignant neoplasm; for just as the secondary developments of a malignant neoplasm, say, a carcinoma, vary according to their anatomical position, etc., so does the tissue construction of a tubercle vary according to its position, the time it takes to grow, etc. Now associated with the subject of pulmonary tuberculosis is the question as to the origin of the giant cell. In the former edition the authors expressed a certain irritability against Schüppel whom they almost accused of purloining the results of their labours. In this edition they suppress their resentment and seem to modify their views as to the origin of giant cells. Here they state that "researches made on the origin of giant cells have led to the discovery that these cells may be developed in the interior of blood vessels; either in the midst of a thrombus composed of fibrin and lymph cells, or in the inflamed and granulating internal wall." This is tantamount to asserting that the giant cell is developed either in or from a part of a blood vessel. We are of opinion that we have seen them in situations which would preclude the possibility of supposing that a blood vessel had been their progenitor. During the past few years an absorbing interest has been taken in the relation of micro-organisms to disease, and especially to disease of the lungs. Stately volumes and almost myriads of monographs have been produced in Germany and England on the bacillus tuberculosis. Messrs. Cornil and Ranvier, after reference to the Monas tuberculosum of Klebs and Reinhart and to the Micrococcus of Toussaint, merely remark in their last lines on tubercle that "still more recently Koch, by cultivating fragments of tubercle, has succeeded in isolating microbes which resemble the bacillus of lepra in shape, but are more delicate. He has succeeded in inoculating many animals with tubercle." This is all they have to tell us about the bacillus tuberculosis and we consider that this unfortunate bacillus has been unfairly dealt with in comparison with the micro-organisms infesting the buccal cavity. For not only are three pages devoted to the consideration of the latter, but methods for staining them and their measurements are given. Now, whatever the future of the bacillus tuberculosis may be, we are certainly not at present in a condition to overlook it. The polemical element is mainly comprised in the first chapter, but ulcer of the stomach offers several opportunities for airing improved theories; as we cannot adduce any probable cause for the origin of this frequently disastrous disease, we will simply point out that in the present state of our knowledge the speculations are purely problematical. The same viscus is stated to be affected with carcinoma in the following order of frequency: encephaloid, scirrhus, colloid, malanotic. Other authorities put scirrhus at the head, and this certainly accords with our own experience. It is obvious that such a statement is misleading, and if the frequency of encephaloid cancer of the stomach in France be greater than elsewhere, some intimation to this effect should be appended. If our remarks seem severe they may be discounted by the fact that they have been made through the medium of a translation, which, judging by our knowledge of the French edition of 1869, seems somewhat to have lost the vitality of the original. We have also noticed a few specimens of continental English, such as "on dividing the lungs" for on section of the lung; "dissociate with needles" for teasing out, etc. The engravings are vastly more numerous than in the first edition (in the proportion of 5–2), but we regret that we cannot praise them highly, as many are so wanting in definition as to seem imprinted from worn-out plates.

An Introduction to Pathology and Morbid Anatomy; by T. H. Green, M.D. Sixth Edition; illustrated by one hundred and fifty engravings. London.—The sixth edition of this very popular manual retains all its old characteristics, and is much enlarged by the addition of a considerable quantity of new matter. The author, by whose name this "Introduction to Pathology and Morbid Anatomy" is known, has associated with himself in the production of this last edition, a surgical colleague, Mr. Stanley Boyd. To the latter are entirely due the chapters on tumours, regeneration, septicæmia, and the vegetable parasites. We think that this association is always, in pathology, a step in the right direction, for however able a single writer may be, he is bound to give a more or less partial view of his subject, his views leaning unconsciously towards the side of his special inclinations. Hence a combination pathology issuing from the pens of at least two authors will be found more useful to the student who is approaching his examination, than most works which are the product of a single hand. This edition is illustrated by one hundred and fifty wood engravings, a very fair quantity as books go, but none too many, at least, in our opinion, for we think that a great deal more can be imparted through the medium of well-executed illustrations, than by the most graphic word-descriptions. The necessity for the latter cannot be abolished, but might be made subordinate to the former. So much is known about this work from its

previous editions, that it would be idle to re-discuss the unaltered portions, while with regard to the new and revised chapters, we are able to say that they are quite up to the standard of their predecessors. The chapter on vegetable parasites furnishes a well-digested epitome of the subject of micro-organisms, and, like all the recently revised portions, will be found to contain quite sufficient for ordinary purposes. We can recommend this new edition as being a work containing a large amount of well-put information brought up to examination date.

Lehrbuch der Auscultation und Percussion; von Dr. C. Gerhardt. Fourth Edition. Tübingen: Laupp'sche Buchhandlung, 1884.—The appearance of a new edition, "increased and improved," of a work so long and favourably known as the above, may safely be interpreted as a proof that its popularity is as great as ever, and that the publication of numerous lesser writings on the same subject have only served as a stimulus to the author, and have not as yet in any way supplanted him as an acknowledged authority on the subject on which he writes. Dr. Gerhardt's book has indeed supplied not only the text, but also much of the material for more than one of the smaller handbooks on auscultation that have from time to time made their appearance for the benefit or otherwise of students and practitioners. It has often been questioned whether so essentially practical a subject can be profitably studied elsewhere than at the bedside, and many very skilled physicians have expressed sentiments nearly approaching to contempt at the laborious efforts sometimes displayed by teachers and students to give a scientific explanation of those sounds and vibrations which assist us in discovering morbid conditions within the chest. An approximate understanding, however, of the causation of these same sounds and vibrations heard and felt in the healthy state of the chest, is essential to the proper comprehension of the morbid modifications of them met with in the course of disease. It is precisely this essential starting-point, however, about which the chief discussions and differences of opinion have taken place. Whether the ordinary vesicular murmur of quiet respiration is itself produced within the vesicles, or whether it is the tracheal or bronchial sound simply modified by transmission through a bad conductor must still remain in the category of things not proven. In Dr. Gerhardt's work will be found a full discussion of the various theories that have been promulgated upon this point, and the reader will, no doubt, be struck with the fact that the author's own views are in close accord with those of Laennec as published in his original treatise in 1819. Whether from a theoretical or from a practical standpoint, the book may be accepted as a thoroughly trustworthy guide, containing everything that a well qualified physician requires to know on the subject, and at the same time presenting, in an attractive form, those debatable matters upon which he may speculate with advantage in his leisure hours.

Discussion on Albuminuria at the Glasgow Pathological and Clinical Society. Glasgow: A. Macdougall, 1884.—This is a reprint from the *Glasgow Medical Journal* of the papers read during the discussion on this subject which lasted over four meetings of the Society. To attempt to analyse all the papers would require a greater amount of space than is at our disposal; we must therefore content ourselves with the briefest allusion to one or two of them. Looking at the subject from a clinical stand-point, Dr. William Roberts expressed his belief in a physiological albuminuria, the characters of which he defined as follows: the albumen is generally small in quantity, its occurrence is intermittent, and it is generally absent in the morning. This albuminuria is transitory, and the urine in other respects is normal in character; there are no other signs of Bright's disease, and the general health is often perfect. The complaint is most often seen in growing boys and girls, persons about the age of puberty, and young adults under thirty. Dr. Gairdner, in the course of his remarks, drew a parallel between albuminuria and pulmonary catarrh, the catarrh in the one case and the transudation in the other being the starting point of numerous lesions, the initiatory process upon which a great number of organic changes may depend, according to the proclivities of the individual, and a variety of other circumstances. The discussion was opened in a speech of considerable ability by Dr. Newman, and the pathological, clinical, and chemical aspects of the subject all received their share of attention.

The Medico-legal Journal, No. 4. Published by the Medico-legal Journal Association, New York.—We are certainly behind our American cousins in matters medico-legal, for there are societies devoted solely to the study of this subject, not only in New York, but in Philadelphia and in Massachusetts, and the New York Society have lately undertaken the publication of a journal, of which a number is now before us. The first paper is on a case of poisoning by arseniate of soda, a rare event in itself, and made additionally interesting by the utter absence of the ordinary symptoms of an irritant poison, the chief phenomena being stupor passing into coma and hurried respiration. This is followed by an important paper on the sanitary building laws in New York, by a sanitary engineer, and by a paper on concussion of the spine in railway injuries, by Dr. J. G. Johnson. He evidently does not believe in the railway spine, and has the greatest contempt for the personal damage doctor, and the personal damage lawyer, to whom he alludes in no very complimentary terms. The reports of the various meetings of the Medico-legal Society take up a good deal of space, and show that there are plenty of important questions ready for discussion at such a society. We consider that the *Medico-legal Journal* constitutes a very valuable addition to periodical medical literature.

ABSTRACTS AND EXTRACTS.

MEDICINE.

Significance of Jaundice in Diagnosis.—Under this title Dr. Quine read a paper at the Chicago Medical Society, of which the *Boston Medical Journal*, July 3, publishes the following synopsis: "After alluding to jaundice of obstructive and non-obstructive origin, and to the various theories that have been advanced in explanation of the latter, the essayist succinctly pointed out that the attendant symptoms were mostly due to the presence of colourless bile-acids, the bile-pigment being harmless. Cerebral disturbance due to hepatic derangement, and associated with cholæmia is not caused by the presence of normal bile, but by a different though unexplained species of toxæmia. Although slight jaundice is often overlooked, and in some instances cannot be distinguished from cachexiæ except by the discovery of bile-acids in the urine, the diagnosis usually relates to the discovery of the cause and not to the mere recognition of the effects. The following points complete a summary of the paper: (1) Jaundice occurring suddenly, in apparent health, and painlessly, is usually of emotional origin, and transitory. (2) When it depends on disease or injury of the brain, acute atrophy of the liver, snake-poisoning, or infectious fever, it always is associated with mental disturbance. (3) If it be attended with fever and well marked, it is secondary to inflammation of the biliary passages, pneumonia, toxæmia, or infective inflammation of the portal vein. (4) If it occur suddenly, and is preceded by paroxysmal pain and vomiting, it is caused nine times out of ten by biliary calculi. (5) If it is preceded by typical symptoms of gastro-duodenitis it is obviously of catarrhal origin. (6) Impassable obstruction of the common duct is shown by great intensity of jaundice, clay-coloured stools, and in recent cases by distension of the gall bladder. (7) Jaundice caused by sudden obstruction of the biliary passages is always associated with paroxysmal pain and nausea, but there is no means of ascertaining the nature of the obstructing body except its discovery in the stools. (8) In the rare cases of sudden obstruction by cancerous, hydatid, and aneurysmal tumours,

there is almost always a history of impaired health, enlargement and deformity of the liver, ascites, &c., which, aided by the revelations of physical exploration, will lead to correct differentiation. (9) Sudden return to normal coloration of the fæces confirms the diagnosis of obstruction. (10) Occlusion of the cystic duct may be attended with as much pain, nausea and distension of the gall-bladder as occlusion of the common duct, but there is no jaundice. In occlusion of the hepatic duct the same symptoms are present, including jaundice, and excluding distension of the gall-bladder. It is often impossible to distinguish between occlusion of the hepatic and of the common duct. The former is rare because the duct increases in size from above downwards. (11) If jaundice persist after the symptoms of biliary colic or catarrhal inflammation have a month since disappeared, or if jaundice have disappeared after a biliary colic, to return slowly and painlessly, it may be assumed that stricture of the duct has resulted from inflammatory thickening, adhesion of the walls, or cicatrisation of an ulcer. (12) A history of repeated attacks points to the probability of gall-stones. (13) If jaundice comes on slowly without antecedent colic or catarrh, and without attendant evidence of impaired health or portal obstruction, it is probably caused either by pressure upon the duct, or by the growth of a tumour within its walls. The pressing body, when large enough, may be readily appreciated, as in the case of pregnancy, ovarian tumour, aneurysm, distended colon, &c., but when it is small, or constituted by enlargement of lymphatics in the fissure of the liver, it is apt to escape detection. (14) Slight but persistent jaundice may be due to incomplete occlusion of the common duct, or to complete occlusion of a branch of the hepatic, but usually it is found associated with either valvular disease of the heart, some disease of the lungs which obstructs circulation, or cirrhosis of the liver. (15) If ascites be associated with it, the disease is either cirrhosis or cancer of the liver. If the liver be abnormally small the disease is cirrhosis; if it be large the disease is either hypertrophic cirrhosis or cancer. Differentiation between the two is seldom attended with difficulty. (16) Absence of jaundice does not imply absence of hepatic disease, since the liver may be destroyed by disease or extirpated by operation without jaundice ensuing. (17) It is not a prominent symptom of hepatitis if catarrhal inflammation of biliary passages be rigidly excluded. It is not characteristic of hepatic abscess where, at most, mere muddiness of the complexion is usually seen. These affections are rare in temperate latitudes, and when encountered are generally found to be secondary to direct injury of the liver, or to infectious inflammation of the portal vein. It is not a symptom of waxy or fatty liver, or of hydatids, excepting as an extraordinary complication."

Acute General Endarteritis.—Under this heading Drs. Scot-Skirving and E. J. Jenkins record a case in the *Australian Medical Gazette*. Their patient was a man aged 52, who, when he first came under observation, had some fever, with paresis of right side and some difficulty in speech. The first sound of the heart was somewhat weak, otherwise there were no definite signs of organic disease about him, excepting a chancre on the penis and an ulcerated sore throat. After admission his temperature oscillated for some ten days and then became normal. The paralytic symptoms almost disappeared, including some hyperæsthesia, which had been noticed, the chancre was getting well, and for five days his temperature was normal. He then had a return of the fever with some diarrhœa, and died in four days' time without any definite signs. The diagnosis was uncertain, resting between typhoid fever and deep-seated syphilitic mischief. At the *post-mortem*, scattered patches of inflammation were found throughout the intestines, the mucous membrane being in many places eroded. The other viscera presented no changes of importance, with the exception of the aorta and its branches. Here changes were found commencing just above the sigmoid cusps, and extending upwards as far as the bifurcation of the common carotid, and downwards to the femoral artery. The lesions consisted firstly in an intense arteritis all over this area, but most marked in the transverse part of the arch and upper part of the thoracic aorta, the inner surface being of a deep blood-red colour. Next, there were many atheromatous ulcers in various stages, and lastly, there were a considerable number of calcareous plates. Miliary abscesses were found in the kidneys, probably of embolic origin, and the authors suggest that probably emboli had been the cause of the paralysis and aphasia noted amongst the early symptoms. They looked upon the arteritis as probably syphilitic.

Tricuspid Stenosis.—M. Chauffard (*Revue de Médecine*, July) concludes the account of a case of this affection, with some general remarks on the physical signs and nature of this condition. At the lower end of the sternum, or a little to the left of this, opposite the fifth left costal cartilage, there is heard a harsh, prolonged *souffle*, both præsystolic and systolic, quite different from the soft and deep murmur of tricuspid insufficiency. The murmur has very little tendency to be propagated in any direction, and does not reach the apex of the heart. Amongst the other signs may be mentioned hypertrophy of the right auricle, so that this can be recognised to the right of the sternum. There is extreme venous congestion, both of the viscera and of the extremities, and yet there is no venous pulse in the jugulars. This negative sign is one to which great importance ought to be attached in a diagnostic point of view. Hitherto this lesion has only been found in adults, mostly women, who have been subject to repeated attacks of rheumatism, and who are already affected with valvular disease of the heart, especially of the mitral valve. In fact, it would appear that the mitral stenosis sets up a chronic endocarditis, slowly progressive, which ultimately leads to tricuspid endocarditis and stenosis.

Diagnosis from Hot Urine.—Dr. Betz, in his *Memorabilien*, 1884, No. 2, calls attention to the fact that in certain conditions the urine when passed is far hotter than in the normal state. Of course, in the normal state it derives all its heat from the bladder; but when its temperature is much raised, and is unaccompanied by any inflammation of the bladder, this will be found to be due to inflammatory action going on either in the pelvic organs or in the peritonæum lining the pelvis, or in the intestinal convolutions lying in its cavity. When the patient, therefore, complains of hot urine, this condition of the pelvis must be borne in mind; and it is not rare for this symptom to be the first indication of the existence of these inflammatory processes.

SURGERY.

Suture of the Median Nerve.—At the meeting of the Academy of Science on the 30th June (*Union Médicale*, July 5th) Prof. Tillaux read a remarkable paper upon two cases of secondary suture of the median nerve, with rapid re-establishment of innervation in the paralysed parts. By "secondary" suture, he observes, we understand the suture which is only applied at a more or less long period after the division of the nerve, when the two ends have become separately cicatrised. (1) Caroline ——, 23 years of age, while cleaning a window (2nd November, 1883), cut her right wrist so deeply as to completely divide the median nerve. Primary suture of the nerve was not practised, and after the healing of the wound all the parts supplied by the median remained completely paralysed. Incapable of working for her living, the girl, on the 4th March (four months after the accident), was admitted to the Beaujon Hospital, and an examination being made of the wrist a rectilinear transverse cicatrix, painful on pressure, was observed. At this spot could be felt a tolerably distinct prominence, which was supposed to be formed by the central end of the divided nerve. The whole of the parts supplied by the median were completely insensible to contact, to pain, or to temperature, the patient not feeling the slightest sensation on plunging the ends of the paralysed fingers into boiling water or in picking up burning coals. The muscles of the thenar eminence were atrophied, and the opposing power of the thumb was lost. The paralysed parts were colder than those of the opposite side, and the skin had assumed a slightly violaceous colour. "The actual state of our knowledge of the physiology of the

nervous system was not of a nature to encourage me to intervene by an operation; and in a work which I published in 1866, basing myself on the results furnished by experiments on animals, I regarded as very doubtful the re-establishment of the nervous current by the peripheric end of a nerve that had been divided. Failure seemed then almost certain; but urgently solicited every day by the patient, and convinced that, owing to the remarkable progress of surgery at the present time, I should not cause her to run any danger, or in case of failure aggravate her condition, I decided to act, and on the 10th March performed the following operation:—The patient being placed under chloroform, the two ends of the nerve were exposed by a vertical incision, and were found separated from each other by about a centimetre—the central end being enlarged and that of the periphery tapered off. The extremities of both of these were excised by scissors, so as to get fresh surfaces of the same diameter; and, instead of employing forceps, which might have contused the nerve, a very fine needle, armed with a *crin de Florence*, was passed from one end to the other. This was gently tightened until perfect juxtaposition of the two surfaces of the section was secured, carefully preventing the neurilemma becoming folded in towards the axis of the nerve, which might have impeded reunion. The thread was tied, cut close to the knot, and left in the wound. The external wound was drained, united by silver wires, and covered with a Lister dressing—the most minute precautions of the antiseptic method having been observed. The hand was maintained motionless in a state of flexion during a whole week, without the dressing having been touched. On the eighth day union was complete. By the third day the index and middle fingers felt the contact of a pin carried gently along their surface; and the sensibility continued to increase from day to day; so that, on the 1st of May, six weeks after the operation, the patient left the hospital, the sensibility and motion having returned to such a point that she could work at the needle or crochet, and was in a condition to resume her occupation. (2) Exceptional cases are rarely solitary, and in the hospital there was a woman, aged 28, suffering from an affection of the abdomen, who having, in 1870, fallen upon a bottle, cut her wrist, with the effect of producing the same paralytic symptoms as those related above. Witnessing the success of the operation in that case, she requested that it might be performed in her own; and her wish was complied with, although some hesitation was naturally felt, so long a period as fourteen years having elapsed since the accident. The result of the operation was completely successful. It is certain that these cases are in contradiction with the actual conclusions of physiology and histology. In what way did innervation become re-established? It would seem natural to suppose that it was through the immediate approach and rapid junction of the central end of the nerve with the peripheral end, and I cannot conceive, until better informed, how it can be otherwise. But Professor Vulpian declares this to be impossible, inasmuch as the peripheric end of the nerve, totally degenerated, had lost all property of transmission, as is invariably demonstrated by experiments on animals. Professor Ranvier, who consented to examine the portions of the nerve cut off for the purpose of vivification, declares also that this explanation is impossible, since the nervous tubules, the agents of transmission, have disappeared in the peripheric end, leaving nothing to be found but fibrous tissue. I willingly bow to such authorities; but I must add that, whatever may be the theory, it is undeniable that my two patients have recovered their sensibility. It is undeniable, because these cases have been publicly observed in a hospital service by a great number of competent persons; and because they have been observed and verified, notwithstanding a strong prejudice both on my own part and that of my pupils. We cannot, then, have deceived ourselves, or been deceived as to the reality of the fact in itself. Analogous cases have also been referred to by Wessentein, in the *Centralblatt für Chirurgie*, 1884, No. 19. This explanation lies with the future."

Instruments for Occluding a Ureter for Diagnostic Purposes.—Dr. Silbermann, of Breslau, has devised an instrument, consisting of a catheter with a fenestra near the end, on the right or left side according to whether the right or left ureter is to be occluded. At the fenestra is a rubber balloon, covered during the introduction of the instrument by a slide, and when in position, distended by quicksilver introduced through the catheter by means of a syringe. Thus a heavy artificial tumour, as large as a small egg, is made to shut off all the urine coming from one kidney by pressure upon the ureter where it enters (? as it passes through the wall of) the bladder. Experiments made upon living dogs, which were afterwards killed, showed that the ureter was thus completely occluded. In the human subject, the quantity of urine secreted during a given time was measured, and was found when the instrument was not used to be twice as great as when it was used. Dr. W. M. Polk has, with a similar object, been experimenting with a double sigmoid catheter for introduction into the bladder, between which and a bulbous-ended rod passed into the rectum or vagina, the ureter could be closed so perfectly, that in the cadaver it had been dilated to five or six times its normal diameter with injections of water without overcoming the obstruction. The distended ureter could be distinctly felt through the rectum above the point of compression. The artificial formation of a temporary vesico-vaginal fistula, and the making of an opening into the male bladder of sufficient size to admit the finger, with the object of directly catheterising the ureters, have been advocated as justifiable proceedures in order to the formation of a positive diagnosis before undertaking so severe an operation as extirpation of a kidney in certain cases.—*New York Medical Journal*, April 19th, 1884.

Treatment of Acute Abscess.—Prof. Stephen Smith, of the University of New York, has published in the *Æsculapian* his treatment of acute abscess, for which he claims, in the case reported, a saving of at least a month to the patient. He advises a similar proceedure in carbuncle and furuncle, and wherever there is necrosed tissue. The method is as follows:—(1) Wash the skin of the part with a brush, and soap and water, and then douche it with a sublimate solution of 1 to 500. (2) Open the abscess with a knife that has been treated with carbolic acid (1 to 30), the aperture being only large enough to admit the nozzle of a Davidson's syringe. (3) Force out the pus by pressure, and when it ceases to flow, introduce the nozzle of the syringe, well disinfected, the edges of the wound being held firmly around it, and distend the cavity to its fullest capacity with sublimate solution (1 to 5,000). (4) Force out the injected fluid by pressure. (5) Repeat this injection as often as may be necessary, until the water flows away quite undiscoloured. (6) Lay the cavity open to its full extent, keeping up irrigation with sublimate solution (1 to 2,000). (7) Cut away all shreds of tissue, and scrape off gently any granulations that may be upon the living surface of the abscess by means of a curette, until a perfectly clean surface is everywhere apparent. (8) Ligature any small vessels that may be bleeding with carbolized ligatures, thorough irrigation being kept up with the sublimate throughout. (9) Close the wound with an interrupted suture, except at the most dependent point, where a small opening must be left for drainage. (10) Over the drainage-opening place a disinfected sponge to absorb discharge. (11) Sprinkle the external wound and adjacent skin with iodoform, and cover the wound well with folds of gauze, between which iodoform is well sprinkled. Over the gauze apply a dressing of borated cotton, and if in a limb, secure all by a light plaster of Paris bandage. In this man with an acute abscess of the thigh, holding a pint, temperature (103° F.) and fever were high before the operation, returning to the normal after its execution, all pain subsiding and the appetite and sleep being good.

External Œsophagotomy.—Dr. Knie read at the Moscow Medical Society an account of a case of a robust man who, while eating hastily, swallowed a solid body, which became arrested opposite the manubrium of the sternum. He saw the patient a week afterwards and found the œsophagus very sensitive to pressure, but without any external swelling. Proceeding to perform œsophagotomy, he found the œsophagus already perforated, and had therefore only to enlarge the aperture. A piece of bone three centimetres in length and two in breadth, was re-

moved, exhibiting four very sharp edges, and the patient did well. This, the writer states, makes the thirty-fifth recorded case of external œsophagotomy for the removal of foreign bodies, and of these twenty-nine recovered and six died.—*Centralblatt für Chirurgie*, May 31st.

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE XIII.

Alcoholic Liquids.

We pass to the consideration of liquids worshipped by more than one ancient gifted race, in picturesque symbol as something precious and divine, but to which a modern sect would apply such epithets as "poisons not foods! essences invented by an evil principle! a foul fiend's waters!" The medical profession as a whole, while inculcating temperance, has never adopted the extremes of either worshippers or revilers. We will here take a common sense view of the matter, and until an inquisitive pathology has afforded us some proof of the injurious effects of the legitimate daily and reasonable social use of spirits and wine, we shall continue to believe that our excretory organs are not so delicate as to be in any way damaged by separating and transforming small quantities of alcohol. This also is an opinion the more likely to be adopted by the majority because there is no really good temperance drink; neither the sweet syrups replacing wine at the recent vegetarian dinner, nor that drink which attained such popularity under the name of zocdone, can compare as regards pleasurable excitement of the palate, or as a stimulator of the digestion with good beer, or light dry wine. Few people drink wine for the sake of its alcoholic content; so long as it is agreeable, of fine flavour, and is made of pure materials, they would prefer the percentage of alcohol to be kept as low as practicable, and, indeed, generally good sound pure wines of feeble alcoholic strength are to be recommended and encouraged.

Of wines, the Exhibition has a goodly show. Messrs. F. T. Denyer and Co. exhibit a great variety; their champagnes are specially to be commended; a sample of 1874 vintage we have carefully examined and found perfect in bouquet and altogether excellent. Their pure "Manzanillar from Sanlucar" is likely to be popular, and to successfully compete with many of the sherries in use. It is a sound wine, containing a little under two per cent. of grape sugar, rather strong in alcoholic content, but of a fine full flavour, and of very moderate acidity.

Mr. W. T. Folks, of Mark Lane, exhibits Lima and Fils' champagne, a wine which, considering its price, is of good quality.

Messrs. MaxGreger exhibit all kinds of Hungarian wines; their Carlowitz, both white and red, we have specially examined—it contains about ten per cent. of alcohol, is very moderately acid, and is absolutely genuine. Carlowitz is a wine which the rather numerous class of persons who are unable to take malt liquors may drink with advantage.

Messrs. Christmas and Co. are endeavouring to develop and improve the trade in British wines; the so-called home-made wines, such as currant, ginger, and the like. There would seem to be no reason that, with careful selection, wines made from materials in our own gardens should not in time rival the products of Australia and the Cape; their chief fault is, as might be expected, excessive sweetness, and facility of decomposition. Messrs. Christmas and Co. have, however, been very successful in overcoming both of these difficulties. Their wines contain but little more sugar than many sherries, are of good flavour, of full alcoholic strength; and generally are very palatable, bright, attractive and good.

Passing from the wines to the spirits, the Dublin Whisky Distillery Company has afforded us the unusual advantage of examining and comparing with a sample of the ordinary retail strength, a considerable quantity of samples of whisky before dilution, and ranging from 1878 to 1881. The changes which spirits generally undergo by keeping, are pretty much the same as in wines; what the chemist would call slow saponifications occur, flavouring ethers are developed at the expense of the alcohol, hence old spirits and old wines are richer in complex ethers, and poorer in alcohols than new spirits or new wines. In whisky recently distilled it is possible to extract some greater or less quantity of fusel oil, whereas in mature whisky, the fusel oil or higher homologues of alcohol are diminished. These remarks are fully borne out by the D. W. D. whisky. The samples submitted are those of a very pure spirit, of fine flavour, and of strengths varying from 7·8 to 15·7 per cent. over proof; these strengths being of course diluted to the ordinary retail strength.

The distinction between Scotch and Irish whisky is simply one of flavour; good Scotch whisky can be distilled in Dublin, Irish whisky in Glasgow, and Messrs. James Saunders and Co., of 15, Charlotte Street, Fitzroy Square, exhibit quite impartially their well known old blended (O.B.) Scotch and Irish whiskies. Our examination proves that they are examples of pure genuine spirits, and to be highly commended.

A sample of the much advertised Glenrosa whisky (Messrs. Merritt and Co.,) is also before us, and those who like a genuine spirit with a highly developed flavour, should try it.

A last word as to the wide-spread belief in the adulteration of spirits. The sale of immature improperly blended spirits not unfrequently produces headache and other evils among the consumers, and they at once rush to the conclusion that something deleterious has been designedly added; but so rare is this the case that out of 2,000 samples analysed annually by the public analysts, in only isolated instances has any adulterant save that of water been discovered, and the addition of fusel oil or acids to whisky is not supported by convictions, the only evidence of its existence being the loose statements of platform speakers, and certain popular journals.

Erratum.—By an oversight in last week's issue, the peculiar dish described at the Chinese dinner at the Health Exhibition, as "Bêche de Mer," is said to be "*Helianthus*" of the naturalist. It should have been "*Holithuria*," which is the generic name of the Sea Slug, or Sea Cucumber, also called "Trepang," species of which are not unknown on our own coasts. "Helianthus" is the sunflower, the seeds of which are sometimes also eaten in the same way as the "Lotus" seeds.

GENERAL CORRESPONDENCE.

REMOVAL OF THE UTERINE APPENDAGES FOR MYOMA.

[To the Editor of the Medical Times.]

Sir,—It is fortunate for my critic, "An Anatomist," that he has concealed his identity under a *nom de plume*, as otherwise his letter would have covered him with ridicule. If he does not know that a tumour ten times the size of one three inches in one diameter by four in another would not form a tumour thirty inches by forty, he needs to go back to school for a training in elementary mathematics.

In answer to my other critic, "F.R.C.S.," I need only say that as I did not publish the case as one of enterotomy for intestinal obstruction, I did not enter into the details of the second abdominal section. I shall do so in the proper place.

May I say further, that if this discussion is to be continued I cannot reply to any further letters till my return from America in October.

I am, &c.,

LAWSON TAIT.

P.S.—I have just had a report on the tumour from Mr. Frederick Eve, in which it is said: "The greatest circumference of the uterus and tumour was 8¼ inches. The anterior wall of the uterus was occupied by an interstitial

fibro-myoma of spherical form, and 2¼ inches in diameter." The statement of "An Anatomist" is therefore as untrue as his idea of globular capacity is defective, and I fear the misstatement was intentionally made for mere purposes of mischief.

L. T.

A SHRUNKEN MYOMA.

[To the Editor of the Medical Times.]

SIR,—I have no personal interest in the questions now pending between Mr. Lawson Tait and his critics; but, in justice to the multiplication table, may I point out that "An Anatomist," in your issue of last week, has scarcely stated his case fairly. Ten oranges, though each were four inches across, could be made to form a mass forty inches in diameter only by placing them side by side in a straight row, in which case, the other diameter of the "body" so constructed would not exceed four inches. Again, if ten oranges, each measuring "three inches in one diameter, and four inches in the other," were combined so as to form "a tumour measuring forty inches by thirty," this "tumour" must be pancake-shaped, and of a thickness almost infinitesimal. And, finally, if ten such oranges were agglomerated into a sphere, the diameter of that sphere would be something less than six inches. In other words, ten cubic inches (which will be admitted to represent a bulk ten times as great as one cubic inch) is not the same thing as ten inches cubed.

I am, Sir, yours faithfully,

ARITHMETIC.

MEDICAL NEWS.

UNIVERSITY OF LONDON.—Intermediate Examination in Medicine.—Pass List.—Entire Examination.

First Division.—Sidney Robert Alexander, Guy's Hospital; Kaikhosro Nasarvanji Bahadurji, University College; Wilfred Balgarnie and Edward Henry Biddlecombe, St. Bartholomew's Hospital; John Rose Bradford, B.Sc., University College; William Henry Breffit Brook and Frederick Nathaniel Brown, St. Bartholomew's Hospital; Frédéric François Burghard, Guy's Hospital; John Shaw Willes Chitty, Charing Cross Hospital; James Jackson Clarke, St. Mary's Hospital; William Frederick Clarke, Guy's Hospital; William Barltrop Featherstone, Queen's and Mason Colleges, Birmingham; Thomas Arthur Helme, University of Edinburgh and University College; Thomas William Pelham Lawrence, University College; Arnold Lyndon, St. Bartholomew's Hospital; Henry John Macevoy, B.Sc., St. Thomas's Hospital; Ernest Paul Alphonse Mariette, King's College; George Rowell, Guy's Hospital; John Anderson Smith, St. Bartholomew's Hospital; James Edwin Thompson and William Henry Tomlinson, Owen's College; John Herbert Tonking, St. Thomas's Hospital; Frederick Sherman Toogood, University College; Edmond Fauriel Trevelyan, St. Bartholomew's Hospital; James Wheatley, King's College.

Second Division.—John Wallwork Ashworth, Owen's College; Wilfred Martin Barclay, Bristol Medical School; Robert Alfred Bindley and Henry John Blackler, Guy's Hospital; Henry Claxton Bowman and Walter Henry Brazil, Owen's College; Herbert Henry Brown, University College; Arthur William Burrell, London Hospital; Bernard Castle, Arthur Holdsworth Davis, and Leonard Charles Talbot Dobson, St. Bartholomew's Hospital; William Henry Wilson Elliot, Guy's Hospital; Bryan Furnivall and William Thomas Gardner, St. Bartholomew's Hospital; Arthur Henry Gault, Owen's College; Frederick William Gee, University College; Albert Edward Godfrey, St. Thomas's Hospital; Duncan McBean Greig and Julius Hamel, University College; Philip Henry Hensley, King's College; Sydney Ernest Holder, University College; Walter Ross Jordan, Queen's and Mason Colleges, Birmingham; Otto Jackson Kauffmann, Owen's College; Albert Lindow, King's College; Arthur Pearson Luff, B.Sc., St. Mary's Hospital; Henry Grabham Lys, London Hospital; Robert Lee Moore, Queen's College, Belfast; John Ernest Nevins, Guy's Hospital and Liverpool School of Medicine; Trayton Charles Pagden, St. Bartholomew's Hospital; William Permewan, University College; John Williamson Pugh, London Hospital; William Halse Rivers Rivers, St. Bartholomew's Hospital; Charles Frederick Seville, Owen's College; Hugh Smith, Guy's and London Hospitals; Ernest Solly, St. Thomas's Hospital; Walter George Spencer, St. Bartholomew's Hospital; Charles Edward Sunder, University College; Walter Carless Swayne, Bristol Medical School; Samuel Walton Wheaton, St. Thomas's Hospital; James Atkin Wheeler, Guy's Hospital; Charles Wheeler Forest Young, St. Bartholomew's Hospital.

Exeluding Physiology:—

First Division—Henry Ernest Hill Smith, King's College.

Second Division—Albert Green, Guy's Hospital; William Harry Kelson, London Hospital; Charles Pye Oliver, Charing Cross Hospital; William Newt Risdon, Guy's Hospital; Arthur Hastings Lanfear Stewart, St. Mary's Hospital.

Physiology only:—

First Division—George John Eady and Charles Henry Taylor, King's College; Walter Essex Winter, Middlesex Hospital.

