On the re-admission of the strangers, after an hour and a half had been spent in discussing this matter, Sir HENRY PITMAN rose and said he thought that the present attempt to deal with the question was impracticable. They had been for four hours already engaged on it, and had come to the conclusion to make no alteration. Was it really desirable to entertain the idea that they could discuss this question properly and fairly during the present session? He suggested that the Executive Committee should be instructed to consider what changes, if any, were requisite on the subject of preliminary education and examination, and confer, if it seemed desirable, with the Branch Councils and report to the Council at their next sitting. If they went on this session it seemed to him that there was a danger that the business would be hurried through.

Dr. AQUILLA SMITH seconded the proposal. The question was one of the highest interest and importance, quite as important as higher branches. They ought to give it their full consideration, and should postpone it rather than run the risk of hurrying. In this way something definite would be brought up.

Mr. SIMON thought that by the course suggested they would be placed in a false position. All their minds were intent upon this subject of preliminary education, they had made good progress with it, and moreover they had entered upon it upon the motion of Sir Henry Pitman himself.

Mr. MACNAMARA asked as a point of order whether the resolution by which on a previous occasion they had decided not to refer this matter to the Branch Councils, did not preclude such a motion as the present, being almost identically the same.

Dr. PETTIGREW could not agree to refer this matter to the Executive Committee; if they did so, when the report was brought up they would have just as long a discussion as now.

The PRESIDENT saw nothing in the motion to prevent it being put.

Dr. STORRAR said he had no strong feeling on the matter. They had recently had the whole subject of preliminary education in dock, and he did not see why they should have it all over again so soon; it only tended to unsettle people, both the examiners and the candidates. The present scheme was so far good that they need not disturb it. He thought that they had taken up this subject hastily and inconsiderately. If they referred it to the Executive Committee he thought they would be very likely to get into trouble. This scheme represented twenty-five years of work, and they ought to keep quiet and see how it worked.

Sir HENRY PITMAN asked leave to withdraw his motion.

The Council then resumed.

A petition from Mr. A. A. Sadgrove for restoration to the register was received, and the Council declined to accede to the request.

On the motion of Dr. FERGUS, it was resolved to warn all the licensing bodies that forged diplomas were in existence.

Eighth Day.—Wednesday, October 15th.

Preliminary Examinations (continued).

The Council again went into committee on the question of the subjects for preliminary education.

Professor Humphry moved that English history be omitted from the subjects required. This was agreed to.

Professor Humphry then moved that modern geography be also omitted.

This was seconded by Professor Struthers.

Dr. Storrar objected to this. He thought the geography was peculiarly requisite for medical students. Medical men were called upon to deal with tropical diseases, and he could not approve of its being supposed that it was desirable that a medical man should have no knowledge of geography. The Geographical Society had founded a prize in this subject, but of late years it had not been awarded because there had not been enough competitors. There was no doubt that geography was much neglected in schools, and it was a matter of general regret amongst educated people that such was the case.

Dr. Lyons characterised this as an important and sweeping amendment. Medicine was to a large extent associated with geography, an interesting branch of it was that in connection with the geographical distribution of disease. He considered that it was a subject which educated and improved the mind, and he attached great importance to it, instancing from what wide localities the materia medica was brought together.

Dr. Chambers quoted the practice of Dr. Butler, the author of a well-known atlas, who only taught geography for a week in the year, because it had no relation to the other subjects, and was not a good training for the mind.

The Rev. Dr. Haughton had never met any boy who knew anything about it. He agreed with the view of a teacher who left out geography on the ground that it was his business only to teach such things as were useless, the pupils would learn the rest for themselves.

The motion was carried by 13 to 4.

Professor Humphry next moved that Latin include translation from specified authors, and translation from easy passages not taken from such authors. He said that the subjects whose omission he had moved were not in his opinion by any means unimportant, all were valuable. The greater the culture, the better, but they were endeavouring to determine what subjects school students should be examined in, and what were not absolutely necessary had better be left out. Too many subjects encouraged cramming. His object was to reduce the number and have them better taught. By this resolution he believed they would really lead to mental education. The teaching of a language was almost worthless if a man could not translate a passage not previously seen; he knew as a matter of fact that specified books were learnt by heart.

Mr. Marshall seconded the motion.

Professor Struthers did not like increasing the Latin, he would rather diminish it and increase all the rest. He did not believe that Latin was the best of all mental trainers, that was a tradition handed down from the middle ages. All depended on how the subject was taught, everything was educational if well taught. He denied that Latin had any advantage as a trainer of the mind, Latin and Greek were cramming subjects. Herbert Spencer's "First Principles" and Darwin's "Origin of Species" were a better training than languages. They ought to have a minimum standard in Latin; a little was useful for the nomenclature and he would retain it for professional reasons and not as a trainer of the mind. They ought not to increase a burden that would be of no utility.

Dr. Pettigrew said that they ought to have a minimum standard in Latin and not a maximum; it was not a good subject for training the mind, any subject did as well if well taught. A man should be taught things that would be useful to him. Latin was one of them but modern languages should be included.

Mr. Simon should support the motion. Education was no doubt a burden to weak-backed people, but this applied to everything and not to Latin alone. The question was whether this was useful. A certain quantity had been admitted to be essential, where were they to draw the line? He thought that hitherto it had been ridiculously low. They had omitted two subjects and they must strengthen the others.

Professor Humphry observed that Professor Struthers had not been very logical in his argument, as he had admitted that any subject if well taught was a good basis for education, and this was exactly what they were trying to secure, viz., that Latin should be better taught.

Dr. Heron Watson thought that an increased amount of Latin was most desirable, it was the very subject in which the boys had been taught at school, and the object of the preliminary examination was not so much to find out how much they knew, as to see how they had applied themselves to the study. Until the day when the peculiar kind of study foreshadowed by Professor Struthers was reached they need not consider it.

Mr. Macnamara reminded them that they had lightened the curriculum on purpose to enable them to demand a better knowledge of Latin.

The Rev. Dr. Haughton said that they were asking a poor minimum in Latin such as they certainly would not accept in regard to French if they were examining in that subject.

The motion was then put and carried.

Dr. Lyons then moved that Greek be inserted in the programme.

Dr. Banks seconded the motion. Everything that had been said about Latin he said applied with equal force to Greek. He was surprised that Professor Struthers should support a minimum standard in Latin. The remarks he had made about the nomenclature were equally applicable to Greek. Efforts had been made in Germany to Germanise the vocabulary and had failed signally. Virchow had framed a large number of words from the Greek. Modern languages had their origin in the dead languages, and nowhere was the medical student ignorant of Greek except in Great Britain.

The Rev. Dr. Haughton had saved Greek on a former occasion by proposing to make it compulsory, when Sir James Paget had tried to cut it out, and he was content that it should have a place amongst the optional subjects; if compulsory it would be a mere sham. He wanted to save it for those who knew it and loved it.

Dr. Storrar said he felt inclined to say "happy is the man who has a knowledge of Greek." For the first few years of the Council he had strenuously advocated it, and it had been a compulsory subject, but after about six years he had seen that it was hopeless, and had given it up as a compulsory subject. It was no use asking for what one could not get and what one did not expect to get. He would retain it as an optional subject, but many boys were in the modern departments of schools which they did not leave till just seventeen, and it was impossible that they should know any Greek.

Dr. Banks said that the removal of Greek was the thin end of the wedge.

Dr. Aquilla Smith said that, as a rule, boys knew very little Latin and less Greek.

The motion was then put and lost, six hands only being held up for it.

Professor Humphry then moved that the first book of Euclid with easy questions thereon be substituted for the two books at present required. This was part of the scheme of diminishing the area and improving the quality. The second book of Euclid was not a good one for examination purposes, and the first one, if the student showed that he understood it, would be much better.

The Rev. Dr. Haughton said that the second book was excellent in its way, but the algebra would make up for its omission.

The motion was agreed to.

Professor Humphry then proposed that elementary mechanics should be passed before the student was allowed to be placed on the register as a student.

Mr. Simon seconded it.

The Rev. Dr. Haughton asked if the footnote exempting the Universities would be affected by this motion, and

was informed that it would be dealt with separately afterwards.

Mr. MACNAMARA said that Professor Humphry had stated that he wanted to make the education more thorough, but this resolution would encourage sham examinations.

Mr. SIMON said that the Council had added the third footnote in deference to strong representations made at the time, but the footnote had been a failure. No machinery had been established by which to ascertain whether a man had passed in mechanics or not if he had once been allowed to be registered without. He considered it would be an immense advantage to the student in his first year to have learnt some elementary mechanics.

Mr. MACNAMARA explained that the College of Surgeons had availed themselves of the footnote which permitted a man to pass in mechanics at his first professional examination. It often happened that a man came to them from some distant part of Ireland where he had had no opportunity of learning mechanics, and so they allowed him to take it up, with other subjects, at the end of his first year, and he should certainly oppose the motion to alter that.

Dr. PETTIGREW said that mechanics certainly ought to be an elementary subject.

Dr. FERGUS observed that if a student had not passed his mechanics before commencing his professional curriculum, he was certainly overloaded with work, considering the shortness of the time.

Dr. STORRAR called attention to the fact that out of the first fifty students on the list, only fourteen had passed their examination in mechanics before being registered. If they mixed up the mechanical with the professional examinations the latter would become a farce and the mechanical examination would be spoiled.

Mr. MARSHALL said that it was evident that they wanted some such preliminary scientific examination as he had sketched out on the previous day. In Ireland they seemed to have something of the kind already. They ought to give the student the option of passing in two stages, and keep the instruments of education, *i.e.*, language separate from the science.

Professor HUMPHRY said that that was the object, that he might pass it separately from the preliminary examination.

Mr. SIMON said that some were trying to make this a postliminary instead of a preliminary examination. If a man was going to study medicine he ought to have a knowledge of mechanics beforehand ; it would be injurious to the medical curriculum to burden it with this.

Dr. HERON WATSON asked what assurance they had that men would not wholly escape that portion of the examination.

The PRESIDENT said that the question was how much was to be compulsory before a man entered on biological subjects. He thought that the subject was too intimately mixed up with the professional examination question, which had already been referred to the Branch Councils, for them to deal with.

Professor STRUTHERS said that the examining bodies must conform to their wishes. Book knowledge on such a subject was a sham ; it required demonstration. It simply meant that the students must go to school earlier.

The motion was then put, and carried by 15 to 3.

Sir HENRY PITMAN then proposed and Mr. Marshall seconded an amendment of the footnote which had hitherto enabled students to get on to the register before passing the examination in mechanics. It required that every candidate should pass the examination in mechanics before being registered, but not necessarily at the same time. Many had availed themselves of the option, and never passed at all. The licensing bodies could not be expected to see that the requirements of the Council were carried out.

Mr. MACNAMARA said that this matter was of vital importance to the College of Surgeons in Ireland, and he went over all the ground he had already been over, concluding by a hope that they would not bring the College of Surgeons into collision with the Council.

The motion was then put, 17 voting for, 3 against, and 4 not voting.

The Rev. Dr. HAUGHTON then moved a fresh footnote in place of the one that had formerly protected the Universities from the operation of this clause. He stated that Trinity College, Dublin, insisted on a year's study of mechanics as a part of the training for the Arts degree, and pointed out to the Council that not to pass some such resolution was to assert that they would not accept the judgment of a body who had much better knowledge than they had themselves, and to refuse a body who aimed at a much higher standard than that contemplated by the Council.

Several members took part in the discussion on this point, Mr. MACNAMARA and Dr. HERON WATSON asking how a man was to be prevented from changing his mind after he had been put on the register as a student of Trinity College and without taking a degree in Arts, or ever passing their examination in mechanics.

Dr. STRUTHERS objected on the ground that it afforded a back door, which was always undesirable. Sir HENRY PITMAN read the minutes relating to the original passing of the footnote, and was in favour of leaving it just as it was. In the end Professor HAUGHTON withdrew his motion, and Professor STRUTHERS moved that the footnote in question should be erased, and this was carried.

The next clause was that the optional subjects be omitted.

Professor HUMPHRY said that as he perceived that the sense of the Council was adverse to the motion he would not propose it. On this an animated discussion took place, some declaring that this was only part of the motion which Professor Humphry had brought forward, others declaring that it was impossible to compel a person to propose a motion of which he had given notice, though it was competent for any one else to do so. Mr. Macnamara tried to act on this principle, but the President ruled that he could not propose it as he had not given notice of it.

The PRESIDENT ruled that as the case was novel, and there was no rule applicable to it he should call upon Professor Humphry to bring forward his motion, as it might be a dangerous precedent to allow a person who had brought forward a motion to withdraw the last part of it when some clauses had already been agreed to.

Professor HUMPHRY explained that he had only been anxious to save the time of the Committee, and it was not on account of any change in his views that he had proposed to leave the matter alone. He had no disrespect for the optional subjects, but he was anxious to diminish the number of subjects the student had to take up, and this was part of the scheme.

Mr. MACNAMARA seconded the motion. He had voted for an increased amount of Latin on the distinct understanding that this subject would come up. He regarded modern languages as of no use. He wished to lighten the burden on the students, and they were only keeping in sham subjects in this list.

Dr. PETTIGREW defended the advantages of a knowledge of French, and referred to its peculiarities of construction. The optional subjects gave a student a good opportunity of showing his knowledge.

Dr. BANKS said they certainly ought to retain the modern languages as they were of the greatest possible value.

Professor STRUTHERS moved that the optional subjects be retained, and then a man who knew some Greek could get credit for it. He thought it ought not to be said that they were not going to recognise modern languages in any form. He would like to see zoology included.

Dr. PYLE seconded the amendment.

Mr. SIMON regarded this as an essential part of the scheme. Two influences were represented in the optional subjects, one was he said the crotchets or idiosyncrasies of members, and the other, as far as the candidates were concerned, represented the element of chance. If they had optional subjects why not have things in general—Shakespeare or Milton for instance ? Mostly, he contended, in this way no real knowledge was gained. The subjects would have been learnt by the student equally without the examination. They were running a great risk of losing the compactness of their examination. All knowledge was useful for the student of medicine, and chance ought not to be rewarded.

Dr. Pettigrew said that Mr. Simon assumed that all medical students were of the same conformation. They ought to encourage idiosynerasies and foreign languages.

Mr. Marshall denied that they were encouraging sham knowledge, but giving an opportunity to the students. These many-sided men were just the sort of people whom they wanted in the profession. They had settled the essential subjects and were now dealing with the ornamental ones. They must retain the optional subjects.

The Rev. Dr. Haughton would support the optional subjects for the sake of the Greek; he thought logic and elementary chemistry were not very good subjects, and zoology would be better than botany.

Sir Henry Pitman asked whether they could not retain the optional subjects and make them all optional, none compulsory; it seemed hard not to give a man credit for them if he knew them.

Professor Humphry's motion was then put, 7 voting for it and 11 against. The motion was therefore lost.

Professor Struthers then moved that zoology be added to the list of optional subjects. This was agreed to.

Mr. Macnamara moved to reject logic.

Dr. Storrar would regret to see logic turned out; it often happened that a good mathematician was a poor logician and he who was good in logic was weak in mathematics. Only a very small amount of men would take up logic, but there was no object in rejecting it from the list.

Mr. Simon said that clearly a large range of subjects should be allowed. It would be an odd course to take to exclude logic, especially when so many of the foreign schools insisted upon it as an essential.

Mr. Macnamara asked leave to withdraw his motion and the Council then resumed and adjourned.

Ninth Day—Thursday, October 16th.

Preliminary Examinations (continued).

The Council went into Committee.

Professor Struthers' amendment, that the subject of the preliminary examination might be passed at one or several examinations, was before the Committee.

The Rev. Dr. Haughton said this would entirely subvert the object of Professor Humphry's resolution. It would be still further lowering the standard, and would, in fact, be like helping the lame ducks over the stile.

Dr. Heron Watson supported Professor Haughton. The object of the examination was simply to test what the candidate had learnt at school, and whether he had such knowledge as would fit him for the medical profession.

Dr. Haldane said that practically a very small number would pass the whole examination, not ten per cent.

Professor Struthers observed that classics and mathematics had no relation to each other; they had adopted the principle in regard to the professional examinations, and it was equally if not more applicable to the preliminary examination. He did not, however, mean to encourage men to go in for bits of the examination at a time.

Dr. Banks said that they did not re-examine men in Dublin in all subjects if they had done badly in one. It was unfair to make them keep up useless knowledge.

Dr. Storrar said that their object had been to secure thoroughness. A boy ought to be required to show knowledge, that is an intelligent grasp of his subject. It was pernicious to allow a boy to come up and take his chance of getting through in one or other subject. He asked Dr. Haldane whether the Scottish scheme did not perhaps encourage a low standard by being too indulgent. Nothing would so tend to a want of preparedness as this.

Dr. Pettigrew would support Professor Struthers.

The Rev. Dr. Haughton said that if this was carried, the preliminary examination would be even more contemptible than at present. They ought not to degrade it further.

Dr. Heron Watson said the motion, if carried, would encourage cramming.

Dr. Aquilla Smith thought examination by instalment a great evil.

Dr. Fergus would certainly not support the motion if he thought it would lower the standard. He believed in future the student would know his subject and not be crammed in it.

Mr. Marshall referred to former resolutions, even so lately as March last, when the opposite principle had been affirmed by the Executive Committee. It was highly desirable that some decision should be come to, their custom ought to be uniform.

Professor Struthers said the examiners would be less afraid to reject a man under the scheme, and so the standard would be raised. He was of opinion that in Scotland they were superior in general education. If a man did well in one subject he should be exempt in that.

The motion was put and carried by 10 for, 8 against.

The Council then resumed.

Mr. Marshall then moved

"That the following Resolutions, passed by the Council in Committee, with regard to the Preliminary Examination of Medical Students, be received and adopted:—

"That the subjects now required for the Preliminary Examination, as set forth in the present Regulations of the Council, be modified so as to stand as follows:—

"No person shall be allowed to be registered as a Medical Student unless he shall have previously passed a Preliminary Examination in the subjects of General Education as specified in the following list:—

"(1) English Language, including Grammar and Composition.

"(2) Latin, including Grammar, translation from specified authors, and translation of easy passages not taken from such authors.

"(3) Elements of Mathematics, comprising (*a*) Arithmetic, including Vulgar and Decimal Fractions; (*b*) Algebra, including Simple Equations; (*c*) Geometry, including the first book of Euclid, with easy questions on the subject-matter of the same.

"(4) Elementary Mechanics of Solids and Fluids, comprising the Elements of Statics, Dynamics, and Hydrostatics. This subject may be passed, apart from other subjects, at an Examination conducted by any one of the recognised examining bodies.

"(5) One of the following optional subjects:—

"(*a*) Greek, (*b*) French, (*c*) German, (*d*) Italian, (*e*) any other Modern Language, (*f*) Logic, (*g*) Botany, (*h*) Zoology, (*i*) Elementary Chemistry."

"That the subjects of the Preliminary Examination for Medical Students be allowed to be passed at one or more Examinations."

This was agreed to.

The clauses were then taken singly. A footnote to the English clause, going into details about dictation, was thrown out by a large majority, on the motion of Rev. Dr. Haughton. The others were carried without opposition, except that relating to Latin, on which Dr. Lyons and Dr. Banks proposed that Greek should be inserted, which was negatived, and the clause on the optional subjects, which led to some discussion, but was finally agreed to.

The Universities in Relation to the Council.

Professor Humphry said that it was exceedingly important that the Council should not set itself in direct opposition to the Universities unless it was absolutely necessary. It had been a great principle with the Council that the Universities should conduct these examinations, and it would be most unwise for the Council to pass resolutions which would interfere with men going up to the Universities. The latter were the best judges and must be left to conduct their examinations on the plan they found best for general education. The Council would be driving students from the higher examinations of the Universities to lower examinations in other parts. The Council should be extremely careful how they did anything to interfere with the Universities, and they should not throw any difficulty in the way of the University of Dublin. He moved as a resolution that the examinations in general education conducted by the Universities be accepted as heretofore, and that if the examination in mathematics was higher, and elementary mechanics was not included, a knowledge of that subject would be accepted at a subsequent date.

Dr. Banks seconded the motion.

Dr. Pettigrew regretted that this subject should be re-introduced, when they had voted on the matter the day before.

Mr. Macnamara said that they were providing one mode of examination for one set of men and another for another. They had the day before laid down the principle that a man must pass in mechanics before commencing his professional education, and it ought to apply to the University student just as much as to others. What security had they that the man would go on with his University career? The Trinity College men were being excluded because they were having a better education.

Mr. Simon objected to mathematics being accepted for mechanics. The vote on the subject on the previous day had been most deliberately given. A little adjustment for exceptional cases might be necessary; but such should be exceedingly carefully guarded. What they wanted was four years of professional study, exclusive of mixing with preliminary subjects. He thought the matter should be deferred in order that the members could confer with their respective Universities, and make exception to cover special cases and no more. It was essential that they should not go upon a wrong principle.

Professor Struthers said a year would elapse before the scheme came into operation. They could not make exceptions for special bodies.

The Rev. Dr. Haughton characterised the examination in mechanics as flimsy. The University of Dublin would not be dictated to by the Council as to how they should teach mechanics, and would not think anything of their opinion. The only result would be that their students would not register.

Professor Humphry reminded the Council that they could not make laws, only recommendations. The Council should beware of running in opposition to the Universities. The University of Cambridge had formerly been at great pains to keep the recommendations of the Council, and had instituted a special junior examination especially for medical students, and not one single candidate had passed although it was infinitely easier than the previous examination. They ought not to let minor points stand in the way of what was much more important, viz., to encourage medical students to have a university education. The advantages of mixing with other young men could not be over-rated, and no slight detail would compensate for losing them.

Mr. Marshall hoped they would defer the subject, as it was evident they would not be unanimous.

The motion was put and lost, 6 voting for, and 9 against.

It was then agreed to send a copy of the amended regulations to each of the licensing bodies, Dr. Storrar observing that they had added nothing, and made all round reductions.

On the motion of Professor Struthers, the junior local examinations of Aberdeen and Glasgow were admitted, subject to the approval of the Executive Committee.

Strangers were then ordered to withdraw, and the Council received a report from their solicitor, and considered a case of counterfeit diplomas which was referred for further legal advice.

Dr. Quain presented a return showing the additional qualifications held by Licentiates of the Royal College of Physicians of London registered during the years 1882 and 1883.

Dr. Lyons made a statement on a series of resolutions which he put on the order of business, but which he was allowed to withdraw.

A letter was read from the Master of the Society of Apothecaries, which was practically a protest against the sanction of the Council having been given to the co-operation of the two Colleges to the exclusion of the Apothecaries' Society.

On the motion of Dr. Lyons a Select Committee was appointed to consider the possibility of providing a more suitable place of meeting for the Council.

After some valedictory remarks from the President, who again thanked the Council for the honour they had done him in electing him a President for the third time, the Council adjourned, and in accordance with their usual custom met again and read the minutes of the meeting just concluded.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

Friday, October 10th, 1884.

Sir Andrew Clark, Bart., M.D., President, in the Chair.

The President called attention to the new volume of the "Transactions" and made a few introductory remarks upon the coming work of the Society.

Nerve Symptoms in Rheumatic Affections.

Dr. W. B. Hadden read a paper on this subject. The first case was one of glossy skin following on an acute joint affection. The patient, a woman, aged 35, was under the care of Dr. Bristowe, at St. Thomas's Hospital. A year before admission she was attacked with articular rheumatism which lasted for six months. She was jaundiced for six weeks after the attack. A month before admission she had rheumatic pains in the knees, back, and hands. On examination no swelling or tenderness of joints was found, but she complained of rheumatic pains in various parts. All the fingers of the right hand were extended, the fore and middle fingers were wasted and sensation a little impaired. She could only flex them very slightly, but could bend ring and little fingers more readily. She could not separate the fingers of the right hand so well as those of the left. All the fingers of the right hand were wasted, smooth, and shiny, and the nails were long and filbert-shaped. There was atrophy of the muscles of the forearm and of the thenar and hypothenar eminences. She rapidly recovered under the use of the continuous current. The second case was that of a young woman, aged 26, who had had swelling and tenderness of various joints, but chiefly of the right fingers, for a week before admission. She complained chiefly of two small round superficial sores, one on the extensor surface of the second joint of the right little finger, and the other on the extensor surface of the left middle finger, near the base of the nail. They appeared about the time the joints became affected, were very tender and itched a good deal. During the last six months the catamenia had become irregular, and this fact seems to support Dr. Hadden's idea that there is a relation between menstrual disorders and joint affections. The third case was that of a man, aged 57, who was the subject of chronic rheumatoid arthritis of some months' standing. His face was curiously expressionless, and the whole body was held stiffly, with a marked forward inclination. The skin of both hands was smooth and shiny. The ends of the finger joints were much thickened, and there was extensive dislocation of joints. Both of the hands were flexed at the meta carpo-phalangeal joints but the fingers were hyper-extended. There was slight affection of some of the larger joints. There was very extensive anæsthesia of both upper extremities. The prick of a pin was not felt over the front and back of left leg and dorsum of left foot, but elsewhere in the lower limb there was no impairment of sensation. The interossei and extensors of both forearms were atrophied. They responded to the interrupted current, but less actively than normally. The left extensor communis digitorum had the reaction of degeneration. The skin and tendon reflexes were exaggerated everywhere and there was double ankle clonus. The gait of the patient was spastic; an extension of the inflammation from the joints to the nerves might partially account for the various nerve disorders, but the author

believed that it was more likely that there was an independent rheumatic neuritis. The nerve disorders were neither concerned with the causation of the gout affection, nor dependent upon it. In the two first cases the trophic disorders, occurring during the subsidence of the gout affection, seemed to be a relapse affecting the nerves. The author referred to a case of anæsthesia in the course of the ulnar nerve, which he had observed in a patient convalescent from acute rheumatism. The muscular atrophy, affecting chiefly the extensors, seemed to be trophic. In shoulder-joint disease the wasting of the deltoid, and in hip-disease the wasting of the glutei supported the law that the extensors suffered more than the flexors. It was urged by some that this depends on some selective action of the spinal cord, but the cases of lead palsy and alcoholic paralysis, in which the disease is due to the peripheral nerves, renders it possible that in joint affections a similar cause holds good. The occasional occurrence of rigidity and ankle clonus, perhaps, depends on affection of the spinal cord, although the author believes that such conditions are sometimes due to lesion of the peripheral nerves. The duration and intensity of the joint affection has nothing to do with the cause of these trophic disorders. The cases given neither support nor disprove the theory of articular rheumatism.

The PRESIDENT called attention to Dr. Hadden's statement that loss of sensation does not occur in rheumatism. From his own experience in the out-patient department of the London Hospital he had continually observed such lesions as loss of power and sensation. In private practice he had also noted it. He was not familiar with the glossy skin condition in rheumatism but had observed it frequently in gouty cases.

Dr. BARLOW referred to a case of rheumatism with hyper-pyrexia in which loss of sensation was observed in the course of the ulnar nerve with wasting of muscular tissue. In another case there had been a very high degree of wasting of the interossei muscles. Both these cases recovered. A boy with mitral disease of rheumatic origin, presented paralytic symptoms which could only be explained by assuming some lesion of the brachial plexus. He believed that all these cases were due to rheumatic inflammation of the sheath of the nerves.

Dr. STEPHEN MACKENZIE, without impugning Dr. Hadden's diagnosis, thought that some of these cases were in reality due to disease of the spinal cord. He related a case sent in to hospital as an instance of acute rheumatism, in which incontinence of urine and bedsores followed with muscular wasting. The reaction of degeneration was found in the wasted muscles but the case eventually recovered.

Dr. WILBERFORCE SMITH mentioned a similar case to that related by Dr. Mackenzie.

Dr. ORD referred to a paper read by himself at a former meeting of this Society on the influence of nervous disorder upon the diseases of joints. Since reading that paper he had been inclined to take a wider view of the subject. He thought however that in a certain series of cases there could be no doubt of the central origin of the disease. Charcot had published cases in which the wasting of muscular tissue was far in excess of the extent of the joint lesion. He thought that Dr. Hadden's case would add materially to the difficulties in making a diagnosis in these joint affections, but he considered that we are still too apt to classify such cases as rheumatoid arthritis.

Dr. HADDEN, in reply, observed that no cases of rheumatic anæsthesia had been published, although, being so familiar to the President and Dr. Barlow, it was evident that they occurred frequently.

Preputial Calculi.

A paper on preputial calculi occurring among Fiji Islanders was read by Mr. JOHN CROFT, but the author has not provided an abstract of the cases for publication. No discussion followed the reading of the paper.

Urticaria Pigmentosa.

Dr. RADCLIFFE CROCKER showed the drawing of a case of this disease occuring in a girl, aged 4½ months. She came as an out-patient to University College Hospital, on Sept. 22nd, 1883, with a history of its having commenced when she was 3 weeks old, coming out first as tubercles singly or in groups. Each tubercle was the size of a small pea, of a yellowish brown colour, with a pink areola; on some of them a small bulla was formed, the contents of which got absorbed in a few days, leaving a permanent tubercle of yellowish red, some of them got larger, and the older ones paler, forming lesions varying in size from a hempseed to a bean, and in colour from a brownish red to a pale fawn, but mostly yellowish; they were not pruritic at first, but latterly itched at the period of evolution. They covered every part of the body, including the palms and the soles, but were thickest upon the trunk and neck; a few shrunk a little, but most remained unaltered, except that fresh vesicles formed on some of them; there were never any ordinary wheals, nor was fictitious urticaria present. The child died of whooping-cough and bronchitis in May last, but signs of improvement in the skin had commenced about a month before death. In reviewing this and the other nineteen published cases, Dr. Crocker summarised the facts known about the condition, and remarked that while cases like Dr. Tilbury Fox's worst and his own were very unlike urticaria, the intermediate cases brought it into closer relationship with that disease; moreover, nearly everyone of the special features of urticaria pigmentosa were seen in exceptional cases of ordinary urticaria. The remarkable point was that in this disease all these rare symptoms combined in one individual to form a definite clinical variety.

Perforation of the Vermiform Appendix, with Peritonæal Abscesses: Death after a Long Interval from Pyæmia.

Dr. D. W. FINLAY read a case with the above title. John L., a baker, was admitted into the Middlesex Hospital on January 4th, 1884. He complained of severe pain over the whole abdomen, which was moderately distended, tender and tympanitic. The areas of liver and splenic dulness were normal. Heart and breath sounds were normal. Tongue dry and coated, with a brown strip down the centre, cheeks flushed, lips dry and cracked. Pulse was 96, compressible, temperature 99·6°, respiration 24, and entirely thoracic. The urine was turbid with lithates, and very acid, specific gravity 1,034, free from albumen and sugar. As to history, he stated that he had had a similar attack three years previously, suffering from abdominal pain, with sickness and feverishness. Otherwise his health had been good. His present illness came on a week before admission with griping pains across the lower part of the belly, followed by vomiting, headache, and diarrhœa. He was treated with opium, and put upon a diet of milk and beef-tea, and three days after admission appeared much better; the general tenderness of abdomen had disappeared, but there was a spot midway between the costal margin and iliac crest on left side, where tenderness remained, and the percussion note was dull. On January 9th his bowels were opened for the first time after admission, the motions being loose and light in colour, with a few small scybala. During the night he had been seized by pain in both parotid regions, and this was followed by swelling and tenderness, with inability to open the mouth. Both swellings suppurated, and were incised; his temperature slowly rose, and he became delirious, and sank somewhat suddenly on January 16th. He had had no rigors. At the *post-mortem* examination three large and as many small abscess sacs were

found within the peritonæum, the oldest-looking being round the vermiform appendix, which was perforated about half way from its attachment. The appendix was plugged by a small mass of fæcal matter on the cæcal side of the perforation. The peritonæal surface generally showed old fibrous bands and greasy-looking flakes uniting the coils of intestine together, with some recent injection, but almost no recent lymph. The other organs were fairly normal, except that the lungs were œdematous, and the left pleura contained a quantity of clear serous fluid. The case seemed interesting from the prolonged latency of the disease, the perforation of the appendix having probably taken place on the occasion of the previous attack, adhesions being then formed which prevented for the time a fatal result. It was certain at all events that the abscess sacs were of very considerable age, and it was a striking fact that the man should have been able to go about his daily work apparently in good health with such a condition of his abdominal cavity.

Dr. MAHOMED had been lately considering the subject of recurrence of peri-typhlitis and had been proposing to himself to perform an operation for removal of concretions from the cæcum by means of abdominal section. He had designed what he considered to be a suitable operation, by practice in the *post-mortem* room. He found that by means of an incision, as for ligature of the external iliac artery, the vermiform appendix could be easily reached, in some cases without opening the peritonæal cavity. In conjunction with Mr. C. J. Symonds he had successfully removed a calculus from the vermiform appendix of a patient suffering from recurrent attacks of peri-typhlitis. He thought that a certain amount of induration was a necessary feature in such a case, to act as a guide during the operation. He quoted Professor Austin Flint's observation of the loss of hepatic dulness in cases of cæcal perforation. Such a sign, if true, was a useful point in diagnosis. In reply to the President he said that the calculus which he had removed was mainly phosphatic.

Dr. C. THEODORE WILLIAMS mentioned a case in which a localised peritonitis from perforation of the appendix was diagnosed. The patient recovered, but after his subsequent death from pneumo-thorax, it was found that a small and perfectly closed sac had become formed around the seat of the ulceration. Looking at the frequency with which concretions might take place within the vermiform appendix and the numerous instances of recovery after peri-typhlitis which had been recorded, he thought we ought to pause before considering such a serious measure as operation and be quite sure that recovery in any other way was impossible.

The PRESIDENT expressed the gratification of the Society on seeing Dr. C. Theodore Williams again upon the scene after his long and serious illness and offered him congratulation on his recovery.

Mr. HOWARD MARSH urged the importance of early recognition in these cases. He fully agreed with Dr. Mahomed in the advisability of operating in such cases and he believed that in course of time the operation would become a recognised practice. He pointed out the possibility of the anatomical relation of the vermiform appendix, varying with respect to the peritonæum. The first step in diagnosis must be to determine this relation. He mentioned a case lately seen in which perforation of vermiform appendix was not found when it had been diagnosed.

Mr. BRYANT believed that the operation suggested by Dr. Mahomed was the best that could be devised in such cases. He thought however that an exact diagnosis of the position of the vermiform appendix was not possible. The inflammation generally begins in the connective tissue around the vermiform appendix, in other cases the ulceration is in the cæcum itself and spreads around it. Suppuration may occur and pus may burrow its way in all directions, in which case the result is almost always fatal sooner or later. He thought that the practice of early incision was right and mentioned three cases in which pus had been evacuated by this means. The diagnosis was not difficult on the whole, but he thought that a very valuable symptom, that of pain in the course of the anterior crural nerve, was not sufficiently recognised. In one suspected case he had found that by using forced extension, pain was produced in the inflamed cæcum, thus indicating the seat of lesion. He should have occasion elsewhere to refer to this subject, but suggested that this question of early operative interference in peri-typhlitis should be seriously considered.

Mr. CHRISTOPHER HEATH thought that the diagnosis of perforation of the vermiform appendix outside the peritonæum was generally rendered easy by the occurrence of emphysema along the course of the cæcum.

Mr. R. W. PARKER mentioned a case of a boy who had injured his abdomen when suffering from inability to pass water. Vomiting ensued for twenty-four hours before death. The vermiform appendix was found to have been perforated, several hard concretions lying within it. There was local peritonitis and general peritonæal inflammation of more recent date.

Dr. MAHOMED observed that he would put aside the question of operating during an attack of peri-typhlitis. He thought that an operation would only be admissible between the acute attacks.

Dr. LONGHURST mentioned a case where five attacks occurred in two years, ending in ulceration and abscess. He asked if any treatment could be suggested to prevent the liability to such recurrence.

Dr. FINLAY referred to the observation of Dr. A. Flint, mentioned by Dr. Mahomed, and said it was familiarly known at the Middlesex Hospital that intestinal perforation might lead to obliteration of hepatic dulness.

The following living specimens were exhibited:—

Congenital tumour of the arm in an infant, by Mr. BARKER.

Obliterative arteritis, by Mr. PEARCE GOULD.

Bullous iodide eruption, by Dr. RADCLIFFE CROCKER.

Results of pseudo-hypertrophie paralysis, by Dr. BARLOW.

Pigmentation of tongue, by Dr. J. K. Fowler.

GENERAL CORRESPONDENCE.

OVER-PRESSURE IN ELEMENTARY SCHOOLS.

[To the Editor of the Medical Times.]

SIR,—Holding views which are to a very large extent contrary to those put forth so eloquently by Dr. Crichton Browne, I find, on serious consideration that, in common with many other medical writers on this topic, these views are drawn from general impressions which have been gradually forming unconsciously during the examination of a large number of children, and not from a collection of instances in which the mother's suggestion of over-work has been noted as a determining cause of disease, for what it is worth. Without a special course of enquiry devoted to this particular question, it is obviously impossible to ascribe any bounds to the influence of educational pressure, or even to affirm or to deny its existence in the elementary schools. It is possible, however, to state that my experience leads me to think that mothers who do not appreciate the importance of any kind of education, frequently are disposed to attribute the blame wholly unnecessarily to the influence of school work. The complaint is by no means uncommon, but it is unusual, so far as I have seen, to find that it is well founded, or that the school work can even in the remotest way be charged with producing diseases for which other simpler exciting causes can be found. I am far from saying that over-work, and over-excitement attendant on examinations are inoperative for evil, but the cases which have come under my notice are very few and far between, coming rather as abnormalities to indicate the employment of a wrong system in special cases, instead of crowding into our out-patient rooms daily. Indeed, so few cases have I seen, that when some years ago writing a paper on "Educational Pressure," I found that all my instances were drawn from medical students instead of from my out-patient room; and even then, the mischief appeared to me to be far more due to spasmodic efforts

than to the total amount of work done, to the fallacious tendency of cramming into a short period before the examination the energy which should have been distributed over a lengthened term.

I do not imagine that Dr. Crichton Browne is not perfectly sincere in his methods and statements, but it appears to me that his method of enquiring for the commonest symptom, headache, was particularly prone to mislead. By leading questions, almost any child may be induced to say it has pain in any desired locality. Certainly the cases of headache I have met with at the Evelina have more commonly been due to malnutrition or constipation than to over-work. I have only seen one hospital case in which the headache and langnor was obviously produced by school; the wrong system employed in that instance could have had no other result. The child lived some way from her school, and had to hurry to and fro directly after her meals; she had all her work in one room, and remained seated on the same form through the whole morning, and had night-work to do at home—an accumulation of evils hardly to be met with at the present time. This has been my one *undoubted* case; in other instances I have suspected it, but they have been rare, and I cannot but feel, from all I have seen, that the benefits resulting from our elementary schools infinitely outweigh the importance of the few cases of temporary inconvenience produced—indeed, I am quite prepared to agree with the writer of a recent letter in the *Times*', in thinking that the true causes of the large majority of cases of so-called educational pressure are to be found rather in faulty hygienic conditions than in over-work and cram.

I am, Sir, yours, &c.,

NESTOR TIRARD.

Physician to the Evelina Hospital for Sick Children.

King's College.

GASTROSTOMY.

[To the Editor of the Medical Times.]

SIR,—Absence from town has prevented my seeing your issue of October 4th till to-day. I am gratified to find that in your notice of the second volume of my book on "Diseases of the Throat and Nose" my endeavours to do justice to other workers are fully acknowledged. You are, however, good enough to invite my attention to one apparent failure in this respect, when you say that in treating of gastrostomy and the improvements in the details of that operation introduced by Mr. Howse, I might have "more clearly noted that the essential point in its success, viz., the delay in making the opening into the stomach until after adhesions have formed, was entirely original in his hands." Although, so far as I am aware, Mr. Howse himself has not advanced any such claim, I have assuredly no wish to deprive him of any portion of the honour to which he is fairly entitled, nor do I seek to deny his *subjective* originality in the matter. For my own justification, however, I beg to refer my critic to the report of a gastrostomy performed by Sédillot so long ago as 1853 (see the *Gazette Médicale de Strasbourg* for that year, p. 69), in which the first part of the operation was done on the 20th of January, whilst the stomach was not opened till the 25th. The reason for the delay is given in the following words, which, curiously enough, are an almost literal anticipation of those used by the reviewer: "On remet l'incision de la paroi stomacale à l'époque où des adhérences se seront formeés entre cet organe et les parois de l'abdomen." I may add that Egeberg himself, who is admitted to have been the first to suggest the operation, insists on the advisability of allowing time for the formation of firm adhesions before opening the stomach. (See his paper on the subject, read before the Medical Society of Christiania, May 8th, 1837).

I am, Sir, yours &c.,

MORELL MACKENZIE.

Harley Street, W., Oct. 12th, 1884.

MEDICAL NEWS.

THE ROYAL COLLEGE OF SURGEONS.

THE first ordinary meeting of the Council was held on Thursday last, Mr. Cooper Forster, President, in the chair. The sanction of the Medical Council to the scheme of co-operation between the Colleges for purposes of examination was announced. The revised regulations as to the curriculum are to date from the 1st instant. Mr. Forster, Mr. Marshall, and Mr. Savory were appointed representatives of the College on the Committee of Management of the Conjoint Board, and to report on all the arrangements of the scheme. Mr. John Wood was re-elected on the Court of Examiners, and Mr. H. Moon was elected a Dental Examiner. A letter of condolence was ordered to be written to Lady Wilson. A report from the solicitors of the late Sir Erasmus Wilson was read, informing the Council that they were appointed residuary legatees under the will. A letter from Lady Wilson, on behalf of her late husband, was read, thanking the Council for the Gold Medal of the College which had been conferred upon him. It transpired that the news of the bestowal of the Medal reached Sir Erasmus about 48 hours before his death. A letter from Mr. Wheelhouse on the uncertain results of the College examinations was read; it was referred to the above-named Committee.

Mr. Ebenezer Bryceson's diploma of membership, dated April 26th, 1884, was recalled, and declared to be void; he accordingly ceased to be a member of the College, under Sec. 22, Vict. 7. A committee of the members of the Council was appointed to consider the urgent need of additional accommodation for examination purposes. It was understood that one of the objects in view was to avoid interfering with the use of the library.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology, at a meeting of the Board of Examiners on the 13th instant, and when eligible will be admitted to the Pass Examination, viz.:—

Messrs. J. L. Davison and E. Furrer, of the Toronto School; J. Z. Torres, University of Colombia; F. R. Ozzard, London Hospital; W. H. Stevens, Bristol; G. F. Johnston and J. E. Davies, University of Edinburgh; S. H. Harrington, Liverpool; G. W. Rowe, Cambridge; J. A. Nowell, Leeds; T. A. Robson, Newcastle; and W. A. Loxton, Birmingham.

Ten candidates having failed to acquit themselves to the satisfaction of the Board of Examiners, were referred to their Anatomical and Physiological studies for three months, and two for six months.

The following gentleman passed on the 14th inst., viz.: —

Messrs. W. W. Paterson and J. Hughes, Glasgow; H. T. Evans, London Hospital; R. Bullock and A. J. Bulger, Birmingham; E. H. Young, University College Hospital; A. S. Brewis, C. W. Steenberg, and T. Lund, Newcastle; E. T. Wynne, Cambridge; A. Leche, Bristol; J. T. Harvey and W. J. Morton, Edinburgh.

Ten candidates were referred for three months, and one for six months.

The following gentlemen passed on the 15th inst., viz.:—

F. Pain, C. S. Pethick, W. W. Ewbank, P. H. V. Hammersley, A. de Lisle, and F. R. Miller, of St. Bartholomew's Hospital; L. Raby of the London Hospital; P. B. Mackay and H. R. Mansell, of St. George's Hospital; E. Jennings and L. W. Pockett, of University College Hospital; J. W. Sprigge, of St. Mary's Hospital; W. F. M. Shells, R. Thompson, and W. H. Harvey, of Guy's Hospital.

Six candidates were referred for three months, and one for six months.

APOTHECARIES' HALL.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a Certificate to Practise, on Thursday, October 9th, 1884:—

Jno. William Lynch, 372, Commercial Road, E.

NAVAL MEDICAL DEPARTMENT.—The following appointments have been made at the Admiralty:—John K. Conway, Staff Surgeon, to the *Himalaya*; Thomas L. Horner, Staff Surgeon, to the *Dreadnought*; George D. Twigg, Surgeon, to the *Mallard*; Alexander J. J. Johnston, Surgeon, to the *Dreadnought*; William S. Lightfoot, Surgeon, to Haslar Hospital.

DEATH OF MR. WILLIAM EPPRETT.—Some of the many visitors to the Museum of the Royal College of Surgeons will be sorry to hear of the rather sudden death, on Friday last, of this kind and zealous assistant in the Museum, ever ready and most willing to find and point out to enquirers the particular preparations which they desired to inspect. Those of his past and present colleagues able to leave the examinations now going on at the College, attended his funeral at Kensal Green, on Thursday last.

APPOINTMENTS.

AITCHISON, HENRY HYSLOP, M.B., L.R.C.P., L.R.C.S., and L.M. Edin. — Medical Officer to the Wallsend District, Tynemouth Union, *vice* Dr. James Aitchison, resigned.

BERINGER, JOHN JACOB, F.C.S. — Analyst for the Borough of Falmouth.

DONALD, ARCHIBALD, M.A., M.B., C.M., M.R.C.S.—House Surgeon and Resident Obstetric Assistant Surgeon to St. Mary's Hospital, Manchester.

ELIOT, E. F., L.R.C.P. and L.M. Edin., L.S.A. Lond.—House Physician to the Queen's Hospital, Birmingham.

HARTRIDGE, GUSTAVUS, F.R.C.S.—Consulting Ophthalmic Surgeon to St. Bartholomew's Hospital, Chatham, *vice* Henry Power, F.R.C.S., resigned.

KITE, E. W. D., M.R.C.S., L.S.A.—House Surgeon to the West Bromwich District Hospital, *vice* R. Aneas Delaney, L.R.C.P., re-resigned.

MORRIS, DAVID WILLIAMS, M.R.C.S. Eng., and L.K. and Q.C.P. Ire. —Medical Officer to the Third District, Dursby Union, *vice* Mr. A. S. Connellan, resigned.

NEWMAN, D., M.D., C.M., Glas. and F.F.P.S.—Surgeon to the Dispensary for Diseases of the Throat, Glasgow, *vice* Dr. Eben Watson, resigned.

OPENSHAW, T. H., M.B., L.R.C.P.—Resident Accoucheur to the London Hospital.

RIDLEY, G. W., M.B., Dur. M.R.C.S.—Senior House Surgeon to the Ingham Infirmary, South Shields, *vice* S. Lowes, M.B., L.R.C.S., resigned.

SMAILES, THOMAS, L.R.C.P. and L.M. Edin., M.R.C.S. Eng. — Medical Officer to the Honley District, Huddersfield Union, *vice* Mr. Andrew Daly, resigned.

SPICER, ROBERT HENRY SCANES, M.D. St. Andrews, L.R.C.P. Edin., and M.R.C.S. Eng.—Medical Officer to the Second District, South Molton Union.

TENNANT, CHARLES, M.R.C.S. Eng.—Medical Officer to the Newbottle District, Houghton-le-Spring Union, *vice* Mr. George Chalmers, resigned.

WALLER, C. B., M.R.C.S., L.S.A. Lond.—House Surgeon to the Westminster Hospital, *vice* A. Scanlan, resigned.

VACANCIES.

ABERYSTWITH INFIRMARY.—House Surgeon. (*For particulars see Advertisement.*)

BRISTOL GENERAL HOSPITAL.—House Surgeon. Salary, £120 per annum, with board, washing and residence in the house. Candidates must be Members of the College of Surgeons of London, Edinburgh, Glasgow or Dublin, and also Licentiates of the Apothecaries' Company of London or Dublin, or some other recognised medical qualification and must produce testimonials of good moral character and ability and must send certificate of registration. Applications to be sent to the Secretary, on or before October 27th.

CHICHESTER INFIRMARY.—House-Surgeon and Assistant Secretary. Salary £100, with board, washing, and lodging. Applications, with testimonials, to be sent to the Chairman of the Committee, on or before October 25th.

CLUTTON UNION.—Medical Officer for the Cameley District and the Workhouse, in succession to Mr. W. B. B. Perrin, resigned. Area, 3,438 acres. Population, 798. Salary, £14 per annum; for Workhouse, £60 per annum.

EAST WARD UNION.—Medical Officer. (*For particulars see Advertisement.*)

GREAT NORTHERN CENTRAL HOSPITAL, CALEDONIAN ROAD, LONDON, N.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

HALIFAX UNION.—Medical Officer to the Skircoat District, in succession to Mr. G. E. Scholefield, resigned. Area, 3,753 acres. Population, 12,763. Salary, £35 per annum.

HULL BOROUGH ASYLUM.—Assistant Medical Officer. (*For particulars see Advertisement.*)

SHEPPEY UNION.—Medical Officer for Eastchurch District, in succession to Dr. Bland, resigned. Area, 21,245 acres. Population, 3,905. Salary, £75 per annum.

STANLEY HOSPITAL, LIVERPOOL.—Junior House-Surgeon. Salary, £70, with board and rooms. Applications, with testimonials (copies only, which cannot be returned), to be sent to J. E. Bennett, Treasurer, on or before October 23rd.

SWANSEA HOSPITAL.—Resident Medical Officer. Salary, £100 per annum, with board, furnished apartments, &c. Candidates must be registered in Medicine and Surgery. Applications and testimonials to be sent to the Secretary, on or before October 28th.

THE BOARD OF WORKS FOR THE WANDSWORTH DISTRICT.—Medical Officer of Health. (*For particulars see Advertisement.*)

WIMBORNE AND CRANBORNE UNION. — Medical Officer to the Second District, in succession to Mr. W. Wyke-Smith, resigned. Area, 16,441 acres. Population, 5,413. Salary, £95 per annum.

WYCOMBE UNION.—Medical Officer to the Eighth District, in succession to Mr. Alfred Warren, resigned. Area, 3,464 acres. Population, 2,585. Salary, £29 per annum.

DEATHS.

BURNETT, FERDINAND, M.D., at Dover, on October 9th, in his 81st year.

GUISE, Surgeon-General, at the Knoll, Clifton, on October 4th, aged 68.

NOTES, QUERIES, AND REPLIES.

Primary Examinations.—The first Anatomical and Physiological examination for the membership of the Royal College of Surgeons, for the present session, was commenced on Friday last the 10th instant, when 136 candidates presented themselves as against 94, at the corresponding period last year.

The following were the questions on *Anatomy*, four of which, and no more, the candidates were required to answer between one and three o'clock, viz.—1. Describe Hunter's Canal; its boundaries and contents. Mention the parts in relation to it. 2. Give the dissection required to expose the Suboccipital triangle. 3. Give the attachments and relations of the Pronator radii teres. 4. Enumerate the Sutures of the Cranium. Give their course, the bones which respectively enter into their formation, and the class of suture to which they severally belong. 5. Describe the origin, course, and termination of the Saphenous veins, and enumerate their chief tributaries. 6. Give the attachments and relations of the Pharynx.

The following were the questions on *Physiology* to be answered between 4 and 6 o'clock, viz.—1. Describe the Structure and Uses of the different forms of Cartilage met with in the human body. 2. What is the Pulse? Why is it in general confined to the Arteries? Under what circumstances does it appear in the Capillaries and Veins? 3. Describe the Nervous Mechanism of Respiration. By what conditions and in what manner may the Rhythm of Respiration be modified? 4. Describe the Distribution of Blood in the Liver. By what forces is the Movement of the Blood through this organ maintained? 5. What gases are contained in the Blood? State the average amount of these gases in Arterial and Venous Blood? How may these quantities be determined? 6. Describe the Structure of the Cornea. Name the Refractive Media of the Eye in the order of their relative importance.

A Metropolitan Teacher.—The primary examinations at the College of Surgeons took place last year in November, when only 94 candidates presented themselves, of which number 31 were rejected. At the examinations this October the number has increased to 136. The oral examinations are now going on; the names of the successful candidates are published on another page of the *Medical Times*.

J. W. Hopkins.—E. H. Schroeder, 137, Möckernstrasse, Berlin, S.W.

M.R.C.S.—Essays for the Jacksonian and Collegiate Triennial Prizes of the Royal College of Surgeons must be sent in on or before Thursday, the 31st of December next. Write to the Secretary.

COMMUNICATIONS RECEIVED—

Dr. CRICHTON BROWNE, London; Dr. GOODHART, London; Dr. S. WEST, London; Dr. HERMAN, London; Dr. NORRIS WOLFENDEN, London; Dr. HARDWICKE, Sheffield; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; Dr. W. J. REID, Glasgow; THE SECRETARY OF THE SOCIETY FOR RELIEF OF WIDOWS, ETC., OF MEDICAL MEN, London; OUR LIVERPOOL CORRESPONDENT; THE HON. SECRETARY OF THE QUEKETT MICROSCOPICAL CLUB, London; Dr. W. H. BARLOW, Manchester; THE HON. SECRETARY OF THE MEDICAL SOCIETY OF LONDON; THE SECRETARY OF ST. THOMAS'S HOSPITAL MEDICAL SCHOOL, London; Dr. MITCHELL BRUCE, London; Dr. FREDK. TAYLOR, London; Dr. HENRY ASHBY, Manchester; OUR GLASGOW CORRESPONDENT; Dr. SHELLY, Hertford; THE REGISTRAR-GENERAL FOR ENGLAND, London; Mr. JEAFFRESON, Newcastle-on-Tyne; Dr. MORELL MACKENZIE, London; Dr. TIRARD, London; OUR DUBLIN CORRESPONDENT; Mr. CHATTO, London; Dr. H. CAMPART, Paris; Mr. MUNRO SCOTT, London; Mr. J. W. HOPKINS, Isle of Wight; Mr. T. M. STONE, London; THE SECRETARY OF THE CLINICAL SOCIETY OF LONDON; Dr. DONALD FRASER, Paisley; Mr. HENRY MORRIS, London.

BOOKS RECEIVED—

Eyesight in Civilisation, by Robert Brudenell Carter, F.R.C.S.—Transactions of the Academy of Medicine in Ireland, Vol. ii.—Corpulence and its Treatment, by Dr. Wilhelm Ebstein—School-Hygiene in England, von Dr. Med. Hermann Weber—Transactions of the American Otological Society—A Consideration of the Causes of Insanity, by Walter Channing, M.D.—Cases of Interest, by Prof. W. H. Carmalt, M.D.—On the Teaching of Natural Science, &c., by Henry E. Armstrong, Ph.D., F.R.S.—Ein Neues Fleischpepton, von Dr. W. Kochs—Chlorsaure Kali, von Dr. J. V. Mering—The Condition of Gaols, &c., by James Blake Bailey—On Diseases of the Rectum and Anus, by Harrison Cripps, F.R.C.S.—The Sun's Changes in the Ecliptic, by Miss Mary Macleod—Calendar of the Royal College of Surgeons of England.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Révue Médicale—Gazette Hebdomadaire—Nature—Boston Medical and Surgical Journal—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medicin—Philadelphia Medical News—New York Medical Journal—New York Medical Record—The Edinburgh Clinical and Pathological Journal—Centralblatt für die Medicinischen Wissenschaften—Berliner Klinische Wochenschrift—Louisville Medical News—Weekblad—Maryland Medical Journal—The Philadelphia Medical Times—Le Progrès Médical—The Ophthalmic Review—The Birmingham Daily Gazette—North Carolina Medical Journal—The Archives of Pediatrics—The Buckinghamshire Advertiser, October 11, 1884—Mental Journal—Indian Medical Gazette—Newcastle Daily Chronicle—The Chemist and Druggist—Revue des Sciences Médicales—Nordiskt Medicinskt Arkiv.

APPOINTMENTS FOR THE WEEK.

Friday, October 17 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday, October 18.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

ROYAL COLLEGE OF PHYSICIANS, PALL MALL, EAST, 4 p.m.—Harveian Oration by Dr. Russell Reynolds.

Monday, October 20.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

MEDICAL SOCIETY OF LONDON, 11, CHANDOS STREET, CAVENDISH SQUARE, 8.30 p.m.—Address by the President. Paper by Sir Joseph Lister, Bart. At 8 p.m. a New Invalid Bed Lift will be shown by Mr. Newham.

Tuesday, October 21.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

PATHOLOGICAL SOCIETY OF LONDON.—Dr. Charlewood Turner and Dr. Carrington, on "Dysenteric Abscesses in Liver;" Dr. Wickham Legg and Dr. Theodore Acland, on "A Case of Hæmophilia, and one of Purpura;" Mr. Pepper and Dr. Silcock, on "Tabes Dorsalis with Perforating Ulcer of the Foot;" Dr. Hadden, on "Two Fatal Cases of Alcoholic Paralysis;" Dr. Hale White, on "Coarctation of the Aorta, Chronic Ulcer of the Stomach with Secondary Changes in the Pancreas" (card); Dr. Ormerod, on "A Case of Sclerodema" (living); Dr. J. F. Payne and Dr. F. Semon, on "Rhino-Scleroma" (living).

Wednesday, October 22.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

HUNTERIAN SOCIETY, 8 p.m.—Dr. Thorowgood, on "Some Forms of Irritable Heart."

Thursday, October 23.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Friday, October 24.