Second Division—Charles Kingsley Ackland, King's College; Reginald Muzio Williams, St. Thomas's Hospital.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 7th inst., viz.:—

Messrs. Harman Visger, L.S.A., Clevedon; H. E. H. Matthews, L.R.C.S. Edin., Longsight, Manchester; H. J. C. Godfrey, L.R.C.P. Edin., Lee Park, S.E.; Henry Waite, L.R.C.P. Edin., Leeds; L. J. Shepherd, L.R.C.P. Edin., Torquay; C. S. Spong, L.S.A., Clapham; A. Y. Reily, L.S.A., South Norwood Hill; W. H. Hodge, Middletou, Tamworth; and C. E. Dumbleton, L.S.A., Tasmania.

The following gentlemen passed on the 8th inst., viz.:—

Messrs. J. H. Greenway, L.S.A., Belvedere, S.E.; W. J. C. Tomalin, L.S.A., Northampton; Frank Hinds, L.S.A., Goudhurst; C. E. Humphreys, L.S.A., Llanfair; C. W. Low, L.R.C.P. Lond., Plumstead; J. S. Robertson, L.S.A., West Kensington Park; S. G. Allen, L.R.C.P. Edin., Maida Vale; T. A. Evans, L.R.C.P. Edin., Clapham; and James Milner, L.R.C.P. Edin., Barnsley.

Three hundred and fifty-two candidates presented for the examinations just completed, as compared with two hundred and seventy at the corresponding period of last year. With this meeting the examinations for the present session were brought to a close.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, 7th inst.:

Howard Decimus Buss, 37, South Hill Park, Hampstead; Jno. Walter Carr, 40, Bloomsbury Square; William Joberus, Aldridge, Walsall; William Tratman Wallington, 3, Kimpsford Road, S.E.; Charles Stuart Spong, Clapham, S.W.; Harman Visger, 219, Brompton Road.

The following gentleman also on the same day passed the Primary Professional Examination:—

Jno. Oliver Pemberton, of London Hospital.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—*Double Qualification.*—The following gentlemen passed their first professional examination during the recent sittings of the Examiners:—

Reinhard Johann Reinecke, Cape of Good Hope; John Cram, Dollar; Walter Benjamin Garvin, Colombo; John William Fawcitt, Yorkshire; Herbert Henry Wild, Weston-super-Mare; Edward Kershaw, Yorkshire; Arthur Masy Fraser, Colchester; Alfred Henry Pearson, Ireland; James Samuel Reynolds, Wexford; Digby Francis Baynes Cotes, Wiltshire; Robert Marr, Randalstown; Thomas James Walker, Yorkshire; Abraham Haynes, Cork; Edward Joseph Brady, Westmeath; Andrew Craig Hunter, Glasgow; William James Coppinger, Midleton; John Richard Hinkson, Dublin; Robert Enwraight Lauder, Dublin; Henry Benson Goulding, Dublin; John Sudlow Swindell, Kingston; William Henry Fordham, Fiji; John Joel Mason, Bollington; William McCoull, Ovington; Alan Joseph, Ceylon; Arthur Joe Rollinson, Kirton in Lindsey; Bartholomew O. Regan, County Mayo; Fennell Evans, Cork; Alfred Owen Davies, Barmouth; William Overton, York; William John Evans, County Limerick; John McClymont, Ayr; Edward Johnson Williams, Dublin; Cornelius Joseph O'Donnell, Kilkenny; William Shaw, Plandmagee; Bhou Nath Basw, Bengal; James Butler, Tipperary; Charles Wesley Withinsham, Nantwich; Adolphe Frederick Sedameyer, London; Richard Joseph Tristan, Roscommon; Charles Wicks, Maxwelltown; Karl Randolph Marx, Germany; Edward Ratcliffe Fidler Maso, Derbyshire; Charles Chambers, Wales; James Thomas Moore Giffen, Belfast; William John Robertson Dunn, Liverpool; George Bowar, Macclesfield.

The following gentlemen passed their final examination, and were admitted L.R.C.P. Edinburgh and L.R.C.S. Edinburgh:—

Edward Muscroft Taylor, Scarborough; Arthur Wyndham Martin, Shropshire; Henry Bennett, Staffordshire; Samuel Alexander McKeague, Ontario; George Alder Blumer, Sunderland; William Edward Sprague, Belleville; James Johnston, Huntly; George Franklin Shiels, San Francisco; Frederick John Clendinnen, Melbourne; Duncan Clark, Argyllshire; William Alexander Warters, Ripon; Edward James Sheppard, Warburton, Sussex; Joseph Henry Zepero, Trinidad; Joseph Gillis Wynne, Armagh; James David Black, Cockburn's Path; Robert Lloyd Legate, Queen's County; Major Henry Court Irving, Allahabad; Alfred Ernest Weighiman, Liverpool; Joseph Fitzgerald, Limerick; Benjamin David Craigie Bell, Shetland; Horace Smith, Cambridge; Johnstone Delavil John Harris, Australia; James Hindle, Accrington; Louis Vallee, Paris; John Paterson, Glasgow; Francis Sidley Edgar, County Kildare; William Bowie Barclay, Kilwinning; James Alexander Hutchinson, Montreal; Oran Merton Belfry, Ontario; William Porteous, Ontario; Robert Ovens, Ontario; James Rose, County Carlow; James Bernard Wall, Shustoke; Charles Edwin Solomon, Penryn, Cornwall; Alexander Stewart Thompson,

London, Canada; Eli Thomas Eade, Kingsville, Canada; Robert John Draper Hall, Poona, India; Samuel Wilbraham Griffith, Pwllheli, N. Wales; Daniel Joseph Patrick MeNabb, Greenock; Patriek Gill Griffith, County Mayo; John Herbert Staey, Norwieh; Riehard Crawshaw Holt, Acerington; William Henry Clark, Aylesbury; Johu William Ridley, Wallsend-on-Tyne; James Wallaee Moore, Coleraine; James Mungle, West Calder; Walter Eyre Lambert, South Carolina; Benjamin George Broek, Caithness; Edward Mortimore Smith, Glouecstershire; Charles Thomas Blaekwell, London; Benjamin Allen Maturin, Lymington, Hants; Henry Aked Pearson, Roehdale; John Frederiek Sturroek, Montrose; William MeDermott, Ballymoney; Samuel Burnside Boyd Keers, Ballymoney; Charles Hawkins Copley Woodhead, Thirsk; Riehard Harrison, Yorkshire; Edward Rateliffe Fidler Mason, Derbyshire; Edward Kershaw, Saddleworth; Robert William Felkin, Beeston.

Royal College of Surgeons, Edinburgh.—During the July sittings of the Examiners, the following gentlemen passed their final examination, and were admitted L.R.C.S.E:—

Samuel Ebenezer Johnson, Newport, Isle of Wight; John Tingle Butterworth, Coventry; Alfred Leaeh, Hants; Edwin Alfred Bennett, Dublin; John Andrew Webb, Leitrim; William Knott, Oldham; James Edwin Cheyne Wilson, Devonport; William Frederick Abbot, County Cork; George Dall Orroek, Edinburgh; Alfred James William Keenan, Melbourne; Alexander Gordon, Dublin; Robert Alexander Lundie, Birkenhead; Perey Meredith Earle, Brentwood.

The following gentlemen passed their first professional examination for the Licence in Dental Surgery:—

Benjamin John Douthwaite, London; Thomas Prittie Ritehie, Edinburgh; David Browne, Montrose; William Hopper Harrison, Guiana; and Andrew Burns, London; and James Main Nieol, London, passed his final examination, and was admitted L.D.S. Edinburgh.

Good *v.* Whittle and Others. — At the Liverpool Assizes, Mr. Justice Cave and a special jury were occupied for five entire days in hearing this case. The plaintiff was a Mrs. Mary Good, and the defendants were Drs. Ewing Whittle, Glynn Whittle, and Hutcheson, of Liverpool, and Dr. Mold, Superintendent of the Public Lunatic Asylum at Cheadle. The alleged libel and conspiracy consisted in certifying her as a lunatic on October 29th, 1882, when she was quite sane, and in detaining her in an asylum. Mrs. Good had been previously in the asylum, from 1877 to 1880. During that time she frequently petitioned the Lunaey Commissioners for her release, but an inquisition held on her pronounced her of unsound mind and incapable of managing her affairs. In August, 1880, after repeated examinations by the Lunacy Commissioners into her state of mind, she was at last released on probation with the consent of her brother. There seems to have been no doubt of her insanity at this period, as she was habitually dirty and undressed, and possessed the delusion that her brother was squandering her money, and that her friends as well as the Roman Catholic hierarehy were leagued against her, to keep her children from her, &c. This state of mind was the result of drink, and of low thoughts and habits frequeutly indulged in. In March, 1881, Dr. Ewing Whittle was asked by plaintiff's brother, a Mr. Edwards, to see her for the first time. Dr. Whittle considered her eccentric, but not sufficiently insane to warrant the restraint of an asylum. Soon afterwards she committed bigamy, by marrying a man much beneath her in social position, whilst Mr. Good was still alive, and in consequence of this erime she was arrested by the police. Her brother, Mr. Edwards, who seems to have acted very kindly and considerately all through, got her released on the plea of insanity, and Drs. Whittle, father and son, were called in to certify to her state of mind. Dr. Hutcheson saw her at the request of Dr. Glynn Whittle, so as to support their opinion, as a rumour had reached the certifiers that a lawyer was taking up the patient's case. On these certificates she was again sent to Cheadle, under Dr. Mold's care. The certificates were not considered strong enough by the Lunacy Commissioners, even after their amendment by the certifiers, and in consequenee of this she was discharged on a lunaey order, December, 1882. Next day she was re-examined and recommitted to the asylum, on the certificates of Drs. Renaud and Braddon, and detained there till March 10th, 1883. Two Commissioners then examined her, and although they were not satisfied as to her sanity and veracity, she was discharged on probation, and her solicitor took her away. The evidence for the plaintiff consisted in her own statements, and in general statements of belief in her sanity by the greengrocer and his wife, the dressmaker, domestic servant, and the rent-collector of the plaintiff. Drs. Warburton and Utting, of Liverpool, had seen her occasionally and thought her sane, whilst Dr. McMillan, of Liverpool, and Dr. Hefferman, of St. Helen's, came to the conclusion, from their examination of her at Cheadle, just before her discharge in 1883, that she was sane. From the evidence of Drs. Whittle (father and son), Drs. Hutcheson, Braddon, Renaud, and Mold, the plaintiff was still possessed, in October and December, 1882, by the delusion that her property was being squandered by her brother (who has since died). This was proved to be a delusion at the trial, as all the accounts were quite correct, and not only so, but the brother had assisted to keep her out of his own means when in the asylum. The weak points in the defendants' case consisted in the insufficient certificates and the close alliance in interests of the certifiers, father and son. The latter point was corrected to some extent by the presence of Dr. Hutcheson, an old experienced practitioner. The judge in summing up said that he felt inclined to agree, that the possibility that a person might be shut up on the certificates of two medical gentlemen who had attained the age of 21 years was startling, and one was sorry that that was the state of things; but the remedy for that was legislation. It is also startling, from the medical aspect, that a medical man may, after the greatest exercise of care and skill, be exposed to the necessity, expense, and inconvenience of defending himself from the charge or suspicion of illegally assisting in incarcerating a sane individual. It is pleasant to have to state that in this case the jury returned a verdict for the defendants on all the counts of the indictment. Probably the doctors are now sorry that they saved Mrs. Good from the punishment due to her adultery and bigamy. At any rate, it would be well for ordinary medical men in such cases to let the law take its course, unless the insanity be very pronounced; for persons of the type of Mrs. Good suffer as much from wickedness and depravity as from insanity, and they will turn on their best benefactors just as she did upon her brother. More for the medical profession than the public is it necessary that the law should be changed. That medical men have hitherto exercised this great power without any serious abuse, is one of the greatest compliments that could be paid to the profession. If, however, vexatious consequences frequently follow a careful exercise of certifying functions, then all wise medical men will do well to let the public manage their lunatics as they wish, and to refuse to certify until they are guaranteed freedom from assaults afterwards on their character and their purse.

Naval Medical Department.—The following appointments were announced on August 11th: Staff Surgeons—William H. Stewart, to the *Clyde;* Alfred G. Delmege, to the *St. Vincent;* Henry T. Cox, to the *Canada;* Horace E. H. Cross, to the *Cambridge.* Surgeons — Jeremiah Sugrue, to the *Watchful;* Alexander G. P. Gipps, to the Haslar Hospital; Donald S. Gunn, to the *Canada.* In accordance with the provisions of Her Majesty's Order in Council of 1st April, 1881—Fleet-Surgeon Donald Maclver, M.D., has been placed on the retired list.

The Radcliffe Infirmary.—A petition has been presented to Her Majesty in Council by the Earl of Jersey and others, and the Chancellor, Masters, and Scholars of the University of Oxford, praying for the grant of a charter for the incorporation of the President and Governors of the Radcliffe Infirmary, Oxford. The petition has been referred to a Committee of the Privy Council, by whom it will be considered on the 25th of September.

Handsome Legacies.—The following are among the public bequests of the late Mr. Alex. Martin, Ochilview, Southfield, Stirling: Stirling Royal Infirmary, 500*l.*; Glasgow Royal Infirmary, 1,000*l.*; Glasgow Western Infirmary or Hospital, 1,000*l.*; Liverpool Royal Infirmary, 1,000*l.*; Liverpool Northern Hospital, 500*l.*; Liverpool Southern Hospital, 500*l.*

Died in Harness.—Dr. Donald Cochrane Campbell, Medical Superintendent of the Essex County Lunatic Asylum, died on Friday evening, in the 65th year of his

age. He had been superintendent of the asylum from the date of the opening of the institution in 1853, and had held the appointment for the long period of 31 years.

Queen's College, Edinburgh.—A petition has been addressed to Her Majesty in Council by Dr. Henry J. Littlejohn and others, praying that a charter of incorporation may be granted to the Queen's College, Edinburgh, and has been referred to a Committee of the Privy Council, by whom it will be taken into consideration on the 25th of September.

The late Sir Erasmus Wilson.—The remains of this lamented member of our profession were interred on Wednesday last, the 13th instant, at Swanscombe, Kent, the parish church of which it will be remembered he restored, at his sole expense, in 1873. It is stated that the College of Surgeons, as residuary legatees, will come in for about £180,000.

Cooking Castor-Oil.—The French method of administering castor-oil to children is to pour the oil into a pan over a moderate fire, break an egg into it and stir up. When it is done, flavour with a little salt, or sugar, or currant jelly.

American Medical Novelists.—A novel from the pen of Dr. Weir Mitchell, founded upon events which occurred in the American War, is now publishing in the *Atlantic Monthly*. And, according to the *New York Medical Record*, Dr. W. A. Hammond, who held the post of Surgeon-General during a large portion of the American War, announces that he has four novels written, and intends hereafter to publish two a year. He states that he would rather be a novelist than a doctor, and thinks that it is time that medical men gave, in a literary way, some of the results of their rich and peculiar experience with human nature.

Medical Sickness, Annuity, and Life Assurance Society.—The first general meeting of this society, which has recently been established to enable members of the profession to secure for themselves payments in times of sickness, annuities in old age, and certain sums at death, was held recently in the Greek Lecture-room, Queen's College, Belfast. The report of the committee stated that nearly 500 members had joined during the first quarter, that there was an available cash balance on the 30th of June last of 1,434*l.* 16*s.* 3*d.*, and the present premium income of the society 5,500*l.* per annum, an amount which it was anticipated would be rapidly increased. The report and accounts were adopted after a short discussion, and a code of rules presented by the committee accepted. It was also resolved to register the society under the Friendly Societies' Act.

The Apothecaries Hall.—The following gentlemen have been elected examiners by the Society of Apothecaries for the ensuing year, viz., Henry Bullock, F.R.C.S., Esq.; Alfred Carpenter, M.D., University of London; Henry R. Crocker, M.D., University of London; Robert Fowler, M.D., University of Edinburgh; F. de Havilland Hall, M.D., University of London; Frederick J. Hensley, M.D., University of Cambridge; Robert J. Lee, M.D., University of Cambridge; W. Withers Moore, M.D., University of Edinburgh; George H. Savage, M.D., University of London; John S. Stocker, M.D., University of London; John C. Thorowgood, M.D., University of London; Francis Warner, M.D., University of London.

Collegiate Statistics.—Perhaps the following results of the examinations for the diploma of membership of the Royal College of Surgeons, which were brought to a close on the 8th instant, will be read with some interest by metropolitan and provincial teachers and members of the profession generally:—There were 352 candidates as against 270 the corresponding period last year. Taking them in numerical order—St. Bartholomew's sent 53 candidates, University College 39, Guy's 27, St. George's 23, King's College 19, St. Thomas' 15, London 15, Charing Cross 13, the Middlesex 13, St. Mary's 12, and the Westminster 11. The provincial schools were represented by—Manchester 24, Cambridge 13, Leeds 11, Birmingham 8, Bristol 8, Liverpool 7, Newcastle 5, and Sheffield 3. Edinburgh and Glasgow sent respectively 21 and 4, Dublin 3, Madras 2, Calcutta 1 and Bombay 1; McGill, Montreal, 3; Toronto 2 and Amsterdam 1. Of the 352 candidates, 60 passed in Surgery, and when qualified in medicine and midwifery will be admitted Members of the College. Of those who failed to acquit themselves to the satisfaction of the Court of Examiners, 1 was referred to his professional studies for twelve months, 6 for nine months, 108 for six months, and 40 for three months, making a total of 155 rejected candidates out of the 352 who presented themselves. Of those who were admitted members, 81 held medical qualifications.

The Brompton Consumption Hospital.—A quarterly court of the governors of this charity was held on August 7th, Mr. T. P. Beckwith in the chair. From the report of the committee of management it appeared that since the annual court, both buildings, containing 331 beds, had remained fully occupied; but the committee were now about to close part of the older building for needful colouring and cleaning. The question of funds continued to be an anxious one for the committee, the expenses being increased to about 24,000*l.* a year by the opening of the extension building. There was only one bequest to announce—viz., the residue of the estate of the late Mr. Stallibrass, from which very little, if any, benefit was expected to accrue to the charity; but the sum of 1,500*l.* had been received from Mr. J. D. Allcroft, a friend of long standing, and a further donation of 250*l.* from Mr. and Mrs. Vertue Edwards, instead of a legacy. But for this assistance the committee would have been compelled to order a further sale of stock. Mr. H. Herbert Taylor had been appointed assistant resident medical officer. The number of in-patients admitted since the 29th of May was 287; discharged, many greatly benefited, 285; died, 59; new out-patient cases, 2,403.

Women as Pharmacists.—The *Philadelphia Medical News*, July 19th, states that Louisville has established the first school for educating women in pharmacy, and this has recently observed its annual commencement. The address delivered on the occasion by Dr. Yandell, contained some wise and practical remarks, informing the graduates that as they had entered into competition with men, they must expect just the same treatment that men give to their fellows:—"You have chosen to align yourselves with man, you have become his competitor for bread—his rival in work; look out for no other treatment than he gives his fellows. The lines of commerce are merciless, and true banking knows no friends." "This truth," the *News* observes, "is of great importance, and we sometimes think it is not sufficiently appreciated by those who enter this contest, whether in the professions or trades hitherto occupied exclusively by men. Undoubtedly woman possesses faculties which peculiarly adapt her to pharmacy, and her success she alone must determine. It is well that the experiment is being tried, for the just tendency of the time is to demand more and better paid work for women."

Activity of an Old Vaccine Crust.—A remarkable instance of the preservation of the activity of a vaccine crust is related in the *North Carolina Medical Journal*. A package of vaccine at some period between 1803 and 1825, was sent to the Hon. Willis Alston, which remained unopened until it fell into the hands of his grandson, Dr. Alston, in 1869. It was a crust embedded in wax and enclosed in a wooden box. Dr. Alston vaccinated his servant with a part of this crust, and "in due time," he writes, "it took effect, leaving a well-defined scar."

Weight in Relation to Life Assurance.—Dr. Seaverns read a paper upon this subject to the Massachusetts Medical Society (*New York Medical Journal*, June 21), in which he stated that among 974 deaths which had occurred in an assurance society during the last six years, he had found that 138 of the persons on their admission had weighed 15 per cent., and afterwards less, than the normal standard. From the details which he furnished, it appeared that the mortality among these persons had been large, and was in a great measure due to tuberculosis and other wasting diseases; and that this tendency was not manifested simply among those who were 20 per cent. lighter, but was also present in those not more than 15 per cent. less than the standard. In assurance societies it was

generally assumed that a variation of 20 per cent. might be allowed, without danger of incurring loss, but Dr. Scaverns felt satisfied that where a deficiency of even 10 or 15 per cent. existed, the risk must be looked upon as hazardous, or at least that the case should be thoroughly scrutinised and tested, to prevent the possibility of this deficiency being overlooked when it was only a symptom of constitutional disease, or an evidence of some pretubercular condition. A table was also presented of 122 from the same 974 deaths which occurred in persons who were 15 per cent., or more, above the standard weight when they joined the society; but this class was made up of much older men, who died from a different group of diseases to those which the other class had died of. With those who were not above 15 to 20 per cent. above the standard, the results were much more favourable than with the light weights in the same range; and it was not until the excess became from 20 to 25 per cent. that the mortality was large—and even with those above this rate, there was no such evident result of fatty degeneration or general cachexia as might have been anticipated. Deaths from cerebral and cardiac changes were prominent, as were also sudden deaths, but not so markedly as expected. In conclusion it may be stated, "that men, especially young men, who were deficient in weight, even when this was not more than 15 per cent., were more hazardous risks than those whose weights were 20 to 25 per cent. above the usual standard, and especially because of the great liability of the former to become phthisical—a tendency which need not be feared among the corpulent. Care, however, should be taken with the latter to see that the heart and kidneys were in a healthy condition, and that there was no hereditary tendency to cerebral disease."

Wood Wool.—Messrs. Essinger and Neuberger, of 11, Hatton Garden, desire us to state that they are the sole consignees for Hartmann's Wood Wool, which was noticed in our last number.

Erratum.—In the report of the Conference on School Hygiene, Mr. R. von Schweitzer is made to say that he had been a football player until he had passed his *sixteenth* (16th) year. It should have been his *sixtieth* (60th) year.

APPOINTMENTS.

Aldred, John Charles, L.K. and Q. Coll. P. Ire. L.F.P. and S. Glas.—Medical Officer to the Fourth District, Ecclesall Bierlow Union, *vice* Dr. Wm. McBeath, resigned.

Barling, H. G., M.B., F.R.C.S.—Demonstrator of Anatomy to Queen's Hospital, Birmingham.

Baron, B. J., M.B., C.M., Edin.—Physician to the Bristol General Hospital, *vice* G. F. Burder, M.D., F.R.C.P., resigned.

Benthall, W., M.B.—Honorary Physician to the Derbyshire General Infirmary.

Birch, de Burgh, M.D., F.R.S.E.—Professor of Physiology in the Yorkshire College, Leeds.

Carter, Thomas Edward, M.R.C.S. Eng. and M.B. Lond.—Medical Officer to the Stamford District and the Workhouse of the Stamford Union, *vice* T. M. Heward, deceased.

Dixon, J. R. L., M.R.C.S., L.R.C.P.—Junior House Surgeon to the Royal Southern Hospital, Liverpool, *vice* A. H. Gordon.

Gordon, A. H., M.R.C.S., L.R.C.P.—Senior House Surgeon to the Royal Southern Hospital, Liverpool, *vice* W. H. J. Sellers, M.B., C.M., resigned.

Greaves, C. A., M.B., LL.B.—Honorary Physician to the Derbyshire General Infirmary.

Greensill, Edward Samuel, M.R.C.S. Eng., L.R.C.P., Edin., and L.M.—Medical Officer to Witley District, Martley Union, *vice* Mr. J. N. Greensill, resigned.

Greensill, John Nicholas, M.R.C.S. Eng. and L.S.A. Lond.—Medical Officer to the Martley District, Martley Union, *vice* Mr. E. S. Greensill, resigned.

Hall, Thomas Lambert, M.R.C.S. Eng. and L.S.A. Lond. Medical Officer to the Dilwyn District, Weobley Union, *vice* Dr. Samuel Wilson, resigned.

Jones, Evan, L.R.C.P., L.R.C.S. and L.M. Edin.—Medical Officer to the Western District, Llandilofawr Union, *vice* Mr. W. L. Jones, deceased.

Kitchen, Charles Frederick Hewick, M.R.C.S. and L.R.C.P. Lond.—Medical Officer to the Cheetham District, Prestwich Union, *vice* Mr. R. Crean, resigned.

Knight, F., M.B., M.R.C.S.—Second House Surgeon to the Royal Southern Hospital, Liverpool, *vice* F. J. Allen, M.A., M.R.C.S., L.R.C.P., resigned.

Knox, Dr. D. N.—Surgeon to the Glasgow Royal Infirmary.

Ley, H. J., M.B., C.M., M.R.C.S.—Resident Surgeon to the Birmingham General Dispensary.

MacAlister, D., M.D.—Physician to Addenbrooke's Hospital, Cambridge, *vice* G. E. Paget, M.D., F.R.S., resigned.

Main, W., M.R.C.S.—Medical Officer to the Convalescent Home, Clacton-on-Sea.

Pringle, J. J., M.B., M.R.C.P.—Assistant Physician to the Royal Hospital for Diseases of the Chest, City Road, *vice* Dr. Coxwell, resigned.

Robertson, Dr. Alexander.—Physician to the Glasgow Royal Infirmary.

Strugnell, W. T., M.R.C.S., L.S.A.—Junior House Surgeon to the Metropolitan Free Hospital, *vice* A. S. Nance, M.R.C.S., resigned.

Turner, John Kemp, M.B. and M.C. Aberd.—Medical Officer to the First District, St. Columb Major Union, *vice* Mr. W. E. Fulford, resigned.

Wheeler, Daniel Martin Brumwell, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the Workhouse, Chelmsford Union, *vice* Mr. Daniel Wheeler, resigned.

Whitson, Dr. James.—Assistant Surgeon to the Glasgow Royal Infirmary.

Wilson, Edward, M.R.C.S. Eng., and L.R.C.P. Lond.—Medical Officer to the Downham District, Ely Union.

VACANCIES.

Charing Cross Hospital.—Chair of Physiology. (*For particulars see Advertisement.*)

Chesterfield Union.—Medical Officer to the Bolsover District, *vice* Mr. W. Wallace, resigned. Area, 9,211 acres. Population, 2,758. Salary, £21 per annum.

General Hospital for Sick Children, Pendlebury, Manchester.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

Royal United Hospital, Bath.—House Surgeon. (*For particulars see Advertisement.*)

St. Bartholomew's Hospital.—Dental Surgeon. Applications with Testimonials must be left, on or before September 4th, at the Clerk's office. Further particulars from Wm. Henry Cross, Clerk.

The General Hospital, Birmingham.—Resident Registrar and Pathologist. (*For particulars see Advertisement.*)

University College, London.—The office of Surgical Registrar in the University College Hospital will shortly be vacant. Applications and Testimonials to the Secretary, Talfourd Ely, M.A., on or before September 30th.

Victoria Dock District Dispensary, London, E.—Assistant Resident Medical Officer. Salary, £120, to commence, with furnished rooms, coals, gas, and attendance. Candidates must be qualified and registered. Applications, accompanied by six or less recent testimonials, to be addressed to the Secretary, and marked on the outside A. R. M. O., not later than August 18th.

West London Hospital, Hammersmith.—Registrar and Pathologist. Honorarium of £25 per annum. Applications by Aug. 21st.

DEATHS.

Campbell, D. C., M.D., at Warley, Brentwood, Essex, on August 8th.

Harris, F. W., Surgeon-Major, late Bombay Army, at Torquay, on August 7th, aged 62.

Reid, A. W. W., Surgeon, Royal Navy, at 10, Madeira Road, Streatham, on August 13th.

Watson, Henry, F.R.C.S., late of Plumstead, on August 7th, aged 84.

Wilson, Sir Erasmus, F.R.C.S., at Westgate-on-Sea, on August 8th, in his 75th year.

NOTES, QUERIES, AND REPLIES.

SIR ERASMUS WILSON.

Let Science veil awhile her guiding light
And her true votaries bow the mournful head,
For lo! an earnest labourer lies dead—
The skilled Anatomist, the Surgeon bright;
Whose name revered a multitude shall bless—
The leprous throng, the tetter tainted train
That sought his potent aid, nor sought in vain.
His monument shall be: not even less
Than that which stood of yore by mystic Nile,
And his rich largess set on Britain's isle.

Clarence Fost

MEDICAL DIRECTORIES.

[to the editor of the medical times.]

Sir,—I heartily agree with the remonstrances of "F. R. C. P." contained in your last issue, against the ridiculous accumulation of memberships, appointments, &c., in the Medical Directory, and I would seriously urge on the Publishers of that useful volume to take the matter in hand at once, by entrusting the revision or expurgation of the text to a committee of men like yourself and two or three others, generally well informed as to the constitution

of the Universities and Corporations, and the Profession. Many medical men seem to be unaware that there are appointments which, though necessary to be held by some one, do not enhance, and may even detract from a man's professional status, being held, as a rule, only by an humbler, however personally respectable a class of practitioners: and there are honours which belong to one's professional infancy that may well be put away in later years with other childish things. I would excise all club appointments, all class medals and certificates, which in small schools mean next to nothing, and even in the larger not much. Again, when a man is a graduate, what is the use of adding that he is a member of convocation or of the general council of his university? Refereeships to insurance and benefit societies, too, are of no value, and are quite different from appointments as medical officers to the same. Surgeoncies to emigrant and other ships are rarely held by the *élite* of the profession, the P. and O., and a few like them excepted.

There are resident appointments, as those to lunatic asylums, which, as indicating special experience, are of lifelong value, but house surgeoncies, even at the great London hospitals, might be dropped after ten years or so, as they are by all men who have really attained high positions in the profession.

I have begun by erasing two such, as well as a dispensary appointment (honorary) which I held for fifteen years.

The bulk of the volume might thus be materially reduced, and room made for other matter of interest to the profession at large if thought fit.

I am, Sir, yours &c.,

M.B. (Lond.)

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—In your last issue I see a letter from "F. R. C. P." objecting to "Mr. A." or "Dr. B." appending to his name, in the Medical Directory, the information that he is a "member of the ——— Pathological Society, or the ——— Medical Chirurgical Society," on the grounds that "every respectable member of the profession can be admitted a member of our Local Medical Societies on payment of a guinea." That "every *respectable* member of our profession" can do so is certainly true, but the entrance to most of them is by proposition, seconding, and ballot; and the fact of a medical man being a member is, in the great majority of instances, some guarantee of the "respectability" before mentioned, and on these grounds I am of opinion that the information is useful, and not merely for self-glorification, as "F. R. C. P." would lead one to believe.

I fail to see either the "absurdity" of the practice, or the force of the parallel drawn in "F. R. C. P.'s" reference to "Mudie's."

Had "F. R. C. P." directed his tirade against such information as "Surgeon to the United Order of Pig-stickers," "Honorary Physician to the Stumpton Cycling Club," and the like, he would have found many sympathisers.

I am, Sir, yours &c.,

Leeds, August 11th, 1884. "ACHATES."

APPOINTMENTS FOR THE WEEK.

Friday, August 15 (*this day*).

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday, August 16.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, August 18.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, August 19.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Wednesday, August 20.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday, August 21.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

ON INFECTIOUS DISEASES AND VACCINATION FOR RABIES.[1]

By LOUIS PASTEUR.

Gentlemen,—In addition to the fact that they are meetings at which the most important problems of medicine are subjected to examination, Congresses also serve to indicate to posterity the chief directions of progress. Three years ago when the Congress met in London the microbe theory in its application to the ætiology of infectious diseases was still the subject of violent attack. Many who opposed themselves to advanced ideas persisted in maintaining that diseases exist "in us, from us, and by us."

One would imagine that those who hold that these diseases arise spontaneously, would in London have shown themselves eager to defend this thesis, but opponents to the doctrine that the principal cause of infectious diseases is an external one, did not venture to come forward, and discussion on this question was not even opened. In such an assembly as this, when all are prepared for a new triumph of truth, we see at length a way open for these men to give in to it.

For the rest, all clear-sighted men had foreseen that as soon as one would be able to show that the spontaneous origin of microscopic life was a chimerical hypothesis, and on the other hand that this microscopic life had relations to organic decomposition and fermentation, theories as to the spontaneous origin of disease would cease to exist. In like manner it is from the London Congress that another important advance dates its confirmation, namely, the possibility of attenuating the different viruses, varying their infectivity and preserving them by means of suitable cultures, and lastly, the application of this discovery to veterinary medicine. To the vaccine-microbes of fowl-cholera and splenic fever, one has been able to add others; and the animals that are protected against the attacks of fatal infectious diseases are now to be counted by hundreds of thousands. The violent opposition which this innovation has encountered will soon be swept away in the current of new ideas. Is the application of this new advance then to be confined in the future to the prevention of the diseases of animals? Besides the fact that one need never despair of a discovery and its fruitfulness, can we say that

[1] Address delivered at the International Medical Congress at Copenhagen, August 11th, 1884.

this question is already solved in its principal points? Splenic fever for example is common to animals and man; and we can say for certain, that if it were worth while, nothing would be simpler than to produce in man insusceptibility to this disease. The procedure which is successful in animals, would be applicable without modification so to speak. It would simply depend on one's proceeding with an extraordinary degree of caution, such as the life of an ox or a sheep does not require. Instead of vaccinating with vaccine of only the second degree, one could take three or four of variable virulence, till one chose the first weak enough not to cause the slightest symptom, but which would yet produce insusceptibility to the disease. In the case of human diseases the difficulties lie then, not in the application of the new prophylactic method, but rather in the knowledge of the physiological properties of the virus. To attenuate the virus to the proper degree, it is necessary to control our efforts by experiment; but the experiments which are allowable in animals are criminal when we have to do with man. In relation to the diseases which exclusively affect mankind, this is the chief cause of the difficulties of the investigation. Let me in the meantime remind you that the enquiry, of which we are speaking, dates so to speak from yesterday, that it has already been fruitful in results, and that we have a right to expect new advances when we obtain a closer acquaintance with the diseases of animals, especially those which attack both man and beast. It was the desire to penetrate further into this twofold knowledge which induced me to study rabies, in spite of the obscurity in which that disease was enveloped.

It is now four years since the study of rabies was first commenced in my laboratory, and it has been continued without any other interruption than the enforced cessations which depend on the conditions of the enquiry, conditions which are very unfavourable. The incubation of the disease is always of long duration. There are never sufficient facilities to enable one at a given moment to multiply experiments. In spite of these material hindrances, which however the French Government, in its care for the great scientific interests involved, has done everything in its power to remove, the experiments which we, my fellow-workers and I, have carried out, have nevertheless passed beyond the possibility of numbering them. To-day, gentlemen, I shall only describe the most recent results of our enquiries. Every disease, and especially such a disease as rabies, immediately makes one think of its cure, but to set oneself forthwith to search for remedies is to expose oneself to what is only too often a fruitless labour. It is in a manner to trust to accident for advance. Better is it to undertake in the first place to study the nature of the disease, its cause and development, in the distant hope of thereby discovering means of preventing it. If the problem of rabies is to-day no longer insoluble, it is to these last-named methods that we owe this advance. Thus we have proved that the virus of rabies always develops itself in the nervous system, in the brain, the spinal cord, the nerves, and the salivary glands, and never simultaneously invades every part. It may for example fix itself in the spinal cord, and then attack the brain; or one may find it in one or more parts of the brain and not in others.

If one kills an animal, when the disease is at its height, it is often difficult to find the virus of rabies at any given point in the brain or spinal cord, but we have fortunately discovered that in every case in which death occurs as a natural result of the development of the disease, the uppermost portion of the spinal cord, which forms the point of transition between the cord and brain, and which one calls *the bulb*, is invariably the seat of the poison. When an animal dies of rabies (and we know that the disease invariably ends in death), it is absolutely certain that one will be able to obtain from the animal's *bulb* rabies-virus, which will produce the disease by inoculation on the surface of the brain in the arachnoid cavity, after previous trephining.