CLINICAL SOCIETY OF LONDON.—The following Papers will be read:—Mr. Golding-Bird, "A Case of Dislocation of the Patella;" Dr. James Anderson, "A Case of Myxœdema;" Dr. Carrington, "A Case of Eruption, probably due to Bromism;" Mr. Godlee, "A Case of Nephrectomy for Tumour in an Infant."

QUEKETT MICROSCOPICAL CLUB, UNIVERSITY COLLEGE, GOWER STREET, 8 p.m.—Ordinary Meeting. Dr. W. B. Carpenter, C.B., F.R.S. (President), on "The Relations of the Various Types of the Genus Orbitolites."

THE HARVEIAN ORATION.

Delivered before the Royal College of Physicians of London, October 18th, 1884.

By J. RUSSELL REYNOLDS, M.D., F.R.S.,

Consulting Physician to the University College Hospital.

Sir Thomas Brown has said, in one of his sadder moods, "Our fathers find their graves in our short memories, and sadly tell us how we may be buried in our survivors. . . . . The greater part must be content to be as though they had not been—to be found in the register of God, not in the memory of man." This is, without doubt, true, as he said, of the "greater part," but it is not true of all; for our meeting here to-day is an assertion that there is at least one who has not yet found his grave in our vanishing power of recollection; but whose life, unburied, still lives in the lives of living, acting men. It is not of the sorrows and "unavailing tears" that were shed, nearly two hundred and thirty years ago, over Harvey's grave, that it behoves me now to speak; but rather of the fact that nearly three centuries have passed since he became a part of this College; and that only last year, on the eighteenth day of October, our College repaired to his grave in Hempstead, to do honour to his memory; and with gratitude and gladness to assert that he still lives "in his survivors;" and that, although three hundred and six years have passed since Harvey's life began, we now, and here, meet again to say that he is neither dead nor sleeping.

1. Let me ask you, for a few moments, to think over that act of last year. It is not meet to call it a "ceremony" or "performance," for those words may have a doubtful meaning. It was a something done; and that with purpose. It was done with reverence and solemnity, and fitting formal circumstance. The like of it has not often been seen in this country. It was simple, but it told of much complex thought and feeling. It was grave, but it was not sad; it was official, but it was not heartless. It was unnecessary, but it was urgent; it was a duty to the remains of Harvey, but it was also an honour to ourselves. Its voice could not "provoke the silent dust," but its tone could stir the now living "ear" and heart, and quicken the still acting brain.

A. One thing that this College did last year was to show regard for the *bodily* remains of Harvey. There was something of him—that neither painting nor bust could be—which it still wished to cherish. It would try to hold together, yet longer, the last remnants of what was once the medium through which he saw Nature, and by which he read many of her secrets, and revealed them. This wish is natural, and old because it is so. If some Eastern nations, in their great

reverence for the soul, have taken means to display their contempt for their body, such peoples have been the exception. The Pyramids, the abbeys, the great burial grounds in town and country, and the world's great surface, scattered over with its complex or simple tombs, all tell the same story of regard for the dust and ashes of those who have gone. Even if the body has been burned, there has been found the urn to hold together the ashes that the flames have not had power to kill. We may know and admit "to what base uses we may return;" but still we resent or recoil from the degradation. There is a widely spread human struggle against allowing the bodies of those we have known, and reverenced, and loved, to merge into the common earth. We set up our barriers against it; we entomb, and we embalm; we carry on a fight as strong in feeling as it may be futile in effect; but still, a real fight against physical disintegration. This may be all very foolish and unscientific; but still we will, if we can, keep together something of the individual, so long as time and outside forces are not too strong for us; and we utter a parable, as we do so, of our regard not only for the bodies, but for the lives of those individual men, as we tell of, or come to know, them, in the thousand biographies that surround us, each one of which is, in its very essence, "a feeble struggle with death." The notion that some spark or germ of life might lie hidden in the ashes that were buried or inurned ("lateat scintilla forsan") may have had much to do with the careful keeping of the ashes in the past; but that is not all. Even if Science could quite put out this faint "scintilla," the human instinct would remain, and would show itself beside almost every open grave, and sometimes display itself in such solemn and remarkable event as that which took place last year at the tomb of Harvey. It was a graceful and an honourable act of this College to take upon itself the work of "Old Mortality," and to travel away from its ordinary home that it might chisel afresh the marbles that held the remains of its greatest son; but much more than this was accomplished at that time; for therein was shown a profound and still living affection, reverence, and gratitude for Harvey's life.

B. We, again, to-day, would do homage to the *life* of Harvey; looking at it in its threefold aspect of moral mental, and active energy. We commemorate his character; his rare combination of faculties; and his work achieved. In him there was that due proportion between all those powers which a great thinker of this generation has regarded as the root-fact of what we call "genius."

We like to picture to ourselves what he, now dead in body, resembled when he lived; how he thought; and about what he thought; how and what he did; in what light he regarded his own work; its relation to the work of others; to his ancestors in science, to his immediate predecessors, his associates, his antagonists; and to those who must come after him. This is as natural as is the regard for the bodily remains; but it is on a higher level. Ancient "songs" handed down, in earlier days, the noble deeds, thoughts, words, and characters of those whom it was a religion to venerate and whose memory it was a bounden duty to prolong. Our short biographies in epitaphs, our longer biographies in books, bear witness to our dislike to the cremation of ideas and of individual life. There is, doubtless, much disintegration and cremation of a very healthy sort now going on among the works of the living as well as of the dead; and very small urns might hold all that is worth keeping of the life-work of many. Still, even on these, we should like to engrave the names. Perhaps in most lives there are many things that those who lived them might gladly see burned way; but (as Sir Thomas Brown says) "we cannot hire oblivion," and even if "a wise oblivion be a greater good than a strong memory," we still like to preserve the individuality of the really great ones of the earth, with all their faults; and we resent—as we do with quite small people—either a flattering, or disparaging, or a one-sided picture.

Reading Harvey's own writings, his theses, their introductions, their dedications, his disquisitions, exercises, letters and "obiter dicta," we find him writing, all unconsciously, his autobiography; and this confers an unspeakable charm upon his works. He does not tell us of his birthplace, or parentage, or where he was taught, or how he lived—which, thanks to many who have written of these things, from Aubrey and Ent to Willis, we know fairly well—but he reveals his very soul and life, his method of work, and his mode of thinking about it all, as he spent those long years of research, experiment, discovery and disputation, together with all the toils of a teacher, and the cares of a busy practitioner of medicine. Thoughts, discoveries, and lives are quickly disintegrated in this fast-moving, restless age, the rate of whose movement shows acceleration every year; and so there is much individual work that must soon pass into, and be lost in, the sum of common knowledge, and become only the groundwork upon which many a superstructure may be raised; but the personality of Harvey can never be lost sight of, so long as this College stands, and so long as there are men who care to "read between the lines" of his great works, and find in them the portrait of himself. It is important, in our attempt to realise this portrait, that we should look—in order to judge of its value—both before, around, and after the time in which the great artist sketched it.

Harvey's work of discovery, like that of all great discoveries—into whatever reach of knowledge and of thought they may have broken—was not unprepared. Men were eagerly looking for a light that they felt sure was coming; and there were streaks of dawn in the Eastern sky that led them to find the Man, and the Truth, for which they had been seeking, so that what before had been mysterious was now clear; what had been dark was now illumined; what they had sought for now they found. The contents of the "shell," on the like of which Harvey afterwards wrote so much, were teeming with a growing life that showed but vague signs upon its smooth, unbroken surface; but Harvey cracked the shell, and there burst forth at once into a seen life, a form and meaning for which all the growing processes within that shell were made. There was a new thing, a new thought, a new generalisation. There was the solution of the problem of yesterday, the answered riddle, the platform for to-morrow's work. All honour to those who, toiling slowly in the night, or in the dawn, with its mist and mystery, have yet made some headway forward and upward, and prepared the path for one among them who has shared their labour, their weariness, their disappointments, and their woes; but who suddenly makes, as it were, a leap to a wider range or to a higher level, and thence holds out the hand of strength and fellowship to place them by his side. We honour the worker, wherever he may be, so long as his labour is honest, and is his best; but we have only scant words to express the regard in which we hold the man whose discerning thought and practised skill has lifted all workmen higher; opened to them new ranges for their toil; given them new methods to follow, and left behind him footprints in which some of them may tread, as he goes before them, and passes out of sight.

Great men have always foreseen much; or, at all events, have said or seen things of which they perhaps did not and could not fully appreciate the meaning. They have scattered germs of thought around them as they passed through the varying fields of life, to the

point or end that their determination impelled them to attain ; and some of these seeds of future discovery have "fallen on good ground, and brought forth fruit." There is here some instance of the process of "Evolution" in regard to scientific discovery. Harvey reaped much that he had not sown ; but he sowed much more which others, after him, might reap.

There is one thing more, however, that this College has done for many years, and that is, by this annual oration, to *hand down* to coming generations the memory of him from whom we have learned so much, and to whom our debt of gratitude is larger than we, perhaps, as yet can know ; certainly much larger than falls within the range of my powers to express.

We speak of the "immortal Harvey," but in what sense? To many, his own words would convey all the meaning of that attribute. "The eternity of things," he says "is connected with the reciprocal interchange of generation and decay ; and as the sun, now in the east, and then in the west, completes the measure of time by his ceaseless revolutions, so are the fleeting things of mortal existence made eternal through incessant change ; and kinds and species are perpetuated, though individuals die."[1] True—grandly but sadly true—and yet our meeting of this day is a declaration that such truth is not universal. Much of his work has become a part of common knowledge ; and so will live on in the lives of those who are the "interpreters of Nature" so long as Nature lasts. But the wish that animates us to-day is to hand down to those who follow us some knowledge of the individual to whose life we owe so much, and whose personality we would not "willingly let die." There are many ways in which this may be done, but I would allude to only two.

1st.—The *names* of some great men have been associated with the discoveries that they have made ; and they perhaps are used, many of them, in such familiar way that they convey little or no suggestion of their meaning. In some generation or two yet to come may it not be that the etymology of such words as Fallopian tube, Meckel's ganglion, Bright's disease, Addison's disease, Corrigan's pulse, Galvanism, Faradism, an Ohm or a Volt have become somewhat obscure? Or if the meaning of such phrases may be found in lexicons, are there many who will try to find out those meanings? It seems to me probable that individuality will not be maintained by such means ; and that future students may sometimes be disposed to ask—as I once heard the question put quite seriously—whether or no the "portal vein" was not named after the distinguished French physician Portal. While the progress of science is constructive of generalisation and so-called "laws," it is destructive, as Harvey says, of the individual life ; but yet we give "names" to organs, functions, forces and shrewd connotations of phenomena, in order—while finding them convenient at the time—to delay if not arrest the disintegration of the work of those men whose names we thus hand down to those who follow us. Do we not think it probable that, as future research proceeds, some of these names—which have passed into many countries and many tongues—may be lost sight of, and be so decomposed that they pass out of common use? At this hour, and still in the lifetime of our honoured President—whom may God long preserve—the phrase "continued fever" has passed into practical disuse ; and this has been due, mainly if not exclusively, to the industry and genius which led him to disintegrate the name, and define the maladies that had long passed under that common term.

2nd.—Again there are certain *days* by which the memory of great men is perpetuated. From very olden times until now, and from the far east to the far west, "days" are set apart for the purpose of recalling individual lives. Ceremonies, of all kinds, have been parts of these human, national, and instinctive acts. They begin in the smallest families with the "birthdays" and they stretch out to the acts of the greatest nations. This is "St. Luke's Day," in the calendar of millions. There are days still set apart compared in antiquity with which the observance of St. Luke's Day is but a modern event. Two hundred and eighty years have passed since Harvey was a member of this College : for two hundred and fifty-six years his great work (de motu cordis et sanguinis) has been before the world : two hundred and twenty-seven years have elapsed since he was buried in the quiet little church of Hempstead. And yet only one year has passed since this College removed his remains "lapt in lead" from the vault in which they had long lain, and placed them in the safer keeping of new and carefully selected marble. With us, although it is not so named, this is "Harvey's Day," and three hundred years have passed since he was born. How long this commemoration will continue we cannot tell. Our knowledge of the future is but scant. Who knows whether, when another sixty-nine years have passed, "Waterloo Day" will be kept in memory of Wellington?

No one can answer us in our questions. But this we may do—we may look to the past, and learn its lessons ; we may look to humanity and read its instincts ; we may read the record of this College, and know its feeling ; and of this we may be sure, that—although Harvey's name may be unknown to many in the days to come—yet so long as disease lasts ; so long as the movements of the blood form part of the study of the physiologist and the art of the physician ; so long as any further light is to be thrown upon them, by cardiograph or sphygmograph, or by any as yet unthought-of method of investigation ; so long as "the circulation" is a recognised fact of science, his work will live ; and although much of it may lie hidden in the common notions of the future, yet the life of Harvey will be maintained in its integrity by the future Fellows of this College ; and the greatness of his character will be brought, again and again, to light by many who will, more adequately than I can do, discharge the duties of this day.

It has been my wish, in what has hitherto been said, to lay before you some explanation of the motives that bring us together now ; and also of those that led this College last year to the grave of Harvey. But further,—

II. If we would appreciate the work of Harvey well, let us for a moment try to eliminate from our knowledge the fact of "the circulation of the blood," and then imagine ourselves to be face to face with the diseases that we are daily treating ; with fever, apoplexy—hæmorrhagic, embolic, or diathetic ; with dropsy ; with cardiac disease, recent or old ; with degeneration of structure, or with functional derangement. It requires some force of fancy to realise what would be our position. The thermometer might teach us much ; but it is difficult to see in what way either stethoscope, cardiograph, or sphygmograph could do other than augment our bewilderment. Those who have made out for us the meaning of the cardiac sounds ; those who have skilfully constructed apparatus so as to make the heart itself record, in some fashion, its own marvellous movements ; and those who have delineated in some sense, the curve and time-ordered elements of the radial pulse, would all admit that their work was based upon this foregone conclusion, the accepted fact that the blood moved onwards in a circle. They have attained to knowledge that Harvey could not reach ; but let me ask, could they have known what they now do, unless Harvey had raised the platform upon which they stood? The "thoughts of men are

[1] On Generation, p. 226.

widened by the process of the suns;" and by slow degrees others might have done the work, or made the discovery that he made; but the effect of his energy was a grand upheaval of the crusted surface of the past; a Titanic throe that brought to the birth a new and mighty force and fact; and when some of the dust and boulders had been cleared away, placed all who followed him on a higher plane, and in a clearer light.

It is given to the few great men to save the time and labour of the many. They not only make strides that would be impossible for those of lesser build, but they carry with them, over the bridge that they have thrown across the great gulf between the question of yesterday and the answer of to day, all those who have eyes to see, ears to hear, and hearts to follow.

III. Next, let me bring before your notice some of the main features of Harvey's "character," as this displays itself in his written "work." Chronologically, his character must precede his work; but the former was developed by the latter. These things act and react; moral forces become greater as our toil grows harder; and, in so doing, give not only fresh impulse, but increased strength for work.

A. Throughout Harvey's writings there is an eminently religious tone; a devout and reverential recognition of God; not only as the great primal, ever-acting force, behind, outside, and before all the works of Nature; but as the being, "the Almighty and Eternal God," to whom, as he says in his last will and testament, "I doe most humbly render my soule (as to) Him that gave it; and to my blessed Lord and Saviour Jesus Christ."[2]

But Harvey did not let his religious convictions hold him in the tight grasp of what has been termed the "theologic stage" of development; nothing prevented him from seeing all that he could see, and frankly telling all that he believed; and so we find him spurning some of the figments about "the spirits . . . . . of a sublime, lucid, ethereal, celestial, or divine nature," when they are employed to fill up gaps in the physiology of his day; and comparing those who use them "to the vulgar and unlettered who, when they do not comprehend the causes of various effects, refer them to the immediate interposition of the Deity."[3]

Harvey, although saying that the Divine mind of the Eternal Creator which is impressed on all things creates the image of itself in human conceptions;"[4] and again, that all the arts are but imitations of Nature . . . . as our reason or understanding is a derivative from the Divine intelligence manifested in his works;" and still further to affirm as follows—"wherefore, according to my opinion, he takes the right and pious view of the matter who derives all generation from the same eternal and omnipotent Deity, on whose nod the universe itself depends;" yet shows his freedom from theologic dogma, and his wide range of thought in adding, "Nor do we think that we are greatly to dispute about the name by which this first agent is to be called or worshipped; whether it be God, Nature, or the soul of the universe—whatever the name employed—all still intend by it, that which is the beginning and the end of all things; which exists from eternity and is almighty; which is author or Creator, and, by means of changing generations, the preserver and perpetuator of the fleeting things of mortal life; which is omnipresent, not less in the single and several operations of natural things than in the infinite universe."[5]

We are reminded by this passage of the well-known dialogue, in which Faust, replying to Margaret's examination of his creed, says—

> "Call it whate'er thou wilt—heart, love, or God,
> Or happiness!—I cannot give it name."

And the fair Margaret gives answer—

> "All that is very good and true;
> Nearly the same the Priest says too,
> Only in somewhat other words than you."

But Harvey recurs to the same theme, and after saying that "the most perfect man, whose highest excellence is that he knows himself;" adds, "we ourselves, as is seeming in these days (hold) as the Almighty first cause of all things . . . . the Creator and Father of all that is in heaven and earth, on whom animals depend for their being, and at whose will and pleasure all things are and were engendered."[6]

"It is true," said he, in conversation with Dr. Ent, "the examination of the bodies of animals has always been my delight; and I have thought that thence we might not only obtain an insight into the lighter (? higher) mysteries of Nature, but there perceive a kind of image or reflex of the omnipotent Creator himself."[7]

B. If Harvey, though a devout believer in God, was yet free from all the restraints of the so-called "theologic stage;" he also, although a learned and keen metaphysician, had escaped from the trammels of what has been termed the "metaphysic stage." He had "cast them off with as much ease as Samson his green withes." He meets the metaphysician on his own ground with clever dialectic; but he pours contempt on those "who advocate incorporeal spirits, having no ground of experience to stand upon;" adding that "their spirits indeed are synonymous with powers or faculties, such as a concoctive spirit, a chylopoietic, &c., they admit as many spirits as there are faculties or organs." And, before this, with regard to the nature of "the spirits," he says, "There are so many and such conflicting opinions, that it is not wonderful that the spirits whose nature is thus left so wholly ambiguous should serve as the common subterfuge of ignorance. Persons of limited information, when they are at a loss to assign a cause for anything, very commonly reply that it is done by the spirits; and so they bring the spirits into play upon all occasions; even as indifferent poets are always thrusting the gods upon the stage as a means of unravelling the plot, and bringing about the catastrophe."[8]

C. If it be asked what was, then, Harvey's position, and what was the method he employed?—my reply is that he, being one of "the freemen whom the truth makes free," held the position of an observer, a questioner, and an interpreter of Nature. In the letter, by which he dedicates to the President and Fellows of this College, his "Anatomical Disquisition on the Motion of the Heart and Blood in Animals," he declares himself "the partisan of truth alone,"[9] and throughout all his writings that follow he never swerved from the position he had taken. To him "virtue," as it has been well said by Emerson, "lay in the adherence in action to the nature of things; and the nature of things made it prevail."

The intense love that Harvey felt for Nature led him to choose her as his constant companion, and his guide in the search for truth. There was nothing that she could show him that was too great for him to attempt to understand; nothing too small for him to pass by, or to regard with other feelings than those of affection, of reverence and wonder. The teaching of Nature was to him absolute in its authority. "The facts cognisable

[9] On the Motion of the Heart.

by the senses," he says, "wait upon no opinions, ... the works of Nature bow to no antiquity; for indeed there is nothing either more ancient or of higher authority than Nature"[10] Harvey "observed" the facts before him—and he had eyes to see—but not content with the "experiments prepared by Nature," he "made" new facts, by his skilful manipulation of the materials that were lying at his hand; and thus he asked pertinent questions, and obtained their answers. He thought about all these things; he reasoned upon them all; he sought and found all the help that metaphysical method and learning of the schools could render him; and then he became their "interpreter."

His mode of progression may be defined as "longitudinarian" (if I may use a word, coined some years ago, in opposition to one very familiar to us all)—*i.e.*, he looked and worked straight from end to the end. His line was the shortest one that he could draw between the simplest—the first—fact observed and the most remote object of his gaze. He thought in "a straight line;" he never swerved in his forward march; but, as he passed onwards, he saw things outlying, on by-paths, but his own force of movement dragged them into his own well-chosen course, and he made them help him on his way. Arrived at his goal, he arranged his materials with care, and proceeded to explain their meaning by a simple inductive process. But, still keeping the same point in view, he approached it from other sides. Sometimes his lines, although converging, did not meet at the point he quite expected. Here, his power of thinking outside of, and beyond the facts came to help him; he made new observations, new experiments, and at last focussed them on a point made bright by the rays of his own genius. Dr. Ent spoke but the truth when he said to the President and Fellows of this College, "Our Harvey rather seems as though discovery were natural to him; a thing of ease, and, of course, a matter of ordinary business; though he may nevertheless have expended infinite labour and study on his works."[11]

D. Harvey made use of working hypotheses; but he never confounded them with either facts, inductions, or laws. He claimed in one of his ingenious theses the liberty which he willingly yielded to others, "to put forward as true (in matters full of obscurity) such things as appear to be probable until proved to be manifestly false;"[12] and after demolishing many theories of others, "prayed for a place" for his own "conjecture until something certain should be established in the matter."[13]

E. If some fact, apparently opposed to a truth that Harvey believed himself to have established, confronted him in his way, he rode over it, with a force that could only come from the momentum that his strong conviction had given to his movement onwards. For example, he says, "There is one experiment which I would have every one try who is anxious for truth, and by which it is clearly shown that the arterial pulse is owing to the impulse of the blood. Let a portion of dried intestine . . . . be taken and filled with water, and then secured at both ends like a sausage: by tapping with the finger at one extremity, you will immediately feel a pulse and vibration in any other part to which you apply the fingers, as you do when you feel the pulse at the wrist." After referring to the manner in which such percussion may be made of use in distinguishing between air and fluid in the abdomen, he continues,—"Having brought forward this experiment, I may observe that a most formidable objection to the circulation of the blood rises out of it, which, however, has neither been observed nor adduced by any one who has written against me;" and then he falls back upon his observations which show that, in spite of this seeming difficulty, the circulation has been proved. He says that he had "already satisfactorily replied to this difficulty;" and such is true, inasmuch as he had pointed out that all the blood did not pass through the vessels, but that some of it was detained for nutrition; he had spoken of the contractility of the arteries, and of the impulse wave; but his solution of the difficulty, that he himself alone had seen, was founded on his confidence in the truth of his main assertion.

This reminds me of a characteristic incident in the life of one much lamented by many here—I mean the late Professor Sharpey. He was taken once to a celebrated clairvoyant, who, blindfolded and mesmerised, lay on a sofa, and clasped to his epigastrium card-cases, with cards in the inside of each, wrapped in sheets of paper; and on the kernel cards of which was written anything that the experimenter chose to write; and immediately the man read the number, the name, or the quotation that was enclosed. "It is very clever," said Sharpey, "but a man cannot see with the pit of his stomach, for all that;" and so he devised a simple means of showing, at the next *séance*, that the card-case was opened, and the inner paper and card taken out. He could not see how the trick was done, but confident belief in his physiological creed enabled him to point out a transparent lie in the pretended new faculty of vision.

F. Boldness was a great feature of Harvey's character when he told any of the truths he knew. "It were," he said, "disgraceful . . . . with this most spacious and admirable realm of Nature before us . . . . did we take the reports of others upon trust. . . . . Nature is herself to be addressed; and the paths she shows us are to be boldly trodden. . . . ."[14] And again, at a later period, he writes: "The doctrines inculcated on the subject of the humours, and which, as being entertained by the ancients, Fabricius regards as certain truths, requiring no further proofs, are inconsistent and false."[15]

G. But Harvey, although bold and strong, was meek, cautious, and polite. He preferred "being wise with the few . . . . to going wrong with the many . . . ."[16] Dr. Ent, in conversation with Harvey, said to him: "You yourself, I well remember, informed me once that you had never dissected any animal—and many and many a one you examined—but that you discovered something unexpected, something of which you were formerly uninformed."[17] He was greatly afraid lest he might be charged with presumption, did he lay his work before the public at home, or send it beyond seas for impression . . . . unless, as he says, I had first proposed its subject to you (the President and Fellows of this College), and had confirmed its conclusions by ocular demonstrations in your presence, had replied to your doubts and objections, and secured the assent and support of our distinguished President."[18] Perhaps it might be well if a similar submission were sometimes adopted in this nineteenth century. But so much has been added to what is called our scientific literature during the third quarter of this century and its now current fourth, that, perhaps, no officer of the College will thank me for the suggestion.

H. Harvey fully realised the value to be attached to the "conclusions to which others had come who had looked" at facts themselves; but he adds, "he who truly desires to be informed . . . ."

must be held bound to *look for himself* . . . . for "it is our duty to approve or disapprove, to receive or reject, everything only after the most careful examination . . . . to examine, to test whether anything has been well or ill advanced, to ascertain whether some falsehood does not lurk under a proposition . . . . it is imperative on us to bring it to the proof of such, and to admit it or reject it on the decision of such." [19]

I. In much of his writing, Harvey was both humorous and eloquent, and he could exhibit high indignation when he dealt with his detractors, yet "to return evil speaking with evil speaking" he held "to be unworthy in a philosopher and a searcher after truth." The passage, however, that follows this, shows that Harvey could (as Sir Anthony Absolute says), if he were tempted to do so, use "strong language;" for he comforts Riolanus by assuring him that "it cannot be helped that dogs bark, and vomit their foul stomachs, or that cynics should be numbered among philosophers; but care must be taken that they do not bite or inoculate their mad humour, or with their dog's teeth gnaw the bones and foundations of truth;"[20] but we must remember that this was not said *to* his detractors, but only *of* them; said to his friend Riolanus; and, moreover, it was said in Latin, and that makes all the difference!

But with the exception of a few scattered passages of just wrath, Harvey was always dignified, lenient, and calm. He was, as his contemporary Ent said of him, "beyond all praise," and it may be justly repeated when regarding the strength and gentleness of his great heart:—

"He has outsoared the shadow of our night,
Envy and calumny, and hate and pain,
And that unrest which men miscall delight,
Can touch him not and torture not again."

He acquired fame, which certainly was not to him "the spur" that might his

"clear spirit raise
To scorn delights and live laborious days."

It may be, as was said of others in his day, that it was "the last infirmity of noble minds," but it was not so with our illustrious Harvey. Truth was what he sought, and what he found; and if fame went with him and followed him to his grave, and waits upon him now, there was no seeking for it on his part; nor could he well have imagined, with all his force of fancy, such a tribute to his memory as that of last year, in the churchyard at Hempstead.

K. Harvey's great achievements were the result of his method—viz., that of observation and experiment. Nature "displays" much; "the Heavens declare the glory of God," and she is always "revealing" as she moves, and she is never still; but Nature is ever moving "onwards" to some unknown goal; and at each onward step, she, while revealing, "hides;" leaves behind in her wake something of the past, which now we cannot see, and presents new facts and new combinations for man—one of her factors—to interpret. Harvey was one of her keenest and most devout interpreters. To him, as he stood by and listened, the Nature-spirit sang, and with profoundest meaning,

"So work I at Time's rushing loom,
And weave the living robe of God."

L. In reverence Harvey knelt before her, but not satisfied with what he saw and heard, he asked her questions—and this with no notion of confusing her, or misreading what she had already written,—for he was just the kind of questioner to ask the kind of question to which she readily gave answer. He examined her "in chief" to find out the *right;* he "cross-examined" her, but in no unfriendly tone, to bring her answer to a "yes" or "no," and so disprove the *wrong*, the untruth which other questioners had placed in evidence.

"Nature," said he to Ent, "is the best and most faithful interpreter of her own secrets; and what she presents either more briefly or obscurely in one department, that she explains more fully and clearly in another. . . . . Truth," he continues, "scarce wants an advocate."[21] Nature to him was a perfect verity: the one witness that could never be abashed or shaken; the one witness in whom there could be no false way; the one witness who could not lie. There was no need to put her "on her oath," for she, in her prime, had been adjured, by the Almighty God, to tell the truth, and "nothing but the truth." This she has always done, and now is doing, and will, as we believe, go on to do. But can she tell "the whole truth?" Will Nature ever tell, or teach, us this? I cannot presume to answer the question which yet I dare to ask; but my own conviction is, that she neither will nor can do this thing until the last hour of Time has struck, and has ushered in the dawn of that one, long, clear, eternal day,—whose "sun shall no more go down,"—and in whose ever-growing light those that abide shall hail the presence of that

"far-off Divine event,
To which the whole creation moves."

A CASE OF MYXŒDEMA WITH RECOVERY WHICH WAS MARKED BY PROFUSE PERSPIRATION.

By DONALD FRASER, M.D.,
Visiting Physician, Paisley Burgh Asylum.

In view of the numerous cases of myxœdema which have of late been recorded, I should not have thought it necessary to report this one but for the fact of a spontaneous recovery having taken place, and also that this recovery was coincident with free perspiration, and presumably largely due to it.

The patient was lately under my care in the Paisley Burgh Asylum, and, as above said, the period of recovery was marked by almost continuous and profuse sweatings of a purely spontaneous character, in that they were not the result of treatment or external stimulation of the sweat glands.

My patient was a male in middle life, and a most unlikely case for recovery, both as to his mental state and his physical condition. The recovery was most gradual in its course, so much so that it was difficult to say when it began. If we regard the sweating as an indication of a curative process going on, then it began very soon after the myxœdematous condition became established.

The mental state of this man was of the character usually described as associated with myxœdema. He was in a high degree apathetic, appeared slow of apprehension, could with difficulty be got to answer questions, and would do so only by means of a whispered monosyllable slowly uttered. He would stand for considerable periods in any position in which he might be placed, with his head carried on his breast, and with expressionless face, while he required to be pushed about like an automaton. Contrary to the more usual history in such cases, this mental state preceded the appearance of the myxœdema, which only became noticeable about eighteen months after his admission to the asylum. The following details

partly taken from the case book will demonstrate the features of the case.

Hugh M'Queen, aged 36, a starch-work labourer, of somewhat intemperate habits, was admitted into the Paisley Burgh Asylum on the 11th September, 1880, from the Burgh Poor House, with a history of having been two months insane, and of having lately refused food. He had been a poorly paid labourer, of the slow and stupid sort, who drank as much whisky as he could get. He was a heavy large-boned man in poor bodily condition, and on examination there was found to be dulness on percussion and feeble respiratory murmur over the base of the right lung, and measurement showed the right side of the chest to be larger than the left. There were the marks of old varicose ulcers on both legs. For several months after admission he continued to lose weight, and the dulness to percussion remained on the right side of the chest. There were no indications whatever of any swelling or fulness of face or limbs; he was indeed emaciating. On June 3rd, 1881, the following note was made :—Patient is completely apathetic, and appears to be losing ground steadily. This morning he was looking so blue about the face and ears that he was put to bed for examination, when the base of the right lung was found to be dull on percussion, and the respiratory murmur tubular in quality but very feeble, while the vocal fremitus was exaggerated. At the right apex, in front, there was also dulness and very well marked tubularity of the respiration, which was also jerky. The respiration was also peculiar on account of the length of the pause, which appeared longer than either inspiration or expiration. The heart sounds were normal, but were almost metallic in quality. There was at this time no fever but great sluggishness of all the bodily and mental functions. He was ordered to be kept a good deal in bed, and tonics with a suitable diet prescribed. In about two months he was going about as usual. Three months after the above note was made it was found that the right lung was very much in the condition indicated by the above described physical signs, while mentally there was no improvement. Towards the end of 1881 or the beginning of 1882, the myxœdema began to be observed. The legs were found to be swollen and œdematous, and the face swollen. Its onset was very gradual, and at first was taken to mean Bright's disease which, with the feeble circulation, was considered to be the cause of the swelling of the lower limbs, until repeated examinations of the urine showed that there was no albumen or other evidence of kidney disease. This solid œdema, for it was soon seen to be of this character, was marked in the legs by an œdematous state for which he was occasionally put to bed, but there always remained, even after prolonged rest in bed, a pork-like state of the limbs. The face had, in a striking degree, the characteristic appearance of myxœdema, being swollen, not pitting on pressure, with clear waxy-looking skin, particularly under the eyes, and red, almost livid-like patches over each malar bone, and was expressionless. The hands were cold, blue, and swollen. The mental symptoms, while showing great sluggishness and some enfeeblement of the mind, were not those of dementia. It was, however, very difficult, if not impossible, to ascertain the existence of delusions or hallucinations. The temperature was generally subnormal. The skin was never observed to be dry or harsh but, if anything, moist.

On February 18th, 1882, it was noted that he had been again confined to bed, as his legs were getting very œdematous, and there was a slight ulcer on the anterior and lower part of each leg. He has been noticed to perspire very much, and on the least exertion profuse perspiration occurs. I was at this time, and afterwards, in the habit of pointing him out to medical visitors as a case of myxœdema, but with a wet instead of a dry skin. When lying in bed, as he used to be for days and portions of days at a time, his skin was always found to be bathed in perspiration, while large drops of sweat stood on his brow. Dr. Love, formerly Assistant Medical Officer, now of Glasgow Royal Asylum, compared his face to a bacon ham frizzling in the sun.

During 1883 his urine was repeatedly tested and was always free from albumen. The quantity was at times under the normal, and was from 36 ozs. to 66½ ozs. in the 24 hours.

The quantity of urea which was tested by Russell and West's apparatus ranged from 240 grs. to 399 grs. in the 24 hours. No evidence of any change in the thyroid gland could be obtained.

Towards the end of the year he steadily improved. The solid œdema of the face and limbs gradually disappeared, I say face and limbs, because on these parts it was most obvious and striking. The mental apathy also passed away, and he began to take an interest in his surroundings, made himself useful in the house, would answer questions readily, and give an account of his history before admission.

On January 25th, 1884, Dr. Love, who was visiting the house after an absence of several months, saw him, but at first did not recognise him, so altered was his appearance, though the patient recognised Dr. Love and spoke readily to him.

February 17th, 1884, it was noted that his mental condition is much improved within the past five months. The bodily condition is also satisfactory. There is a slight translucency of the skin about the lower eyelids, which is the only trace left of his myxœdematous condition.

On June 23rd, 1884, he was discharged recovered, and left the asylum very much against his will as he preferred its ease and comfort to the life he had been accustomed to before admission.

In view of the fact that pilocarpine has been suggested and used in the treatment of myxœdema, this spontaneous cure, marked as already said by almost continuous and at times profuse perspiration, has some interest. The case differs from most of the recorded ones in that the skin never was dry and harsh. We have, however, a general condition marked by great sluggishness of function, bodily and mental, followed by the appearance of the solid œdema of the subcutaneous tissues which disappeared as above described. In other respects the case does not throw much light upon the essential pathology of the disease, though it lends no countenance to the idea that in this disease the mental state is secondary to and dependent on the myxœdema.

CASE OF LABOUR WITH KYPHOTIC PELVIS, AND RELATIVE SHORTNESS OF THE CORD.

By G. ERNEST HERMAN, M.B., Lond.,

Obstetric Physician and Lecturer on Midwifery to the London Hospital,

On May 18, 1884, I was sent for by Mr. H. J. Sequeira to see, with him, Mrs. C., aged 38, pregnant for the second time, the first child having been born dead, prematurely, she thought at about 8 months' pregnancy, without assistance.

Labour pains had begun on May 17, at about 6 p.m. At about 1 p.m., Mr. Sequeira found the os uteri fully dilated, and ruptured the membranes, but as, in spite of strong uterine action, the head did not advance, he

sent for me. I arrived about 3.30 p.m. There was lumbar kyphosis. The head was presenting, but seemed arrested at the brim in a state of extreme flexion, the posterior fontanelle being comparatively low down, the right limb of the lambdoidal suture running to the middle of the symphysis. The sagittal suture ran backwards and slightly to the right, dividing the presenting part of the head into two parts, which, as nearly as could be ascertained, were equal. The anterior fontanelle was too high up to be felt.

The forceps was applied, and Mr. Sequeira and I alternately made perscvering attempts to deliver; but we could not produce any advance of the head. It was, therefore, perforated, and the cephalotribe applied, by which delivery was easily accomplished. The right blade of the instrument was found to have seized the head above the right eye, the left behind the left ear.

After the head had been extracted, difficulty was met with in the delivery of the body. Direct traction was ineffectual, and the body was, therefore, drawn backwards in order to assist the disengagement of the anterior shoulder, at the same time being held loosely so as to be frec to turn. It then spontaneously and quickly rotated through half a circle, so as to bring the face to the front, and then during extraction slowly rotated through a quarter circle further, so as to bring the face looking to the left thigh of the mother. As the body emerged, the cause of this rotation became apparent in the cord, which was twisted round the body of the child, and tight.

An internal examination of the pelvis showed that it was of the shape usual in lumbar kyphosis. The sacrum was straighter than natural, and the sacral promontory did not project as usual. The brim was, therefore, rounder than usual, and the conjugate seemed to slightly exceed the transverse diameter; each measurement was more than $4\frac{1}{2}$ inches, but as they were only measured with the hand, the exact excess over $4\frac{1}{2}$ inches could not be correctly estimated. The outlet was contracted, the distance between the tubera ischii being between $3\frac{1}{4}$ and $3\frac{1}{2}$ inches, and from the pubes to the coccyx about the same. The extent to which the latter measurement might have been enlarged by backward movement of the coccyx could not be estimated. The child was a very large one.

The record of this case is unfortunately, as so often unavoidably happens in private practice, not so complete as might be wished. But it exemplifies two points of interest. First, as to the mode in which the head enters the brim in this kind of deformed pelvis. Dr. Champneys, who in, his paper on "The Obstetrics of the kyphotic pelvis,"[1] has given us the most comprehensive and exact account of the mechanism of labour with this deformity that we possess, comes to the conclusion, judging from the published reports of cases, that a position more transverse than usual is common. In the discussion on that paper, Dr. Galabin remarked, and writers quoted by Dr. Champneys had also pointed out, that we should expect the position of the head at the brim to more approach the antero-posterior diameter than is usual. The present case bears out what would *à priori* have been expected, and suggests that the published accounts contain, as collections of published cases often do, an undue proportion of exceptional cases. The position of the head, as ascertained by examination, and as afterwards shown by the impressions of the blades of the cephalotribe, was rather nearer the antero-posterior position, and certainly not more transverse than usual. The head was also more flexed than is common, a condition which accounts for the cephalotribe having seized it above the eye.

[1] Obst. Trans., Vol. xxv.

The case is also interesting as one of relative shortness of the cord; that is, a cord of natural length, shortened by being twisted round the body of the child. It exemplifies the "spontaneous evolution" described by Dr. Matthews Duncan[2] as occurring in that condition. Dr. Duncan says: "during the evolution the fœtus rotates so as to bring its anterior surface to look forwards. This rotation is in a direction such as to partially undo the encircling and thus diminish the strain on the cord; and the strain on the cord is the cause which produces it." This quotation exactly describes what occurred in the case now reported.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

CUMBERLAND INFIRMARY, CARLISLE.

INTESTINAL OBSTRUCTION — ABDOMINAL SECTION—ARTIFICIAL ANUS MADE IN A MECKELS' DIVERTICULUM — DEATH ON THE TWENTIETH DAY.

By H. A. LEDIARD, MD., F.R.C.S. Eng.,
Surgeon to the Infirmary.

Jane R., aged 47, was admitted on June 4th, 1884. One week previously she was suddenly attacked with pain in the umbilical region, accompanied by vomiting, followed by constipation. The patient was first seen by me, in consultation with Dr. Harris, of Dalston, on June 4th. Her expression was anxious; the vomiting was constant and fæcal in nature; the abdomen was slightly distended, and marked with the outlines of coils of intestine; and as it was considered probable that an operation would be called for, she was removed to the infirmary. After reaching the hospital all vomiting ceased, and although the bowels were very imperfectly relieved by enemata, the patient improved. Distended coils of intestine in motion could always be traced, so that a sharp out-look was kept for a return of the urgent symptoms. There was no indication of any kind as to the seat of obstruction, but as the uterus was less mobile than natural, it was thought possible that some adhesions about it might have entangled a coil of intestine.

Upon the evening of the 10th, or seven days after admission, the fæcal vomiting returned, and the next morning the patient was much worse. After consultation, it was decided to explore the now distended abdomen.

An incision between the navel and pubes exposed coils of small intestine, which were searched in vain for the seat of obstruction; towards the lower part of the ileum a diverticulum was found, which was held in view, whilst the cavity of the pelvis was explored with a finger; some morbid adhesions were felt behind the uterus in connection with the broad ligament, but no cause for the obstruction was apparent; the large gut was not seen, and it was not considered wise to enlarge the incision for further examination.

The diverticulum, which was as long and as thick as the thumb from the carpo-metacarpal joint, and somewhat expanded at the extremity, was cut away, and the base stitched to the abdominal wall.

The patient did not suffer from shock, and with the exception of a single return of fæcal vomiting, after

[2] Obst. Trans., Vol. xxiii.

the wound was dressed in the evening, all went on well. Large quantities of liquid fæces passed through the artificial anus, and the healing of the wound progressed satisfactorily.

On June 18th, eight days after the operation, she began to pass motions *per* rectum, and the fæcal matter from the artificial anus began to diminish, so much so, that it seemed as if it would be necessary to close up the wound, and allow the rectum to perform its function unaided.

On June 29th the patient suddenly became worse, fæcal vomiting, absent for twenty days, recommenced, and she died in a state of collapse on the following day.

On *post-mortem* examination, the artificial anus was found unobstructed, but a coil of small intestine was bound by well-organised adhesions to the intestine which had been opened; no peritonitis was present, but there was a suspicious injection of the peritonæum.

Remarks.—In the absence of any self-evident cause for the original obstruction, it is suggested that peristalsis was checked in some portion of the small intestine low down, and that the artificial anus relieved this; and then, that again peristalsis was arrested by the adhesion of a coil of gut in the vicinity of the wound. The *post-mortem* record was by no means as full as could be desired, but probably a more prolonged examination would not have brought any further information to light. The points of interest which seem to stand out are :—(1) that the onset of the pain and vomiting was coincident; (2) that without rise of temperature or much swelling of the abdomen these symptoms lasted for one week, when the vomiting became fæcal; (3) for seven days all symptoms, except visible peristalsis and partial constipation, were in abeyance; (4) that on making an artificial anus low down in the small intestine, the improvement commenced and continued uninterruptedly for twenty days, when the patient died with a sudden return of fæcal vomiting. There is always a remarkable interest attached to cases of intestinal obstruction, not only from the variability of the symptoms, but also from the kind of pathological puzzle which is presented to the surgeon to make out. That a slight adhesion of a portion of intestine is sufficient to arrest normal peristalsis has been often shown. Sir Spencer Wells has recorded a death after ovariotomy from this cause; and some years ago I opened the colon in the loin for intestinal obstruction, and came upon collapsed bowel, the cause of the obstruction being the adhesion of a portion of the circumference of a bit of small intestine to the edge of the umbilicus. In this case the navel projected but very slightly, and presented a ring capable of containing a surface of gut not larger than a shilling.

TWO CASES OF FRACTURE OF THE PATELLA TREATED BY SILVER SUTURE.

The following cases are, I consider, fair samples of what may be expected to happen in carrying out this method of treatment, advocated more especially by Sir Joseph Lister.

Case I.—James R., aged 25, living at Patterdale, and working at the Silver-Lead Mines, so well known to tourists ascending Helvelyn, was admitted on May 30th, 1883. He said that six months previously he was thrown from his horse, falling he did not know how, for he was stunned, but his left knee-cap was broken, and attended to by a bone-setter, as is the common custom amongst the lower classes in Cumberland and Westmorland. At first the fragments were not very far apart, but they have been gradually separating.

The patient was robust and healthy. The left patella was transversely fractured, the fragments being about 1½ inches apart; very little tissue of any kind intervened between them, for the articular surfaces of the femur and tibia could be felt with ease. He was able to flex and extend the limb, but the former movement was imperfect, and the latter feeble. The chief complaint was that the limb was not trustworthy, "letting him down" whilst walking.

On June 1st, with strict antiseptic precautions, an incision was made over the knee, and the joint and fragments exposed; very little uniting tissue lay between the broken surfaces. The edges were freshened with a saw, but although the tendon of the rectus was divided subcutaneously, they could not be brought into exact apposition. Two silver wire sutures were passed through holes drilled in the fragments, and two drainage holes cut, one on either side of the joint.

The subsequent history may be summed up as follows :—Great pain in the joint with swelling, free escape of synovial fluid; abscesses in many places round the joint, but probably not within; the suppuration may be described as aseptic, and the gauze and spray precautions were continued up to the end, some three months, a weary time for patient and surgeon, and much anxiety probably to both. With visions of a stiff joint and even amputation continually present, the suppuration subsided, the wires were withdrawn, and the patient went home.

In July of this year, *i.e.*, thirteen months after the operation, the patient came to show himself. The joint is sound and healthy, the patella is still ununited, but the fragments are half inch apart instead of 1½ inches, and the limb never lets him down. Upon the other hand, he cannot bend the joint to more than an obtuse angle, although he is perfectly satisfied with the result. The nurse made great complaint of the restlessness of the patient whilst under treatment, and this may have contributed to the imperfect result. Experience of this kind would make any surgeon hesitate before again attacking a case of six months' duration.

Case II.—Before dealing with this man, I had the advantage of reading Sir Joseph Lister's address at the Medical Society of London, and I endeavoured to follow his directions; indeed, the wire I used was courteously sent me by him.

William B., aged 30, living at Maryport, fractured the left knee-cap on October 22nd, 1883. It appears that, with the limb flexed, the handle of a crane struck the knee, and he was sent to the infirmary by Dr. Dalzell two days later. The knee-joint was distended with a semi-fluid mass, the joint was discoloured from extravasated blood, the mark of the crane handle visible, but the patella was only felt with difficulty.

On the 26th the joint was aspirated without materially reducing the swelling, but in a few days the effusion and swelling declined, and it was possible to see that the knee-cap was rather unequally fractured transversely, and somewhat obliquely, there being but half-an-inch between the fragments.

On November 14th a thick silver wire was passed through the bones, one drain cut low down on the outer side of the joint; the bones came together easily enough, and under strict antiseptic precautions, the wounds healed in a very short while. The ends of the wire were twisted and hammered down, but probably this was badly done, for on moving the knee a pricking was felt, and as this continued the wire was withdrawn upon February 11th, 1884, the patient returning for the purpose. The union was as perfect and satisfactory as could be desired, and although the patient could not kneel, he could walk well enough. It was our intention to give him ether and bend the joint, but he got drunk, and was discharged from the infirmary and has not been seen since.

My experience thus coincides with the results obtained elsewhere, and it comes to this, that with good material to work upon and a recent fracture, good

results may be looked for; but even with good material, an old-standing fracture will be better left alone; for I regard the gain in the first case purchased far too dearly at the risk to which the patient was exposed.

I believe that these cases will be more usefully published, without waiting until half-a-dozen have accumulated, seeing that years may pass before further suitable opportunities occur.

Medical Times and Gazette.

SATURDAY, OCTOBER 25, 1884.

The past week has been made memorable by a most important statement communicated by Sir Joseph Lister to the Medical Society of London, on the opening of its one hundred and twelfth Session on Monday evening last. The father of antisepticism always "draws", and there was a large number of Fellows present. After a few words of greeting, Mr. Durham, the President, referred to the general prosperity of the Society. Its present condition and its future prospects, he said, were alike satisfactory. Their new rooms fulfilled their purposes well; the library was being gradually got into working order, and the financial condition was such that, when all the year's expenses had been paid, there was a respectable balance in hand with which the first instalments of their funded debt could be met. The losses among the Fellows, whom the Society had to deplore, included Sir Erasmus Wilson. A vote of condolence to Lady Wilson was carried unanimously. The President said the number of Fellows was increasing, and the amount of work done, no less than its quality, was more satisfactory than it had ever been before.

Sir Joseph Lister then commenced his address on corrosive sublimate as an antiseptic dressing, an abstract of which is published in another column. His audience listened with intense interest to what must fairly be admitted as a recantation of his *absolute* faith in the modes of dressing hitherto in use. "When," Sir Joseph said, "in an address delivered at the opening meeting of last session, I expressed myself in what some of my hearers regarded as terms of overweening confidence in the trustworthiness of antiseptic treatment, I little thought that, a year later, I should have to tell you of failures on my own part." Such an admission on such a subject and from such a man will be heard with widely different feelings; by a few probably with pleasure and exultation, but by the majority of surgeons, and especially continental surgeons with something akin to consternation. The failures fortunately deal only with the methods, and if we may say so, not with the most approved methods, although they occurred to Lister himself. After a most careful consideration of the subject, the failure was traced to imperfection in the manufacture of the gauze which had been used. It appears that Sir Joseph Lister was using eucalyptus gauze. Now eucalyptus oil is very volatile, and owing to the length of time during which the gauze had been exposed, a considerable portion of this oil had been volatilised, and thus the gauze had become less effectual than usual. Carbolic gauze, though liable to the same deterioration, keeps good a longer time, and moreover, carbolic acid is more potent than eucalyptus; it is probable therefore that had freshly prepared carbolic gauze been used, the failures would not have occurred.

With characteristic energy, Lister, nothing daunted and in no way shaken in his confidence, commenced some experiments with corrosive sublimate, a non-volatile substance, and a germicide of great power. Unfortunately, solutions of even 1 part in 500 cause excoriation of the skin if applied for any time, while if weaker solutions are used, the germicidal properties would of course be reduced. It became a question then whether means could be devised for lessening the irritating properties of this drug After careful experiments, it is found that albumen possesses this property, and that if the salt be dissolved in blood serum, solutions containing as much as 1 in 30 can be used without any unpleasant effects. Thus, then, an antiseptic of great power, easily obtained, easily manipulated, and very much cheaper than carbolic acid, is ready to hand in corrosive sublimate dissolved in a solution of albumen. Sir Joseph Lister, at the instance of the President, promised to communicate some further details as to the methods of using this new antiseptic. They will be looked forward to with great curiosity. Meanwhile, it may be said that any absorbent material after being soaked in a solution of "albuminate of corrosive sublimate" and dried becomes a reliable surgical dressing.

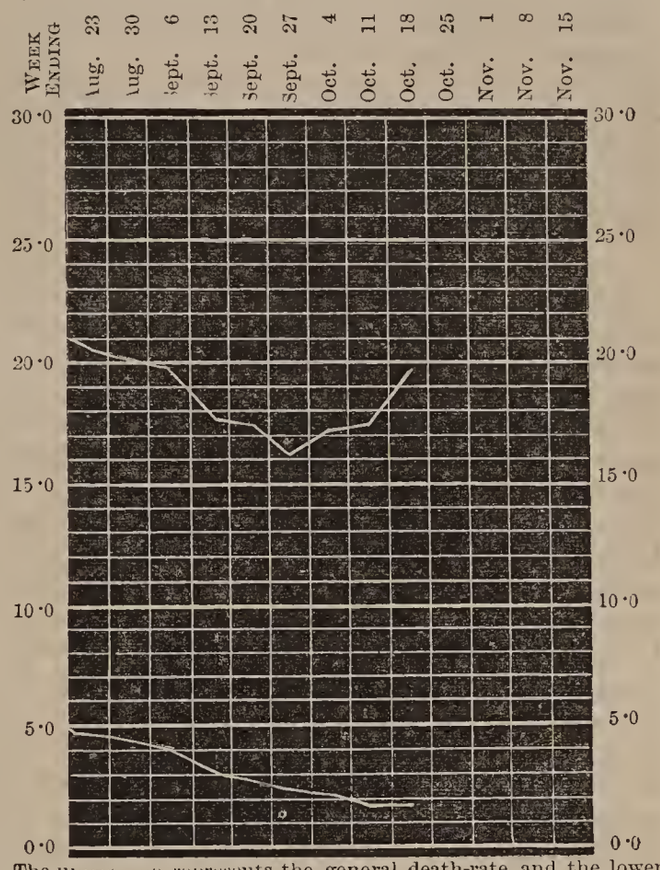
On Saturday last, St. Luke's day, the Harveian Oration was delivered at the Royal College of Physicians, by Dr. Russell Reynolds, in the presence of an appreciative audience. We give a somewhat abbreviated version of the oration in another column, and everyone who peruses it will admit that Dr. Reynolds has treated a well-worn subject with singular freshness. But that periodical orations in honour of Harvey and Hunter now and then bring out a scholarly and thoughtful address like that of Dr. Reynolds, we should be inclined to entertain grave doubts as to the advisability of these reiterated laudations of the two deceased worthies. Their lives and writings have been ransacked, revolved and commented on, until there is scarcely anything left for future orators. Meanwhile, there are other deceased masters of our own and other countries whose lives have been hardly studied at all. Would not Harvey, if he could look in upon us, think himself more honoured by our bringing his spirit to the study of other lives, than by reiterated commentaries on his own? Is it not a little provincial, this persevering worship of our two local heroes?

The opening meeting of the Pathological Society this session, on Tuesday last, was well attended, a long and attractive programme having been provided. The chief interest centred in Dr. Legg's and Dr. Acland's cases of hæmophilia and purpura. Fatal cases of the

former disease are still rarities, so that every case has to be made the most of. That Dr. Klein should not have been able to detect any changes in the blood vessels is a fact of great importance, as excluding these from being the real seat of the disease; so that, notwithstanding the antecedent probability in their favour, it seems as though we should be obliged to fall back upon the blood theory after all. The joint changes were most clearly laid down by Dr. Legg, who speaks with some authority on the subject, having recorded three out of the four cases in which, up to the present time, the joints have been examined. Dr. Legg attributed his case of purpura, with good reason we think, to syphilis, all other causes having been fairly excluded.

A DISCUSSION as to the cause of abscess of the liver generally results in the same conclusion, viz., that English observers have never found the large abscess apart from dysentery, and the reading of papers on this subject, by Dr. Turner and Dr. Carrington, led to much the usual conclusion. As no Anglo-Indians were present, Dr. Wilks did battle for them, though admitting that his own experience led him to believe in the close relationship between the two diseases. Mr. Pepper and Dr. Silcock had a grand case of bone disease in connection with disease of the cord and peripheral nerves, though the lesions of the nervous system were so extensive that the relation of cause and effect was not quite so clear as it might have been. The disease of the peripheral nerves was so extreme that it could not be supposed to have travelled down from the cord. The lesions in the cord itself were those of diffuse myelitis, both acute and chronic; and as the vessels were found to be much diseased, it would seem probable that this may have been the starting point of the malady. Another contribution to nervous pathology was afforded by Dr. Hadden, who had had two fatal cases of the so-called alcoholic paralysis, in which careful examination of the central nervous system had revealed no lesion, though in one case peripheral nerve degeneration was well marked.

THE death-rate in London last week was 19·7 per 1,000, exactly 2·5 per 1,000 higher than it was a fortnight ago. As will be seen directly, this rise is entirely due to the diseases of the respiratory system, the zymotic death-rate showing no increase at all over last week. Scarlet fever caused 27 deaths, or only one-third of the corrected average; measles had 12 deaths, being 3 more than last week, but 16 below the average; and diphtheria numbered 21 victims, as compared with 16 last week. The deaths from diseases of the respiratory system amounted to 286, 60 more than last week, and nearly double the amount recorded five weeks ago. Bronchitis is credited with 156 of these and pneumonia with 78, the vast majority of the deaths so caused, viz., 144, being either of persons over 60 or of infants under 1 year. The highest death-rates amongst the 28 great towns were Bolton 30·2 and Preston 29·9. The Registrar-General for Scotland records that the deaths in the 8 principal towns from measles, scarlet fever, and whooping-cough were each 18, a somewhat unusual coincidence. The deaths from



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past nine weeks.

bronchitis, pneumonia, and pleurisy together amounted to 96, of which Glasgow furnished 51.

THE death of Dr. Samuel Rabbeth, the Senior Medical Officer of the Royal Free Hospital, removes from our ranks one who had given great promise of rising rapidly in the profession, both on account of his mental powers and of that geniality which made him one of the most popular men of his school. It would be difficult to point to any who have surpassed him in this happy combination so valuable to medical men. He possessed that indefinable charm of manner and conversation which so certainly gains friends in all quarters. During his student career at King's College, although he obtained sundry prizes, it was always felt that he was one who was working well within his powers, and this opinion was justified during the time that he held office as Assistant House Physician and House Physician at King's College Hospital, an amount of strength of character, tact and skill being suddenly evolved with the best possible results. In grappling with the practical work of the profession, he seemed to have found his proper sphere; hence no surprise was excited on his being awarded the Scholarship and Gold Medal for Obstetric Medicine at the last M.B. examination at the University of London. It was thought that he was but putting forth his full strength and realising the high expectations of all who had watched his career from its commencement. Now, alas, that career is cut short, but in a way which further bears testimony to his high sense of duty. His death adds another to the long list of doctors who have sacrificed themselves in endeavouring to save the life of their

patient. It is the old story of devotion and of disregard for personal risks involved in sucking at a tracheotomy tube to remove an obstruction due to diphtheria. We lose one whom we can ill afford to spare, one full of vigour and full of promise, one whose death is truly regarded by the lay press as an act of heroism, but none the less we lose him in an act of self-sacrifice which makes us proud of having such men amongst us.

Such an example of self-sacrifice is by no means unique. The number of deaths from a similar cause, especially in the children's hospitals in France, shows that our profession is truly one to be proud of. In every case the doctor has been fully aware of the risks he was incurring, and yet, apart from the published accounts of fatalities, we have seen this act repeatedly performed, both in the wards of a general hospital and in those of children's hospitals. The necessity for immediate action arises, and, although the medical man would warn others of the dangers involved, he unhesitatingly takes that course which he deems best calculated to secure the recovery of his patient. "Do as I tell you, and not as I do," is a medical rule which has a special significance in view of danger. Just as we have students always willing to help in curing aneurisms by digital compression, to assist in saving life by transfusion, so too we always find that in the hour of need there are few men in the profession who hesitate to place their lives in danger to save that of their patient. Long may it be so.

Since our last issue we have been favoured with the following particulars regarding the new entries at the metropolitan schools of medicine. At University College there are 76 full entries and 60 for the Preliminary Scientific Examination. At Guy's 68 students have entered for the full curriculum, 8 for special classes, and 3 for the preliminary scientific class. At the Middlesex there are 39 full and 4 occasional students. At St. Thomas's 86 full entries, and 24 special. At the Westminster there are 9 full entries, and 9 partial. At King's College 37 full students and 27 occasional. At St. Mary's 35 full students and 21 occasional students. At Charing Cross 46 full and 12 partial students.

The vacancy in the office of Curator of the St. Thomas's Hospital Museum, caused by the transference of Mr. Stewart to the College of Surgeons, has been filled by the appointment of Mr. S. G. Shattock, F.R.C.S. Having held a similar appointment at University College for the past five years, Mr. Shattock carries with him very considerable experience; moreover, he possesses in an unusual degree the qualifications which go to make a good and successful curator—varied knowledge, technical dexterity, unwearied industry, and a great love of his work. We congratulate Mr. Shattock on his appointment, and St. Thomas's Hospital not less on having secured in him so efficient a substitute for the able curator they have just lost.

The reply of Mr. Fitch to Dr. Crichton Browne's trenchant letters in the *Times* is a valuable support to the now obvious contention that a good case for enquiry into "*Over-pressure*" has been made out. All the points on which Mr. Fitch attempts to answer Dr. Browne are of subordinate interest, and fail to touch the main question. Mr. Fitch declines to enter into the "personal questions" which he says Dr. Browne has discussed, and thus evades the grave difficulty of showing himself to be either a weighty witness or a fair controversialist, for the so-called personal charges made by Dr. Browne, and not unsupported by evidence, were those of bias and inaccuracy in important matters of fact. The extreme lameness of Mr. Fitch's defence is well exemplified by his venturing to justify his previous statement that "it was in his company that Dr. Browne paid most of his visits to Elementary Schools;" by alleging that "in at least seven or eight of the schools he saw the beginning, and in some of these much more than the beginning, of the kind of enquiry described in his memorandum"! On this head, however, which was by far the most serious part of Mr. Fitch's original attack, we have already seen that Dr. Browne's reply is conclusive. Another attempt that Mr. Fitch makes to rehabilitate himself, is by means of a sorry quibble that a report asked for and sent in to the Vice-President of the Education Department is not quite the same thing as a report to the department itself, intended for parliamentary publication. We may freely concede to Mr. Fitch that it is not; but he unfortunately ignores the fact that Parliament was formally told of the promised enquiry by Mr. Mundella himself, and that it was not to be supposed that nothing more would be heard of it. In answer to Dr. Browne's allegation that his opponent has occasionally misquoted him, Mr. Fitch may perhaps have shown that in one or two instances, regarding "payment by result," Dr. Browne's report was corrected in proof, and that he had himself only the MS. before him when he wrote his criticism; but for the most important of his alleged misquotations, by means of which he managed to impugn Dr. Browne's logic, he apparently has no excuse to offer. Mr. Fitch has, indeed, had a very bad time of it since he obeyed his chief's behest in penning the memorandum, and is doubtless sincere when he says that he shall take no further share in the personal part of the controversy.

The clear opinion of the lay press generally is that there is an important case for investigation; and this, it must be remembered, is the whole of Dr. Crichton Browne's contention as stated in his original report. It is only those who shut their eyes to the possibility of over-pressure who have represented Dr. Browne, and those who largely agree with him, as urging that a change ought to be promptly made in the Education Code. No better outside evidence of there being a good case for investigation can be given than the changed sentiments of the *Times'* leader-writer on this matter. A month ago, the leading journal said that Dr. Browne's report showed a "foregone conclusion in almost every page, that his reasoning was deplorably loose and inconsequent," and that "the Education Department might far more safely be trusted in this

matter than Dr. Crichton Browne." But now we find the same authority saying that "Dr. Browne has established the laboriousness of the investigation and his competence to undertake it, and has carried the war with some effect into the enemy's country." The *Times* is further of the opinion that Dr. Browne's report "raises too vital an issue and is too much in accordance with probability to be left neither proved nor disproved," and regards with approval the promised discussion of the matter by the London School Board. We trust that the School Board will institute an intelligent enquiry into this question ; but must still hold that its importance necessitates its grave consideration in higher quarters.

We have already had evidence that the outcry against the dangers of educational over-pressure is not a mere English "fad." M. Jules Simon has been lately raising his voice in lamentation and in warning inspired by a consideration of the number of subjects supposed to be taught in the schools of his own country, and the amount of time devoted to their study. He deplores the steady increase of the pressure—"more algebra, more chemistry, more classics ;" and while admitting that an adequate re-arrangement of the details of study would have been too lengthy a business to allow of any prompt relief being afforded, he is not content that, by a recent decree of the Minister of Education, the hours of study exacted in the *lycees* have been restricted, while the range of subjects continues unreduced. The French schoolboy is in many respects so un-English in his habits of play that he lacks much of the healthy exercise which comes as a welcome and most valuable antidote to the evils of protracted mental application in the case of the children of this country. It is not wonderful, therefore, that, despite his generally quicker and more precocious wit, he should suffer from educational strain at least as much as they.

Last week, writes our Vienna correspondent, witnessed two important ceremonies in connection with the University here. The first was the formal opening by the Emperor of the magnificent new buildings of the University, which were commenced fourteen years ago. The ceremony took place on Saturday week at 2 o'clock. The Emperor was attended by four of the archdukes and by a brilliant suite. He was met at the entrance by the Rector Magnificus, Dr. Hermann Zschokke, Professor of Theology, by the Pro-Rector, Professor Lang, and the Deans of the four Faculties of Divinity, Philosophy, Medicine and Law, and after mutual compliments was conducted to the "Festsaal," which had been richly decorated for the occasion. Here were assembled all the professors and docents of the University, and a certain number of the students. The Rector, addressing the Emperor, gave a brief sketch of the history of the University, showing how five centuries had elapsed since the University, originally founded by Rudolph IV., had been reorganised by Duke Albrecht III., who made it a real "universitas litterarum," and how a new University building had been projected by his present Majesty in 1854, but had not been commenced till 1870, when the Emperor had offered them a site in one of the most beautiful situations of his capital. The magnificent edifice was now complete, receiving its final dedication from the Emperor, and the only source of regret was that its gifted architect had been taken away from them before he could witness the finished work of his hands. "This University," concluded the Rector, "is sacred to the pursuit of science and culture, its function is to extend the bounds of knowledge by scientific investigation and literary labour, it is the focus of the four faculties, united into one body for half one thousand years, faculties which, however they may differ, have but one common aim, viz., to verify and make manifest the harmony of human knowledge, to prepare faithful and earnest servants for the State and Church, and thus to further the intellectual and material progress of their common native land." The Emperor replied in suitable terms, and after the repeated "Hochs" with which his words were greeted had died away, he was conducted round the building, passing through the library and lecture-rooms. When he appeared in the "Arcaden-Hof" he was greeted with loud acclamations by the students, who had been allowed to assemble there after giving their word of honour to the Rector that they would behave in a seemly manner. The Emperor before leaving expressed his satisfaction at seeing so many students assembled to receive him. It may be remarked that this has been the first *fête* of the kind at which the maintenance of order has been entrusted, not to policemen or soldiers, but to the students themselves. On the same day the students laid a wreath of flowers on the tomb of the Freiherr von Ferstel, the architect of the University building, whose untimely death has been alluded to above.

The second ceremony, which took place on the 12th inst., at 12 o'clock, was the inauguration of Dr. Hermann Zschokke as Rector Magnificus of the University for the ensuing academical year. It is a long-standing custom in the German Universities to elect every twelve months a rector magnificus, who shall represent the whole University and direct its affairs during his year of office. The rector is elected in turn from among the members of the professoren-collegium of each of the four faculties. Last year it was the turn of the faculty of philosophy and Professor Lang was rector. This year it is the turn of the faculty of theology and the ex-rector, Professor Lang, assumes the office of pro-rector. The inauguration of the new rector takes place with some ceremony at the beginning of each academical year in the presence of the representative of the Minister of Education, the professors of the different faculties and the students. This year the ceremony took place for the first time in the newly-opened Festsaal of the University. At twelve o'clock the rector, the pro-rector, and the members of the senate entered the hall, Wagner's "Tannhäuser" March being played. Professor Lang gave a highly satisfactory report of the progress of the University during the last two years, mentioning the names of the professors and docents of the University who had died during that period, and then, amidst the

applause of the students, handed the rector's insignia of office to his successor. The new rector ascended the rostrum amidst a fanfare of trumpets, and proceeded to deliver an address. At its conclusion the University Gesangsverein sang the "Gaudeamus," and the ceremony closed as it had commenced, with the "Tannhäuser" March.

Lectures have already begun in the Vienna Medical School. Professor Auspitz delivered his first lecture on Monday week, when he gave an account of the labours of the late Professor Zeissl, whose wards and clinic have been placed under his charge. Several Ministerial Councillors and teachers in the University were present at the lecture, the subject of which was, "Our Modern Standpoint with regard to Syphilis." The Emperor has conferred the title of Ritter von Edenberg on Dr. Charles Langer, Professor of Anatomy. Dr. Schnitzler, Professor of Laryngology at the Vienna Polyclinic, has been appointed director of that institution on the promotion of Professor Auspitz.

The distinguished *savant*, Geheim-Rath Dr. R. Koch, has refused the invitation to Leipzic to fill the chair left vacant by the death of Professor Cohnheim, having determined to remain at Berlin, where certainly he will find greater scope for his genius than by engaging in an ordinary professorial career. It is, however, understood that before taking this step he has received positive assurances as to his future position, and no long time will elapse before he is installed in the Chair of Hygiene, which is to form part of the new hygienic institute which is to be founded on a very comprehensive scale. With this will be associated the directorship of the *Reichsgesundheitsamt*, which has remained in abeyance since the resignation of Dr. Struck.

Some further communications may shortly be expected from Professor Koch on the subject of the properties of the comma bacillus. It is prominently announced in a Vienna medical journal that he has succeeded in proving the communicability of cholera to animals by means of the bacilli and that rabbits have been so infected. Dr. Koch's own convictions of the correctness of his views, as set forth in a late number of the *Berliner Klinische Wochenschrift*, were referred to and reiterated by Professor Virchow in a short address delivered last week in Berlin.

An important link in the chain of circumstantial evidence which must eventually convict or acquit the comma bacillus of the crime of producing cholera, has lately been furnished by Drs. Finkler and Prior, of Bonn. It was recently announced that these observers had detected the microbe in the dejections of cases of sporadic cholera. They have now published some further facts in connection with it which go far to prove that its life history is a more complicated matter to decipher than was at first supposed. In appearance, the comma bacillus of the sporadic cases is not to be distinguished from that described by Dr. Koch. The bacilli appeared, however, in the earlier alvine discharges only; examinations of the later excreta showed only small cocci, arranged in chains and resembling those found in the intestines during typhoid fever. The explanation of this was obtained by means of cultivation in various media, by which it was found that the period of reproduction of true comma bacilli is limited and does not extend beyond 72 hours. At the end of that time only small cocci are to be seen. This rapid development and disintegration forms the explanation of many otherwise unaccountable failures to find the bacilli in suspected places. If, however, these microbes are so very short lived in their comma-shaped form, it follows that they must exist permanently in some other stage of development. Dr. Finkler thus describes the various processes of formation, as far as he has been able to follow them. "After some time the bacilli become thicker, swell up and appear transparent, they then take the form of a hone, at both ends of which a kind of small spur becomes attached. These 'spore-bearers' then throw off their spores which in their turn grow to be small rods; these are at first straight and afterwards take on a curved form. These curved rods grow into variously twisted thin threads and spirilla, which become thicker and develop into shapeless, or in some cases S-shaped figures. A little later there appear, amongst these spirilla, any quantity of small distinctly curved comma bacilli. All these bacilli only attain to a certain size and then again become 'spore bearers,' and the same process is repeated." As regards the existence of a permanent form, Drs. Finkler and Prior succeeded in obtaining perfect bacilli by cultivation from the excreta, fourteen days old, of a cholera patient, in which, previous to the cultivation, not a single bacillus or spirillum could be detected. In the mode of their development, therefore, a marked difference would appear to exist between these otherwise similar bacilli. If Koch's comma bacillus should on further examination be found to undergo similar changes to that of *cholera nostras*, as these sporadic cases have been christened in Germany, it will become of still less importance as a diagnostic sign than it is at present. Not the cause of cholera, but the cause of the cholera bacillus will then form the burning question of the day.

Naples, if we may believe some of the highest authorities in Italy, is really about to turn over a sanitary new leaf. The sewers it is declared will be the most urgent object of attention. A wide street is to be made through one of the most perilous quarters of the town, and new quarters are to be provided for the operatives. The destruction of houses found to be insanitary, as well as of wells and cisterns, is promised, and it is to be the duty of the municipality to enforce the use of pure water only. Let us sincerely hope that these excellent resolutions will not remain on paper only, but that no time will be lost in giving effect to measures which seem to show that at length those in authority are beginning to believe that there is perhaps after all something in English ideas of how to meet cholera.

The statement made by the veteran Dr. Ricord at a recent meeting of the Paris Academy of Medicine, deserves the careful consideration of his countrymen. He stated that his first experience of cholera occurred in 1832, when he was left in sole charge of 600 hospital patients, his two colleagues having fled from Paris in a fit of panic. "I took note of the fact that not a single non-choleraic patient caught the disease, and that the doctors, house-surgeons, attendants, and nurses who attended the cholera cases exclusively, enjoyed complete exemption from the malady. This convinced me that the cholera could not be contagious; and I have seen no reason to alter my conclusion, viz., that cholera breaks out spontaneously in given localities, and that quarantines are not only frivolous and vexatious, but positively dangerous. That cholera is generated spontaneously does not imply that it has not a special cause; and what that cause is I do not know. The only sensible quarantine would be that which would prevent a man in good health from migrating to a cholera centre. Common sense and prudence should suffice for this."

The Faculty of Physicians and Surgeons of Glasgow recently called the attention of the Medical Council to the fact that within the last three months two forged diplomas of Doctor of Medicine of the Vienna University have been presented to it by candidates for its final examination. The fictitious character of the diplomas was detected in each case by the presence of grammatical errors in the part filled up in writing. The forms otherwise appeared to be genuine. The Registrar of the Medical Council communicated with one of the counterfeit diplomates, who stated in reply that he had seen an advertisement in the *Lancet* which led him to visit a certain practitioner, living in Paddington. He was catechized and told he was eligible for the Vienna M.D. He accordingly set out for the Austrian capital, but on his arrival found that his name had not been entered, and that examinations were only held in June or July. On his return, the Paddington practitioner, who had represented himself as "M.D., and Gold Medallist of the Vienna University," sent him his diploma, charging him the modest fee of 30*l*. "Therefore I concluded that my examination was conducted through the agency of Dr. —— as interpreter." The Glasgow Faculty, commenting on the two cases, naïvely remarks that they "appear to indicate the existence of some kind of organisation for the fabrication of counterfeit diplomas." They appear also, we opine, to indicate the existence of a considerable amount of credulity in the persons who are taken in by such an organisation. If this very silly gentleman who thought he could get a first-class degree—for the Vienna degree is one of the best on the Continent—by a short conversation in a back parlour in Paddington, had taken the trouble to study Dr. Hardwicke's "Medical Education and Practice"—a book which ought to cut the ground from beneath all bogus diploma-dealers—he would have seen, on almost the very first page, that the conditions for the degree are very different from those which he fulfilled. Let us hope that this case will serve as a warning to all aspirants to foreign and colonial degrees. They will get much more reliable information from Dr. Hardwicke, than from any advertising diploma-monger and that about one hundred times more cheaply.

THE LESSON OF THE ENTRIES.

We have often before called attention to the steady falling off in the yearly number of entries at the London hospitals, and we mean to call attention to it again and again, for in the whole range of subjects relating to medical education in this country, there is none which demands careful thought and bold action more than this. In 1879 the entries at the eleven London hospitals numbered 731. In 1881, the year in which the largest aggregate of new students that has yet been registered in the United Kingdom joined the profession, the London entries numbered 722, the next year, 1882, they fell to 634; in 1883 they again fell to 605; and this year there is little sign of increase. During the same period, the entries at the Scottish schools have shown a steady rise, for, according to the Medical Registrar's returns, 540 entries were registered in Scotland in 1879, while in 1883, the last year for which we have returns, the number of entries was 596. That is to say, whereas six years ago four students entered in London for every three that entered in Scotland, the numbers last year were almost exactly equal, and this year it will probably be found that Scotland has passed considerably ahead of London. It must be remembered that we are comparing unlikes, viz., the deans' figures in the case of the London schools and the Medical Registrar's in the case of the Scottish. This is necessary because so large a proportion of English students first register when studying at small country hospitals or with a general practitioner, a custom which does not obtain in Scotland. The comparison is, however, entirely in favour of the London schools, for it may be assumed that their several deans do not err on the side of modesty in announcing their returns. The rise of the Scottish and the decline of the London schools is very evident from the following table:—

	1879.	1880.	1881.	1882.	1883.
Total Entries in England and Scotland	1528	1572	1631	1428	1413
Entries at London Schools ...	731	702	722	634	605
Entries at Scottish Schools ...	540	589	567	585	596
Percentage ratio of Entries at London Schools to Total English and Scottish Entries ...	47·8	44·6	44·2	44·0	42·8
Percentage ratio of Entries at Scottish Schools to Total English and Scottish Entries ...	35·4	37·0	34·8	40·6	42·1

It is clear from the above table that the total number of students entering the profession has fallen off considerably within the last few years, but it is equally obvious that the loss and more than the loss has fallen entirely on the London schools. Taking the

average amount paid by each student who enters in London at 100*l.*, it is clear that the Metropolitan schools received from last year's students 7,000*l.* less than they would have done if the *percentage* of 1879 had been kept up; and they received 13,000*l.* less than they would have done if the *number* of entries had been the same in 1883 as it was in 1879. This is perhaps a somewhat sordid if forcible way of setting forth the matter, and we should be sorry for it to be supposed that we are only exercised about the waning prosperity of the London schools, because it means an annual loss of from 30*l.* to 40*l.* a year on an average to some two or three hundred metropolitan teachers. This is the least important aspect of the question. The really vital fact is that a constantly increasing proportion of our future practitioners are getting their whole medical education without once coming into personal contact, except perhaps at examinations, with the best of English physicians and surgeons. The influence of the large array of clinical talent in London, and the advantages of its vast clinical material are being made less and less available in the professional education of British practitioners. There are able teachers both at the Scottish and at the provincial schools, but the combined staff of Guy's, St. Bartholomew's and University College could furnish half-a-dozen sets of Edinburgh professors, and yet the united entry of these three hospitals will this year probably fall far short of that of the modern Athens.

The *causes* of this decline in the popularity of the London schools are not far to seek. The modern student and his friends must be singularly uninstructed if they do not understand that for the bulk of students a London medical education means paying more and getting less than an education at Edinburgh, Aberdeen, Glasgow, Newcastle or Manchester. There is no doubt that in the future the schools whose rivalry London teachers are likely to have most to fear will be Edinburgh and Manchester. Both possess teachers, at any rate in the primary subjects, who are confessedly superior to the teachers in the corresponding subjects at any but the best two or three London schools, and both can give a degree which is within the reach of the average student; at both too education is cheaper than at a first-rate London school. We do not attach very much importance to the latter point. The most expensive school in London, St. Bartholomew's, keeps up its numbers well, and we can scarcely believe that a difference of twenty or thirty pounds in the total amount of fees influences the decision of more than a small percentage of parents, other things being equal. But in the present case other things are not equal. The student who comes back from Edinburgh with his M.B., C.M., is distinctly in a better position than the London student with his two College diplomas. He is not necessarily a better educated man, but he starts in his career with a marked advantage over his London rival. This consideration is no doubt telling on an increasing proportion of aspirants to a medical education, and it is beginning to be generally felt by London teachers that no improvement in their teaching arrangements will have much effect on the entries, unless they can promise the student a reasonably easy degree.

To secure this seems almost hopeless. There are three ways in which it might be done, and each of the three seems blocked by equal difficulties. The London University might lower its requirements so as to bring its M.B. degree within the reach of the average student, but every London graduate would strenuously oppose such a departure from the long-established principles of his University. Opposition on the part of the graduates would not necessarily be actuated by a selfish fear of the depreciation of their degree, for the most influential of them have attained positions in which the relative value of a degree counts for little. They would contend, however, and we should have some sympathy with the contention, that it is very desirable to have degrees of varying difficulty, and that for the University of London to offer a degree to the average student would be to surrender that influence on the higher medical education which it is generally admitted to have hitherto successfully exercised. Such a plea in the mouth of a London graduate would of course preclude his opposing the institution of an easier metropolitan degree. But here we are met with difficulties of another kind.

It has been suggested that the Colleges of Physicians and Surgeons should combine to give a degree in medicine and surgery carrying with it the right to the title of "Doctor." If the governing bodies of the two Colleges were to take up the idea, and earnestly press it on the Government, we have no doubt that they could get a charter which would give them the necessary powers. But they would have to make some sacrifice of sentiment, if not of privilege. No Government would hear of a new degree which was not open to women as well as men, and we may be pretty sure that both the Colleges would need a stronger stimulus than the despairing cry of London teachers to induce them to surrender their darling prejudice against female doctors. Possibly when things get a little worse, and London schools begin to shut their doors one by one, considerable pressure may be brought to bear on the Councils in Lincoln's Inn Fields and Pall Mall, but nothing short of insurrection will convince them that the time has come to accept an accomplished fact and to make their policy square with it.

The third course open would be to establish an entirely new degree-granting body. This way out of the difficulty, though favoured by many to whom we have spoken on the subject, appears to us to be even more hopeless than either of those already considered. It would arouse opposition on all sides. The College of Surgeons would oppose it tooth and nail, and their new friends in Pall Mall might be counted on to back them up. A new University giving a reasonably cheap and easy degree would be a formidable rival to both the Colleges and would possibly in the end relegate them to the position of corporations of consultants. The Government too would think a great many times before it consented to establish a new licensing corporation, and it would certainly refuse to give it that pecuniary support without which it could not come into existence. So all ways alike the difficulties seem insuperable, or only superable when the whole meaning of the recent decline in the London entries has been much more clearly realised than appears to be the

case at present. The question is one, we fear, that will have to wait, but we shall ourselves let slip no opportunity of helping to ripen it, and we shall be glad to receive and publish letters from all who have reasonable suggestions to offer. Meanwhile the London teachers, if they will, may do much to restore the prosperity of their schools, and render them attractive as places of clinical, if not of primary medical instruction. But on this point we must reserve our views for another article.

EXAMINATION FOR PROMOTION.

We understand that it is in contemplation to institute an examination before promoting Surgeons Major to the rank of Brigade Surgeon. It is only natural that such a step should be unwelcome to the Officers of the Medical Staff; but we think their opposition will be based rather on the fear that the new test will be unfair, than on dislike to examination itself. Promotion for some years past has been by seniority, or by selection, and there are valid objections sometimes both to those who have survived to await promotion and to the lucky ones who, for special reasons, have been selected out of their turn. Age and good general conduct are not all the qualities necessary for the higher ranks of the Army Medical Department, which are administrative as well as executive; and personal gallantry and self-sacrifice give no claim at all to professional advancement, although they demand recognition in the shape of decorations or of pensions. Selection has been also exercised in the olden days for not very satisfactory reasons, although of more professional nature. Efficiency with economy, and *particularly* economy, appealed feelingly to the instincts of former rulers, and if, in addition, the cautious doctor was a man of the world, and knew how to make things pleasant all round, he was pretty sure to find himself in or out of his turn a Deputy Inspector General of Hospitals, of the old Army Medical Department. But examination for promotion to be acceptable needs careful watching. Such tests have been, and may again be, greatly abused. When the War Office appointed a Committee some years ago to enquire into the causes which tend to prevent sufficient eligible candidates from coming forward for the Army Medical Department, they noticed in their report the dislike to examinations and the reason why. They said —"We have it in evidence that the examination is directly deterrent to the candidature of some of the most eligible students; and, as a matter of fact, the *competition* has virtually ceased on account of the paucity of entries," and then the Committee proceeded to give the reason why. "During several years the student at the Medical School has been passing examination after examination, in successive branches of his professional education: portions mastered early in the curriculum have been laid aside, and though remembered in general principles, have partly passed, as regards details, from the memory. Anatomy and botany may be taken by way of example. In these subjects a student, it is stated, usually passes early. It is afterwards one thing to remember the broad features of each science, and to know to what text-book to refer for any detail required in practice. It is altogether another thing to be ready for a searching examination into the minutiæ of every bone, muscle, and ligament, and into every subdivision of the botanical classification." The Committee, therefore, while still resolved, to a certain extent, that competition should be retained, recommended "the examination being of a more *practical* character than heretofore."

After the Crimean War, examinations were instituted before promotion to the rank of Surgeon Major. We can well understand why old medical officers should have objected to ill-judged and badly regulated tests. The grievance must have been felt by the authorities to be a reality, for the Warrant of April, 1876, which instituted the ten years' system, *abolished* the examination for the rank of Surgeon Major. There seems no reason why such a test should be re-introduced; but we are doubtful whether examination for promotion to the higher rank of Brigade Surgeon might not be advisable. We are not, indeed, prepared to accept the recommendations of Lord Morley's Committee; they went too far when they recommended "that the system of examinations for promotion should be restored; that between three and seven years service, every medical officer should pass through an examination more especially in practical subjects, such as operative surgery, on which should depend his promotion to the rank of Surgeon Major." We imagine that too many examinations would prove the destruction of the Service. It is an honourable and a good Service enough, but the prizes to be gained are not many, nor particularly well distributed; and many might hesitate to enter the Army if they were required to keep themselves perpetually in training for a scientific contest, more particularly when the accidents of war or service might put it out of the power of a good man to consult his books as carefully as examiners would require. At the same time it would be wrong to allow men to rust, and doubtless there is a temptation to idleness in military life, but it is fostered and increased by the fact that there is no encouragement for a doctor who loves his profession to keep himself in the foremost ranks. The questions put by Lord Morley's Committee to Surgeon General Longmore and his replies deserve consideration. He was asked—"At the present time have Army Surgeons in this country any opportunities, except what they have at Netley, of keeping pace with the progress of medical and surgical science?" He answered—"It is entirely voluntary whatever opportunities they may take for that purpose, there are *none* arranged." It would be hard indeed to punish officers for want of opportunity to perfect themselves; and we see a difficulty about competitive examination, when the necessary training for the race must often be a mere matter of chance. There is no military school excepting Netley, and it could scarcely accommodate all the Surgeon Majors who might try to qualify for promotion. There is hope, however, in another direction. The Committee asked Surgeon General Longmore—"Do you think it desirable that Army Surgeons should have opportunities of passing through a course of practical surgery in a civil hospital?" He replied—

**

"It would be difficult to arrange that, but if it could be done it would certainly be advantageous at certain periods." We think that if the instruction can be fairly given to all who honestly seek it, the examination for promotion to the rank of Brigade Surgeon would meet with little objection. If the opportunity cannot be afforded, it would be as well to leave promotion in the hands of the Director General. The authorities of civil hospitals might perhaps be willing to afford aid to their military brethren; but we doubt whether the War Office would let their servants enter the wide open doors in any considerable number. The Medical Department is too shorthanded and too hard worked for its members to be allowed leave even to improve themselves.

REVIEWS AND NOTICES OF BOOKS.

Abstracts of some of the Medical and Surgical Cases treated at the General Hospital for Sick Children, Pendlebury, Manchester, during the year 1883. Compiled by the Medical Staff, pp. 142. J. E. Cornish, Manchester. —This volume, which is the third of the series, contains the records of some 350 cases treated in hospital, including upwards of 100 *post-mortem* examinations and tables, in which the cases of typhoid fever, croupous pneumonia, and chorea are analysed. The general arrangement of the volume is somewhat similar to the University College Abstracts, only in the abstracts under notice no attempt has been made to include every case which has passed through the hospital, only the most important being noticed. The medical portion, which occupies the greater part of the book, begins with some remarks upon the cases of scarlet fever, of which some 215 had passed through the wards during the year, 35 proving fatal. The complications observed, especially the renal and rheumatic, are noted. The histological appearances presented by both the post-scarlatinal and septic forms of nephritis are summarised, and an opinion expressed that the glomerulo-nephritis so often noted in the former is the result of a gorged condition and stasis of blood in the intertubular and glomerular capillaries. In the septic form of nephritis the capillaries were constantly found distended with plugs of fibrin laden with micrococci. Seven or eight cases of scarlatinal synovitis are reported, one with suppuration in the joints. A *resumé* of the treatment employed is given. As might be expected, considerable space is devoted to the cases of general tuberculosis; full clinical records and *post-mortems* are given. Details of ten cases of empyema are given, two of which appear to have been fatal from complication with purulent pericarditis. Under the heading of hepatic disease, a full account, including the *post-mortem* appearances, of a case of mediastinitis with an engorged and cirrhotic liver is given; a case of biliary cirrhosis is also given. Among the cases of nephritis a remarkable case of granular contracted kidney, in a girl of 11¾ years, is recorded. Under diseases of the nervous system the details of ten cases of cerebral tumours are given, including a glioma of the pons, and a periosteal sarcoma growing from the base of the skull. The surgical abstracts deal largely with the results of excision of joints and osteotomy of the femur and of the tibia. Many interesting details are given of cases of periostitis, abscess in bone and acute necrosis. Having expressed our hearty approval of these abstracts we must for a moment exercise our right to grumble. There are two things with which we have to find fault, one is that on p. 32 a distinction is implied to exist between laryngitis and croup, which certainly is not evident from the records of the cases there given. The other is that in the admirable tables and reports of the cases of chorea, no mention is made of the presence or absence of nodules, which, thanks to Barlow and others, have now a recognised place among the associations of chorea.

Transactions of the Obstetrical Society of London; Vol. xxv., for the year 1883. London: Longmans, 1884. Pp. 315.—The volume before us is one rather above the average of the series to which it belongs. By general consent the first place in interest will be given to the paper which stands last in the volume, but is from the pen of Dr. Robert Barnes. In it that distinguished writer considers the mechanism of ordinary labour, and defends the view of Naegelé as to the obliquity which goes by his name. We are sure that the obstetric world will welcome this contribution, not only for its intrinsic value, but also as an evidence of the interest which its much occupied author still takes in the scientific aspect of his specialty. The subject is additionally elucidated by an elaborate geometrical argument by Dr. Galabin, illustrated with diagrams, by which he demonstrates that there is a mechanical advantage gained by the presence of this obliquity. As in Dr. Galabin's other writings on similar topics, the subject is set forth with such accuracy, and argued out so thoroughly, and with strict mathematical method, as to make us wish for further contributions of the same kind from the pen of this able obstetrician. The volume is rich in matter bearing upon the science of midwifery, for beside this paper of Dr. Robert Barnes's, we have two elaborate monographs by Dr. Champneys, one on the obstetrics of the kyphotic pelvis, the other on the influence of the pressure of the femora in modifying the shape of the pelvis, two papers of the highest interest and value, although from the closeness of the reasoning and the highly technical nature of their subjects they may not appear entertaining reading. The tale of good work is not yet ended, for we should not be doing justice if we did not particularise also a short paper by Dr. Braxton Hicks, on the state of the uterus in puerperal eclampsia, a record of original observation, which, from the reputation of the author, will be regarded as authoritative as to the points on which it touches. There are papers by Mr. Lawson Tait, notably one on pyo-salpinx, which will doubtless receive close attention from all interested in the progress of gynæcology. Dr. Henry Bennet, in a paper on the os internum, tries to galvanise a dead (or dying) controversy into life. Dr. Herman describes a case of gangrene of the vulva in an adult, and illustrates it by a summary of the literature of the subject. There are other shorter papers which we have not space to separately mention, and descriptions of many exhibited specimens, as to some of which we must confess we fail to see the reason either for their exhibition or for the mention of the fact in this volume.

Porro's Operation; by Clement Godson, M.D. (Reprinted from the *British Medical Journal*). Pp. 20.—This reprint, from the columns of a contemporary, contains an account of a successful case under the author's care, with some comments thereon; a table of all the cases, 152 in number, that the author has been able to find; and remarks upon the paper, made by different speakers at the time it was read. Many of the cases included in the table have not before been published, and, perhaps, would never have been made known had it not been for Dr. Godson's zeal. He has, moreover, included (but put separately) cases differing slightly from the ordinary Porro's operation, although alike in essentials. The table is one of great value, and for it, we think, the author deserves praise, although his remarks do not exhaust the subject.

Anatomische Vorlesungen für Aerzte u. ältere Studirende; von Prof. Ad. Pansch. Theil 1. Brust und Wirbelsäule. Berlin: Robert Oppenheim, 1884. Pp. 222.—Professor Pansch, of the University of Kiel, is known in Germany as the author of an excellent Students' Anatomy, and of other Anatomical works. The work before us is one dealing with Topographical Anatomy, and the methods of preparing and preserving subjects. The matters embraced in this book are of that special branch of anatomy which is so much neglected in this country, and good descriptions are given of the statics and mechanics of the body, the movements, and disorders of movements, of the vertebral column and of the thoracic parietes. Though we fear that the author's teaching is out of the reach of the majority of our

readers, from the fact of its being in German, yet to any one who has an acquaintance with this language we can recommend Professor Pansch's work as a useful and good exposition of a practical branch of Anatomy. An ingenious use is made of an instrument which is sold in England as a toy, and by the amplification of which, under the name of a tachygraph, the outline of any body, however large, can be rapidly drawn to reduced scale and preserved for future reference. Professor Pansch has executed his task well and has produced a very readable and particularly useful book.

Lehrbuch der Physiologie, für Akademische Vorlesungen und zum Selbstudium. Seventh Edition. By Dr. A. Gruenhagen. Hamburg and Leipsic: Leopold Voss.—We have before us the first and second parts of this favourite German physiology. Originating with Wagner, re-edited by Otto Funke, and later by Professor Gruenhagen, it has now reached its seventh edition. That the work should have been so popular is due no doubt to the fact that it is easily written, and the style is good, which is more than can be said for all similar works. When a work reaches its seventh edition it needs no further recommendation. Professor Gruenhagen, who edits this edition, has preserved the lucid style and clearness of expression, while adding all new facts which are of essential importance. The labours of our own physiologists find copious mention, and the editor has brought his work down to the latest point. Such is the popularity of this work abroad that we feel sure that if a good English translation were only published, it would meet with equal favour in this country. It is being published in numbers now, which will appear at intervals of six or eight weeks, and the whole will be completed in about a year and a half. The price of each number is three marks. The two parts already published include the physiology of the blood, the circulation, digestion and absorption.

ABSTRACTS AND EXTRACTS.

SURGERY.

Cerebral Abscess.—As was recently pointed out in our own columns by Dr. Alexander, the surgery of the cranial cavity has hardly kept pace with the advances that have been made in other regions of the body, and he gave very good reasons why this should be so. In the American *Journal of Medical Sciences* for July, however, there is a paper of much interest on this subject by Drs. Fenger and Lee. The starting point of their paper so to speak was the case of a policeman who received a bullet wound just over the left eyebrow, in consequence of which certain cerebral symptoms made their appearance. The bullet did not enter the cavity of the cranium, and indeed there was no fracture of the internal plate of the bone at all, but a short time after the injury, and when the local damage had been satisfactorily treated, certain symptoms appeared referable only to some intra-cranial disturbance; they were sighing, gradual slowing of pulse, and somnolency deepening into coma. Under these circumstances the doctors determined to trephine. On doing so the dura and pia mater were both found to be healthy, and the surface of the brain showed nothing amiss. A hypodermic syringe was then pushed in and after one or two failures, some turbid sero-purulent fluid was reached at a depth of about two to two and a half inches. Forceps were then inserted and a passage made for the exit of the pus; a drainage tube was put in and the cavity was washed out daily at first with boracic acid, afterwards with carbolic acid. Some delay was caused in the after treatment by the premature shortening of the tube, but ultimately the abscess cavity closed up in the most satisfactory manner, and the patient made a good recovery. In discussing this case, the authors admit the great difficulty in diagnosing abscess especially in the absence of any localising symptoms, but their main object is to direct attention to the treatment. With regard to the exploration by the hypodermic needle, we confess that we cannot regard it as so free from danger as they do. If the needle was driven through the motor region, we should consider that there must be some risk of damage being done which would leave indelible traces, and this is not a mere hypothetical difficulty, for we remember to have read a few years ago, in the St. Bartholomew's Hospital Reports, of a case of a young man who had permanent hemiplegia induced by a knitting needle being pushed into his brain through the orbit. However, we approve of an exploratory puncture in a supposed case of abscess, only we cannot admit that there is no danger in such a proceeding. Again, we fail to see the advantage of tearing the brain substance with forceps, and incline to think that the amount of damage done to the surrounding brain substance thereby would quite outweigh the risk of hæmorrhage involved in the use of the knife. It must be remembered that in the case under notice the authors were particularly fortunate in having to do with a region of the brain, injury of which is not followed by lesions that we can at present appreciate, and that if they had been dealing with the motor area they could not have adopted these measures with such complete immunity. Washing out the cavity seems to be in accordance with the generally approved principles of treatment, but we think that especial precautions should be taken to keep the head in such a position as to leave the opening at the most dependent point as far as possible.

Introduction and Extraction of Needles.—M. Desprès in a lecture which he delivered at La Charité (*Gazette Médicale*, May 17th), made some interesting observations. A young woman striking a table with the palm of her hand thrust a needle into the base of her middle finger, and this, striking against the first phalanx, broke and became fixed there. When seen two days afterwards the fragment of needle had completely disappeared amidst the inflamed tissues. On pressing at the base of the middle finger, however, a foreign body, pressure on which occasioned pain, could be felt. An incision was made at this point, and a fragment of needle, measuring 1½ centimetre, removed by the forceps. Here the incision was justified by the fact that the foreign body was firmly fixed. The subject of a second case was a young woman into whose breast a needle was driven obliquely by a blow, and entirely disappeared under the skin. Guided by the patient the presence of the needle could be ascertained; but in this case an incision for its removal would be improper, for the integuments of the breast are so mobile that an incision made in the skin would not correspond to the foreign body. The presence of the needle having been exactly determined, we should seize it in its length and make pressure on its two ends. At one of these we may perceive a slight cracking sound, and here the patient also feels a sharper pain than elsewhere, and this is the point of the needle. If we now press firmly upon the other end this point will be forced through the integument and can then be seized with a forceps. An incision should never be made except when the body is fixed in the tissues as in the first case. One caution must be borne in mind, and that is, we should never attempt an extraction on the mere statement of the patient that a needle is present in the tissues, and when we are unable to verify its presence; for sometimes persons declare that they have needles in their tissues when they have not; or when we are consulted the needle may have already migrated to another part of the body, this migration sometimes taking place very rapidly.

Fracture of the Fibula.—In a clinical lecture, delivered at the Pennsylvania Hospital, Dr. Levis, speaking of the diagnosis of fracture of the fibula, observed that this was chiefly derived from the great lateral mobility of the foot, and the outward displacement of the ankle and foot. Grasping the foot we elicit crepitus, and this with the pain produced by forcing the foot out, and its extreme range of lateral motion, determines the nature of the accident. But the diagnosis is more difficult when there is but slight displacement, and the patient is fat or muscular. One procedure, however, answers admirably, viz., feel for the head of the fibula, just near its junction at the tibia, in the neighbourhood of the annular ligament. At this point make decided pressure, tilting the distal end of the bone, and, if fracture be present, pain will be felt, not at the point at which pressure is made, but at the point of fracture. This fracture is peculiarly the fracture of the leg, consequent on falls from a height, especially when the foot is slightly everted.

"Further, where there is lack of co-ordination in walking, as with drunken men, fracture of the leg, if it take place, seems to select the lower end of the fibula as its favourite seat. Indeed, so commonly do we admit drunken men to this hospital suffering under this lesion, that I call it 'the drunken man's fracture.'" Dr. Levis cautions his hearers against the prevalent practice of supposing that when a splint is applied, the reduction of the fracture is thereby accomplished. Splints may be arranged according to the case and its circumstances, but the primary object should be the proper reduction or coaptation of the fragments. "The medical mind seems to be so associated with splints for fractures, that not enough care is bestowed upon this item of proper reduction. A pillow for the leg and foot to rest upon, and to make equable pressure, in order to retain the parts properly *in situ*, together with a fracture-box, will answer all purposes in ordinary simple cases."

Downward and Backward Dislocation of the Acromial End of the Clavicle.—Dr. Wescott, of Chicago, records the following rare case. "Mrs. K., aged 26, while going downstairs, made a false step and fell three steps, sinking against the baluster so as to drive the acromion process of the scapula *over* the end of the clavicle. I saw her 24 hours after the accident. There was little swelling and no pain, except upon motion of the arm; notable absence of the usual prominence of the clavicle at its outer half, but by burying my fingers deep in the neck I could outline the bone to its extremities as it passed beneath the acromion, and demonstrate the absence of fracture. I reduced the dislocation by placing my knee between the shoulders and drawing them forcibly backwards. Some difficulty was experienced in maintaining the reduction, but the patient recovered without impairment of function and with no visible deformity. Professor Andrews, in the 'International Encyclopædia of Surgery,' says that only five similar cases have been reported."—*New York Medical Record.*

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

Monday, Oct. 20th, 1884.

Arthur Durham, F.R.C.S., President, in the Chair.

Corrosive Sublimate as a Surgical Dressing.

Sir Joseph Lister delivered an address on "Corrosive Sublimate as a Surgical Dressing," of which the following abstract summarises the chief points. The speaker began by adverting to his address at the opening of the last session, in which, according to some of his hearers, he had expressed himself in terms of overweening confidence. He little thought then that a year later he would have to tell of failures on his part, and yet such was the case. Within the past few months, several instances had occurred of results deviating from what he considered the normal type in aseptic wounds; in one instance a fatal result occurred from a form of spurious septicæmia, such as he had not seen for many a year. It was in the case of a lady, on whom he had operated for scirrhus of the breast and axillary glands. There was pus two days later, an unusual occurrence in his experience so early after operation. In the pre-antiseptic days, when sound tissues were operated upon and when primary union did not take place, three or four days usually elapsed, in children something less, and in warm weather less time than in cold. For pus to appear, therefore, so soon, and in some quantity, seemed to him to indicate, that an organism must have been present. After death, organisms were found in the abscesses, and in the pleural cavity. This was the only fatal case he had had, but other cases with delayed union and pus formation had occurred, undoubtedly of a septic character, that is to say, dependent upon the development of micro-organisms, although in none of the cases was there any offensive smell. These untoward results had made him reflect very carefully, for he had hitherto considered his mode of dressing absolutely free from danger. Mr. Cheyne's and Dr. Ogston's experiments had conclusively shown that the ordinary means he used were amply sufficient for the purpose of keeping wounds pure, and excluding micro-organisms. Latterly he had been using eucalyptus gauze; and owing to the great volatility of the eucalyptus oil, he had come to think that so much of it volatised during the manufacture and drying of the gauze as to lessen materially its protective power. Formerly he had used dammar gum as holding the oil more securely than ordinary resin, but dammar was very expensive. After some further trials with resin, he had felt justified in substituting the cheaper material, and for a while had seemed to get very satisfactory results; more recently, however, the results had proved far from satisfactory. He found further that the manufacturer had deviated from his instructions and had left the gauze exposed to the air for a longer period than formerly, and it was to be feared that much of the eucalyptus oil had evaporated away. He had little doubt that the untoward results he had just referred to were due to imperfections in the manufacture and quality of the gauze he had been using. Thus he had been led to a reconsideration of the subject, and to a fresh appreciation of the disadvantages of volatile substances. They doubtless had many advantages, but also very many disadvantages; thus, dressings became less and less antiseptic the longer they were worn, and they were also much at the mercy of the manufacturers. He had been accustomed to regard one week as the limit for a dressing to remain serviceable, but without definite grounds. On the whole, experience had shown that their results were under these circumstances satisfactory. Sir Joseph Lister then referred to some non-volatile substances—salicylic acid and iodoform—and pointed out their capabilities. He then referred to corrosive sublimate to which in late years especial attention had been drawn by Dr. Koch. He mentioned "the admirably conceived and the remarkably conclusive experiments" which Dr. Koch had conducted, and by means of which he had conclusively shown the remarkable "germicidal action" which the sublimate exerted on all forms of low organisms, including the bacillus anthracis, the spores of which were among the most resistant. He (Koch) had ascertained that a solution of sublimate, 1-20,000, was adequate to absolutely destroy the vitality of the spores of the bacillus anthracis. Koch had shown that other fluids were capable of arresting the growth of the spores so long as the spores remained in these fluids, but on withdrawing them and placing them in cultivation fluids, they subsequently developed. This "inhibitory" action was all that was required in antiseptics for wounds which were free from organisms, and the dressings required would have to be so designed as to prevent contamination from without of the discharges soaking into the dressings. Corrosive sublimate had already been extensively used as a surgical dressing in Germany, chiefly in the form of "wood-wool," that is pine wood reduced to shreds by suitable machinery, and impregnated with ½ per cent. of the sublimate. It was a very unwieldy form of dressing, on account of the bulk required. He had, therefore, turned his attention to the subject, with the view to the preparation of a more strongly impregnated dressing. He had used in one case

gauze containing 1 per cent. of sublimate; after the operation the wound was covered with a piece of protective, soaked in a 1-500 solution of sublimate; over this the gauze, and over this again an abundant eucalyptus dressing. On removing this, he found considerable vesication of the skin beneath the protective, and also on the arm where the perspiration had moistened the dressing. But the wound finally healed without the formation of any pus. This irritation of the skin, however, showed that the sublimate was a double-edged tool; and he had since turned about for a means to obviate the disagreeable effects. After carefully considered experiments, he found that corrosive sublimate formed with serum of the blood a compound which retained the antiseptic properties of the corrosive sublimate. Under such circumstances it was not an albuminate of mercury in a chemical sense, but an albuminate of the compound corrosive sublimate; and this was a matter of great interest to the surgeon; for it was not only innocuous as regards the skin, but thoroughly antiseptic in its properties. Thus the discharges from a wound in passing through a sublimate dressing became associated with, but not precipitated by, the contained sublimate; and the sublimate in this way was rendered very much milder in its action, and could, therefore, be applied in a more concentrated form. Sir Joseph found that with blood serum, 1 part in 70, or in 50, or in 30, it was perfectly amalgamated, and when dried gave off no deposit or crystalline separation whatever; it was free from smell, and applied to the skin was quite unirritating. The question of course had occurred to him how far this new compound could be relied upon as an antiseptic. He detailed a number of experiments testing its antiseptic powers, and comparing it with other well known antiseptics, and he had found it thoroughly trustworthy and quite equal to freshly-prepared carbolic gauze. French charpie, made of old rags, might be saturated with the solution, and would then form a very efficient and cheap dressing. If serum were treated with a certain proportion of sublimate, not sufficient to make it solid, it could be kept for an indefinite time. Perhaps one day sublimated serum might come to be an article of commerce, to be used in hospital and private practice. Perhaps even, dried and powdered, it might come to be mixed with vaseline, and used as an ointment, or be scattered over wounds as iodoform powder was used at the present time.

THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, OCT. 9TH, 1884.

JONATHAN HUTCHINSON, F.R.S., President, in the Chair.

Prevention of Blindness.

THE SECRETARY read a letter which had been received, stating the steps which the Local Government Board for Ireland had taken in response to the resolution passed by the Society on June 5th, 1884, and transmitted to him. A circular letter, calling attention to the subject, had been addressed by the Secretary of the Local Government Board for Ireland to the medical officer of each dispensary district, to the midwives of each district, and to the clerk of each union.

Central Choroiditis with Good Vision.

Mr. NETTLESHIP showed a drawing of the case. The choroid over the whole of the yellow-spot region was superficially atrophied, and to a great extent covered by large densely black patches of pigment. The retinal vessels were normal, and the optic disc healthy. There were a few detached patches of pigment beyond the yellow-spot region. Vision was $\frac{20}{20}$ fairly, and 1 J. No scotoma could be made out, but the visual field was defective at the periphery. The appearances were those of superficial choroiditis, with great proliferation of the pigment-epithelium, and infiltration of some of the pigment into the retina. Such changes, involving the fossa centralis, would seem to be incompatible with such good vision as the eye preserved. Two alternative explanations were suggested: either that a slightly eccentric fixation had been acquired, or that the choroiditis had in reality occurred in the deepest larger layers of the choroid. But the fact that the pigment-masses lay in front of the large choroidal vessels militated against the latter view.

Mr. WAREN TAY asked if any cause could be assigned.

The PRESIDENT noticed the remarkable extent and severity of the disease involving the yellow spot with excellent vision.

Dr. ANGEL MONEY mentioned a case of disease at the yellow-spot region with good vision, which had been under the care of Mr. Tweedy.

Mr. NETTLESHIP thought the changes were most probably due to hæmorrhages, and he referred to another case, which had been under Mr. Hutchinson's care at Moorfields, where vision was also remarkably good.

Pseudoglioma: Death from Meningitis.

Mr. NETTLESHIP said that, in a previous paper, attention had been drawn to the frequency with which attacks of destructive ophthalmitis, simulating glioma, coincided with some general illness, often presenting pyæmic symptoms. The patient, a girl aged two years and a half, died of cerebro-spinal meningitis, secondary to purulent otitis. The disease of the eye, which was purulent irido-cyclitis, with suppuration of the vitreous, was most probably pyæmic, as was also the meningitis. The case threw some light on the rare cases in which meningitis occurred after excision of an acutely inflamed eyeball; both occurrences might be set down as local pyæmia, or spreading phlebitis. If, however, pseudoglioma in children were really the result of a pyæmic process, it was necessary to assume that children recovered from pyæmia with considerable frequency. The previous history of the patient in this case was negative. She was taken ill on March 2nd, shivered, vomited, and had some diarrhœa. The eye was noticed to be inflamed on March 3rd, and she was brought to the hospital on March 5th; when purulent inflammation of the left cornea was noted, and a mass of semi-transparent lymph blocking the pupil, and lying in flocculi in the anterior chamber. On the following day, the temperature ranged between 102·2° and 103·6°, and there was a small firm swelling over the head of the right fibula. Next day, both knees were slightly swollen and tender; the lymph was disappearing from the pupil and the anterior chamber of the left eye; there was marked papillitis of the right eye. The left eye subsequently shrank rapidly, and the patient died of exhaustion six weeks after admission. The necropsy revealed no important lesions, except in the brain and spinal cord. The crura cerebri, optic tracts, and chiasma, the pons, and fore part of the cerebellum, were covered with thick yellowish-white lymph; the roof of the middle ear on the right side was yellowish and softened, the membrana tympani was softened and partially detached, and the middle ear and mastoid cells contained much thick pus. The whole posterior half of the cord, from the upper dorsal region downwards, was covered with yellowish lymph.

The PRESIDENT asked if there was no proof of phlebitis; he had not gathered whether the history of ear disease was definite.

Dr. SKINNER asked if there had been any affection of the semi-circular canals.

Dr. ANDERSON referred to the frequent occurrence of cerebral abscess in ear-disease without any discoverable tract between the two points.

Mr. NETTLESHIP, in reply, said that the disease was very marked in the right ear; there was some thick yellowish muco-pus in the left ear, as to which he would not like to express a positive opinion.

Amblyopia and Nervous Depression from the Vapour of Bisulphide of Carbon and Chloride of Sulphur.

Mr. NETTLESHIP said that he had recently met with a case of amblyopia in a young man, aged 20, who had been engaged in the "curing-house" for about nine or ten months. After about three or four months of the work his health began to fail; he felt great weakness in all his limbs, and a liability to nausea; for some weeks before admission he had severe headache, and about three weeks before admission his sight became, apparently suddenly, so bad that he could not see people on the pavement; vision grew worse, and when admitted vision was $\frac{5}{70}$ with each eye, and 12 J. He stated that he saw worst in bright daylight; the fields of vision were not curtailed. After admission, improvement commenced, and on the nineteenth day vision was $\frac{20}{20}$ on the right, and $\frac{10}{70}$ on the left; the optic discs were pale, and there was a filmy haze over them; the neighbouring retina showed the "watered silk" appearance. He returned to work in the india-rubber works, but not in the curing-house, on leaving the hospital on August 25th. On October 6th sight was a good deal improved (vision was $\frac{20}{50}$ and 6 J); there was a large and ill-defined scotoma for red, a little to the outer side of the centre of each field; the scotomata were quite symmetrical. The optic discs were paler and clearer. He was well and strong, and more cheerful. In the manufacture of certain kinds of india-rubber, the material was "cured," vulcanised, by being passed through a bath consisting of bisulphide of carbon (thirty-two parts) and chloride of sulphur (one part); a strong vapour arose during the process, and the work was believed, by the men, to be unhealthy. Dr. Ernest Fuchs, Professor of Ophthalmology, in the University of Liege, who had happened to see the above case, had communicated to Mr. Nettleship the notes of a similar case. The patient was a young girl, aged 23; she was pale, thin, and weak; the muscles of the thenar eminence, and the interossei muscles were atrophied; sight was very imperfect; right vision was $\frac{2}{60}$, left $\frac{4}{60}$; there was slight neuritis of each eye; the optic discs were pale and hazy, but not swollen. The patient stated that since she began working with the bisulphide of carbon bath she had suffered from weakness of the limbs, coldness, formication, headache, giddiness, and loss of appetite. She was admitted into the hospital, and slowly improved under treatment with strychnine administered hypodermically. About eight weeks after admission, it was noted that there was a small well-defined central scotoma for red in each eye. Sixteen weeks after admission sight had much improved, vision was $\frac{5}{18}$. About seven months after admission, the scotoma had disappeared, and right vision was $\frac{5}{12}$, left $\frac{5}{9}$. Eight months and a half after admission, the optic discs were paler than normal, but sharply defined; the atrophy of the interossei and thumb-muscles had disappeared; vision had improved; right vision $\frac{5}{9}$, left $\frac{5}{6}$. Mr. Nettleship also referred to a similar case which had been recorded by Dr. Alexander Bruce. In this case the man lost his sight rapidly after an unusually prolonged exposure to the fumes, but there had been previously, for some months, great nervous and muscular weakness; there were no ophthalmoscopic changes, and the patient entirely recovered in about four months. Dr. Bruce had also recorded two other cases of poisoning by bisulphide of carbon, in which the same weakness and depression were noticed, but not amblyopia. The cases were of great interest in Mr. Nettleship's opinion, as illustrating in a new way the peculiar liability of the optic nerves, as compared with other nerves of special sense, to be damaged by influences which depressed the whole nervous system.

The PRESIDENT asked whether any enquiry had been made of the masters to ascertain whether they were aware of the injurious nature of the process of "curing" with bisulphide of carbon and chloride of sulphur, or as to the numbers engaged and the number who suffered.

Mr. NETTLESHIP said that there were only two men in the curing room, the other man was older and was fairly healthy. Only certain kinds of rubber were thus vulcanised, the best sorts of black india-rubber tubing.

Messrs. Nettleship, Gunn, and Adams Frost were requested to act as a committee to make an investigation into the question.

Remarks on three recent cases of Detachment of the Retina.