If you take any street-dog you please and inoculate rabies in this manner by trephining, using as inoculating-material a portion of the bulb of an animal which has died of the disease, you will invariably convey rabies. The dogs to which the disease has been communicated in this manner are to be counted by hundreds. The method has never failed. The same operation has been performed on hundreds of guinea-pigs and on a yet greater number of rabbits, without a single failure.

These two remarkable results, the invariable presence of the virus in the bulb of animals dead of the disease, and the certainty that one can communicate rabies by inoculation in the arachnoid cavity are axioms firmly established by experiment and are of extreme importance. Thanks to the careful application and the so to speak daily employment of these criteria we were able to proceed with certainty in a study of such difficulty. But however solid this experimental basis may be, it is not in itself able to show us the way to a vaccination-method against rabies. In the present position of science to presuppose the discovery of a means of preventing infectious disease by vaccination —(1) one must have at one's disposal a virus which can exist in different degrees of virulence, the weakest of which may serve as a vaccine; (2) one must have discovered a method of producing these varying degrees of virulence. Hitherto science has known only one kind of rabies, that which occurs in dogs. All hydrophobia, in dogs, men, horses, cattle, wolves, foxes, &c., comes originally from the bite of a mad dog. Rabies never arises spontaneously, either in the dog or any other animal.

None of the instances on record of rabies occurring spontaneously are really authentic; I will add that in making this assertion I do not ignore the fact that there must have been a *first* case of rabies. To come forward with this kind of objection, when it is a question of solving the enquiry which engages us, helps no one, but touches a problem which even now is still inscrutable—the very problem of life. It is like answering one who should maintain that an ovum always originates from an ovum, but nevertheless that the first ovum must have originated spontaneously. Science, which knows itself, sees that it benefits nobody to argue about the origin of things; it sees that such origin for the moment at least lies beyond its province.

In short, the enquiry whether the rabies-virus can occur in different degrees of virulence like the virus of fowl-cholera, of splenic fever, &c., that is the first question to solve in order to arrive at the prophylaxis of hydrophobia. But how does one obtain the knowledge that there are various possible degrees of virulence in the virus of fowl-cholera? And to what signs does one have recourse to determine the strength of a virus which kills whenever it infects?

Does rabies present any symptoms to help us? No, these symptoms are very variable. They depend essentially on the brain or spinal cord, where the virus instantly concentrates itself and flourishes. The mildest rabies that occurs—for such does occur—may in another animal of the same species produce the most violent rabies. Can one then determine intensity by means of the duration of the incubation period? No, nothing is more variable. A mad dog bites several dogs; one of these goes mad after an interval of a month or six weeks, another after two or three months' interval, and so on. Further, nothing can be more variable than the duration of the incubation period, according to the various modes of inoculation. Does one never see hydrophobia now occur, and now fail to occur, after a bite or hypodermic injection under exactly similar circumstances in every other respect, whilst inoculation on the surface of the brain never fails, and the incubation period is in such case of proportionally short duration?

Nevertheless, it is possible to determine, with sufficient certainty, the strength of a rabies-virus according to the duration of the incubation, but on two conditions. One must make use of intracranial inoculation, and one must bear in mind that the manner in which inoculation takes place furnishes one of the most powerful sources of irregularity in the results according as inoculation is by bite, by hypodermic or intravenous injection. The duration of incubation may really depend very much on the quantity of active virus, that is, the virus which reaches the nervous system without diminution or change. Notwithstanding that the quantity of virus which will produce rabies may be, so to say, infinitely small—it has been shown that, as a general rule, hydrophobia occurs in consequence of a bite, whereby the quantity of virus introduced into the body must generally be so small as to be almost indefinable—it is easy to double the length of the incubation, simply by taking a still smaller proportion of the small quantity inoculated. I will quote some examples:—

On May 10th, 1882, there were introduced into the popliteal vein of a dog ten drops of a fluid, which had been obtained by macerating in three to four times its weight of sterilised broth a portion of the bulb from a dog, which had died of rabies after being found in the streets in a mad condition.

A second dog was inoculated with a hundredth part of the quantity, and a third dog with a two-hundredth. The first dog was seized with rabies after an incubation period of 18 days, the second after 35 days, the third remained unaffected, *i.e.*, in this last case, and by the method of inoculation used in this experiment, a certain quantity of virus proved insufficient to produce rabies. This last dog was susceptible of rabies, as all dogs usually are, for it was again inoculated on September 3rd, 1882, and was seized with rabies 22 days later.

I take another example, which occurred in rabbits, and in which another mode of inoculation, viz., trephining, was employed:—The bulb of a rabbit, which had died of rabies after inoculation with a very virulent virus, was dissolved in two or three times its bulk of sterilised broth. After it had been allowed to stand for some few seconds, two drops of the supernatant liquid were inoculated into a rabbit by trephining, another was inoculated with a fourth of that quantity, and other rabbits were subsequently inoculated with $\frac{1}{16}$th, $\frac{1}{64}$th, $\frac{1}{128}$th, and $\frac{1}{512}$th of the same quantity respectively. All these rabbits died of rabies, and the length of incubation was eight days in the first, nine in the second, ten in the third and fourth, and twelve to sixteen days in the two last. This variation in the period of incubation was not occasioned by an attenuation of the actual virulence of the virus, such as might be produced by solution; for there was a return to the eight days' incubation period if fresh rabbits were inoculated with the virus obtained from these rabbits after death. We see from these examples that in the case where rabies is produced by a bite, or by hypodermic injection, interference with the length of the incubation period must be chiefly ascribed to the great variation which is possible in the amount, always indefinite, of inoculated poison which reaches the central nervous system.

If then we wish to determine the intensity of the virus from the length of the incubation period, it is unavoidably necessary to have recourse to inoculation by trephining, which is absolutely certain in its effects, and to employ larger quantities than such as would be necessary simply to produce rabies. When we operate in this way, irregularities in the length of incubation with the same virus will show a tendency to entirely disappear, because we always obtain the maximum of effect which the virus can produce; that maximum corresponding to the minimum duration of incubation.

Thus we have at length obtained a method which has enabled us to enquire into the possible existence of varying degrees of virulence, and to mutually compare them. The only secrets in this method, I repeat, are to inoculate by trephining, and to use a quantity of virus, which, although very weak, is more than sufficient to produce rabies in and by itself. This method eliminates the causes which might interfere with the duration of the incubation period, and makes it dependent exclusively on the activity of the virus, the comparative strength of which varies according to the minimum duration of incubation, which is determined by its effect.

The first application of this method was in connection with the study of rabies, and expressly in connection with attempts to discover if rabies is always one and the same, only with such differences as the varying nature of different kinds of dogs might produce. Let us then take wandering mad dogs at any season you please in the same year, or in different years, and belonging to the most different varieties. Let us in each case isolate the bulb, and, with the material obtained from it, inoculate by trephining from one to

two rabbits, using two drops of the fluid obtained by macerating the bulb in two or three times its bulk of sterilised liquid ; all proper cleanliness being observed. Let the inoculation be performed with the help of a Pravaz' syringe, somewhat bent at the end, introducing it through the dura mater into the arachnoid space. The following will be observed :—In all the rabbits, no matter what mad dog was used to inoculate them from, the incubation period will fall almost without exception between the twelfth and fifteenth days—you will never meet with an incubation period of eleven, ten, nine, or eight days ; though you may sometimes meet with periods of several weeks or several months.

Rabies thus clearly enough possesses one poison only ; its modifications, which however are very limited, depend simply on the known difference in the susceptibility of various kinds of dogs. But we shall now see a very marked change in the virulence of rabies-virus.

Let us take after death one of the numerous rabbits which we have inoculated with the virus taken from a mad dog, and let us introduce two drops of its bulb, prepared in the way given above, into another rabbit, whose bulb again shall serve to inoculate a third rabbit, and its bulb again to inoculate a fourth, and so on. You will then observe, even from the first transmission, a diminution in the incubation period in the various rabbits. I will give an example :—

In the last month of 1882, fifteen cows and one bullock died of rabies on one farm near Melun, a principal town in the Department Seine et Marne, in consequence of having been bitten, on October 2nd, by the farm-dog, which had gone mad. The head of one of the cows, which died on November 19th, was sent to the laboratory of M. Rossignol, a veterinary surgeon at Melun. Numerous experiments, performed on dogs and rabbits, showed that only the following parts were the seat of the virus, viz., the cerebrum, bulb and cerebellum, the frontal and temporal lobes. The rabbits which were inoculated from these parts were seized with the disease on the seventeenth or eighteenth day after inoculation. With the bulb taken from one of these rabbits after death, two other rabbits were inoculated, one of which was attacked by the disease on the fifteenth day, and the other on the twenty-third day after inoculation. I will observe once for all, that if we transmit rabies from one animal to another of a different species, before the virus has reached its maximum in the former, considerable irregularity is met with in the duration of the incubation period. We have here an instance of this, for the same virus in one rabbit gave an incubation period of fifteen days, and in the other one, of twenty-three days, though all the other conditions were apparently similar.

With the bulb taken from the former of these two dead rabbits, two other rabbits were inoculated. In one of these the disease appeared after an interval of ten days ; in the other after an interval of fourteen days. The bulb of the former of these was in like manner used to inoculate two more rabbits, in whom the disease appeared after intervals of ten and twelve days respectively. In the fifth transmission to two rabbits the disease appeared in both after eleven days' interval, in the same manner in the sixth transmission the disease appeared after eleven days' interval, in the seventh after twelve days' interval, in the eighth after ten days' interval, in the ninth also after ten days' interval, in the tenth after nine days, in the eleventh after eight days, in the twelfth after nine days, and so on, with variations of not more than twenty-four hours at the outside right down to the twenty-first transmission, when rabies appeared after eight days' interval ; the same interval of eight days was obtained in further transmissions, down to the fifteenth, which has recently taken place. This series of experiments which commenced on the 19th November, 1882, is still in progress.

Allow me at this point to draw your attention to the extreme certainty and facility which characterises trephining and subsequent inoculation with rabies-virus : for on every twelfth day for a period of about twenty months a succession of rabbits have been trephined and inoculated with a rabies-virus procured from a single individual, and that without any interruption in the success of the experiments.

Guinea-pigs most rapidly attain the maximum virulence peculiar to them. In these animals the incubation period, which varies and is irregular at the beginning of successive transmissions, quickly attains a definite duration of five days. Seven or eight transmissions from guinea-pig to guinea-pig brings us to the maximum virulence. Moreover, both in guinea-pigs and rabbits, one observes according to the origin of the virus variations in the number of transmissions required to obtain the maximum virulence. If we transmit this maximum degree in rabbits and guinea-pigs to dogs, we obtain a virus which far surpasses in virulence that of the rabies which is commonly met with.

But I hasten to say, that whatever may be the usefulness of the discovery which I have just described, there exist and can be produced different kinds of rabies—all of which are more violent and kill more rapidly than the rabies which occurs in dogs. Scientific men overlook nothing which can be discovered in the field of science ; but many whom the very thought of rabies strikes with fear look for something more than scientific curiosities. How much greater interest would man have in becoming acquainted with a rabies-virus which had been attenuated in its virulence! One then might cherish a hope of obtaining a vaccine from the rabies-virus, such as we have obtained in fowl-cholera, splenic fever and even acute septicæmia. Unfortunately the methods of procedure which were used in regard to these poisons proved themselves inapplicable in dealing with the virus of rabies. It therefore became necessary to try new and independent methods, for instance, cultivation of the rabies-virus in glass.

Jenner was the first to propound the idea that the poison which used to be called "grease" in horses, but which we now more accurately describe as "horse-pox," must be attenuated in its poisonous activity, if I may use the expression, by being transmitted through cows, before it could be introduced without danger into the system of man. This induced us to think it might be possible to attenuate the rabies-virus by passing it through the bodies of certain animals. Many attempts were made, but in the majority of the experiments on

animals, the poison increased in virulence, just as in rabbits and guinea-pigs ; fortunately this was not so in the case of monkeys.

On December the 6th, 1883, the bulb of a dog, which was known to be mad from the fact that a child which it had bitten had died of hydrophobia, was used to inoculate a monkey by trephining. The monkey was attacked with rabies eleven days later; from the first monkey the virus was transmitted to a second one, which was also attacked with rabies after eleven days' interval. In a third monkey rabies declared itself after an interval of twenty-three days, and so on. With the bulb of each of these monkeys two rabbits were inoculated by trephining. The rabbits which were inoculated from the first monkey were seized with rabies after intervals of thirteen and sixteen days respectively ; those inoculated from the second monkey after fourteen and twenty days ; those from the third after twenty-six and thirty days ; those from the fourth after twenty-eight days, in each case ; those from the fifth after twenty-seven days ; and those from the sixth after thirty days.

It is thus impossible to doubt that by transmission from monkey to monkey, and from the different monkeys to rabbits, the strength of the poison is weakened in the latter just as it is weakened in the dog. A dog which was inoculated with the bulb of the fifth monkey had an incubation period of not less than fifty-eight days, although inoculation was performed by trephining. Other experiments of the same nature, which were performed on a series of monkeys, led to results of a like character. We are thus in possession of a method which enables us to attenuate the virulence of rabies. Successive transmissions from monkey to monkey produce a virus which, on being transmitted to rabbits, communicates rabies after an incubation period, the length of which gradually increases. If, on the other hand, one passes on from these rabbits to successively inoculate fresh rabbits, the rabies comes under the law of increasing virulence on transmission from rabbit to rabbit, of which I have already spoken. The application of these facts yields a method of vaccinating dogs as a protection against rabies. We take as a starting point one of the rabbits which have been inoculated from monkeys, to such a sufficient degree that hypodermic or intravenous injection does not cause death. The succeeding preventive inoculations are performed with the virus-containing bulbs of the rabbits which have been the subjects of successive transmissions of infection from rabbit to rabbit, proceeding from the first infected.

In our experiments we have as a rule employed inoculation with virus from rabbits which have died after an incubation period of four weeks, but three or four times we have renewed our preventive inoculation from the bulbs of rabbits, which have been inoculated from the rabbit which served as our point of departure.

After I had brought into use this method of vaccinating dogs as a protection against rabies and had collected a large number of dogs, which were rendered insusceptible of the disease, foreseeing a more extensive application of the method, and remembering the opposition which was at first shown to Jenner's discovery, I determined to lay before a scientific commission such of my results as it was obvious must serve in the future as the basis for the vaccination of dogs for rabies.

The Under-Minister of Instruction, M. Tallières, to whom I mentioned my project, was willing to support it, and appointed MM. Béclard, Paul Bert, Bouley, Tisserand, Villemin, and Vulpian to enquire into the facts, which I had already communicated to the Academy of Sciences at its meeting on 29th May. After having chosen M. Bouley as President, and M. Villemin as Secretary, the Commission at once set to work, and I have the satisfaction of being able to tell you that it has quite recently presented its first report to the minister.

I will now give a brief account of the results with which the first report of this Commission deals. I presented to the Commission nineteen vaccinated dogs, all of which had been rendered insusceptible by preventive inoculation, and thirteen of which after vaccination had been proved by inoculation by trephining. These nineteen dogs were compared in different ways with nineteen dogs chosen from others for the purpose of the experiments. In the first place, on the 1st of June, two of the protected dogs and two of the trial dogs were inoculated by trephining under the dura mater with the bulb from a mad street-dog. On the 3rd of June, one protected dog and one trial dog were bitten by a mad street-dog. On the 4th of June, the Commission made the same mad dog bite another protected and another trial dog. On the 6th of June, the mad dog which had been used on the 3rd and 4th of June died, and with its bulb three protected dogs and three trial dogs were inoculated by trephining. On the 10th of June, the Commission had one protected dog and one trial dog bitten by a fresh mad dog from the streets. On the 16th of June, the Commission had two fresh dogs, one protected and one trial dog, bitten by one of the trial dogs of the 1st of June, which had gone mad on the 14th, as a result of the trephining performed on the 1st of June. On the 19th of June, the Commission had three protected and three trial dogs inoculated in one of the popliteal veins with the bulb of a mad street-dog. On the 20th of June, the Commission also had ten dogs, viz., six protected and four trial dogs, chosen from several others, inoculated in a vein. On the 28th of June, it having been brought to the knowledge of the Commission that a veterinary surgeon, M. Paul Simon, had a mad dog in his hospital, four dogs were brought to it, viz., two protected and two trial dogs, in order that it might bite them.

The Commission on rabies has thus performed experiments on thirty-eight dogs, nineteen of which had been supplied by me as insusceptible to rabies, while the other nineteen could be made mad. Those of the dogs which have not died as a result of the experiments are under observation, and will be kept under it for a long time. As to the present condition of the dogs which have been the subject of enquiry, the Commission report that in the case of the nineteen trial dogs, of six which were bitten, rabies occurred in three, of seven which were inoculated in a vein it occurred in five, and of five which were inoculated by trephining it occurred in all, while *not a single sign of*

*

rabics has shown itself in any of the nineteen vaccinated dogs.

During the course of the enquiry one of the protected dogs died on the 13th of July from a sanguineous diarrhœa, which first declared itself in the early days of that month. In order to determine whether rabies had any share in its death, three rabbits and one guinea-pig were at once inoculated with its bulb by trephining. All of these four animals are still in the best of health, which is a certain proof that the dog did not die of rabies, but of a common disease.

The next report of the Commission will contain information as to the insusceptibility to rabies of twenty dogs which have been vaccinated by the Commission itself.

THE BRADSHAWE LECTURE

ON

THE PATHOLOGICAL RELATIONS OF THE ABSORBENT SYSTEM [1]

By GEORGE HARE PHILIPSON, M.A., M.D., D.C.L., F.R.C.P.

Professor of Medicine in the University of Durham; Senior Physician to the Newcastle-upon-Tyne Infirmary, &c.

The occasion of the present assembly of this College is for the delivery of the fourth Bradshawe lecture. By the munificence of the widow of William Wood Bradshawe, of Andover and Reading, a Member of this College, a Master of Arts and a Doctor of Civil Law of the University of Oxford, a sum of money was bequeathed, whereby a lecture might be delivered at this College annually, with the object of perpetuating the memory of her husband, it being stipulated that the subject of the lecture should have a bearing upon some question of medicine, and that the lecture should be delivered upon the 18th day of August, the anniversary of his death. The munificence of the benefactress and generous founder is well deserving of an expression of respectful and appreciative commendation, in that, while endeavouring to preserve the name of a loving husband, she was actuated with the laudatory idea of associating such with a formal discourse for the advancement of the profession to which he was devoted and which he adored. This home-loving, studious, and scholarly man, who diligently cultivated his mind in literature and science, may, therefore, be fittingly extolled as an example for others to follow. His name will be justly venerated and transmitted in good repute, as well as that of his generous and devoted widow.

In undertaking the important duty that has been entrusted to me, I feel the honour and estimate the responsibility of the position. It shall be my earnest endeavour to justify the choice of our revered President, to whom I beg to offer my grateful acknowledgments for this distinctive mark of his favour.

I have selected "The Pathological Relations of the Absorbent System" as the title of the lecture. The absorbent system occupies a prominent place in relation to several important pathological processes and conditions, and is at the present time receiving considerable attention from histologists and pathologists. As illustrations of these relationships, it may be mentioned that this system is undoubtedly concerned in many septic conditions, and the late Messenger Bradley classified glanders, malignant pustule, snake bite, dissection wounds, and erysipelas as forms of septic lymphangitis. Moreover, it is supposed to play an important part in relation to various zymotic diseases, such as plague, typhus and typhoid fevers, and diphtheria. The serous cavities are also now regarded as parts of the lymphatic system, and some cases of inflammation of serous membranes, for instance, of puerperal peritonitis, are considered as being due to lymphangitis. Again, the absorbents are concerned in conveying to various parts of the body morbid products, such as those of cancer, syphilis and tubercle, and thus of disseminating these diseases through the system. Again, they are often involved in connection with diseases of internal organs. Some structures consist mainly of lymph follicles, and their chief diseases are associated with these follicles. Certain skin diseases, such as erythema, have been attributed to inflammation of lymph rootlets, and changes in the lymphatics seem to constitute an important element in the morbid anatomy of elephantiasis and several other affections. These illustrations will suffice to show the importance of the pathological relations of the absorbent system, and justify the selection of this subject for this commemorative lecture.

As an introduction to the consideration, it will be fitting that a short reference should be made to the anatomy and physiology of the absorbent system. For without such a statement the pathological changes, or the departures from the healthy state to those of disease, could not be indicated with the same precision and comparative exactitude as this method will ensure. Having in regard, also, that physiology, in its true acceptation, is the science which treats of the conditions, phenomena, and laws of the life of the human body, in the state of health, while pathology comprises the departures from such, manifested to the observer in disease, this process commends itself as the right and true way for this dissertation to be conducted.

The lymphatic and the lacteal systems together constitute the absorbent system. There is no essential difference between the two systems. The process of absorption has for one of its objects the introduction into the blood of fresh materials from the food and air, and of whatever comes into contact with the external or internal surfaces of the body, and, for another, the gradual taking away of parts of the body itself, when they need to be renewed. In both these offices, absorption from without, and absorption from within, the process manifests some variety, and a very wide range of action, and in both two sets of vessels are, or may be, concerned, namely, the blood vessels and the absorbents. The lymphatic system may, therefore, be considered as an appendage of, or supplementary to, the blood vascular system, the materials which they take up being, in fact, merely the spare nutrient substances forced into the intertextural spaces, that is, the commencement of the lymphatics, by the continued exudation of fresh fluid from the capillaries.[2] The lymphatics never come quite close to the surface of the dermis, but the blood capillaries are superimposed upon them (Teichmann and Belajeff). The lymphatic system consists of vessels, both trunks and capillaries, and of collections of a peculiar kind of connective tissue, adenoid, the meshes of which are crowded with round colourless cells. When these are situated in the course of the lymphatic vessels, and are invested with a capsule, they are termed lymphatic glands, but if there is a mere reticulum enclosing the cells, and so forming a patch in the sub-mucous or sub-serous tissue, it is described as a lymph follicle. Around all such follicles

[1] Delivered before the Royal College of Physicians of London, August 18th, 1884.

[2] Broadbent. "Humphry and Turner's Journal of Anatomy and Physiology," vol. i., 1870, p. 14.

there is a large plexus of lymph capillaries.[3] The principal vessels of the lymphatic system are, in structure and general appearance, like very small and thin walled veins, and like them are provided with valves. By one extremity they commence by fine microscopic branches, the lymphatic capillaries or lymph capillaries, in the organs and tissues of nearly every part of the body, and by their other extremity they end directly or indirectly in two trunks which open into the large veins near the heart. Their contents pass only in one direction, from the finer branches to the trunk, and so to the large veins, on entering which they are mingled with the stream of blood, and form part of its constituents. The lymphatic capillaries commence most commonly either in closely-meshed networks, or in irregular lacunar spaces between the various structures of which the different organs are compounded. They are composed of a single layer of flattened cells, nearly equal in length and breadth, with a marked sinuous outline. When passing into the large lymphatic vessels they present a varicose appearance, from an incomplete valvular appearance in their interior. In the extremities, the lymphatic vessels are divided into superficial and deep. The superficial anastomose freely with one another, and so do the deep, but there is no communication between the two sets, except in the glands, which may be common to both. To this is due the remarkable circumstance that either set may be separately diseased and that superficial and deep lymphangitis may be spoken of as distinct affections, although inflammation spreads from one growth to the other. The mode of anastomosis is peculiar. A lymphatic vessel will run for a certain distance parallel to two other vessels, and then divide, it may join both of them, or one of the branches will continue onwards and the other run into an adjacent vessel. In this manner a plexus with large meshes is formed. The rapidity with which inflammation spreads from vessel to vessel is thus easily explained.

In certain parts of the body openings exist by which lymphatic capillaries directly communicate with parts hitherto supposed to be closed cavities. These openings have a roundish outline, never exceed the size of an epithelial cell, and have been termed stomata. An absorption into the lymphatic system, also, takes place in membranes by epithelium or endothelium, through the interstitial or inter-cellular cement substance, and not through the cells themselves. This mode of absorption may be said to take place through pseudo-stomata. Stomata have been found in the pleura, and as they may be presumed to exist in other serous membranes it would seem as if the serous cavities hitherto supposed closed form part of a large lymph sinus, or widening out, so to speak, of the lymph capillary system, with which they directly communicate.

The current of lymph is much aided by the valvular mechanism. All occasional pressure on the exterior of the lymphatic and lacteal vessels propels the lymph towards the heart. Muscular and other external pressure accelerates the flow of the lymph, as it does that of the blood in the veins. The actions of the muscular fibres of the small intestine, and probably the layer of organic muscle present in each interstitial villus, seem to assist in propelling the chyle. For the general propulsion of the lymph and chyle it is probable that, together with the *vis a tergo* resulting from absorption and from external pressure, some of the force may be derived from the contractility of the vessels. The respiratory movements, also, favour the current of lymph through the thoracic duct, as they do the current of blood in the thoracic veins[4].

Blood and lymph are the essential juices of the body. They stand in the closest relation to the vital processes which go on in the tissues. By means of the blood the constituent elements of the body are supplied with the nutrient substances and the oxygen which they require. By the blood and the lymph are conveyed away the waste and surplus matters which have ceased to be useful to the tissues. The nutrient substances and the oxygen are derived from without. The former usually enter the body from the alimentary canal; the latter usually through the lungs. But most parts of the body are, under certain conditions, capable of directly assimilating both nutriment and oxygen. The channels of entrance are in such cases the smaller blood-vessels and lymphatics. The matters which have to be removed from the tissues are partly surplus nutriment, partly the products of tissue waste and metabolism. These matters are carried off, either to be utilised elsewhere within the system, or to be ejected altogether. Under normal conditions, the incomings and outgoings balance each other in amount. The channels by which the normal constituents gain access to the blood and lymph may also serve to admit matters which are noxious or at least abnormal. These matters may be either wholly extraneous, or produced within the body itself, in virtue of some morbid or abnormal metabolism. The result of their admission is a more or less enduring pollution of the blood and lymph. In many cases the blood is able to eliminate them harmlessly and speedily, chiefly by means of the kidneys and the liver, but in other cases the pollution is more permanent. The composition of the blood often suffers in consequence, and its renovation may not be effected until some of the tissues or organs have been more or less injured by malnutrition.[5] The lymph is merely the liquid transuded from the blood-vessels, together with certain products of tissue metabolism and certain matters taken up by the lacteals from the outside. To this the lymphatic glands contribute a number of lymphoid elements, in addition to the few cells derived from the blood. The sources of the lymph being thus somewhat various, it may be expected that morbid changes in the composition will not be uncommon. Changes in the blood and disorders of the tissues generally give rise to changes in the lymph, and various impurities of the blood are all of them apt to pass into the lymphatic system on leaving the blood-vessels.[6]

With this narration of the anatomy and physiology of the absorbent system we are in a position to enter upon the disquisition of its pathological relations. The anomalies in the distribution of the lymph will first receive attention. Every change in the circulation, which determines an increased transudation of liquid from the blood, leads by consequence to an increased saturation of the tissues. This increased saturation is generally balanced by an increased discharge through the lymph channels. But this compensating action has its limits. If the transudation from the blood-vessels still increases, then at last comes a time when the saturation of the tissues with liquid can no longer be kept down, and so it rises above the normal degree. The condition in which fluid collects in the substance of the tissues is called œdema, when in the greater cavities of the body, hydrops or dropsy. The liquid transudation in œdema and dropsy has never the same composition as blood plasma, it is always markedly poorer in albumen. Three varieties of œdema may be distinguished, according to their mode of origin; these are the œdema of engorgement, inflammatory œdema, and hydræmic œdema.

The œdema of engorgement, as the name implies, depends upon a disturbance of the circulation. If from any cause the outflow of blood from the veins is hindered, the blood tends to accumulate in the capil-

[3] Curnow. *Lancet*, vol. i., 1879, p. 397.

[6] Ziegler, Macalister's Translation, part ii., p. 33.

laries and venules. If the degree of obstruction exceeds a certain limit, the plasma seeks a lateral exit and escapes from the vessels. The amount of liquid thus escaping is proportionate to the discrepancy existing between the inflow and the outflow. The escaped liquid is always poor in albumen, poorer even than the normal lymph. It contains, however, a certain proportion of red blood-cells, depending on the intensity of the engorgement. The immediate consequence of increased transudation is an increased flow through the lymphatics. Often enough this may be quite insufficient to convey away all the liquid which escapes. If it is insufficient, the liquid collects in the tissues, and the result is œdema, or dropsy. Obstruction to the outflow through the lymphatics does not usually bring about œdema; direct experiments have demonstrated this. In the first place, the lymphatics of most parts of the body possess ample anastomoses, so that it is not easy for a stagnation of the lymph to occur. Even when the thoracic duct is occluded, collateral channels may be opened up and the circulation restored. Furthermore, when in a limb, for example, the whole of the lymphatic outlets have been closed, if no more than the normal amount of transudation from the blood-vessels goes on, no œdema is produced. The blood-vessels themselves have the power of taking up again the lymph they have produced. If the thoracic duct be completely occluded, and no collaterals are opened up, then œdema is the result—it takes the form of ascites. At the same time, the larger lymphatics become greatly distended with accumulated lymph. Though lymphatic engorgement alone is inadequate to produce œdema, it may possibly increase an œdema which has already been produced by increased transudation from the blood-vessels. The quantity and the nature of the liquid which escapes from the capillaries and veins depend not only on the intra-vascular pressure, and the resistance of the flow, but also to a great extent on the character and conditions of the vessel wall. Alterations in the amount of transudation may thus be referable, not to disturbance of the circulation, but to changes in the vessel wall, and especially in their endothelial lining. The vessel wall may, in fact, be made more permeable for the corpuscles as well as for the liquid constituents of the blood, by various causes. One of them is long-standing engorgement, involving incomplete renewal of the blood supply to the vessel. More serious causes of injury are persistent ischæmia, imperfect oxygenation, chemical changes in the blood, very high or very low temperatures, and traumatic lesions. What the exact injuries are which these bring about we are not as yet able to say, but it may fairly be imagined that they amount to a loosening of the connections between the endothelial cells of the intima. It is in virtue of such alterations in the vessels that inflammatory and hydræmic œdema are produced.

As regards inflammatory œdema, no doubt can exist that it originates in some vascular change. It occurs as an independent affection in the form of a more or less local and circumscribed swelling with dropsical effusion; but it may also, as a secondary phenomenon, accompany other processes, like severe inflammation. In the latter case, it is often characterised as collateral œdema. Inflammatory œdema is distinguished from the œdema of engorgement by the fact that in the former the exudation is very much richer in albumen and white blood-cells. It is also common for coagulation to take place in the dropsical tissues.

Hydræmic or cachectic œdema is very near akin to inflammatory œdema. It was formerly believed that hydræmia, in which the blood is impoverished of its solid constituents, and hydræmic plethora, or over-dilution of the blood with water, might directly give rise to increased transudation from the vessels. It was conceived that the vessel wall acted like other animal membranes, through which liquids, poor in albumen, filter more readily than liquids rich in albumen. This is incorrect. Cohnheim has shown that the vessel wall is not to be regarded as a dead membrane, it is a living organ. When hydræmia is artificially produced it is not followed by œdema. Even hydræmic plethora produced by over filling of the vessels with diluted blood, though it does lead to increased transudation, does not do so till the dilution has been carried to an extreme degree. Even then, the œdema does not make its appearance at the parts which are the usual seat of hydræmic œdema in man. We must, therefore, look for another explanation of the œdema of cachexia and of nephritis, in which disease the function of the kidneys is disturbed. According to Cohnheim, they owe their origin to a change in the vessel wall. This change is due to the watery character of the blood, or to some deleterious substance circulating in it. Hydræmic œdema is near akin to inflammatory œdema, but it is not identical with it. This appears from the fact already alluded to, that the liquid effused in the former is much poorer in albumen than that in the latter, and that it contains considerably fewer of the corpuscular elements.[7]

As to the diffusion of disease by the lymphatics. The granulative formations are all distinguished by similar characters. Their development usually stops short at the fibro-blast stage, and having reached it, or even before that, the constructive process gives place to retrogressive changes. Cicatricial development being arrested, the granulation tissue persists for a time unmodified, and often develops to a considerable amount. For this reason Virchow described the formation as granulative growths or granulomata. All of these growths have furthermore the clinical character of infectiveness. Hence they have been termed infective growths by Klebs and Cohnheim, and specific inflammations by Rindfleisch. Their infective character may be recognised by various signs. Thus they are all locally invasive, that is, the granulation tissue spreads centrifugally from a centre into the surrounding structures. At the same time the central or oldest part of the new formation usually dies and disintegrates. In many cases the lymphatic system becomes affected, so that secondary granulative foci are formed in it.

From the lymphatics, the process is at times transferred to the blood, or it may invade the blood-vessels directly. The final result is the spread of the disorder to various organs, or throughout the system.

In most of the granulomatous disorders, we may have not merely a diffusion of the disease throughout the individual organism, but also a transference of it from one individual to another—the affection is inoculable. If one person be inoculated with the inflammatory products derived from another, he acquires a disease whose course is exactly similar to that of the original one, and which yields identical inflammatory products. This latter character of infectiveness is that by which it is most readily recognised.

To this group of infective granulomata belong the neoplastic formations found in tuberculosis, syphilis, leprosy, lupus, glanders, and actinomycosis. All these affections are due to the invasion of the body by a virus or poison derived from the outer world, or from the body of another individual. This virus may probably be produced by vegetable parasites. In leprosy (Hansen, Neisser), tuberculosis (Koch), and in syphilis (Klebs), bacteria have been found, and in actinomycosis, a special fungus. These are declared to be the originating causes of the respective diseases. Our ideas as to the nature and character of these affections are as yet

[7] Ziegler, Macalister's Translations, part i., p. 48.

mainly based upon their clinical course, but we have also derived something from inoculation experiments. Tuberculosis and syphilis are thus known to be communicable from one person to another, tuberculosis is also communicable from man to the lower animals.[8]

Inoculation with sputa containing bacilli of tubercle gives rise to tuberculosis, which is developed more rapidly when the bacilli are abundant. The inoculated bacillus multiplies in the organism, and invades the lymphatic system, liver, spleen, and serous membranes; by its presence it sets up a chronic inflammatory process, with the formation of products which become casefied and subsequently soften, producing gradual destruction of the organs. The bacillus is found in the centre of the tubercles in their earliest stage of formation, and hence is the cause, and not the effect, of the morbid process. The lymphatic vessels, amœboid cells, and the blood-current, are the means by which these micro-organisms are transported from one organ to another and diffused throughout the body.[9]

(To be continued.)

THE ÆTIOLOGY OF SPINAL CURVATURE.

By F. CHURCHILL, F.R.C.S.
Surgeon to the Victoria Hospital for Children.

The influence of posture in the development of the bony framework of the body is a subject which cannot be adequately discussed when considered only in connection with regulations for school management. The causation of spinal curvature needs a much wider range of thought for its solution.

Therefore to attribute "the largest proportion of deformities and of cases of defective eyesight to the faulty attitudes induced by badly constructed seats and desks, together with want of sufficient and proper exercise, especially among girls," as Mr. Noble Smith did at the International Health Exhibition Conference, is to arrive at a conclusion without sufficient data.

The fact that girls suffer much more frequently than boys from spinal curvature is well known to surgeons who have made a special study of the diseases of children. To focus the blame for these distortions almost entirely at the door of the modern schoolmistress is to show an imperfect conception of the multiple causation of this deformity. Deportment lessons have their proper place, I consider, in every well regulated school. Rigid rules as to general deportment ought, I think, to favour spinal rigidity, rather than relaxation. The breach and not the observance of such rules must encourage awkward postural habits in young people inclined to curvature of the spine.

If we adopt Mr. Noble Smith's argument we should expect to find an increase of curvatures of spine among upper class young ladies, and especially those who go to "boarding schools." Home-taught young ladies, with plenty of sofas to lie on and other *articles de luxe*, ought to be relatively free from such deformities.

My experience tends in a precisely opposite direction, and I believe I have one of the largest surgical clinics in London for children's diseases. I prefer to discuss this question on broader principles.

I find that the children of the poor are blessed with more solid backs and larger bones. Yet these suffer far more than the elegant spider-like bodies of "the upper ten." And why? Children with broad chests have wide pelves with prominent ilia. The spine is therefore relatively at a greater distance from the iliac crest where all the burdens have to be borne, and so the lateral ligaments of the spine yield to the leverage action of the many burdens which are carried by poor children on the side opposite to the curve.

London children have not the stamina and solid framework of country lasses, and their mothers partake of the general decline in milk secretion. The "fat of the land" is not their portion.

The hygienic derangements of London slums require no comment from me as to their baneful influence upon the health of the rising generation.

The family arrangements usually provide that the elder girl, say from 7 years of age, shall "mind the baby," carry it upstairs, and take it for "an airing;" whereas cottage babies have to shift for themselves at the cottage door, or on the roadside.

There is one point of agreement between Mr. Smith and myself when he alludes to the beneficial effects of outdoor games, swimming, &c. Let the girls have as much as the boys, if they like, of sports and active exercise for all the muscles. Nevertheless the "walks in stately file," condemned by Mr. Smith, have their proper place in school hygiene, as also drilling, in moderation, to brace up the shoulders.

I prefer to combat these deformities, and to provide against them by the use of general principles of treatment so as to strengthen and consolidate the fabric of the body in its totality.

The tendency of specialists is, I think, to direct too much attention to the local disease or deformity. Let us attend, first of all, to improvement in the general health and the provision of suitable methods of school training, outdoor exercise, calisthenics, &c., so that these deformities may be avoided as far as possible.

Mr. Roman's plan for the methodical exercise on scientific principles of each group of muscles, in order to attain the highest possible development of every part in perfect harmony and symmetry, is the method which, I think, deserves to be more generally understood and accepted.

In short, the causation of spinal curvatures will, I think, be found more frequently traceable to the pernicious system of burden-bearing by young and delicate children, badly fed and improperly housed.

Curvatures of the spine in upper class society occur much less frequently, and may be traced to children having a general laxity of ligamentous structures; to infantile causes of degeneracy, as, for example, improper feeding; to scrofula, rickets, and other inherited diseases, and to parental follies, &c.

We know how extensively rachitis prevails among children living in unhealthy dwellings with everything to favour poverty of blood and defective growth. The spine quickly participates in this retarded growth. All the epiphyses and bone centres ossify very imperfectly. No wonder that the articulations yield to the superincumbent pressure. The bodies of the vertebræ, the transverse processes, and inter-articular fibro-cartilages, in consequence of undue softness and compressibility, are easily pressed out of shape, and slowly yield to the inclination from the mesial line which weight carrying is sure to produce in delicate overburdened children.

The pathology of rickets is still, I believe, a *terra incognita*. I think we must go further back for the causation than the hand-feeding and general management.

The infant betrays its proneness to rickets very early. May we not trace the cause to a marasmic condition of the mesenteric glands, whereby the chyle and products of digestion, being obstructed in their transit to the thoracic duct, fail to reach the circulation in sufficient quantity, and so the bones, which of all tissues of the body are the most removed from the centres of nutrition, have to suffer most from imperfect chylification of the pabulum of the food.

[8] Ziegler, Macalister's Translation, part i., p. 183.
[9] Sormani, *London Medical Record*, 1884, p. 53.

Or, again, may we not trace the causation to a congenital cause? For example, we know that one of the earliest signs of rickets is frontal perspirations during sleep. If we take the temperatures of such infants we often find considerable elevation of body heat. Oft-repeated febrility must favour the absorption of the earthy salts from the bones, such as we find so commonly in febrile diseases, the exanthemata, &c. The bones soften in consequence, and so become nodulated and enlarged at all the articular extremities where excessive mobility causes the cartilages to expand and become spongy in texture.

To oblige such children to carry burdens, or to toil like healthy children would be certain to cause spinal curvature and other deformities.

REMARKS ON THE TREATMENT OF CHOLERA EPIDEMICS IN INDIA.[1]

By Surgeon-General JOHN MURRAY.

In the present state of excitement and panic in France and on the Continent, and with the prospect of cholera soon appearing in England, I think it would be useful and tend to avert similar unreasonable acts, to give a short account of how cholera epidemics are treated in India, where absence of epidemic attacks is the exception to the rule in ordinary years, and where the mortality is recorded by hundreds of thousands, and in 1877 amounted to 627,579. An annual mortality exceeding 100,000 is not uncommon; but were cholera not restrained by the measures pursued by Government, it would be much greater. Panics are very dangerous in depressing the spirits of the individual, and leading in many instances to the neglect of attendance on the sick and dying, or even to the desertion of the dying and the dead. These panics arise from ignorance of the disease, combined with want of trust in the administration of the Government, and lack of faith in the executive, or doctor. The disease is very fatal, and in many instances medical aid is of no avail, especially when late in being applied; but experience shows that when applied in the earlier stages of the disease, very simple remedies will check, and generally cure, a very large proportion of the cases. It is in connection with this point that I wish particularly to call attention to the practice in India. This is not a time or place to argue on the various theories of the disease, and whether Dr. Koch's microbe is the true cholera microbe, or only one of the legion of microbes visible in cholera cultivations which further research found in many situations unconnected with cholera; nor to discuss M. Pasteur's hope of cultivating the germ, and producing a milder form of cholera, which, like vaccination in small-pox, might prove a protection from the disease. In so far as a severe attack of cholera affords no protection from subsequent attacks, it is not probable that a milder attack would be more efficacious.

There are one or two practical points which guided the measures of Government in 1861 which will elucidate the practice then enforced, and which still prevails. The first is the early recognition of the presence of the disease. Up to that date the stage of malaise was not usually recognised; whilst the second stage of diarrhœa was loudly denied by many, who stated that cholera could only be recognised when collapse and suppression of urine were present. It is my opinion that those who do not diagnose cholera till the stage of collapse has arrived, will sacrifice many sick who might have been saved. The earlier the disease is diagnosed, the simpler and milder are the remedies required to assist nature to conquer it. The medicine recommended, and generally used in India, is a mild carminative pill, which if taken needlessly will do no harm, but which if taken early has checked the disease in tens of thousands of cases. If the cholera pills are not given till collapse has supervened they are powerless as well as the strongest stimuli. I do not consider the chemical ingredients of these pills as antidotes to the poison; but they are stimulants to the stomach, whilst its sensibility, though *impaired* by the presence of the poison, is not *paralysed* as it is in collapse. The benefit of the medicine is in promoting the action of the stomach, in the secretion of the gastric juice, which is known to be the most powerful agent in destroying all the microbes, or lower vitalities, which accompany or produce putrefaction or fermentation. The excessive rapidity with which these lower vitalities increase when unrestrained, is a fact of natural history; they multiply by tens of thousands in a few hours. The stomach and intestines appear to be the primary seat of the germ, and should this view be correct it would explain the extinction of the disease in the earlier stages by the increased flow of the gastric juice caused by the carminative action of the medicine. When cholera runs its course, the inner or involuntary life becomes paralysed, whilst the outer or voluntary life continues in action, and the mind remains clear till life slowly fades away. The practice to which I allude is the general distribution over the infected country of the carminative cholera pill referred to. It is distributed through the police, with instructions for its use, and an earnest command for its early application. The success of these measures is reported by all the civil authorities as most satisfactory, while any want of success is equally attributed to delay in its use, till the disease had advanced to the stage of collapse. The treatment of the disease after this stage can only be conducted by the members of the medical profession, and successfully only by those who have assiduously studied the disease, and observed the action of the different remedies in aiding nature to overcome it.

With regard to the prophylactic treatment, the measures employed are directed to restrain the dissemination or spread of the disease from the sick to the healthy, by the isolation of the affected, and by the removal of causes, which experience has proved to facilitate its development, such as non-sanitary crowding, impure air or water, &c., &c.

I have no doubt that the disease is communicable; but the channels by and through which it is communicated are often doubtful. Our experience in India shows that personal contact is not the ordinary channel; as proved by the relative exemption of hospital attendants, and more clearly by the great proportion of villages attacked in severe epidemics in which only one death is recorded, or when only two appear; as in many instances these were two affected pilgrims or visitors. In four late epidemics (1877–8–9–80) there were 154,986 villages attacked; in 58,972 of these there was only one death, and in 20,596 only two deaths, yet in these years the total mortality was 1,380,226.

A thorough knowledge of the channels through which the disease leaves the body, as well as the channels through which it enters it, also of the changes through which it passes when outside the body, and what develops or impedes its action, and to what articles it most readily attaches itself, is essential to those who legislate for the protection of the people from this fatal disease; but these are not points suitable for discussion here even if time admitted. The practical part of the subject which I would like to allude to now, is the means employed by the Government in India

[1] Delivered at the Conference of the Epidemiological Society, at the International Health Exhibition.

for protection from the disease. For troops and prisoners, the measure that has proved most beneficial has been removal into camp, with isolation of the affected, and prompt treatment. But these measures are not applicable to the civil population of large towns, and hospitals are provided for the treatment and isolation of the sick, with proper medical attendance. Medicines are distributed all over the towns by the hands of the police, with instructions for their use, and the necessity for early application is enforced, as a delay of one or two hours in many instances involves the safety or death of the affected. Similar measures are equally applicable here should the disease reach London, and a knowledge that the authorities are prepared for its advent would ward off the panic which now spreads so rapidly in other countries.

The medicine most generally used is a compound of one part opium, two parts assafœtida, and three parts black pepper made into five grain pills.

It will generally cure, and at least it will delay the course of the disease till medical aid can be procured.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ROYAL FREE HOSPITAL.

CASE OF EMBOLISM OF THE RIGHT MIDDLE CEREBRAL ARTERY—PRODUCING LEFT HEMIPLEGIA, WITH LEFT HEMI-ANÆSTHESIA—BLINDNESS OF LEFT EYE—AND RIGHT-SIDED CONVULSIONS.

By SAMUEL WEST, M.D.

Physician to the Chest Hospital, Victoria Park, and to the Royal Free Hospital, Medical Tutor and Medical Registrar to St. Bartholomew's Hospital.

Catherine Strong, aged 64, a poorly nourished, weakly woman, was admitted under my colleague, Mr. Mackinlay, for chronic glaucoma, for which an operation was performed by him upon the right eye on January 11th, 1884. The operation was in itself successful, and the patient seemed in her usual health, which was, however, never very good. On February 13th after dinner, at 2 p.m., the patient was seen to fall back in bed, and her face was then found to be drawn, and her left leg and arm paralysed. She never lost consciousness, but complained of pain in the right side of her head. At 5 p.m. she had a fit, during which she was unconscious, and the whole right half of the body and face twitched convulsively. The fit lasted three or four minutes.

As far as the paralysis went, it was a case of complete ordinary hemiplegia in every respect, except that the whole left half of the body, including the face, was completely anæsthetic (hemi-anæsthesia).

The tongue was protruded to the left side—but the defects in her teeth might account for this.

Both urine and fæces were passed unconsciously, although, with the exception of the time of the fit, the patient was never unconscious.

On the next day (February 14th) the patient had another fit of about three minutes' duration of exactly the same kind as the former.

The pain on the right side of her head was more severe. She complained also of acute pain in the right axilla, and in this spot some pleuritic crackling was audible.

The head and eyes were at times turned towards the right side, but this condition appeared to be variable. There was no difficulty in swallowing.

The pulse was 112, weak and occasionally intermittent, the temperature 100° in the left axilla.

She understood everything that was said to her and answered rationally.

The pain in her right side was still severe, and here some pleuritic friction was audible with crackling.

She was ordered mustard plaisters to calves of her legs, and to the right side. The diet was milk, eggs, and beef-tea, and no stimulants.

Feb. 15th.—Patient felt in less pain. There had been no more fits, and her intelligence was good as before. The pulse was irregular and feeble

Feb. 18th.—Hemi-anæsthesia absolute as before.

Feb. 20th.—The patient complained that she was quite blind of her left eye. She said that it seemed "like 10 o'clock at night" to her. The vision was, as far as could be judged, entirely lost. From the irregularity of the pupil from old mischief, nothing could be stated on this point. There appeared to be some paralysis of the external and superior recti on the paralysed side.

The vision in the right eye was very defective as a consequence of the glaucoma and operation, but no change had occurred in this since the attack.

Feb. 22nd.—The patient died of gradual exhaustion, the breath becoming very laboured and difficult towards the end of life. In other respects her condition continued unchanged.

The hearing in the two ears was unfortunately not tested, and there was no evident loss of power.

The autopsy was made fourteen hours after death.

On opening the skull the dura mater was found normal, the convolutions somewhat small, and a slight excess of sub-arachnoid fluid. Pia and arachnoid otherwise healthy. No excess of fluid in ventricles.

On the right side a focus of softening was discovered, occupying about the posterior half or two-thirds of the caudate nucleus, extending longitudinally from about the level of the anterior pillars of the fornix to that of the posterior border of the pineal gland. Anteriorly the softening was limited to the outer portion of the lenticular nucleus and adjacent portion of the external capsule, while the internal capsule here was quite intact. Posteriorly the softening was more extensive. The whole thickness of the caudate nucleus and of the lenticular nucleus was involved, and the internal capsule implicated. The optic-thalamus had completely escaped. Small ecchymoses were scattered throughout the whole softened area.

The right middle cerebral artery was plugged for about three-quarters to one inch of its extent, the plug commencing at the first division and involving both branches, but unequally. The greater number of the perforating arteries had escaped. The cyst was only slightly adherent.

The vessels at the base of the brain, as well as the walls of the plugged vessel, were quite healthy.

The left hemisphere was quite healthy.

Heart and pericardium, healthy.

Lungs, emphysematous, with considerable congestion at bases. Several infarcts, some of considerable size, existed in the base of both lungs, most numerous in the left. Clots were found in the branches of the pulmonary artery leading to these portions of lung. Liver, nutmeg. Spleen, small and firm. An infarct of recent date existed in the left kidney. The veins of the abdomen, pelvis and orbit were all healthy.

The infarcts in the different parts of the body seemed to be of the same date, and their origin and cause could not be discovered, though carefully looked for.

The sudden access, without loss of consciousness, pointed clearly to embolism as the cause; the complete hemiplegia, associated with hemi-anæsthesia, indicated with probability the vessels affected; viz., the lenticular and lenticulo-striate arteries—and this lesion the *post-mortem* established. It is interesting to note the complete loss of sight and the partial loss of power in some of the external muscles of the eye on the paralysed side, and that the blindness did not become complete until about four days after the attack.

With the hemi-anæsthesia may be associated the involuntary passage of urine and fæces as being due probably rather to the loss of sensation than to loss of power in the sphincters.

The epileptic convulsions which occurred twice, and which were limited to the non-paralysed side of the body, may be explained by the congestion of the unaffected side of the brain, due to the sudden alteration in its circulation. The first fit occurred three hours after the attack, and the second about twenty hours later, and though the patient lived for eight days longer, no further fits occurred.

Medical Times and Gazette.

SATURDAY, AUGUST 23, 1884.

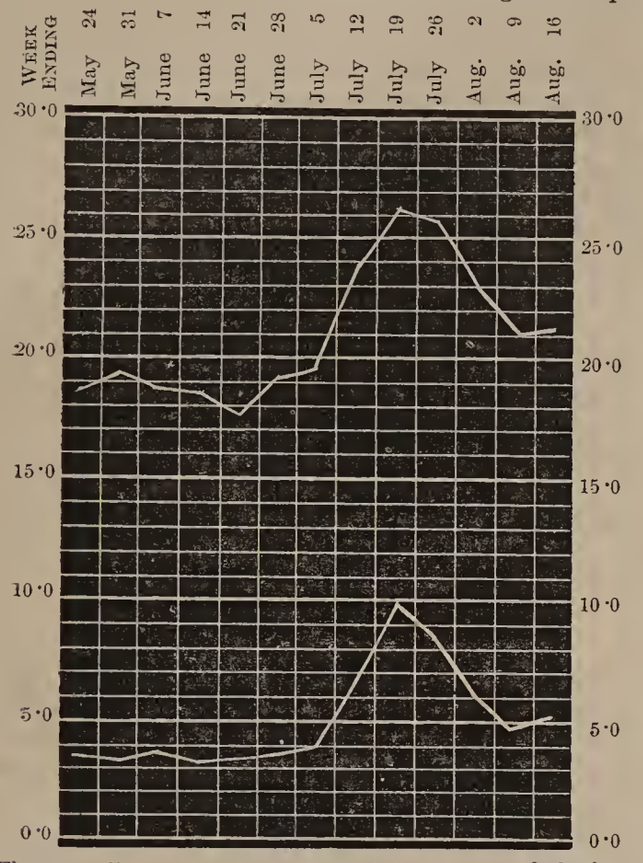
The International Medical Congress at Copenhagen broke up on Saturday last, after deciding to hold the next meeting at Washington, in 1887, in the month of September, by which month the American seat of Government begins to get habitable. It is stated that the American Committee have offered to provide a free passage to all members who are desirous of being their guests, and if this is an earnest of the scale on which the Ninth Congress is to be carried out, we may expect something which will throw the London meeting far into the shade. Believing as we do that the one danger which threatens these Congresses in the future is international rivalry in entertainment and display, we trust that the American Committee will think twice before they depart from the excellent example of simplicity without dulness, and economy without parsimoniousness, set by the Copenhagen Committee. Of the leading features of the late Congress we have said sufficient elsewhere.

The cholera—the brutto morbo, as the Italian papers are calling it—has extended considerably since our last note on the subject. The cases which have been reported at Birmingham and at Dunkirk appear not to have been cases of true cholera, though they have caused a considerable scare in their respective neighbourhoods; but there is no doubt as to the rapid extension of the epidemic in France and Italy, every day adding one or two names to the long list of infected places. The cases too appear to be of a more fatal and rapid nature than hitherto. At Puit de Bon, a little hamlet in the Yonne, of 150 inhabitants, the majority of those attacked have died after a very short illness, and at Brignolles many deaths have occurred with "terrible" rapidity. Many villages around Auxerre, which is not much more than 100 miles from Paris, are infected, but so far no undoubted case has been recorded in the French capital. At Marseilles, Toulon, Narbonne, Nimes, Avignon, Perpignan and Arles the mortality is still considerable, the condition of the last-named town being described as especially serious. The epidemic too is spreading in the Southern Provinces of Italy, and the authorities continue to establish cordons around the infected provinces. On Sunday an "imposing demonstration" took place at Palermo, with the view of pressing on the Italian Government even more rigorous sanitary measures.

By the death of Dr. Cohnheim the medical faculty of the Leipsic University has lost one of its most famous professors. Few of the great men whom the German school has produced within the last half century have been larger or more widely known than the late professor of general pathology and pathological anatomy at Leipsic. His discovery of the migration of the white blood corpuscles through the walls of capillary vessels is his chief title to fame, but in many other branches of histological study he made important researches, notably in connection with the distal terminations of nerves. M. Burq, whose death is announced from France, was a man of a different sort, an enthusiastic visionary, who spent his whole life in advocating metallotherapy, or Burquism, as the French have done him the compliment of terming it. He was of Irish descent, and his family was related to that of Edmund Burke, but he Gallicised the spelling of his name to conceal his origin. Years ago he studied mesmerism under Dr. Elliotson, but he subsequently took up with metals, and devoted the rest of his life to advocating his views as to the specific effect of their contact with the skin in cases of hysterical paralysis. Burq would have been happier had he died a few years ago, for after being long derided by the Academy of Medicine, he at length gained the ear of Charcot, and for some months nothing was heard of in the Paris hospitals but "metallotherapy." It passed, however, as rapidly into oblivion as it rose into fame; and though Burq believed in it to his death, he must many times have confessed to himself that he had had his chance and failed. Another death recorded from the Continent is that of Baron Thénard, the son of the celebrated chemist of that name, and himself a chemist of considerable renown.

The death-rate of London did not rise last week to the degree that might have been expected, considering the spell of hot weather—the mean temperature of the week was 6·4° above the average, and that on Monday the 11th as much as 14·5° above it. The effect of the heat seems indeed to have been felt more in the 27 other large towns, if one may judge by the diarrhœa statistics. In the week previous to last, 219 persons died of diarrhœa in London to 364 in the other 27 great towns; last week the numbers were respectively 242 and 547. The diarrhœa death-rate was 13·3 in Wolverhampton, 12·7 in Norwich, and 12·6 in Leicester. Turning to other of the zymotic diseases we find London comparing not so satisfactorily with the large towns. What can

be the explanation for instance of the fact that while 19 deaths occurred from diphtheria in London last week, only two occurred in all the other large towns put



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London in each of the past thirteen weeks.

together? And why did nine out of the ten deaths from smallpox that were registered last week in the 28 large towns occur in London? In spite of this fact the deaths from smallpox in the metropolis last week were for the first time for many weeks below the ten years average, and altogether the smallpox epidemic continues steadily to decline. The weekly admissions are still falling and the number of cases in hospital is not more than half what it was six weeks ago.

According to the recently published quarterly returns of the Registrar-Generals for the three Kingdoms, the *birth-rate* during the quarter ending June 30th was in England and Wales 34·2 per 1,000, or 1·6 below the average; in Scotland 35·2 or 1·1 below the average; and in Ireland 25·4 or 1·1 below the average. During the same period the *death-rate* was in England and Wales 18·9 per 1,000, or 1·5 below the average; in Scotland 19·5 or 1·66 below the average; and in Ireland 19·2 or 1·1 below the average. The *death-rate from zymotic diseases* was in England 2·13 per 1,000, or 0·25 below the average; in Scotland 4·22 (but how much below or above the average the registrar sayeth not), and in Ireland 1·5 per 1,000. In England the death-rate from each of the principal zymotic diseases, except diphtheria and smallpox, was considerably below the average; that from smallpox being exactly the average, and that from diphtheria being 0·2 above it. Similar statements cannot be made in the case of Scotland and Ireland, not because they may not be true, but because their respective Registrar-Generals do not give us the required information. It would be an advantage if these two officials, especially he of Scotland, would study and copy the admirable quarterly reports that proceed from Somerset House. It would be still better if the registration statistics of the three countries were dealt with and reported on by a single central office. It is, however, only fair to add that the Meteorological record in the Irish report could not be better done.

"What will they do with it?" must have been the cry that rose to many a pair of lips when their owners heard that the Royal College of Surgeons had been remembered in Sir Erasmus Wilson's will to the extent of 180,000*l*. The College has never received a bequest anywhere near approaching to this magnificent legacy. The largest donation it had previously received was that of 5,000*l*., bestowed on it by the same generous benefactor, who has now placed it beyond the faintest danger of bankruptcy. Next to that in amount comes the Hunterian Trust Fund of 1,684*l*., then the Bradshawe bequest of 900*l*., the Gale's Annuity Fund of 689*l*., and the Jacksonian Fund of 425*l*. We do not suppose that the Council will be in want of ideas or advisers as to what to do with their increased income. The Museum and Library will each no doubt be able to consume a good many hundreds a-year more without showing any signs of undue repletion; and perhaps it might be worth considering whether it would not be to the benefit of the College to lower the membership fee. But we shall be disappointed if something more than these minor readjustments is not forthcoming. Now is the opportunity to establish a pathological institute on a scale worthy of the scientific reputation of the English school, an institute duly supplied with professors and assistants, and all the appliances required to carry out the complicated procedures of modern pathological research. No institution in the country is better qualified to initiate and direct this advance than the College of Surgeons, with its traditional connection with John Hunter, and its great pathological museum. We should not however grudge a few thousand pounds to the Marine Biological Laboratory, which is now so nearly an accomplished fact, and the aims of which are not altogether outside of those wide views which have always actuated the College, at any rate in its management of the Museum.

In connection with the somewhat acrimonious correspondence which we publish in another column, it may be worth while to quote the latest statistics bearing on vaccination, contained in the report of the Homerton Hospitals, which has just been published. From January 1st to March 7th, 1883, during which time the smallpox patients were treated in the Fever Hospital, 62 cases were admitted; of these, 43 were vaccinated, of whom 3 died, or at the rate of 7·0 per cent.; 12 were doubtfully vaccinated, of whom 3 also died, or at the rate of 25 per cent.; and 7 were unvaccinated, of whom again 3 died, or at the rate of 42·85 per cent. From the 7th March to the end of the year, 325 patients were admitted, viz.: 237 vaccinated, 30 doubtful, and 58 unvaccinated. Amongst these 17, 5, and 25 deaths respectively occurred, or at the

respective rates of 7·02, 16·6, and 43·1. Dr. Gayton, the indefatigable superintendent of the hospital, is perfectly justified in claiming that these figures furnish "their quota of evidence in showing that epidemics of this appalling disease, which have appeared within our memory, have been mercifully stripped of the horrors of those before our time, by the immortal Jenner, to whom mankind owes so much. It is only really during the past fourteen or fifteen years that any very extended observations have been made and records kept of the value and efficiency of vaccination, and beyond doubt, as by years they accumulate, one fact will continue to stand out prominently from the rest—a fact indisputable and incontrovertible—viz., that vaccination, *successfully* and *efficiently* performed, prevents in a remarkable degree the tendency to death from smallpox; and the agitation-mongers, who go about day by day trying to stir up against it the passions and prejudices of the ignorant, are deserving of the severest condemnation."

The arrangements for the opening of the Winter Session at the Medical Schools of the Metropolis have, with one exception, been made. The Session of the London Hospital Medical School will commence on Wednesday, October 1st, when the prizes for the past session will be distributed, at 8 p.m., by the Lord Mayor. At King's College, the prizes will be distributed on the 1st October, at 4 p.m., and an address will be given by the Rev. H. Wace, D.D., the Principal. The Winter Session both at St. Bartholomew's and Guy's Hospital will commence on the 1st October, but at neither will an opening address be delivered. At St. Thomas's Hospital the Winter Session will be opened on October 1st, at 3 p.m., with an introductory address by Sir Risdon Bennett. At University College the introductory lecture will be given by Dr. W. R. Gowers, and at the Middlesex Hospital, by Dr. David W. Finlay. At St. Mary's Hospital the Winter Session will be opened with an introductory address by Dr. Lees on October 1st, and next day, at 8.30 p.m., a *conversazione* will be held in the new school buildings. The Winter Session at St. George's Hospital will commence on Wednesday, October 1st, with an introductory address by Dr. Champneys, at 4 p.m. The medical school attached to Charing Cross Hospital will be opened on the same date, without an introductory address.

The very able address of its President, Mr. John Williams, and the fact that the proceedings were not over-shadowed as usual by the British Association, have gained for the British Pharmaceutical Conference this year a greater share of public attention than it usually obtains. The remarks which Mr. Williams made on Wednesday week on the compilation of the British Pharmacopœia were perhaps not uncalled for. We are not in the secrets of the Pharmacopœia Committee, but we do not suppose that they are so inept as not to avail themselves of the best expert advice which they can command on purely pharmaceutical questions. If so, the question is one of sentiment; and no one in the medical profession, we imagine, would object to see the pharmaceutists formally represented on the Pharmacopœia Committee. The time is not perhaps yet ripe for turning over the whole volume to the chemists to let them do what they like with it, while retaining for ourselves a small codex of the score or two of drugs which are likely to retain the general confidence of the profession. But the more we advance, the less importance will attach to such subjects as those which engaged the attention of the Pharmaceutical Conference. Meanwhile, we cannot quite accept the grotesque assertion of the *Times* that the public "go to the doctor to be cured of illness, but have recourse to the chemist for preventives against ill health," a circumstance which "lends to the position of the pharmaceutist an ever swelling importance," and suggests that "the status which he may claim from his attainments should be ungrudgingly recognised." The *Times*, under its new editor, has renounced its old prejudice in favour of "chymists" and "chymistry," but there is room for improvement in logic as well as orthography.

The lecturers of the Extra-Mural School at Edinburgh have petitioned the Privy Council to allow them to incorporate themselves by Royal Charter under the Limited Liability Companies Act, taking for their style and title "Queen's College, Edinburgh." According to legal regulations the petition must lie on the table of the House of Commons for a month before being submitted to the Privy Council, and it is customary, further, to take the Lord Advocate's opinion upon it before a final decision is given. The result of the petition cannot, therefore, be known until late in the autumn. Meanwhile, all who are in favour of free trade in medical education will cordially desire that the efforts of the Extra-Academical School to place itself in a position in which it can compete on more equal terms with the University of Edinburgh may be successful. At present the school cannot hold property, or elect suitable officers to manage its affairs, or establish bursaries, or share in benefactions left to the Edinburgh School of Medicine. By obtaining the small measure of State recognition implied in incorporation by Royal Charter the Extra-Mural School will be able to increase its efficiency, and then, if the authorities of the University are wise, they will allow their students to take out a larger proportion of courses extra-academically, and so bring about that increased competition which is required to stimulate even professors to do their best.

The annual election of the Medical and Surgical Staff of the Glasgow Royal Infirmary took place on the 7th August, when the following new appointments were made:—Dr. Alexander Robertson, Physician; Dr. David N. Knox, Surgeon; Dr. James Whitson, Assistant Surgeon. The members of the staff holding appointments at the day of meeting were re-elected. From the above it will be seen that the managers have decided to give the title of Assistant Physician or Surgeon to those medical men who attend to give advice to out-door patients. Formerly there were two dispensary physicians and surgeons on duty daily, and

each of these received a salary of 50*l.* a year; in addition there were four extra dispensary physicians and surgeons, without salary, and these were called upon to act at the dispensary in the absence of the paid members. But the managers, wishing to deal equally with all those who are connected with the out-door patients, have decided that, in the place of those above mentioned, there shall be six assistant physicians and surgeons, each receiving a salary of 25*l.*, and attending the dispensary, during nine months in the year, upon three days a week. Dr. Whitson was appointed in the place of Dr. Lothian, who a few months ago was elected Surgeon to the Burn, Erysipelas and Lock Wards. The result of the election of a physician to take the place of Dr. Maclaren, who retires, has created a little surprise. There were five applicants, four of whom were members of the dispensary staff of the Royal or Western Infirmaries, had acted temporarily as physicians in the wards of these hospitals, and were confessedly qualified to discharge the duties of the vacant post, and to improve, or at least sustain the reputation of the hospital as a medical school. It was not unnatural to suppose that the choice of the managers would secure promotion to one of these gentlemen, and although Dr. Robertson, who has been for many years Medical Officer of the Poorshouse in the City Parish, Glasgow, is well known in the West of Scotland as a man of extensive experience and great ability, as well as an authority on diseases of the nervous system, it was scarcely expected, considering the claims of his opponents, that he would be so fortunate as to obtain the appointment.

The result of the election raises a very serious question as regards the future of the Royal Infirmary. The relief given to the patients attending the out-door department of hospitals is as grateful to the sufferer as that given to the in-door, the cases are similar in kind, and the work which has to be done by the medical attendant is much more laborious. Both departments must be thoroughly attended to if any hospital is to fulfil its objects—the relief of suffering and the training of future medical men—and, what is quite as important to the Royal Infirmary, gain the sympathy and support of the "masses." Until this time, medical men have been content to do the hard and often unpleasant work connected with the out-door department with either no remuneration, or with such an amount as by no means repaid them for the time devoted to the work. And they have done this in the expectation that, in course of time, they would be appointed to the in-door department with its lighter work, larger remuneration and better professional position. If, however, it is found that the higher places are conferred upon "outsiders," whether men unconnected with hospitals and students, or men connected with other hospitals, it is to be feared that the result will be that the treatment of the patients in the out-door department will be conducted by men of less standing in the profession, and that the teaching there will suffer considerable deterioration.

The Provost and Senior Fellows of Trinity College, Dublin, have conveyed to Mr. Butcher a most cordial expression of their regret at his resignation of his office of University Lecturer in Operative Surgery, and of their gratitude to him for the valuable services he rendered while in that capacity for the past sixteen years to the College and to Sir Patrick Dun's Hospital. They especially thank him for the important services rendered both to the College and to the hospital during the critical years in which the hospital was being transformed, under the School of Physic Amendment Act, from a purely medical one. There will not, we believe, be a successor appointed in Mr. Butcher's place as University Lecturer on Operative Surgery.

There are few more complicated problems, writes our Belfast correspondent, than that involved in the financing of some of our oldest and best known hospitals. It is true that it is being gradually solved in many instances by the radical changes in their constitution, whereby some are becoming provident establishments which formerly existed solely as pure charities in the strictest sense of the word. But there are many hospitals which hesitate to adopt these revolutionary changes and some of these are in a parlous state. They attract to their working boards the most philanthropic and generous members of the community, and such are apt to go on in faith increasing the usefulness and expenditure of the institutions under their charge, to meet the growing wants of rapidly increasing populations, without perhaps pausing to balance expenditure and income. Thus, the medical profession, than whom no class is more interested in the success of hospitals, periodically finds itself harassed by the threatened bankruptcy and ruin of institutions which have been the means of doing incalculable good in relieving human suffering and raising the standard of medical education. The position of one of the largest and most useful hospitals in Ireland—the Belfast Royal Hospital, is somewhat unique. It has, all told, something like 250 beds, and a large Medical School (until recently the second or third largest in the kingdom) associated with it. Its expenditure and work have gone on increasing till the annual outlay has reached nearly 9,000*l.* For a long time it had a comparatively small permanent income, the deficiency being made up by the utilization of all donations and bequests not especially bound up by conditions of investment. The authorities, however, recognising this rather precarious method of finance, and not wishing to cripple the usefulness of the hospital, set about putting its funds upon a more secure basis. In this they succeeded beyond their expectations, the yearly subscriptions and contributions from the working classes being doubled. But the unexpected, and it is to be hoped accidental, result has been that bequests and donations have so fallen off during the last two years, that the charity now finds itself, almost for the first time in its existence, in receipt of a respectable and permanent income, whilst its finances are perhaps more crippled than at any other period of

its history. In this grave condition of affairs the committee met and considered the question of closing a portion of the building, but they unanimously decided that to do so would curtail its usefulness, and in a great centre like Belfast, would inflict a hardship upon the poorer members of the population. They, therefore, resolved to go on, and admit every deserving case which presented itself. We cannot but admire their courage and enterprise, and hope they will be rewarded. Simultaneously, however, with this decision, a strenuous effort is being made to double the subscriptions and establish immediately a Hospital Saturday movement. We are glad to learn that this latter promises to be a very decided success.

Dr. J. Moore, the Senior Surgeon to the Belfast Royal Hospital, has signified that it is not his intention to offer himself for re-election, his last four years term of office having expired. Two candidates are in the field, and the staff will have good reason to be satisfied upon securing the services of either. They are Dr. T. K. Wheeler, who is at present one of the assistant surgeons, and Dr. T. Sinclair, Demonstrator of Anatomy at the Queen's College, Belfast. Both are graduates of the Royal University, and hold surgical appointments upon the staff of the Ulster Hospital for Children and Women. The contest, it is anticipated, will be a close one. Its interest is rather increased by the fact that the House Surgeon, Dr. Barron, has resigned his office with a view of becoming a candidate for the assistant surgeoncy, in case Dr. Wheeler should succeed in being elected to the staff. Dr. Barron's resignation has had the effect of calling into the field two candidates for the resident post, both being young men of some local influence; and altogether the electors will have no easy task in deciding upon the claims of so many able and willing competitors for the three vacancies. The ability and qualification of the candidates reflect credit upon the School of Medicine which never has been so active and successful as it is at present, though recent legislation has caused a feeling of insecurity and unrest which has had the effect of diminishing the number of students.