Dr. W. A. BRAILEY read a paper on the treatment of recent detachment of the retina founded on three cases. The first patient was a man, aged 43. The eye was previously normal, judging from the history and from the condition of its fellow. A complete detachment of the retina had apparently occurred fourteen days earlier, during a severe fit of coughing. Gradually perception of light returned, till, on admission, he could count fingers at a foot. When he presented himself six days later for treatment by scleral puncture, vision was $\frac{6}{24}$, and the field very much larger than before. Indeed, no detachment was now to be made out, but there were large opacities in the vitreous, especially near the seat of detachment. This improvement was maintained when last seen (three months later). The second case was a boy, aged 12. The retina was detached at its upper and outer part, probably after a blow from a stone three months earlier. The lower and inner part of the field was wanting, the defect passing the horizontal line above and the vertical meridian below. It just embraced the fixation-point. The retina so far reapplied itself after treatment by scleral puncture, rest, atropine, and jaborandi, that, except for some little peripheral limitation, corresponding to the seat of the previous detachment, the only absolutely blind part was a band or track extending directly inwards to the fixation-point, which it involved. This band corresponded to the lower edge of the detachment as first seen ophthalmoscopically; but that edge of the retina lay, when the patient was last seen, in a flat fold. Two weeks later the improvement was still maintained. The third case was that of a man, aged 40. The defect first appeared six months before admission, when he was suffering from a violent cough. It gradually increased till September 25th, when he was sent to Guy's Hospital, by Dr. Reynolds, of High Wycombe. Then the inner half of the field was wanting, the defect extending beyond the fixation-point and vertical meridian above, but not quite so far below. He was able only to count fingers at 3 feet. After scleral puncture, atropine, jaborandi, and eight days in bed, the field was conspicuously enlarged, the fixation-point being now free. Vision was $\frac{6}{60}$; nor could any detachment be made out any longer; but there were numerous floating opacities in the vitreous, especially near the seat of the detachment. Dr. Brailey remarked that since in at least two out of the three cases, the eye had been presumably normal, the detachment would appear to have occurred in association with a healthy vitreous. He found it impossible to understand how either a blow or any violent pressure on the globe could cause a detachment under such circumstances without rupture of the retina, of which he had not been able to find indications in these cases. The rupture would, he thought, be more reasonably attributed to the recoil of the tunics than to the original pressure. The value of the treatment was demonstrated in the third case, where the affection was progressing up to the time of operation. Though valuing puncture, rest, and atropine, he was not convinced as to jaborandi. He thought, in face of these two cases, that a simple puncture, if large enough, was quite as effective as any more complicated process; and, indeed, that it excelled the latter in rendering anæsthesia unnecessary. A bent iridectomy-knife, 5 millimètres wide, seemed to him to be the most effective instrument.

Mr. NETTLESHIP referred to a case of a man, the subject of myopia, in whom a retinal detachment occurred very rapidly. In this case he tapped, and made the patient lie on his back. Great improvement followed, and the operation was repeated with further improvement, but two months later he came back as bad as ever, and the other eye had become similarly diseased. He had tapped about a dozen eyes, but this was the only one in which any even temporary improvement occurred.

Dr. BRAILEY said that two of his patients were not myopic, the third had mixed astigmatism.

Night-blindness.

Mr. W. ADAMS FROST read notes of two cases of night-blindness. The first was that of a painter, aged 34, who had had six attacks of night-blindness, each coming on

whilst he was painting white houses in the spring, the weather, except on two occasions, being very bright. Each attack lasted about a fortnight, and disappeared under treatment by rest, tonics, and the use of eserine. Vision during the attacks was $\frac{2}{3}\frac{1}{0}$, and the visual field was normal. The patient was somewhat anæmic, but there was no history of any illness. He was in receipt of good wages, and had not been underfed. He had never had any symptoms of lead-poisoning, nor had he ever been out of England. The second was that of a lamplighter, aged 19, who for six weeks had been engaged in painting the lamp-posts on country roads in excessively bright weather. After three weeks painting, he suffered severely from pain and lacrimation. Three weeks later, he suddenly found that he could not see one evening, and this inability to see in a dull light continued until his visit to the hospital two weeks later. His vision then, in ordinary daylight, was normal ($\frac{2}{2}\frac{0}{0}$ and 1 J), visual field normal. He presented no signs, and had had no symptoms of lead-poisoning. He was treated with tonics and instillation of eserine, and recovered in about five weeks. A month later he had a relapse, from which he recovered in about a fortnight. Since the previous attack he had been following his ordinary occupation of lamp-lighting.

Mr. W. H. Jessop asked Mr. Frost whether he had noticed any patches on the conjunctiva in his cases, and said that, in three cases coming under his own notice lately suffering from night-blindness, they were present in both eyes, looking like small bubbles of air, and easily scraped off. On these dry patches were numerous bacilli of uniform size; these facts had been noted by Snell and others. Two of the cases were under Mr. Nettleship's care at Moorfields, and the third was under Mr. Jessop's care at the Paddington Green Children's Hospital. Two were children underfed, one nearly starved, and the third case was an adult man, suffering from albuminuria. Artificial cultications from two cases showed the same characteristics, especially as to slowness of growth. In the three cases, the dry patches disappeared at the same time as the night-blindness.

Mr. Frost replied that there had been no patches in his cases. He asked whether the night-blindness was functional in Mr. Jessop's cases, or whether there were other changes.

Action of Hydrochlorate of Cocaine on the Eye.

Mr. Arthur Benson (Dublin) contributed some observations on the action of hydrochlorate of cocaine on the eye. He had experimented with a 2 per cent. and a 4 per cent. solution on himself and about twenty-five others, and found that anæsthesia of the cornea and conjunctiva was produced by a drop instilled into the conjunctival sac; that this anæsthesia came on almost immediately after application, and lasted only about five or six minutes, when it gradually but rapidly faded away. So far as his experience went, the drug was of no appreciable assistance in operations, the anæsthesia being too imperfect. In most cases, it produced slight paresis of accommodation, with partial dilatation of the pupil for about half an hour, followed by contraction of the pupil and spasm of accommodation, which again gave way to the normal condition of parts in about one and a half or two hours. He had extracted cataract, done iridectomy and some minor operations with its aid, but found no appreciable benefit except in the most trivial cases. The anæsthesia was very transitory, and it was therefore necessary, in order to obtain the best results, to use the drug very shortly before operating.

Mr. Marcus Gunn had used hydrochlorate of cocaine in three cases, scraping the cornea, tattooing, and needling, and had come to the same conclusions as Mr. Benson.

Mr. Nettleship had tried it in two cases; it had produced marked anæsthesia without any inconvenience, and he suggested that, if the drops were frequently instilled so as to maintain the effect, the drug might be practically useful.

Living Specimens.

Dr. W. A. Brailey: 1. Detachment of retina of left eye; decided benefit after scleral puncture. 2. Optic neuritis with increased tension (relieved by eserine), associated with numbness of the face and recent severe pains in the head; some loss of power of the left side, and slight albuminuria. Vision was deteriorating.

Card Cases.

Mr. Nettleship: Drawing of new formation of pigment on the front of the iris.

Mr. Marcus Gunn: Peculiarly shaped eyeball. Vision was myopic (− 4 D), while the inner part of the fundus was hypermetropic (+ 3 D).

PATHOLOGICAL SOCIETY OF LONDON.

Tuesday, October 21st, 1884.

George Lawson, F.R.C.S., Vice-President, in the Chair.

Abscess of the Liver.

Dr. F. C. Turner brought forward a case of tropical and multiple abscesses of the liver. The patient was a seaman, aged 34, who had been suffering for some time from diarrhœa, with slimy motions, and had an abscess in his liver tapped when at Aden, five ounces of pus being removed with great relief. There was, however, a return of the dysenteric symptoms, and when he came under observation his motions were loose, slimy, and contained blood; the liver was enlarged but not tender, he was much wasted. He died in the course of a couple of days, and at the *post-mortem* there was found extensive disease of the mucous membrane of the colon with sloughing of the walls in places, and perforation with escape of the intestinal contents into the peritonæum. The mucous membrane of the lower portion of the ileum was likewise necrotic. At the anterior part of the right lobe of the liver was a large abscess, and a smaller one in the middle of the left lobe. These had each a thick fibrous capsule, and their lining membrane was smooth; there were firm adhesions to the diaphragm. On the surface of the right lobe were numerous small abscesses. The lungs were adherent to the diaphragm. The kidneys were enlarged and one contained an abscess. The points he specially noted about the case were the limitation of the multiple abscesses to the right lobe which he considered to result from some condition unfavourable to its nutrition, and that he attributed to the impediment to its blood supply, by the projection of the large abscess against the hepatic artery, displacing its cystic branch. Local conditions he believed were of the chief importance in determining these abscesses. The infective intestinal condition played an essential part. He thought that their formation might be due in part to traumatic causes, rupture of the liver being possibly produced.

Dr. Carrington also brought forward a case of hepatic abscess. The patient was a Portuguese, aged 22, who had rigors, fever, wasting, and a swelling under the right ribs, with more or less pleurisy. An incision into the swelling let out some two or three pints of pus of that grumous character peculiar to abscess of the liver. The man did not improve much and ultimately died. The liver was found to be much enlarged, containing two large abscess cavities, one of which had been opened and was much contracted, containing about a fourth of a pint of pus; the other, unopened, held a like quantity. Besides these, the substance of the liver was riddled with small abscesses, some in an early stage, not softened. The walls of the large abscesses were very thick and they were evidently of old date. The right pleura was adherent to the diaphragm. There was dysenteric ulceration of the large bowel. The concurrence of large with multiple abscesses was rare. If the large abscess was due to absorption form the intestine, why was there such a difference between it and the small abscesses? If the small abscesses were pyæmic what was the source of the poison? They occurred in every part of the liver, but there was no disease of the portal system or of the hepatic artery, was it possible that the lymphatic system was the cause of it?

Dr. Ewart had recently had two patients under observation, one of whom recovered after a single aspiration, the other, whose pleura was aspirated several times, died after

a relapse of his dysentery, and a large abscess which had burst into the pleura was found, as also numerous small abscesses, many partially softened. The colon contained many ulcers of pale, sodden, waxy, necrotic aspect, very like that of the small abscesses. He thought there was some direct connection between the lesions of the intestine and the small abscesses in the liver by means of the portal vessels.

Dr. CURNOW said, that since he had been connected with the Seamen's Hospital, there had been no case of abscess of the liver in which there was not dysentery at the time or shortly before. He believed that all tropical abscesses were of this nature, and asked if *post-mortem* examinations had been made in the cases where dysentery was said not to have been present. The cases shown confirmed that opinion and supported the doctrines of Budd in opposition to those of Murchison.

Dr. WILKS observed that the opposite view was held very strongly by those of Indian experience, notably by Sir Joseph Fayrer. His own experience had always found the two co-existent: the converse, however, did not hold, ulceration of the intestine was often found without hepatic abscess. Perhaps some other element was essential, and that might be climate.

Hæmophilia.

Dr. WICKHAM LEGG had recently had a fatal case of this disease in a boy, aged 13, who died of epistaxis; he had swellings of his joints and bruised very readily. His brother had died of bleeding. Dr. Klein had examined the vessels and tissues, and had found nothing. This made a total of six cases in which the examination had been made; in four no lesions could be discovered, in one there was also lichen ruber and icthyosis, so that, being so complicated, it had better not be counted, and Dr. Percy Kidd's case was the only one in which any lesions in the vessels had been found. The joints were also examined, this being only the fourth case in which that had been done. The changes in the joints appeared to occur in the following order. In the first stage there was extravasation of blood only; in the second the synovial membrane was coloured rusty, and the cartilages were slightly eroded; in the third the synovial membrane was of a deep red and the cartilages were deeply eroded and destroyed.

Dr. THEODORE ACLAND had also recently examined the body of a boy who died from hæmophilia. He had had a lacerated wound of the tongue, the bleeding from which could not be stopped; he had been liable to petechiæ and bruises, and his brothers were bleeders, the sisters, three in number, being healthy. The maternal grandfather of the patient's father was known to have been a bleeder. The blood examined after death was pale and watery, and showed an increase of white corpuscles. The vessels were perfectly normal. The parotid and submaxillary glands showed an increase of deeply staining nuclei in their substance, and some blood was found in the museles of the tongue. In the thymus were seen spheroidal masses a, good deal larger than the striated corpuscles of Hassell, bounded by flattened elongated cells containing epithelioid cells surrounded by the lymphoid cells of the gland; the gland itself was enlarged. He could offer no explanation as to the significance of these bodies, perhaps they represented a stage in the evolution of the corpuscles of Hassell. He had only found them in one other case out of a considerable number. That was a case of pelvic abscess, but the patient had previously had purpura.

Purpura.

Dr. WICKHAM LEGG detailed a fatal case. The patient was a man, aged 36, who had had syphilis two years previously; he had been intemperate formerly. For the last six months of his life he had been ill-fed, and had eaten very few vegetables. A purpuric eruption came out, and one month before his death it became very abundant; he also had vomiting and diarrhœa. When he came to the hospital, there was well-marked purpura and joint swellings. He got better, but then had a recrudescence of his purpura, the spots coming out at first like urticaria, hæmorrhages later taking place into the wheals; they spread all over the body from one elbow in a very short space of time. At the *post-mortem* the intestine, from within a few feet of the jejunum, was ulcerated throughout. This however was not uncommon in purpura. The skin, on microscopical examination, showed a large amount of corpuscles in all its layers, especially in the lower layers of the epidermis, and around the sweat glands and hair follicles. There were also masses of them corresponding to small extravasations. In the papillæ and under the epidermis the vessels were in many cases dilated. The arteries of the subcutaneous tissues were much thickened. In the intestines there were hæmorrhages into the villi, just as into the skin. As to diagnosis, against scurvy there was the absence of spongy gums; and the fact that though put upon lemon juice and fresh vegetables he did not improve. Against alcoholism was the fact that the liver was healthy. In favour of rheumatism it might be said that there was swelling of the joints, though *post-mortem* no disease was found in them; and the hæmorrhages had been associated with urticaria, though the case could not be said to have been one of purpura urticans. Against the idea of rheumatism was the fact of the disease of the vessels, which was in favour of syphilis being the cause of the disease, the view at which he had arrived. Ever since 1881 he had been examining the blood of patients with purpura for micro-organisms, but had only found them on three occasions; there were none in the case shown that evening, either in the blood or in the skin after death.

Dr. BUZZARD was clear that this was not a case of scurvy. He had never seen such an eruption in connection with syphilis, but had had a very similar case where the eruption was due to alcohol.

Mr. HORSLEY, referring to Dr. Acland's cases, confirmed the opinion that the peculiar bodies in the thymus were associated with endarteritis; every variety of size could be seen. He believed that the appearances were due to a degenerative proliferation of the endothelium carried so far that the original cells lost their outline. There was some resemblance with psammoma.

Dr. O'CONNOR asked if there had been any local peculiarity about the joints, and made some further remarks on the cases.

Dr. PERCY KIDD regretted that no changes had been found in the vessels; in the case which he had examined there had been distinct changes in the veins and capillaries in remote parts. He thought that changes in the vessels would explain the presence of the smaller bodies in Dr. Acland's case, but not the larger ones.

Tabes Dorsalis, with Perforating Ulcer of the Foot.

Mr. PEPPER and Dr. SILCOCK showed the foot and specimens of the nerve centres from this case. The patient was a woman, aged 60, who denied syphilis or alcoholism. She had suffered from numbness of the toes of the right foot for two years, and this was followed by the formation of a painful corn on the sole of the right foot, which she picked off, causing it to bleed, and her foot did not heal up afterwards. There was no ataxy, the patella reflex was absent, the muscles were flabby, and there was partial ptosis. Her foot was acutely inflamed, and after temporary improvement it was amputated. Four days later the flaps sloughed, and from then matters went badly; bedsores formed, and black sloughs even where there was no pressure, the internal saphenous veins became plugged, and she died. The lower end of the fibula was found to be eroded and carious, and the tibia also to a less extent. The vessels of the brain were atheromatous, and the posterior root zones of the cord showed grey degeneration to the naked eye. Microscopically the cord was altered in its whole length all round the grey matter, this being involved in places. The posterior columns of the white matter were most affected. Numerous ragged cavities were found, both in the white and grey matter, containing a homogeneous hyaline material, and were evidently the result of recent inflammatory softening. The blood vessels were notably thickened, there were hardly any healthy nerve fibres in the posterior root zones. The anterior and posterior roots were abnormal, the myelin being broken up into masses with dark irregular margins, the nuclei of the nerve fibres were increased; the changes were more marked in the posterior than the anterior roots. The anterior and posterior tibial

nerves were in a more advanced state of disease and contained hardly any healthy nerve fibres. The internal popliteal showed similar changes, but less marked and more recent. They did not know of any case having been recorded where the changes were so extensive and so recent. He thought the disease of the cord was the primary thing, then came the injury to the foot, and the tissues having little recuperative power the ulcer was formed. The late changes were due to the acute degeneration of the posterior nerve roots.

Dr. WILKS objected to the use of the word tabes for this disease, it was a word that was much too commonly used.

Dr. BUZZARD asked whether the peripheral nerves had been traced in their whole length. Some French observers had found an intervening healthy portion between disease of the cord and disease of the peripheral nerves. These cases suggested the possibility that thickened arteries had a good deal to do with the commencement of changes in the peripheral nerves.

Alcoholic Paralysis.

Dr. W. B. HADDEN showed specimens from two cases. The first was a woman, aged 33, who had been a heavy drinker. She had had loss of memory for three months, and ten days before her death came for loss of power in legs and œdema. She had retention of urine, and was noisy and delirious. There was no power in her legs, but no tremor, the reflexes were absent, and the muscles of the legs did not respond to the electrical current. The liver was enlarged. At the *post-mortem*, generalised tuberculosis was found, and ulceration of the intestine. The medulla and brain were normal, also the spinal cord. The second patient was aged 42; her father had died of diabetes. She had suffered from delirium tremens; she could not walk alone. There was no loss of power over bladder or rectum. Her limbs were cold, the arms wasted; there was drop wrist, the extensors being more affected than the flexors; the interossei were affected. The reflexes were absent, the muscular sense was normal, there was no anæsthesia of the trunk. The legs were emaciated, drawn up, and she could not bear to have them touched. At the *post-mortem* examination there was some atheroma of the aorta and a little broncho-pneumonia. The liver was cirrhotic, the brain healthy, and the cord, on microscopical examination, was also healthy. The sciatic nerve showed the tubes much reduced in size, and the medullary sheath and axis cylinders reduced also; there was no segmentation of the myelin. There was some thickening around the nerve tubes. The right gastrocnemius showed absorption of the muscular fibres with interstitial fat in considerable amount. Thus in both cases the cord was healthy, confirming the view that the disease was one of the peripheral nerves. In another case he had found atrophy of the hypo-glossal nerve. The association of cirrhosis of the liver and general tuberculosis was found to be common in these cases.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, OCTOBER 8TH, 1884.

H. GERVIS, M.D., F.R.C.P., President, in the Chair.

THE following were the specimens shown:—

(1) Two cysts of the broad ligament filled with tarry fluid removed by abdominal section—Dr. MALINS.

(2) The ovaries and tubes removed from a case of pyo-salpinx by operation—Dr. MALINS.

(3) Tumour of the upper part of the vulva, removed by ecraseur—Dr. POTTER.

(4) Pelvis from a case of mollities ossium—Mr. GRIFFITH.

(5) Cyst of the uterus—Mr. GRIFFITH.

(6) Ovarian tumour—Dr. W. DUNCAN.

(7) Neugebauer's intra-uterine glass tube—Dr. BARNES.

(8) Glass female catheter—Dr. BARNES.

On Post-partum avulsion of the uterus, with a case followed by recovery.

A paper with this title was contributed by Mr. J. HOPKINS WALTERS. In April, 1882, Mr. WALTERS was called by Mr. COCHRAN, of Caversham, to a patient, aged 22, in her third confinement. She had been attended by a midwife, who, after the birth of the child, finding the placenta did not come away, pulled at the cord, which broke at its attachment. She then introduced her hand and tore away the whole of the uterus with the right ovary and fallopian tube, portions of the round ligaments, left fallopian tube and ligament of the left ovary attached to it. Mr. Walters saw the patient 21 hours after the accident, and found her under the influence of opium, and somewhat recovered from severe collapse. A large quantity of omentum protruded from the vulva, and in the upper part of the vagina was an enormous rent. Mr. Walters ligatured and cut away the omentum, which was cold and badly bruised at the level of the vulva; the parts were washed with solution of permanganate of potash, and a pad of salicylated wool applied. The opiate was continued; catheterisation ordered every eight hours, and the diet limited to milk and beef tea. The patient did well until the fifth day, when she was seized with shivering, her temperature fell to 97·4°, and pulse rose to 170. Mr. Walters irrigated the vagina with solution of permanganate of potash, and finding that the vaginal fundus had well closed round the omental stump, afterwards used a solution of carbolic acid, quinine in large and frequent doses was combined with the opiates and the vagina syringed every eight hours. On the 28th day the patient was able to drive five miles to the Royal Berkshire Hospital, where she remained under Mr. Walters' care until the beginning of July, when the omental stump had frittered away, and the vaginal wound was perfectly cicatrised. At the present time, two-and-a-half years after the mutilation, the patient is in perfect health and attending as usual to her ordinary occupations. After a diligent search Mr. Walters has found reports of 36 cases of accidental removal of the puerperal uterus, of which 14 recovered. Of all these only 3 were without doubt unattended by previous inversion of the uterus. Having regard to the medico-legal aspect of these cases, Mr. Walters draws an important distinction between the accidental removal of the previously inverted uterus, and of the uterus that has not undergone inversion, on account of the possibility of uterine separation through spontaneous rupture. According to present experience inversion of the uterus is not found to co-exist with rupture either of that organ or of the vagina; and where it is shown that the uterus was inverted before being torn away, it becomes tolerably easy to estimate the degree of criminal responsibility attaching to the attendant. On the other hand, where it can be proved that the uterus was never inverted, it is impossible to assert that the separation of the uterus was wholly due to violence and not contributed to by a spontaneous rupture through the uterine or vaginal walls. Mr. Walters quotes cases and authorities to prove the occasional insidious occurrence of uterine rupture, the suspension of symptoms, and the completion of child-birth in spite of it, in some cases independently of manual interference and without any disproportion between the maternal passages and the child; and concludes that in giving evidence in such cases these facts should be most carefully remembered.

Case of Rupture of the Uterus.

A case of this accident was contributed by Dr. HORROCKS. M.B., aged 34, was in her ninth pregnancy, at the eighth, fifteen months ago, twins were born. In her ninth pregnancy labour came on at full term, and nothing abnormal was noticed when she was first examined; the os was dilated and the membranes bulged through it; presentation vertex. Two or three severe pains came on following one another very quickly, and the vertex appeared at the vulva covered by the unruptured membranes. These were immediately ruptured, and the child (alive) was driven entirely outside the vulva by the powerful parturient action which had at the same time caused a rupture of the uterus running nearly longitudinally but inclining obliquely downwards to the left, and involving part of the body, the whole of the cervix, and a portion of the upper part of the vagina. There was not any external hæmorrhage, and the patient seemed all right for about ten minutes when she became faint and collapsed, vomiting some dark brownish fluid. The placenta was expelled by the uterus after injecting hot water into

the vagina. The author arrived soon after this and found the rent already described. The patient died before anything could be done. There were only a few clots in the pelvis, death having resulted from shock.

The PRESIDENT remarked on the value of Mr. Walters' paper both from the forensic and obstetric point of view. He did not quite gather in what way the projecting omentum had disappeared, and he would also like to ask Mr. Walters whether examination had detected any undue softening of the uterine tissues.

Dr. AVELING asked if any penal action had been taken against the midwife. He thought the case another strong proof of the necessity of passing a Bill to ameliorate the present ignorant and dangerous class of midwives.

Dr. BRAXTON HICKS thought that in Mr. Walters' case there was already a rent of the junction of the uterus and vagina, and that the midwife had passed her hand through the rent in mistake for the flabby os uteri, had pulled down the omentum in mistake for the placenta (an error he had seen before), and then the uterus. Rupture of the uterus and vagina is produced by the contractions of the uterus, and bearing down pains are not essential. When an obstacle occurs to the head of the fœtus after its escape from the os, the uterine force is expended on the uterus and upper part of the vagina as a kind of recoil. When a laceration has once begun, but little force is needed to extend it, and when the fœtus is placed nearly symmetrically, the vagina may be torn all round. The broad ligaments are not capable of resisting much force, nor are the round ligaments. A very slight force will free the uterus after the severance of the vagina. In the case of Popperwell's, alluded to in the paper, he was assured privately that no force had been used. He did not think that in simple removal of the placenta from a sound uterus and vagina it would be possible to tear the uterus away. After the uterus has been torn away from the vagina, and most of its attachments, bearing down might conceivably complete its detachment and expulsion.

Dr. CHAMPNEYS said that the uninverted uterus might conceivably be torn away by inserting one or more fingers through the cervix, retroverting the fundus, hooking the fingers backwards, and pulling.

Dr. BARNES confirmed the view taken by Dr. Hicks, that the uterus had the power, by virtue of its *vis in situ*, of contracting and pulling on the vagina and broad ligaments, even apart from any central nervous supply, for a short time at least. Expression of the placenta (practised by the midwife in Mr. Walters' case) requires caution, and may produce inversion. The proper way is to use both hands, and press the anterior wall against the posterior.

Dr. HERMAN said that in any future case of the kind in which evidence on the subject might be required in a law court, all available facts would be found in Mr. Walters' paper, which had shown that in certain conditions avulsion of the uterus is effected with great ease, and had been frequently effected by qualified men. Remembering the rarity of these cases, and the sudden emergency which arises, a medical man should not be hastily condemned as a criminal, and still less a midwife.

The PRESIDENT said that while avoiding hasty condemnation in any individual case, in the absence of a knowledge of all the facts, he could not but regard the avulsion of a whole uterus, inverted or not, as a very grave and responsible proceeding.

Dr. GRIFFITH referred to a case in which a fibroid had been mistaken for the placenta; post partum hæmorrhage had induced the practitioner to use some force, which might have inverted the uterus.

Dr. BRUNTON thought that the removal of an inverted uterus was, in his opinion, the sign of incompetence, or even criminality, seeing that the absence of inversion can be easily proved by abdominal palpation of the parturient uterus.

Dr. BARNES replied that the uterus might be, by natural efforts, or aided by slight and not culpable manipulations, entirely detached. Casper mentions a case in which the broad ligaments even were torn through by spontaneous force. When the uterus was lying loose, the hand, introduced to remove the placenta, might easily bring it away, and the practitioner be blameless. Those of largest experience would judge most mercifully.

Mr. WALTERS, in reply, said that the omentum, after becoming highly vascular, slowly disintegrated by molecular death, and disappeared. He did not receive the uterus until many days had elapsed, and consequently no microscopical examination of its fibres was made. It looked however, perfectly healthy and of quite average thickness throughout its walls. No penal action was taken against the midwife, and he was thankful this was so, as, although he still believed great violence was used, he should have given much stronger and positive evidence against the woman than subsequent study of the histories of these cases would have justified. Comment had been made on the various ways in which, during operative procedure, the uterus might be detached from its connections, but one mode had not been mentioned, viz., in the attempted introduction of the hand within the uterus either for turning or to remove retained secundines, the organ might be forced up and the tissues of the cervix or vagina, if friable, torn through. He would feel greatly obliged if Fellows would bring to his notice any account of similar cases not included in his paper.

GENERAL CORRESPONDENCE.

OVER-PRESSURE IN ELEMENTARY SCHOOLS.

[To the Editor of the Medical Times.]

SIR,—In the history of mankind each age has presented problems for solution peculiarly its own. Amongst several to which answers are sternly demanded at the present time are—(1) Is there really any "over-pressure" in our elementary schools? (2) If so, does this over-pressure result in any *permanent* injury to the juvenile portion of the community? To ask questions is always easy, to answer them often difficult, and the solution to the above queries is surrounded by difficulties of no ordinary kind. All children of a certain age, and over it, now go to school, and in such a number there must of necessity be some that are constantly ill or ailing; so that we must be carefully on our guard as to how we connect school and illness as cause and effect. Idle children too dislike school, and are only too ready to complain if by so doing they can get out of going there. Again, a large number of the poor are *always below par* from underfeeding and exposure; and their inability to withstand slight attacks of illness, which in their cases rapidly take on severe forms, may easily be placed to the account of "School Board pressure." After making full allowance for all this, however, I think there can be little doubt in the mind of any physician constantly engaged in the treatment of children's diseases amongst the poor, that the existing system of education, at any rate as regards the health of many children, is an exceedingly unsatisfactory one. My own experience goes to convince me that in a large number of instances, so-called "nervous" diseases are traceable to over-pressure at school. Under this head I would particularly mention chorea in almost every grade of mildness or severity, and a peculiar condition of twitching of single muscles, or groups of muscles, quite involuntary in their character. Insomnia, frontal headache, and the occurrence of cardiac palpitation are extremely common. I certainly am not of opinion that any amount of over-work *per se* would *produce* the dread disease tubercular meningitis; but am fairly assured that *given the constitutional tendency* to tubercle, over-pressure and worry may just turn the balance between quiescence and development, on the wrong side. There is one factor which I am convinced acts on our children with much ill-effect at the present time, and that is *dread of failure and of punishment*. This is ever hanging over the heads of the

weakest and most wretched, and the worry of this dread itself causes them to fail in learning, and results in punishment, which again produces fresh dread, and more punishment in its turn.

Whatever the result of this controversy may be, the public will most certainly soon demand some arrangement in our elementary schools, in which the amount of work expected from a child shall be in some way commensurate with its physical and mental powers. At present the great aim seems to be to get the children "on," that is merely to fit them for the higher standards at the earliest possible moment. Surely in this age of "progress" we are forgetting that knowledge and wisdom are by no means synonymous terms, and that cramming the young head with facts is not that "training of the mind," that instruction in the art of self-government, which in an age of competition and selfishness is so sadly needed; that prefcrence for others' welfare before our own, which, if rightly tended, developes into a noble life of self-sacrifice for the general good; the true "Nirvâna" where the spirit rests, the "land of the Leal."

I am, Sir, yours, &c.,

W. BARRETT ROUÉ.

Physician to the Bristol Hospital for Sick Children.

THE DANGERS OF DIPHTHERIA.

[To the Editor of the Medical Times.]

SIR,—The death of a useful member of the medical profession, brought about by his unselfish efforts to save the life of a pauper's child, calls to mind once more the question of the dangers of diphtheria, and of the means at our disposal for limiting the risks in dealing with them. First, as to the propriety of employing immediate suction to a tracheotomy tube, plugged with virulent membrane. Some doubt appears to exist as to whether it becomes the surgeon's *duty* to apply it when other means for the removal of such a plug have failed, and it is greatly to be desired that this point should be decided once for all by the arbiters of medical ethics. Assuming that no other means of suction were available than the direct application of the surgeon's own mouth to the wound, it can hardly be supposed that such a proceeding could ever come to be sanctioned as a part of a routine practice. But it appears to me that if proper means were provided whereby indirect oral suction could be applied in such a manner as would effectually prevent the entrance of any foreign material into the mouth, the practice might become not merely justifiable but perfectly safe. In the course of an india-rubber tube, two feet long, or less, there might easily be introduced a series of "stops" by which solid particles might be arrested and even the inspired air rendered antiseptic without diminishing the force of the current. Similar contrivances have long since been employed for catching the coarser impurities in tobacco pipes, and unless the virus of diphtheria be really in a gaseous form it is conceivable that a filter of wool or other material might be constructed of sufficient density to bar the passage of morbific germs. A filtering suction tube of this kind, if the idea be not too Utopian, should then become a part of the regular furniture of the surgeon's tracheotomy case. The simplest way to avoid the risks of suction in such cases would be found in an absolute prohibition of the practice. But would such a prohibition be regarded! One of the most coveted rewards in the Queen's service is obtained only by such as have successfully risked their own lives in saving others; but I venture to think that any man who has thus saved the life, even of an out-patient baby, at the deliberate risk of his own, need not envy the feelings of any recipient of the aforesaid decoration, although it be delivered by the hand of Royalty itself.

I am, Sir, yours &c.,

E. CLIFFORD BEALE.

London, October 22nd.

INVENTIONS AND IMPROVEMENTS.

BOLANACHI'S CHOCOLATE.

BOLANACHI'S chocolate has the appearance of ordinary chocolate paste, but it is distinctly a new departure, and different in composition from anything else in the market. It is composed of cocoa, and the sweet, clear, honey-like extract of ceratonia silique (St. John's Bread). The analysis corresponds to about 40 per cent. of real cocoa.

	Per cent.
Moisture	15·70
Cocoa butter	21·10
Albumenoids	8·02
Theobromine	·71
Sugar	34·80
Dextrin	9·42
Starch, gum, &c.	8·71
Ash	1·54
	100·00

The price of the chocolate is low, and the peculiar flavour imparted to it by the St. John's Bread is relished by a number of people. We may add that it is made of pure materials, and seems very nutritious and wholesome.

J. C. AND J. FIELD'S SAMPHIRE SOAP.

THE manufacturers claim to have incorporated into Samphire Soap the principles of the olive, the palm, and the lemon-thyme. The soap is certainly delicate in colour, and agreeable in odour. Not a few toilet soaps are tinted with mineral pigments; for example, pink soaps are often coloured with cinnabar. This particular soap is, however, coloured merely with a vegetable pigment, one that is perfectly innocuous, and incapable of irritating even a sensitive skin.

MEDICAL CONSULTATIONS.

No. I.

THE COLLEGE OF PHYSICIANS.

SCENE — *A back drawing-room in Mayfair.*

DRAMATIS PERSONÆ.

F.R.C.P.—*A risen consulting physician.*
M.R.C.P.—*A rising physician.*
L.R.C.P.—*A general practitioner.*

F.R.C.P. The case is clear enough, I think. I see no reason to arraign the labyrinth. As far as I can judge it is nothing more than a simple stomach giddiness—what in my youth we used to call "Vertigo a stomacho læso," the giddiness of a wounded stomach. But in these days of blunt simplicity, such solemn formulæ have become obsolete.

L.R.C.P. But why "wounded," Dr. F.? Her ladyship, I am sure, has far too reverent a care of her organism to willingly wound the meanest cell of it.

F.R.C.P. Not "wounded" in the surgeon's sense, but "injured," "offended;" "overpressed," if you prefer a more modern rendering. If you had to work every hour of the twenty-four like that poor viscus in the other room, would you not feel a sense of injury? Three good meals a-day, beef-tea in between, and cold soup twice in the night! A black slave could not be more overdriven. Believe me, our forerunners condensed a great deal of sound sense and shrewd observation into their quaint latinity.

L.R.C.P. Then I suppose a more restricted diet and a simple placebo——

M.R.C.P. Shouldn't it be a "placebimus" in this case, Mr. L.? (*with a smile to* F.R.C.P.)

F.R.C.P. Neither, if you please. I never sign a placebo. I leave that to sceptics and quacks. If you think medicine will do your patient no good, tell him so like a man. For my part, however, I never met with a case—a case of disease, I mean, a healthy patient is not a "case"—in which there was not a clear indication for some one or more of the many therapeutic agents at our disposal.

L.R.C.P. (*Sitting down to an escritoire*). Then what shall it be?

F.R.C.P. O, a little gentian and soda, I suppose, or potash and calumba. Do you agree? Before meals, if you please, Mr. L. By the way, have you looked into the *Lancet* to-day? The Council, I see, is to have its own way and to play ducks and drakes with the time-honoured privileges of the College.

M.R.C.P. For a consideration, I presume?

F.R.C.P. Ah, you have the modern way of looking at things. For my part, I never thought to see the day when the old College of Sydenham and Harvey would come down into the streets and join in the scramble for guineas. But nowadays prestige means nothing but a good balance at the banker's.

M.R.C.P. But surely the College intends to earn its gains? It will give *quid pro quo*.

F.R.C.P. It seems to me more like *taking* quid *pro quo*.

M.R.C.P. Ha ha, good! But surely, after all, the money is quite a secondary consideration. There will be its influence on the curriculum, and its extended relations with the profession at large.

F.R.C.P. Will it improve the physician's curriculum? Will it knit closer together the men for whom the College was founded? You will see what it will lead to. The next step will be to abolish the membership, and the next after that to choose the Fellows from the ranks of successful general practitioners. They seem inclined to the latter, as it is. We shall no longer have physicians educated as such, and the prizes of the profession will be given not for work, but for success. That is to say, our President will be elected by his patients. Then the licentiates, as they grow in numbers and influence, will claim a voice in our management, like the Members are claiming it from our new friends the Surgeons, and they will get it too. If you have your way you will turn the College into a vulgar democracy. We might as well be in America.

M.R.C.P. The prospect does not frighten me. Anything is better than stagnation. For my part, I see no reason why the general practitioner, if he be only as highly educated as our friend here, should not claim the rank as well as the name of a physician. I do not see why a Council elected from and by the licentiates should be less able to manage the affairs of the College, and keep up its traditions, assuming that it is advisable that they should be kept up, than a Council elected, as they practically are now, by themselves. I will not admit that successful general practitioners are a whit less honourable or honest than successful physicians, and the chances are, that they will show themselves quite as much men of the world.

F.R.C.P. Yes, I grant the latter, but that is the very thing I am fighting against. The fault I find with our present Council is that they are too much men of the world. Their aim is to be pleasant all round. In every question that comes before them their only solution is a compromise. They are wanting either in convictions or in the courage to own them. We ought to be ruled by men strong enough to do what is right and just without regard to their popularity. A body like the College ought to be above playing to the gallery. If you wish to turn us into a Commercial Company, and make a fortune by going into the market with a cheap article, contrived for the meanest capacity, you are setting the right way about it. The action of the Council means levelling down the licence to the capacity of the dullest student. Where else is he to get his diploma? Are you willing that all the dunces shall continue to cross the border for their qualification? I wonder, Mr. L., you have nothing to say to this degradation of a diploma which I am sure you value.

L.R.C.P. Value it? I suppose I do. But really in the full swing of practice one almost forgets what diplomas one has. Patients know nothing and care nothing about it, and I fancy that most of us, if we are successful, look upon our qualifications much as we look upon our school prizes. They are there on the shelf, but they don't mean very much. You see, we are conscious of having passed through a stiffer examination since we obtained them. Secure in the confidence of our patients, we can afford to forget the honours of our youth. You don't help us to remember them, you know.

F.R.C.P. Humph! Well, when our friend M. has his way, you will be masters in Pall Mall.

L.R.C.P. O, I am not anxious for a share in your responsibilities. I am too busy. I have no time for medical politics.

F.R.C.P. (*Triumphantly to* M.R.C.P.) You see? And you would entrust our welfare to men who are too busy to take any interest in the matter, or rather the whole affair would fall into the hands of those who are not busy, that is, who are not successful, that is, who are not capable.

M.R.C.P. (*Aside to* L.R.C.P.) A string of gratuitous inferences. (*Aloud*). Not so, give the busiest man a share in your management, and he will soon find time to interest himself in it. I am not aware that our President and Councillors are invariably men of leisure.

THE PATIENT. Excuse me for coming in, but you have been talking about me such an interminable time, that I fear my case must be very obscure.

F.R.C.P. Not at all, my dear lady, only extremely interesting.

MEDICAL NEWS.

UNIVERSITY OF CAMBRIDGE.—At a congregation, held on the 8th instant, the following degrees were conferred:—

Doctor of Medicine—

William Edward Steavenson, Downing.

Bachelors of Medicine—

George Tucker Clapp and Charles Edward Henry Cotes, Gonville and Caius.

Bachelor of Surgery—

Charles Edward Henry Cotes, Gonville and Caius.

The Examiners in State Medicine (Dr. Hubert Airy, Mr. W. H. Corfield, Mr. F. de Chaumont, and Mr. Alfred E. Carpenter) have issued the following list of those examined and approved for Certificates in Sanitary Science:—

A. Allan, M.D. Edin.; C. J. Covernton, L.R.C.P. Edin.; John J. Eyre, L.K.Q.C.P. Ireland; D. A. Gresswell, M.B. Oxford; K. P. Gapta, F.R.C.S. Edin.; H. Handford, M.D. Edin; J. B. Hurry, M.B. Cantab.; J. J. Macan, M.A., F.R.C.S.; T. J. M'Gann, F.R.C.S. Edin.; F. Marsh, F.R.C.S.; L. W. K. Phillips, F.R.C.S.; F. Welsh, F.R.C.S.; and W. C. Wise, M.D., St. Andrews.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Board of Examiners on the 16th instant, and when eligible will be admitted to the pass examination, viz.—

Harry Adams, University of Melbourne; Franz F. F. Foster, Guy's Hospital; Henry H. Hatter, and Joinville J. Blancard, University College Hospital; Onslow A. Wickham, London Hospital; Henry R. Blee, and Archibald B. Brockway, St. Thomas' Hospital, and Charles C. Braine, Charing Cross Hospital.

Sixteen candidates were referred.

The following gentlemen passed on the 17th inst., viz.—

J C. Molson, and W. A. J. Nottingham, London Hospital; F. A. Collington, H. M. Brownfield, and T. F. Christal, Guy's Hospital; H. E. Mortis, Charing Cross Hospital; J. Fayrer, St. George's Hospital; J. Jones, and W. Malden, St. Bartholomew's Hospital, and A. P. Blenkinsop, University College Hospital.

Twelve candidates were referred for three months and two for six months.

The following gentlemen passed on the 18th inst., viz.—

R. B. Popham, and F. Boxall, University College Hospital; A. d'Ede Vallancey, St. Thomas' Hospital; W. H. H. C. Davey, Charing Cross Hospital; R. Powell, King's College Hospital; T. Halliwell, Guy's Hospital, and B. S. Mankar, Bombay.

Nine were referred for three months.

The following gentlemen were admitted members of the College at a meeting of the Court of Examiners on the 20th instant, viz.—

George Louis Rugg, L.S.A., Stockwell Villa, Clapham Road; J. Mc H. Gell, M.B. Glasgow, Isle of Man; H. Shackleton, M.D., Trinity College, Dublin, Dublin; Charles Caldecott, L.S.A., Basingstoke; Thomas Pennington, Hyde; F. M. Blackwood, L.S.A., Sunderland; Oliver Scattergood, M.A. and M.B. Oxon, Leeds; A. F. Clay, L.S.A., Birmingham; E. W. Panl, L.S.A., Langport; Howard Davis, L.S.A., Pontypridd; B. W. Thomas, L.R.C.P. Edin., Heathcote Street; Joseph Hick, L.R.C.P. Edin., Leeds; C. K. Bond, L.R.C.P. Lond., Lupus Street, S.W.; Herbert Bidwell, L.R.C.P. Lond. Ely, Camb., and W. M. Bristow, L.R.C.P. Edin., Liverpool.

Seven gentlemen were approved in Surgery, and when qualified in Medicine will be admitted members of the College, and five candidates having failed to acquit themselves to the satisfaction of the Court of Examiners were referred to their professional studies for six months, and four for three months.

The following gentlemen passed on the 21st inst., viz.—

R. G. Silverlock, L.S.A., Northwold, and E. S. Marder, Lyme Regis; R. A. Jackson, Oswestry; A. E. Dodson, L.R.C.P. Edin., Downes Park Road, S.E.; A. J. R. Tyler, L.S.A., Islingtou; D. A. de Montboun, Trinidad; G. R. R. Paine, L.S.A., Old Woolwich Road; John Gay, Hampstead; J. E. Walker, L.S.A., Huddersfield; Gregory Jordan, M.B., Edin., York Road, S.E.; F. E. H. Piggott, L.S.A., Richmond; C. H. Hall, L.R.C.P. Lond.' Bicton, near Shrewsbury; Horace Hartley, L.R.C.P. Edin.,' Cold Harbour Lane, S.E.; W. J. T. Barker, L.S.A., Bristol; H' G. O. Wharry, L.S.A., Gordon Square; S. K. Alcock, L.S.A.' Burslem, Staffordshire, and S. H. Youel, L.R.C.P. Edin., St' John's, S.E.

Seven gentlemen were approved in Surgery and when qualified in Medicine will be admitted members of the College, four candidates were referred for three months, and four for six months.

The following gentlemen passed on the 22nd inst., viz.—

Herbert E. Counsell, Worcester; Watkins L. Rhys, Treherbert, S. Wales; Joseph H. Patrick, Birmingham; William A. Wills, Westminster; Charles E. Tanner, Marlborough; Herbert Fox, L.R.C.P. Lond., Croydon, and Raymond Courteen, Monmouth.

Seven candidates who had previously passed in Surgery, having subsequently obtained Medical Qualifications, were admitted members, viz.—

Edward C. Greene, L.R.C.P. Lond., Chelsea; Herbert Fitton, L.R.C.P. Edin., Dewsbury; Joe N. Kaye, L.R.C.P. Edin., Kirkstall; Arthur J. Barnard, L.R.C.P. Edin., Buxton; Richard E. Genge, L.R.C.P. Edin., Waterston, Dorset; Arthur J. N. Smith, L.R.C.P. Edin., Sutton, near Ely, and Frank Jefree, L.S.A., Clapham Park.

Ten candidates who had previously qualified in Surgery, having passed in Medicine and Midwifery were also admitted members, viz.—

George E. Stewart, Pocklington, Yorks; Thomas L. Archer, Clapton; Alfred M. Page, Belsize Park Gardens; George A. T. Walton, Brook Street, W. Arthur Trower, St. Mary-at-Hill; George M. Bluett, Regent's Park Terrace; Richmond E. St. Romaine, Calcutta; Robert H. Currey, Liverpool; Henry J. Butler, Bradford, and Frederick W. Weir, Bristol.

Five candidates passed in Surgery, and when qualified in Medicine and Midwifery will be admitted members of the College. Ten candidates were referred for six months and two for three months.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, October 16th, 1884:—

George Herbert Bennett, 40, Granville Square, W.C.; Percy Dean Bray, Bognor, Sussex; Ronald Angus Daniel, 118, Cornwall Road, Bayswater, W.; Charles Jno. Jacomb-Hood, Broadwater House, Tunbridge Wells; Frank Jeffrec, Howard Lodge, Atkins Road, Clapham Park; Caspar Robert Laurie, "The Elms," Buckhurst Hill, Essex; William Alexander Bowes McCabe, St. Heliers, Jersey; Jno. Robert Isaac Raywood, Thoone, Doncaster; Francis Gerald Southern, 50, Broad Street, Ludlow, Salop; Alexander Bishop Voisin, St. Lawrence, Jersey.

ROYAL UNIVERSITY OF IRELAND.—*Second University, Examination in Medicine.* The Examiners have recommended that the following candidates should be placed in the Upper Pass Division, and those marked with an asterisk should be admitted to the further examination for Honours:—

Patrick J. Burke, Cork; *John R. T. Connor, Cork; *John Flynn, Catholic University School of Medicine; William Hackett, Cork; William B. Hayes, Cork; *John A. Keogh, Cork; Charles R. Leader, Cork; *Samuel J. M'Ivor, Belfast; *William MacSweeny, Cork; *William Milligan, Galway; John J. Redfern, Belfast; *Francis L. Sealy, Cork; *William W. White, Cork; *E. M'N. Woods, Belfast; *William Bartley, Q.C., Galway; Robert Alfred Carter, Q.C., Belfast; Maurice Connery, Q.C., Cork; Charles James Cooke, Q.C., Cork; *J. T. Daly, Catholic University School of Medicine; Charles R. Elliott, Q.C., Belfast; Thomas Frizell, Q.C., Belfast; *Thomas Grainger, Q.C., Belfast; *Benjamin Hosford, Q.C., Cork; *John Kearney, Q.C., Cork; *Philip A. M'Carthy, Q.C., Cork; *Robert J. Macnamara, Q.C., Galway; *James Morwood, Q.C., Belfast; *Denis Sheahan, Q.C., Cork; *William White, Q.C., Belfast.

The Examiners have further recommended that the following candidates be also adjudged to have passed the examination:—

James Aherne, Cork; J. F. St. John Annesley, Belfast; Robert James Boyd, Galway; Patrick J. Cahill, Cork; William Henry Carlisle, Belfast; Charles J. Coumhan, Ledwich School of Medicine; Daniel Crowley, Cork; Tom C. Donaldson, Belfast; James Donelan, Royal College of Surgeons, and Carmichael College, Dublin; William Jamison, Belfast; Richard W. Leslie, Belfast and Galway; Edmund A. Lightburne, Queen's College, Belfast; Joseph M'Knight, Belfast; William K. MacRoberts, Medical School, Trinity College, Dublin; David Mark, Belfast; Joseph Thomas G. May, Galway; Michael J. Moran, Catholic University School of Medicine; William H. Murdoch, Belfast; Frank E. Murray, Belfast; Charles O'Neill, Belfast; Timothy O'Riordan, Cork; John J. Orr, Cork; Edward F. O'Sullivan, Cork; Edward Robiuson, Galway, and Anderson's College, Glasgow; William Stewart, Belfast; George S. Thomson, Belfast; John J. Tobin, Catholic University School of Medicine; Francis E. Townsend, Cork; Eaton W. Waters, Galway; Richard T. Young, Cork; William Frederick Bailey, Q.C., Belfast; Patrick Blackall, Q.C., Cork; Arthur Blackwood, Q.C., Belfast; Frederic James Burns, Q.C., Belfast; George Clarke, Q.C., Belfast; John N. Corbett, Q.C., Cork; Patrick G. Cotter, Q.C., Cork; Warren R. Crooke, Q.C., Cork; James C. Ferguson, Q.C., Belfast; Joseph Giusani, Q.C., Cork; Charles H. P. D. Graves, Q.C., Belfast, and Carmichael College; Edward Greene, Q.C., Cork; Charles Hayden, Q.C., Belfast; Peter Joseph Horkan, Q.C., Galway, and Catholic University School of Medicine; Samuel Roger Hunter, Q.C., Cork; Hugh Lewers, Q.C., Belfast; Marcus M. Loudon, Q.C., Belfast; James M'Avoy, Q.C., Belfast; Nicholas J. M'Donnell, Q.C., Belfast; Joseph B. M'Kay, Q.C., Belfast; Morgan M'Swiney, Q.C., Cork; Edward Magennis, Q.C., Belfast; James F. Magner, Q.C., Cork; Donald C. Martin, Q.C., Belfast; John Moore, Q.C., Cork; Hugh Smith Harrison, Q.C., Belfast; Cornelius O'Dohertv, Q.C., Cork; Michael O'Halloran, Q.C., Cork; Patrick Joseph O'Hara, Carmichael College; J. Joseph Prendergast, Q.C., Cork, and Guy's Hospital; Frederic C. Sinclair, Q.C., Belfast; Alfred J. Smith, Catholic University School of Medicine; Patrick J. Soraghan, Catholic University School of Medicine; E. Alfred Starling, Guy's Hospital, London; George Scott Tate, Queen's College, Belfast; William A. Wadsworth, Q.C., Galway; George Alex. Waters, Q.C., Galway; George Nesbitt Wynne, Carmichael College, and Ledwich School of Medicine.

The Diploma in Obstetrics.—The examiners agreed to recommend that the following should be adjudged to have passed the examinations:—

Patrick Blackall, Q.C., Cork; Arthur Blackwood, Q.C., Belfast; John W. Bullen, Q.C., Cork; Patrick G. Cotter, Q.C., Cork; Charles R. Elliott, Q.C., Belfast; James C. Ferguson, Q.C., Belfast; Joseph Giusani, Q.C., Cork; Thomas Grainger, Q.C., Belfast; Samuel Hamilton, Q.C., Belfast; Benjamin Hosford, Q.C., Cork; John Kearney, Q.C., Cork; Hugh Lewers, Q.C., Belfast; James M'Avoy, Q.C., Belfast; Philip A. M'Carthy, Q.C., Cork; Nicholas J. M'Donnell, Q.C., Belfast; James F. Magner, Q.C., Cork; James Morwood, Q.C., Belfast; Cornelius O'Doherty, Q.C., Cork; Michael O'Halloran, Q.C., Cork; Denis Sheahan, Q.C., Cork; Alfred J. Smith, Catholic University School of Medicine; Alfred E. Starling, Guy's Hospital, London; William White, Q.C., Belfast,

Students whose addresses are given as Belfast, Cork, or Galway, are from the Queen's Colleges in these towns.

Degree of Master of Surgery.—The Examiners have recommended that the following be adjudged to have passed the Examination :—

William Frederick Bailey, Arthur Blackwood, Robert A. Carter, George Clarke, Charles R. Elliott, James C. Ferguson, Thomas Frizell, Thomas Grainger, Charles H. P. D. Graves, Charles Hayden, James F. Hunter, M.D., Hugh Lewers, Marcus M. Loudon, James A. M. Macaulay, M.D., Matthew M'Auley, M.D., James M'Avoy, Nicholas J. M'Donnell, Joseph B. M'Kay, William N. M'William, M.D., W. A. P. Martin, M.D., James Morwood, George Scott Tate, and William White, of Queen's College, Belfast; Patrick Blackhall, Maurice Connery, Charles James Cooke, John N. Corbett, Patrick G. Cotter, Warren R. Cooke, Jacob Fairbrother, M.D., Joseph Giusani, Edward Greene, Benjamin Hosford, Samuel R. Hunter, John Kearney, Philip A. M'Carthy, James F. Magner, James O'Connel, M.D., Cornelius O'Doherty, Michael O'Halloran, and Denis Sheahan, of Queen's College, Cork; William Bartley, Peter Joseph Horkan, Robert J. Macnamara, and George A. Waters, of Queen's College, Galway; Joseph Thomas Daly, Alfred J. Smith, and Patrick J. Soroghan, of the Catholic University School of Medicine; John D. Kenny, M.D., of Ledwich School of Medicine; Patrick Joseph O'Hara, of Carmichael College; E. Alfred Starling, of Guy's Hospital, London; Geo. Nesbitt Wynne, of Carmichael College and Ledwich School of Medicine.

King and Queen's College of Physicians in Ireland.—At the monthly examination for the licentes of the College, held on Monday, Tuesday, Wednesday, and Thursday, October 6th, 7th, 8th, and 9th, 1884, the following candidates were successful :—

For the Licence to Practise Medicine—

Mary Emily Dowson, London; Switzer Soutter Harwood, M.D., Univ. Pennsylvania, Sydney, N.S.W.

For the Licence to Practise Midwifery—

Robert Bell, M.D., R.U.I., Moneymore, Co. Derry; Mary Emily Dowson, London; Nicholas Charles Ferguson, M.B., Univ. Dublin, Dublin; Switzer Soutter Harwood, M.D., Univ. Pennsylvania, Sydney, N.S.W.; Archibald Pollock Bailey Moore, M.D., R.U.I., Belfast; Robert T. A. O'Callaghan, Bagenalstown, Co. Carlow.

The following Licentiates in Medicine of the College, having complied with the by-laws relating to membership, pursuant to the Supplemental Charter of December 12th, 1878, have been duly enrolled Members of the College :—

Alexander Fry, Lic. Med. 1845, Mount Alton, Templeogue, Co. Dublin; James P. Ryan, Lic. Med. 1865, Melbourne; Robert Henry Robinson, Lic. Med. 1867, Surgeon-Major, Army; Michael Austin Boyd, Lic. Med. 1869, 90, Upper George's Street, Kingstown; John Sheridan Kennefick, Lic. Med. 1870, Clonmel, Co. Tipperary; Henry Walter Butler Boyd, Lic. Med. 1872, Surgeon, Bombay Army; Samuel Keays, Lic. Med. 1876, Surgeon, R.N.; John Alfred Frend, Lic. Med. 1877, Rosario, Argentine Republic; Edward Daniel O'Neill, Lic. Med. 1878, Richmond Lunatic Asylum.

Royal College of Surgeons, Edinburgh.—At the annual meeting of this College, held on the 15th instant, John Smith, M.D., LL.D., was unanimously re-elected president for the ensuing year.

Westminster Hospital.—The Entrance Scholarships for 1884 have been awarded as follows: (1) J. Dickinson (Fence, value 40*l.* per annum); (2) G. T. James (value 40*l.*)

St. Thomas's Hospital Medical School.—An Entrance Science Scholarship of the value of 100*l.* has been awarded to Francis Charles Abbott and one of 60*l.* to Charles James Martin.

King's College, London.—The Entrance Scholarships have been awarded as follows :—Warneford Scholarship of 75*l.* each to Messrs. A. S. Sandifer and T. B. Beach. Sambrooke Exhibition of 50*l.* to Mr. H. S. Ballance; and Clothworkers' Science Exhibitions of 50*l.* and 25*l.* to Messrs. T. G. Brodie and C. W. Atkinson.

University of Edinburgh—Faculty of Medicine.—The Vans Dunlop Scholarship for the subjects of the first year's study in medicine, viz., chemistry, anatomy, botany, and zoology, has been awarded to John Clarence Webster, B.A. (Halifax), of New Brunswick, Canada. This scholarship is of the annual value of 100*l.*, tenable for three years.

Admiralty.—At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on the 14th instant, Sir W. R. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of 58*l.* was distributed among the several applicants.

Naval Medical Service.—Staff Surgeon T. D'Arey Bromlow, M.D., has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet. Fleet Surgeon J. W. S. Meiklejohn, M.D., has been placed on the Retired List, with permission to assume the rank and title of Deputy Inspector General of Hospitals and Fleets. The following surgeons have been promoted to the rank of Staff Surgeon in Her Majesty's Fleet:—W. F. Spencer, M.D., R. W. Williams, A. C. Queely, O. P. Browne, B.A., M.D., F. R. M. Loftie, A. H. Kelly, B.A., M.D.

Army Medical Department.—In accordance with the Royal Warrant just issued the "Army Medical Department" has disappeared from the official nomenclature of the medical officers of the army, the official designation of the department being in future the "Medical Staff," and that of the Army Hospital Corps the "Medical Staff Corps." In the official list just issued both the Army Medical Department and Army Hospital Corps appear under the heading of "Medical Staff."

Glasgow Royal Infirmary.—Dr. Thomas, the superintendent, has been seriously ill with acute bronchitis; it is, however, gratifying to say that he is now considered out of danger.

Recent Legacies.—Mr. William Robert Mitchell has bequeathed 1,000*l.* to the Middlesex Hospital. Mr. Thomas Browning has bequeathed 52*l.* 10*s.* each to Charing Cross Hospital; the Hospital for Consumption and Diseases of the Chest, Brompton; the Cancer Hospital, Brompton; the Asylum for Idiots, Earlswood.