Professor Dr. Braun, of Heidelberg, has received a call to Jena as Professor of Surgery, and the Chair of Physiology at Königsberg, rendered vacant by the resignation of Professor v. Wittich, is to be filled up by Professor Hermann, of Zurich. Professor Dr. L. Mauthner is mentioned as the most likely successor to the Chair of Ophthalmology at Vienna, vacant by the death of Professor E. von Jaeger.

SCIENCE IN SCANDINAVIA.

It would be an enterprise of some difficulty, if not perhaps one of great pith and moment, to collect and classify all the many happy and unhappy similes which our writers and speakers have applied to international medical congresses, in obedience we suppose to that law which ordains that a man shall never think of one thing without immediately being driven to think of something else. It would be a still more arduous task, and one for which we do not feel ourselves competent, to excogitate a new similitude. Nor is there any need to do so, considering the wealth of comparisons at our disposal. Years ago, when international congresses were in their infancy, M. Boillaud compared them to the Olympic games, and last week M. Pasteur likened them to sign-posts pointing out to posterity the directions of scientific advance; while Prof. Panum, in his inaugural address, chose for his figure that of a concourse of ships of different nations drawn together to freely exchange their treasures. Other and lesser writers have compared these leech-motes—*Danicè* Lægemöder—to judicial assizes, to a scientific areopagus, to crusades, to ordnance surveys, to shopkeepers' stocktakings, to autumn manœuvres, to halts on the line of march arranged with the view of picking up stragglers and enjoying a little quiet refreshment, to dinner at a country-house, and to a hundred other things, according as the mind of the writer inclined to military, judicial, mercantile, social, or nondescript ideas. In our opinion, however, the best simile was that of the man who said they were like nothing else on earth—intending, we suppose, not to preclude their possible likeness to something in other spheres of existence.

The Congress which concluded its labours and its pleasures at Copenhagen on Saturday last was, according to the reports of all who were present, a remarkable success. The President claimed for it in advance that it would be a working congress—*un congrès de travail*—and the event justified his prediction, as will be seen from the brief reports of the sectional meetings which we publish in another column. But it was not less successful as a social gathering, as it could not indeed fail to be, considering the weather, the scene, and the exertions of the hosts. The hospitality of the town and citizens of Copenhagen knew no bounds. The great excursion to Elsinore, the banquet with the municipal authorities, the reception by the King, and the *fêtes* in the Tivoli Gardens, were models of organi zation, and perfect examples of thorough and not extravagant hospitality. A still more striking feature to the eyes of the average Londoner was the interest taken by the towns-people at large in the success of the Congress and the entertainment of its members. The universal tone of welcome which pervaded even the roughest of the crowds was unmistakable, and formed a pleasing contrast to the air of absolute indifference or uncomplimentary criticism with which such gatherings are apt to be regarded by the uneducated and unwashed many in our own towns. The tone of the representative newspapers in speaking of the Congress, which formed as might be expected the chief topic of the day in Copenhagen, was most eulogistic. They were also very energetic in the correct reporting of the principal meetings. The reports of the speeches, however, were not so generally useful to the members of the Congress as they might have been, owing to the fact that they were all published in Danish, instead of in the language in which they were delivered. An elaborate address of welcome which appeared on the

opening day, was, however, rendered in five distinct languages. The addresses delivered at the general meetings were not perhaps so elaborate, or so diversified as those which the London Congress had the pleasure of listening to ; but the oration of Sir William Gull, which we presented to our readers last week, and the interesting lecture of M. Pasteur, which we have re-translated not without difficulty from the Danish, and publish in the present number, are memorable, not only for their rhetorical excellence, but as furnishing important landmarks in the progress of scientific thought. They serve as apt complements to each other, dealing as they do with the two different modes of research—the experimental and the observational, the communistic and the individualistic —on which the progress of science depends. Such a research as that so tellingly described by M. Pasteur, within a few days after it had received, by an almost dramatic coincidence, its confirmation at the hands of a scientific commission, is quite beyond the scope of the mode of investigation fathered by Sir William Gull. On the other hand, even M. Pasteur, with all the help that he could command from his Government, from his able assistants, and from his own genius, would be quite unable to provide an answer to the problems with which the Collective Investigation Committee proposes to deal. The other general addresses, that of the President, in which he gave an interesting *resumé* of the history of these international congresses, and his final address on Food Rations, that of Prof. Tommasi-Crudeli on Malaria, that of Prof. Verneuil on the Neoplastic Diathesis, and that of Prof. Virchow on Metaplasia, were scarcely less important, and, together with the proceedings in the sections, will furnish material for much thought and study.

Turning from the general and international aspects of the recent Congress to one of more limited importance, it is a matter for some regret that the meeting was attended by such a comparative scarcity of the representatives of the English hospitals and schools. Of the leaders of the profession there was a brilliant series of names, which compared favourably with that presented by any of the other European nations ; but of those who are actively engaged in the teaching in the schools and in the regular work of the societies, there was a manifest deficiency. The rank and file of the profession, so to speak, who do not contribute to debate, but who, nevertheless, have their usefulness on occasions of this kind, were almost entirely absent. In the list of members who had enrolled themselves before the opening of the Congress, we find less than one hundred English names, and very many of these allowed their names alone to appear at the Congress meetings. Exclusive of the Scandinavian members, the Congress attracted thirteen hundred persons of various nations, of which scarcely one hundred were Englishmen, whilst no less than seventy found it worth their while to come from various parts of America. This absence of Englishmen was somewhat of a disappointment to the Copenhageners, who have not forgotten the Congress of 1881, and were naturally anxious that their efforts to repay the debt of hospitality should be duly appreciated by their former hosts. The audiences in the various sections, being so largely composed of members to whom the English language was unfamiliar, were on more than one occasion addressed in French or German by English speakers. Here also our countrymen did not show to the best advantage. Although, as Sir James Paget observed, we tend to become "cosmopolitan in mind," notwithstanding our insular position, by the repetition of international congresses, it can hardly be claimed for us that we are becoming cosmopolitan also in tongue. The necessity for a ready appreciation of French and German idiom was more than ever felt during the Congress, owing to the fact that the abstracts of the papers delivered were not translated, and in many instances were not even published in the language of their authors. The time will come, let us hope, when English will become the language of science, as it is becoming the language of commerce ; but meanwhile nothing is more important to the young physician and surgeon than an intimate acquaintance with those continental languages in which so much of medical interest is written and said ; and it will not be the least important result of these cosmopolitan gatherings, if they should induce the members of the profession in England to make these languages their own both in word and script.

THE BRADSHAWE LECTURE.

In his choice of a subject to fulfil the conditions imposed by the founder of this lectureship, Dr. Philipson has, to a certain extent, followed along the lines adopted by his predecessors in the chair. He decided to take a general survey of the pathological relations of the absorbent system, and not so much to give us new matter or observations as to sum up clearly our knowledge up to the present time concerning the least known and least studied system of the human body. His choice has been singularly fortunate as all will admit who read the lecture which he delivered at the College of Physicians on Monday. There can be no denying the fact that the lymphatic system is more neglected than any other in our *post-mortem* rooms. A hurried glance at the state of the mediastinal and mesenteric glands is all the attention devoted to it nine times out of ten, and we do not believe that we should exaggerate if we said that the thoracic duct is not examined and traced out in its whole length once in a hundred *post-mortem* examinations. Surely this neglect is altogether undeserved. We cannot get on without our lymphatic system, and it is quite time that it should receive its fair share of attention. Dr. Philipson has done his best to remove this reproach, and to arouse our interest in this fertile though somewhat unknown field. It cannot be regarded as other than a most happy coincidence that we should have this able exposition of the pathology of the lymphatic system brought before us at a moment when the brilliant address on the same subject from the physiologist's standpoint, by Professor Redfern, is still fresh in our memories.

The lacteals and the lymphatics are constantly engaged in providing the blood with fresh material partly derived from the air, partly from the food ; and

in this respect they may be considered as supplementary to the blood vascular system. We need not follow the learned lecturer in his description of the anatomy of the absorbents further than to remind our readers that in the extremities the deep and superficial lymphatics communicate only in the glands, and that the pleuræ, peritonæum and pericardium are not closed cavities but huge lymph sacs communicating with the lymphatic capillaries by means of stomata. From the point of view of the pathologist these have a great interest from the active share they probably take in the re-absorption of inflammatory products that may have been thrown out into the pleura or peritonæum, by making a way for these to escape into the lymph-channels, in their course along which they are much assisted by the respiratory movements, and especially by what Professor Redfern calls the pump-like action of the diaphragm.

Passing then to the pathological aspect, the first point considered was the mode of causation of œdema. Three varieties of œdema were to be recognised, viz. : the œdema of engorgement, inflammatory œdema and cachectic œdema. The first variety was the result of impeded circulation through the veins. When this occurred, at first there would simply be an increased flow through the lymphatics, and it was only when this became inadequate to carry off the extra quantity of fluid that œdema would appear. This view raises some nice points in reference to treatment, which we can hardly touch upon here ; it would render it probable that the old-fashioned treatment of dropsy by purgation was not successful simply by its mechanical action, but that the intestinal irritation thereby induced stimulated the lymphatics in the abdomen to renewed exertions, and that they in their turn demanded more work of those in the extremities. Lymphatic engorgement alone would not as a rule produce œdema, even when the thoracic duct itself was occluded. This was owing to the completeness of the deep anastomoses. Further, it was pointed out that when the lymphatic obstruction was complete, œdema was not a necessary consequence, as the blood vessels were able to take up a certain quantity of the transuded fluid again. Inflammatory œdema, the second variety, differed from the above chiefly in the fact that the fluid was much more rich in albumen and white corpuscles. It originated in some vascular change. The third variety or cachectic œdema included the dropsy seen in Bright's disease. In this case, too, there was probably some change in the walls of the blood vessels due to the action of the impoverished blood upon them. The fluid was poorer in albumen and solids than in the inflammatory variety.

After referring to the part played by the lymphatics in the diffusion of disease, the lecturer passed on to the consideration of certain diseased conditions of the lymphatics. Dilatation, he pointed out, might vary in degree from a simple dilatation of the capillaries to a well-marked lymphangioma. The causes of this condition were numerous; sometimes it was congenital, at others it followed upon inflammation, at others it was attributed to hypertrophy of lymphatics or plexuses, or paralysis of the coats of the vessels. External pressure too was a probable cause. Dilatation of the lymphatics was more common in warm and moist climates. One cause of this condition in tropical climates has been demonstrated beyond all possibility of doubt by the labours of Manson chiefly, and that is the plugging of the lymphatics by the aborted ova of the filaria sanguinis hominis. Whether other causes for its greater prevalence in these regions will hereafter be discovered, it is impossible to say. But it is probable that a larger number of such cases than has hitherto been believed will be found to be of this parasitic nature, when the method of recognising the disease, *i.e.*, the examination of the blood at night, becomes more generally known.

Lymphatic nævi, it was pointed out, were probably much more common than was generally supposed, and played the chief part in the causation of the hypertrophy of elephantiasis. Obstruction of the thoracic duct itself might be due to coagulation of lymph within, or to pressure from without by enlarged glands or aneurysm ; disease of the valves was also said to be a cause. Complete obstruction was a serious affection, being almost infallibly followed by emaciation and anæmia. If the obstruction remained unrelieved, some of the smaller vessels might burst from over-distension, either externally, or into the urinary tract or rectum, or into the peritonæum, as actually happened in the remarkable and interesting case brought before the British Medical Association at Belfast.

Inflammation of the lymphatic system was considered under the heads of lymphangitis, or inflammation of the vessels, and adenitis or inflammation of the glands, the two being often co-existent. The readiness with which the lymphatics in the neighbourhood sympathise with a wounded or inflamed part is so well known that we need not dwell further on this part of the address. Enlargement of the glands was of three kinds, simple hypertrophy or lymphoma, scrofulous enlargement and lymphadenoma. In a true lymphoma there was an increase in the lymphoid cells in a lymphatic gland with an overgrowth of its normal reticulum. Scrofulous enlargement usually commenced in a single gland and then spread to others in the immediate neighbourhood. At first there appeared to be an ordinary hyperplasia, but after a time the gland became opaque, yellow and caseous, breaking down in the centre. But though often followed by tubercle, scrofulous glands were not to be regarded as tubercular, they often developed in persons in the best of health. Tubercular inflammation was to be distinguished by the development of tubercles in the lymphatics as well as in the glands, and by the surrounding inflammation which was always present. We feel somewhat doubtful as to whether this distinction between scrofulous and tubercular disease of the lymphatic glands will be able to bear investigation. If it should ultimately appear that there is a group of cases in which glands become caseous without ever containing tubercle bacilli, then the distinction will be established. We do not think that has been done yet, and we doubt whether it ever will be. Lymphadenoma, the third variety of enlargement, was the last subject dealt with; its ætiology has still to be fathomed, though several causes were mentioned as contributing to its development.

THE INTERNATIONAL MEDICAL CONGRESS.

The work of the Congress began in earnest on Monday, August 11th, most of the sections being constituted within a few minutes of the appointed time. The attendance in every one was good, and in some it rather exceeded the accommodation. As in former Congresses, it was evident that the Surgical Section was by far the most popular, and indeed the presence of so many distinguished leaders in that branch of the profession was a sufficient explanation. Medicine, Pathology, Ophthalmology, and Gynæcology were also very largely attended. The office of President in the respective sections was filled by different persons at each sitting, these being selected, where possible, from the list of the honorary presidents appointed at the inaugural meeting on August 10th. The list includes, as the representatives of England, the names of Paget, Gull, MacCormac, Acland, Bennett, Lister, Spencer Wells, Erichson, Watson, and Marshall. Many points of difference are to be observed in the method of conducting the meetings, from the system in vogue in our own societies. One of the chief of these is the custom which prevails of allowing each author to reply at once to his critics instead of dealing with their criticisms in a single speech at the close of the debate. A good deal of wasted time is a natural result of this arrangement.

SECOND GENERAL MEETING.

Monday, August 11th.

M. Pasteur on Vaccination for Rabies.

The general meetings were held in the great hall of the University, a building admirably adapted for the purpose. It is a magnificent chamber, oblong in shape, and half-panelled throughout with carved cedar. Above the panellings are a series of wall paintings representing scenes in the history of Denmark. For the occasion of the Congress numerous trophies of the flags of all nations were displayed at either end of the hall. The tribune, from which the speeches were delivered, was placed in the middle of the one side of the oblong, immediately opposite the Rectorial Chair upon the other, over which floated the gorgeous white and gold banner of the University. Long before the hour fixed for the delivery of M. Pasteur's address, the whole of the available space in the hall and every point in the narrow gallery which runs just underneath the roof was densely crowded with an audience, including very many ladies, and nearly all the representative men whose faces are now familiar to members of the present and former Congresses. The chief points in the speech, which we publish in full in the present issue, have been already made known, and the words of the President, M. Bouchard, in which he referred to M. Pasteur's work as deserving "the gratitude of the people and the respectful admiration of all men of science," have been fully endorsed by all who are in a position to appreciate their truth.

THIRD GENERAL MEETING.

Tuesday, August 12th.

Addresses by Prof. Tommasi-Crudeli on Malaria, and by Prof. Verneuil on the Neoplastic Diathesis.

This general meeting, which was held under the presidency of Sir William Gull, was not by any means so largely attended as that of the previous day, when M. Pasteur's address was delivered. A fairly large audience, however, including many ladies, assembled to hear Professor Tommasi-Crudeli's address on the natural production of malaria, and the sanitation of malarial districts. His speech, delivered in the French language, dealt with the history of malarial affections, and especially with the popular views of the disease and its treatment, which have so largely influenced scientific men in combating it. He detailed his own views as to the conditions which combine to give rise to it in Italy, and especially in the city and neighbourhood of Rome. Whilst recognising the beneficial action of the planting of the eucalyptus in districts only slightly affected with malaria, he believed that effective drainage of marshy districts would afford the most real immunity. He advocated somewhat strongly the prophylactic virtues of arsenic in warding off attacks of malarial fever in individuals, giving it a decided preference in that respect over quinine.

A very long and positive address from M. Verneuil, of Paris, was next delivered, on the subject of the Neoplastic Diathesis. The subject, vague and indefinite in itself, was rendered by no means clearer by the numerous digressions in which the author indulged whilst reading his paper. His chief contention, not by any means new to the profession, was to the effect that a special diathesis is present in all persons affected with any form of new growth, whether it be a simple papilloma, or the most malignant cancer. This diathesis is hereditary, and renders its victims at any time liable to any and every form of neoplasm.

In proposing a vote of thanks to the two speakers, Sir W. Gull took occasion to point out the indefinite character of such speculations as these, although fully recognising the ability which had been brought to bear upon them.

A formal invitation was then presented by Dr. Billings, of Washington, on behalf of his American colleagues, offering to hold the next International Congress in the city of Washington, in September, 1887, and promising a cordial welcome to all who should accept it. At the request of the fifty-five American members of the Congress, he added, in support of the formal invitation which had been given to the Secretary-General in May last, a few words to show that it was something more than a mere formal invitation. At the commencement of this series of international gatherings, he said, the physicians of America had not as a body taken an active interest in their proceedings. Some Americans were always present, and their number steadily increased, until at the last two Congresses they had a fairly large representation. They had their own work and their own problems, which in sociology were somewhat apart from those of Europe; but in medicine, as in other sciences, the problems of the individual were those of humanity at large. It might adopt the motto of the "Three Guardsmen"—"all for one and one for all." Realising this more and more every year, the desire was now widespread among American physicians that one of these great reunions should be held in their own country, to which the wise men of the East should come, that they might be seen face to face. This invitation had not been decided upon without due consideration of the important responsibilities which it involved, and of the possibility of providing for the Congress a suitable reception. There was, he said, with a touch of American humour, a significant proverb, well known in their newspaper offices, to the effect that many fortunes had been lost in the attempt to conduct a daily paper in a weekly town. But they now felt old enough and strong enough to take care of their friends, if they would come to them. The reply to this invitation was reserved, to allow of further discussion of

the question, very many members, and especially those from Germany, desiring to hold the Congress in some European city.

WEDNESDAY, AUGUST 13TH.

Excursion to Elsinore.

To those members who had been diligently attending the meetings of the Congress, the programme issued on Wednesday morning was not unwelcome. It was short and to the point:—"Pas de Seances dans les Sections; Excursion à Elseneur et Kronborg." Accordingly, at ten in the morning, the docks, in which all the ships were gaily dressed with bunting, were crowded with members and the ladies who accompanied them. Six well-fitted and commodious steamers, generously provided by the General Steam Navigation Company of Denmark, awaited them. A pleasant passage of two hours' duration, under a bright sunny sky and over a smooth sea, brought them to their destination. On landing, the stewards conducted their guests to the old castle of Kronborg, situated in the narrowest part of the Sound, and commanding a magnificent view of the surrounding country and the opposite coast of Sweden. A lunch, sumptuous enough to satisfy the most fastidious, was served in the castle, and the two or three thousand persons who were present were regaled right royally. The afternoon was spent in listening to the band and exploring the rooms, towers and dungeons of the fortress. The party, who expressed general satisfaction with the arrangements, and astonishment at their completeness, was conveyed back to Copenhagen in three special steamers chartered for their accommodation.

FOURTH GENERAL MEETING.

THURSDAY, AUGUST 14TH.

Sir William Gull's address on International Collective Investigation.

There was a large attendance to hear Sir William Gull deliver his address on the International Collective Investigation of Disease, which we had the privilege of publishing in full in our last issue. At the close of the address a committee was appointed to carry out the scheme, the English members being Sir W. Gull, Dr. Humphry, Dr. Mahomed and Dr. Isambard Owen.

The Municipal Banquet and Fête.

The day's programme on Thursday was agreeably brought to a close by an entertainment offered by the town of Copenhagen to the foreign members of the Congress, in the shape of a banquet, concluding with a fête in the Tivoli Gardens, the Champs Elysées of Copenhagen. For the accommodation of the 1,300 guests (exclusive of Scandinavians), an immense area by the side of the harbour had been converted into a dining hall during the few previous days. Built entirely of wood and glass, and with a ceiling formed by broad festoons of canvas; this gigantic apartment contained forty-one tables, each seating thirty guests, exclusive of three large tables placed upon a central dais, and reserved for the leaders of sections and others more or less distinguished in medicine and surgery. According to the national custom the toasts and speeches were introduced between the courses of the banquet, and were interspersed with vocal and instrumental music. A novel feature, to Englishmen at least, was the singing in unison by the whole of the assembled guests of a series of laudatory songs composed expressly for the occasion. The simplicity of the melodies and the easy rhythm of the words enabled everyone to join with a vigour worthy of the occasion. Complimentary speeches were delivered in abundance, Sir James Paget amongst others delivering a hearty eulogium on the hospitality and also on the hygienic excellence of the town of Copenhagen. At the close of the banquet the whole company adjourned on board three large steamers, drawn up to the adjacent quay to receive them, and from thence, amid the most hearty cheering from the thousands of the townsfolk assembled along the whole route, were slowly conveyed to a landing place near to the Tivoli Gardens.

The latter, which constitute the great centre of amusement for all parts of the city, and include concert and ball-rooms, theatres, restaurants, and every kind of entertainment, were brilliantly illuminated for the occasion and thronged with a vast crowd, estimated at 30,000 persons. A brilliant display of fireworks brought the whole entertainment to a close about 11 o'clock. Too great praise can hardly be awarded to the absolute perfection of the organisation employed in this great undertaking. Marked throughout by the most thorough attention to the little details which make or mar the pleasure of those who take part in it, the whole affair was triumphantly successful from the beginning to the end. The Danish gentlemen present did everything in their power to make the occasion memorable to their foreign guests, and their efforts were in this respect successful in the highest degree.

FIFTH GENERAL MEETING.

FRIDAY, AUGUST 15TH.

Prof. Virchow's Address on Metaplasia.

A large audience assembled to hear Professor VIRCHOW'S address on Metaplasia. Professor Semmola, of Naples, occupied the chair. The following is a short abstract of the speech, which occupied rather over an hour in delivery. After referring to the early views with respect to the processes of life, which prevailed at the beginning of the present century, and to Schwann's famous theory of the formation of cells by crystallisation, Professor Virchow observed that the doctrine of the formation of tissues, which came originally from England through the teachings of Hewson and John Hunter, maintained their origin from plastic lymph. This view would not have received much attention had it not been followed by Schulze's doctrine that formation of tissues and their subsequent nourishment were alike to be attributed to the "intercellular humour," or plasma, of the blood. This view gave rise to the belief that the healing art consisted in the maintenance of this nourishment. About thirty years ago, Virchow himself made the first step towards the "cellular pathology" by originating the phrase "Omnis cellula e cellulâ," an idea which was in strong contrast to the doctrine of cell formation from plastic material. He explained how the object of nourishment was to keep the cell alive, and how the process of growth consisted in the formation of cells from previously existing cells. The two processes of formation and nourishment were thus distinct. All organic processes took place inside the cells and never outside them. He then defined automatic nourishment and that change of matter which he called transit-change, which consisted essentially in the taking up and giving off of nutritive matter by certain parts of the body, without employing the matter so taken up for their own nutrition. Having thus separated nourishment and formation from one another, he proceeded to speak of the processes of growth, and especially of the production of new tissue

forms, to which he gave the name of Metaplasia. He showed how this metaplasia was the foundation of important pathological processes, and one of the pre-suppositions of the Darwinian theory. Taking bone as an illustration, he referred to the numerous theories of its formation, and explained the formation of marrow, which he defined as a tissue of changing forms, and therefore an excellent instance of metaplasia. He followed the processes of new tissue formation through many of the different kinds of tumour, and made especial reference to the pathological phenomena of myxœdema. With respect to the white corpuscles of the blood and the possibility of their metaplasia, he was inclined to believe that there was a definite limit fixed beyond which it did not go.

At the close of his address a cordial vote of thanks was offered to Professor Virchow, on the motion of Professor Semmola.

The Supper at the Christiansborg Palace.

The announcement by His Majesty the King of Denmark, of his intention of entertaining the members of the Congress at the Palace, was received on Wednesday, the 13th, with the greatest satisfaction, as a further evidence, if any were wanting, of the cordial recognition of the value and importance of this great international gathering which pervades all classes in Copenhagen. In obedience to the Royal command, the members began to assemble at the Christiansborg Palace punctually at the appointed hour. The long series of saloons, opening out of one another, which constitute the whole front of the building, so well known to English tourists, were speedily thronged with an immense assembly of guests, probably including in their number a good many who would have found some difficulty in substantiating their claim for admission. Very few, however, of the genuine members of the Congress were absent. After about an hour spent by the members in general conversation and the observation of the historical and legendary paintings with which many of the saloons are decorated, the King and Queen of Denmark, the King and Queen of Greece, the Crown Prince and several junior Members of the Royal Family, entered the principal room and conversed freely with all those members who were able to push themselves forward in the crowd of aspirants for this mark of the Royal favour. A general adjournment then took place to another series of rooms, in which a most lavish display of the good cheer of Denmark was prepared, to meet the vigorous onslaught which was subsequently made upon it. At a table at the head of the beautiful White Hall, in which also were tables for the less exalted members of the Congress, the Royal hosts entertained the principal leaders who had taken part in the week's work. In a short and clearly delivered speech in French, the King of Denmark offered a welcome to the foreign members present, expressing at the same time his sense of the value of the Congress in the interests of the medical sciences, and his gratification at the selection of the city of Copenhagen as its place of meeting. To Sir William Gull was entrusted the honour of replying to this toast, which he did very briefly in English. His call for cheers for the King and Queen was most vigorously responded to.

SIXTH GENERAL MEETING.

SATURDAY, AUGUST 16TH.

Prof. Panum's Address on Food Rations.

The final general meeting of the Congress was held under the Presidency of Professor His. An address was delivered, in French, by Professor PANUM, on the food rations for men in a state of health and disease, especially in hospitals, infirmaries and prisons of different countries, in which he dwelt upon the necessity which exists for a better understanding of the chemical composition and physiological action of the food in daily use in various countries. He gave an elaborate account of his investigations into the subject of his paper and suggested that efforts should be made by members of the Congress to secure for themselves and their patients some more accurate knowledge of the nature and actions of food, not only for hospital use, but also for the exigencies of private practice. He did not believe that any good could come of an International Cookery Book, on the model of a pharmacopœia, but thought that physicians of all nations might work together, after the manner of the Collective Investigation Committee, with a view to obtaining a common method of procedure with respect to the ordering and use of food. He would further advocate the employment of definite tables indicating the composition of all ordinary forms of food, which should be suspended on the wall of every consulting room. Special attention ought also to be paid to the instruction of the poor in the use and abuse of food.

At the close of the address, Professor His resigned the chair to Professor Panum, and offered the thanks of the Congress to him for his address. He also read the report of the Committee which had been appointed to decide upon the place of meeting for the Congress of 1887. Three cities had given invitations, viz., Berlin, Rome, and Washington, and the reasons for and against the choice of these were entered into at some length. It had been decided to accept the Washington invitation, but the question remained for final settlement by the vote of the members present.

The question of acceptance of the invitation was then put from the chair by Professor Panum. A large majority voted in favour of the proposition, and it was finally settled that the International Medical Congress of 1887 shall be held in Washington.

Dr. BILLINGS, on behalf of his American colleagues, thanked the members for the honour of their choice, and promised that all those present who should take the trouble to cross the Atlantic in 1887 should be enabled to see something of American cities, American institutions, and American hospitality. He could not sufficiently express his sense of the extreme hospitality, or his admiration of the perfect organisation which had rendered the present Congress so thoroughly successful. He knew that too much popularity was apt to render a gathering such as this forgetful of its business, but he was convinced that a vast amount of valuable work had resulted from the steady and industrious labours of the sections.

Professor ROSSANDER, speaking on behalf of the non-Danish Scandinavian members, returned thanks, in a vigorous speech, to the Danish authorities, to whose exertions the success of the Congress was entirely due.

Sir RISDON BENNETT expressed the feelings of all the British members of the Congress in making a hearty acknowledgment of the unbounded hospitality and the brilliant entertainments provided for their guests by the Danish Executive. The resources of London, great as they were, could hardly exceed in their results the magnificent reception which had been accorded in Copenhagen.

Professor VIRCHOW, speaking in French, proposed that the thanks of the Congress be offered to His Majesty the King of Denmark, to the Municipal Authorities of the town of Copenhagen, and lastly to the President, Professor Panum.

All these propositions were received with the utmost enthusiasm.

Professor PANUM, in reply, disclaimed any praise for himself, and paid a high compliment to the other working members of the Committees, and especially to the Secretary-General, Dr. C. Lange, the mention of whose name was received with prolonged cheering. In bidding farewell to the members, he expressed the hope of meeting them in equal numbers at Washington in 1887:—"The work of our present sitting is now concluded. *Messieurs, Adieu! Au revoir!*"

MEETINGS OF THE SECTIONS.

I. & II. SECTIONS OF ANATOMY AND PHYSIOLOGY.

ON Monday in the Anatomical Section papers on the Rotation of the Arm were read by Messrs. Morris, of London, and Hejberg, of Christiania; and in the Physiological Section, a long paper on the part played by the "fugitive corpuscles of the blood" in the formation of fibrin and in coagulation, and on the relation which the "Hæmatoblasts" of Hayem and the "Piastrines" of Bizzozero hold to the "fugitive discs of the blood," was communicated by Professor Norris, of Birmingham.

On Tuesday, August 12th, the Anatomical and Physiological Sections held a combined sitting for the reception of a paper by Professor VON EBNER, on the histology of striated muscle with demonstrations by Professors Engelmann, Merkel, and Retzius. Professor Kronecker described the approximate position of the centre of co-ordination for the movements of the ventricles of the heart of the dog, about one centimetre behind the descending branch of the left coronary artery. Injury to this centre stopped pulsation at once, irregular vibrations and twitchings alone remaining. By a series of experiments Professor Kronecker has ascertained that this centre is neither inhibitory nor motor, but distinctly co-ordinating.

Dr. GASKELL of Cambridge, read a paper on inhibitory actions and the inhibitory nerves in general. After referring in detail to the present views on inhibitory and exeitor impulses in single nerve trunks, and to Foster's experiments on direct inhibition of cardiac muscle of snail, Dr. Gaskell described experiments on portions of tortoise cardiac muscle, upon crocodiles in which the vagi had been mutilated so as to ensure complete degeneration of their cardiac periphery, and upon the cardiac nerves of frogs, in which the vagus and sympathetic rami were completely isolated. Some recent experiments in the Cambridge Laboratory were also quoted as entirely disposing of Foster's experiments upon the snail's heart. Dr. Gaskell's experiments, the records of which were exhibited in the shape of most complete polygraphic tracings, led him conclusively to state that muscle functions are not inhibited except through nerve stimuli. As to the condition of inhibited tissues or organs, whether the state is one of death or increased potential energy, he showed tracings of cardiac contractions during stimulation of the sympathetic after or during stimulations of the vagus, which emphatically supported the latter view.

III. SECTION OF GENERAL PATHOLOGY AND PATHOLOGICAL ANATOMY.

(A report of Monday's proceedings in this section appeared in our last issue.)

Tuberculosis.

TUESDAY, August 12th, was occupied throughout the day with the consideration of papers dealing with the subject of tuberculosis. A paper was read by Professor CHAUVEAU, of Lyons, on the importance which must be attached to the tubercular affections of domestic animals, in respect of the possibility of tubercular infection from them to human beings. Tuberculosis of the cow udder was described by Professor BAUG, of Copenhagen. It consists essentially in the development of a diffused, painless swelling, generally limited to one quarter of the udder, hard in consistence, and exuding a milky secretion. The quantity of milk secreted by the affected part of the udder is generally, but not always, diminished. The general health of the animal is but little affected. The milk from the affected udder invariably contained tubercle bacilli, which could be somewhat separated with the cream by centrifugal separators, but which, nevertheless, remained in large numbers in the milk. Even the milk from the unaffected parts was sufficient to set up tuberculosis in rabbits.

An interesting paper by M. GRAUCHER, of Paris, giving a history of the theories and discussions with respect to the identity or distinction of scrofula and tuberculosis, and relating the results of a series of inoculation experiments, left the question still as unsettled as before, although Professor Graucher himself took the view that tubercle may exist in a variety of degrees of virulence, and would regard the scrofulous secretions as simply an attenuated form of tubercle. Professor WEIGERT, of Leipzig, on the other hand, maintained that the virulence of tuberculosis is directly dependent upon its localisation. He instanced the lymphatic swellings of children as proving the fact that where the morbific material remains firmly encapsuled it also remains inert and local, but that the spread of the disease so common in children is due to the material getting into the lungs, where, from the anatomical peculiarities of the tissue, it is rapidly spread over the whole organism.

During the sitting of the section under the presidency of one of the committee, a diversion was caused by the entrance of M. Pasteur, who, amid general applause, was called to the chair for the rest of the sitting.

Chronic Nephritis.

IN the meeting of this section, on August 14th, M. CORNIL, of Paris, read a paper on the Relation between the Changes of Connective Tissue, Parenchyma, Blood Vessels, and Heart in Chronic Nephritis. He was followed by Sir W. GULL, who, reserving the full text of his paper for publication in the "Transactions," presented an abstract in French of the principal points contained in it, supplementing the statements with comments in English. He insisted very decisively on the universality of the changes which he has described, and called especial attention to the alterations which take place in the interstitial circulation in addition to those more easily recognised in the capillary vessels themselves. His remarks were confined to a form of so-called nephritis with contracted kidney and cardiac hypertrophy, occurring at or after the middle period of life. This affection had been termed Bright's contracted kidney in the third stage, granular kidney, cirrhotic kidney, the kidney of interstitial nephritis, but these terms were open to objection. Bright's investigations had no relation to one particular form of disease of the kidney. They included every form of renal change, associated only by albuminous urine during life. The persistence of the term Bright's kidney was due to the idea that renal lesions were always of one form and character, had a local origin, and were the source of the systemic lesions which were associated with them; and in a vague way, that albuminuria indicated one pathology. Similarity of morbid histological forms was, however, no criterion of pathology. Granulation and contraction might have various meanings. Criticism of differences required wider survey, including morbific cause, clinical history, and tissue changes in other organs. Morbid histological forms were limited in expression, however originated. Whilst fully acknowledging re-active effects of renal lesions on the organism, he held that such admissions did not close the chapter of renal pathology. There was an arterio-capillary fibrosis which might begin in any part of the vascular area, after the middle period of life. The kidney textures were not necessarily first affected in this change; though from their vascular supply they were apt to be first affected. Cardiac hypertrophy might precede defect of renal function, and arterio-capillary fibrosis, with cardiac hypertrophy, might begin whilst the urine was quite healthy. In this cachexia the intima and adventitia of the arterioles and capillaries were changed by fibroid, or hyalin fibroid, deposit. The muscular coat was thickened, and the muscle-cells mostly degenerated. Death might occur from cerebral hæmorrhage (ingraveseent apoplexy), with cardiac hypertrophy; whilst after death the kidneys might be found but little

affected. The fibroid change in the kidney here treated of had no acute beginning, no stage which could be called inflammatory. Its early stage coincided with vascular changes in other organs, causing a train of symptoms not yet referred to a recognised pathological basis. Intercurrent inflammation in organs was common in this state of the vessels. If albumen happened to be present in urine, investigation had hitherto been closed. Independent pathologists agreed that the renal fibrosis was not the result of acute inflammation; and one stated that this condition was due to a chronic atrophy, the primary change being a peri- and endo-arterial fibrous thickening; another, still maintaining the inflammatory character, regarded the process as of an essentially chronic nature, partaking more of the character of growth than inflammation. The description of the changes in the renal vessels and textures in this state, given by independent observers, entirely accorded with what he had described as occurring in other organs; as, for instance, in sections of the cord, in arterio-capillary fibrosis either with or without renal disease, and the same occurred in other organs, lungs, stomach, skin, &c., proving that the renal change had common characters with those more widespread through the organism. The heart was liable to these degenerative changes; but death usually occurred before they were much advanced in it. The hypertrophy was referable to loss of arterio-capillary elasticity, and hindrance to circulation of plasma through the tissues (interstitial circulation). Whilst in the cases in question the arterio-capillary changes could not be referred to the kidney as their source, it still remained to be determined how far a change, beginning in the kidneys, might promote a cachexia, inducing arterio-capillary fibrosis. This arterio-capillary change was entirely absent in a large class of renal diseases, though occurring at an earlier period of life; and might be of long duration. Defective renal function would seem to have a weakening influence on the circulation, and to produce anæmia as well as uræmia. Many changes in the functions of organs in renal disease, hitherto considered due to uræmia, were more truly referable to arterio-capillary changes.