The Late Mr. W. Bates, M.R.C.S., of Birmingham.—A correspondent in "Notes and Queries" gives an appreciative sketch of the late Mr. Bates, of Birmingham, a frequent contributor to that serial, and a well known scholar, antiquary, and *virtuoso*. Mr. Bates had a fine collection of pictures of the English School, and in the course of his rambles had rescued from obscure book-stalls many engravings and documents of interest.

Death of Dr. Charles Barham.—We regret to announce the death of Dr. Charles Barham, the oldest physician in Truro, at the age of 80. Dr. Barham took the degree of M.B. at Cambridge in 1827, and afterwards studied in Edinburgh and Paris. He was a justice of the peace for Truro, a vice-president of the Royal Institution of Cornwall, and consulting physician of the Royal Cornwall Infirmary. He was author of a "Report on the Condition of Children in Mines," of "The Sanitary State of Truro."

The Parkes Museum.—The winter course of lectures will commence on Thursday, November 13th, when Mr. G. J. Symons, F.R.S., will give an address on the relation of Meteorology to Hygiene. On November 27th, Dr. Alfred Carpenter will speak on progress and co-operation in Sanitary work. Other lectures will be given by Sir Spencer Wells, Bart., Mr. Shirley Murphy, Mr. Cantlie, and Dr. Crichton Browne.

Lectures on Sanitary Subjects.—Miss Barnett, of the National Health Society, 44, Berners Street, W., has again started on a lecturing tour in the provinces. Manchester, Carlisle, Keswick, Workington, Cockermouth, and many other towns are to be visited. Her subjects are likely to prove attractive at a time when sanitary precautions are more than ordinarily needed :—"How to Oppose the Cholera," "Prevention of the Spread of Infectious Diseases," "Air and Ventilation," "Good Food," "Sensible Dress," "Management of Infants," and kindred subjects are all treated in a simple, practical manner, and we cannot help wishing that such teaching could be constantly and thoroughly carried out in every town and village of the United Kingdom. That "Prevention is better than Cure" is a motto we should all do well to remember.

The Microscopist run Mad.—The following words will be read with interest by all prayerful souls who are looking for the millennium of medicine. They are from an article upon the "Microscope in Analysis" in the *Scientific American* :—"The student of medicine is to-day enabled to unravel before the potent glance of the perfected microscope the deepest mysteries of the medicinal plant, flower, herb, or root. The nature and virtues, attributes, &c., of

these can be studied at leisure, and gazed upon with an eye that magnifies from a few hundred to thousands of diameters."—*Boston Medical Journal*, September 18th.

Hospital Sunday Fund.—A meeting of the Council of the Metropolitan Hospital Sunday Fund was held on the 10th instant, for the purpose of distributing among the various hospitals and dispensaries the sum of 4,500*l.*, the result of the recent hospital *fête* at the Health Exhibition. Sir Sydney Waterlow said the distribution committee recommended that the sum in question, with 713*l.* which had also been paid into the fund, making 5,213*l.* in all, should be distributed *pro ratâ* among the various hospitals and dispensaries which had recently received the bulk of the fund. The grant would be equal to about one-sixth of what they had received already this year. This was agreed to. In the course of a subsequent discussion Sir S. Waterlow controverted the statement made in recent correspondence to the effect that the Hospital Sunday movement was losing its popularity, this year's fund being the largest ever collected. Writers in the press had been advocating that the collections on Hospital Sunday should be divided into districts for the sake of the institutions in those particular localities, but that suggestion, if adopted, would kill the movement, for its object was to collect in rich districts as well as in poor funds for the relief of the sick and suffering throughout the whole metropolis. He thought the managers of the hospitals had fallen into the mistake of relying too much upon the results of Hospital Sunday, and of relaxing their exertions for their respective institutions in the rest of the year.

Site for an Infectious Hospital at Liverpool.—On the 8th inst., the Liverpool Health Committee proposed to the City Council a piece of ground at Edge Lane on which to erect a municipal hospital for infectious diseases. The evening before the medical men of Liverpool were convened at the Medical Institute by Drs. Gee, Cameron, and Carter, to consider this site. Its close proximity to the "gridiron" of the London and North Western Railway was thought to be a fatal objection. The "gridiron" is a net-work of rails over which 299 passenger trains, and 149 goods trains pass daily and where 2,000 trains are shunted or made up every twenty-four hours. The dreadful and frequent noises of these trains were described in graphic language by several speakers, and a resolution condemning the proposed scheme was unanimously agreed to and directed to be forwarded to the Mayor. Next day the Council dropped the matter and determined to see if the temporary small-pox hospital could not for a time at least be made available for all infectious diseases.

King and Queen's College of Physicians.—At the annual stated meeting of the College, held on St. Luke's Day, October 18th, 1884, the following officers were elected for the ensuing year:—*President*, Francis Richard Cruise, M.D. *Vice-President*, George Frederick Duffey, M.D. *Censors*, Geo. F. Duffey, M.D.; John Mallet Purser, M.D.; Francis J. B. Quinlan, M.D.; John Rutherfoord Kirkpatrick, M.B. *Additional Examiners*, John Magee Finny, M.D.; Arthur Wynne Foot, M.D.; Christopher J. Nixon, M.B.; John Mallet Purser, M.D.; Francis J. B. Quinlan, M.D.; Walter George Smith, M.D. *Registrar*, John William Moore, M.D. *Treasurer*, Aquilla Smith, M.D. *Examiners in Midwifery*, Stephen M. MacSwiney, M.D.; Wm. J. Smyly, M.D. *Professor of Medical Jurisprudence*, Robert Travers, M.A., M.D. *Representative on the General Medical Council*, Aquilla Smith, M.D. *Agent to the Trust Estate*, Charles Uniacke Townshend, Esq. *Law Agents*, Messrs Stephen Gordon and Son. The following member of the College was elected to the Fellowship—Joseph M. Redmond, Physician to the Mater Misericordiæ Hospital. *Examiners for the Certificate in Sanitary Science*, Dr. Duffy V.P. (in Ætiology and Prevention of Disease); Dr. Walter Smith (in Chemistry); Dr. Quinlan (in Meteorology, Climatology, and Vital Statistics); Mr. George R. Price, B.L. (in Law); Mr. Wm. Kaye Parry, C.E. (in Engineering). *Librarian on the Foundation of Sir Patrick Dun and Clerk to the College*, Mr. Samuel W. Wilson.

Birmingham and Midland Eye Hospital.—Mr. Chesshire having resigned his appointment as honorary surgeon, the committee have unanimously passed the following resolution:—"That the resignation of Mr. Chesshire as one of the honorary surgeons of this hospital be accepted by this committee with sincere regret. In doing so the committee desire to express their high sense of the valuable services which have been rendered to the hospital by Mr. Chesshire for the long period of more than forty years, and to acknowledge the energy which he has always displayed in promoting the interests of the institution, both as honorary surgeon, and also during the earlier years of its existence, as honorary secretary, and the committee are also pleased to find that Mr. Chesshire does not desire to entirely sever his connection with the hospital, but is willing to continue his services to the institution as a consulting surgeon."

Au Bon Droit.—We extract the following eloquent counterblast against the crime of adulteration from Dr. William Hitchman's "Lectures on Health":—Urge the most punctilious observance of normal skin, natural temperature, intellectual recreation, regulation of work, sleep, and waking hours, not omitting scientific ventilation and improved dwellings for the poor, cheap food, good cookery, as well as singularly minute attention to clothing and changes of weather—physical puritanism, in fact, with avoidance of alcohol, tobacco, snuff, and *every* intemperate habit; yet none shall raise Britannia's present veil of darkness until each child is radiant with the beauty of individual reform. Nobility of character is the only real life. In justice to the working classes, however, with whom I have been largely and intimately associated for some half century past, either as medical student, hospital surgeon, or poor-law medical officer and Sunday lecturer, let me say that—opposed to their progress is a social fiend; in the *adulteration* of food and drink is to be found a veritable "demon of inhumanity," or coldness of heart and barbarous cruelty. Surely that man *is* a devil in deed and in truth who, "when asked for bread, giveth a stone." Why does not a competent board of chemists scientifically declare on each article *ex cathedrâ*, that the veriest necessaries of life are really what they seem to be? Some of these sophistications, comparatively speaking, are perfectly harmless—I know from analysis—whilst other foods and drinks are absolutely poisonous, and often, alas! fatal. Why is not the adulteration of *these* murderous tanners and quack-like dyers wholly prevented? Because, severe as the law of the land now is, they contrive to evade it by some device or cunning. And "the thing pays!" Adulteration of food and drink results in the daily construction throughout the country of mansions urban and suburban, whose foundations are the graves of its helpless and indigent victims.

The Lunacy Laws and Imbecile Children.—At the annual meeting of the Royal Albert Asylum for Idiots—an institution which is deservedly held in high estimation in Lancashire—a very important suggestion was brought forward, which must receive attention whenever the impending revision of the lunacy laws takes place. At present weak-minded and imbecile children are regarded in law as on the same footing as all other insane persons, and cannot be received into special schools for training and education without the formal order, certificates, and statement that are required for the consignment of adult lunatics to asylums. The consequence of this regulation is not only that undue delay and expense occur in sending such children to school, but that parents and other members of a family object and refuse to incur the fancied stigma of having a relative under certificates; and thus an imbecile child loses altogether the immense benefit of special training—very often goes completely without education. Whatever safeguards are necessary in the committal of adult lunatics to asylums—and we have never been disposed to minimise or reduce them in any way—such safeguards are surely unnecessary in the case of weak-minded children. Every father possesses the right to send his children to any school that he chooses. Why should the right be denied him if one of his children is of weak mind? All children while at school have their liberty interfered

with. No additional hardship is felt by an imbecile child. If safeguards against ill-usage are required they can be given by inspection, regulation and if necessary licensing of the schools, but for this purpose no obstacle to admission is required or would be effectual. Nothing would be easier than to fix a limit of age, say fourteen or fifteen, below which the ordinary statutory requirements for admission and retention in an institution should not apply; and on the attainment of this age it might be made obligatory for certificates to be obtained in order to legalise the further detention of the patient. By some such regulation the liberty of the subject would be sufficiently safeguarded, the obstacles to speedy treatment would be removed, and the necessity for a formal examination at a fixed age would be an additional incentive to the asylum authorities to do their best, and would at the same time prevent any possibility of an unduly long detention under asylum treatment.

The Medical Council and the Apothecaries' Society.—The following is the letter from the Master of the Apothecaries' Society, which was read at the recent meeting of the General Medical Council, but which the Council decided by a large majority should not be entered on the minutes.

Apothecaries' Hall, October 15th, 1884.

Dear Sir Henry Acland,—I beg leave to acknowledge the receipt of the several reports of the meetings of the General Medical Council during the past week, which have been forwarded to me as Master of the Apothecaries' Society. Permit me to point out to you a serious discrepancy in these reports which materially endangers the interests of the Society. It will be in your recollection that when a Conjoint Board for England was originally proposed (see General Medical Council Revision, June, 1877), the Society of Apothecaries could not then join in the movement with the Royal Colleges. In order to do so we were compelled to make important sacrifices and surrender certain powers and privileges. The basis of that scheme, approved and adopted by the General Medical Council in February, 1879, consisted in giving a majority of examiners in Medicine to the Royal College of Physicians, the Society was accredited with a majority of examiners in Chemistry, Materia Medica, &c., whilst the departments of Surgery, Anatomy, &c., were to be undertaken by the Royal College of Surgeons, since the Apothecaries' Act does not confer the power of examining in surgery for our licence. Final arrangements were further made for carrying out the three portions of this Conjoint Board in its examinations; the first was to take place at the Apothecaries' Hall, the second at the College of Surgeons, the third at the College of Physicians. From this scheme the Royal College of Surgeons withdrew some time after the above arrangements. In your address of October 7th you suggest the adoption of three short clauses legally binding on the Examining Boards, in the first of which the Council shall not admit to the Medical Register any person who has not passed an examination satisfactory to the Council in Medicine, Surgery, and Midwifery. The Society adopted the scheme of 1878-79 upon these very grounds and which the General Medical Council sanctioned and approved at that period. But now it appears that the Council have negatived their former resolutions in rejecting the amendments A, B, C, D, to Sir H. Pitman's motion of October 9th, 1884, by which, B, C, amendments, specially the Society of Apothecaries is refused the privilege of co-operating with the above-named colleges though the General Medical Council had previously agreed to adopt the scheme referred to. In deference to the judgment of the General Medical Council it appears that two errors are now committed; one of injustice in allowing the two colleges to combine at all after the decisions of 1878-9. The second is a still greater injustice in excluding the Society of Apothecaries, who were parties most interested in that scheme, and who had made the greatest sacrifices in furthering the views of the General Medical Council in their recommendations. I wish to press upon the attention of the General Medical Council that the Society is still willing to recur to the original project as laid down by the Committee of Reference in their report to the co-operating medical authorities and approved by the General Medical Council, February 1879, Parts 1, 2, 3.

I remain, Dear Sir Henry Acland,
Yours truly,
Sir Hy. Acland, K.C.B. Geo. Corfe.

Society for Relief of the Widows and Orphans of Medical Men.—The Quarterly Court of the above society was held in the rooms of the Royal Medical Chirurgical Society, on Wednesday, October 8th, at 8 p.m., the President, Sir James Paget, F.R.S., in the chair. One new member was elected at the meeting. The election of a member was declared void, and the deaths of four were reported, including those of two Vice-Presidents, Mr. Cæsar Hawkins, and Sir Erasmus Wilson, Dr. Quain moved, Sir Henry Pitman seconded, that the President be requested to communicate to Mrs. Hawkins and Lady Wilson an expression of the sincere sympathy of the Board of Directors of the society on the occasion of their great loss, and to Lady Wilson their grateful appreciation of the munificent legacy of 5,000*l.* bequeathed by Sir Erasmus Wilson. On the recommendation of the Acting Treasurer, Mr. Fuller, it was agreed to give the usual present at Christmas to the widows and orphans receiving grants from the society. The present has been given now for ten years, but its continuance must depend on the state of the funds. Applications for grants were read from 59 widows, 5 orphans, and 3 orphans on the Copeland Fund, and it was resolved to recommend that a sum of 1,259*l.*, be distributed among them at the next court. Applications were read for the first time from 2 widows and 5 orphans, and grants were made, subject to the approval of the Committee of Visitors. Another application of a widow for herself and child was referred to the visitors to report on to the next court.

Fees to Medical Witnesses in Sanitary Cases.—The Chairman and magistrates at Nenagh Quarter Sessions, county Tipperary, were occupied for a considerable period on Friday, October 10th, in investigating an appeal against a decree made by magistrates at the instance of the guardians of the Roscrea Union, against Mr. Michael Minton, for 5*l.* for his not providing certain sanitary requirements for houses of two tenants of his, whereby a nuisance was caused. The decision was affirmed with costs. A question then arose as to the costs to be given to meet the expenses of the medical officer, who was in attendance for two days, Dr. Blacker C. Powell. A claim of 2*l.* 2*s.* was made, being the sum which the guardians were bound to give, under "the Public Health Act of 1882," and as approved by the Local Government Board for Ireland. It was contended that the doctor, being the sanitary officer of the board (salary 10*l.* per annum), was bound for this sum to do all the sanitary work required; also that no more than 2*l.* for costs could be awarded in any appeal. The court ruled that the doctor was entitled to 2*l.* 2*s.* a-day, and granted him 4*l.* 4*s.* which, with other costs given, amounted to a sum of 12*l.* 12*s.*, no sum being limited by the Act. The judge declined to state a case for the superior courts. Mr. Sheppard, solicitor, appeared for the guardians, and Messrs. Nolan and Minton for the appellants.

Cinchona from Southern India.—The Tambracherry Company have this year planted 75,000 cinchonas, which, added to those of previous years, bring up the total to 760,000. The nurseries contain about 100,000 seedlings to supply any vacancies in this year's planting, and the seed laid down consists almost entirely of the valuable Ledgeriana variety, with which the directors hope to complete the nulbon trees. The present season has been remarkable for only one-half the usual rainfall up to the middle of August, and the heaviest burst of monsoon so late as the last week of that month, instead of June. Such abnormal weather has not been without a detrimental effect on the crop, but has had the advantage of giving the finest season for planting experienced for many years. The latest estimate of the growing crop on this company's estates alone is 170 tons, and but for the absence of the usual blossoming showers in some places, and a heavy fall of two inches on one estate on the very day the principal blossom came out, there would doubtless have been about 200 tons. The harvesting of cinchona will commence fairly this season, and 16,000 trees will be shaved, while in the following years there will come into bearing—1880 planting, 23,000; 1881 planting, 114,200; 1882 planting, 111,000; and 1883 planting, 140,000. The directors of the Tambracherry Company attach very considerable importance to the fact that no country in the world can compete with Southern India in the cost of the production of bark, and when the accumulated stock of old Peruvian and the excessive supply of half-matured Ceylon barks have been cleared away, a most promising future lies before the production of India. With this prospect, the directors have willingly joined in a small syndicate for the extraction of the alkaloids on the spot, which has been started under promise of support from the Government of India, and which, if successful, will result in the saving of a considerable freight, and admit of the utilisation of a large quantity of prunings and twigs which at present are not worth the cost of shipment. A qualified chemist has just left England with the necessary apparatus for a year's trial at Calicut.

THE LAW IN RELATION TO BAD PLUMBING IN NEW YORK.—The law on this subject, as exemplified in a case reported in the *New York Medical Record*, September 20th, seems far more stringent than our own. "In a suit for rent claimed to be due from a tenant for a suite of rooms in an apartment house, it appeared that the defendant's wife and servants were taken sick by inhaling a malarial or poisonous gas in the apartments occupied by them; that this unhealthy condition of the apartments was owing to the defective condition of the general plumbing work of the house, of which the landlord was notified by orders received from the Board of Health, requiring him to have changes made in the plumbing work, and which unhealthy condition could have been removed if he had complied with these orders; that the defendant waited for two weeks, when, finding that nothing was done on the part of the landlord, he left under the apprehension that he was imperilling the health of himself and family by remaining. Under these circumstances, the judge who tried the case thought that this is what is called in law a constructive eviction, and the tenant could not be forced to pay rent during that portion of his lease subsequent to his removal. The decision has recently been affirmed by the General Term of the Court of Common Pleas, and unless reversed by the Court of Appeal, which is unlikely, will be the law in future."

SOME THERAPEUTICAL DELUSIONS.—The *New York Medical Record* (October 4), noticing a communication in which a valued correspondent urges the necessity of a more critical and careful analysis of therapeutical experience, observes that while nihilism in therapeutics is greatly to be deprecated, a more critical study of the action of remedies and of alleged therapeutical results is earnestly to be desired. "We have carefully examined the 'delusions' set forth by our correspondent, and find that in the main they agree with the results of the more conservative clinicians and of pharmacological experiments. They are as follow:—It is a delusion that veratrum viride or aconite will abort croupous pneumonia, or essentially modify its course; that chlorate of potash is of any use in catarrhal angina; that nitrate of potash is an anti-pyretic, anti-rheumatic, or (to any appreciable extent) a diuretic; that lime-water will dissolve a diphtheritic or croupous membrane; that nitrate of silver is of any value in epilepsy; that the excessive and continuous use of iron induces plethora, with dizziness, flushings and palpitations; that iron should be given in phthisis; that mercury is anti-plastic and anti-phlogistic; that arsenic has any value in diabetes; that iodide of potassium promotes absorption of serous exudations and of non-specific connective tissue in hyperplasia; that sulphur and sulphur in baths is of any value in rheumatism; that charcoal, when moist in the stomach and intestines, has any absorptive power, or is of any use in flatulence by virtue of that power; that dilute acids are 'cooling,' *i.e.*, lower temperature and lessen heart-action in the non-febrile; that colchicum is beneficial in rheumatism; that drinking sulphuric acid prevents chronic lead-poisoning; that iodoform given internally is anything but a poor substitute for iodide of potass; that croton-chloral has a specific effect on the fifth cranial nerve; that tannic acid (or the plants containing it) is of any value given internally for hæmorrhages, except perhaps those of the stomach and bowels, or that it is of any value as a gargle in chronic pharyngitis, or that it is an astringent to mucous surfaces or blood-vessels; that turpentine is a stimulant to the heart and nervous system; that musk is a nerve or heart stimulant (it belongs with turpentine to nerve depressants); that ox-gall is of the slightest therapeutical utility; that hydrocyanic in ordinary medicinal doses is either a local or general sedative (it is rather an irritant); that quinine in either large or small doses is a stomachic, except in convalescence from malarial attacks; that hydriodic acid has any specific effects other than those possessed by the iodides."

PER OS AND PER OREM.—Prof. Goodell in the *Philadelphia Med. Times*, July 12, says: "Just let me call your attention to a mistake that is very commonly made. There is a widespread idea that the Latin word *os* is of the masculine gender, and you will frequently see written *per orem*. *Os* is a neuter noun of the third declension, and its accusative is like the nominative; so that 'by the mouth' should be written *per os* and not *per orem*."

SYSTEM OF PROMOTION AMONG GERMAN PROFESSORS.—A stranger in selecting his courses should consult some student who has been already at work, for not unfrequently he will find that he can gain more from the course of a privat-docent who is comparatively unknown than he can from the instruction of the more celebrated professor. The young teacher knows the wants of the student, his memory of his own needs being fresh, and he does his best to supply them. All the successful professors in Germany have begun as privat-docenten, and there are many docenten teaching small classes in small universities who are destined to attain the highest positions in a few years. One of the reasons why the professors in German universities are so superior, is because of their preliminary training as privat-docenten, and the fact that they have been chosen on the principle of the "survival of the fittest." In France, all positions are obtained by *concours*, and the competitive examination determines every man's advancement. In Germany, the vacant positions are filled by appointments made by the Minister of Instruction on the recommendation of the faculties of the universities. That these faculties are watching the course of the privat-docenten in every university, and appreciate merit whenever found may be illustrated by the history of Nothnagel, now Professor of Clinical Medicine at Vienna, and probably the most brilliant medical lecturer in the world. He graduated at Berlin in 1863, and from 1864 to 1868 he was privat-docent in Königsburg. He was then called as privat-docent to Berlin, where he remained until 1870, when he received an appointment as assistant professor at Breslau. After two years, Freiburg offered him the chair of materia medica, and two years later he was called to Jena as Professor of Clinical Medicine and Pathology. He left that only last year to take the high position of head of a clinic in the Vienna School. As long as German universities thus select the best talent available in the whole country, it will not be surprising that their halls are crowded with students from the entire world.

COCA OR CAFFEINE.—The experiences of different investigators as to the properties and therapeutic value of erythoxylon coca have been various and often disappointing. A sufficient explanation of these discrepancies is supplied by the publication of some "open secrets" of the coca trade. Dr. Squibb, in his *Ephemeris* for last July, stated that the search for good coca, alike in the ports of Central and Southern America, in London, Hamburgh, and New York, even without limitation as to price, was almost invariably unsuccessful. Not that the drug, putting the condition of quality aside, was scarce, hundreds of bales being attainable at any time, but that it was so poor as to be quite unfit for use. Coca is much like tea as regards its capacity for transportation, being very sensitive and perishable, and only fit for use when fresh and green, and well cared for during packing and carriage. Dr. Squibb believes that unless treated throughout with all the care devoted to the preparation of the best tea, and like it, imported in lead lined or at least "air-tight" packages, it is simply impossible that it should be obtainable in any other than a worthless condition. He adds: "It is pretty safe to say that nineteen-twentieths of the coca seen in the United States market within the past two years must be inert and valueless; yet all is sold and used, and its reputation as a therapeutic agent is pretty well kept up. At least many thousands of pounds of the brown ill-smelling leaf, and of preparations made from it, are annually sold. And worse than this, considerable quantities of a handsome-looking green leaf, well put up and well taken care of, have been sold and used as coca, when wanting in nearly all its characteristics." Another large manufacturer has seen but one or two small lots of moderately good coca for more than a year past, with no prospect of a supply of better quality; and, uninfluenced by the fact that popular faith in the remedy seems to grow in inverse proportion to its declining therapeutic value, frankly states that he has finally "decided to give up making a fluid extract of coca and has left it off his list, adopting a fluid extract of tea instead as a superior

substitute for those who may choose to use it, and regrets that this course was not taken a year ago." Some experiments carefully conducted with the view of estimating the comparative value of coca and of caffeine as sleep evaders appeared to indicate that three fluid drachms of a good specimen of the fluid extract of coca were therapeutically equivalent to three grains of pure caffeine. An equivalent amount of the coca preparation is said to have assayed 0·45 grain of cocaine. Hence cocaine is about 6·5 times as effective as caffeine; but the coca accessible, and even the very best coca, contains a very much smaller proportion of its alkaloid than caffeine-yielding articles do of that principle.

Glasgow Southern Society.—At the annual meeting of this society, held on the 9th instant, the following gentlemen were elected for the session 1884–85, as office-bearers:—President—Alexander Napier, M.D. Vice-President—Wm. Carr, M.B. Treasurer—Edward McMillan, L.R.C.S.E. Secretary—David Tindal, M.D. Editorial Secretary—Jas. Hamilton, M.B., C.M.

The Epidemic at Kidderminster.—Acting under the instructions of the Local Government Board, Dr. Parsons is again on a visit to Kidderminster, and has commenced what it is stated will be a house-to-house visitation of the numerous residences where typhoid fever exists. There is a strong desire for a public enquiry, and a communication has been addressed to Dr. Parsons on the subject. The epidemic has now taken a more favourable turn, but there are a large number of cases still under treatment.

Edinburgh Royal Infirmary.—At a recent meeting of the managers of the Royal Infirmary it was reported that 7,624 cases had been treated during the financial year ending 30th ultimo. This number, as compared with 6,829 in the previous year, shows an increase of 795 patients who have received the benefits of the institution.

A Precaution in Post-Mortems.—Before undertaking a *post-mortem*, Dr. Chevenger recommends the holding the hands over strong liquid ammoniæ, when the smarting which ensues will reveal all sensitive or abraded places that need a touch of caustic before beginning the examination.

Royal Caledonian Asylum.—Dr. Mitchell Bruce has been appointed Physician to the asylum in place of the late Dr. Tweedie.

Medicine Bottles.—M. Pierre Vigier, in continuation of his useful pharmaceutical communications in the *Gazette Hebdomadaire*, expresses in the number for October 3rd the desirableness that every pharmacy should contain two sorts of bottles of different colours and shapes, viz., cylindrical white bottles for medicines taken internally, and blue and square bottles for those used externally. The difference of *shape* is a great preventive of accidents, for even in the night the simple touch of the bottle indicates the nature of its contents. When the Minister of Commerce some time since rendered it obligatory to affix an orange-coloured label to all bottles containing medicines for external use, M. Vigier endeavoured to induce the Société de Pharmacie to exert its influence to have the order extended to the shape of the bottles; but that body, while acknowledging the great utility of the suggestion, refused to press it upon the Minister on the ground that carrying it out would bear hard upon the small and rural pharmacies by obliging them to keep bottles of two shapes! Many *pharmaciens* have, however, of their own accord adopted the plan, and it is in the hope of inducing others to follow their example that M. Vigier now writes. He observes that most practitioners can call to mind cases in which liniments, collyria, &c., have been taken by mistake, which they would not have been had the mere shape of the bottle given its warning.

Houses of Refuge in Contagious Diseases.—The Paris *Conseil d'Hygiene Publique* has determined to establish "Houses of Refuge" into which, on the appearance of croup or any other contagious disease in one of their children, parents who are not in a position to protect their other children from contagion, may obtain admission for them.

APPOINTMENTS.

Alexander, W., M.R.C.S.—Assistant Medical Officer to the Mile End Old Town Infirmary, *vice* Beattie, resigned.

Chadwick, C. M., M.A., M.B. Oxon, L.R.C.P. Lond.—Physician to the Leeds Public Dispensary, *vice* Thomas Churton, M.D., resigned.

Chambers, H. W., L.R.C.P., M.R.C.S.—Senior Assistant House Surgeon to the Hull General Infirmary, *vice* Arthur Jackson, M.B., &c., resigned.

Davies, J. T., L.R.C.P.—House Surgeon to the Denbighshire Infirmary, *vice* J. J. Lloyd, L.R.C.P., resigned.

Elphinstone, Robert, M.R.C.S., L.R.C.P., and L.S.A.—Medical Officer to the Silverstone District, Towcester Union, *vice* Dr. J. B. Weir, deceased.

Evans, E., B.A., Cantab.—Demonstrator in Physiology at St. Mary's Hospital Medical School, Paddington, W., *vice* Dr. Nall, resigned.

Fleck, William, M.D. and M.C. Queen's Univ. Irel.—Medical Officer to the workhouse, Wycombe Union, *vice* W. G. Hayden, resigned.

Parrott, T. G., L.R.C.P., M.R.C.S.—Resident Medical Officer and Secretary to the Bournemouth Cottage Hospital, *vice* T. Fred. Gardner, L.R.C.P., M.R.C.S., L.S.A., resigned.

Pigeon, W. H., M.A., M.B., B.C. Camb., M.R.C.S.—Resident Surgical Officer to the Royal Infirmary, Manchester, *vice* Bilton Pollard, M.D., &c., resigned.

Pullen-Burry, Henry Burry, L.R.C.P. Lond. and M.R.C.S. Eng.—Medical Officer to Milland District, Midhurst Union, *vice* Dr. T. F. Pearse, whose term has expired.

Wade, Charles, M.R.C.S. Eng. and L.S.A. Lond.—Medical Officer to the Hatfield District, Dunmow Union, *vice* Mr. C. G. Firman resigned.

Wilson, James Scott, M.D. and M.C.—Medical Officer to the Borough District, Walsall Union, *vice* Mr. T.C. Hubbard, resigned.

VACANCIES.

Asylum for Idiots, Earlswood.—Assistant Medical Officer. (*For particulars see Advertisement.*)

Basford Union.—Medical Officer to the Arnold District, in succession to Mr. R. S. Wallace, resigned. Area, 4,508 acres. Population, 5,745. Salary, £30 per annum.

Bristol General Hospital.—House Surgeon. Salary, £120 per annum, with board, washing and residence in the house. Candidates must be Members of the College of Surgeons of London, Edinburgh, Glasgow or Dublin, and also Licentiates of the Apothecaries' Company of London or Dublin, or some other recognised medical qualification and must produce testimonials of good moral character and ability and must send certificate of registration. Applications to be sent to the Secretary, on or before October 27th.

Carlisle Dispensary.—Senior House-Surgeon. Salary, £130 per annum, with apartments (not board.) Applications, stating age and qualifications, with copy of testimonials, to be sent to the Honorable Secretary, Mr. John Austell, 14, Bank Street, Carlisle, on or before October 28th.

Chichester Infirmary.—House-Surgeon and Assistant Secretary. Salary £100, with board, washing, and lodging. Applications, with testimonials, to be sent to the Chairman of the Committee, on or before October 25th.

Dental Hospital of London, &c., Leicester Square.—Lecturer on Dental Surgery and Pathology. (*For particulars see Advertisement.*)

East Ward Union.—Medical Officer. (*For particulars see Advertisement.*)

Great Northern Central Hospital, Caledonian Road, London, N.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

Hospital for Consumption and Diseases of the Chest, Brompton.—Surgeon. (*For particulars see Advertisement.*)

Kidderminster Union.—Medical Officer to the Kidderminster District, in the room of Mr. William Roden, deceased. Area, 9,679 acres. Population, 11,569. Salary, £165 per annum.

Manchester Royal Infirmary.—Resident Medical Officer. (*For particulars see Advertisement.*)

North Riding Infirmary, Middlesbrough-on-Tees.—House Surgeon. Salary, £100 a year, with lodging, board and washing. Candidates must be possessed of a Medical and Surgical qualification, recognised by the General Medical Council, and be unmarried. Applications to be sent to Angus Macpherson, Secretary, up to November 3rd.

Royal Free Hospital, Gray's Inn Road.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

Swansea Hospital.—Resident Medical Officer. Salary, £100 per annum, with board, furnished apartments, &c. Candidates must be registered in Medicine and Surgery. Applications and testimonials to be sent to the Secretary, on or before October 28th.

Whitby Union.—Medical Officer to the East District and the Workhouse, in succession to Mr. John Taylerson, deceased. Area, 9,901 acres. Population, 5,921. Salary, £25 per annum. Salary for the Workhouse, £25 per annum.

DEATHS.

Barham, C., M.D. Cantab., at Truro, on October 20th, aged 80.

Chavasse, T., F.R.C.S., at Wylde Green House, Wylde Green, near Birmingham, on October 19th, aged 84.

Mercer, A. R., M.R.C.S., at Equira, West Coast Africa, on September 15th, aged 38.

RABBETH, SAMUEL, M.B. Lond., M.R.C.S., &c., at the Royal Free Hospital, Gray's Inn Road, on October 20th, aged 26.
SCOTT, A. J., M.D., late Madras Medical Service, at St. Leonards-on-Sea, on October 21st, aged 67.
WORRALL, J. C., M.R.C.S., L.S.A., of Overndale House, near Bristol, on October 11th, aged 79.

NOTES, QUERIES, AND REPLIES.

LONDON DOUBLE QUALIFICATION.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—At the various meetings for the discussion of the above, I do not remember having noticed any suggestion for the advantage of the practitioner holding the single Licence.

It would be a wise and considerate act to allow the insertion of a clause in the new regulations, by which the holder of one or other of the Licences, viz.: M.R.C.S. Lond., or L.R.C.P. Lond., may obtain the second, simply on presentation of his qualification, and the payment of the requisite fee, and devoid of *any examination.* That act could extend to all registered up to the date of the union of the two Colleges; but any person qualifying after that period would be required to go through the regular course. Some of the older hands of the profession may be disposed to regard that as too great and an unjust concession. But on second consideration, I think they will, with me, perceive that no injustice would result. The College of Physicians confers a Double Diploma, or rather has only done so for some years by the interpretation of the word *Physic*, as implying Medicine, Surgery, and Midwifery. That privilege is based on what may vulgarly be called a "Fluke." The College of Surgeons require that its candidates shall show that a fair Medical education has been received, by the fact of its demanding attendance, and requiring the signing of certificates on the various branches of Medical study. Though many have the Diploma of Surgeon, for the most part they are practising as Physicians, and in many cases are by no means undistiuguished men in that special department, or even in that of Obstetrics. They are practitioners of Medicine, Surgery, and Obstetrics, and neither one College nor the other can draw the line of where one special branch can begin, or another terminate. Again, as another reason, I am given to understand that in your country (I am writiug as a foreigner), about the year 1815, any Chemist, Druggist, Quack Doctor, Herbalist, Blockman, who dabbled with Physic or Broken Bones (mark you, Sir, the men without any education whatever, either in General Literature, or in Medicine!) were allowed, on payment of a fee, to be registered as competent to practise Physic, Surgery, Obstetrics, and Pharmacy; not only to practise them in a general way, but to be able to appear in any Court of Law to give evidence, and also to demand payment for professional services as "Doctors," to hold Civil and Military appointments. Now compare the admission of that vulgar rabble, the οι πολλοι, to the full privilege. Surely, if the law then could admit such, should it not be more willing, at the present day of advanced education and liberal views, to allow the giving of the Physician's Diploma to the Surgeon, and *vice versâ?* In fact, confer a period of grace, and let old Medical bygones be erased, and let the year of 1884 be as a new era in Medical history.

I commend these remarks for the consideration of the Heads of the Profession. At the same time I would offer auother suggestion, the subject of which you touched upon in your last issue. The London University M.D. is all well and good in its way; let those who aspire to its title seek it, but for my part I think it is too severe—and there is no special marketable value to be placed on its paper. For the extra study no extra remuneration can be received; in fact, as the bulk of its graduates are stuffed with theory, they are for a long time after passing very incompetent men at the routine of general practice; and they are not unfrequently corrected in Physic by men holding the Diploma of M.R.C.S. I do not make this remark in an enviable and unbecoming spirit, simply because I am not a M.D. (London), or likely to possess that honour. I make the remark as based on actual facts that have been placed before my notice. But to revert to the original subject. First let the Double Diploma be so worded as to include Medicine, Surgery, Obstetrics, and *Pharmacy.* It is necessary that the word Pharmacy be included, thus giving the general practitioner power to dispense his own drugs, charge for them, and, where nccessary, enforce payment. I do not mean to imply that he shall on the strength of that Diploma be able to open a Drug Store—for that is somewhat derogatory to the calling of the Physician, and should be handed over to the regular Druggist.

If that word be left out, all general practitioners will then be only partially qualified, and be obliged to fly to the Apothecarics' Hall for an extra certificate; and Medical matters will be in as great a confused state as before. The Archbishop of Canterbury has now the power of granting the M.D. (Lambeth), in his hands it is neither of use nor ornament. Let him hand over that power to the College of Physic and Surgery; and they could grant the M.D. after a course of *five* years' study, *i.e.*, an extra year beyond that required for the Licence. It would be regarded as a higher degree, and obtained after examination in special branches, viz., Operative Surgery, Lunacy, Ophthalmology, Laryngology, Dermatology, &c.

I am vain enough to believe I have put the whole matter clearly and in the compass of a nut-shell; and that by following the above course, Medical Qualification will be arranged on a satisfactory basis. I trust you will pardon my having made so great a demand on your space.

I am, Sir, yours &c.,
M.D. (of the University of the State of Vermont, U.S.A.)

Collegiate Examinations.—At the Primary or Anatomical and Physiological examinations for the Diploma of the Royal College of Surgeons, which were brought to a close on the 18th instant, 136 candidates were examined, against 94 at the corresponding period of last year; 64, having failed to acquit themselves to the satisfactiou of the Board of Examiners, were referred to their Anatomical and Physiological studies for three months, and six for six months.

At the "Pass," or Surgical and Medical examination for the Diploma of Member of the College, which was commenced on the 17th instant, 125 candidates presented themselves, as against 129 at the correspondiug period of last year.

The following were the questions on *Surgical Anatomy* and the *Principles and Practice of Surgery*, submitted to the candidates, on Friday the 17th instant, when they were required to answer at least four, including one of the first two, out of the six questions, between 1.30 and 4.30 p.m., viz.: — 1. Describe the relations and attachments of the Palmar Fascia and the sheaths of the Flexor Tendons. What is their Surgical Importauce? 2. Give the Anatomy of the Brachial Artery. Describe the operation of tying it in the middle of its course. Mention the anastomoses by which the blood-supply of the Forearm is carried on. 3. What are the Pathological Conditions which may occasion the presence of Blood in the Uriue? How can these be clinically distiuguished? 4. Give the immediate and remotc symptoms of a Punctured Wound of the Knee-Joiut, with the appropriate treatment. 5. Give the causes, course, and usual termination of Seuile Gangrene. How would you treat it? 6. Define the terms Presbyopia, Hypermetropia, and Myopia. Give the diagnosis of these conditions, and their correction by glasses.

On the following day, the 18th instant, the following were the questions on *Midwifery* and the *Diseases of Women*, when candidates were required to answer three out of the four questions between 12.30 and 2 o'clock p.m., viz.:—1. What are the causes of Presentation of the Funis? How would you treat this complication? 2. You are called to a patient who believes herself pregnant, and whose abdomen is greatly distended, and fluctuates freely. To what morbid states may these physical signs be due, and how would you distinguish between them? 3. Mentlon the common causes of Abortion? How would you endeavour to prevent its occurrence? 4. What injuries to the External Genitals are apt to occur in Parturition? To what consequences may they give rise? How would you try to prevent them? How would you treat them?

To those candidates who had not previously passed any recognised medical examination, the following were the questions on the *Principles and Practice of Medicine*, when they were required to answer three out of the four questions, including No. 4, between 2.30 and 4.30 p.m., viz.:—1. Discuss the causes, symptoms, and cousequences of the differeut forms of Œsophageal Obstruction. 2. Describe an attack of Gout, and discuss the pathology of the disease, and the morbid states of internal organs and tissues occurring in it. 3. Give a cliuical account of Purpura, and discuss the causes of death in that disease. 4. What are the actions, therapeutical uses, and doses of the following preparations: — Nitro-Muriatic Acid; Tannic Acid; Bicarbonate of Potash; Bromide of Potassium; Sulphate of Zinc; Liquor Arsenicalis; Extract of Indian Hemp; Tincture of Belladonna; Elaterium; and Wine of Aloes?

The names of the successful candidates are published iu another page of the *Medical Times and Gazette.*

Hard upon Doctors.—In "defiuitions of the height of meanness" our contemporary, *Truth*, gives some funny illustrations, as "gettiug advice and medicine gratis from a friendly doctor and asking him to buy back his own bottles"—"To recover from a dangerous illness and fail to pay the dobtor's bill"—"A lady after being attended and physicked gratuitously by a medical man, because her husband was a clergyman, sending the doctor's own bottles back to his surgery to be sold."

COMMUNICATIONS RECEIVED—

Sir SPENCER WELLS, Bart., Lond.; Dr. J. RUSSELL REYNOLDS, F.R.S., London; Dr. SAUNDBY, Birmiugham; Dr. BURNEY YEO, London; Dr. NORMAN CHEVERS, Londou; Dr. CLIFFORD BEALE, London; Dr. OCTAVIUS STURGES, London; Mr. G. S. APPOINTMENTS FOR THE WEEK.

Friday, October 24 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY OF LONDON.—The following Papers will be read:—Mr. Golding-Bird, "A Case of Dislocation of the Patella;" Dr. James Anderson, "A Case of Myxœdema;" Dr. Carrington, "A Case of Eruption, probably due to Bromism;" Mr. Godlee, "A Case of Nephrectomy for Tumour in an Infant."

QUEKETT MICROSCOPICAL CLUB, UNIVERSITY COLLEGE, GOWER STREET, 8 p.m.—Ordinary Meeting. Dr. W. B. Carpenter, C.B., F.R.S. (President), on "The Relations of the Various Types of the Genus Orbitolites."

Saturday, October 25.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; Loudon, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Ceutral London Ophthalmic, 2 p.m.

Monday, October 27.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

MEDICAL SOCIETY OF LONDON.—Mr. Spencer Watson, on "Hypertrophic Rhinitis;" Dr. J. Kingston Fowler, on "Functional and False Cardiac Murmurs;" Dr. J. Braxton Hicks will show a Machine for "Dry Air Disinfection."

Tuesday, October 28.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 p.m.—Mr. William Adams, "Excision of the Head of the Femur in a case of Unreduced Spontaneous Dorsal Dislocation, occurring during Fever;" Dr. Walter Edmunds, "A Case of Cirsoid Aneurism, on the Dorsum of the Foot, with remarks."

Wednesday, October 29.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday, October 30.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

CLINICAL LECTURES ON THE TREATMENT OF DISEASE.

Delivered in King's College Hospital,

By J. BURNEY YEO, M.D., F.R.C.P.,

Physician to the Hospital.

Lecture IV.

Catarrhal conditions of the Respiratory Passages.—Chronic Bronchial Catarrh.

Gentlemen,—There is perhaps no disease which you will be called upon more frequently to treat in this country than *Chronic Bronchial Catarrh.*

Our insular, humid, changeable climate is especially favourable to the maintenance of catarrhal conditions of the air passages when once they are established.

The chronic form of bronchial catarrh is often the result of repeated *acute* attacks, or it is due to continued exposure to unfavourable meteorological conditions. It is often secondary to other diseases—to typhoid fever, to heart disease, to phthisis. It is sometimes caused by occupations which entail exposure to irritating dusts or gases. It is frequently associated with pulmonary emphysema, in the production of which it plays a predominant *rôle*. It is often encountered in connection with the gouty diathesis, as well as in association with rheumatism, scrofula, and syphilis.

It is met with at all ages, and is most troublesome to deal with, and most dangerous at the two extremes of infancy and old age.

It is sometimes comparatively slight, recurring regularly in severe weather in the form of what we call a chronic *winter* cough.

There is what is termed the "dry" form, the *catarrhe sec* of French authors, characterised by violent irritative cough, and scanty, tenacious expectoration difficult of expulsion. This is regarded by some as a "gouty" form.

There is also the more common form, attended by abundant muco-purulent secretion from the bronchial mucous membrane, the "*catarrhe pituiteux*" of the French; the "bronchorrhœa" of other writers.

Occasionally this chronic form of bronchial catarrh is accompanied by structural changes in the walls of the bronchi, leading to dilatation of those tubes, and to the formation of the so-called bronchiectatic cavities.

The stagnation and decomposition of bronchial secretions in these cavities may impart an offensive odour to the breath and to the sputa, or this may also arise from putrid ulceration of the bronchial mucous membrane, and thus we get what is termed *bronchitis putrida*, or fœtid bronchitis.

I need scarcely enumerate the familiar symptoms, and physical signs of this very common malady; the

cough more or less severe, the expectoration more or less abundant, the dyspnœa more or less grave, according to the extent of the diffusion of the disease or the presence of complications; the combination of good, often exaggerated, percussion resonance with diffused harsh respiration, and various sonorous *râles*, rhonchal and sibilant, crepitating and humid, or musical and dry, while gurgling *râles* are heard over the bronchial dilatations.

The indications for treatment will vary with the nature of the case.

It is, in the first instance, important to remove all source of injury or irritation to the bronchial mucous membrane, in which the disease may have originated, or which may favour its continuance.

If it is dependent on occupation, change it! If on climate, let your patient seek a better one! Is it dependent upon the existence of some other disease or constitutional state, as heart disease, syphilis, scrofula, gout, &c., then our remedies must be selected with due regard to the original disorder.

There are other indications for treatment which may be deduced from the symptoms of the disease itself. These are:—

(1) To modify the morbid secreting action of the bronchial mucous membrane.
(2) To promote the expulsion of the morbid secretions which tend to accumulate in the air tubes.
(3) To calm irritative cough.
(4) To give tone to the enfeebled bronchial walls.
(5) In fœtid bronchitis, to suppress the putrid decomposition of the bronchial secretions.

The foregoing are the chief indications for the rational treatment of cases of chronic bronchial catarrh.

Now, in the first place, let us consider the treatment of that distressing form of chronic bronchial catarrh which has been termed by French physicians the *catarrhe sec*, or "dry catarrh." In cases of this kind we meet with severe paroxysms of cough, attended by very scanty secretion, which is tenacious and sticky, and difficult of expulsion. The seat of this form of catarrh is in the smaller bronchi, and it is not unfrequently found associated with the gouty constitution. These cases are greatly benefited by the free administration of warm alkaline drinks, and the inhalation of hot saline alkaline sprays, or the steam of hot water.

The mineral waters of Ems, Apollinaris, Bourboule, and Selters are excellent for this purpose. They may be given by the mouth, drunk warm or mixed with a small quantity of hot milk or whey; or they may be inhaled directly into the air passages by means of a Siegle's steam spray producer.

Four to six ounces of Ems or Apollinaris water, with two ounces of hot milk or whey should be taken four or five times a day and the hot spray of these waters inhaled twice a day or oftener.

If the Bourboule water is used, it must be given in smaller quantity on account of the arsenic it contains, only two to three ounces three times a day.

If these mineral waters are not available, we shall find a very good substitute in a mixture containing carbonate of soda and chloride of ammonium or sodium, and with this mixture we may often advantageously combine some pills containing tartarised antimony (or ipecacuanha) and morphine, the latter for the purpose of allaying the irritative, hyperæsthetic condition of the bronchial surface, the former to increase the amount and fluidity of the bronchial secretion, and so facilitate its expulsion.

The following prescription is a useful one:—

℞ Sodæ Bi-carbonatis, gr. lx.
Ammonii (v. Sodii) Chloridi, gr. xxx.
Succus Conii, ʒ ij.
Spiritus Chloroformi, ℥ cxx.
Aquæ ad ℥ vj.

M. ft. Mist.

Two tablespoonfuls, with two of hot water, every four to six hours.

℞ Antimonii Tartarati, gr. $\frac{1}{6}$.
(v. Pulveris Ipecacuanhæ, gr. i.)
Morphiæ Acetatis, gr. $\frac{1}{4}$.
Extracti Hyoscyami, gr. ij.

M. ft. pil.

To be taken every night at bedtime.

In the gouty this treatment should be combined with a saline alkaline aperient draught every morning, and nothing answers better than one or two teaspoonfuls of Carlsbad salts in a tumblerful of hot water. I must not omit to mention iodide of potassium as a most valuable remedy in certain obstinate forms of chronic bronchitis in constitutions which are presumed to be gouty. I say presumed to be gouty, for I must candidly admit that I have seen iodide of potassium of great use in cases of chronic bronchial catarrh where I should have been puzzled to give any other proof of the existence of a gouty constitution.

The cases in which iodide of potassium proves of so much benefit are those in which there is usually some tendency to asthma, and in which the bronchial secretion is tenacious and difficult of expulsion.

In cases of chronic bronchial catarrh with profuse secretion, the object of our treatment should be, as I have already pointed out, to modify the morbid secreting action of the bronchial mucous membrane. We have several drugs which are believed to possess this power in a greater or less degree; notably, certain "balsams" and "gum resins."

Copaiba, turpentine, tar, creosote, the balsams of Peru and of Tolu, ammoniacum, are members of this group of remedies.

Some of these drugs contain substances which, when taken into the blood, are eliminated by the bronchial mucous membrane. This is well known to be the case with copaiba, one of the most volatile constituents of which is eliminated in this way, and may thus exercise a direct local influence over the existing morbid conditions.

The objection to the use of copaiba on account of its odour and taste, and the evil reputation which attaches to it has been attempted to be overcome in various ways. In Paris it is often given combined with tar in capsules.

The following is the formula for its administration contained in the Pharmacopœia of the Brompton Hospital:—

℞ Copaibæ, ʒ ii.
Mucilaginis Acaciæ, ʒ vj.
Spiritus Chloroformi, ℥ xxx.
Aquæ Camphoræ ad ℥ vj.

M. ft. Mist.

Two tablespoonfuls three times a day.

Turpentine, like copaiba, is in part eliminated by the pulmonary surface, and like copaiba, it is often given in capsules, or what the French call "perles." It may also be prescribed in the form of confection. That of the British Pharmacopœia consists of oil of turpentine rubbed up with liquorice powder and honey. A teaspoonful of this may be given for a dose, wrapped up in wafer-paper, so that its taste is completely concealed, or the same quantity may be rubbed up with an ounce of peppermint water and taken in a fluid form.

Or it may be given as an emulsion, according to either of the following prescriptions. The first is suggested by Dr. Whitla; the second is in the Pharmacopœia of the Brompton Hospital:—

(1) ℞ Olei Terebinthinæ, ʒ ij.
Pulv. Gum. Acaciæ, ʒ ij ss.
Syrupi Aurantii, ℥ i.
Misturæ Amygdalæ ad ℥ viii.

M. ft. Mist.

Take two tablespoonfuls twice a day.

(2) ℞ Olei Terebinthinæ, ʒ ij.
Mucilaginis Acaciæ, ʒ ij.
Aquæ Cinnamomi ad ℥ vj.

M. ft. Mist.

Two tablespoonfuls for a dose.

Turpentine is also well and readily administered by inhalation. There are various means by which the air of the patient's room may be charged to any extent with the vapour of turpentine.

A teaspoonful or two of the oil of turpentine may be poured on the surface of a hot water plate previously charged with boiling water, or it may be placed on the surface of hot water and directly inhaled with the vapour of water from any suitable vessel, or cloths may be dipped in turpentine and hung about the room; or the patient may wear a light perforated zinc respirator, such as I show you, the sponge of which is charged from time to time with spirits of turpentine; this is a very convenient method of inhaling, more or less continuously, any fluid vaporisable medicament.[1]

Tar is also frequently given in the form of capsules, in the form of tar water, the popular *eau de goudron* of the French, in pills, and as an inhalation. It possesses decided virtues in the treatment of chronic bronchial catarrh. A chemist (Wheeler) at Ilfracombe has made an excellent emulsion of tar by means of the Laminaria Saccharina (Sea Belt); in this form it can be mixed with water in any proportion and taken internally or inhaled from any suitable apparatus. It is an expectorant as well as a tonic to the bronchial mucous membrane, and it has been suggested that it exerts its beneficial tonic effect on the respiratory mucous membrane in the act of its elimination, "and while stimulating the epithelial elements of the secreting surface it is probable that the cilia are also stimulated to sweep along irritating and adhesive secretions more rapidly."—(Whitla.)

Tar water can be made by stirring one part of tar with ten of water for fifteen minutes and decanting. A wineglassful may be taken several times a day.

Tar can also be made into pills either with liquorice powder or powdered gum acacia. Equal parts of tar and liquorice powder may be mixed together and made into five grain pills, two or three of which should be taken three times a day.

Tar may be inhaled in the form of spray by pulverising tar water in a Seigle's spray producer; it may also be used as a fumigation; for this purpose good ship's tar should be employed, to which ten per cent. of carbonate of soda should be added to neutralise the pyroligneous acid contained in it which might prove irritating to the respiratory passages. At first it is best to dilute the mixture with water so as to get, at the same time, the emollient action of aqueous vapour on the part affected; subsequently the amount of water may be reduced, and at last the pure tar mixture with soda may be employed; this is simply poured on to a flat dish and heated to boiling over a spirit lamp. The tar vapours are evolved in the vicinity of the patient for a quarter of an hour or more at a time once or twice a day, but it is desirable that the patient should remain all day in the room the air of which has been impregnated with tar vapour.

Much that I have said with respect to tar applies to its derivative, *creosote*. Creosote is useful both administered by the stomach and by inhalation in chronic bronchial catarrh, acting much in the same manner as tar does. It can be given in the form of capsules or "perles"; in the latter, which are prepared in France, it is dissolved in ether and enclosed in a protective covering. It is important to remember not to give these when the stomach is empty as their concentrated contents might give rise to some gastric irritation. A few tablespoonfuls of warm milk or soup should be taken at the same time. There is a creosote mixture in the British Pharmacopœia which contains one minim of creosote to the ounce; it also contains spirit of juniper to cover the unpleasant taste, glacial acetic acid and syrup. Two tablespoonfuls of this mixture can be given three times a day. Creosote can also be given in the form of pills mixed with castile soap and crumb of bread according to the formula suggested by Dr. Whitla:—

℞ Creasoti, ♏ xij.
Pulv. Saponis Castil. gr. xv.
Micæ Panis, gr. xxx.

M. et divide in pilulas xij.

One or two to be taken three times a day.

Or it may be mixed with glycerine and any agreeable tincture, with a view of covering its taste, such as the following:—

℞ Creasoti, ♏ xxxij.
Tincturæ Cardamomi Compositæ,
Glycerini, aa. ʒ j.

M. ft. Mist.

One tablespoonful in water or milk three or four times a day.

But creosote is especially useful and convenient for inhalation and it can be very readily inhaled by means of the light perforated zinc respirator I have already referred to.

If there is much bronchial irritation as well as profuse secretion, the sponge of this inhaler can be charged with equal parts of creosote and ether, or creosote and chloroform; or if a less decided sedative is required, an excellent mixture for the purpose consists of equal parts of creosote and spirits of chloroform.

If it is desirable to combine the emollient effect of the vapour of water with the creosote, the latter may be vaporised by dropping it on the surface of hot water and their vapours inhaled together.

The employment of turpentine, tar, and creosote is especially indicated in cases of profuse bronchial secretions (bronchorrhœa), especially when the sputa are offensive, owing to the existence of putrefactive processes in the air passages, and the presence of bronchiectatic cavities.

The balsams of Peru and Tolu, benzoin and storax are also given in chronic bronchial catarrh with the view of modifying the morbid secreting action of the respiratory mucous membrane. There is a well known tincture in the British Pharmacopœia containing three of these—Benzoin, Storax and Tolu; this is the *compound tincture of benzoin*, and I have often found it of great service in lessening the amount of secretion and so diminishing the cough in some cases of chronic bronchial catarrh.

It is necessary that the tincture should be ordered to be rubbed up carefully with some thick syrup or mucilage, so as to make an emulsion with the gum resins it contains, otherwise it will not mix with water. The Brompton Pharmacopœia contains the following formula:—

℞ Tincturæ Benzoini Compositæ, ʒ ij.
Tincturæ Tolutanæ, ♏ xxx.
Oxymellis Scillæ, ʒ iii.
Vini Ipecacuanhæ, ♏ xxx.
Aquæ ad ℥ vj.

M. ft. Mist.

Two tablespoonfuls three times a day.

Another gum resin of value in the treatment of the chronic bronchial catarrh of old people is ammoniacum. Its use has been unnecessarily depreciated. It is of much value as an expectorant in certain cases. Dr. Whitla very justly observes of this drug, "It will always be found beneficial in assisting the aged and emphysematous in getting up with greater ease the

[1] These respirators can be obtained at Squire's, 413, Oxford-street, for 6*d*. Wyeth Brothers, of Philadelphia, supply them in a slightly modified form.

tough viscid secretion of the chronically inflamed mucous membrane. Probably it acts by some of its constituents being excreted by the membrane depriving the secretion of its adhesiveness. Considerable experience of its effect in a large infirmary of aged invalids convinces me that in some way it greatly facilitates expectoration." It is given rubbed up with water as in the Mistura Ammoniaci of the British Pharmacopœia and is often combined with squills as in the following formula from the Brompton Pharmacopœia :—

℞ Tincturæ Camphoræ Compositæ, ℥ iii.
Oxymellis Scillæ, ℥ iii.
Misturæ Ammoniaci ad ℥ vj.
M. ft. Mist.
Two tablespoonfuls for a dose.