Dr. Mahomed observed that we appeared to have arrived at this position, that Bright's disease consisted of two factors, the nephritic and the cardio-vascular. Professor Cornil and Sir W. Gull both recognised these factors, but regarded them from different standpoints, the former maintaining that the nephritis was the primary condition, whilst the latter believed that the general cardio-vascular change might in many cases precede the kidney affections. Dr. Mahomed would go farther than this, and say that the disease commenced either in the blood vessels, or in the tissues along the line of the interstitial circulation. Increased arterial pressure was the first indication of this condition, and was a purely functional change in the first instance, due, as in scarlatina, to the circulation of morbific material. It might come and go in the course of twenty-four hours. The whole process of stasis and delayed circulation of blood cells might be easily observed in the frog's foot. With the persistence of the increased arterial pressure and delayed interstitial changes, the characteristic nephritic symptoms might be induced. In certain forms of acute kidney mischief, a nephritis might come and go without any general systemic changes either preceding or following it.

On August 15th, Professor Heller, of Kiel, read a paper on congenital syphilis of the lungs, which he considered to be a somewhat neglected subject. He characterised syphilis of the lung as one of the commonest changes, whether occurring alone or in combination with other syphilitic affections, and above all as the direct or indirect cause of death in all syphilitic children. He brought forward these data on the strength of a very large series of pathological observations. His remarks were not challenged in debate.

Professor Langalli, of Pavia, read a long communication upon the succession of pathological tissues, and especially of the relation of fibrous tumours of those sarcomatous or carcinomatous nature, a subject which Professor Virchow, in complimenting Professor Langalli, characterised as one of the most difficult and complicated with which pathologists have to deal. The paper was not discussed. During the sitting of the section the news of the death of Professor Cohnheim was received, and a vote of condolence to his family was proposed from the chair by Professor Virchow.

IV. Section of Medicine.

The first sitting of the Medical Section, on August 11th, opened with a few introductory remarks from Professor Trier, who briefly reviewed the forthcoming work of the section, and regretting the absence of Professor Grainger Stewart, nominated several honorary presidents, amongst whom were Sir Risdon Bennett and Sir Henry Acland, as the representatives of England. Dr. Isambard Owen was also nominated as English Secretary for the Section.

Sir Risdon Bennett then took the chair, and called upon Dr. S. Laache, of Christiania, to read a paper on the value of recent researches on blood corpuscles for the pathology of anæmic and leukæmic diseases, the greater part of which is contained in his recently published work on the subject. The relative number and hæmoglobin contents of the red corpuscles in the respective diseases and the variations to which they are liable, formed the chief substance of his paper.

Drs. Paul Guttmann, of Berlin, and Biermer, of Breslau, discussed the paper, the latter maintaining the existence of three kinds of white corpuscles and of nucleated red cells.

Nomenclature of Auscultatory Sounds.

Dr. Austin Flint presented a list drawn up by the Members of the Committee, appointed at the last Congress for the purpose, of a proposed series of terms to constitute a uniform nomenclature of auscultatory sounds in the diagnosis of the diseases of the chest. He found that the terms proposed by the various members did not present any material points of difference, and none of the really important signs had been omitted. Some variation in the interpretation of the term "râle" was to be noted, some indicating a moist sound thereby, whilst others restricted it to the dry sounds. The definitions of bronchophony and of pectoriloquy were not quite in accord. He suggested that the report should be considered as provisional only, and that certain representatives of other countries should be added to the list to prepare a second report for the Congress of 1887. This proposal was accepted by the section on the motion of the President, who expressed the thanks of the members to the framers of the present report.

Malarious Infection in Man.

At the afternoon sitting, at which Dr. Liebermeister was called upon to preside, Professor Tommasi-Crudeli, of Rome, read a paper on Malarious Infection in Man. The human organism, he observed, presents different degrees of resistance to the action of malarial poisons. In some instances this degree is very high, and is hereditary in nations by a kind of natural selection. In the most civilized countries the conditions of life are opposed to the beneficent action of this natural selection. The specific ferment attacks the red blood corpuscles and causes necrobiosis, as a final result of a series of alterations in the protoplasm of the cells. These changes are characteristic and pathognomonic as a sign of infection.

In illustration of his paper, Professor Tommasi-Crudeli demonstrated, on Friday, a series of microscopical specimens of red-blood corpuscles, taken from cases of malarial disease in the human subject. These had been stained with aniline. In each preparation the healthy blood corpuscles were to be seen unstained, the others containing one or more small coloured particles, which he believed to be the germs of a bacillus. In a specimen of a blood-vessel of the pia mater, the contained blood-cells were seen to present large numbers of these particles.

Dr. Goldschmidt, of Lyngby, exhibited a chart, showing the progress of epidemics in Denmark and their close connection with floods from irruption of the sea, and from excessive rainfall.

Dr. Kering, of St. Petersburg, communicated a paper on Cerebro-Spinal Meningitis.

On Tuesday, August 12th, the section was presided over by the Dr. Bouchard, of Paris, and was occupied during the entire sitting with papers on the well worn subject of

The Treatment of Pulmonary Consumption.

Drs. Ewald, of Berlin, Graucher, of Paris, Quinlan, of Dublin; and Shingleton Smith, of Bristol, read papers, the two latter advocating the treatment of pulmonary consumption with verbascum thapsus and iodoform respectively.

Dr. Jaccoud, of Paris, pointed out with some force the fact that the discovery of the bacillus tuberculosis has been singularly sterile in its effect upon the treatment of phthisis. In prophylaxis also, he showed that precautionary measures against possible infection had been taken long ago. The main point at which to strive was to maintain the health of the upper part of the lung, and so render it insusceptible of infection. The good effect of high altitudes he believed to be due to the fresh air and means of exercise; he had himself pointed out the freedom of such localities from micro-organisms in the air. He considered that Koch's discovery was of great nosological interest, but not of any value in a therapeutic sense. Possibly in the future, owing to the discoveries of M. Pasteur, it may come to be of some prophylactic importance.

At the afternoon sitting in this section, Dr. Austin Flint took the chair.

Myxœdema and its Pathology.

A paper on Myxœdema and its Pathology, of which the following is an abstract, was communicated by Dr. W. B. Hadden, London. Myxœdema is a disease characterised by a general swollen condition of the body. The appearance of the patient suggests ordinary dropsy, but the parts do not pit on pressure. The face is swollen and puffy, the lips and alæ nasi thickened, the eyelids œdematous looking, and on each cheek there is a well defined flush. The general expression is placid and inert—in a word, cretinoid. The skin everywhere is dry and harsh, perspiration and the secretion of the sebaceous glands are almost absent. The hands are broad, clumsy, and "spade-like." The hair is soft and scanty, and tends to fall out. The nails and teeth share in the general malnutrition. The thyroid gland wastes, although it is difficult often to determine this, in consequence of the swelling of the tissues of the neck. Soft masses are usually to be felt in the supra-clavicular regions. The temperature is almost constantly subnormal. The speech is slow, thick, monotonous, nasal. The tongue seems to be too large for the mouth. There is general muscular feebleness, the gait is slow and tottering, and all movements are retarded. There is marked mental lethargy. An indisposition to all bodily and mental activity is one of the most striking features of the disease. The urea excreted by the urine is much diminished, but with this exception there is no constant change. In the later stages albuminuria and true dropsy may supervene. Somnolence, insanity, impairments of memory, disorders of the special senses, and certain subjective sensations are frequently experienced. The tongue, uvula, soft palate, and larynx are generally swollen, and difficulty in deglutition is often observable. The appetite is bad, and defæcation usually difficult, in consequence, probably, of swelling of the mucous membrane of the rectum. The disease usually attacks adult women, but it occasionally commences before twenty, possibly sometimes in childhood. It occurs among rich and poor. Climate and race are probably without influence. Syphilis and excess of alcohol have no share in its causation, but serious mental disturbance and exhaustion from excessive child-bearing are occasional antecedents. As regards family history, phthisis is remarkably frequent, acute rheumatism and insanity occasional, and in at least one case myxœdema has been observed in the collaterals. As to morbid anatomy, the constant factor is a diminution in size of the thyroid gland. According to Dr. Ord there is solid œdema of the connective tissue throughout the body, and a great increase in the amount of mucin —hence the name myxœdema (*mucus*, *œdema*). The author believes that the disease is probably dependent on changes in the sympathetic nervous system, and he thinks it not unlikely that the thyroid is in some relation with the peripheral sympathetic nerve-fibres. This view has recently been borne out by *post-mortem* evidence. Improvement has occasionally been effected by drugs, especially jaborandi.

After the conclusion of this paper, Professor Brandes exhibited a living specimen of myxœdema. The patient was 40 years of age, and had been ill for eleven years. All the characteristic symptoms were present.

Sir W. Gull referred to his paper on Adult Cretinism, published eleven years ago, which disease he considered to be identical with myxœdema. In these cases of sporadic cretinism, met with in England, he regarded the myxœdema as accidental and not the essence of the disease.

Dr. Mahomed thought that Sir W. Gull's early observations were remarkably confirmed by the latest knowledge of the subject, although his remarks did not include the whole of our information. Was the disease a permanent one? He believed that it was not only not permanent, but also not universal, and that single parts might become affected with myxœdema. It consisted essentially of perverted nutrition, but this need not be universal in character. Many cases had been observed to improve under treatment. The true origin of the disease remained a matter for speculation.

On Chronic Diarrhœa and Dysentery in persons returned from Tropical to Temperate Climates.

Sir Joseph Fayrer and Dr. Joseph Ewart read a paper on this subject. The disease is variously known as "diarrhœa alba," Hill diarrhœa, and in China "Sprue" (Manson). It may occur in persons who have not had any preliminary symptoms of malaria, but most frequently happens in the progress of convalescence from such fevers. The extreme variations of vaso-motor nerve equilibrium which accompany malarial attacks tend to weaken the resisting power of the abdominal organs and it is for this reason that the transference from one climate to another is liable to cause catarrhal affections of the intestines. This form of diarrhœa is essentially periodic, it is marked by progressive deterioration of the secreting apparatus with a tendency to shedding of the epithelium of the villi. Granular and fatty degeneration are generally present and may be accompanied by amyloid infiltration. The liver and kidneys are often found in a state of chronic inflammation. The symptoms are at first, those usually associated as indicating "indigestion." Then follow more grave changes, anæmia, continued diarrhœa with abundant offensive flatus, thirst, scanty urine, general wasting. The attacks of diarrhœa are still periodic and cannot be controlled for long together. The third stage is one of extreme emaciation, continued white diarrhœa, extreme flatulence, tendency to dysentery, anasarca, purpura followed by death, generally from exhaustion. The treatment as suggested by Sir J. Fayrer is simple, consisting of absolute rest, good ventilation and purely milk diet, given at first in small quantities and frequently, and gradually increasing in quantity until from three to four quarts are consumed in twenty-four hours. Occasional small doses of opium may be given but other drugs are to be avoided. The time for gradual return to ordinary diet must be determined by the circumstances of each individual case. Several illustrative cases are appended. The value of absolute rest in the treatment of chronic dysentery is also insisted upon. A purely milk diet and occasional evacuation of the lower bowel by mild enemata, has superseded the treatment by astringent remedies, although stimulant doses of twenty minims of turpentine in milk are often useful in very indolent cases. Healing of the local ulcers is the main point to be aimed at, and when that is accomplished the general health is often fully restored.

Peritonitis from Perforation.

On Friday, August 15th, Dr. Prilram, of Prague, in the chair, Professor With, of Copenhagen, brought forward a paper on peritonitis, resulting from the diseases of the vermiform appendix. Perityphlitis, he considered, took its origin from ulceration and perforation of the vermiform appendix. A peritonitis from this cause he would call "appendicular peritonitis." This might be either adhesive (before perforation), or general (after the perforation).

Physiological rest to the intestinal canal was chiefly indicated for treatment, obtained especially by means of opium and a complete abstention from laxatives for as long a time as twenty-four days, if necessary. Considerable restrictions must be put upon anything like operative interference.

Dr. Austin Flint referred to an interesting point in the diagnosis of perforation of the intestine, viz., the value of the persistence of hepatic dulness on percussion as constituting proof that perforation has not taken place. A very small quantity of air within the peritonæal cavity suffices to abolish hepatic dulness. This may be shown by the simple experiment of introducing into the peritonæal cavity of the cadaver, a small quantity of air through a trocar. A tympanitic resonance is thereby produced over the region of the liver. Dulness over this region, even if the vertical diameter of the space in which it is found be ever so small, is proof that perforation has not taken place. The presence of tympanitic resonance however is not a clear proof to the contrary, since considerable distension of the colon may produce it over the whole hepatic area to its junction with the lung resonance. The treatment by opium had long been practised in the United States, where it was introduced, thirty years ago, by Professor Alonzo Clark. Professor Clark had ascertained that in certain cases of peritonitis the tolerance of opium is increased enormously and that, in these cases, in order to secure the advantage of the treatment, the doses should be in proportion to the increased tolerance. The degree of tolerance could only be determined by closely watching each case individually. Although laxatives must be avoided it was sometimes necessary to remove accumulations in the rectum.

V. Section of Surgery.

On Monday, August 11th, formal business commenced at 10 a.m., by a speech from Professor Plum, in which the death of Professor Hohner, who was to have presided in this section, was feelingly referred to. The following gentlemen were then nominated Presidents of Honour:—Sir J. Paget, Sir J. Lister, Sir Spencer Wells, Sir W. MacCormac, Messrs. Marshall, Bryant, and G. Buchanan; MM. Ollier, Verneuil, Trélat; Herrn Esmarch, Volckmann Gurlt, Koch, Tilanus, Sklifossoffsky, and Drs. Sayre and Billings; lastly, Messrs. Chiene, Ogston, Kölliker, and Lauenstein were nominated to act as secretaries. Professor Plum stated that having been so unexpectedly invited to take the chair, he should avail himself of the services of the different Presidents of honour to preside at the various meetings, and Professor Volckmann was unanimously invited to take the chair for the day.

Before proceeding to actual business, Sir Hy. Acland, as a personal friend of the late Professor Hohner, spoke of the loss sustained by the section in the following terms:—After the very touching and affecting manner in which the death of Professor Hohner has been adverted to by your President and others, words seem unnecessary, still more so from one engaged in the pursuit of another branch of the profession; yet as one who had the honour and advantage of his friendship, I feel entitled to express on the part of the strangers present in Scandinavia the regard and esteem in which that admirable man has been held. I accidentally gained his acquaintance while on a visit here several years ago, and was at once struck by his singularly beautiful character, unsurpassed modesty, and scientific earnestness, combined, I believe, with superior qualities as a practitioner. As a visitor with him in his daily round of hospital work I was only too proud to receive a lesson from him, and when only the other day I heard of his death, I could hardly bring myself to come to a city where I had met him. I am glad to have this opportunity of expressing, as a stranger, the loss which we feel has fallen on surgery and science, as well as our regret at having no more amongst us such an example of high character in public and private life.

Operations for Cancer of the Rectum.

The subject of the operative treatment of malignant disease of the rectum was then opened by Professor Esmarch, who read a paper on Extirpation of the Rectum for Cancer. The principal point in Professor Esmarch's communication was the expression of his belief that a permanent cure might follow the excision of the cancerous rectum. He pointed out that recent advances in technique had lowered the death percentage from 50 to 20, and expressed the conviction that better results are still to be obtained.

Professor Esmarch was followed by Mr. Bryant, who presented a tabular arrangement of 82 cases of colotomy performed by him, from which he drew the following conclusions:—(1) That in all cases of cancerous stricture of the rectum or colon, including the annular (which are not amenable to lumbar colectomy or anal excision) right or left lumbar colotomy is strongly to be recommended with the well-grounded hope of relieving suffering, retarding the progress of the disease, and of prolonging life even for five or six years. (2) That lumbar colotomy is valuable as a *curative* operation in syphilitic and simple ulcerations of the bowel which resist other treatment, including cases of recto-vesical fistula, and that it is remedial in examples of volvulus of the sigmoid flexure, as well as of obstructions caused by tumours. (3) That to secure these advantages it is necessary for the operation to be performed before the pernicious effects of obstruction occur. He adverted also to his recent modification in operating directed towards the prevention of the passage of fæces into the lower end of the bowel. The usual colotomy incision is made and the bowel is exposed; this having been done, traction is made on the pelvic end, and a knuckle of colon is easily drawn out after free separation of the cellular connections with the finger. The knuckle of colon is left projecting in the wound, unsecured by stitches, and on the fourth day punctured. Mr. Bryant would have no objection to stitches if the operator thought them necessary. The operation has been at present performed in two cases, with eminently satisfactory results.

M. Verneuil considered colotomy a palliative measure only, preferring iliac colotomy as a simpler and equally effective operation. He spoke at some length of the palliative operation of linear rectotomy, practised by himself during the last 18 years in cases which he considered unfit for colotomy or extirpation. The operation is performed in the following manner: The left forefinger being introduced as far as the upward limit of the growth, the thermocautère is introduced external to the sphincter ani in the posterior raphe well without the limits of the growth. When the cautery has been pushed so far that the finger is in danger it is withdrawn and a thick probe introduced into the canal, upon which the complete division into the lumen of the bowel is made. Professor Verneuil claims for this operation that it relieves pain and obstruction.

Professor Trélat stated that he practised all three operations of colotomy, rectotomy and extirpation in suitable cases; but his results forced him to the conclusion that all three were palliative measures and not curative. Of ten cases of extirpation in his practice, recurrence had taken place in eight, in four early and in four late. He remarked on Mr. Bryant's statement that in 82 cases no anomaly of position of the colon had been met with, and quoted a case in which the small intestine, 62 cm. from the duodenum, had become adherent to the kidney and was opened. Mr. Sampson Gamgee spoke of some cases of colotomy seen in the practice of M. Verneuil and himself. Professor Marshall spoke of the recession of urgent symptoms noticed in cases of malignant stricture of the rectum on the formation of fistulæ as bearing on M. Verneuil's operation of rectotomy, and stated that the observation had led him to make irregular incisions with a view to forming fistulæ which he kept open with sea tangle in five cases; the results had been such as to make him look favourably on the improved method of M. Verneuil.

Professor Volckmann spoke at considerable length on the subject. He pointed out that the prognosis in different forms of cancer differed much with their topographical distribution, instancing the nose as a situation in which it was relatively good. He stated that in rectal carcinoma especially was the prognosis a good one, recurrence often taking place as late as five, six or seven years. The prognosis was also better in cases of chronic progress; and again in a certain number of cases the new growth was surrounded by a wall

of inflammatory new formation. These latter at the time of operation, were often thought unpromising from the indurated nature of the tissue cut through, but experience showed that they were most favourable, the wall of inflammatory new formation appearing to act as a barrier against the spread of infiltration in the lymphatic vessels. He spoke in detail of the three forms of carcinoma met with, adverting to the occurrence of scirrhus in young subjects, as well as its tendency to affect long areas of the gut, and expressed the opinion that all other forms of new growth are exceedingly rare. With regard to the treatment, cases are divisible, he said, into two classes, according as the peritonæum is or is not opened; in the latter the prognosis is good and in the former of course less so. A surgeon's results with excision of the rectum improve with practice, as has been the case with ovariotomy and nephrectomy; hence a gradual improvement in statistics is to be looked for, though from the nature of the case so good an average as that obtained in ovariotomy is not to be expected. Drainage is necessary when the peritonæum is opened; the peritonæum however should be sutured between the openings left for the tubes. The operation is indicated when the upper limit can be reached under chloroform, and when the growth is so moveable as to allow the assumption that the bladder is not implicated. The gut should always be brought down and sutured. In the one case where he omitted plugging the wound with iodoform a long stricture resulted. The cases for colotomy were few in number, belonging to a neutral zone of gut, too low for laparotomy and excision, too high-reaching for extirpation. In these cases he preferred anterior colotomy, the lower end being separated, sutured and returned, to prevent the possibility of the formation of a *cul de sac*. As to the mortality after operation—of Mr. Bryant's 60 cases of colotomy, 26 had died in the first four weeks, a much higher death-rate than had ever followed extirpation, and lastly when patients did get a recurrence after extirpation they usually died without the pain and suffering commonly attending death from rectal carcinoma.

Mr. Hy. Morris presented a table of 23 cases of colotomy arranged as Mr. Bryant's. He stated that the reasons which led the surgeons at Middlesex Hospital to practise lumbar colotomy were: (1) The fact that the peritonæum is not opened. (2) That right lumbar colotomy is practicable in some cases where ante-sigmoid colotomy is impossible, and (3) That in many cases the patients were exhausted and bedridden, so that the posterior opening offered a more convenient and dependent drain. The discussion was closed by Professor Kuster. He expressed his approval of iodoform as a dressing after extirpation and dwelt on the value of the scraping as a substitute for colotomy or rectotomy. He stated that so great an improvement followed scraping as sometimes to allow the patient to think himself cured for three or four months.

Dr. Paquet, of Lille, read two communications: (1) Unilateral hyperostosis of all the bones of the head, excision of the upper jaw, arrest of the hyperostosis in all the other bones. (2) Removal of the thigh bone, or disarticulation of the hip joint with the thermo-cautère. Two cases. Cure.

Dr. A. Van Deveer contributed a paper on the treatment of the intermaxillary bone in cases of cleft palate with double hare-lip, and Mr. Reginald Harrison read a paper on the treatment of certain cases of prostatic obstruction by section of the gland. The objects aimed at by the operation and the after-treatment are: (1) To obtain a precise knowledge of the impediment to micturition caused by a prostatic bar, by means of digital exploration. (2) The removal and division of any barrier formed by the prostate which was found seriously to obstruct micturition. (3) To provide for the permanency of the section or cleft so formed in the floor of the prostatic urethra (*a*) by the use of a suitable drainage tube, and (*b*) by the subsequent employment of bougies. Professor Volckmann preferred the simple boutonnière operation with subsequent passage of a bougie the size of the finger, and where this failed, the old practice of making a lateral lithotomy incision.

The Section of Military Medicine was joined with that of Surgery for the first day's sitting.

Resection and Arthrotomy in Tubercular Diseases of Joints.

The day's work on Tuesday, August 12th, commenced with a paper by Professor Ollier on the above subject, which was followed by a prolonged discussion, in which Professors Volckmann, Trélat, and Chiene took part. Professor Ollier advocated arthrotomy and canalisation in many cases of tubercular joint. Professor Volckmann thought arthrotomy a bad term as it might extend from simple puncture to scraping of bones and complete extirpation of all joint structures. He dwelt on the tubercular nature of the diseases known as white swelling, pulpy degeneration, strumous joint, spina ventosa, &c., and stated that in his opinion the point in treatment was the extirpation of the tubercular granulations which should be as complete as that of a round celled sarcoma. Professor Chiene mentioned the treatment adopted by him in the different joints, and Professor Trélat made some observations much in accord with what had fallen from Professor Volckmann.

Osteoplastic Resection of Foot.

A case of Mikulicz's osteoplastic resection of the foot was exhibited by Dr. Lauenstein, of Hamburg. The operation (which consists in the removal of the articular surfaces of the tibia and fibula, the entire os calcis and astragalus, together with about half the scaphoid and cuboid bones, the sawn surfaces of the scaphoid and cuboid being then applied to those of the tibia and fibula, the patient afterwards walking on the metatarso-phalangeal line, the foot being in the position of extreme equinus) was performed for caries of the os calcis and astragalus. Six weeks after the operation the patient could walk in a plaster of Paris bandage, and at the end of ten weeks he resumed his work as a mason which he has carried on up to the present, a period of twelve months. The advantage claimed for the operation is that it can be resorted to where the state of the soft parts about the heel renders Syme's amputation impossible, and it is then a substitute for amputation of the leg. The patient can walk in a boot made by an ordinary shoemaker. Dr. Lauenstein quoted eight cases, one for syphilitic disease of os calcis, seven for caries; of these latter, four were definitely cured, two died during the first year of pulmonary tuberculosis, and in one case only had a secondary amputation of leg to be performed. Professor Sklifossoffsky, of Moscow, claimed priority for Dr. Vladimiroff, of Kasan, who performed this operation as early as 1872. He thought it good for traumatic cases, but not for caries.

Osteotomy for Genu Valgum.

Mr. MacEwen, of Glasgow, read a paper on osteotomy for genu valgum, quoting results of 1,304 cases, in which his supra-condyloid method had been resorted to, with ten deaths, only one of which could be attributed to the operation, comparing these results with those obtained by other methods. In the discussion which followed, Dr. Ogston very handsomely renounced his own operation in favour of MacEwen's, and Mr. Chiene expressed his intention to give it a fair trial. Dr. Schede spoke in favour of MacEwen's method, pointing out that in many cases the tibia should be divided rather than the femur. Mr. Bryant also spoke in favour of the supra-condyloid method.

Dr. Robin, of Lyons, exhibited an instrument for supra-condyloid fracture of the femur, from two to four fingers' breadth above the epiphyseal junction in cases of genu valgum. The method consisted in fixing the thigh, and then fracturing the femur by a lever, the force being applied in an antero-posterior direction. He had used the method 93 times without any accident, and exhibited photographs of the cases.

Mr. W. Adams read a short paper, and exhibited a series of photographs taken from cases of Dupuytren's finger contraction.

Dr. Howe, of New York, exhibited a calculus, weighing 3,541 grains, which had been removed by supra-pubic lithotomy, combined with urethral puncture. The calculus was composed of five layers of mixed phosphates on a compound oxalic nucleus.

Discussion on the Treatment of Wounds.

On Thursday, August 14th, Professor Trélat occupied the chair, Sir Joseph Lister, who had been confidently expected, not arriving. The discussion on wound treatment was opened by Professor Esmarch. He enunciated his general principles and went at rather more length into his practical method. He stated that the majority of the vessels were tied with catgut before the removal of Esmarch's band, in some cases the dressing being also applied before loosening it. He laid stress on infrequent dressings, and stated that he was in the habit of not introducing drainage tubes, which necessitate dressing, but in their place he leaves larger gaps between the sutures at the dependent points. The principal antiseptic at present in use at Kiel is bichloride of mercury (1 in 1,000). The spray is used before but not during the operation, and the wound during the operation is washed with filtered distilled water, the sublimate solution being applied once only, immediately before the permanent dressing. The permanent dressing consists of bags of turf moss.

Professor Mosetig Von Moorhof followed with a paper on the iodoform treatment of wounds. He stated that he was the only surgeon who used the pure iodoform treatment, all other surgeons employing other antiseptics at the same time. He uses spring or distilled water only, to wash the wound. The hand, instruments and the neighbourhood of the wound are disinfected with some fluid medium. He thought perhaps its antiseptic power was greater with living than dead tissue and quoted Binz to the effect that when applied to a wound it checked the migration of leucocytes. He praised it as pain-stilling, and recommended iodoform gauze moistened with 1 part of glycerine and 2 of water as a dressing for burns. He also uses a solution in benzol mixed with vaseline, 1 part in 9 or 1 in 12 for similar cases. He affirmed its local action in tubercular granulations, cure being more permanent with less chance of recurrence than with other treatment. With regard to iodoform intoxication he had never seen it follow the pure iodoform dressing although he had made from 9 to 10,000 dressings; if it did occur it depended on the use of too much iodoform, or too frequent dressings, especially where much loose connective tissue exists, in other cases perhaps on renal disease. As to erysipelas he had never seen it except in the winter 1881-1882, and in that winter it abounded throughout Europe. He did not consider iodoform a better antiseptic than many others, but relatively it was more useful, especially for the poor doctor, the country doctor, and the army doctor, to all of whom its ease of application was a very great advantage, possessed by no other antiseptic at present in use. He had had 42 large amputations of which 37 had healed per primam with one dressing.

Dr. Schede said that when at the Frederichshain Hospital in Berlin, he had never had any erysipelas or pyæmia, but when he came to Hamburg, he found that slight and severe cases of sepsis occurred, but no actual pyæmia, although he continued the same antiseptic practice he had carried out at Berlin. He therefore looked out for a new antiseptic, and chose iodoform; this he employed for one year. The results were unsatisfactory. Erysipelas increased in frequency (29 cases with 15 deaths in 13 months), pyæmia and septicæmia occurred, besides cases of iodoform intoxication. Iodoform was therefore discontinued, and bichloride of mercury substituted; since then he had seen no more septic cases, in fact the wounds had followed an ideal aseptic course. Statistics of a very favourable nature were given of 1,780 cases, including 229 large amputations, in which suppuration occurred 17 times, deaths 12, none septic; 170 large resections, 63 healed per primam, 8 deaths; 75 osteotomies, no deaths; 8 uterus extirpations, 1 death; 25 ovariotomies, no death; and many other series of operations. With regard to mercurial poisoning, he had lost one case, a very cachectic woman with mammary carcinoma; she showed signs after the first dressing, these receded to re-occur after the next dressing, and again on a third occasion after which she died. Diarrhœa, bloody stools and salivation were occasionally seen, but disappeared when the dressing was discontinued. He now uses the 1 in 1,000 solution only for disinfection of wounds inflicted some time before coming under the surgeon's hands, or septic wounds; for other cases a solution of 1 in 5,000. He finds this sufficient, and has had no case of intoxication for 18 months. Children are very tolerant, and the whole body may be safely bathed in a solution of 1 in 1,000. No protective is used, but a small pad of glass wool soaked in 1 p. c. sublimate solution. Protective keeps the blood clot in the lips of the wound moist, and allows more chance of putrefaction. Over the glass wool, moss bags are applied, a soft, cheap and easily disinfected dressing, and the whole is fixed with a bandage, without macintosh. Sublimate catgut is used, and, if the surgeon likes, sublimate gauze instead of the moss.

Professor Mikulicz strongly recommended iodoform plugs for operations about the mouth, nose, pharynx, vagina, or rectum. Iodoform was only of use as a permanent dressing, not for primary disinfection. His experience with regard to erysipelas differed from Dr. Schede's, he had only had one case in 104. Thirty to fifty per cent. iodoform gauze was used, and separate drainage was not found necessary. He had seen iodoform intoxication, but rarely after large wounds; if symptoms occurred a weaker dressing must be applied or the iodoform discontinued.

Professor Neudörfer spoke of the difficulty, for those who did not work in large hospitals, of keeping the sponges aseptic, and recommended their disuse. He thought blood serum underwent decomposition in the absence of any special ferment from without. The principles of wound treatment on which he worked were three. (1) The preservation of the wound from foreign organisms. (2) The prevention of putrefaction. (3) The rapid advancement of the necessary changes in the blood serum, best attained by a supply of oxygen, such as is ensured by the use of peroxide of hydrogen.

Professor Buchanan (Glasgow) spoke of Lister's first operations; Dr. Schelkly, of antiseptic practice in the colonies.

Professor Koeberlé adverted to the difficulties of obtaining strict asepsis, which he thought unnecessary, and recommended the use of oxydising agents. Professor Blom was in accord with his German colleagues, and spoke of the importance of cleanliness in the hands of the assistants.

Professor Trélat closed the discussion with a statement of the general rules which guided him in wound treatment. (1) Complete apposition. (2) Removal of all foreign matter either mechanical or septic, here adverting to the difference in town and country practice, in regard to surroundings and consequent purity of atmosphere. (3) Preservation from external infection. (4) The use of antiseptic means, of what nature the surgeon liked if only effective. (5) Dressings to be as infrequent as possible. He followed the following plan:—(1) Irrigation of the wound with carbolic acid, or sublimate solutions. (2) Final disinfection before closing. He used antiseptic gauze, iodoform gauze for cavities, and elastic bands to fix the dressing when necessary.

Professor Blom paid a tribute to the esteem in which Sir J. Lister was held, and invited the section to rise as a body, to express their sense of the benefits conferred by him on science, the sick, on those present, and on all.

Dr. Whitson, of Glasgow, read a paper on the treatment of talipes by paraffin boots, made by applying bandages which had been dipped in melted paraffin. He also cited two cases of varus successfully treated by excision of the cuboid bone.

On Friday, August 15th, Professor Sklifossoffsky having taken the chair, Dr. Phelps, of New York, read a paper on the treatment of certain cases of talipes varus, by an open incision carried down to the medio-tarsal joint; in one case combined with section of the neck of the astragalus, and in others with division of the post-tibial tendon (ten cases were included). The operation is commenced by subcutaneous division of the tendo Achillis, and the incision in the sole leads down to the mid-tarsal joint, all structures except the external plantar artery and nerve being divided. He repeated Mr. Davy's experiment of dividing the superior calcaneo-cuboid ligament subcutaneously, showing that an extreme varus could so be produced.

Renal Surgery.

Mr. KNOWSLEY THORNTON read a paper on nephrotomy, nephrolithotomy, and nephrectomy. He quoted fifteen cases (four nephrotomies, three nephrolithotomies, eight nephrectomies) occurring in his own practice, of which fourteen were still living, one having died of extension of tubercular disease to the second kidney. The principal points of interest were his advocacy of the abdominal incision, as allowing the neighbourhood of the calculus to be ascertained, the condition of the other kidney to be made out, and steadying of the kidney should nephrolithotomy be the operation. The loin incision should not communicate with the peritonæum, and should only be one inch to one inch and a half in length. The relative prognostic importance as to incision of the renal substance and of the pelvis, as to the formation of urinary fistula was spoken of, and two cases quoted where incision of the renal substance had been followed by long continuing fistulæ, while in his third case the pelvis had been incised and no urine escaped after the fifth day. In the eight nephrectomies Langenbach's incision was employed four times, the median three times, and once the incision was made parallel, but external, to the outer edge of the recti. On the whole, preference was given to Langenbach's incision. The importance of fixing the cut-end of the ureter to the inferior angle of the wound was spoken of and a case quoted where this was not done, and where a septic abscess followed. Mr. Thornton thought that renal operations fairly promised to rival ovarian ones in success.

Professor KOSINSKI related a case in which he had performed nephrectomy by an anterior incision, running from above the umbilicus obliquely outwards parallel to the fibres of the obliqnus externus. The case was one of tubercular disease with calculus.

Dr. TSCHERNING, of Copenhagen, also read notes of a case of lumbar nephrectomy. The incision was a longitudinal one at the edge of the erector spinæ, with a horizontal branch travelling forwards.

Mr. HENRY MORRIS thought lumbar nephrotomy or nephrectomy very much safer when no large renal tumour had to be removed. He objected to fixing the ureter to the anterior abdominal wall, suggesting that it formed a band, behind which coils of intestine might get strangulated. He thought Mr. Thornton's two incisions apt to weaken unnecessarily the abdominal wall, and that the examination of the other kidney was not a very strong reason for their adoption. As to nephrectomy for pyonephrosis, he thought that considerable time should be given, quoting a case of nephrotomy in his practice where the patient had been entirely relieved, although still obliged to wear an apparatus to collect urine escaping from a fistula. He suggested extensive probe incisions before extirpating a kidney in which a calculus was supposed to be lodged. As to the question of incision of renal substance or pelvis, he thought it of little importance, the indication for either being the position of the stone alone. He suggested that in some cases, perhaps not very uncommon, where the calculus was arrested close to the entrance of the ureter into the bladder it might be removed by cystotomy.

Mr. GRIFFITH, in relation to the question of suturing the ureter to the wound, mentioned a case where he had made a *post-mortem* examination after a nephrectomy for a sarcomatous tumour, and found the ureter very much dilated. He suggested the introduction of a permanent catheter to obviate this danger.

Mr. BRYANT spoke strongly in favour of nephrotomy, rather than nephrectomy. He had never performed the latter, but had every reason to be satisfied with the result of twelve to fifteen cases of nephrotomy which had occurred in his practice. He thought the free incisions into the kidney and pelvis, suggested by Mr. Morris, quite advisable when doubt existed as to the presence of a calculus.

Mr. THORNTON, in reply, upheld the abdominal incision. He thought an incision into the peritonæal cavity unattended by any danger, except that of taking an anæsthetic, if asepsis was ensured. He thought that the sutured ureter would so soon atrophy as to be a very unlikely source of the danger suggested by Mr. Morris, and his lumbar incision was so small in nephrolithotomy, as to give little chance for the development of a hernia. He was quite in favour of exploratory incisions in the kidney. He thought a permanent catheter inadvisable from the danger of cystitis. He thought the suggestion of cystotomy in certain cases good. Lastly, he thought his cases must have been of a widely different nature from those of Mr. Bryant, as in none of them would any one have thought of suggesting nephrotomy.

The afternoon sitting was principally taken up with a discussion on the two papers read, on the Treatment of Talipes.

VII. SECTION OF OPHTHALMOLOGY.

ON Monday, August 11th, this section was principally occupied by two papers on the practical value of light-sense examination in ophthalmology, by Drs. Samuelsohn, of Cologne, and Bjerrum, of Copenhagen. The former, disagreeing with Förster's rule on the subject, believes that although an affection of the perceptive cells in the retina is followed by a diminution of the light sense, the reverse of this is not true for all cases, and instances certain forms of haziness of the vitreous, certain conditions of cataract and glaucoma, all of which require to be looked for in cases of failure of qualitative light perception. Dr. O. B. Bull, of Christiania, also presented an interesting paper on his investigations on the perception of light and on photometry.

On Tuesday, August 12th, Dr. MAYER, of Paris, presided. Papers were read by MM. Radard, of Paris, Libbrecht and W. Thomson, on testing vision of railway employés. A committee on the subject was proposed but deferred for further consideration.

Professor SATTLER, of Erlangen, read a paper on jequirity infusions and their use, embodying all the facts already known on the subject. He employed it in granular affections of the conjunctiva, although with occasional injury to the cornea.

Dr. BENSON, of Dublin, who had had considerable experience of the use of jequirity, extolled its value in granular conjunctivitis and pannus. In some of his cases he had not been able to detect the presence of the characteristic bacillus.

On Thursday, August 14th, Professor SCHMIDT RIMPLER, of Marburg, described a new method of estimating the refraction of the eye, by means of indirect ophthalmoscopic examination. The lens is held at a fixed distance in front of the eye, whilst a tape measure is extended from this to the ophthalmoscope, thus fixing the distance between these two points. An image of the lamp is then observed and according to the distance at which this image becomes clear and well defined, so Professor Rimpler is able to estimate the refraction.

Mr. BERRY, of Edinburgh, approved of Professor Rimpler's method since it enabled one to get over the difficulty of estimating refraction in the region of the yellow spot. The refraction in this region often differs considerably from that in the neighbourhood of the optic disc.

Dr. NOYES, of New York, thought that the diagnosis of errors of refraction should always be confirmed by means of test-glasses.

Mr. JULER, of London, wished to see something more of Professor Schmidt Rimpler's method, and agreed with other speakers as to its value in estimating refraction in regions where vessels were scarce. He considered that the shadow test (retinoscopy) formed the best means of estimating the refraction in astigmatism, but it required that the eye under observation should be fully atropised.

Dr. E. MAYER, of Paris, read a paper on the artificial maturation of cataract, advocating a process of "massage" of the lens, after tapping the anterior chamber of the eye. He had found the proceeding to be efficacious, and innocuous, and he thought it might well be employed in dealing with cataractous lenses, requiring removal, which were not yet fully matured. He showed a rabbit's eye in which he had produced opacity of the lens by this means three days previously. No definite pathology could be given in explanation of the results produced.

Dr. Christensen, of Copenhagen, read a paper on blennorrhœa neonatorum, and Dr. Martin, of Bordeaux, brought forward the subject of inflammation of the eye and its surroundings caused by astigmatism.

On Friday, August 15th, Professor Gayet, of Lyons, read his paper on the result of great loss of substance of the cornea. He advocated the substitution of peripheral section of the cornea with a large iridectomy, for the simple method of opening abscesses.

Mr. Berry had seen the results both of corneal section and the iridectomy treatment. He thought it was not necessary to incise more than the part most affected. Cases were at times unsuccessful under both modes of treatment and, as a rule, these abscesses should be treated on the same principles as abscesses elsewhere. He thought that the dangers of anterior synechia were exaggerated.

Dr. Hansen Grut, of Copenhagen, in reply to Dr. Noyes, had found from experience that the re-opening of the corneal section generally does harm, and increases the risk of adhesions. In case of failure of incision, he would use the actual cautery.

Dr. Mayer, of Paris, also deprecated interference with a section once made.

At the afternoon sitting, on Friday, Mr. Cowell, of London, in the chair, Dr. Hansen Grut, of Copenhagen, read a paper on latent divergent squint, which he defined as a defect of convergent impulses, and pointed out that it was neither a paralysis nor a disturbance of muscular equilibrium. He thought that the frequency of muscular asthenopia was very much exaggerated, its symptoms being very uncertain and its presence being very difficult to prove.

On Saturday, August 16th, Mr. Cowell, of London, being again in the chair, Dr. Jannik Bjerrum, of Copenhagen, read a paper on the refraction of new-born children. Professor Holmgren, of Upsala, communicated a paper on colour sense. Mr. Juler, of London, gave demonstrations of—(1) McHardy's perimeter; (2) Frost's artificial eye. Krebs electro-magnet, for removing particles of steel from the eye, was also exhibited.

XI. Section of Laryngology.

On Monday a combined sitting of this and the Otological Section was mainly occupied with a discussion upon the structure of the tonsils and their diseases, regarded from a practical point of view.

Laryngeal Paralysis.

At the meeting of the Laryngological Section, on August 12th, held under the presidency of Dr. Morell Mackenzie, Dr. Felix Semon, of London, read a paper on Laryngeal Paralysis, which contained many points of interest. It will be remembered that he drew attention some years ago to the fact that in commencing paralysis of the motor nerves of the larynx, from whatever organic cause, the fibres supplying the abductor muscles appeared to be the first to give evidence of failure. In his present paper he stated that he had been for years hampered in his efforts to determine the cause of this phenomenon by the consideration of a simple physiological fact, viz.:—that the width of the glottis during quiet respiration (both inspiration and expiration) was considerably larger than that seen after death. He had established this fact by large numbers of direct comparative measurements. As a result of a long series of observations, of which he gave details, Dr. Semon had come to the conclusion that this greater width of the glottis during life was not due to the greater strength of the abductor fibres, but really to a distinct innervation which they received, in virtue of their respiratory function, directly from the respiratory centre. This extra-innervation bore the character of a reflex-tonus, the respiratory centre being in turn constantly stimulated through centripetal fibres, contained in the trunk of the pneumo-gastric nerve. He believed that this was the true explanation of the apparent preponderance of the abductor fibres in the trunks of the nerves.

Dr. Krause, of Berlin, communicated a very long paper on the same subject, the reading of which had to be considerably curtailed. He had, however, come to exactly the same conclusions as Dr. Semon, with regard to the existence of tonicity of action of the abductors, due to reflex influences. As the result of certain experiments upon dogs, he had, however, arrived at a different explanation of the abductor paralysis, and believed that the phenomena produced were to be explained as "contractions of the abductors." He proposed to give a more detailed account of this condition in a forthcoming number of *Virchow's Archiv.*

The following is a brief record of the proceedings in some of the other sections, on Monday, August 11th:—

In the Obstetric and Gynæcological Section a lively debate took place upon the subject of removal of uterine myomata by means of laparotomy, in which Sir Spencer Wells and many others took part. The subject was introduced by a paper of Dr. Koeberlé, of Strasburg, in which the aspects of the disease and its treatment were fully considered. The indications for the operation were chiefly these: Reduced condition of the patient from hæmorrhage; particular circumstances whereby the presence of the tumour rendered life almost insupportable; relative age of the patient in respect of the menopause. Contra-indications were presented by the presence of vascular adhesions to the abdominal wall, rapidly recurring ascites or the presence of other disease. He advocated removal of the tumour per vaginum in every possible case, but in all others he would perform laparotomy. Pedunculated tumours might be ligatured, and the stump returned. Hysterectomy, which was quite feasible in cases of tumour within the uterine wall, became exceedingly difficult and dangerous when the tumour was situated in the ligaments, or bound down in the cavity of the pelvis. Enucleation of tumours presented many dangers. He would regard the operation of laparotomy as a real advance in abdominal surgery, and one worthy to be taken into serious consideration by the profession. Other papers on the treatment of uterine tumours by electrolytic puncture were read by Drs. Apostoli and Ménière, of Paris.

In the Section for Children's Diseases, Dr. Rehn, of Frankfort, read a paper on the so-called Acute Rickets, to which Dr. Barlow, of London, contributed some specimens; and Professor Herschsprung, of Copenhagen, recorded his observations on hæmo-globinuria in the first year of life, and gave demonstrations.

In the Section for Psychiatry and Neurology, a proposal for uniformity in the annual reports of lunatic asylums in the various countries was brought forward by Dr. v. Schwartzer, of Buda Pesth, after which the curability of labes dorsalis was introduced by Professor Eulenburg, of Berlin. His experience led him to class the curable cases only in the proportion of one per cent. No criterion of curability could be at present suggested, nor was it possible to understand any real recovery from the local pathological changes. Cases had been observed, however, where the clinical symptoms gave evidence of recovery, whilst the subsequent pathological changes were found to be as well marked as in the progressive cases.

ABSTRACTS AND EXTRACTS.

M. STRAUSS' REPORT ON THE CHOLERA AT TOULON.

At the meeting of the Academie de Medicine on August 5th, M. Strauss made the following communication on behalf of himself and his colleagues in regard to their investigations on the cholera at Toulon. In their first autopsy they had been able to establish the identity of the lesions with those which they had found in the Egyptian epidemic. In Egypt they had endeavoured to find a specific microbe in the walls of the intestine. The method they had adopted consisted in staining sections of portions

of the small intestine, hardened in alcohol, with methylene blue. Divers micro-organisms in varying numbers were thus discovered in the superficial portions of the mucous membrane, in the ducts of the tubular glands, amongst the villi, and here and there in the sub-mucous tissues. The majority of these organisms were bacilli, varying in size and appearance. From these anatomical data, it had not been possible to draw any positive conclusions as to the cause of the disease. At Toulon they had again tried to find the specific organism in the intestinal wall. According to Koch, cholera was characterised in Egypt as well as in India by the constant presence, in the mucous membrane of the small intestine, of a characteristic bacillus.

The new observations of MM. Strauss and Roux enabled them to confirm what they had found in Egypt. In the intestinal mucous membrane of a certain number of cholera patients, the most varied organisms were met with, especially in cases where the disease had been somewhat prolonged. But in more rapid cases these organisms were not nearly so numerous, and in the most rapid cases of all it had not been possible to detect their presence. Like Koch, Strauss used a watery solution of methylene blue. In a good number of cases no micro-organisms could be found in the mucous coats of the intestines. In some of his reports dated from Calcutta, Koch had given more exact details as to the organism which he regarded as the cause of cholera. His investigations were made on the contents of the intestines and on the stools. "The bacillus of cholera," he had said, "is not quite straight, but somewhat curved, sometimes in the shape of a comma, sometimes in the form of a semi-circle." Koch had used no special method of staining in order to demonstrate this microbe. The specimen of the stools or of the intestinal mucus was spread in a thin layer on a cover glass, and dried. The preparation thus obtained was slightly warmed and stained with a solution of some aniline base, preferably methylene blue.

In Egypt M. Strauss and his colleagues had also obtained these microbes. When the characteristic choleraic stools were examined, it was seen that they mostly contained a great number of different micro-organisms, and in many instances only a few of the comma-shaped organisms were found, even when the stools had the rice-water appearance. The contents of the intestines taken from the dead body under the most favourable conditions showed, in the majority of cases, various sorts of micro-organisms, amongst which were found comma-shaped bacilli, without, however, there being any marked predominance of these over the others. In a very malignant case in which the autopsy was made with M. Koch, MM. Strauss and Roux found the small intestine as it were lined with mucus, a thin layer of which, spread out and stained in the manner already described, showed a large quantity of comma-shaped bacilli. They were led, therefore, to attribute an important part to the comma-shaped organism in cholera. But there were some cases where so great a variety of organisms was found in the contents of the intestinal canal, that no one of them could be said to predominate. In such cases M. Koch had had recourse to cultivation in order to demonstrate them. A specimen of the contents of the intestine was diluted by being placed in a gelatinised infusion, rendered fluid by the application of a gentle heat, and the fluid thus fertilised was transferred to a watch glass. In the little islets of organisms which were developed, were some having the aspect of refracting masses, formed by comma-shaped organisms, which rendered the gelatine immediately around them fluid, and could then be seen under the microscope to possess rapid movements. During the period of their vegetation, these organisms sometimes remained joined end to end, and were then S-shaped or in the form of spirillæ. It was this appearance of the cultivation on the gelatinised infusion which M. Koch regarded as characteristic. The comma-shaped organism required an alkaline medium for its development; it proliferated with the utmost readiness in the majority of alkaline media, at a temperature of from 16° to 42°. Were we justified in concluding that the comma-shaped microbe was the organism of cholera? Until success had been obtained in transmitting cholera by means of the administration of a pure cultivation of this organism, this could not be considered to be proved. For lack of direct proof furnished by the inoculation of animals with the comma-shaped organism, M. Koch had endeavoured to show that the organism which he had described in cholera, was only met with in the intestine of cholera patients, and never in healthy persons, or in those who are suffering from any other disease than cholera. It would be sufficient that the organism of M. Koch should be found even once only, in a case of something other than Asiatic cholera, to put an end to the question. The comma-shape alone could not be regarded as characteristic of the organism of cholera. M. Malassez had shown them some comma-shaped bacilli detected in the stools of a patient with dysentery, and M. Strauss had found comma-shaped bacilli himself, similar to those in cholera, in the vaginal mucus taken from a woman suffering from epithelioma of the neck of the uterus. If the comma bacillus was the cause of cholera inasmuch as it only lived in the contents of the intestine, and, in rapid cases at any rate, did not invade to any appreciable degree the mucous membrane of the intestine, it must be admitted that in order to produce such rapid and intense effects as it did, it secreted a soluble ferment, a ptomaine, some poison which when absorbed provoked symptoms of cholera. We must then endeavour to extract from pure cultivations in which the bacillus had lived, a soluble poison which would reproduce in animals symptoms analogous to those observed in persons suffering from cholera. It would also be especially interesting to note whether in cases of undoubted cholera nostras the comma bacillus was met with. The minute particles in the blood which had been met with in Egypt were also found at Toulon; they were due to a peculiar alteration of the hæmoglobin. Thus it will be seen that M. Strauss in his general results agrees with the opinions recently expressed by Dr. Klein.

OPHTHALMOLOGY.

The Ætiology of Ophthalmia Neonatorum — Zweifel's Experiments. — Some time ago Zweifel reported in *Archiv für Gynäkologie*, Band XXII., some experiments which he had made with lochial secretion. The conclusions drawn from the experiments throw some light on the question as to the ætiology and the prophylactic treatment of ophthalmia neonatorum, and they have also considerable value from a medico-legal point of view. In 1882, Schirmer, Zweifel's assistant, published a case of ophthalmia neonatorum in a child of six days old, produced by the entrance of lochial discharge into its eyes, which up to that moment were perfectly healthy; in about 40 hours after, the affection appeared. The mother was perfectly healthy and had never suffered from a venereal affection. The child was cured under Professor Sattler's treatment, who examined the discharge microscopically and found that it contained the gonococcus of Neisser, which is the characteristic of gonorrhœal pus. The importance of this case consisted in it being the first observation of the disease arising from the lochia of an alleged perfectly healthy person. If it were an accurate observation, it would tend to modify our views as to the specific character of ophthalmia neonatorum. In order to test the correctness of Schirmer's conclusion Zweifel made the following experiments: By means of a fine glass pipette he conveyed lochial secretion from undoubtedly healthy persons, directly into the conjunctival sacs of infants, having previously made certain that there was no possibility of infection. Six such experiments were made, and although the secretion was taken at sundry times between the third and thirteenth day after delivery, and was consequently bloody, serous or purulent, the results were negative—ophthalmia was in no case produced. Two of the women from whom discharge was taken had previously suffered from leucorrhœa. These may appear somewhat hazardous experiments, but Zweifel trusted, on the other hand, to his conviction that pure secretion cannot possibly give rise to a specific affection, and, on the other hand, he confided in Professor Sattler's ability to cope with any attack which might follow the inoculation. These experiments afford strong confirmatory evidence of the specific nature of the affection, and tend to show that ophthalmia neonatorum arises from

gonorrhœal inoculation. In a supplementary note in a subsequent number (*Archiv für Gynäkologie*, Band XXII, 325), Zweifel reports that one of the children, with whose mother's discharge the experiment was made, had subsequently an attack of purulent ophthalmia which threatened to upset the above conclusions, but it turned out to be a case of diphtheritic conjunctivitis; the child's father having been laid up with diphtheria at the same time. Further, Zweifel thinks very justly that these results indicate in what cases the recommendation of Credé should be adopted, according to which a 2 per cent. solution of nitrate of silver is instilled into the eyes of new born children as prophylaxis. Since the disease is apparently specific, this treatment is quite unnecessary in private practice, in cases where there is no suspicion of any danger of infection. It is, however, a proper precaution in a lying-in hospital to employ Credé's treatment for all the children. It does no harm, and since its introduction into his institutions, no child has suffered from the disease.

The Prevention of Ophthalmia Neonatorum.—A recent number of the *Archiv für Gynäkologie* (Band XXII., Heft 2), contains an article on this important practical subject, by Dr. G. Krukenberg. Its object is to put before the profession the experience of the obstetric clinic at Bonn, with regard to the prophylactic measures recommended by Credé. During the six years preceding the adoption of these precautions, ophthalmia occurred in 7·3 per cent of the children born. In February, 1881, prophylactic treatment, after the method of Olshausen, was begun: that is, immediately after the birth of the head the eyelids were washed with a 2 per cent carbolic acid solution, and the conjunctiva mopped with a similar solution. This was practised till June, 1881, in which period 82 children were born, and 11 of them developed ophthalmia, or 13·4 per cent. This treatment therefore was a failure. In June, 1881, the method of Credé was adopted, with the modification that instead of a 2 per cent. solution of nitrate of silver in water, a vaseline ointment of the same strength was employed. The eyelids were, when possible, washed immediately after the birth of the head with a 2 per cent. solution of carbolic acid, and then the lids opened so widely as to expose the cornea, upon which a piece of the ointment was laid with a glass rod, and the lids then closed. The result has been that out of 703 children born up to November, 1883, only four have suffered from ophthalmia, or 0·56 per cent. In three of these cases Dr. Krukenberg believes that the child was infected subsequent to birth, from the fact that the disease did not appear till the 7th, 8th, and 9th days respectively. If this view be accepted, the percentage of ophthalmia caused during delivery is reduced to 0·14 per cent. The four cases all recovered well without injury to the cornea. Dr. Krukenberg discusses the respective advantages of the vaseline ointment and the watery solution. The vaseline adheres better, but he thinks the watery solution, which has only to be dropped in, safer in the hands of a midwife. Credé's own results, too, are a trifle better than those at Bonn, and therefore at the latter institution they adopted the solution in place of the ointment. The first case in which the solution was employed developed ophthalmia, which was cured by using the ointment.

The Rapid Artificial Ripening of Cataract.—The operation proposed by Professor Förster at the Heidelberg Ophthalmological Congress, in 1881, consists in performing a broad irideetomy, usually upwards, and, after all bleeding has ceased, making stroking or rubbing massage-pressure upon the cornea opposite the coloboma with the elbow of a strabismus hook or some similar smooth instrument. In properly selected cases, the partially opaque lens is observed to increase very rapidly in opacity. Dr. Stedman Bull gives (*New York Medical Journal*, May 24th) an analysis of thirty cases in which he has employed this method. He has found it especially applicable to the very slowly ripening cataract of middle life, and the immature senile cataract with yellow nucleus and cloudy cortex; and, with Förster, he recognises that the existence of a hardened opaque nucleus is essential to its success. Too strong a pressure may rupture the zonula and dislocate the lens; and short of this, it has sometimes produced "a striated or radiating opacity of the cornea, which seems to be confined to the anterior layers, frequently remains for a long period, and fades out but slowly." A rotatory rubbing or massage seems to answer better and to be more easily performed than the stroking from the centre to the periphery of the cornea recommended by Förster. In contra-distinction to the latter's experience, Dr. Bull has frequently observed a slight iritis follow the operation, but it is always amenable to treatment. Like Samelsohn, he has noticed that the opacity extends much more rapidly if the anterior chamber be absent for several days by reason of the external wound remaining open. The pain is very slight and the operation can almost always be done without an anæsthetic. In five of Dr. Bull's thirty cases, the operation was followed by a slight plastic iritis which readily yielded to ordinary treatment. In none was the zonula ruptured or the lens dislocated. In no case was an eye lost through the later operation for the extraction of the cataract. In three cases, ten per cent., the resulting vision was less than $\frac{20}{100}$. In ten cases, or 33⅓ per cent., the vision after extraction was $\frac{20}{40}$. In the remaining 17 cases the vision ranged between $\frac{20}{100}$ and $\frac{20}{40}$. In no case was the preliminary operation for ripening the cataract performed, except on account of an extremely urgent demand for the restoration of useful vision within as short a time as possible. The average duration of the confinement to house or hospital after the first operation was six days. The period occupied by the apparent complete ripening of the cataract after the preliminary operation varied between six days and five weeks. In no case was the extraction of the cataract attempted until four weeks had elapsed after the first operation.

Eye Symptoms in Disseminated Sclerosis.—M. Parinaud has recently (*Progrès Médical*, No. 32) summed up the result of his three years' investigations on this point. The symptoms are referable either to the external muscles, the iris, or the optic nerve. The *muscular* troubles consist of paralysis or paresis of the associated movements of the eyes; as a result diplopia is very common, especially in the early stages of a rapid case. Nystagmus is the most constant symptom resulting from this paresis of associated movements, and corresponds exactly to the trembling on voluntary movement so characteristic of the disease. Another common result is the vague expression, which is so often present, and is so typical. Ordinary paralyses, such as of the external rectus or ptosis, are by no means common. As regards the *iris*, inequality of the pupil is not uncommon in the early stages; later on, miosis is the rule, the reflexes both for light and accommodation being preserved and even exaggerated in some cases. This fact forms a most important point of distinction between the symptom in this disease and in locomotor ataxy, in which as is well known there is also miosis, but in which the light reflex is abolished. In sclerosis, then, the miosis must be looked upon in the nature of a contracture. The affection of the *optic nerve* results in three varieties of amblopia, all tolerably characteristic. In the first of these there is a lowering of the visual acuity, without any limitation of the field of vision, but there is some degree of dyschromatopsia as regards red and green, and this often constitutes the first sign of the disease. The ophthalmoscopic changes (if any) at this stage will be confined to a slight pallor of the temporal half of the disc. The second variety is ushered in more quickly, and there may be complete transient blindness, the dyschromatopsia is more marked, and the visual field is affected, the disc is markedly white. Even when the atrophy of the disc has reached an advanced stage, the blindness is hardly ever total, forming a striking contrast with what is seen in ataxy. The third form is more rare, the effect of sight is unilateral, is more marked, and more persistent. The field of vision is irregularly contracted, and there is no colour blindness, but atrophy of the disc is very marked.

The Cerebral Localisation of Homonymous Hemianopia.—In an interesting paper published in the *Boston Medical and Surgical Journal*, for May 22nd, three cases of homonymous hemianopia are reported by Dr. O. F. Wadsworth. As an accompaniment of other cerebral disorders, hemianopia is not uncommon, and in some cases is probably present without being recognised; but as an isolated symptom, appearing suddenly without paresis or

disturbance of sensation, it is infrequent; such, however, was its character in each of these three cases, in one of which it was discovered only accidentally during the routine examination of the field of vision. The patients were adults—a male aged 60, another aged 59, and a female aged 54 years. The left half of the field of vision was found to be wanting in each case: in all other respects the eyes and vision were normal. The paper is too lengthy to allow of its adequate condensation within these limits; but it may be stated that, after a careful examination of the some half dozen similar cases at present recorded, and especial reference to the two cases reported by Cursehmann (*Centr. für Augenheilk.* 1879, p. 181), and Haab (*Monatsbl. für Augenheilk.* 1882), in both of which there occurred simple left hemianopia, while the only cerebral lesion discovered *post-mortem* was situated in the right occipital lobe; referring also to Munk's experiments on animals (dogs and monkeys), and to the evidence furnished by the pathological anatomy of Huguenin's cases (blindness of the left eye from childhood in a man, death from pneumonia at æt. 53, atrophy of posterior median part of both occipital lobes, most marked on the right; almost total blindness of both eyes from childhood, death from typhoid at 43, and atrophy of corresponding parts of both occipital lobes); Dr. Wadsworth concludes from the absence of demonstration of a sufficient lesion within the tractus, and from the evidence afforded by such cases as those quoted, that it may be assumed that "when homonymous hemianopia occurs as an isolated defect, the seat of injury is to be found in the occipital lobe." Dr. G. Hay points out that such a position of the visual centre, so remote from the eye, is consistent with the doctrine that something more than the eye itself is concerned in vision; that light and colour may perhaps have some special relation to the retina, while the conception of form and distance is more intimately associated with another part of the nervous apparatus.

Hysterical Blindness Cured by an Imitation Magnet.—Dr. Harlan's patient suffered with hysterical uniocular blindness with mydriasis and blepharospasm. After having been treated in different ways for some time, a Charcot magnet was finally applied, to see what effect it would have on a severe spasm of the face which was then present. It relieved the spasm and also improved the sight. The experiment was repeated several times and always with the same result. It was then decided to try the effect of an imitation magnet made of wood. With this the results were even better than with the real magnet. An hysterical affection of the elbow joint, which followed a fall during the course of the treatment, was also successfully treated with the imitation magnet.—*New York Medical Journal*, July 26.

Polycoria.—A lady, age 32, sought advice on account of compound myopic astigmatism. On examination five pupils were found, the largest being in the centre. After correction, V = $\frac{20}{20}$. This lady's father had two pupils in one eye, the lower one being divided into two by a band passing across it. In neither case had there been any failure of vision. Dr. Seely had studied a number of cases occurring in one family; in the instance which he had seen the patient eventually became blind with choroiditis.—*New York Medical Journal*, August 2.

GENERAL CORRESPONDENCE.

"ANTI-VACCINATION ARGUMENTS."

[To the Editor of the Medical Times.]

Sir,—Having been compelled by the State to consider the question of vaccination seventeen years ago, and having done my best ever since to find out the facts bearing on it, may I be permitted a few words of protest anent your leader of the 9th? Let us take the question of compulsion—"Do the benefits of vaccination justify its compulsory performance?" These words of yours fairly describe our main query. Naturally you occupy most space with other points; but other points we would gladly leave you to carry, if you would abandon compulsion. Further, compulsion is not necessary. It does not exist in Italy, in Belgium, and scarcely in France, save in the army. These countries will, in respect of small-pox, contrast favourably with England, where some thousands of parents are annually prosecuted under compulsion. I do not like to speak positively, but I feel clear that the incidence of small-pox is as great, if not greater, in England than in these freer countries. Thus the benefit of compulsion is not manifest. It is not from your own point provable. The only argument worth anything in its favour is, that it gives the supply of vaccine virus. Yet this is managed in all the countries named without compulsion; and as Dr. Boëns says, "according to us, all governments should abstain from taking sides in favour of, or against any scientific theories which are not yet actually demonstrated, incontestable, or universal." The abolition of compulsion would leave us as we were in 1850; and the fifty years of the century, up to that time, were not marked by more extraordinary small-pox epidemics than those since. And I again point to Belgium and Italy as proof that compulsion cannot be justified. Picture abolition abandoned—no one would be prevented from adopting vaccination, and probably for some time, something under half of the births would be vaccinated. The doctors' influence, however, would be far more powerful than it is now. And if you confess to the need for justifying compulsion, a strong case must be shown. This cannot be done. Our own English experience is surely enough; and it does not justify compulsion. Ninety-two per cent. of the Highgate small-pox patients are confessedly vaccinated. Seventy-five per cent. of the many thousands of London patients are vaccinated, without doubt. If English experience does not justify it, foreign cannot. The figures respecting the French and German armies are fabricated. You should not use them after Dr. Carpenter has publicly withdrawn them (*Daily News*, January, 1883). Dr. Flinzer's need confirmation; for of 2,400 patients, at Cologne, only 49 were non-vaccinated, and 2,351 vaccinated or re-vaccinated, 1870-1-2. But, as I said, we deal with England where compulsion exists. Here prove your case. You speak of Dr. Boing, of Germany. This error is indicative of the carelessness which you show in respect of our contention. You, no doubt, mean Dr. Hubert Boëns, a very talented Belgian member of their Royal Academy of Medicine, whom I have quoted. Examine our case. We ask for freedom from cow-pox, as from all self-inflicted ills. Freedom to use our judgment to the best of our knowledge. At present we believe health better than disease, be it cow-pox, small-pox, or any other ill. You, if you advocate compulsion, must degrade healing into diseasing. This we deplore, and hope to alter.

I am, Sir, yours &c.,

ALEX. WHEELER.

Darlington, August 17th, 1884.

[Before a man ventures to charge a writer with carelessness and ignorance he would do well to find out whether the ignorance is not on his own side. We know, what Mr. Wheeler does not, the difference between M. H. Boens, the Belgian who writes in French, and H. Böing the German who writes in his native tongue, and we recommend to Mr. Wheeler's careful study the article by Dr. Böing in the *Deutsche Vierteljahrschrift für öffentliche Gesundheitspflege*, 1882, Heft 4. together with the crushing exposure of the fallacies and misrepresentations contained therein by Dr. Lotz, in the same number of that invaluable periodical, and one by Dr. L. Voigt in the first number of the following year. If Mr. Wheeler will give us facts and figures we should doubtless be able to do for him as Lotz has for Böing (not Boens!), but he deals only with assertions. The few figures he does give are easily disposed of. Seventy-five per cent. of the small-pox cases in certain hospitals, and ninety-two per cent. in one were vaccinated. Perhaps they were after a fashion, but did we not say that the effect of even a thorough vaccination wears off in time, and of imperfect and insufficient vaccination in a very short time? Again, will he give us the mortality in each

elass? or explain the immunity of the attendants with the exeeption of such as refuse to be re-vaeeinated? Will he explain the ehange that has come over the scene in Berlin and Hamburg sinee vaecination, from being far from general and rarely performed before school age, has been made compulsory and universal as far as human power can make it? He does not give any statisties of France, Italy, and Belgium, but if he did it would be manifestly unfair to compare a densely aggregated population like that of London with the scattered populations of those countries. We should not compare London or Paris with Wales or Ireland, as we have compared Berlin with Vienna, and would fearlessly compare it with other towns of a million or so inhabitants. We should be grateful to Mr. Wheeler for the small-pox mortality of Belgium in the epidemic period 1870-73, since he declines to notice the results we gave of optional and compulsory vaccination at that time in the neighbouring kingdom of Holland and in Bavaria. We should have thought that the contrast between a mortality of 593 per 1,000 under five years of age under the former system, and of 44 per 1,000 under the latter, these 44 being largely composed of children *not yet vaccinated*, would be considered pretty satisfactory. We have not seen Dr. Carpenter's repudiation of the figures, which we gave on *French* authority, as to the mortality in the French and German armies, but we shall not fail to enquire into it. Our position is quite strong enough to dispense with any questionable figures. It suits Mr. Wheeler no doubt to cast suspicion on Flinzer's statisties, though neither Böing (not Boens) nor Vogt (not Voigt), with better opportunities than he, have attempted to dispute their accuracy. On the contrary, they thought it more prudent to ignore altogether eight of his fourteen tables and to play such tricks with the others as that to which we alluded, viz., reckoning all those persons who having had small-pox were most thoroughly protected with the unvaccinated, in order to bring down the mortality among the latter to something like that which obtained among the vaccinated! Our complaint against the anti-vaccinators is that they refuse to meet us in fair argument, either, like Mr. Wheeler, ignoring facts and dealing in mere assertions, or, like Pearce, Böing, and Vogt, falling into, or we fear deliberately availing themselves of, one or other of the various fallacies with which students of vital statistics are painfully familiar.

Ed. *Medical Times*].

MR. LAWSON TAIT'S CASE OF ENTEROTOMY

[To the Editor of the Medical Times.]

Sir,—In reference to a letter signed "F.R.C.S." in your impression of August 9th, I think it only just to state that, in the case spoken of, which was under my care as a private patient, the symptoms were those of complete intestinal obstruction, neither fæces nor flatus passing per rectum for about ten days; there was constant stercoraceous vomiting, and all the signs of impending death from exhaustion; the treatment by opiates did not allay the symptoms. I certainly think the operation was justifiable as the only chance of life. Perhaps it will not be out of place whilst writing on the above case to point out the error of "An Anatomist," in thinking that a tumour ten times as large as the one spoken of (three inches by four inches) would be 30 inches by 40 inches. Let "An Anatomist" try how many oranges of the former size he would be able to get into a bag of the latter dimensions. I believe it would be just 100 and not ten.

Yours, &c.,

Matt. Hall-Wright, M.R.C.S, &c.

Hayley Road, Birmingham.
August 19, 1884.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, August 14th, 1884:—

Frank Charles Butt, St. Margarets, Richmond; Jno. Edward Gemmell, 17, Queen Street, Waterloo, Liverpool; Samuel Hughes, 6, Princes Road, Liverpool; Henry William Martindale Kendall, Renfrew, Bexley Heath; Robert Chambers Priestley, 17, Hertford Street, May Fair.

Royal College of Surgeons in Ireland.—At a meeting of the Court of Examiners, held on August 12th and following days, the undernamed gentlemen passed their several examinations for the first professional examination for the Letters Testimonial of the College under the new scheme viz.:—

John Abbott, William P. Barter, Alfred W. Bewley, Shenstone Bishop, Charles E. Boyce, John J. Byrnes, Stafford M. Cox, William Cremin, James Crumley, Edwin T. Cummings, Roland Delaney, William H. Doran, John D. Ferguson, Daniel F. Finucan, Robert A. Flynn, Edward Frazer, John F. Greene, William R. Gore, William R. Graves, Eugene Glynn, Richard J. Hewitt, Robert E. Hickie, Charles L. Hughes, Richard B. Hunt, George A. Johnston, Peter P. Keane, Laurence E. Keegan, Victor E. Ludlow, Charles J. Lyons, Michael Mahony, Joseph F. Mannix, John R. Meek, Henry M'Dermott, John M'Ginn, John Mulqueen, Denis P. Murphy, James O'Connor, Peter O'Dwyer, James O'Rafferty, Eugene P. Pentony, John H. Reynolds, Charles R. Scott, Michael Shanley, Thomas A. Sheahan, Laurence Skelly, Laurence Slevin, John B. Spearing, John Stewart, Thomas W. Talbot, Timothy T. Teahan, James Trant, Wilford P. Wynne.