It is also one of the constituents of the Pilula Scillæ Composita and the Pilula Ipecacuanhæ c. Scillâ of the British Pharmacopœia ; and this leads me to say a few words on the use of squills as a stimulating expectorant in chronic bronchitis.

Squill is a useful expectorant in many cases of bronchitis, especially in those cases which are intermediate between the acute and chronic forms ; when an acute bronchitis is assuming more or less of a chronic form. It is often combined with small doses of ipecacuanha and opium, as in the *Pilula Ipecacuanhæ c. Scillâ* of the British Pharmacopœia, a very useful preparation, of which five to ten grains may be given at bedtime with much advantage in many cases of chronic bronchial catarrh.

The following formula from the Brompton Hospital Pharmacopœia is a good one in those cases intermediate between the acute and chronic forms to which I have just referred :—

℞ Tincturæ Scillæ, ℥ ij.
Tincturæ Camphoræ Comp., ℥ iii.
Spiritus Ætheris Nitrosi, ℥ iii.
Liquoris Ammoniæ Acetatis, ℥ iss.
Aquæ Camphoræ ad ℥ vj.
M. ft. Mist
Two tablespoonfuls every five or six hours.

(To be continued.)

A REMARKABLE CASE OF RENAL COMA.

By ROBERT SAUNDBY, M.D., Edin., M.R.C.P., Lond.
Assistant Physician to the General Hospital, Birmingham.

Harriet B., aged 20, was admitted into the General Hospital, on September 6, 1884, complaining of severe pain in the left hypochondrium which came on suddenly fourteen days ago, and had continued ever since. This was attended by vomiting and purging. On the night of admission there was some epistaxis, which did not recur. Ten months ago she had typhoid fever, for which she was an in-patient at the Queen's Hospital, and she states that she has never been well since. When she was 5 or 6 years of age, she had scarlatina, but can remember no other illness. On admission she appeared an anæmic girl with an anxious expression of face. She complained of lancinating pains in the region of the spleen. On examination the tenderness was too exquisite to permit of very exact exploration ; but there was evidently a resistant mass occupying the whole of the left hypochondrium. The heart, lungs and liver were apparently normal. Her tongue was moist, streaked with brown and white paste, but clean in the centre. Her bowels were relaxed, with about three motions in 24 hours. She vomited two or three times daily. Her urine amounted to about 20 ounces daily, it was albuminous, and contained a little pus, but no sugar. The needle of an aspirator passed into the swelling failed to withdraw any fluid. The day after admission the quantity of pus in the urine increased very much, so as to constitute nearly half a column of deposit in the urine glass.

September 9th, at 8 a.m., she had a convulsive attack which lasted five minutes, and she afterwards passed into a semi-comatose condition. When seen at 10.25 a.m., she was lying apparently insensible, but on being shouted to opened her eyes and turned her head. Her eyelids were partially open ; there were sordes on the teeth and lips. Her pupils did not react to light, but the conjunctivæ were sensitive to touch. Pulse 120. Respirations 24, *deep and sighing.* On auscultation air could be heard entering freely into the thorax. The nurse said that just before the convulsions she complained of *pain in the stomach.* 4 p.m —Pulse 132. Respirations 28. Respiration noisy ; slightly delirious, crying out occasionally. At 6.30 p.m., Dr. Morrison saw her, at the request of the House Physician's Assistant, with the idea of performing venesection. He found her with sighing respiration, pulse small and scarcely perceptible. Every now and then she moaned "Let me die." Temperature 97°. At 6.45 p.m. she was pulseless, and apparently *in articulo mortis.* A vein at the bend of the right elbow was opened and 24 ounces of a solution of sulphate of soda in distilled water injected. The fluid was neutral, sp. gr. 1018, at a temperature of about 100° F. The apparatus consisted of a glass funnel connected with a fine pointed pipette by rubber tubing. This was first filled with fluid, and the pipette was then inserted into the vein and the funnel raised. By this means a steady flow into the venous system took place. Within a few minutes the pulse returned at the wrist and the breathing became deeper. After 24 ounces were injected, the fluid in the end of the pipette was reddened from the blood and fluid mingling ; the flow was then stopped and the arm bound up. The patient revived, became conscious and spoke ; said she was thirsty and drank some milk. Temperature 98·6°. At 7·45 p.m. about a drachm of foul urinous pus was drawn off by the catheter. She died at 10.25 p.m., about fourteen hours after the convulsion.

During the last 36 hours of her life her temperature was taken every hour. Before the convulsive attack it ranged between 98° and 99·5°. At the time of the attack it was 98·5°, and then rose steadily, till at 10 a.m. it had reached 100 6°, falling again by 12 to 98°, and as mentioned above, when Dr. Morrison saw her at half-past six the temperature was only 97°. After the operation it rose to 98·6, and this was maintained at the last recorded time, 9 p.m. This rise of temperature after the convulsive attack is usually observed in uræmia.

At noon on the day of her death, as she had passed no urine since the night, a catheter was introduced into the bladder and about six ounces were drawn off. It was examined the following day by myself. My note taken at the time says : Colour reddish brown, putrid, alkaline, deposits one third column of pus ; sp. gr. 1011. *Gives a deep brown colour with ferric chloride* not diminished by heating.[1] Albumen about one-third column. No sugar. Deposit under the microscope consisted of

[1] Since writing this paper, I have read the article by le Nobel, in the June number of the *Archiv für Experimentelle Pathologie,* in which he says that acetic, formic, and sulpho-cyanogen compounds, any of which may occur in the urine, give a red coloration with ferric chloride, indistinguishable from the re-action with aceto-acetic acid, except by its non-disappearance on heating. This statement affords a reasonable explanation of the re-action met with in the urine of my patient, which I was quite unable to ascribe to the accidental presence of salicylic or carbolic acid, while its non-disappearance on heating threw doubt on the presence of aceto-acetic acid.

granular cells, squamous and pyriform epithelium, bacteria and blood corpuscles.

On the following day a careful *post-mortem* examination was made by Mr. C. E. Purslow, who has kindly favoured me with the following notes :—

External appearances.—The body was that of a young woman. *Post-mortem* rigidity was well marked in the lower extremities. There was a small incision in the fold of the left elbow, and the mark of a puncture in the left lumbar region. *Head.*—There was a slight increase of the sub-arachnoid fluid, but otherwise the cranial contents were normal. *Thorax.*—The *heart* weighed 9½ ozs. The left ventricle was slightly hypertrophied. Both *lungs* were congested and œdematous, and the lung tissue was friable. The *blood* was very watery with no disposition to clot. (The result of the intra-venous injection resorted to just before death.) *Abdomen.*—The *liver* weighed 43 ozs., and appeared normal. The *spleen* weighed 6½ oz., but was otherwise normal. The *stomach* showed signs of chronic catarrh. The right *kidney* weighed 1¼ ozs. only ; its ureter was patent ; its pelvis was dilated and contained a calculus the size of a pea. The medullary and cortical substances were indistinguishable and together measured only a quarter of an inch in breadth. The capsule stripped off readily. In the left hypochondrium there was a large mass, on the upper surface of which, and adherent to it, were the duodenum, pancreas, and descending colon. The surface of the mass was purple coloured, and the colon over it also appeared to have blood extravasated under its mesentery and peritonæal investment. On removing the entire mass it weighed 38 ozs. At the upper part there was a cavity the size of an orange containing purulent fluid, which was accidentally ruptured. On section it was composed of an external cyst wall within which was a mass of recent blood clot ; inside this was the left kidney in a condition of saccular dilatation. All normal kidney structure was absent. The pelvis contained an irregularly shaped calculus the size of a bean, and another smaller calculus lay in one of the saccules. The *ureter* was dilated but patent. The *bladder* was not enlarged, or its walls hypertrophied. Its mucous membrane was dark coloured and presented several wart-like outgrowths about one line in height with rounded surfaces. The *uterus* and *ovaries* were quite normal.

This very interesting case suggests many points of enquiry, but I desire specially to draw attention to the pathology of the terminal phenomena.

How long this poor girl had managed to maintain life with such poor apologies for kidneys as the *post-mortem* examination disclosed must remain unknown to us, though it is certain that the process had been a chronic one, and it is probable that her acute symptoms dated from the occurrence of the hæmorrhage into the wall of the sac.

It is most probable that the disease in the kidneys was set up by the irritation of small calculi which in the right side remained in the pelvis and led to atrophy of the organ, while on the left side an obstruction occurred in the lower part of the ureter, which had ceased before death, and was probably never complete.

The peculiar interest which attaches to this case is that it presented striking analogies to that form of coma which Kussmaul described as occurring in diabetes and which goes by his name.

The characteristic symptom of Kussmaul's coma is dyspnœa with free respiratory movements and unobstructed air passages.

It was this phenomenon that arrested Kussmaul's attention, and which has since been accepted by Senator as a typical symptom. The other symptoms are rapid feeble pulse, epigastric pain, excitement, followed by coma. In a certain number of cases the breath has a peculiar odour, variously described as like apples, hay, sour beer, acetone, &c., but this is by no means constant. And lastly, a symptom to which much attention was at one time paid, though lately it has fallen into disfavour, the peculiar reddish brown, or Burgundy red reaction of the urine with the perchloride of iron. Convulsions have been noted in a few cases, but they have been exceptional. The temperature is normal or sub-normal.

It is pretty well known that Kussmaul attributed these phenomena to intoxication by acetone, and for a time the reaction of the urine with ferric chloride was held to indicate the presence of this substance, but chemical investigations have hitherto failed to afford evidence of the presence of acetone in either the blood or urine in more than faint traces and exceptionally, but the substance which gives the peculiar reaction is now pretty generally admitted to be aceto-acetic acid.[2] Salomon has failed to find acetone in the expired air of diabetics with the characteristic odorous breath.

Furthermore, in a large number of experiments undertaken on animals and men, including persons suffering from diabetes, large doses of acetone and aceto-acetic acid have failed to produce any of the characteristic phenomena of this form of coma, although more recently Professor Penzoldt, of Erlangen, found that by retarding excretion through the lungs, intoxication, hebetude, and coma followed[3] the introduction of large quantities of acetone into the circulation of rabbits, and he contends that when the lungs are disabled by any cause these results will follow.

With reference to Professor Penzoldt's suggestion, I may refer to the observation of Dr. S. Mackenzie, who found that pulmonary disease was absent, or only recent and slight, in fourteen out of nineteen cases of diabetic coma, while at Guy's Hospital, fourteen out of twenty-six cases of coma presented no visceral lesions whatever, and several cases dying with phthisis or pneumonia presented no coma.[4]

But returning to our case, we must not lose sight of the very prominent fact that we had present in it very serious visceral lesions, amounting to the almost entire destruction of the kidneys. The small quantity of urine, and its low specific gravity, even in the absence of an exact analysis, enables us to be certain that the urinary solids excreted were far below the normal and necessary quantity.

It would therefore seem at first sight as if our enquiry was very simple, and that the case might be described as one of uræmia. If a name was all that we required, that would do as well as another. But what do we mean by uræmia ?

Confining our attention to cases in which the urinary excretion is obviously at fault, two very distinct types of toxic disturbance may be recognised. In the first the patient has a moist tongue, headache, loss of vision, vomiting, or diarrhœa, convulsions, and coma. This is the classical type of uræmia associated with Bright's disease. In the second the patient is in a typhoid condition, with dry tongue and a feeble pulse, but his intelligence and special senses are normal, and there may be neither convulsions nor coma, and yet such a patient may not excrete by the urinary passages a single drop of urine for days or even weeks. Such

[2] Aceto-acetic acid = acetone and carbonic acid. This re-action has been frequently found in the urine of non-diabetics, who presented no comatose phenomena.

[3] Deutsches Arch. f. Klin. Med., vol. xxxiv., p. 127.

[4] As there was no excess of fat in the blood, I have not referred to the fat embolism theory of Sanders and Hamilton (*Edinburgh Med. Journ.*, 1879), but I have elsewhere shown (*Journ. of Anat.*, July, 1882) that even when present it is doubtful if it is capable of causing any of these phenomena. It is curious that this explanation (fat embolism) was discussed and rejected by Kussmaul in his original paper published in 1874. A recent writer (Minkowski) has suggested oxybutyric acid as the toxic agent, but this contribution is too recent to be discussed here.

*

symptoms are met with in cases of obstructive suppression of urine.

It is very hard to explain these differences on the assumption that the simple retention of urine in the blood is the cause of either of them.

When we go a step further and enquire into the various theories that have been propounded to explain these phenomena, we find our difficulties increase.

These theories may be divided into two groups: (*a*) Mechanical (*b*) Chemical. In the first group, Owen Rees, Traube, and Rilliet have attributed the nervous phenomena to œdema of the brain, but this view has failed to meet with acceptance for the brain may be very œdematous without causing convulsions. The œdema observed so invariably by Traube is probably the consequence rather than the cause of the convulsions. This led to the theory of Rosenstein, who supplemented Traube's hypothesis by imagining that the initial change was a vaso-motor constriction of the cerebral blood vessels, leading to convulsions by cutting off the blood supply, and followed by exudation of serum into the lymph spaces of the brain. But plainly such an hypothesis needs supplementing by the assumption of the presence of some toxic agent capable of stimulating the vaso-motor centre, and this leads us to those chemical theories which have attracted most attention in later years.

The chief chemical theories are :—(1) That it is due to urea in the blood, hence the name uræmia, originally given to it by Piorry, and which was supported by Christison. This theory is the one which, in spite of opposition, has managed to hold its ground; although numerous experimenters have failed to produce any toxic phenomena by the injection of urea into the blood of animals or by making them ingest quantities of urea with their food.

(2) The theory of Frerichs and Treitz, that the urea is converted into carbonate of ammonia in the intestine which is re-absorbed into the blood. With reference to both these theories Dr. Roberts, in the last edition of his work on urinary and renal diseases, says (p. 433): "The recent experiments of Oppler, Schottin, Perls, and Zalewsky seem to have given the *coup de grace* both to the ammonia and to the urea theories of uræmia." (3) It has been suggested by M. Gautier that ptomaines may play some part in the phenomena of uræmia, but this remains at present a barren hypothesis. (4) Voit, Feltz and Ritter, and Astaschewsky, have proved by a number of careful experiments that the potassium salts of the urine alone are capable, when re-introduced into the circulation, of producing phenomena resembling those of so-called uræmia. This conclusion, while apparently supported by good experimental evidence, is so much opposed to the preconceived opinions of the profession that it has made but little way.

The conflict of experimental evidence is unfortunately so frequently the result of that method of investigation, that I have come reluctantly to the opinion that it justifies the condemnation of it expressed by Bartels. Speaking of this very question of uræmia, he says :—

"One of the chief reasons why we are compelled, even at the present day, to confess our inability to solve this question, lies, as I believe, in the circumstance that our attention has been chiefly devoted to experiments upon animals—a useful enough adjunct in research—while the prime source of our knowledge, clinical observation, has been all too little tapped."[5]

Professor Gamgee[6] thinks that uræmic phenomena depend upon many factors. The blood is rich in water, poor in albumen and corpuscles, and contains, besides urea and uric acid, "an excess of other proximate principles which may exert a specially poisonous action."

Vulpian[7] and Bouchard[8] regard the clogging of the tissues with non-eliminated waste products, and the consequent impairment of nutrition as the real cause. Voit says, "Symptoms of disease originate wherever any substance which does not belong to the economy accumulates within the body, and is not eliminated from it," and he proceeds to explain that it is not any particular substance which does harm when the urinary secretion is suppressed, but the total mass, any extraneous salt, such as sulphate of soda, being equally deleterious under similar circumstances. The toxic effects are the result of the interference with the normal exchanges which take place between the blood and the tissues, and upon which the vital phenomena of the latter depend.

We should not fail to notice that the broad clinical distinctions already pointed out, which are presented by cases identical so far that in both instances the urinary excretion is diminished or abolished, have received no elucidation, and, in fact, do not seem to have attracted the attention of these enquirers.

But these types are associated with fundamental pathological divergences. In the first type, the classical uræmia, the kidney is the organ primarily at fault. It is this type which we see in scarlatinal nephritis, and especially in the later stages of the contracting kidney. On the other hand, the second type is that met with in bladder diseases, and in suppression of urine by the impaction of calculi in the ureters.

It is difficult, nay impossible, to understand, why sudden suppression of urine or the nephritis of scarlatina should be followed by an attack of convulsions, while suppression by a calculus gives rise to no nervous phenomena; and the remarkable and well authenticated cases of hysterical suppression of urine without any uræmic phenomena at all make the problem still more obscure.

The case I have related differs essentially from the classical type of uræmic coma in important details. As already mentioned, it corresponds more nearly with that observed by Kussmaul in diabetes. I am not sure that there is anything very novel in this observation, as I find that Dr. Roberts gives "slow panting and laborious breathing" among the symptoms of obstructive suppression of urine.[9] But of late years so much prominence has been given to it in connection with those sudden deaths from diabetes which have been recorded by Dr. Foster and others that we have been in some danger of regarding it as specially associated with diabetes. On the Continent several writers have alluded to its occurrence in other diseases.

Reiss[10] has met with it in 8 cases of pure anæmia, 5 cases of anæmia with renal disease, and 4 cases of gastric and hepatic cancer. In none of these cases was sugar present.

Senator[11] has also observed it in chronic cystitis, gastric cancer, anæmia and atropine poisoning.

Were there any features by which this case might be distinguished from Kussmaul's coma? In the latter condition convulsions are rare, but yet they do occur; the temperature is normal or subnormal, but so it is in uræmia, except after a convulsive attack, and, so far, I am not aware that any observations have been made on the temperature under similar circumstances in diabetic coma. Lastly, the red colouration with ferric chloride did not disappear or diminish on heating.

[11] Ibid, vol. vii., Heft. 3.

This is held to distinguish the reaction from that produced by salicylic or carbolic acid in the urine, but neither of these drugs was being used in any way about the patient, and it is inconceivable that either could have been present in the urine.

We must therefore no longer regard this type of breathing as peculiar to the coma of diabetes, but as a phenomenon which may occur in connection with the terminal coma of a variety of conditions, of which the only connecting link is that there is profound disturbance of the nutrition of the tissues.

No one can be surprised at the fatal result in this case. But even when *post-mortem* examination has failed to show such serious organic disease, the result in presence of this form of coma has been equally fatal. Frcrichs regards all therapeutic measures hitherto suggested as useless. Injections of ether, camphor, and similar stimulants have been tried without effect. Dr. B. W. Foster has suggested the use of thymol to arrest the action of any fermcnt which might be giving rise to fermentations productive of toxic substances. I do not know that this has been tried. Usually the cases run too rapid a course for such a remedy to have an adequate chance. But it is certain that all these symptoms have supervened and run a fatal course in patients who were taking large doses of other antiseptics such as salicylic and carbolic acids.

Kussmaul tried transfusion of blood with only temporary results, and inhalation of oxygen was also without effect. Bence Jones employed peroxide of hydrogen and stimulants with no better result. Hilton Fagge and Taylor have injected a weak solution of phosphate of soda and sodium chloride into the veins, in one case with benefit for some hours, but after a dose of codeia the coma returned and proved fatal. In another case no result followed. Dr. Morrison was quite justified by these results in trying this plan and it seems to have been of some temporary service.

Although in the presencc of such extensive organic disease as was revealed by the *post-mortem* examination no recovery was possible, yet it is right to bear in mind that these symptoms are not necessarily fatal, instances of recovery having been recorded.[12]

SANITAS AS A DISINFECTANT.

By C. T. KINGZETT, F.I.C., F.C.S.

In your issue of the 11th inst. you publish some criticisms of Mr. A. Wynter Blyth on the exhibits of disinfectants at the Health Exhibition, and among them I find some notes relative to "Sanitas" for the knowledge and use of which re-agent I hold myself responsible. I shall be glad if you will allow me to make a few remarks upon this subject.

Mr. Blyth admits that "Sanitas" is a good antiseptic, but from certain microscopical observations made upon the spores of anthrax he adds, "I would not rely upon it in serious disinfection, that is, in cases of disease." In another place he says, "A non-poisonous disinfectant is certain to be useless as a germicide."

Now to take this last statement under consideration in the first place, I dispute its accuracy. Upon what grounds is Mr. Blyth certain? He states none, but makes the barren assertion. As grounds for disputing this statement, I may mention the following facts:—(1) Oxygen (a non-poisonous substance) acts as a germicide to all micro-organisms classified by Pasteur as anærobies. (2) Peroxide of hydrogen (a non-poisonous substance) has been proved by my own investigations[1] to act as a germicide to the micro-organisms that originate putrefaction, and my results were subsequently confirmed by Guttman and Frænkel.[2] They were also confirmed by Mr. W. M. Hamlet,[3] who observed that of all the many chemical substances he examined, peroxide of hydrogen acted most fatally to bacterial life. Further proof of the germicidal character of this substance has been given by M. Baldy, and emphatically by MM. Paul Bert and Regnard.[4] "Sanitas" in all its forms contains or yields peroxide of hydrogen. (3) Thymol can scarcely be called a poisonous substance, and it is admitted to be a powerful germicide. "Sanitas" contains thymol. (4) It does not follow that because a chemical agent is non-poisonous to man it will prove harmless to micro-organisms. There is nothing in common between the two orders.

Secondly, I cannot accept Mr. Blyth's provisional classification of disinfectants. It is sufficient, in my opinion, to call those substances, broadly, disinfectants which by their use limit in any sense the spread of disease. The precise ways in which disinfectants may act are very numerous. It is doubtful (even upon Mr. Blyth's own showing) whether any chemical substances can act as direct poisons to anthrax spores. Many substances, including Sanitas, kill off fully developed micro-organisms as they are produced.

Disinfectants, then, may act in the following ways, among others: (1) They may affect micro-organisms in the sense that anæsthetics act on man and cause death in consequence. (2) They may act as direct poisons to micro-organisms. (3) They may also lead to the death of micro-organisms indirectly in a number of ways, as, for instance, tannin does by chemical combination with albuminous principles resulting in the production of substances that micro-organisms cannot so readily, if at all, decompose. Or they may change the character of the nidus by oxidation, or chlorination, or otherwise chemically, so that it no longer serves as pabulum to the micro-organisms which then die off in consequence.

In all probability, further investigation will prove the ubiquitous character of pathogenic micro-organisms and while lending confirmation to the view even now largely entertained as to the folly of ever hoping to exterminate them by direct attack with parasiticides which kill the host also, it will accentuate the necessity of directing measures to the prevention of their development under certain conditions at present very imperfectly understood. In the meantime, just as Sir Joseph Lister has said there is no necessity to believe in the germ theory as a foundation to the practice of antiseptic surgery, the practical study of putrefaction, its causes and prevention alone sufficing, so also the same study will suffice to guide the principles of disinfection at large. All good antiseptics are necessarily good disinfectants, and all the experiments that can be devised or the arguments that may be employed will, I am confident, fail to disprove the fact. As Dr. Gamgee has expressed it,[5] "I am now convinced that every good antiseptic is really a destroyer of disease germs; an arrest of development is ensured."

I go further and say, that so far as the treatment of the human body is concerned, substances which are poisonous, or exhibit toxic effects, should never be used as antiseptics and disinfectants, for science has provided innocuous and non-poisonous substances which do all that is wanted.

Finally, a few words regarding Mr. Blyth's observation on anthrax spores. Of all the substances examined by him, none killed the spores, but many of them (including Sanitas) delayed their growth. Now Mr. Blyth says nothing as regards the action of these re-agents upon the fully developed micro-organisms and their functional activity. Assuming, that is to say, that the spores were unmistakably anthrax spores, and could produce disease in infected animals, he fails to show that after treatment with Sanitas *or in its presence* the spores retained infectivity, and until that is proved I decline to accept the conclusion that Mr. Blyth would draw respecting the treatment of this cattle disease, and even if he could prove it (and I am convinced he cannot) I would only accept the conclusion in regard to that one particular disease.

To properly test the value of any disinfectant it is necessary to test all its properties and not one particular property alone, and in relation to not one infectant but all infectants. Mr. Wynter Blyth has only made a few passing observations. On the other hand I can, if called upon, adduce a great mass of evidence in substantiation of my assertion that in "Sanitas" we have the best disinfectant and one that can be fully relied upon in the most serious cases of disease. I do not, however, seek to obtain a gratuitous advertisement for a preparation in the sale of which I am interested. My only object is to direct attention to the defects of Mr. Blyth's observations, and as a scientific man, who has made the subject at large a matter of special study, to contest his conclusions. One most important matter is left entirely out of consideration by Mr. Blyth, and that is the probability that micro-organisms convey disease and death not by their mere presence in the human body, but by the direct chemical and physiological properties of their secretions or life-products. The yeast plant secretes a chemical substance which splits up sugar into alcohol and carbonic dioxide. Other micro-organisms give rise to the production of sepsin, which is a chemical infectant. It is almost certain that the infectious and contagious diseases which owe their origin indirectly to micro-organisms, are similarly directly produced by chemical products elaborated or secreted by them.[6] If that be so, the use of caustic and poisonous disinfectants sinks into insignificance, and cultivations should be conducted not merely for obtaining pure growths of particular micro-organisms but with the object of ascertaining the effects of inoculating animals with the cultivation mixture before and after sterilisation (conducted without chemical alteration of attendant substances) and before and after attempted disinfection. This subject is of the very greatest importance, and I should gladly welcome any results in this clearly defined direction. In conclusion I may add that this is a matter to which I have paid much attention in the forthcoming new edition of my "Nature's Hygiene."

Society of Apothecaries.—The following medals have been awarded by the society during the past year:—In Materia Medica and Pharmaceutical Chemistry—Gold Medal to John Henry Garrett, of University College; Silver Medal and Books to Henry Hamilton, of the Bristol Medical School. In Botany—Gold Medal to Ernest Henry Starling, of Guy's Hospital; Silver Medal and Books to Wm. Beecroft Bottomley, of St. Mary's Hospital. Young Women—Gold Medal to Bertha Whitehead; Silver Medal to Sarah Elizabeth Wright. The society's gardens at Chelsea have been visited during the year by 3,248 students, of whom three-fifths were males, and the rest females.

[6] Klein has also arrived at this conclusion. See his articles on Micro-organisms and Disease. *Practitioner*, Sept. and Oct., 1884.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL.

FRACTURE OF THE SKULL IN A BOY—RUPTURE OF POSTERIOR BRANCH OF THE MIDDLE MENINGEAL ARTERY—TREPHINING—DEATH—AUTOPSY.

By RICKMAN J. GODLEE, M.S., F.R.C.S.
Assistant Surgeon to the Hospital, &c.

Alvero L., a boy aged 10 years, was admitted under my care into University College Hospital at about one a.m. on July 20th, 1882. At seven o'clock on the previous evening he fell on the pavement, and at once returned home. On arriving, soon after seven, his parents said that he had the appearance of a drunken man; he was pale and giddy, but he gave a clear and connected account of the accident, and complained of pain in the back of his head. He at once lay down and vomited some mucus. Soon he became a little wandering in his talk, and then drowsy, saying that he had been dreaming about a cart. His condition did not alter much, but yet sufficiently to alarm his parents, who thereupon brought him to the hospital, where he arrived about one o'clock in the morning, some six hours after his accident.

He was able to stand in the casualty ward, and to answer questions; but the drowsiness was evidently rapidly increasing. He was at once taken up to the ward, and when put to bed he lay turning himself about, and groaning. There was no recent wound, but a large hæmatoma, 3 inches by 3½ inches in extent, was found above the right ear, extending over the parietal eminence of this side. The movements of the left arm and leg were evidently weakened. The right angle of the mouth was a little higher than the left, but the face was otherwise symmetrical; there was no inequality about the pupils.

At 1.45 a.m. the pupils had become unequal, the right being larger than the left. His optical perception also appeared to be depressed. He took no notice when spoken to, but struggled when the tender area was touched.

After this, he rapidly became insensible, and was seized with convulsions, which had the following peculiarities: They were not of a very definite character in the groups of muscles affected, or in the rhythm, or force of the movements; but this much was noticeable, that the right limbs moved far more than the left, and this was especially the case at the commencement of the convulsion, seeming to show that the irritating stimulus was affecting both sides of the cortex at once, but that the centres in the right hemisphere were handicapped, *e.g.*, by anæmia and by actual compression. The convulsions were brought on whenever it became necessary to examine the patient, but scarcely, if ever, occurred except from some such exciting cause.

They commenced by irregular flexion and extension movements of the right limbs, which were feebly imitated on the left side; the lad then usually flexed his spine, and curled himself up towards one or other side; now and then he buried his head among the clothes, while on one occasion he cried out (apparently reflexly) "Oh! my head!" The movements continued for not more than two minutes. They were fairly powerful, and (with the exception of the difference between the two sides as noted above) were never quite alike in detail.

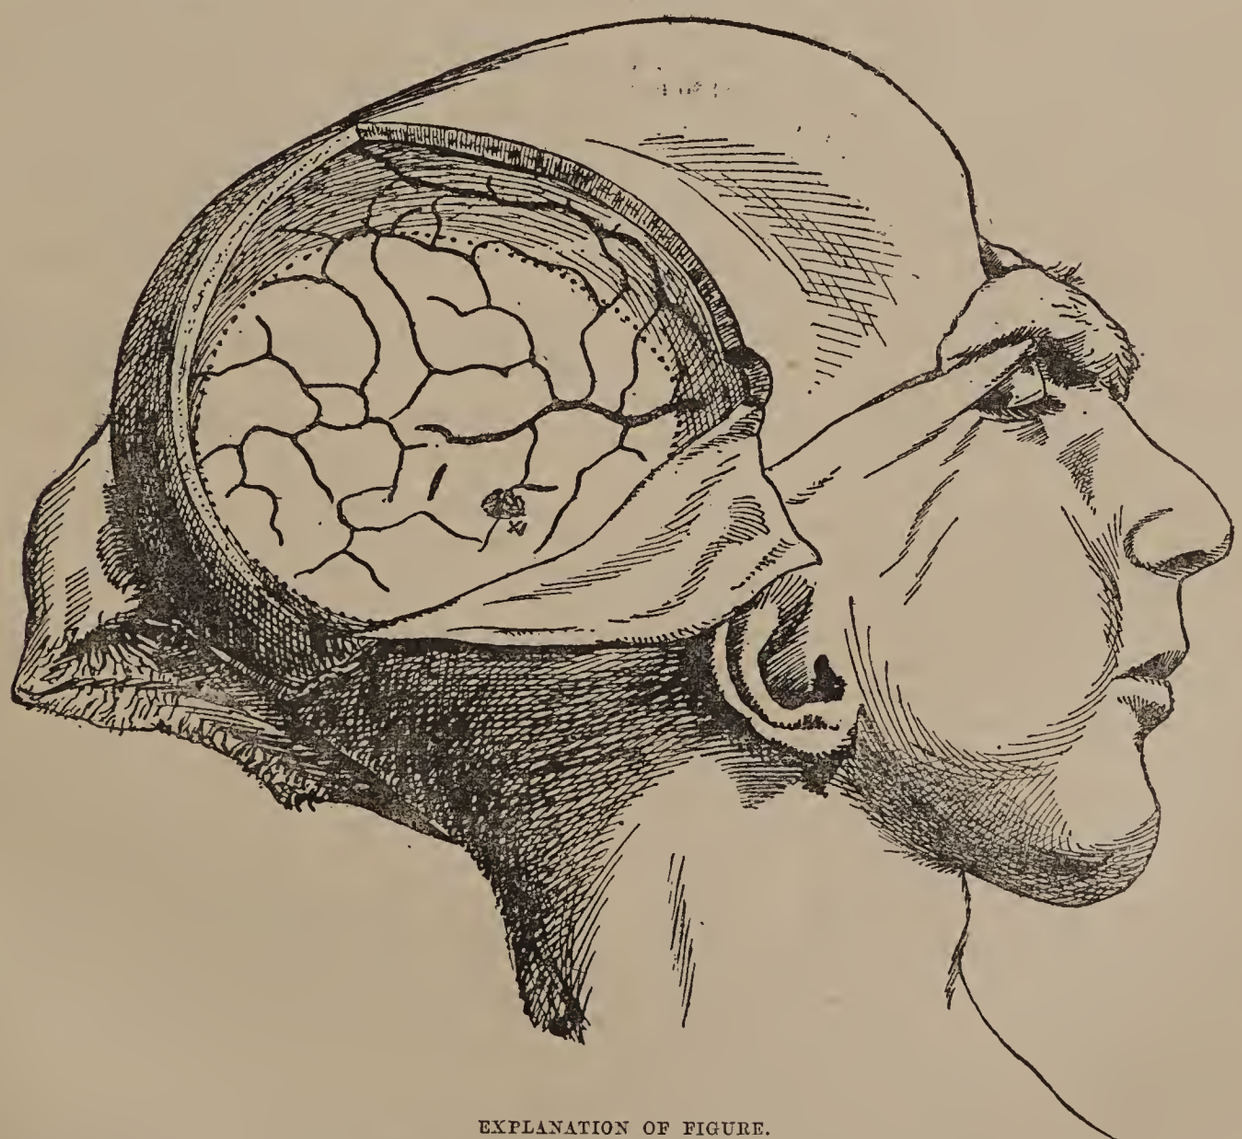
By 3 p.m. he was much more drowsy, and the convulsions rapidly increased in frequency and severity. The left pupil became dilated as the patient struggled,

and the pulse increased in frequency; when he was quiet the pulse was quiet, beating not more than 54 to the minute. The respirations had become catching and short; his expression was worn, and he was evidently growing weaker. He yawned at intervals.

His symptoms seemed to me clearly to point to pressure on the right side, and judging from the interval of time which elapsed between the accident and the onset of these symptoms, I concluded that they depended upon rupture of some branch of the middle meningeal artery, or other vessel of the dura mater on the right side. There did not, however, seem to be any clear indication as to whether the blood was likely to be found beneath the seat of injury, or in the usual situation (near the tip of the small wing of the sphenoid) of the anterior branch of the middle meningeal artery, which might have been torn across by a fissured fracture in the bone.

As the boy's condition was getting desperate, it was at last decided to trephine in the latter situation; and accordingly a spot was selected 1½ inches above the zygoma, and an equal distance behind the external angular process of the frontal bone. Considering the active movements which occurred when the injured part was touched, I thought it would not be prudent to attempt the operation without administering chloroform. It was given on lint. The administration had not been commenced very long when the breathing, which had hitherto been short and jerky, suddenly altered its character, the inspiration remaining as before, but the expiration becoming prolonged to a most unusual length. The administration was at once stopped, but the breathing was not improved. Presently all voluntary respiration ceased, and we were obliged to do artificial respiration, the pulse meanwhile continuing to beat forcibly. I proceeded with the trephining, and rapidly removed the circle of bone, across the centre of which was seen the groove for the artery. The opening, however, corresponded with the outer limit of the clot, as was proved by passing a probe backwards between the dura mater and the bone. It entered a large cavity, filled with blood-clot, and from which also a considerable quantity of fluid blood escaped. It seemed reasonable to suppose that this proceeding must have relieved very considerably the intracranial pressure, but no effect was produced upon the cerebral condition. It became increasingly difficult to make the air enter the chest by the artificial respiration which was still being kept up. The pulse now began to get weaker and weaker, and the boy died.

The Autopsy was made the same day. Rigor mortis was marked. The scalp was first separated from the right side of the skull, and it was then seen that a fracture ran horizontally forwards from the junction of the lower and middle fourths of the lambdoidal suture to a point one inch behind the highest part of the temporal suture. A portion of the side of the skull cap was then sawn through, and removed as shown in the figure :—



EXPLANATION OF FIGURE.

Appearance of brain, after turning down the scalp and removing a portion of the skull, including the fracture and part of the trephine hole, and reflecting the dura mater. The trephine hole is seen at the lower part of the anterior saw-cut in the skull. The dotted line shows the extent of the clot, and the convolutions compressed. XI indicates the laceration immediately beneath the fracture, and the spot at which the posterior branch of the middle meningeal artery was torn. The two thicker lines represent—the vertical one the fissure of Rolando, the horizontal one the fissure of Sylvius.

Beneath was found a large disc-shaped clot, weighing 2¾ oz., depressing the brain an area 3¾ inches in circumference, the extent of which is indicated by the dotted line in the accompanying drawing. The posterior branch of the middle meningeal artery was torn through at the point at which the fracture crossed it. The opening was demonstrated by injecting water through the carotid exposed in the neck. It was interesting to note that the vessel had been apparently plugged by a small clot which was found at the seat of rupture. It was only indeed after this clot had been sponged away that the small jet of water could escape. The seat of the rupture was vertically above the mastoid process, and 1½ inches behind the centre of the trephine hole. After removing the clot, it was found that a very considerable portion of the side of the brain had been compressed, and as far as could be judged little or no expansion of the compressed portion had occurred. The centre of pressure appeared to be over the extremity of the posterior limb of the fissure of Sylvius. Three small ecchymoses, not extending more deeply than the grey matter, were present in the centre of the middle temporo-sphenoidal convolution (XI in Figure). The actual flattening, as indicated in the drawing, involved the following convolutions: the supra-marginal, angular, posterior third of superior and middle temporo-sphenoidal, and the second and third annextant gyri. The convolutions of the entire brain showed considerable flattening except the anterior half of the left frontal and both the orbital lobes. There was considerable ecchymosis in the pia mater over the left frontal lobe. Both the grey and white substances were disorganised to the depth of one centimetre over an area of about one centimetre in the marginal convolution above the tip of the frontal lobe. There was also a little bruising to the outer side of tip of both temporal and sphenoidal lobes. The vessels at the base of the brain were healthy. The whole brain was extremely pale and anæmic. The fourth ventricle was normal; medulla and cerebellum also normal. Base of skull normal. Nothing remarkable or worthy of mention in either the thoracic or abdominal viscera.

Remarks.—The diagnosis of this case was one of considerable difficulty. There were in the first place unequivocal signs, as it seemed to us, of pressure from a gradually increasing clot, as opposed to those of a severe injury to the brain itself. They were:—(1) The interval of complete consciousness after (2) a severe injury to the head. (3) The gradual onset of drowsiness accompanied by vomiting. (4) The drowsiness gradually passing into complete unconsciousness. (5) The obvious paresis of one side of the body. (6) The slow pulse, and (7) the slow respiration. A complication was also introduced by the presence of the convulsions, the cause of which is obscure, and the nature of which was not very definite. It was thought by Mr. V. Horsley (then Surgical Registrar at the hospital), who observed the case with great care and to whom I am indebted for many of the observations and suggestions in this paper, that they were the result of some general cortical irritation and were more apparent on the right than on the left side because of the paresis of the latter.

It also seemed clear that the clot was on the right and not on the left side, the only unilateral symptoms present, viz.:—(1) The left paresis, and (2) the dilatation of the right pupil obviously pointing in this direction. It is much the most common occurrence for the fracture to pass to the opposite side of the skull to that struck, taking the line through the foramina in the middle fossa, and thus rupturing the anterior branch of the middle meningeal artery of the opposite side; but in this case where the clot was on the same side as the injury, we were without any data as to the probability of the hæmorrhage having occurred beneath the seat of injury or at the usual situation which was somewhat further forwards. It is easy to speculate on the data supplied by the *post-mortem* examination, but I doubt whether we had sufficient facts at our command to lead us to decide that the lesion was more behind than in front of the fissure of Rolando, and this was the point which it was after all required to know.

It is interesting to note that there appeared to be an arrest in the degree of coma, and indeed at times a slight return of voluntary movement and even of speech, although the general condition was clearly becoming worse. I have pointed this out in another case of the same kind (*Lancet*, 1880, Vol. II.), and would draw attention to it now merely to show that such symptoms must not be taken as a counter-indication to trephining.

It was a most unfortunate occurrence that the effect of the chloroform upon the respiratory centre, already in a state of more or less incompetence, was so great and so lasting. The lesson to be gained from it is no doubt that the operation in these cases should always be performed without the aid of an anæsthetic, even though considerable inconvenience should arise from the movements of the patient.

Whether or not he would have recovered if the chloroform had not been administered cannot of course be asserted. I believe the brain does not by any means always recover so completely from the effects of the compression as is generally supposed, and expand at once to occupy the position previously filled by the clot. The pressure must have been very considerably relieved by the operation which was performed; and had the slightest improvement on the symptoms shown itself, I should not have hesitated, or at all events I should not hesitate if a similar case were to present itself, to make a second opening with the trephine, and evacuate the clot as completely as possible.

Medical Times and Gazette.

SATURDAY, NOVEMBER 1, 1884.

THE Association of Fellows of the College of Surgeons are not allowing the grass to grow under their feet. We are enabled to print in another column the recommendations and alterations in the charters which the sub-committee, specially appointed for the purpose by the association, have drawn up, and which will be presented for discussion, approval or amendment, at a general meeting of the association to be held at the rooms of the Medical Society, on Saturday next, the 8th instant, at 4 p.m. A copy of these recommendations will be posted to every member of the association within the next day or two; any other Fellows who have not yet joined the association, can do so by sending their names to one of the honorary secretaries (Mr. Bruce-Clarke and Mr. Morgan) together with the subscription, 5*s.*, and they will doubtless be at once enrolled, and eligible to take part in the meetings of the association.

WE must cordially acknowledge that the sub-committee have done their work well, and have shown great judgment in dealing with a difficult and delicate task. Some of the recommendations have already been conceded by the Council of the College; indeed they

are actually by-laws of the College which have been allowed to remain "inoperative." As will be seen by referring to the full text of the report, the sub-committee desire to render the duties of the president somewhat less arduous, in order to induce him to hold office for a longer period than one year; and as regards the other members of Council, they hope to ensure from them due attention to their duties by causing them to seek re-election more frequently than at present. Such a mode of procedure we are sure will recommend itself to every sensible man. As regards the mode of election of president it is advised that the time honoured rotation and seniority should be abolished. The sub-committee propose that the Council should nominate three candidates from among the actual or past members of Council, one of whom shall be the retiring president, and leave the fellows at large to elect. As regards the *Court* of Examiners, the sub-committee propose their re-election every year, with a limit of five years, and that members as well as fellows of the College should be eligible for election on to the *Board* of Examiners. They recommend an annual meeting of the fellows and members, and give to any thirty fellows or members the right to requisition a general meeting at any time.

It will be granted that the sub-committee have grasped the subject they had in hand very thoroughly, and that, while recommending radical changes in the charters, they have suggested a most conciliatory method of securing them. Thus the election of president will virtually be in the hands of the fellows at large, but the Fellows will never be able to elect a president who is not *persona grata* to the Council, for the Council first select *from among themselves* the men whom they think best fitted for office. As to the right of public meeting of the members of a large and powerful corporation, there will be no dissentients; and as to the desirability of electing the Board of Examiners from the widest possible constituency few will entertain much doubt. There are several able teachers of anatomy in the London schools alone who are excluded from the Board of Examiners by the present regulation, which largely defeats one of the objects the Council had in view in establishing the Board. On the all-important question as to what title shall be given to the licentiates of the newly united examining authority the sub-committee is silent; but it will be difficult to keep the question out of the discussion at the coming meeting.

The interesting nature of the papers submitted to the Clinical Society on Friday last fully accounted for the somewhat unusually large attendance of members. The subject of myxœdema, already most familiar to regular frequenters of the Society, was brought to the front once more by a concise, though complete, history of a case, by Dr. James Anderson, in which some novel changes had been observed in the retina. A most valuable contribution to the present knowledge of the causation of the disease was presented by Dr. Semon. It consisted in the translation of the history of a case observed by Dr. Bruns of Tübingen, in which a patient had suffered complete extirpation of the thyroid gland eighteen years previously, and was now living, a cretinoid dwarf. The body growth had apparently been arrested, although the development of the head had continued. Within the last few years the patient had begun to present all the symptoms characteristic of myxœdema. So complete a proof of the connection between removal of the thyroid gland and the conditions of myxœdema and cretinism has never before been recorded.

A paper by Dr. Carrington, descriptive of a case of a skin eruption due to bromism, led to a short but instructive discussion as to the anatomical seat and probable causation of rashes due to iodide and bromide salts. Mr. R. J. Godlee contributed an interesting account of a case of nephrectomy for tumour in an infant, which opened up two important questions for discussion—the advisability of operating at all in cases of renal sarcoma, and the respective advantages of the lateral and median incision in the operation of nephrectomy. The extreme liability of sarcomatous tumours to recurrence in other organs is well known and was fully illustrated by several of the cases mentioned in debate. Extirpation of a kidney attacked by sarcoma would appear to be thought advisable if the tumour be of recent growth and of small size. The diagnosis of such a tumour, however, is in itself a matter of no ordinary difficulty, and possibly before such a diagnosis can be made with certainty, the disease has advanced beyond the stage when an operation can be of service.

At the Medical Society, on Monday last, Mr. Spencer Watson read a paper on the Treatment of Chronic Hypertrophic Rhinitis. In severe cases, removal of the hypertrophied mucous membrane, and even of the inferior turbinated bone (which is found much thickened), was recommended; for lesser degrees, douches which should be warm, with or without a little carbolic acid to destroy fœtor, when present, are sufficient. In a few cases the dilatation of the nasal passages with graduated ivory plugs gave good results. Sometimes this condition was associated with polypus. Mr. Watson felt unable to say much on the causes which gave rise to this distressing malady. Solutions of chromic acid were of great benefit in some cases; its application in cases where caustic action was desired, caused the patient much less pain than either nitric acid, nitrate of mercury, or nitrate of silver. He had used iodoform with advantage in a few cases; but its disagreeable odour rendered it an unpleasant application. At the same meeting Dr. Braxton Hicks showed an instrument for dry air disinfection. Ingenious, but not novel in principle, the instrument secured for the air of a room a thorough admixture of antiseptic substances. He advocated its use for medical men who had been exposed to possible infection, before again visiting a patient, for the lying-in room, and for the disinfection of linen, which was often a source of danger. Dr. Barnes concurred, and enlarged on the importance of absolute cleanliness for lying-in mothers, for the infant, and for the nurse; and thought Dr. Hicks' apparatus well calculated to

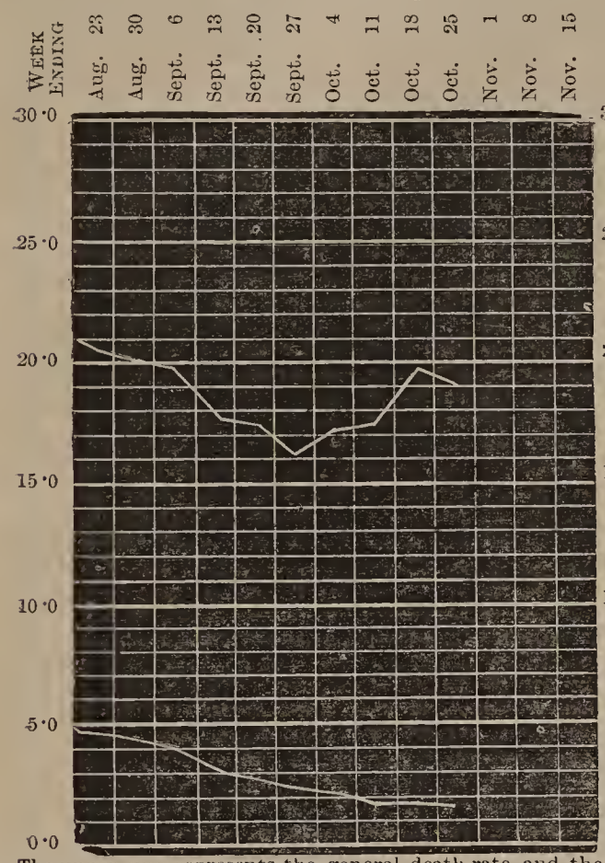
ensure this. Subsequently Dr. Kingston Fowler read an interesting paper on Functional and False Cardiac Murmurs.

The opening meeting of the present session of the Royal Medical and Chirurgical Society, on Tuesday last, was but very sparsely attended. In this respect it stands in marked contrast with the younger societies, the opening meetings of which have been crowded. Dr. George Johnson, on taking the chair, welcomed the Fellows and hoped that the session would be a thoroughly successful one. He referred to certain important alterations which had been made during the vacation, especially to the improved lavatory accommodation which had been provided. The drains, he said, had also been thoroughly overhauled by Mr. Rogers Field. The work had been rather costly, but the Council had decided that it was pressing and it had therefore been carried out. The Fellows, he thought, would be pleased to know that their house, in this respect, was in a most satisfactory condition. The first paper of the session was one by Mr. Adams, on excision of the head of the femur for unreduced spontaneous dislocation. Following the lead of Dr. Rawdon, of Liverpool, who had first performed this operation in a similar case, Mr. Adams had operated on a boy, aged 11 years, whose hip joint had become dislocated in the course of rheumatic fever. Owing to stiffness and malposition, the limb was very unserviceable. The result of the operation in this particular case was as good as it had been in Dr. Rawdon's case, and both children were exhibited, sound and well. In the discussion, Mr. Hulke gave expression to what subsequently appeared to be the general feeling of the surgeons present, that such a severe operation could only be necessary in a few exceptional cases. It was probable that, had time been given in both these cases, the bone would have made itself a new socket, and that an equally good result would have been obtained without operation. Mr. Barker thought it would have been better to have tried to reduce the head of the bone by cutting away any shreds of capsular ligament that interfered with reduction and which could not be otherwise dealt with, an opinion in which we fully concur. It was to be regretted that the plan of introducing specimens from the pathological museums illustrating the paper under discussion was not carried out. The late president, Mr. Marshall, on the opening night two sessions ago, said that the Council had decided to do this, and it was at once felt that such a practice would add greatly to the value of the paper, to the interest of the meeting, and that it would make the museums better known than they are at present. Had this practice been carried out on Tuesday last, Fellows would have been better able to appraise the various arguments *pro* and *con*, than without such specimens. On the whole it may be said that the cases in which such an operation is indicated must be few and far between.

When charging the Grand Jury, at Bedford, the Lord Chief Justice lately took occasion to remark on some of the methods by which society manufactures crime. One of these, he insisted, was the unreasonably severe punishments which are too commonly allotted to small offences against propriety. If such excessive punishments should be awarded to the petty pilferer, there is no kind of severity which the law can, with relative adequacy, administer for the greater and more serious crimes. Commenting on a case in which two little boys had been sentenced to three months' hard labour for stealing apples, after a previous conviction, he said that it was monstrous to make these boys felons for life for having done what some of the best men in the world had done, and for which they certainly deserved to have their ears boxed, but not to be sent to prison with hard labour. There can be no doubt that, as Lord Coleridge says, most of the crime of the country is the work of the same society which afterwards takes upon itself to punish the criminal it has manufactured, and we cordially agree with him in condemning these excessive punishments which defeat the very object they are supposed to secure; and especially the substitution of long terms of imprisonment for the shorter, sharper, and more suasive discipline of some form of corporal chastisement. Some official encouragement of the more extensive use of the birch, an increase in the permissible range of its employment as a punitive alternative, especially for juvenile offenders, would not only lighten the labours of the magistrates, but would tend also to lessen the dangers of developing a scapegrace into a criminal. We must protest, however, against that particular form of chastisement which his lordship has thought fit to sanction. We have already, and more than once, drawn attention to the evils which are apt to attend the practice of boxing the ears, and we believe that the progressive enlightenment of public opinion on the matter has already done much to reduce its frequency. But there can be little hope of its abolition so long as there are to be found in high places those who continue to endorse a means of chastisement which is always ready to the hand, and which members of the lower orders are not so delicate in applying as they are ignorant and careless of its risks. Imprisonment with hard labour is certainly not desirable for those who might become "some of the best men in the world,"—nor are such blows upon the head as may, only too easily sometimes, result in permanent injury to ear and brain. To the manufacture of criminals there are other alternatives, surely, than the production of deaf or imbecile virtue.

There were 1,463 deaths in London last week, giving a rate of 19·0 per 1,000, which shows a slight fall on that recorded during the week before. The deaths from zymotic diseases numbered 127, being at the rate of 1·7 per 1,000. These included 15 from small-pox, just half as many again as in the previous week, 16 deaths from measles, and 22 each from scarlet fever and diphtheria. We have over and over again drawn attention to the large mortality from this disease, and we would once more point out, as we have had occasion to do before, that in all probability this number does not represent all the deaths from diphtheria, as under the head of croup we find the deaths of 7 children recorded whose ages ranged from 1 to 5 years, the majority of whom, there can be but little doubt, really died of diphtheria.

The deaths from enteric fever declined from 17 to 12, and those attributed to diarrhœa and dysentery only numbered 27. Diseases of the respiratory organs were



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past ten weeks.

credited with 274 victims, no less, however, than 92 below the corrected average for the week. Of the 28 large towns, Preston has performed the somewhat unusual feat of having a death-rate (31·5) which is 5·1 per 1,000 higher than that of any of the other large towns.

The winter session was formally opened at the three Glasgow medical schools on Tuesday last, with the usual introductory addresses. Professor Leishman was the lecturer at the University, and his remarks were mainly devoted to medical education and examination. He spoke of the objections to the system of divided examinations, and advocated the extension of the curriculum. The address concluded with some practical advice to the students. They might confidently count on a moderate livelihood, but certain preliminary conditions, such as energy, punctuality, and sobriety, were essential to even moderate success. There was another kind of success to which he sincerely trusted none of them would ever attain. He meant that which sprang from blatant self-assertion, and even from unblushing fraud. When they became practitioners they would often hear of quacks and quackery, and they might possibly join in the cry for legislative protection against them. But so long as there was no limit to human credulity there was no possibility of suppressing quackery. There were quacks within as well as without the pale of the profession, and he took it that the moral turpitude of these was even greater than that of the bolder rascal who could not shelter himself behind the robe of a professional title. He asked his hearers by all means to aim at success, but let them never try to found success on anything but honest effort and honest work. Dr. Barr's address, at Anderson's College, dealt mainly with the legislation required in the interests of the public health; while at the Royal Infirmary Dr. Glaister discussed a somewhat allied subject, viz., the necessity of legislative reform in regard to uncertified deaths in Scotland.

Amalgamation of medical schools is almost as much needed in Glasgow as in London. There are already many medical schools in that city, and the number is shortly to be increased by the removal of the Andersonian School to the neighbourhood of the Western Infirmary. For at present the Andersonian and the Royal Infirmary School, although provided with two sets of lecturers, may be regarded as one, having the large hospital as their centre. If the principle of disruption were not congenial to the Scottish intellect, we might suggest to the governors of the two institutions to consider whether an amalgamation of the two schools might not be advantageous to both. It is not to the interest of the Royal Infirmary to let all the students drift away to the Western Infirmary, and the success of the Andersonian in the proposed new building will greatly depend upon the passing of a Medical Bill. If the University retains its present monopoly, the extramural teachers, however eminent and painstaking, will have no fair field. The funds for raising a new building might be better invested in the endowment of lectureships in one large medical school, by which means something substantial might be gained for the interest of medical education as well as for that of all parties concerned.

As our readers are probably aware, the medical session in the Irish hospitals and schools begins only nominally on the 1st of October. The courses of lectures are not formally inaugurated until the close of this month, or the beginning of November. We are at a loss to know why such an awkward arrangement is adhered to. It seems to us that the first and therefore the best month of the winter session is in this way sacrificed, and that the students are, on the very threshhold of their studies, likely to be impressed with the idea that, after all, time is not so very valuable. We are strongly of opinion that an effort should be made to get the classes together on October 1st, and to start punctually on the solemn business of a medical session.

In accordance with existing custom, however, the "introductory" in the School of Surgery of the Royal College of Surgeons in Ireland was not delivered until Monday last, the 27th ult., when Mr. Theodore Stack, Professor of Dentistry in the College, held forth in the lecture theatre before a large audience of the Fellows, professors, and students. As was to be expected, Mr. Stack spoke in particular of the progress which dental science had of late been making in the medical schools of the United Kingdom, and he pointed out how essential to dentistry was a knowledge of anatomy, chemistry, materia medica, toxicology, physiology, and mechanics

Of course the lecture did not pass off without some sallies of wit from the students, as when the lecturer was removing some teeth from a model of the palate and upper gum, several voices in the audience cried out "Painless Dentistry." And again, when Mr. Stack spoke of disease attacking "the pulp of the tooth" nearly all the students present commenced to groan in an agonised manner. At St. Vincent's Hospital, Dr. F. J. B. Quinlan, Senior Physician, gave an introductory address on Tuesday, October 28th. He chose as his subject an account of the work done at the recent International Medical Congress at Copenhagen. The address, which occupied only half-an-hour, was listened to with attention by a large audience.

We English have very little idea to what lengths religious rancour and sectarianism are pushed in Ireland. A signal instance occurred the other day, when the Corporation of Dublin were engaged in passing the annual corporate grants to the hospitals and charitable institutions of that city. It was proposed to renew a grant of 300*l.* to the Rotunda Lying-in Hospital, an institution which has a cosmopolitan reputation, and which yearly attracts numbers of students from all parts of the world. The proposition was at once opposed on the ground that the governors were almost all Protestants, and that a Roman Catholic candidate had been lately defeated on the occasion of the election to fill a vacancy on the Board of the hospital. In the course of the debate the curious fact came out that the gentleman in question was defeated by *one vote, which was given in mistake by a Roman Catholic elector*. In the end the vote to the hospital was reduced by 50*l.*, thus giving effect to a suggestion of one of the speakers, who said: "Let us, for every Roman Catholic candidate thrown overboard, cut the grant by 50*l.*" Such narrow-mindedness and bigotry in the name of religion almost surpasses belief.