Twenty-seven were stopped. The College is now closed for the autumnal recess until October next.

Royal College of Surgeons.—The library of this institution will be closed as usual on Monday the 1st proximo, for the usual dusting and cleaning, and be reopened on Wednesday, October the 1st.

Congress for Criminal Anthropology.—Among the almost innumerable congresses occurring at this time of the year, it is announced that one will be held at Turin, from 25th September to October 1st, at which subjects relating to criminal anthropology are to be discussed, and criminals will be chiefly regarded from the psychical and organic point of view. It is warmly supported by the profession in Italy.

Charitable Bequests.—The late Mrs. Armitage, of Redcliffe Square, has bequeathed 200*l.* each to the Charing Cross Hospital, and the Hospital for Hip Disease in Queen's Square. The late Mr. Nutter, of Halifax, has left 1,000*l.* each to the Halifax Infirmary and the General Infirmary, Bradford; 500*l.* each to the Bradford Fever Hospital and the Ripley Convalescent Home; and 100*l.* each to the Eye and Ear Infirmary, of Bradford, and Ilkley Bath Hospital.

Proposed Fever Hospital at Alcester.—It has been proposed to establish a fever hospital at Alcester, as a memorial to the late Marquis of Hertford, and a meeting was held at Leamington a few days since at which, on the motion of Lord Leigh, seconded by Mr. W. Willes, it was resolved to carry out this project, and an influential committee was appointed to receive subscriptions and take such other steps as were needful. Several subscriptions have been received, and it is hoped that the 1,500*l.* or so which is required will speedily be found to complete the work.

Guy's Hospital Medical School.—The following medals and prizes have been awarded:—The Treasurer's Gold Medal in Medicine, Albert Martin, M.B., Wellington, New Zealand; the Treasurer's Gold Medal in Surgery, George E. C. Anderson, Oudtsboorn, Cape Colony; the Mackenzie Bacon Prize for Ophthalmoscopy, James Henry Targett, M.B., Idmiston, near Salisbury; the Mackenzie Bacon Prize for Nervous Diseases, William Leonard Braddon, Upton-on-Severn; the Burdett Prize for Hygiene, Hubert H. Du Boulay, Winchester; Fourth Year's Students, George E. C. Anderson, Oudtsboorn, Cape Colony, First Prize, 25*l.*, William Leonard Braddon, Upton-on-Severn, Second Prize, 10*l.*; Third Year's Students, Frederick Lever, Epsom, First Prize, 25*l.*, Sidney Watcher,

Canterbury, Second Prize, 10*l.*; Second Year's Students (Joseph Hoare Prizes), Henry, W. Drew, Southwark, First Prize, 25*l.*, Fridiric Francois Burghard, Kensington, Second Prize, 10*l.*; First Year's Students, Ernest Henry Starling, Bombay, First Prize, 50*l.*, Guy Bellingham' Smith, Lee, Second Prize, 25*l.*

Improved Ambulance Vans.—With the view of avoiding risk of contagion in the conveyance of patients suffering from small-pox or contagious fevers to hospitals, Dr. Gayton, Senior Medical Officer of the Metropolitan Asylums Board, has constructed an ambulance van of new and improved form. Instead of having open glass and wooden louvre shutters, its apertures consist of a double layer of perforated metal, enclosing an absorbent material saturated with an acknowledged germicide or destroyer of the minute microscopical particles which tend to propagate disease. Fresh air is admitted through modified and improved "Tobin" ventilators of a horn shape, with the larger end opening externally, whilst inside the van the smaller extremity of this air-tube is provided with a disinfecting air-chamber, constructed like those attached to the other apertures or windows. The Metropolitan Asylums Board use these ambulances for conveying small-pox convalescents from Hampstead to their river wharf, *en route* to the hospital ships off Purfleet.

Society of Public Analysts.—This society held their annual country meeting at the Royal Hotel, Mattock, Derbyshire, on Saturday, under the presidency of Professor Cameron, of Dublin. The subject discussed was "Milk Adulteration." A paper by Mr. Allen, of Sheffield, advocated the addition of twice its weight of alcohol to every sample of suspected milk which had to be produced in court under the provisions of the Adulteration Act. Samples of milk, when kept for several weeks, were often found to be in such a state that the Government analysts at Somerset House could not properly analyse them, and hence differences of opinion arose between them and the public analysts. The general opinion of the meeting was in favour of a milk standard being adopted by Act of Parliament. The proceedings terminated with a dinner.

The Writings of the late Dr. Farr.—It has long been felt that the works of this most eminent statistician, and especially those bearing on vital statistics, were much too valuable to be left in a scattered condition, and a movement, which will commend itself to all students of statistics, is being made by the Sanitary Institute of Great Britain to bring together Dr. Farr's official reports and papers in a volume of some 400 pages, and publish them by subscription, if a sufficient number of subscribers should come forward to justify the expense. Mr. Noel Humphreys, F.S.S., of the Registrar-General's Department, has been entrusted with the selection and editorship; and it may safely be anticipated that so valuable a work, which indeed may be said to form the basis and text-book of our knowledge of vital statistics, will not be allowed to halt in its way towards completion.

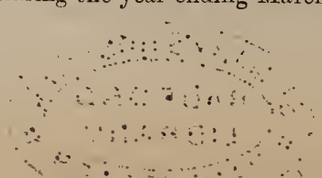
Hospital Saturday Fund.—In anticipation of the recurrence of Hospital Saturday on the 6th of September next, the board of delegates have appealed to the employers of labour in London asking them to remind their workmen of the claims of the metropolitan medical charities upon their liberality, and pointing out that the London hospitals alone contain over 5,000 beds, many of which are unoccupied for want of funds, while more than 1,000,000 of the labouring classes of the metropolis annually receive the gratuitous relief afforded by these institutions. The Board point out that by the development of the existing system of having a collector in each workshop and business establishment of the metropolis ready to undertake the responsible duty of receiving the workfolks' pence periodically and pay it into the central office of the fund, 41, Fleet Street, at least a million of London workpeople can afford a half-penny weekly each towards the support of the hospitals and dispensaries of London, and in this way it is estimated that over 100,000*l.* could be raised.

The Dublin Hospitals.—The twenty-sixth report of the Board of Superintendence of the Dublin Hospitals, just issued, states that during the year ending March 31st, nine hospitals were inspected in a very careful way. The general arrangements and the domestic economy of the several institutions were closely considered in every respect, and statistics made with respect to the following particulars:—The several sources from which income is derived; the expenditure in detail in respect to maintenance and establishment; the admissions, discharges, deaths, the average daily number in hospital during the year, the average sojourn of each patient in hospital, the extent of accommodation, &c.; the average cost per bed occupied throughout the year for maintenance and for establishment, exclusive of building and furnishing such building. On the 1st of April, 1883, there were 815 patients in the hospitals. During the year 9,560 patients were admitted, the total number under treatment was 10,375, of whom 9,226 left cured, relieved, or dismissed; 433 died. The mortality was 4·69 per cent. The total daily average of beds occupied was 746·84. A perusal of the reports respecting the various hospitals shows that these institutions are in a very excellent condition. There are no complaints of any serious kind, and there is much to indicate that the authorities of Dublin hospitals are ready to march with the times and adopt all modern expedients which may tend towards the comfort and well-being of the patients.

Cheese Poisoning.—Dr. Vaughan in a report to the Michigan State Board of Health on numerous cases of cheese poisoning, which occurred at four separate outbreaks in May and June, and were attended with severe symptoms, observes that analysis had found that no mineral poison was present in the cheeses which were eaten and which had all the appearance of a sound article. On being cut, however, a whitish acid fluid oozed out from their pores, in which microscopic organisms were detected. About 163 persons suffered, but they all recovered. Many similar occurrences have been recorded both in Europe and America, but no light has hitherto been thrown upon the cause of the cheese becoming poisonous. In this instance, the poisonous cheese had been manufactured at the same time and the same way as other cheeses which gave rise to no complaint. Good cheese is very slightly acid and is slow in reddening litmus, but a freshly cut surface of the poisonous cheese reddens it almost instantly. This would form a test of easy application by any seller of cheeses.

Paper Towels for Surgical Purposes.—In the surgical dispensary of the Philadelphia Polyclinic, Dr. Roberts has been using, with much satisfaction, Japanese paper handkerchiefs for drying wounds. Sponges are so seldom, and with such difficulty perfectly cleansed after being once used, that they are never employed in the clinic. Ordinary cotton or linen towels are much preferable to sponges, which, if dirty, are liable to introduce septic material into wounds. The paper towels, however, answer the same purpose as cotton ones, and are so cheap that they can be thrown away after being used. They cost from six to seven and a half dollars per 1,000, and the cost of washing a large number of ordinary towels is thus avoided. The paper towels are scarcely fit for drying the hands after washing, unless several are used at once. For removing blood from wounds, a paper towel is crumpled up into a sort of ball, and then used as a sponge. Such balls absorb blood rapidly.

The Treatment of Cholera by Ozone.—The antiseptic treatment is admitted to be the most rational line to follow in a case of cholera, but as we are ignorant of the exact nature of the agent of cholera, and of the conditions under which it flourishes, M. Romain Vigouroux points out (*Progrès Medical*, July 19th) that we ought to seek for an antiseptic whose sphere of activity is wide, and whose destructive action is brought to bear indiscriminately upon all parasitic organisms. Ozone has pre-eminent claims to be considered as having such properties, and its powers have already met with some recognition. The experiments of M. Chappuis demonstrated that ozone neutralises all the germs contained in the air, and further that the essences of the volatile oils owe their undoubted properties to the production of a certain quantity of ozone. All the ozone-producing apparatus in use at the present day is based on the fact that the electric discharge has the power of partially converting oxygen into ozone. The



ordinary electric machine in use for electro-therapeutics would be most suitable for the preparation of the ozone; the patient could be placed on an insulating stool and charged with the ozone. This line of treatment would have the advantage of improving the general nutrition and increasing the vital powers at the same time, and M. Vigouroux concludes his paper by expressing the belief that in electricity we probably have the most efficacious remedy against cholera yet known.

Professor Czerny's Surgical Clinic.—A correspondent of the *Philadelphia Medical News* writing from Heidelberg, furnishes some particulars of Professor Czerny's clinic. Heidelberg and its surroundings supply an immense number of surgical patients, the bulk consisting of cases of club-foot, diseased joints, cancer, lupus, and tumours, and Czerny often operates for ovariotomy. In club-foot he seldom performs tenotomy, but forcibly straightens the foot, and retains it in its position by plaster of Paris bandage. Much plastic surgery is done, *e.g.*, covering erosions from lupus or epithelioma, or building a nose with healthy integument from the forehead. The results are excellent, and sloughing is rare. Almost absolute cleanliness and disinfection are the remarkable features of the clinic. The latter is practised in every department in detail, *e.g.*, in resection of the elbow the part is well-soaped and shaved, and washed with a 1 to 3 per cent. carbolic solution. Professor Czerny, then, with well-disinfected hands and instruments, removes the dead bone, washes out the wound with the bi-chloride (1 to 2 per 1,000), and sews it up. He next introduces some bone drainage-tubes, packed round with gauze, holding powdered iodoform, put up in bags of wood-wool disinfected by carbolic or bi-chloride solution, the whole being bound up with disinfected bandages. The joint is then left at rest for ten days, unless pain, bleeding, or fever occurs. Infrequent dressing is a strong feature of the clinic. In major operations, ovariotomy. large joints, openings, &c., he uses spray. His therapeutic measures are essentially cleanliness, carbolic and bichloride solutions, quinine in large doses, and the liberal use of powdered iodoform. His results are very good, as he attends religiously to the minute details. Professor Czerny is about 45 years of age, with dark hair and broad shoulders. He has an energetic twinkle in the eye, and is genial and good-humoured. He is a demonstrative instructor, a man who talks to the point, and an original operator. His fame rests mainly on successful and original abdominal surgery. He is very kind and instructive to foreign doctors, and speaks good English.

Lady Hospital-Internes. — The *Revue Medicale*, August 2, is somewhat aghast at the news which has reached it that lady candidates are about to be allowed to contest in the *concours* the posts of *internes des hôpitaux* so prized and so fought for by the Paris Medical Students, "Can that be true?" it exclaims. "It is at all events probable enough, seeing the wind of folly which propels the administration of the *Assistance Publique*. By diverting attention to such phantasmagoria, it may delay the great reforms and innovations demanded, while who has ever heard of such a proposal as to convert young ladies into internes? In spite of the youthfulness of the present occupants the waiting-rooms of the internes are not very cheerful rooms, which no doubt is due to the influence of the surroundings, for they are often low and badly lighted places, the administration only handing over to the doctors apartments, which other employés decline to make use of. But all is to be changed, for rays of light are about to inundate these abodes with the free entrance of women. It is even said that the internes have warmly supported this movement of the administration, on the plea that during their watchings and waitings an element of gaiety has become indispensable to them."

A Lithographed Medical Journal.—The most unique medical journal at present published is probably *Le Journal Médical Quotidien*. It is published daily in Paris. All the matter is written out in excellent script and this is then lithographed. The journal is therefore autographic.

THE ALLEGED CASE OF ASIATIC CHOLERA IN BIRMINGHAM.

Dr. Saundby, of Birmingham, has had the kindness to send us the following telegram. From inquiries I have made, it appears that the subject of the alleged case of cholera was a man named Rolfe, a powerfully-built healthy man, aged 47, living in a court in Bishopsgate Street, in St. Thomas's Ward. He was a wheelwright by trade, and was at work on Friday. That night, about half-past twelve, he was attacked with severe sickness and diarrhœa, but did not obtain medicine till the following morning and was not seen by a doctor till Saturday evening. Dr. Richards, who saw him, states that he was then suffering from diarrhœa, with cramp in the abdomen. About midday on Sunday Mr. Hoskins found him collapsed, with severe cramps in the calves of his legs, and very cold. He used strong stimulants and counter-irritants, but could produce no reaction. The man died on Monday evening about 6 o'clock. Mr. Hoskins states that the purging and vomiting ceased after his first visit. Dr. Hill, the Medical Officer of Health, has ascertained that the deceased had been eating a quantity of tainted ham which he had bought cheaply. He also states that he house was free from sanitary defect, except that the sink communicated directly with the drain. There were no other cases of serious diarrhœa on the same premises, and the deceased had had no communication with those countries in which cholera is epidemic. Dr. Waterson, who inspected the body twenty-four hours after death, states that rigor mortis was well marked, the eyes were not sunken, the face was calm, and not at all like the characteristic facies of cholera. Mr. Hoskins says he never authorized the use of the term Asiatic Cholera, but he believed it was a bad case of cholera of sporadic origin. Dr. Hill and Dr. Waterson believe it to have been simply a severe case of diarrhœa, which is now prevalent. The duration of the case, its history, and the surrounding circumstances leave no room to doubt this statement. That it was a case of Asiatic Cholera is absolutely without foundation.

APPOINTMENTS.

Brew, T. F., F.R.C.S.I.—Medical Officer to the Workhouse, Ennistymon Union.

Duffus, George, M.B., C.M. Aberd.—Assistant Medical Officer to the Cheshire County Lunatic Asylum, Macclesfield.

Godwin, Henry, L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the Bovey Tracy District, Newton Abbot Union, *vice* Mr. A. H. N. Lewers, resigned.

Greensill, John Nicholas, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the Workhouse, Martley Union, *vice* Mr. E. S. Greensill, resigned.

Guy, William, L.R.C.P., L.R.C.S. and L.M. Edin.—Medical Officer to the Gosforth District, Whitehaven Union, *vice* Dr. C. A. Parker, resigned.

Jones, T. W. C., M.A. Cantab., F.R.C.S. Edin.—Assistant Surgeon to the Western Ophthalmic Hospital.

King, E. E., M R.C.S., L.S.A.—Resident Obstetric Physician to the Middlesex Hospital.

Rowlands, Hugh Pugh, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer for Llanegryn District, Dolgelly Union, *vice* Mr. J. F. Jones, deceased. Also, Medical Officer to the Towyn District, Machynlleth Union.

Travis, W. O., M.S., M.B. Durh., M.R.C.S. — Demonstrator of Anatomy in the Yorkshire College, Leeds.

VACANCIES.

Charing Cross Hospital.—Chair of Physiology. (*For particulars see Advertisement.*)

Dunmow Union.—Medical Officer to the Hatfield District, *vice* Mr. C. G. Firman, resigned. Area, 14,537 acres. Population, 3,193. Salary, £95 17*s.* per annum.

General Hospital for Sick Children, Pendlebury, Manchester.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

LIVERPOOL NORTHERN HOSPITAL.—Assistant House Surgeon. Salary, £70 per annum, with residence and maintenance in the house. Candidates must possess a Medical and Surgical qualification from one or more British Colleges or Institutions, recognised under the Medical Act. Applications and copies of testimonials to be addressed to the Chairman of the Committee, not later than August 29th.

QUEEN'S COLLEGE, CORK.—Professorship of Materia Medica. (*For particulars see Advertisement.*)

RHAYADER UNION.—Medical Officer to the Rhayader District and the Workhouse, *vice* Mr. Richard Richardson, resigned. Area, 94,261 acres. Population, 4,670. Salary, £55 per annum. Salary for Workhouse, £20 per annum.

ST. BARTHOLOMEW'S HOSPITAL.—Dental Surgeon. Applications with Testimonials must be left, on or before September 4th, at the Clerk's office. Further particulars from Wm. Henry Cross, Clerk.

THE GENERAL HOSPITAL, BIRMINGHAM.—Resident Registrar and Pathologist. (*For particulars see Advertisement.*)

UNIVERSITY COLLEGE, LONDON.—The office of Surgical Registrar in the University College Hospital will shortly be vacant. Applications and Testimonials to the Secretary, Talfourd Ely, M.A., on or before September 30th.

WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, ETC., 73, WELBECK STREET, W. — Physician. (*For particulars see Advertisement.*)

DEATHS.

DANIEL, JAMES STOCK, F.R.C.S., at Ramsgate, on August 14th, aged 80.

KEMPTHORNE, J., F.R.C S., of Callington, Cornwall on August 18th, aged 62.

MCCULLOCH, D. M., M.D., late Medical Superintendent Joint Counties Asylum, Abergavenny, at Wimpole Street, on Aug. 13th.

SCRASE, GEORGE, M.R.C.S., at Lewes, Sussex, on August 15th, in his 81st year.

STEEL, C. W., M.R.C.S., L.S.A., at Southfield, Lewisham, on August 16th, aged 73.

NOTES, QUERIES, AND REPLIES.

M. B.—The continuation of Dr. Gairdner's Lecture will appear shortly.

COMMUNICATIONS RECEIVED—

Dr. CHURCHILL, London; Dr. CURNOW, Penzance; Dr. KNUTSEN, London; Mr. CLARK BELL, New York; Mr. K. STICKELBERGER, Allassio; Dr. JOHN SPEIRS, Glasgow; Mr. J. T. W. BACOT, Seaton; Dr. H. F. BANHAM, Bournemouth; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; Dr. J. W. COUSINS, Portsmouth; Mr. ALEX. WHEELER, Darlington; Dr. F. T. ROBERTS, London; Mr. FRANCIS SCOTT, Edmonton; Dr. HERMAN, London; Dr. WILLOUGHBY, London; Mr. STONE, London; OUR VIENNA CORRESPONDENT; Mr. G. S. GIBBS, Darlington; Prof. MONCORVO, Buenos Ayres; THE REGISTRAR-GENERAL, Edinburgh; OUR PARIS CORRESPONDENT; Dr. CLIFFORD BEALE, London; Mr. G. H. MAKINS, London; Dr. SHELLY, Hertford; Dr. WOLFE, Glasgow; Mr. CHATTO, London; THE REGISTRAR-GENERAL, London; Mr. J. LAWRENCE-HAMILTON, London; THE JAPANESE COMMISSIONERS, HEALTH EXHIBITION, London; THE SECRETARY OF GUY'S HOSPITAL MEDICAL SCHOOL, London.

BOOKS RECEIVED—

Sandefjord Sulphur Bath, by Dr. C. A. Knutsen—Lehrbuch der Physiologie, von Dr. A. Gruenhagen—Army Medical Department, Report for the year 1882—On Tumours of the Bladder, by Sir Henry Thompson, F.R.C.S., M.B. APPOINTMENTS FOR THE WEEK.

Friday, August 22 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday, August 23.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, August 25.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, August 26.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Wednesday, August 27.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday, August 28.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

INTRODUCTORY ADDRESS AT THE OPENING MEETING OF THE EIGHTH INTERNATIONAL MEDICAL CONGRESS.[1]

By PROFESSOR PANUM.

[Abstract].

AFTER expressing the gratitude that he and his colleagues felt to His Majesty, the King of Denmark, for honouring their meeting with his presence, Professor Panum addressed a few words of hearty welcome to the strangers from all quarters of the globe, and then proceeded to trace the history of the congress.

The idea of an International Medical Congress had originated with M. Gintrac, who, at the meeting of the third annual Medical Congress in France, at Bordeaux, in 1865, had suggested the desirability of making the International Exhibition, which was to be held at Paris in 1867, the means of bringing together medical men from all parts of the world. This was no sooner proposed than it was unanimously agreed to, and the French Annual Congress was merged for the year 1867 into the Congress of Paris. It was resolved that the meeting should be purely for scientific purposes, and a committee was appointed, with M. Bouillaud for chairman. This committee issued and scattered broadcast a series of seven questions relating to anatomy, physiology, pathology, surgery, medicine and hygiene. The congress was under the patronage of the Minister of Public Instruction, and its international character was shown in the nomination, as honorary members, of several members of the diplomatic body, besides delegates from some of the governments and learned societies, and the appointment of six vice-presidents from foreign countries as well as six from France.

At the second sitting of this congress, Dr. Pantaleoni expressed, in the name of his fellow-countrymen of Italy, the hope that that international gathering was but the first of a long series of such meetings. This was followed by a proposal that the next meeting should be wherever the International Exhibition was being held, but this was not agreed to, as it was thought better to try and see whether a really international medical congress could not be a success without the attraction of an international exhibition at the same time. Florence was accordingly chosen for the second congress, in 1869, possessing in its skies and its art treasures far greater attractions than an international exhibition. In the evenings an excursion to the royal baths at Montecatani, and a splendid banquet

[1] Delivered at Copenhagen, on August 10th, 1884.

due to the hospitality of the medical men and townsmen of Florence, contributed in no small degree to increasing and cementing the international relationship of the members of the congress.

The third congress, delayed a couple of years by political events, was held at Vienna, in 1873, the year of the great exhibition there. Its organisers departed in several respects from the footsteps of their predecessors. The propositions to be discussed at the congress were drawn up solely by the physicians of Vienna, and not by a committee chosen from foreign countries as on the previous occasions. The committee decided on the official nomination of a number of delegates from the governments of the different countries, and appointed presidents and vice-presidents from other countries to direct the discussions. Relying on the promise of pecuniary support from the government, the committee declined any contributions from their members, with the result that the transactions had to be published out of the funds of the succeeding congress. Several notable advances were however made at this congress. One was concentrating into one week what had occupied two weeks previously, another was their courtesy in allowing the discussions to take place in other languages than the German, and finally the allowing foreigners to take the chair and direct the discussions.

The fourth congress was held at Brussels. Here the organisation of the congress was entirely remodelled by the institution of sections for the various branches of the medical sciences, by which means the interest of those attending, the number of the sittings, the time devoted to work, and the scientific results of the congress were much increased. Here too was first introduced the custom of exhibiting new instruments, as also the plan of excursions to places of interest in the neighbourhood. The congress was favoured by the presence of His Majesty the King of the Belgians at the opening ceremony. Another change was the nomination of honorary presidents of the congress, and of honorary vice-presidents of the sections, who by the way very seldom had anything to do. The mistake, however, was made at Brussels of attempting to decide questions of scientific interest, by voting on them, which was contrary to one of the laws of the congress passed at the Paris meeting.

The three following congresses had completely adopted the arrangements set on foot in Brussels, though in the matter of detail, at each the customs of the city led to certain differences. The number of inhabitants of the country and town evidently bore some proportion to the number of members of the congress. At Paris about 1,200, at Florence 357, at Vienna 671, at Brussels 412, at Geneva 365, at Amsterdam 630, and at London 3,181 members were present.

The size and magnificence of the ceremonies, the dinners and the excursions had increased in proportion to the wealth of the towns and had culminated in London in such a pitch that it would be madness to wish to attempt to imitate them in Copenhagen. They had no such ambition. On the contrary, they believed that it was neither by the number of the members nor by the festivities that the value of the congress could be measured. They had even thought that the development of too great a luxuriousness might prove a source of danger to the congress in the future, and that the need of greater frugality had been one of the reasons why Denmark, well known as a small and poor northern country, had been chosen as the seat of the congress.

The congress at Geneva had the credit of having re-established the Paris plan of having contributors from foreign countries, and in this they had been followed by Amsterdam and London. For their own part they had tried to get as many foreign contributors as possible, and had circulated amongst the leading men of the day some two hundred suggested subjects. The Geneva Congress had rendered prominent the importance of the natural sciences in relation to practical medicine, a relationship which had received further development at the subsequent congresses. The Geneva Congress had, however, made the mistake of reducing the number of sections to six, but at Amsterdam they were restored to nine, and at London this number was increased to sixteen. They had decided to reduce this number by two, leaving out the Section of Pharmacology, and also the Dental Section, these subjects being merged into the other sections. In order to secure success for so great a number of sections, they had determined to make use of the active assistance of the honorary presidents to rule over the various discussions already agreed upon. They had tried to profit by the experience of their predecessors in order to obtain the best possible results. "It will be," said Dr. Panum in conclusion, "for future congresses to continue the progressive development of this international institution, to the advantage of science, of suffering humanity, and of a brotherly alliance of the physicians of all nations in a sacred work, one far above the barriers of languages, and beyond the rivalry of nations."

THE BRADSHAWE LECTURE
ON
THE PATHOLOGICAL RELATIONS OF THE ABSORBENT SYSTEM.

By GEORGE HARE PHILIPSON, M.A., M.D., D.C.L., F.R.C.P.

Professor of Medicine in the University of Durham; Senior Physician to the Newcastle-upon-Tyne Infirmary, &c.

(*Concluded from page* 249.)

THE lymphatic vessels are subject to two principal classes of tubal changes, namely, dilatation and hypertrophy, and obstruction. Dilatation may affect the capillary network of the lymphatics, more commonly the larger trunks; or occasionally the thoracic duct or the receptaculum chyli. It presents various degrees, and assumes different forms. Thus there may be merely a localised reticular dilatation of the lymphatic capillaries, or more frequently varicose, saccular, tubular, fusiform or cirsoid dilatation of the trunks; or the enlarged vessels may form a distinct growth, named lymphangioma or lymphangiectodes, which has been divided by Wagner into the three varieties, simple, cavernous, and cystoid, in which cysts are developed. Moreover, enlarged lymphatics constitute an important element in the structure of elephantiasis and other growths, especially elephantiasis lymphangiectodes. The thoracic duct and receptaculum chyli may be enormously dilated, the former, in extreme cases, reaching the size of the little finger, or even attaining larger dimensions than this. The deep lymphatics and the lacteals are liable to dilatation, as well as those on the surface. Lymphangiectasis is in many cases congenital, and it has been supposed that this may be due to the want of specialisation in the lymphatic system of certain parts. The condition is attributed to different causes. Thus it may follow lymphangitis, in consequence of which the larger tubes are blocked, and the afferent vessels become therefore dilated. In other cases it is not preceded by marked inflammation of the lymphatics, but there is considerable hypertrophy of the cellular tissue, and the vessels enlarge, forming a very free anastomosing network. Again, it is

supposed that dilatation may arise from mere hypertrophy of lymphatic plexuses, or from paralysis of the coats of the vessels. Any obstruction from internal plugging or external pressure may lead to enlargement of the vessels, the circulation through which is thus impeded, and probably the obstruction may be occasionally seated in the glands. Lymphatic dilatation is most frequently met with in warm and moist climates. When lymphangiectasis occurs on the surface of the body, it can be recognised by objective examination. Dilatation of the superficial lymphatics is generally observed on the inner side of the thigh, the sides of the abdomen, the scrotum, and the penis. It is characterised by vesicles like grains of sago, grouped irregularly (Curnow). Sometimes, only ampullæ are formed, which are generally soft and painless. The vessels may rupture subcutaneously, forming vesicles containing a clear or milky fluid. They are also liable to rupture externally, or into various internal parts when situated internally, and it is only thus that the latter can be at all recognised clinically, the escaped chyle or lymph appearing in the fæces or urine. Even superficial dilatation of the lymphatics has been not uncommonly mistaken for other conditions, such as hernia, abscesses, and strumous enlargement. The discharge of lymph confirms the diagnosis. If inflammation attacks dilated lymphatics, it tends to spread rapidly, and may prove fatal.

Multiple lymphatic nævi of the skin, a newly observed disease of the lymphatics, has been recently described by Hoggan. The condition is believed to be not uncommon, quite as frequent, perhaps, as venous nævi, which it often accompanies and complicates. It also forms the initial stage or predisposing pathological condition of other diseases, such as lymphatic varix of the larger vessels, and also of elephantiasis, in the production of which it may often be the most important factor. That this has not been observed before is probably due to the fact that no proper histological examination, as apart from microscopical, has been made of the tissues in the initial stages of the diseases. That the condition has not been recognised clinically, is probably due to the want of colour in such nævi, as compared with venous nævi. But there can be little doubt, from the frequency with which venous nævi have been observed in elephantiasis, that the two conditions of venous and lymphatic nævi are generally co-existent, and that conditions of hypertrophy, due really to the latter form, have, through being unrecognised, been erroneously ascribed to the former. On the other hand, when the lymphatic nævi were small, and placed so superficially in the skin that distension by lymph, produced at will, made them appear above the general surface, like vesicular papules: such a condition would almost certainly have been described as varicose lymphatics.[10]

The absorbent vessels may become obstructed. This condition may involve the lymphatic capillaries, their main trunks, or the thoracic duct itself. It may result from the blocking up of their channels by coagulated lymph, from inflammation of the walls of the vessels, or from external pressure. Thus the thoracic duct may be more or less obstructed, or even completely obliterated, by the pressure of enlarged glands in the thorax, or of an aneurysm. The lymphatic trunks in the limbs may also be compressed by glands, aneurysms, and other morbid conditions; and also the capillaries are subject to pressure in consequence of inflammation of the surrounding cellular tissue. Obstruction of the thoracic duct is said to arise from disease of its valves. It may be remarked, further, that a certain degree of obstruction to the flow of the lymph and chyle may arise from marked interference with the venous circulation, as the result of cardiac disease or direct obstruction of the principal veins. If the thoracic duct is obstructed, and if the chyle cannot reach the venous system by the establishment of a collateral circulation, grave general symptoms arise—viz., marked wasting and anæmia, tending towards a fatal issue. Various degrees of obstruction of this channel have, however, been found in several cases at *post-mortem* examination, in which no symptom had been observed during life. The most obvious direct effects of obstruction in the absorbents are dilatation of the vessels behind the impediment, in the course of the circulation, and the development of lymphatic œdema. These conditions necessarily vary much in their extent and degree, according to the situation and character of the obstruction. The dilatation may ultimately lead to rupture of the vessels.

When lymph or chyle is discharged from the vessels or glands, either on the surface of the body or into some internal part, the amount varying much in different cases, the terms lymphorrhagia or lymphorrhœa are applied in signification of the condition. Lymphorrhagia has been observed as a consequence of a wound, but more commonly of engorgement from closure of the lumen of the duct by inflammation or a tumour. In rare cases it may occur from slight wounds, especially in the neighbourhood of joints, which is probably due to a constitutional defect, a lymphorragic diathesis corresponding to the hæmorrhagic diathesis (Bradley). Usually traumatic lymphorrhagia results from wounds of the thoracic duct of the larger lymphatic trunks, or of the glands. Idiopathic lymphorrhagia is generally due to previous dilatation of the vessels, which ultimately give way. A most interesting case has been reported by Cayley, in which the receptaculum chyli gave way spontaneously as the result of previous extreme dilatation and fatal peritonitis ensued.[11] Lymphorrhagia may be associated with chyluria, and is then believed to be due to the filaria sanguinis hominis. When lymphorrhagia occurs on the surface of the body, the discharge of the lymph is the clinical sign of the condition. The amount of fluid which escapes varies considerably—from one ounce to five or even ten pounds during the twenty-four hours. It also differs at different times, and the flow has been known to assume a periodic character, increasing during digestion. The fluid which escapes after injury may be clear and limpid lymph, or mixed with inflammatory products or blood. That which comes away in cases of rupture from dilatation of the vessels is more or less white and milky, like chyle, and it contains a variable quantity of fat. The quantity of fibrin present varies much, and therefore the power of spontaneous coagulation of the fluid. When lymphorrhagia takes place internally it can only be recognised by the presence of the fluid in the urine or fæces respectively, in the former case giving rise to chyluria, in the latter to fatty stools. Bradley directed attention to the probable origin of certain cases of hydrocele, hydrocephalus, pleuritic effusion, and ascites from a lymphorrhagia into the respective serous cavities. As proved by Cayley's case, the escape of chyle into the peritonæum may set up fatal inflammation. The general condition is more or less affected in cases of lymphorrhagia in proportion to the amount of fluid lost.[12]

The consideration of inflammation of the lymphatic system would now appear to be appropriate. Acute inflammation presents three varieties, namely, when the vessels are alone affected, lymphangitis or angeioleucitis; when the condition is limited to the glands, adenitis, or when both vessels and glands are involved. It will be convenient to consider these varieties together. As a rule the disease is localised, but under

certain circumstances, the absorbent system is more or less widely implicated, especially if the inflammation is of a septic character. It may be set up and extend with great rapidity.

This class of affections may be of traumatic origin, being due to various forms of injury, such as a wound, contusion or strain, or they result from various kinds of irritation, such as that induced by neighbouring inflammation, suppuration, ulceration, or diseases of joints or bones. The implication of the glands under the jaw, in cases of diphtheria and scarlatina, is a familiar illustration of irritation from within. External irritation, as, for instance, the strong heat of the sun, may induce superficial lymphangitis. Special forms of inflammation of the absorbent system are set up by specific kinds of irritation, such as that of the syphilitic virus, and septic forms of the disease are induced by various septic poisons. The lymphatics connected with the internal organs are often inflamed when these are the seat of any irritation. Pus has been found in the neighbouring lymphatics in cases of purulent pleurisy. Some forms of pelvic cellulitis have also been regarded as being due to lymphangitis. Inflammation may be immediately excited in the vessels and then travel along to the glands ; or the irritation may be conveyed by the current of lymph to a more or less distant part, the intervening portion being unaffected, or the glands may be implicated by extension from the surrounding tissue. When a gland is involved, while the vessels between it and the source of the irritation are unaffected, the inflammation is said to be sympathetic, Inflammation is much more readily excited in the lymphatic structures in some persons than in others, and especially in those who are of a strumous habit. The glands are more liable to be affected in the early periods of life. A low state of the health may predispose to inflammation of these structures from slight causes.