The position of a medical officer of health in the Sister Country does not appear to be always a "bed of roses," if we are to judge by an incident which occurred at Kingstown, near Dublin, the other day. Dr. J. Byrne Power, Diplomate in Sanitary Science of the King and Queen's College of Physicians in Ireland, and Medical Officer of Health for Kingstown, had the temerity to read before the Sanitary Institute of Great Britain, at its recent congress in Dublin, a paper, in which he animadverted in no measured terms on the defective sanitary condition of the township of Kingstown. For this he has been severely taken to task by the Township Commissioners, who passed the following resolution at their meeting on Monday, October 27th, viz.:—"Resolved: That this Board desires to express its strong condemnation of the action of its Medical Officer of Health (Dr. Power) in grossly neglecting his duty by not reporting to the Board, as he was bound to do, and in accordance with the Artisans and Labourers Dwellings Act, 1868, any abuse (if such existed) affecting the health or condition of the township from a sanitary point of view; and that this neglect was further aggravated by his disseminating statements injurious to the progress and prosperity of the township at a meeting of the Sanitary Congress."

The returns of the new entries at the provincial schools of medicine contain one very significant fact, viz., that one short of 50 students have entered at Newcastle for the purpose of obtaining the Durham degree, in addition to 30 students who have entered for the full curriculum. Of the 49 students in search of the title of doctor it may be assumed that a considerable proportion have received the major part of their education at a London school, and would no doubt have stopped in London if they had been able to get a degree there on as reasonable terms as at Newcastle. We do not grudge the Northern University its success; such an infusion of new blood cannot fail to give it increased strength. But it is a little hard on London teachers to see students whom they have taken through the most arduous part of their curriculum running off to another place to complete it. The question of a come-at-able London degree is becoming the burning question of the day in medical circles, and we are glad to see that it is being considered by a Committee of the Metropolitan Branch of the British Medical Association. We pointed out the difficulties of the question last week, but we cannot believe that they would prove insuperable before the united efforts of the London teachers. We suppose it would not do to suggest that future students should "Boycott" the London schools until the question is solved.

The tendency of the entries in all but one of the provincial schools from which we have received returns, is towards increase. Birmingham has an entry of 35, compared with an average of 29 during the previous five years. Manchester has an entry of 68, or five more than the average of the three preceding years. The entries for the full curriculum at Newcastle are 30, or two more than the average of the previous four years; but, as we have already stated, 49 additional students have entered for the Durham degree. The entries at Leeds are 35, well above the average, while those at Bristol, viz., 21, are six below the average of the preceding five years. This falling off is probably to be accounted for by the superior attractions of the Northern Schools, at which a degree can be obtained, for we believe that the Bristol School was never in better working order or higher repute.

Mr. Warton has given notice that on Tuesday week he will call the attention of the House of Commons to the manner in which the Government have dealt with the question of poisonous *public* medicines, and move a resolution. The inexorable blocker surely means "private." Whether we regard them in respect to their proprietorship, or in respect to their formulæ, the medicines in question are anything but "public." That is the very thing that medical reformers want to make them.

It is stated that the Association of Members of the Royal College of Surgeons have petitioned Mr. Gladstone to give two representatives in Parliament to registered medical practitioners, on the grounds that "they would form a highly educated and eminently respectable constituency, and that they should not be

placed at a legislative disadvantage with the various universities which already return members." We cannot imagine a more ill-advised proceeding. It is well-known that the Radicals view with great jealousy the anomalous representation of the universities, the disfranchisement of which is probably only a matter of time, and no Liberal Government would entertain the idea of still further extending the representation of classes of the community, however educated and respectable. To petition for a gift which there is not the slightest prospect of obtaining appears to us little short of childish.

We publish in another column a short letter from a correspondent, expressing in a few words the thoughts which have probably passed through the minds of most medical men on reading the account of the death of Mr. Rabbeth, at the Royal Free Hospital. Our feelings of admiration for his unhesitating self-sacrifice are mingled with regret that it should have been exercised in so hopeless a cause. But ought it ever to be necessary for a surgeon to put his life to such imminent risk as is involved in immediate suction of a diphtheritic trachea? Are there no mechanical contrivances by which membranes may be removed without danger to the operator? These are the questions suggested by our correspondent's letter, and in answer to them we can only point to two advances which have been made in this direction. A suction syringe has been devised for Mr. Hulke which is said to work well, but is of necessity somewhat bulky. A more practical form of suction-tube is figured and described in his work on Tracheotomy in Laryngeal Diphtheria, published in 1880, by Mr. R. W. Parker. Whilst allowing a strong current of air to pass through it, the tube is provided with a plug of antiseptic wool which effectually prevents the passage of any shreds of membrane. The necessity either for immediate or mechanical suction ought not to arise except in those emergencies where no means are at hand for breaking up and removing membrane within the trachea. But hitherto it has not been the custom to provide for either of these contingencies. A good supply of suitable feathers and a suction-tube, such as the one to which we have referred, ought to be at hand in every future tracheotomy case.

Sir Joseph Lister has recently called attention to a form of antiseptic dressing which has been proved in Germany to give some remarkably successful results. It consists mainly in the use of wood wool, rendered antiseptic by means of corrosive sublimate. Dr. Paul Bruns, of Tübingen, has published an account of its mode of action and the method of its application in "Von Langenbeck's Archives." It possesses the special advantage of being extremely absorbent in its action, to such an extent, indeed, that the surface of the wound is thus kept perfectly dry, the condition most of all favourable to the process of union by first intention. A further improvement which it presents over many other forms of antiseptic dressings lies in the fact that it may be kept in its place for a much greater length of time without the necessity for renewal. It is easily applied, care being taken to prevent the intervention of anything that might possibly hinder the free absorption of the secretions from the lips of the wound. When soaked through to the surface, it is sufficient to add a small pillow of the same material to the dressing, to permit of the absorbent process continuing without interruption. Dr. Bruns gives a list of cases in which this form of dressing has been used, and it must be admitted that the figures are remarkable, whether exclusively due to the new method of treatment or not. Of 540 important operations performed at Tübingen during fifteen months, only one became the subject of any extraneous infection, and in that instance the wood wool dressing had been discontinued. In 37 cases of amputation of limbs primary union was obtained no less than 32 times. This result, which is equivalent to something over 86 per cent., is very far in advance of the general average in Germany, which usually ranges rather under than over 50 per cent. The occurrence of primary union in the miscellaneous cases was almost equally satisfactory. Such figures as these speak with considerable force in favour of the principle of dry antiseptic dressings, and Dr. Bruns' claim that an important advance is thereby established will doubtless be fully conceded by all English surgeons.

With the exception, perhaps, of forensic medicine, there is no subject in the whole medical curriculum which is worse taught, or on which more time is wasted, than that of Practical Chemistry. The course seems to have been arranged as if the student were destined to become a chemist rather than a doctor, for the simplest chemical manipulations and analyses required in medical practice are, as a rule, entirely omitted from it, and the student has to learn them subsequently as best he may. The brief remarks on the subject contained in a paper read by Dr. H. E. Armstrong at one of the Health Exhibition Conferences, and just published, are not a bit too strong, and it is to be hoped they will not fail to arouse the attention of our medical teachers. "At present," says Dr. Armstrong, "the only practical teaching vouchsafed to the majority of students in our large medical schools is a short summer course, during which they are taught the use of certain analytical tables: as a mental exercise, the training they receive is of doubtful value; the knowledge gained is of little use in after life, and the course certainly ought not to be dignified by being spoken of as a course of Practical Chemistry: *test-tubing* is the proper appellation. It is not a little remarkable also that even the London University Syllabus nowhere specifies that a knowledge even of the elements of quantitative analysis will be required of candidates either at the Preliminary Scientific or First M.B. Examination, and this too, when, as is well known, an analysis to be of any practical value must almost invariably be quantitative. It is little less than a disgrace to the medical profession that a subject of such vital importance as chemistry should be so neglected." Dr. Armstrong, in his paper, is not content with such destructive criticism as the above, but he describes a most rational method of teaching chemistry practically, which, if followed out in our medical schools, would no doubt do much to give the student a fair insight into chemical processes. The subject is one that might engage the attention of the Medical

Council much more profitably than some of the discussions on which time has been wasted this session.

At the ordinary meeting of the Royal College of Physicians held on October 30th, the licence of the College was granted to thirty-five candidates who had passed the required examinations, and six gentlemen who had been examined and approved by the Censor's Board were admitted to the membership. The audited accounts of the College for the year ending Michaelmas Day were before the College, and presented a very pleasing picture of its financial condition. It was stated that Dr. Quain had been nominated Harveian Lecturer for next year, and that Dr. Mahomed would deliver next year's Bradshawe lecture.

THE EXAMINATION OF ARMY SURGEONS.

Another Army Circular, dated 1st November, 1884, supersedes the one issued on the 1st August, so far as regards the Regulations for the examination of officers of the Medical Staff. Surgeons must be examined between the fifth and tenth year of service, and surgeons-major must be *re*-examined before promotion to Brigade rank. We do not like these frequent tests. We do not see why surgeons between the fifth and tenth year of their service should be examined as to their qualifications for promotion to the rank of surgeon-major. What difference exists between the two ranks? The surgeon-major is the senior, and has probably become more a man of the world, and better conversant with War Office forms; but where is the professional difference between the younger and the older man? In all main points, the surgeons who leave Netley are as capable to undertake hospital work as their seniors. Indeed, if they are not fit at the very commencement of their career to act as surgeons, physicians, and sanitary officers, they should never have been given commissions at all. In the olden days assistant-surgeons were in a rather different position. They were under the training, as well as under the orders, of the surgeons of their respective regiments. On entering the Service they would not have held the responsible position that may now fall to the lot of a junior surgeon, who may be at any time called upon to resist disease or repair injuries, alone and unassisted. No doubt those who are advocates of examination will say: This is the very reason why the surgeon should be tried before promotion, to make certain that his knowledge has not lapsed, nor his skill failed. But if this be the reason, why do the authorities allow a number of incompetent men, or presumably incompetent men, to serve for five or ten years before they make sure of their ability to perform their duty? The test for *admission* to the Medical Staff of the Army should be severe, but it should be fitted to the nature of the work, and candidates for the Service should be led to understand the reason for this. Army doctors and general practitioners belong to the same class, and have the same education in the schools, but their fields of practice are widely different. A knowledge of medicine, surgery, midwifery, and hygiene, is essential to both, but to the country practitioner, excepting under peculiar circumstances, operative surgery comes last in the list of qualifications for success, while with the Army doctor it should be the first consideration. Unless a young medical man has an aptitude and even a predilection for operative surgery, he has no right to enter the Army at all. But if the Army doctor has aptitude and taste for this branch of his profession, why torment him with repeated examinations? They are not required for practical work and they may be made unfair, pedantic, academical and unreasonable.

Let us notice Clause No. 4 of the rules for the examination of surgeons; it runs thus: "A report on any subject of a practical professional character to be selected by the officer himself, and certified to be his own composition, and in his own handwriting, will also be required." But mark what follows: "*Considerable importance will be attached to the literary and scientific merits of the report.*" We should like to know how far a pleasant and easy style of writing would count in the way of obtaining marks, and whether a man who had a flow of words like Macaulay might be excused for not having the skill or nerve to "take up" an important wounded artery? We do not attach much importance to Clause No. 3, which is intended to be eminently practical: "A certificate will be required from a recognised teacher of surgery in any medical school, at home or abroad, in which operative surgery is taught, showing that the medical officer has gone through a complete course of operative surgery during the period within which the examination must be taken, and that he is a competent operator." We confess we should like to have a complete list of the schools and their nationalities, as well as the opinions of the teachers of operative surgery on the dead body.

We have less objection to make to the examination of surgeons-major before promotion to the rank of brigade surgeon. There is a special knowledge required here which could hardly be demanded from the average run of medical men. It is not only hospital duty which has to be performed, but hospital organisation and management which have to be mastered, and the relative positions and responsibilities of medical officers to other departments of the Army must be thoroughly understood. It is amusing to notice, however, that the unfortunate surgeon-major under examination will be required to furnish a medico-topographical report of any district or country in which British troops have been or *are likely to be actively employed*. With the pleasant surprises of the Soudan and the Zhob Valley before our eyes, we recognise the enormous geographical information which may be required from candidates. Still we consider, in all seriousness, that men of superior ability should have the chance of distinguishing themselves, and all we need insist upon is, that the necessary leave for special study should be given to every surgeon-major who applies for it. It cannot be given unless the strength of the Medical Staff be increased, and as this will not be done, we see a probability that the *luckiest man*, and not the best of the surgeons-major, will get his promotion.

The re-introduction of examination shows one thing—it proves that the War Office feels sure of its ground, and that it no longer dreads the half-forgotten day when students would not compete for entrance into the Medical Department of the Army. Of course the War

Office only imitates the German system of examination, but it may be more worth while for the German Medical Officer to remain in his service than might be the case with the members of the British Medical Staff. There can be no doubt that young English medical men could exercise their profession more lucratively in the colonies, or in country practice even, than in the Service; and the temptations to choose the freer life of the army may be powerless, with constant examinations staring them in the face, and useless examinations too. If there is *any* reason whatever for these tests, it lies in the desire to keep men up to the mark, and yet the regulations direct that the fellowship of any Royal College of Physicians or Surgeons of Great Britain or Ireland, granted under a higher standard than that for licentiate or member, will be accepted in lieu of an examination in Medicine or Surgery. That is to say, a gentleman who enters the Army with the qualification of "Fellow" can never rust. Lucky man! who needs only to pass his leisure hours in cultivating a literary style, or mastering the topography of the various places where British troops may have to serve.

CLOISTERED VIRTUE.

Some of the lay papers have recently been interesting themselves in the social life of the London Medical Student. The discussion was started by a letter in the *Pall Mall Gazette*, the writer of which, impressed by the fact that the London student has to spend four years of uncared-for life in the very centre of every dissipation, without the discipline and many social advantages of an academic life, naïvely suggests that the General Medical Council should compel each school to have a dean of residence or other such official, who, besides visiting and supervising the lodgings of the students, should watch over the social side of their lives. He further suggests that the Council should appoint paid proctors to supervise the London students as a whole and to take care that those who have so misbehaved themselves as to come within the cognisance of the police magistrate should be rusticated or expelled from their respective schools. And, lastly, he deplores the want of combined lodgings or hostels, the need of amusements like billiards, &c., and the need of libraries for evening study. The schools, he complains, compete with each other in every way except in providing social comfort for their students. As a result of this neglect, he thinks that the whole tone of the profession is lowered. Except for the futile suggestion to work through the Medical Council, there is a good deal to be said for the views expressed in the letter from which we have quoted. The life of the London student *is* often sordid and comfortless. In the case of the working student, it is a life of continued labour, unvaried, for the most part, by amusement, except an occasional visit to the theatre, and relieved by few of those harmless social dissipations, which form so large a part of Oxford and Cambridge life. It is also, we admit, in most cases an uncared-for life. The student is quite at liberty to go to the dogs, without any of his teachers thinking it part of their duty to restrain him, and, in many cases, he takes full advantage of such permission. Nay, at some hospitals, we regret to say, the facile descent to Avernus is not only permitted but is even encouraged by the teachers. A cruel custom has recently grown up at some schools of what is euphemistically termed "getting rid" of a student who is too idle or too imbecile to do credit to his school at his public examinations. While fully admitting the advisability of removing from a medical school every real *mauvais sujet*, who by his example is likely to lower the tone of his fellow students, we cannot believe that medical teachers are honestly fulfilling their contract with the parents in throwing off every student whose wits are merely below the average, and the school which habitually follows such a policy appears to us to thereby confess its incompetence and its untrustworthiness as an educational institution.

While granting, however, that in some respects the teachers might with advantage take a little more sympathetic interest in the personal career of the students entrusted to their care, especially in the case of the dullards, we cannot admit that the life of the London student is in any way inferior, as a discipline, to the life of the older Universities. As a training for future struggles it is distinctly superior to the ideal university life. It might be the better for a few more refinements, but we should strongly deprecate any attempt to introduce the apparatus of deans and proctors which makes an Oxford or Cambridge career little better than an extension of school-life. The one good point in the life of a medical student in London is its absolute freedom. The feeling of responsibility which such freedom brings to every serious student is one of the most important elements in his education. It makes him self-dependent and resourceful, and converts him almost at one stroke from boy to man. That a certain number of students abuse this freedom is a matter of course. They would abuse any good gift. We very much doubt, however, whether the proportion of London students who come to grief through their liberty is much larger than the proportion of university undergraduates who go under in spite of the elaborate precautions with which their lives are surrounded. And in order to keep these floundering students within the lines of virtue, one would have to rob the London life of that very element which makes it so valuable and robust a training for the vast majority. It has often been remarked upon as little less than a paradox that while medical students are proverbially so wild, medical practitioners are proverbially so steady and respectable, but to our thinking the paradox easily explains itself when one looks upon the free unfettered life of the student as the appropriate training for the self-restrained life of the practitioner. Make the student more virtuous and the chances are that you will make the practitioner more vicious. We have as little admiration as Milton had for a "cloistered virtue," and we would much rather see the London medical student as he is, a little wild, a little rough, and guilty, perhaps, of occasional lapses from virtue, than have him surrounded by the refined fripperies, and the polished restraint of an academic life. More billiards, if you like; but proctors, distinctly "no."

CLINICAL PAPERS.

XV.—On The Observation of Symptoms.

It has been said that our official nomenclature does not so much describe disease, but rather gives names to the several ways in which disease terminates. There is the first declension from health, referable to no one region in particular; by and by come certain indications that this or that organ of the body is suffering more obviously than the rest; and at last there is the discovery of some definite material change. But it is only to this final stage of a lengthened process that any formal name is attached. So far indeed are we removed from any other nomenclature than this, that it is difficult to form a conception of what any other would be like or what sort of terms it would employ. The supposition that a day will come when the precise nature of disease will be recognised and appreciated at first starting is so different from the existing state of things that, except for suggesting a metaphysical conflict for priority between structure and function, it is not conceivable.

Yet, inasmuch as people are ill before they are diseased and seek information as to the nature and tendency of their earliest symptoms, it comes to pass of necessity that a number of phrases are current amongst us—"irritation," "loss of tone," "depraved secretion," "perverted nutrition," and the like—which, though they have no precise significance, and are in fact borrowed from the language of theology and morals, are yet needed for daily use. Such phrases serve to designate, or rather to tide over, that stage of disease when the real significance of symptoms is matter of conjecture. They are made necessary by the demands of the public. We are in this dilemma—either symptoms must be interpreted at hazard, so soon as they arise and upon grounds admitted to be insufficient; or else the name of some symptom or group of symptoms must be set up and made to do duty for a disease which is as yet inscrutable.

It is easy enough in our formal school teaching to condemn this elastic language of symptoms and to contrast it with the realities of the *post-mortem* room. No doubt the distinction is a wide one between the mere naming of symptoms, and that process of reasoning by means of which they are explained and harmonized, and it is right to insist upon it. Yet it must be remembered, not only that the actual illustrations of disease which hospital wards afford have passed that stage at which the difficulty in question is encountered, but also that for their own sake and for a full rendering and adequate conception of all the facts concerned, the study of symptoms, as such, is a necessary part of our duty.

Let me give an illustration or two. A child exhibits certain signs suggestive of tubercular meningitis, sickness, convulsion, delirium, perhaps even paralysis; signs which time after time have been found *post-mortem* associated with meningeal inflammation, and which, on that account, are so interpreted in the present instance. But instead of dying, as upon the hypothesis was to be expected, this child recovers, and in the fact of its recovery the diagnosis is proved to be wrong, the symptoms remain unexplained, and are soon forgotten. Or take another case. Take a condition of prostration and pyrexia, which, wanting the more characteristic signs of enteric fever, is regarded doubtfully at first as either typhoid or acute tuberculosis. It happens sometimes that such patients, exceeding the proper typhoid period, will show symptoms of wasting and hectic, insomuch that at last the theory of typhoid fever is abandoned, and that of tuberculosis substituted; a diagnosis, which, in the great majority of cases, death presently comes to verify. But sometimes it will happen (I am speaking of course of the very rare exception) that such patients, in spite of extreme emaciation and prostration, do not die, but turn round and recover. Here again hypothesis is falsified, the picture is left incomplete, and the symptoms, which have thus proved delusive, are regarded as shadowy and unreal and willingly dismissed, or only dwell in the mind in some misty fashion along with other examples of erroneous or unverified diagnosis.

Yet here are facts; facts which are not the less real because they happen to contradict text-books. To speak of "cerebral irritation," or "tubercular fever," is to speak vaguely, but if by such terms I convey the fact that symptoms of the kind just mentioned are of wide signification and not uniformly fatal, they are terms which serve their purpose well enough.

For, observe, that unless symptoms of this sort, having a rare and unlooked for issue (and many other illustrations might be given besides those I have chosen), are kept in full view, the natural history of disease may be distorted and narrowed in many mischievous ways. It is not only the puzzled and mortified student we have to consider in presence of a result contradicting his predictions and discreditable to his diagnostic powers. There is another frame of mind besides his. It is that of the therapeutist who first asserts the presence of a fatal disease, and presently announces that he has succeeded in arresting it. Let any drug of large pretensions be brought into general use—such, for example, as the hypophosphites—and in the nature of things the time must come, sooner or later, when such drug happens to be employed in one of these anomalous cases of unexpected recovery. Nothing is more certain than that such recovery, however rare, is within the scheme of nature and takes place independently of any specific action on the part of the physician. But if that fact be put away and ignored just because it is at present inexplicable, such neglect will assuredly open the door to misrepresentation. And this not from dishonesty, not even from inexcusable ignorance. It is the natural consequence of our partial recognition of the facts of medicine, and the habit of dwelling exclusively upon such portions of it as are understood and assured.

And there are other motives for the independent study and due registration of symptoms. Think how many of these are as yet awaiting interpretation, how pressing is the need for such interpretation if ever we are to get nearer to the root of disease, and how

certain it is that systematic and impartial observation of symptoms is the only method of getting at their use and reason. There are scores of symptoms of uncertain indication which are waiting to be registered and which will find their significance in the future. How many men with bronzed skin passed away, how many women with enlarged thyroid glands, how many children with gigantic calf muscles, before Addison, and Graves, and Duchenne had courage and pertinacity to dwell upon novel and trivial symptoms? Clinical signs which have no assured physical basis, which are, so to speak, unattached, are always in danger of neglect and disparagement. When cardiac murmurs were first revealed, and the valve defects on which they depend were pointed out, those physical signs were eagerly recognised and made use of. But it was many years later before the reality of functional and dynamic murmurs was admitted. They must have been heard often enough; but the evidence of the ear was mistrusted because the sight did not seem to bear it out. It is only the bold and the independent who can pick out and appreciate new symptoms, can seek a meaning in the mark of a finger-nail drawn across the skin, or utilise the schoolboy's trick of tapping the patella ligament.

If any one should doubt for a moment how pressing is the need for more light in the department of symptoms, let him consider—it is but a single illustration—the nature and the incompleteness of our knowledge in regard to cardiac inflammation. There are no *necessary* signs whatever as yet known to us to indicate the onset of inflammation either without or within the heart. The rub of pericarditis is only present by an accident, while endocarditis has at the first absolutely no indication which can be trusted. If it be true, as Dr. Sibson taught, that these morbid conditions may be recognised by the face and aspect, what a flood of light will be one day thrown upon some of the most obscure as well as the most important problems of practical medicine.

The observation of symptoms is indeed the real and only path of advance in practical medicine, and one can but wonder to see it neglected as it is. If it be true that there is a class of practitioners whose minds seldom dwell upon morbid changes which ought to be familiar to them, and who have but vague knowledge in regard to the few pathological terms they employ, it is true also, that in our hospital practice and teaching we deal mainly with disease which is advanced and irremediable. The hospital student can hardly be brought to feel an interest in his cases until such time as they present objective signs which are grossly tangible, and where the main problem is not to cure, but to be able to forecast the precise physical condition of some vital organ in keen anticipation of the day when death shall reveal it. Meanwhile examples of *disease in the making*, of illness which (provided there is the insight to recognise its tendency) there may be time to arrest, get no systematic study whatever. They are observed on and off in such loose fashion as out-patient practice implies, or, worse still, in the case of the well-to-do, they go wandering about from doctor to doctor and are mocked and trifled with under such names as "depraved nutrition," "suppressed rheumatism," or "latent gout." Ψ

REVIEWS AND NOTICES OF BOOKS.

SURGICAL SCIENCE AND SURGICAL PRACTICE.[1]

We gladly welcome the new editions of these standard works, both of which have been eagerly looked forward to. The former of them — and we place it first on the list by reason of its seniority—has stood the test of 30 years trial, and appears now in its 8th edition; the latter, though comparatively young, is in its 4th edition (12th thousand). Measured by their commercial success, therefore, the books must have fulfilled the objects for which they were written, and they have thus placed themselves beyond and above criticism from this particular standpoint. And yet, though dealing with the same subject, and written for the same purpose, by authors equally eminent in their profession, the works are widely different. General readers, students, and critics will all alike agree with Mr. Erichsen that "the teacher of surgery who seeks to give a true and impartial view of the subject of his tuition, is placed in much the same position as a judge who is summing up a great cause," and that "he must endeavour to divest himself of the trammels of the schools, to free himself alike from the partisanship of individual bias and the prejudice of professional antagonism." It shall be our endeavour to shape our criticisms on these broad lines and to see how far the authors act upon such admirable maxims. We will bring out the contrasts and parallels of the two works, and also add something about the individual character of each.

We cannot say much in praise of the arrangement of matter in either book, both being exceedingly faulty artificial, and unscientific. Mr. Erichsen plunges *in medias res* straightway, Mr. Bryant gives an introductory chapter, which we would advise every student to "learn and conn by rote" before going any further. Mr. Erichsen, under the title of "first principles" commences with chapters on "general considerations on operations," "amputations and disarticulations," and on "special amputations." How the doctrine of special amputations, or disarticulations — some of the most dreadful mutilations which the surgeon is called upon to effect—can be ranked as "first principles" we fail to see. Surely before men are taught to amputate, they should learn something about reparative surgery, and the principles which govern it. John Hunter taught that "surgery consists in curing disease rather than in the removal of it by mechanical means," and in accordance with this precept, Mr. Bryant wisely begins with "wounds—repair and inflammation," and gradually passes on to surgical disease, and thence to injuries and questions of surgery generally. Mr. Erichsen's chapters on Inflammation, however, though misplaced and curiously scattered about, are nevertheless admirable essays, fuller and more scientific than Mr. Bryant's.

[1] The Science and Art of Surgery, by John Eric Erichsen, F.R.S., &c. 8th Edition. Edited by Marcus Beck, M.S., and F.R.C.S., &c. 2 vols. London: Longmans, Green and Co., 1884. Pp. 1168 and 1249.

The Practice of Surgery—A Manual, by Thomas Bryant, F.R.C.S., &c. 4th Edition (12th thousand). London: J. and A. Churchill. 2 vols. Pp. 846 and 674.

The former are evidently intended for a scientific surgeon, the latter are condensed, and therefore imperfect, summaries suitable for students desiring to know as little as possible, and yet anxious to pass their examinations. In the former, inflammation is treated from the clinical, pathological and experimental stand-points; in the latter, Simon's now obsolete views are quoted, and the "germ theory" is left conspicuously absent. On the burning question of antiseptic surgery we naturally expected diversity of opinion, but we were not prepared for all we find awaiting us. Mr. Bryant in his first edition spoke so cordially (p. 1042) of the new system, and of what it seemed capable, that we are the more disappointed to read the sneering remarks which are applied to it in the present edition, in the section on "antiseptic irrigation of wounds." Under the catchword "Listerian enthusiasm"—mark the word!—Mr. Bryant says: "Facts have been employed as legal advocates use small data which tell in their favour to support the cause they have in hand, but not as the judge who has to weigh evidence and with an unbiassed mind give judgment." Under which category does he class his disparaging remarks on the theory of Listerism, the use of the spray, and his allusions to "our self-styled antiseptic friends" as well as other similar remarks in this section? Is the statement that "the Listerian mode of dressing has had its day," in his own sense, judicial? In a book for students, wherein the principle upon which it is based is not discussed, should such an *ex parte* statement be made? Does it not partake of the advocate rather than the judge?

We will not venture to say anything about Mr. Bryant's views on theoretical questions, but a comparison of his first edition with the present one will show how greatly his practice has changed even in so simple a matter as the "treatment of wounds." Besides being placed at the commencement of the work, doubtless in acknowledgment of its paramount importance over all subsequent questions in practical surgery, the chapter in the later edition is greatly enlarged and a variety of minor details insisted on which were not thought worthy of mention in the former one. Throughout, for purposes of cleansing wounds, the importance of which is strongly emphasised, a stream of water "medicated with some antiseptic" is recommended as "the best means" and with a view to promote primary union, among other things, drainage, and "protecting the external wound from all such outside influences as may be prejudicial" are strongly insisted upon. Under the latter, Mr. Bryant (p. 33) "for some years past has been in the habit of dressing all wounds with dry absorbent lint. . . . Wet applications, and more particularly watery ones, are now seldom used, and cannot be recommended, since it is well known that by moisture decomposition is encouraged. When they are employed they should be medicated, that is, they should contain some drug which has an influence in preventing or arresting decomposition. . . ." Again (p. 38), "in some cases, a soft sponge which has been wrung out of iodine or carbolic lotion is a good substitute for the wad of absorbent cotton." On p. 39, a difference between a wound made with a "clean" and a "dirty" instrument is emphasised by italics. In the old edition (p. 409), "should pain or swelling follow this primary dressing, and increase, the dressings should be at once removed, and *warm water applications or a poultice applied.*" Again (p. 454), "when an abscess has been opened, it should be left to discharge by itself, *a simple poultice or warm water dressing* being applied over the surface." Again (p. 456), "when used in large cavities, the cavity *should be washed out, with or without* Condy's fluid, at intervals." (The italics are our own). Can any one read these passages in the two editions without being struck with the remarkable change which must have come over the writer's views in the interval between their publication? In the early edition no mention of antiseptics is made; in the later one the subject and its great importance are impressed on the reader on almost every page. Mr. Bryant, however, gives hardly any clue to his altered views, but disclaims "germs" and ridicules those who "claim for themselves the title of 'antiseptic surgeons'."

Mr. Bryant's chapter on traumatic fever, septicæmia, and pyæmia is faulty in that the interpretation of these processes is not attempted and nothing whatever is said about their experimental production. The doctrine of micro-organisms is again conspicuous by its absence. It is satisfactory, however, to find that the mortality from pyæmia has lessened by more than 50 per cent. during the past five years. We should feel no hesitation in ascribing this to the more general use of "antiseptics" which Mr. Bryant teaches and practices, irrespective of all theories as to the mode in which they act. In leaving this part of "the practice of surgery" let us express our opinion that if the last edition had contained nothing new beyond the section (not found in the first) on the "antiseptic irrigation of wounds," the addition would have raised the book immensely in value as a work either for students or practitioners.

Mr. Erichsen's chapter on tumours is very full and clear. After giving the old classification into malignant and non-malignant, with a sub-class of semi-malignant growths, and pointing out the clinical value of such an arrangement, he goes on to discuss the "classification founded upon an anatomical basis" now almost universally accepted as the simplest, the most reliable, and the most scientific. Mr. Bryant, strangely enough, says nothing about this anatomical classification; but Dr. Moxon, who contributes the chapter on "the microscopical anatomy of tumours," just alludes to it. Mr. Bryant classes lymphoma among the "innocent" growths, and sarcoma among the "semi-malignant" ones. Among the "malignant," we find rodent ulcer. Under the term "granulation" tumours he includes "follicular, keloid, gummata, &c." Thus it will be seen that different surgeons attribute different meanings even to such apparently simple terms as "innocent;" else how could lymphoma, one of the most pitiless of growths, come within this category? Mr. Bryant gives a very excellent chapter on diseases of the eye, which will materially enhance the value of his book in the student's opinion. Mr. Erichsen has thought well to exclude the subject as too special and too large for the limited space that could have been given it. Mr. Bryant has given a complete index of the whole work in each of the volumes, an innovation

which we recommend to other authors. In the "contents" (vol. ii., p. 7) under Affections of the Scrotum (in large letters) we find included *sterility*, *impotence*, and *spermatorrhœa !*

Apart, however, from these and many other points to which *as critics* we might take exception, we gladly admit that the books have been greatly improved by their revision and the important additional matter which has been introduced. In all matters of practice they will be found to contain help and suggestions on which reliance may be safely placed. Mr. Bryant especially speaks from an almost unrivalled experience at one of the largest of the metropolitan hospitals; while Mr. Erichsen, if his hospital opportunities at University College have been less vast, has a much longer experience both as surgeon, teacher, and author to guide him. Moreover, in the present edition he has had the assistance of a former pupil, Mr. Beck, whose intimate knowledge of all that concerns surgical pathology, has secured for this last edition just that scientific character which we think Mr. Bryant's book rather lacks.

Amply — even extravagantly — illustrated, well printed, and well published, the works before us are Handbooks of Surgery such as any individual author may be justly proud of.

Atlas of Female Pelvic Anatomy; by D. Berry Hart, M.D., F.R.C.P.E. Edinburgh: W. and A. K. Johnston, 1884.—We are ashamed to have left this magnificent atlas so long unnoticed. It is a production of which the Edinburgh school, which has already contributed so much to the advancement of scientific gynæcology, may well be proud. It consists of thirty-seven plates, most of which contain four or more figures, with the necessary letter-press. Some of the plates are derived from the well-known atlases of Pirogoff, Braune, Bourgery and Jacob, while the works of Hyrtl, Schultze, Ruedinger, and others, have been placed under contribution; but a large proportion of the plates are original, and Dr. Hart has shown great skill and much industry in filling up the gaps in our knowledge of female pelvic anatomy which had been left by previous writers. His plates on the anatomical relations of the vagina and uterus and of the bladder and urethra under varying conditions, especially in the genu-pectoral position, are most valuable from a practical standpoint, and should be carefully studied by every writer and theorizer on uterine disorders and uterine mechanics. The literary portion of the atlas is equally worthy of praise. The plates are described in clear and concise terms and the practical deductions from the anatomical facts are sensible and to the purpose.

On the Origin of Anæmic Murmurs; by J. K. Fowler, M.A., M.D. London: J. & A. Churchill.—This is an honest contribution towards the solution of one of the most puzzling questions of the day, viz.:—the causation of anæmic murmurs. Dr. Fowler commences by accepting the view that all murmurs are hæmic, that is to say, produced in the blood stream, and he finds that two conditions are essential for their production, a certain degree of rapidity of the flow, and a constriction or narrowing of the tube in which the blood is leading to a wider part beyond. As to the typical bruit heard at the left base of the heart, he discusses at some length Naunyn's and Balfour's theory, which would give the auricular appendix as its seat, and rejects it on very good grounds. The explanation which he finds meets all the difficulties is that put forward by Chauveau, based on the fact that in anæmia the volume of the blood is reduced, and that the blood vessels at once adapt themselves accordingly, with the exception of the aorta and pulmonary artery, which are insufficiently provided with contractile fibres, and with the exception of the roots of the innominate veins, which are kept fixed by the cervical fascia; hence in anæmia they are relatively dilated when compared with the jugular or subclavian veins. Therefore, at these points the blood stream passes suddenly from a narrow to a wider space, and hence the production of a murmur. Anæmic murmurs audible at the apex are due to regurgitation through the mitral or tricuspid orifice as the case may be, this regurgitation being rendered possible by the dilated state of the ventricle, the natural result of the impaired nutrition of its walls. In the last part of his thesis, Dr. Fowler demolishes the belief that a systolic murmur audible at the angle of the scapula is a proof of organic disease, and quotes a series of cases in which the murmur was so heard, and in which it disappeared completely under treatment. We are indebted to Dr. Fowler for having put this subject before us in a more clear light than we ever remember to have seen it placed before, and we think he has satisfactorily proved his argument.

ABSTRACTS AND EXTRACTS.

PROF. CHARCOT ON ALCOHOLIC PARALYSIS.

In a lecture upon this subject, delivered at the Saltpetrière (*Gazette des Hôpitaux*, August 28th), Professor Charcot expressed himself as follows:—It is to Magnus Huss that the honour is due of having been the first to mention the existence of paralysis in chronic alcoholism; but at the period when the Swedish author wrote, nervous nosology was still too incomplete to admit of its phenomena being scientifically classified. It was in the article on "Alcoholism" in the *Dictionnaire Encyclopédique des Sciences Médicales*, contributed, in 1864, by Prof. Lancereaux, that the first attempt at a description of this form of paralysis was made, the author insisting on the fact that, just as in saturnine paralysis, it is the extensor muscles of the limbs that are affected by preference. In a note appended to this article, Professor Leudet, of Rouen, mentions a new characteristic, painful paralysis, which affects the lower limbs, and most especially at night. He also, being the first person who made an autopsy in these cases, established the fact of the integrity of the spinal cord, and of lesions of the peripheral nerves and of the muscles to which their diseased branches were distributed. Lesions, analogous to those which are produced by dividing a nerve in its course, have also been since met with by M. Lancereaux. It would seem natural that English authors, living in a country in which a considerable amount of alcoholism prevails, should have long since furnished their contingent; but yet it was not until 1872 that Drs. Wilks and Lockhart Clarke drew attention for the first time to a form of paraplegia, which, it would seem, is rather frequently met with in London — even among ladies—and which they designated as alcoholic paraplegia. Long before this came on, there were motor disturbances, and pains recurring in paroxysms, which the patients compared to electrical shocks.

The ætiology of alcoholic paralysis need not detain us for long; but I must insist upon the fact that the prior history of the cases will have to be sought for; as in the early periods it is very difficult to obtain an avowal, while when the affection is constituted it becomes associated with a mental condition to which I will return. Can we incriminate one form of alcoholic drink rather than another? That is very improbable; but what is more certain is that women are far oftener the victims of the disease than men; and the drinkers in high life who take only the choicest spirits, are affected as well as women of the lower classes who can get only the very worst. The manner in which the disease commences is almost always the same. Besides the other symptoms characteristic of alcoholic intoxication (and among which I may specify especially the *nocturnal dreams*, with their night-

mares and frightful visions), one of the first indications of this form of paralysis seems to consist in the appearance of *vivid pains*, which are especially felt in the lower extremities. These pains sometimes nearly resemble those which are met with in the first stage of locomotor ataxy, consisting in prickling formications, lancinating and true fulgurant pains which traverse the limbs, occurring chiefly at night. So that the patients in apprehension of them regard with terror the period of nocturnal repose, which is interrupted by fearful hallucinations during sleep, and by cruel pains during the hours of wakefulness. These pains soon become generalised, occupying *symmetrically* the two lower limbs by preference, and accompanied by cutaneous anæsthesia, they invade the upper extremities; and after a certain time, varying in different cases, give place to a new phenomenon —analgesia. The sensation of cold, of heat, or of punctures, is no longer felt in the limbs attacked, and contact with the ground is not perceived. It is then that motor paralysis supervenes, which is also symmetrical and affects the upper and lower extremities, especially the latter, influencing by preference certain groups of muscles, namely, the extensors. "Look at these two women, seated on chairs slightly raised, and you observe their feet hanging inert, without any possibility of their raising the points. The patella reflex (as observed by Dr. Glynn, in the *Liverpool Medico-Chirurgical Journal*, July, 1883), is abolished. In one of them you find that the extensors of the two forearms are invaded, although in a lesser degree, but in neither of them the muscles of the trunk, as sometimes occurs, are seized. As to the muscles of the face, the alcohol seems always to respect them. On this occasion I wish to draw your attention to a peculiarity, of which these women furnish a striking example. Examine their feet and legs, and you will see the *vaso-motor phenomena* which are being produced—the diffused red or sometimes violaceous colour, and the peri-malleolar doughiness, which almost constantly exists, without the urine furnishing any satisfactory explanation. At other times there are local sweatings of the hands or feet, which appear suddenly and cease in the same manner, or there are alternating paleness and redness. Finally, at the end of a certain time, there are formed amidst these equine-shaped feet fibrous adhesions of the tendons and thickening of the connective tissue which surrounds the tibio-tarsal articulation, adhesions which render the restoration of the normal movements of the feet impossible. If these patients recover, a surgical operation will probably be necessary. You perceive, moreover, that the paralysed muscles are softened, and I am able to inform you that their electrical excitability is notably diminished.

In regard to the mental state of these patients it is the same with them as with the subjects of morphinism, they always when in the early stages of their malady still retain all their lucidity, and stoutly deny its ætiology, while when the paralysis is confirmed the memory is also lost. The progress of the paralysis is essentially chronic, the acute form being very rarely met with, of which, however, Dr. Broadbent has related a case. Its course is progressive and fatal if the drinking habits are not abandoned, or if the intoxication is already of too long a date. In a young man a paralysis of three months' duration disappeared under the influence of treatment by isolation, the suppression of alcohol, and hydro-therapeutics; but as he yielded again to the pernicious habits which a drunkard throws off with such difficulty, a relapse ensued. The *diagnosis* of this form of paralysis is not always easy, especially at an early period, for the pains then observed may lead to the supposition of commencing locomotor ataxy. Pains of the same kind are also observed in diabetes; but of course mistake here will not occur if the urine has been examined. Saturnism also gives rise to paralysis of the extensors, but its causation will be easily detected. It must however not be forgotten that the subjects of diabetes and saturnism may also be the victims of alcoholism. In the *treatment* of these cases they should be isolated as soon as possible, and placed under persons who can be relied upon to prevent their gaining access to alcohol; and by means of hydro-therapeutics and a tonic regimen, results may be obtained, which, however, too often yield to a recurrence of the inveterate habits of these patients when restored to their liberty and their ordinary passions.

OPHTHALMOLOGY.

The Differential Diagnosis of Amblyopia.—The use of electricity as a therapeutic measure in cases of optic atrophy is no novelty, but its use as a means of differentiating between the various forms of amblyopia, and of aiding in the formation of a prognosis in respect of them, has not, we believe, been hitherto broached. The paper, therefore, by M. Darier, in the bulletins of the *Société Française d'Ophtalmologie*, is of special interest. He has discovered that in the normal state, and in amblyopia without any lesion, a luminous impression is produced on the eye by the closure of an electric current of less intensity than one tenth of a milli-Ampère, whilst in cases where the optic nerve is undergoing atrophy a current of much greater intensity is needed to produce the same minimum luminous impression. It was especially in respect of prognosis that he found this test most useful. When in a case of amblyopia, whether the disc was pale or not, the electrical reaction was normal he found that the sight was eventually recovered, and, on the other hand, when the electrical reaction was diminished then the prognosis as to recovery of sight was unfavourable. The *modus operandi* is simple. The positive pole is placed on the forehead, midway between the eyes, and maintained there by an indiarubber band, the negative pole, which is olive shaped, is made to touch the upper and outer part of the eyeball. The circuit is then completed and a sufficiently strong current passed to produce a very evident luminous impression, in order that there may be no mistake and the patient may understand what it is that he is to be on the look-out for. When this has been explained to him, the strength of the current is very gradually diminished until only at the closure of the current there is perceived the very faintest spark, which is not recognised at the opening. In health it is, as has been already stated, only necessary to employ a current of the intensity of one tenth of a milli-Ampère to obtain this, and this serves as the standard whereby to measure varying degrees of impairment. In optic atrophy, sclerosis of the optic nerves, atrophy after neuritis, after embolism or hæmorrhage, the electric spark is only produced by a stronger current. In amblyopia from alcohol or tobacco the electrical reaction is normal, as it also is in congenital amblyopia and in some cases of hysterical amblyopia.

Meningitis after Enucleation of a Shrunken Eyeball.—Dr. A. Benson records a case in the *Ophthalmic Review* for October. The patient was a girl, aged 17, whose eye was enucleated in consequence of an attack of panophthalmitis which had supervened three weeks previously, the eye having been lost eight years before from scarlatina. On the third day after the operation she seemed ill and had a sore throat. Next day she was worse and had a red blush on her left eyelid (the left eye was the one that had been removed) and cheek, spreading over the nose to the right side. This was considered at the time to be of an erysipelatous nature, but next day it was fainter and the day following it had altogether disappeared and the diagnosis of erysipelas was abandoned. Delirium appeared on the fifth day and she gradually grew worse and died in a state of coma on the eighth day. At the *post-mortem* abundant recent meningitis was found. The author attributed the meningitis to the enucleation, but does not lay any stress on the fact that the eye had been suppurating, for a similar occurrence has been known after enucleation for other diseases than panophthalmitis. In a note at the end, he throws out the possibility that the two things might be a mere coincidence. It seems to us that the meningitis might have been a result of the suppuration in the eyeball, and set up before the enucleation, for the patient is said to have been complaining previously of headache, and the onset in such cases is often exceedingly insidious. But there is also the possibility that the patient really had erysipelas on the third day after the operation, and meningitis, as is known, is not so very uncommon a result of erysipelas.

Uræmic Amaurosis.—Dr. Friedenwald, Professor of Diseases of the Eye, Baltimore, terminates a paper read at the Baltimore Medical Association (*Philadelphia Medical News*, August 9) with the following conclusions:—(1)

When amaurosis suddenly overwhelms a patient in both eyes, with no ophthalmoscopic change, uræmia should be suspected; even in the absence of all other prominent uræmic symptoms. (2) It will continue only as long as the uræmia exists, and will disappear when the function of the kidney is re-established. When permanent injury to sight is observed, it may be due to pre-existing retinal change, not at all uncommon in Bright's disease. (3) The chances of a full return of sight are somewhat impaired when the patient has been the subject of recurring attacks. (4) By exhibiting jaborandi and other means of inducing free diaphoresis, and by free purgation, a catastrophe may be averted in the general forms of uræmia, but when it occurs in pregnancy, premature labour is the only remedy which promises safety to the patient.

Anæsthesia of the Optic Nerve.—M. Dianoux communicated to the French Ophthalmological Society a paper on this subject which appears in their recently issued *Bulletins*. It is an affection which only occurs in women, or in men who are, so far as their nervous system is concerned, women by nature. The onset is sudden, often during sleep, there are no premonitory symptoms, and there is no pain though there is often a sense of a dull weight in the head. From the first the blindness is usually absolute, and may last an indefinite time; it rarely effects both eyes, the eyes are equally liable to be attacked. Examination of the eye yields absolutely negative results. It may undergo spontaneous cure or it may persist for an indefinite time unmodified, or it may gradually pass into atrophy. The diagnosis, he says, is easy; the only difficulty which could arise is with what he calls the weakened form of neuritis which betrays itself by a persistent discolouration of the disc. The prognosis is as a rule favourable, and the cases that are most favourable are those of the longest standing where the blindness is absolute; if atrophy comes on, or if the onset is gradual, the outlook is not so good. Youth, a delicate constitution, a lymphatic temperament, uterine diseases, and hysteria constitute the best known predisposing causes. The author regards anæsthesia of the optic nerve as only a very slight form of the morbid process which leads to neuritis and atrophy of the disc after ischæmia. There is some circulatory disturbance followed by plastic exudation within the sheaths of the nerve, leading to a modification of the myelin which renders it a bad conductor. This exudation may be absorbed without any traces being left behind, or it may organise and compress the capillaries leading to permanent discolouration of the disc; or if the exudation is more abundant, it may lead to œdema of the disc, and ultimately to organisation of the new products "choking" the vessels and nerve fibres. By way of treatment he recommends tonics, quinine, iron, and cod-liver oil, the hypodermic injection of strychnia locally, and the use of the continuous current; the uterine functions should be attended to.

Foreign Bodies in the Eye.—Writing on this subject, Dr. Agnew, of New York, relates an interesting case of a gentleman who for a year or more had suffered from conjunctivitis, his eye having on several occasions been examined in vain for a foreign body. When he came to Dr. Agnew the eye revealed at first no other appearance on careful examination than slight redness of the conjunctiva. But there was something in which the sense of a foreign body in the eye was exaggerated that led him to suspect that there might be a single inverted eyelash. Ordinarily it felt as if some irritant was there which was tolerable, but suddenly there would be something like a cramp-like action of the eyelid, the irritation growing rapidly worse and the eye filling with tears, with temporary relief. The eyelashes were nearly colourless, but on examining the edges of the lids for inverted eyelashes a slight curving of the inner angle of the innermost edge of the lower lid was observed, and a tear having been allowed to gather upon this inner edge a difference in refraction was seen and a delicate eyelash was found springing from the inner edge. The spasmodic action of the orbicularis had embedded the eyelash in the eyelid. On its removal all trouble ceased. An operation will afterwards be required to destroy the follicle which produced the misplaced eyelash.—*Boston Medical Journal*, August 28.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

Friday, October 24th, 1884.

Sir Andrew Clark, Bart., M.D., President, in the Chair.

Myxœdema.

Dr. James Anderson read the following account of a case shown by him at the close of last session. The patient, Jessie A., an unmarried woman, aged 40, came to Moorfields Eye Hospital, in February of this year, as an out-patient, under the care of Mr. Gunn. She complained of swelling of her eyelids, which she had noticed gradually increasing in degree for the past nine years. The patient is one of a family of nine, none of whom have shown any symptoms resembling hers, her four sisters, all older than herself, being in perfect health, one of them, who was seen, contrasting markedly with the case. The patient's father died in old age; her mother at 57 years with hæmorrhage from the mouth and coffee-ground vomiting. There is no history of gout or hæmophilia in the family. Up to the age of 20 the patient lived at home in Liverpool. Thereafter she was for twelve years nurse and maid in a family in Liverpool, and for the last eight years she has held a similar position in a family living in Kendal. She has always had a good home, with plenty of fresh air and exercise, and freedom from anxiety or exposure. For the first twenty-three years of her life she enjoyed excellent health, when, seventeen years ago, she had two teeth extracted, the bleeding from which lasted twenty-four hours, and was very copious. She says she has never been well since, and to this she attributes all her trouble. No marked symptoms, however, were noticed by those around her till twelve years ago, since which time they have steadily increased, with occasional slight remissions. The patient presents the characteristic facies of myxœdema as described by Dr. Ord, the defined scarlet flush of cheek and nose contrasting markedly with the waxy pallor round the eyes and mouth. The loose, baggy, almost translucent lids, the dry brawny cheeks and thick blue lips, with the swollen, red expressionless hands and deliberate speech and volition, make a group of symptoms which only the comparative rarity of the disease can have prevented from earlier recognition, and which, once seen, cannot be forgotten. Her heart and lungs are sound, her digestive system somewhat defective. Her molar teeth have crumbled away bit by bit; her gums are extremely vascular and hypertrophied, and bleed freely, so that her mouth is frequently filled with blood in the morning. Her extremities are always cold, and her axillary temperature always sub-normal. Her urine varies much in quantity, from scanty to copious, but, scanty or copious, the total amount of urea is invariably deficient, only rising to half the normal amount, and frequently being as low as one-fourth. It contains neither sugar nor albumen. She began to menstruate at the age of 14, and has menstruated regularly since. The amount has always been copious, but sometimes after the discharge has ceased it commences again, and may last for three weeks, leaving her very exhausted. With the exception of the deliberate speech, thought, and volition, there are only two points to be noted as to her nervous system. The first is the constant recurrence of a nervous restlessness, which she terms "fidgets," so that she dreads night coming on, as she cannot lie still. The second is her ocular condition. She is slightly hypermetropic, but with the correcting lenses has perfect vision. Under atropine there is seen to be slight peripheral opacity of the left lens, otherwise the media are normal. In neither eye, however, is the retina normally transparent, a haze surrounding the vessels, especially in the neighbourhood of the disc. The appearances differ entirely from those of a past neuritis or retinitis, and, as has been said, do not interfere with perfect vision. Dr. Stephen Mackenzie kindly admitted her under his care at the London Hospital, and to him Dr. Anderson was indebted for detailed observation during her stay there. As regards

treatment, the usual tonics seemed to have no effect whatever either before or after her entering the London Hospital. A fortnight after admission she was put upon half-drachm doses of tinct. jaborandi, which she continued till she left the hospital, three weeks later. Of objective improvement, there was none, or almost none, but she expressed herself as feeling greatly better within a few days after commencing the jaborandi, and this subjective improvement was accompanied by a steady and marked increase in the amount of urea excreted, which doubled itself during the period, and was at its maximum on her discharge from the hospital. Dr. Symington, of Wolverton, had since had her under his care for severe menorrhagia, and he stated that she seemed in very much the same condition as when last seen. The points of interest in the case seemed to be (1) the history of commencement from a severe hæmorrhage, combined with the present hæmorrhagic tendency of the patient; (2) the occasional state of nervous restlessness, so apparently incompatible with the general character of the disease; (3) the retinal condition, which was peculiar, whether characteristic of the disease or not; and lastly (4) the effect of jaborandi on the subjective condition of the patient, and on the amount of urea excreted by her.

The PRESIDENT enquired whether the whole vascular system had been found healthy in Dr. Anderson's case and also whether any other cause had been present which could possibly account for the increase in the quantity of urea that had been observed.

Dr. ANDERSON replied that although there had been no valvular lesion of the heart, its action had been very feeble throughout. No other cause had been found to explain the increased excretion of urea, which he believed to have been due to the action of the jaborandi.

Dr. FELIX SEMON referred to a series of cases which he had brought before the Society a year ago in which Dr. Kocher, of Berne, had found that a train of symptoms not distinguishable from those observed in myxœdema had followed the operation of complete extirpation of the thyroid gland. In cases of only partial extirpation no such symptoms had occurred and in one instance the presence of a small supplementary gland had apparently been sufficient to account for their non-appearance in a case of complete removal. At that time he had made the suggestion that there probably existed some close relation between these cases of goitre and the conditions of cretinism and myxœdema. Another important symptom had been noted at that time, viz., the fact that in some of the young cases an apparent arrest of development of the body had occurred. He was now in a position to supply some information upon this point which formed a valuable connecting link in the history of the affection. Dr. Paul Bruns, of Tübingen, had recorded a case in Volkmann's Klinische Vorträge of a patient, still living, who had undergone complete removal of the thyroid eighteen years previously. Shortly after the operation, the boy, who had hitherto been bright and healthy, became very quiet and reserved, but his mental faculties continued fairly active. He was now living, a dwarf and a cretin. His body in appearance was that of a boy, measuring only 127 centimetres, his head however did not seem to have undergone a similar arrest of development. In every respect the description of his physical condition corresponded with that of a typical case of myxœdema. The peculiar thickening of the subcutaneous tissues, the slow speech and enfeebled intelligence and all the signs of mental and bodily degeneration were well marked. The hair on the head was very thin, the beard altogether absent. The pubic hair scanty, the genitals, on the other hand, well developed. The most prominent degenerative symptoms had only declared themselves within the last few years. The case formed the most complete illustration of the consequences of removal of the thyroid gland. With this evidence now given it seemed to be clearly established that it was to the complete absence or atrophy of the gland that the disease was due, and not to any direct lesion of the sympathetic fibres as had sometimes been suggested.

The PRESIDENT observed that it did not seem yet to be clearly established whether it was the absence or the removal of the gland which gave rise to the disease. If due to the latter cause we should expect to find myxœdema in every case of wasted thyroid.

Dr. HALE WHITE mentioned a case in which temporary improvement had been noted after nitro-glycerine by Dr. Mahomed. The patient subsequently died and the *post-mortem* examination had proved the complete atrophy of the thyroid gland. The sympathetic ganglia in the neck had been found to show similar changes to those seen elsewhere in the body, but no direct evidence of an inflammatory change or other condition pointing to any causal relation with the wasted thyroid.

The PRESIDENT called attention to the fact that a committee was now sitting to investigate the subject and reminded members who might have observed any cases, that accounts of them would be gladly received even if they were not otherwise put on record.

Dr. HADDEN observed that the occurrence of hæmorrhage had already been noted in these cases. Cataract had occasionally been seen also. Having had an opportunity of seeing Dr. White's preparations he was inclined to think that there were some evidences of neuritis present in them.

The PRESIDENT added that in all his female cases of myxœdema there had been menorrhagia.

Dr. ANDERSON in reply stated that the intelligence of the patient had remained unimpaired throughout. He thought that the retinal changes had not been hitherto observed.

Congenital Dislocation of the Patella.

A paper by Mr. GOLDING BIRD on a case of this nature was read by Mr. R. J. GODLEE. The case was one of a girl, aged 11, who for six months had been troubled with displacement of the patella on to, and afterwards quite outside, the external femoral condyle. On bending the knee or straightening it the patella resumed its normal position with an audible click. There was some pain, but the affection was more disagreeable than painful. She walked well, but with stiffened knee. The displacement was first observed after a fall. The author showed the cause of the displacement to be due to structural shortening of the quadriceps extensor following paralysis of the muscle—probably infantile—and had tried, as a rational mode of treatment, tenotomy of the ligamentum patellæ; but the only gain was the disappearance of the click, the dislocation occurring as before. He thought the name paralytic dislocation preferable to congenital. His case agreed with the description given by Heuter. The case had been exhibited at the Society early in the year.

Mr. R. J. GODLEE referred to a case which he had shown previously in which the injury had not been observed for a long time after its supposed cause. He did not altogether agree with the author of the paper with respect to the association of the lesion with infantile paralysis. If the shortening were really due to that cause, we ought to see it more frequently than we did.

Skin Eruption due to the Administration of Bromide of Potassium.

Dr. CARRINGTON read notes of a case of this condition and showed a drawing. There was no history or appearance of syphilis in either of the parents. An elder child when three months old had suffered from impetigo capitis. The patient was born quite healthy, and with trivial exceptions remained so up to about ten months. At that time he began to suffer from convulsions and symptoms which seemed to point to meningitis, and he was treated with an ounce and a half mixture, containing one scruple of bromide of potassium, of which one drachm was given every four hours; this was for a time administered every three hours, and the ammonium was for a time substituted for the potassium salt. This was persisted in for about seven weeks. The eruption appeared in the form of minute red papules, which in the course of three or four days attained the size of penny pieces. The parts affected were the buttocks, legs, thighs, and, to a smaller extent, the scalp and face. When first seen the spots were of variable size, from a pin's head to a penny piece. The smaller ones were of a bright crimson colour and smooth, the largest ones of a dark brownish hue, circular or elliptical in form, with a sharply defined edge of at least one-eighth of an inch thickness. They were of a spongy texture without the least trace of fluid contents. The treatment adopted

by the practitioner under whose care the child came was half a grain of potassium iodide and one minim of liq. arsenicalis three times a day. In a fortnight there was very great improvement. Some of the spots had disappeared and were represented only by pinkish discolouration, and the others were much shrunken and nearly level with the skin. No new ones had appeared. The child made an uninterrupted recovery, and when seen two months after, all the lesions had disappeared with the exception of two or three on the scalp and face, and these took the form of dried up scabs. The eruption was never moist from beginning to end. It was worthy of note that an eruption due to the bromide should disappear under the administration of the iodide of potassium.

Dr. Duckworth observed that the general effects of bromism were usually most marked upon the sebaceous system. Some years ago Dr. Cholmeley brought forward a case which showed very clearly that these structures were chiefly affected, a confluent form of acne being produced which appeared to be peculiar to bromism. The rashes produced by iodide were not of necessity sebaceous, as had often been shown by microscopic examination.

Dr. Stephen Mackenzie mentioned a case already recorded in which Mr. Tay had been enabled to examine the patches with the microscope, and had found the inflammation to be limited to the neighbourhood of hairs and sebaceous follicles. Occurring so frequently in children it would appear to be favoured by some special conditions prevailing in young skins. It was an important point in diagnosis to remember that the rash usually appeared some time after the administration of the drug and might continue for a long time after its withdrawal.

Dr. Barlow corroborated this observation and referred to an error in some former teaching which maintained that the cessation of the drug was followed by the disappearance of the rash. He thought these rashes were really due to some idiosyncrasy of the patient with respect to the elimination of these salts. In a case of his own in which the drug had been discontinued for three weeks, Dr. Stevenson had been able to detect the salts in the urine. As a rule, however, these salts appeared to be eliminated very rapidly. There was no doubt that very small doses were sufficient to produce the rash in some cases.

Mr. Morrant Baker thought that iodide rashes not unfrequently appeared in cases of advanced renal disease. In such cases, however, the patients were usually of adult life.

The President thought that diseased kidneys might at times retard the excretion of drugs.

Dr. Stephen Mackenzie added that a diseased state of the kidneys was not always present, since he had himself watched a case throughout its whole course in which those organs were perfectly healthy.

Nephrectomy in an Infant.

The following case was read by Mr. Godlee:—The child, a boy, aged 1 year and 10 months, was admitted under his care at the North-Eastern Hospital for Children in August, 1883. The tumour was first noticed in June, 1883, and was growing rapidly. It was on the right side, and measured 4 inches in the long diameter and about 2 in the short. It was freely movable, and manipulation caused no pain. There were no urinary symptoms at all. The kidney was removed by the lateral abdominal (Langenbuch's) incision, and was readily accomplished as there were no adhesions to surrounding structures. The cæcum and the duodenum were the only pieces of bowel exposed. One large vein which ran over the tumour alone required ligature. There was no hæmorrhage of consequence, and the whole operation was concluded in half-an-hour. The child had no symptoms of any kind after the operation. It ate and slept as well the next day as before, and the temperature only rose to 99° once, the day after the operation. It left the hospital well six days later. It continued well till February, 1884, when recurrence took place in the right iliac fossa, the tumour rapidly increased in size, passing down into the scrotum, and the child died soon after. Mr. Godlee mentioned eight other cases which had been recorded, showing that five of them had died of the immediate result of the operation, two had recovered well but died afterwards of a recurrence, and one was well when last heard of, but notwithstanding the unsatisfactory nature of the results, he argued that, seeing how hopeless the condition is if left alone, we should endeavour to remove these tumours in a still earlier stage, at all events until it is proved that even this proceeding is invariably followed by a fatal result. He particularly, however, pleaded against attempting the removal of the very large growths which are not unfrequently met with, showing that they will almost certainly have involved surrounding structures, and that thus while no good can follow the operation an immediately fatal result is probable. The tumour weighed about one pound, and was in structure a mixed sarcoma, most of the cells being roundish or oval, but some spindle-shaped. This is probably the usual composition of these growths, but another class was mentioned in which striped muscular fibres occur. The latter are probably congenital, and often affect both kidneys, and are thus not favourable for surgical interference.

Mr. Barwell considered that the society was much indebted to Mr. Godlee for his paper. He doubted whether the operation for removal of a sarcomatous kidney would ever become established as a uniform practice. In the early stages of the disease it was difficult to be sure of the diagnosis. He thought that the incision by the side of the rectus was to be preferred to that of the median line. To ascertain the exact position of the colon was often a point of difficulty.

Mr. Meredith related the particulars of a case in which he had removed a large sarcomatous tumour from the abdomen of a girl. The growth had been very rapid and the tumour was soft in consistency and could not be removed without tearing the capsule; the pedicle was transfixed and tied in two portions, but at the moment of doing so the child's breathing became very rapid, and the pulse failed for a short time. The patient died three days afterwards and it was found that the vena cava had been completely occluded by the ligature. The end of the right ureter was found distended to the size of the little finger with urine, although there was no direct evidence as to how it had become filled. No secondary growths were found in the glands or in the liver, but the lungs were studded with new growths, showing the extreme rapidity of the infection in such cases. He thought that it was most important to secure the end of the ureter to the edge of the wound, instead of returning it to the abdominal cavity. The tumour in his case was a round-celled sarcoma and weighed three and a half pounds. The urine had always been normal.

Mr. Knowsley Thornton agreed with Mr. Barwell as to the doubtful value of the operation. Looking at the extreme frequency with which secondary deposits took place in other organs, he thought that the issue must always be uncertain. Unsuccessful cases of this kind only had the effect of increasing the mortality of abdominal section, a result which greatly prejudiced the aspect of abdominal sections for other purposes, and which was used as an argument in favour of nephrectomy by the lateral incision. He thought that nephrectomy by abdominal section was likely to become one of the most successful operations in surgery. In his own cases he had obtained very favourable results.

Mr. Barker asked which layer of the meso-colon was usually opened. He thought that the colon was generally so displaced that the external layer was exposed. In one case he had opened that layer successfully.

Mr. Meredith observed that in his case he had opened the external layer.

Mr. Godlee in reply referred to the accidental inclusion of the vena cava in the ligature and mentioned a similar case where the renal vein had been taken up in the same way. He thought that this operation should be confined to cases of small tumours. Mr. Thornton's preference for abdominal section was perhaps in some measure due to that gentleman's familiarity with abdominal surgery, but he thought it doubtful whether the operation would be advisable in cases of calculous pyelitis.

The following living specimen was exhibited:—

Pigmentation of the tongue, by Dr. J. K. Fowler.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, OCTOBER 28TH, 1884.

GEORGE JOHNSON, M.D., F.R.S., President, in the Chair.

Excision of the Head of the Femur for Spontaneous Dislocation.

Mr. WILLIAM ADAMS contributed an example of spontaneous dislocation of the head of the femur on the dorsum ilii, occurring during the progress of rheumatic fever, in a boy eleven years of age. The patient was admitted into the Great Northern Hospital on the 4th March, 1882. After two unsuccessful attempts at reduction, having previously divided the adductor longus tendon, he had excised the head of the femur on the 29th March, making a ⅃ shaped incision with the long arm two and a half inches in length directly over the head and neck of the bone; and the small arm, one inch in length, transversely over the head of the bone, which was at once exposed uncovered by capsular ligament, and the articular cartilage in a healthy condition. It was found that the capsular ligament had been ruptured, and the torn margins of the rent passed on either side of, and closely embraced, the neck of the bone. After dividing the margins of the capsular ligament he passed his small subcutaneous saw to the neck of the bone, and cut through it a little below the margin of the articular cartilage. The detached head of the femur was then drawn out of its position after some slight adhesions had been cut through. The round ligament preserved its normal connection with the head of the bone, and was adherent to the articular cartilage, having been divided with the saw a little below the head. The wound progressed favourably without much suppuration, and on the 1st June was completely closed. On the 14th June the patient was allowed to walk on crutches, and on the 1st October without crutches. The limb was perfectly straight, and the movement at the hip-joint freely permitted in all directions. The author observed that in all the cases of spontaneous dislocation which had fallen under his observation the head of the femur had been dislocated on to the dorsum ilii. These he arranged in three classes:—(1) Dislocation occurring during the progress of fever. (2) Dislocation occurring in cases of paralysis, generally infantile, but occasionally in the adult. (3) Dislocation occurring in the first stage of hip-joint disease without suppuration. Excision of the head of the femur in its simplified form as above described the author believed would be found applicable to all these cases, unless sufficient freedom of motion be obtained by tenotomy and passive movements. He also thought it might be applicable to some cases of fibrous anchylosis of the hip after disease when the limb remained contracted, as free motion was seldom obtained by simply dividing the neck of the bone. The cases of dislocation of the hip brought before the Society by Mr. Morris were alluded to, and also the case published in "St. Thomas's Hospital Reports" by Sir William MacCormac, in which he excised the head, neck, and great trochanter in a case of unreduced traumatic dislocation of the hip into the thyroid foramen. The firm adhesions, and, in some cases, new bone thrown out in cases of traumatic origin as the result of the inflammation following the injury, the author observed, distinguished these cases from cases of spontaneous dislocation occurring during the progress of fever, or in cases of paralysis which had chiefly fallen under his observation.

Mr. HULKE had not quite understood why the operation was undertaken.

Mr. ADAMS replied, that when the boy first came under his notice, the limb was in bad position; it was painful and useless, while at present the boy could walk well, and was quite free from pain.

Mr. BARKER referred to a case very similar to Mr. Adams', in which, after cutting down on the displaced femur, he had been able, without much difficulty, to replace the head of the bone. He particularly enquired as to the manipulation which Mr. Adams had used.

Mr. BARWELL had had a case under his care. The displacement had occurred two years previously. He had tried Bigelow's method — reduction by manipulation—without success, and then he applied extension with the pulleys, and this too had failed. His patient returned into the country without having obtained relief. When seen three years later, she was able to walk very well, and there was not more than half-an-inch shortening. He agreed that excision was not the best treatment. If reduction could not be accomplished, extension with abduction of the limb was indicated.

Sir WILLIAM MACCORMAC gave some further details of his case, to which Mr. Adams had referred. The success of his operation had been complete.

Mr. R. W. PARKER agreed with Mr. Hulke that the cases shown were admirable instances of successful excision; but he questioned whether excision was necessary in the majority of cases. Probably, had more time been given, a false joint would have formed, and the final result would have been even as good as in Mr. Adams' case. He was not familiar with the classes of cases, Nos. 2 and 3, given in the abstract.

Mr. SPENCER WATSON had seen the case, and he felt that if the Fellows who had spoken had had the same advantage, none would have doubted the expediency of Mr. Adams' operation.

Mr. BOWLBY remarked the absence from Mr. Adams' classification of cases of the pyæmic variety.

Mr. MORRIS spoke to the great deformity in the present case, and congratulated Mr. Adams on his successful operation. Nevertheless, he would not say whether by dint of time and perseverance in treatment an equally good result might not have been obtained by other means. He thought that subcutaneous osteotomy of the neck of the bone would be a preferable proceeding in many cases, not with a view to get movement, but in order to secure parallelism of the limbs.

Dr. RAWDON, in reply to a question, said that in his case there was less limping shortly after the child's discharge from the hospital than now, and that much of the limping had come on during the past twelve months.

Mr. ADAMS replied.

Dr. Rawdon's patient, who had been specially brought up from Liverpool, as well as Mr. Adams' case, were exhibited.

A Case of Cirsoid Aneurysm on the Dorsum of the Foot.

Dr. WALTER EDMUNDS communicated the case of a man, aged 29, who had an aneurysm on the dorsum of the left foot. Pulsation could not be completely arrested by compression of the anterior tibial artery. Esmarch's bandage was applied, but without benefit. The aneurysm was dissected out, seven communicating vessels requiring ligature. The patient recovered. The various methods of treatment were discussed, and digital compression having failed or being unsuitable, excision was recommended.

Mr. HULKE said he had been consulted about this patient; and the idea of excising the aneurysm had never occurred to him. He was not quite clear as to the nature of the arterial condition, and he found it very difficult to control pulsation. He had seen the man since his operation, and found the vessels of the limb in a very dilated and tortuous condition.

Mr. EDMUNDS replied that the aneurysm was a sacculated one, but not of the ordinary kind.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

FRIDAY, OCT. 17TH, 1884.

Dr. T. O. DUDFIELD, President, in the Chair.

THE first meeting of the session was held on October 17th, when twenty-eight Medical Officers of Health were nominated for election as members, and five other persons as associates.

President's Address—Metropolitan Sanitary Administration.

The PRESIDENT delivered an inaugural address. After congratulating the Society on the complete success of the Conference at the International Health Exhibition, managed by the Society conjointly with the Sanitary Institute and Parkes' Museum, and referring to the services of Dr. J. Northcote Vinen, who had resigned the post of hon. secretary after more than twenty years' service, he proceeded to deal with the subject of his address. First of all he sketched his idea of what a London Government Bill should be, in an abstract of the address delivered by him in the previous session, and then compared the sketch with the scheme of the Home Secretary. There was so much similarity in the two that he could not consistently enlist himself in the ranks of the opponents of the Bill. The Society, moreover, while declining to express any opinion on the Bill generally, had recognised in its provisions a prospect of attaining "much needed unity and uniformity in sanitary administration." After referring to the grounds of opposition raised by the Corporation and local boards, and taking into consideration the probability of the Bill not meeting with acceptance in Parliament, he proceeded in the second place to suggest an alternative scheme. The Corporation might be left alone, or, under a reformed constitution, allowed to rule over the city; the Metropolitan Board of Works being placed, in regard to the rest of London, in the position assigned in the Bill to the new Common Council. The vestries would be maintained in their present position as local executive bodies, subject to efficient control by the Board, so as to secure the desired unity and uniformity. Reference was made to the mode of election of members of the Board and vestrymen, and to plans by which this might be amended. Whatever scheme might be adopted—that of the Government or such a one as he suggested—the Central Board, as the chief sanitary authority, should be endowed with the powers and duties with respect to infectious diseases, provision of hospitals and ambulances, &c., at present exercised and performed by the Asylums Board. It was possible, of course, that no Bill might get adopted. The Bill of the Government might be rejected, and they might refuse to bring in another. He proceeded to ask, therefore, in the third place, whether it was inevitable, in either contingency, that London should wait indefinitely for an instalment of reform in its sanitary administration? Reciting the powers already existing which, *inter alia*, enabled the Metropolitan Board to make by-laws, in regard to a variety of matters, he contended that if such powers were exercised, covering as they did pretty well the whole field of sanitary administration, London Government might be conducted in a fairly satisfactory manner by the existing authorities. He stated his reasons for believing that the framers of the Metropolis Management Act must have contemplated a close union between the Board and the vestries, such as he advocated, and cited several sections of the Act which enabled the Board to make by-laws, for regulating the drainage of houses, disposing of refuse, &c., and to make orders for the guidance, direction, and control of the vestries in regard to sewerage. Theoretically, nothing more, nothing better could be desired, provided only that the vestries carried out their part in the matter by loyally enforcing the by-laws. But no such by-laws for regulating drainage and disposing of refuse were in existence, while, with regard to sewerage, no definite principles had been laid down, each local board having its own views on the proper size and material of sewers, the differing plans being equally approved by the Board. Having in view the probability that no opportunity of dealing with Metropolitan Government would be forthcoming next session, a time of grace was afforded, which, if wisely used in efforts to put existing powers into force, might avert the necessity for any material change. But if the vestries, for instance, desired to prolong their rule, they must prove their utility; and more than one opportunity of doing this was offered. For example: they must deal with the dwellings of the poor in regard to the state of which the public conscience had been greatly stirred; as witness the formation of the Mansion House Council and the appointment of a Royal Commission. The power to make regulations for houses let in lodgings or occupied by members of more than one family, must be exercised. The Society had framed standard regulations for their guidance in 1879. Few of them had exercised the powers, but if they had sinned by their neglect it was in good company, as the Local Government Board had failed until within the last few months to exercise its power, conferred in 1874, of declaring the enactment of Sec. 35, Sanitary Act, 1866, to be in force in all parts of the metropolis. The poor, no doubt, would have to pay an increased rent for their improved dwellings, but this could not be helped. That Parliament was not altogether unwilling to trust the vestries was shown by the Act of last Session by which they were re-constituted as "local authorities" with respect to bakehouses. The Society had framed useful regulations for the guidance of sanitary authorities in supervising bakehouses. Illustrations of the value of by-laws were cited, special reference being made to those made by the Metropolitan Board with regard to foundations and sites of buildings (under the Building Act, 1878); to offensive trades (under the Slaughter Houses (Metropolis) Act, 1874), and to dairies, cowsheds, and milkshops, under the Dairies, &c., Order of 1879. Incidentally the Slaughter Houses Act had led to a great reduction in the number of private slaughter-houses, while the offensive businesses regulated had been conducted, subject to definite regulations enforced by an irreducible penalty for any breach, in a satisfactory manner, quite impossible when they were subject to the general law of nuisances only. The Society had taken a leading part in promoting sanitary reform in connection with offensive trades, dairies, and cowsheds. The legal status of the local authorities, and of their medical officers, in relation to the regulated businesses, was unsatisfactory. They should have statutory powers to carry out the by-laws under the general supervision of the Metropolitan Board. Regulations made by the vestries providing for the periodical removal of manure were rendered nugatory by the reluctance of magistrates to inflict adequate penalties for breaches. Some limits should be set to the power of magistrates to reduce and remit penalties for offences against sanitary laws. Good work might be done under the water regulations if the sanitary authority had concurrent power with the water companies to enforce them. The Local Government Board had urged the vestries to bring about "severance of all connections of waste-pipes of cisterns with drains," but this, as it had been pointed out to the Board, could be done universally by the companies only, viz., by the exercise of their power under regulation 14. The companies had responded in some measure to the representations of the Board by issuing a notice to their customers, calling attention to the advice with regard to waste-pipes, cleansing of cisterns, &c., given by Sir Francis Bolton, the water examiner, in his monthly and annual reports, and such advice was to be endorsed in future on the companies' call-papers. The power of water companies to cut off water for non-payment of rates should be totally abolished. There was a variety of powers under Nuisances Removal and Sanitary Acts which should be put in force to which attention had been drawn by the excellent digests prepared under the direction of the President of the Local Government Board. When all existing powers had been exhausted Parliament would confer whatever additional powers were proved necessary. Among others, the Metropolitan Board should have that of fixing upon sites for mortuaries and disinfecting chambers, and for baths and wash-houses upon a plan so arranged as to provide for the needs of the population irrespective of local boundaries. In course of time the powers of the Asylums Board would naturally devolve upon the central authority. It would be well if any one of the sanitary authorities would set a good example by getting the Sclater-Booth model clauses for the notification of infectious diseases embodied for use in its own district, in a Local Act. Having so far dealt with "sanitary powers," the address next dealt with "sanitary difficulties," which were partly inherent in the law itself, and partly incident to the method of its administration after this had passed from the sanitary to the judicial authority. There

was no power to punish the person who created a nuisance, however grave or long-continued it might be, and it took an inordinate time to get a nuisance abated, when the author of it proved recalcitrant. The public, naturally supposing sanitary law to be the embodiment of common sense as applied to matters of public health, were too apt to regard the sanitary authorities as all-powerful but apathetic, and to lavish blame upon them for not abating nuisances immediately upon discovery or report. But the law was too considerate of the rights of property, and too leisurely in its movements, to allow of this being done. Nuisance-mongers knew that they ran little risk by long-continued disregard of sanitary notices. By way of illustration the mode of procedure in cases when the authority of the Vestry was disregarded was sketched. It was shown that weeks, and in an extreme case, months, might elapse before a nuisance could be abated; the dwellers in the insanitary house, meanwhile, suffering in health and comfort. They were liable, moreover, to be made to pay compensation to the aggrieved landlord, in the shape of increased rent, for the trouble and expense to which he had been put. The remedy for the state of things described was two-fold. The magistrates should have power (as outside London they have, under Sec. 96 of the Public Health Act, 1875) to inflict, by their order, a substantial penalty on the author of the nuisance, and the vestry should have power to enter upon the premises to abate the nuisance when it was certified by the medical officer to be dangerous to health, and the time allowed in the vestry's notice for its abatement had expired. Such powers, which would lighten and make easy the duties of magistrates and sanitary authorities, would seldom have to be exercised, for law breakers would soon discover that their tricks of delay and resistance were alike useless and unprofitable, and so all reasonable notices of the sanitary authority would be respected and obeyed. Reference was made, in conclusion, to cases that had come before the courts, in which tenants had proceeded against their landlords to recover damages for injury to health, resulting from drainage and other structural defects. Decisions had been given in their favour and were of importance as precedents. It was to be expected, therefore, that in course of time bad landlords would find out that it was dangerous, in more senses than one, to let an insanitary house. There should be an implied warranty when a house was let that it was fit for human habitation, and before long he hoped this would be established as a principle of English law.

On the motion of Dr. Bristowe the thanks of the Society were given to the President for his address, and on the motion of Mr. Shirley Murphy, seconded by Mr. F. M. Corner, it was resolved to print the address and forward it to the Local Government Board, the Metropolitan Board of Works, the Vestries, and District Boards, and other parties interested in the question of London Government.

The proceedings of the meeting were brought to a close by the presentation of a testimonial to the retiring Honorary Secretary, Dr. Vinen, in the shape of a handsomely engrossed and framed copy of a resolution passed at the Annual Meeting held at the International Health Exhibition in June.

GENERAL CORRESPONDENCE.

THE LATE MR. RABBETH.

[To the Editor of the Medical Times.]

Sir,—Everyone who has read the account of Mr. Rabbeth's death must have admired the self-devotion with which he sacrificed his life to save that of a patient. But surely self-devotion in this case was carried too far. A surgeon has to run many risks in following his profession, but in this instance there was more than a risk. To suck out the membranes of diphtheria was to incur all but certain death. Could not the membranes have been removed by means of a suction-syringe? If not, it is high time that an efficient instrument for that purpose was invented.

I am, Sir, yours &c.,

October 23rd. J. D.

A SUGGESTION.

[To the Editor of the Medical Times.]

Sir,—I have for some time been engaged in experiments and trials of various antiseptics, carbolic acid, eucalyptus, thymol and iodoform, and since reading your article on Sir Joseph Lister's address, have made some on the following, which I think would be worth a trial. The modification which I venture to propose is as follows:—Corrosive Sublimate, ℥ii; White of Egg, ℥vi; Barff's Boroglyceride, ℥ xii; Distilled Water, ℥ cxxv. M. The strength of corrosive sublimate in this solution will be nearly 1 to 500. As it would be almost impossible to add the precise quantity of albumen to render the bichloride of mercury unirritating and safe, it is desirable to add an excess of albumen; but an excess of albumen on the other hand, if allowed to decompose, would be objectionable in the extreme, to obviate which I suggest the introduction of boroglyceride which, without in any way interfering with the action of albumen, whether used from blood serum or white of egg, will guard against the products of decomposition from the use of an excessive amount. The proportion of mercury used in the compound may be increased or diminished as occasion may require, and all are non volatile. Charpie, cotton wool, or oakum saturated in such a solution would in my opinion form one of the best antiseptic dressings that I have yet seen, and for the chief part of this I am indebted to Sir Joseph Lister, my only contribution being the introduction of boroglyceride.

I am, Sir, yours, &c.,

JOSEPH BULFIN, B.A.,
M.B., B.Ch., T.C.D.

Warrenpoint, Co. Down.

INVENTIONS AND IMPROVEMENTS.

THE CELLOIDIN PROCESS.

The importance of any method which protects the tissue elements of an organ from falling out during manipulation and thus producing errors and deficiencies in pathological investigations, induces us to say a few words on the method of embedding in celloidin, a method which as yet has hardly received the recognition it deserves. The seeming elaborateness of the process is purely superficial, for there is, even at first, but little difficulty in its manipulation, and it has certain special advantages, one of the chief of which is that specimens once embedded in the celloidin may be left there for an indefinite period without suffering deterioration; but its principal recommendation is that a thin solution of celloidin finds its way into all the interstices of a tissue and when it becomes set by a mixture of methylated spirit and water, the adjacent parts are welded together so that there results a section of celloidin holding together all the parts of the specimen. Now, in certain tissues as for example, spinal cord, lung, abscesses, etc., this is of inestimable advantage. The preliminary hardening of the tissue is effected in the usual manner. After this the specimen is immersed for at least two days in absolute alcohol. It is then transferred to a thin solution of celloidin. At the expiration of two or three days it is placed in a wooden or paper pill-box and this receptacle filled up with a celloidin-solution of a consistency equal to treacle. The box is then immersed in a vessel containing methylated spirit diluted to 82° or about. In another two or three days the celloidin mass, now consolidated, will be found ready for cutting.

Sections may be cut in several ways, but the most perfect are obtained by the machine made by Katsch, of Munich. (This microtome, the knife of which works under alcohol, allows very large and delicate sections to be made with monotonous regularity. The machine is, however, costly, and there seems no reason why a better instrument on similar lines should not be made in England for less money.) The embedded specimen may also be cut by a freezing microtome, but owing to the fact that celloidin freezes too hard, the shavings are extremely liable to chip. This,

however, may be averted in several ways known to those conversant with the freezing microtome; such as, leaving a small quantity of alcohol in the celloidin, or thawing the surface immediately before cutting with warm water or the breath, &c. The sections having been obtained, several methods of mounting may be adopted. If the celloidin is to be got rid of it may be dissolved out in a mixture of equal parts of absolute alcohol and ether and the specimen treated as usual. If the celloidin is to be retained, a variation of the usual course must be adopted. Thus, dehydration is effected by the aid of methylated spirit because absolute alcohol softens celloidin. Yet, with some experience of celloidin, dehydration may be finished off rapidly by a very short immersion in absolute alcohol. Finally the specimen should be cleared up in oil of bergamot, because oil of cloves is a rapid solvent of celloidin. These methods of clearing up specimens are those usually adopted, but quite recently it has been discovered that pure anilin or anilin oil is quite as effective as cloves or bergamot for clearing up sections with or without celloidin.

MEDICAL NEWS.

ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

RECOMMENDATIONS AND ALTERATIONS PROPOSED TO BE INCLUDED IN A NEW CHARTER OF THE COLLEGE.

THE following recommendations have been drawn up by a Sub-Committee of the Association, and having received the approval of the General Committee, will be submitted to a general meeting of the Association of Fellows, to be held on Saturday, November 8th, at 4 p.m., at the Medical Society's Rooms, Chandos Street, Cavendish Square, W. The marginal notes refer to the various Sections and Clauses of the Charters and By-laws concerned in the recommendations, and also give the page in the College Calendar on which they are to be found. Charters are privileges granted to the College by the Sovereign. By-laws, though liable, under certain conditions, to be made, altered, or abrogated by the Council of the College, must receive the approval of the Crown.—*Vide* Calendar, pp. xlii.-lv.

I.—Respecting the Conditions of Eligibility of Fellows to be Members of Council.

Calendar, p. xlvii., Charter Vict. xv., Sect. 7.

(*a*) Candidates must be Fellows: and either Fellows of fourteen years' standing or Members of twenty.

This recommendation proposes to remove all restrictions, which now prevent any Fellow from sitting on the Council who is not actually practising pure surgery.

Recommended:

(*a*) That subject to such limitations of standing as Fellow or Member, as defined in Section VII. of the Charter Vict. 15, any Fellow of the College shall be eligible to be a Member of Council.

Calendar, p. lvii., By-law, Sect. 5.

(*b*) As it is proposed later on to make the President hold office for a longer period than one year, it is considered desirable to render his duties less arduous.

The Council being limited in number, it is desirable to secure a due amount of attention to business of the corporation from each of its Members.

(*b*) Should any Member of Council other than the President be absent from more than two successive quarterly meetings, or from more than four successive ordinary meetings, he shall thereupon cease to be a Member of the Council, unless a reason for such absence satisfactory to the Council be assigned.

(*c*) Only a proportion of the Examiners should also be Members of the Council by whom the appointments are made. At present all the Members of the Court of Examiners and one Member of the Board are in the Council.

A resolution of Council to this effect was passed fourteen years ago, but has never yet been acted on, because it is not *binding* on the Council.

(*c*) That not more than one-half of the Members of the Court of Examiners, and not more than two Members of the Board of Examiners in Anatomy and Physiology, shall have seats in the Council.

(*d*) His immediate resignation might cause inconveniences at the next examination.

(*d*) If any Fellow, who is also a Member of the Court or of the Board of Examiners, shall be elected into the Council, he shall, within a period of two months of such election, vacate his office as a Member of the Court or of the Board.

II.—Respecting the Conditions of Candidature of Fellows for the Council.

Calendar, p. xlviii., Charter Vict. xv., Sect. 9.

A corollary to the first recommendation abolishes nomination by six Fellows and certificates of character from three.

Recommended:

That Section IX. of Charter 15 Vict. do read as follows:—That every Fellow who shall intend to offer himself as a candidate for a seat on the Council of the said College, shall within such time as the Council shall from time to time direct from the publication of the *London Gazette*, in which the day of election shall be announced, transmit or deliver to the Secretary of the same College a notice signed by himself of such his intention.

III.—Respecting the Conditions and Term of Tenure of the same Office.

Calendar, p. xxxviii., Charter Vict. vii., Sect. 12.

(*a*) At present three go out of office annually. It is thought desirable to increase the responsibility of Members of Council by causing them to seek re-election more frequently, and thus increase the control of the Fellows over the administration of the College.

Recommended:

(*a*) That the six Members of the Council who shall have served longest on the Council without re-election, shall vacate their office every year instead of three, as provided for by Section XII. of Charter 7th Vict.

IV.—Respecting Substitute Members.

(*b*) A substitute Member is now elected in case of death or resignation of a Member of Council, and only completes the term of his predecessor's tenure.

Recommended:

(*b*) That "Substitute Members," as defined by Section XIV., Charter 7th Vict., be abolished.

V.—Respecting the Mode of Voting.

Already conceded by the Council, and to be embodied in the new Charter. *Vide*, Proposed alterations submitted to a General Meeting of Fellows and Members held in the College on March 24th, 1884.

Approved:

The proposed alteration in the Section XV. of 7th Vict., abolishing compulsory personal voting, and permitting the alternative of voting by voting paper.

VI.—Respecting Payment of Fees by Members of Council.

Calendar, p. lvii., By-laws, Sect. iv.

At present each Member of Council, on election, pays twenty guineas.

Recommended:

The payment of a fee by a Member of the Council be no longer required.

VII.—Respecting the Election and Tenure of Office of President.

With a view to increase the dignity and status of the President. At present it is, in effect, *election by rotation.*

Recommended:

That the President of the College be elected annually by the Fellows from among the existing or past Members of the Council, at the time, in the manner, and under the conditions hereinafter described:—

(*a*) That he be elected at the time and in the manner that Members of the Council are elected, on the nomination of the Council.

(*b*) That the Council shall submit at least three names to the Fellows, one of which shall be that of the retiring President, provided he be eligible and does not decline to serve.

(*c*) That no one shall hold the office of President for a longer period than five consecutive years.

(*d*) If the President be elected from amongst the past Members of the Council, he shall become "ex officio" a Member of the Council during his tenure of office as President.

VIII.—Respecting the Office of Treasurer.

Calendar. p. lxix., By-laws, Sect. xxvi.

(*a*) At present the President and Vice-President are joint Treasurers; thus the office changes hands annually, and there is no public audit of accounts.

Recommended:

(*a*) That a Treasurer be appointed from amongst the Members of the Council, and that his accounts be audited by a professional auditor, whose report shall be submitted to the Annual Meeting of Fellows and Members.

(*b*) That the Treasurer's balance sheet duly audited shall be submitted to the Annual General Meeting of Fellows and Members, and that such balance sheet shall be published with the advertisements convening such Meeting.

IX.—Respecting the Constitution of the Court of Examiners.

(*a*) A Resolution of Council was passed eighteen years ago, that no Member of the Court of Examiners should hold office for more than two periods of five years; but this, like other Resolutions, not being "bindiug," is "inoperative."

Recommended:

(*a*) That Members of the Council of Examiners shall be elected annually, and that no Member of the Court of Examiners shall hold office for more than five consecutive years, and at the expiration of this time he shall not be again eligible until after a period of two years has elapsed.

(*b*) That all vacancies in the Court of Examiners shall be advertised in at least two of the weekly medical journals of the United Kingdom, with an announcement of the names of those Members of the Court who are eligible for re-election, and inviting Fellows desirous of being considered candidates to send in their names to the President.

This By-law exacts a fee of twenty guineas from each Member of the Court of Examiners on his appointment.

(*c*) That Section VIII. (3) By-law be omitted.

X.—Respecting the Board of Examiners in Anatomy and Physiology.

Proposes to make Members eligible as well as Fellows.

Recommended:

That Members of the Board of Examiners shall be elected annually from amongst the Fellows and Members of the College, and that no Member of the Board shall hold office for more than five consecutive years, and at the expiration of this, his term, he shall not be again eligible until after a period of two years has elapsed.

XI.—Respecting the Election of Fellows without Examination and Honorary Fellows.

(*a*) This provision of the Charter should be carried into effect more liberally than heretofore, but such elected Fellows should pay the same fee as Members who are admitted after examination, and not be elected without fee, as the Council proposes.

Recommended:

(*a*) That the alteration proposed by the Council in Section V. Charter 15 Viet., be not adopted, and that the words "any two persons," read "not more than five."

(*b*) This is a custom with similar bodies, and would add lustre to the College.

(*b*) That the Council may nominate distinguished members of the medical profession, whether Members of the College or not, as Honorary Fellows, to be elected by the Fellows and Members at the Annual General Meeting.

XII.—Respecting Meetings of Fellows and Members, separately and collectively.

Calendar, p. lxii. — By-law. Sect. XVIII.

(*a*) At present no meeting can be convened except by the President or Council, and the body corporate is entirely excluded from a knowledge of the affairs of the College; whilst important changes are made without the consent of the constituents.

Recommended:

(*a*) That there shall be an Annual General Meeting of the Fellows and Members at which the Annual Report of the Council, including the Treasurer's Statement of Accounts, duly audited, shall be presented, discussed, and if approved, adopted.

(*b*) The Council has recently, without the consent of the Fellows and Members, entered into a combination with the Royal College of Physicians, which materially alters the constitution and relations of the College.

(*b*) That no alteration in the constitution or in the relations of the College shall be effected without the consent of the Fellows and Members, convened specially to discuss such alterations.

(*c*) A resolution of Council over fourteen years ago permits of such Meetings, provided the Council APPROVE OF THE OBJECT OF SUCH MEETING.

(*c*) That on receipt of a requisition signed by thirty Fellows or Members the President shall convene a meeting within twenty-one days of the Fellows and Members collectively (or, if demanded in the requisition, separately). At this Special Meeting or Meetings the question or questions of which notice shall have been given in the requisition, shall alone be discussed.

(*d*) That such Meetings shall be duly advertised in the weekly journals.

XIII.—Recommended as a By-law.

Fourteen years ago a resolution of Council was carried that the Minutes of the Council Meetings should be suspended in the Hall after lapse of five days, but it still remains "INOPERATIVE."

That the Minutes of each Meeting of the Council shall be suspended for the inspection of Fellows and Members in the College Hall, or other convenient place, within twenty-four hours of the holding of such Meeting, and that they remain suspended for a period of at least seven days.

GEO. D. POLLOCK, *President.*

JOHN H. MORGAN, W. BRUCE CLARKE, } *Hon. Secs.*

UNIVERSITY OF CAMBRIDGE.—At a congregation held on Thursday the 23rd ultimo, the degree of Bachelor of Medicine was conferred on—

R. W. Seeming, Christ's; A. W. C. Peskett, Downing.

THE ROYAL UNIVERSITY OF IRELAND.—*M.B. Examination.*—The Examiners have recommended that the following Candidates should be placed in the Upper Pass Division, and that those marked with an asterisk should be admitted to a further Examination for Honours:—

Robert Alfred Carter, Charles R. Elliott, Thomas Frizell, *Thomas Grainger, *James Morwood, *William White, Queen's College, Belfast; Maurice Connery, Charles James Cooke, *Benjamin Hosford, *John Kearney, *Philip A. M'Carthy, *Denis Sheahau, Queen's College, Cork; *William Bartley, *Robert J. Macnamara, Queen's College, Galway; J. T. Daly.

The Examiners have further recommended that the following Candidates be also adjudged to have passed the Examination:—

William Frederick Bailey, Arthur Blackwood, Frederick James Burns, George Clarke, James C. Ferguson, Charles H. P. D. Graves, Charles Hayden, Hugh Lewers, Marcus M. Loudon, James M'Avoy, Nicholas J. M'Donuell, Joseph B. M'Kay, Edward Magennis, Donald C. Martin, Hugh Smith Morrison, Frederic C. Sinclair, George Scott Tate, Queen's College, Belfast; Patrick Blackall, John N. Corbett, Patrick G. Cotter, Warren R. Crooke, Joseph Giusani, Edward Greene, Samuel Roger Hunter, Morgan M'Swiney, James F. Magner, John Moore, Cornelius O'Doherty, Michael O'Halloran, J. Joseph Prendergast, Queen's College, Cork; Peter Joseph Horkan, William A. Wadsworth, George Alexander Waters, Queeu's College, Galway; Patrick Joseph O'Hara, Carmichael College; Alfred J. Smith, Patrick J. Soraghan, Catholic University School of Medicine; E. Alfred Starling, Guy's Hospital, London; George Nesbitt Wynne, Carmichael College, and Ledwich School of Medicine.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen having undergone the necessary examinations for the diploma were admitted members of the College at a meeting of the Court of Examiners on the 23rd ult., viz.:—

Edward Jessop, Nottingham; H. H. Fisher, Sittingbourne; G. S. Clayton, L.S.A., Hampstead; H. J. Bury, Hampstead; G. C. Bell, Blackheath; H. J. Hillstead, L.S.A., St. John's, S.E.; R. J. Kirby, L.R.C.P. Lond., Crouch Hill, N.W.; E. M. Hewish, M.D., Toronto; George Byrne, L.R.C.P. Lond., Manchester; Ernest Noad, L.R.C.P. Edin., Christ's Hospital, E.C.; A. J. Wrakly, L.R.C.P. Lond., Leytonstone; H. G. Shaw, L.R.C.P. Edin., Stratford-on-Avon; C. J. J. Hood, L.S.A., Tunbridge Wells; C. W. J. Bell, L.R.C.P. Edin., Dulwich; Henry Lloyd, L.S.A., Denbigh, and F. W. H. Penfold, Rainham, Kent.

Seven gentlemen were approved in Surgery and when qualified in Medicine will be admitted members of the

College, and six candidates having failed to acquit themselves to the satisfaction of the Court of Examiners were referred to their professional studies for six months and three for three months.

The following gentlemen passed on the 24th ult., viz :—

J. W. Carr, L.S.A., Bloomsbury Square; Ernest Cusse, L.S.A., Great Ormond Street, W.C.; P. R. W. Santi, L.S.A., Doughty Street, W.C.; Charles Averill, L.S.A., Stafford; A. S. Gubb, L.S.A, Southampton; Harry Tuck, L.S.A., Surbiton; C. S. Blair, M.D. Durham, Newcastle-on-Tyne; R. T. Cann, L.R.C.P. Lond., Lambeth Palace Road, S.E.; R. M. Williams, L.S.A., Beaumaris, Anglesey; W. R. Tytheridge, L.R.C.P. Edin., St. James' Square, S.W., and W. J. Best, L.S.A., Queensdown Road, E.

Six gentlemen were approved in Surgery and when qualified in Medicine will be admitted members of the College, and six candidates were referred for six months and as many for three months.

The following gentlemen having undergone the necessary examinations were admitted Licentiates in Dental Surgery at a meeting of the Board on the 29th ultimo, viz :—

William R. Ackland, Exeter; James C. V. Crocker, Penzance; Peyton G. Levason, Hereford; Herbert S. Parkinson, Sackville Street, W., and Charles A. Roberts, Weymouth Street, W.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, October 23rd, 1884 :—

William James Best, Richmond House, Queensdown Road, Clapton, E.; Jno. Arnallt Jones, Abergwesyn Vicarage, Llanwrtyd, Brecon; Henry Lloyd, Llanrhaiadr, Denbigh; Alexander McDonnell, 413, Kingsland Road, E.; William Francis Tronson, 9, Oxford Gardens, W.; Reginald Muzio Williams, TreCastell, Beaumaris, Anglesea.

University of Cambridge.—The following appointments are announced :—Dr. Donald MacAlister, to be the University Lecturer in Medicine. Dr. Robert Nicholls Ingle, to be the University Lecturer in Midwifery, Dr. Bushell Anningson, to be the University Lecturer in Medical Jurisprudence.

Oxford Graduates Medical Club.—The Committee of this club have announced that the next dinner is to be held at Limmer's Hotel, on Thursday, November 20th. Members are to be allowed the privilege of introducing one guest apiece who must be a member of the Universities of Oxford or Cambridge. The club already numbers upwards of 80 members, and so far as possible communications have been made to everyone in the profession who possesses an Oxford degree. In case any have not joined who may wish to do so they should write at once to one of the secretaries, Dr. Samuel West, or Mr. John H. Morgan.

The Royal Commission on the Housing of the Working Classes.—The Commission are still considering their report. It is stated that there are considerable differences of opinion on some points, and that the preparation of the report is likely to occupy several sittings. The document will necessarily have exclusive reference to England, as Scotland and Ireland are to form the subject of subsequent enquiry.

Aberdeen University.—The winter session began on the 22nd ult., when most of the classes in the Faculty were opened. In the Institutes of Medicine class Professor Stirling gave a general account of "animal electricity." He paid a high tribute to the genius of Emil du Bois Reymond, to whom we owed almost all our knowledge of animal electricity. The recent discoveries in connection with the "insectivorous" plants, such as the Venus' fly-trap, as regards their digestive powers depending on the presence of an acid and a ferment, were made the basis of a sketch, showing the identity of the physiological processes occurring in plants and animals. In the study of animal physiology the student merely continued in a more specialised way the study of those principles which obtained in other natural sciences; while in the study of disease the same processes were manifested under different conditions, so that certain principles linked all these subjects into one grand organic whole. Professor Struthers, in opening the anatomy class, gave a lecture, dealing with his experiences in America while attending the meetings of the British Association.

Royal University of Ireland.—At a meeting of the Senate held at the University Buildings, Earlsfort Terrace, Dublin, on Friday, October 24th, it was ordered that application should be made to His Excellency the Lord Lieutenant of Ireland for his approval of the recognition of the Edinburgh Royal Maternity and the Royal Edinburgh Asylum for the Insane as institutions from which the University will receive certificates for degrees in Medicine. The Senate also ordered that—(1) At the First Examination in Medicine, the following orders shall be added to those already prescribed :—*Papaveraceæ*, *Fumariaceæ*, *Caryophyllaceæ*, *Malvaceæ*, and *Valerianaceæ*, and that Prantl's "Work on Botany" shall be added to the list of ordinary text-books recommended, and "Packard's Zoology" to the list of books recommended to be read. (2) The course for the examination for the Stewart Scholarship for proficiency in mental diseases, shall include mental diseases, diseases of the brain and spinal cord, and diseases of the nervous system; practical examination of patients labouring under such diseases, and written reports upon the same, to be submitted to the examiners; examination with the microscope of pathological specimens and preparations illustrative of those diseases; and the examination shall not occupy less than three days.

Medical Representation in Parliament. — The following resolution has been passed at a committee of the Association of Members of the Royal College of Surgeons of England, and sent by Dr. Collum, the President, to Mr. Gladstone :—Resolved : "That the Prime Minister be respectfully requested to provide in the 'Redistribution Scheme' that two representatives in Parliament be given to the registered medical practitioners of Great Britain and Ireland, and for the following reasons :—1. Because they number over 30,000, and would be a very highly educated and eminently respectable constituency. 2. That they should not be placed at a legislative disadvantage with the various universities which already return members. 3. That large numbers of the profession are at present practically disfranchised, and unfairly so, as compared with other bodies of men with less pretensions, intellectually, morally, or socially. 4. That it would be to the advantage of science and material progress, as well as to the public health."

Infant Mortality in Sunderland.—The medical officer for Sunderland has issued a statement in which he shows that the distress in the borough has for some time past considerably *affected the death-rate of the town. In the first quarter of this year* 159 *infants under a year old died, in the second quarter* 183, *and in the third quarter the large number of* 321 *succumbed.* Again, as regards children who are over twelve months but under five years old, 95 died in the first quarter, 102 in the second, and as many as 140 in the third. Last year the deaths of all children under five years were only 38 per cent. of the total deaths, and the average for ten years was only 48 per cent. Similarly, among infants under a year old, the deaths last year were only 23 per cent. of the total deaths, and for ten years averaged only 28 per cent. In order more clearly to see the difference, the medical officer has tabulated the deaths of children per 100 total deaths :—

	Under a year.	Under five years.
Last ten weeks	46	66
1883	23	38
Average of ten years ..	28	48

"Figures like these," he says, "must appeal strongly to the people. Children are dying in unusually large numbers. The weak and the delicate are going first, to be followed no doubt by the stronger later on. Infants a few months old are dying because their mothers cannot nourish themselves, and hence are unable to suckle their offspring, and cannot buy them the milk which is so necessary for their existence. The winter is at hand, and I fear there will be no decline in the mortality unless a strong and systematic effort be made to relieve the people.

The Vienna Policlinic.—The following are the most important courses during the present winter session. Internal Medicine, by Professor von Stofella; Therapeutics, including Hydrotherapy and Diet, by Dr. Winternitz;

Pathology of Circulatory and Respiratory Organs, by Dr. von Basch; Laryngoscopy and Rhinoscopy, by Professor Schnitzler. The same professor, who is the newly-appointed Director of the Policlinic, will also give courses on Diseases of the Larynx, and on the more modern methods of examining and treating cases of Heart and Lung disease. Dr. Leopold Oser will hold a course on the diseases of the Stomach and Intestines. Professor Benedikt will lecture on diseases of the Brain and Spinal Cord; on Electrotherapeutics; and on Clinical Craniometry. Dr. Robert Ultzmann will give a course on diseases of the Urinary Organs, and Professor von Frisch will give courses on diseases of the Bones and Joints; on the Relation of Microorganisms to Infective Diseases; and on Experimental Bacteriology. Dr. Wolfler will lecture on the diagnosis of treatment of Surgical Diseases. The specialties, for which the policlinic is so much besought by foreign students, will be divided as follows:—Syphilis and Dermatology, by Dr. Hans von Hebra, and Dr. Edward Schiff; Diseases of the Eye, by Dr. Hock and Dr. Von Reuss; Diseases of the Ear, by Dr. Urbantschitsch; Children's Diseases, by Dr. Monti, Dr. Ludwig Fürth, and Dr. Maximilian Herz; Diseases of Women, by Professor Bandl.

The International Congress of Surgical Instrument Makers.—The second congress of the makers of surgical instruments, orthopædic apparatus and bandages, held in September at Dresden, when seventy members met, shows that the society formed last year has met with speedy recognition of its utility. In a year the number of members has almost doubled, amounting now to 175; and one of the chief objects of the present congress has been to forward the foundation of a journal, in which all novelties and improvements will be explained by good illustrations, and made known to the medical profession at large. Another object in view is the establishment of good schools in which assistants will have the opportunity, after becoming sufficiently acquainted with the practical surgical requirements, of hearing anatomical and other lectures, and visiting surgical and orthopædic clinics. A detailed prospectus of what is intended in this direction will be prepared for next year's congress, to be held at Berne. The proceedings of the present congress terminated with demonstrations of new instruments, and apparatus, and addresses on their practical employment.

Population of France in 1883.—It results from the statistics published by the *Journal Officiel* that the total excess of births over deaths in 1883 was only 96,843, which is about the same as in 1882, but is sensibly less than in 1881, when it was 108,229. It is found that the excess of births is largest in the industrial departments, and those in which the *petit culture* prevails, such as the Nord, Seine, Pas de Calais, Finisterre, Morbihan, Loire-Inférieur, &c. An excess of deaths, on the contrary, is met with in the rich departments, such as the Orne, Eure, Calvados, Seine-et-Oise, &c. The total number of deaths amounted in 1883 to 841,101, while it was 838,539 in 1882, 828,828 in 1881, and 858,000 in 1880. The number of births has progressively increased from 920,000 in 1880, 937,057 in 1881, 935,566 in 1882, to 937,944 in 1883—a gratifying fact, although somewhat damped by the increase, being entirely due to the greater number of natural children.

The Berlin Laboratories.—A Berlin correspondent of the *Philadelphia Medical News*, September 13, supplies some interesting information on this subject. He states that there are several good chemical laboratories at which a "mediciner" may work, but that of Professor Hoffmann, on account of the fame of its director, is filled and overfilled, and the securing a place at this does not follow that the possessor shall be under the distinguished professor's own teaching. In his own case, the writer was consigned to another department never even visited by him; so that he naturally does not speak very well of it. There are several laboratories for physiological chemistry, each guided by a teacher of distinction. The oldest of these is that of the Pathological Institute in connection with the Charité Hospital, and which was founded as long ago as 1856, owing its existence to the insight of Virchow, who was able to appreciate at an early period the relations and importance of chemistry to medicine. Hoppe-Seyler and Kühne have formerly been connected with it, and it is now directed by Professor Salkowski. It is to be recommended to anyone wishing to work at medical chemistry, whether physiological or pathological. The Physiological Institute has also an admirable laboratory for physiological chemistry, under Dr. Kossel, who until recently was an assistant of Professor Hoppe-Seyler, at Strasburg. "It is remarkable how many practising physicians still, at the age of 35 or 40, manage to maintain a lively interest in physiology, and often undertake investigations either in the chemical or experimental departments. Sometimes this work has a direct reference to practical medical questions, and sometimes seems to be done purely to maintain an old scientific love. They have, in fact, never been divorced." The Institute for Physics, under the direction of Helmholtz, that for Physiology, under Du Bois Reymond, and that for Pharmacology, under Liebreich, are so close together that they form one magnificent and compact pile, only surpassed in beauty by the Military Academy opposite. A course on physiological optics is given in the Institute of Physics, but the "mediciner" who would get much from this must be well versed in mathematics. The case is different with another course on physics, given in the Institute of Physiology, by Professor Christiani, which is expressly designed for the "mediciner," and comprises what is most important for the understanding of experimental physiology, the microscope, &c. The experiments are most admirable, and leave but little to be desired. The mathematics of the subject are not neglected, but by the use of the graphic method many mathematical formulæ which otherwise would be very difficult for such auditors, are rendered clear. The same remark applies to the more difficult theories, such as the wave theories. Altogether the course is unique, and the teacher of any department of experimental science can get many valuable suggestions as to the best modes of making his subject clear and expressive. Physiology is in a highly flourishing condition in Berlin. Reference has already been made to the abundant provision for physiological chemistry. A course of lectures on general physiology is also given at the excellent Veterinary School, by Professor Munk, which are both clear and well adapted to the hearers. The principal course of lectures in the Physiological Institute is given by the venerable and long-famous director, Professor Du Bois Reymond. His lecture-room is large, comfortable, and exceedingly elegant in all its appointments, and the lectures are illustrated by the most beautiful and best adapted apparatus to be had. Professor Kronecker gives one lecture a week on the physiology of the heart, and one on muscle physiology, both in much detail, and well illustrated; and upon this energetic and accomplished professor most of the laboratory work in the experimental department of physiology devolves. "Apart from conducting many special researches, a course on the 'methods of investigation' in physiology is given. In this course, vivisection and the graphic method are taught very much apart; and in general the separation of what may be called the *technique* of physiology from the theory and the facts of the science observed in this laboratory seem to me to deserve much consideration. How much loss of time and confusion of ideas are avoided by such a course, only those who have seen the reverse method pursued can thoroughly appreciate. I should be glad to see such a separation in some way applied to chemistry and some other departments, for I know of no laboratories in which so much time is simply pottered away as in chemical laboratories. A preliminary course on *technique* or manipulation would obviate much of this, and also probably prevent the student from becoming the mere mechanical worker." From what has been said, it will appear that ample provision has been made in the Berlin Physiological Institute for teaching, under the best conditions, the physics of medicine, the chemistry of medicine, and the experimental physiology of medicine; and it only remains to add that a full course on histology, &c., is given by Professor Fritsch, to indicate how thoroughly this institute deserves its name. The adjoining Pharmaceutical laboratory, under the direction of the well known Liebreich, is, in the completeness of its various departments, perhaps unequalled in the world. No expense seems to have been spared to make it as nearly

perfect as possible for the purposes both of teaching and of investigation. A noteworthy regulation exists, requiring all students to take a course in antiseptics, and a special department of the laboratory is devoted to this purpose. In conclusion, the writer suggests to the authorities of the Berlin University the propriety of repealing the regulation which obliges all foreigners, irrespective of age and status, to pay a matriculation fee, and go through all the forms (and these are not few) pertaining to matriculation before they can participate in the advantages of the university.

SUDDEN DEATH FROM GANGRENE.—Dr. Messemer, the deputy coroner of New York, writes that he has met with a great many cases of persons dying suddenly, who were affected with gangrene of the right hand or arm, caused by injury or frostbite. The gangrenous gases pass through the veins of the right arm into the vena cava and right side of the heart, causing instantaneous death by syncope or collapse. When the right side of the heart is cut into, after death, a puff of gangrenous gas can be distinctly discerned.

EXTRA-UTERINE PREGNANCY.—At a meeting of the New York Obstetrical Society, Professor Gaillard Thomas read a paper upon this subject in continuation of a communication which he had made to the American Gynæcological Society in 1882, and in which he had recorded the particulars of the 24 cases that had occurred in his practice. Since then he had met with six other cases, making 30 cases, which he believed to be an unusual number to occur in the practice of one man. Of these six cases he now gives a succinct account, and the conclusion he draws from them is that surgical interference should be avoided by every means in our power. He had tapped three cases with a needle, and in each with a fatal result. Every one knows what has hitherto been the result of removing the mass in such cases, and although no doubt this would be better under antiseptic procedure, yet such wonderful results have been obtained by electricity that he thinks it should be adopted in every case in which the diagnosis has been made in time, and that all the more because when it does no good it does no harm.

APPOINTMENTS.

ANGLIN, W. G., M.D., C.M.—Resident Physician to the Royal Edinburgh Hospital for Sick Children.

APPLEFORD, S. H., M.R.C.S., L.R.C.P.—Surgeon to the Eastern Dispensary, *vice* J. E. Adams, resigned.

BARBER, F. S., M.R.C.S.—House Surgeon to the Kidderminster Infirmary.

BLACKET, ERNEST, M.R.C.S. Eng., and L.R.C.P. Edin.—Medical Officer to the Workhouse, Clutton Union, *vice* Mr. W. B. B. Perrin, resigned.

CALEB, C. C., M.B., M.R.C.S. — House Physician to the North London Hospital for Consumption and Diseases of the Chest, Hampstead.

DWYER, F. CONWAY, M.D., B.Ch.—House Surgeon to the Mater Misericordiæ Hospital, Dublin, *vice* Dr. Cruise, resigned.

MACKINTOSH, GEORGE DOUGLAS, L.K. and Q.C.P. Ire.—Medical Officer to the Sixth District, Market Harborough Union, *vice* Mr. T. Macaulay, resigned.

MARTIN, THEODORE, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the Cameley District, Clutton Union, *vice* Mr. W. B. B. Perrin, resigned.

SHAW, H. C. C., M.R.C.S., L.R.C.P. Lond.—Resident Medical Officer to the Richmond Hospital, Surrey.

WEBB, M., M.B. Lond., M.R.C.S.—Resident Medical Officer to the Royal Infirmary, Manchester.

VACANCIES.

BRISTOL ROYAL INFIRMARY. — ASSISTANT Resident Officer and Pathologist. (*For particulars see Advertisement.*)

ECCLES AND DISTRICT MEDICAL ASSOCIATION. — Medical Officer. (*For particulars see Advertisement.*)

HOLSWORTHY UNION.—Medical Officer to the Third District and the Workhouse, in succession to Mr. E. T. Pearce, deceased. Area, 17,197 acres. Population, 1,619. Salary, £25 8*s.* 4*d.* per annum. Salary for the Workhouse, £22 per annum.

NORTH RIDING INFIRMARY, MIDDLESBROUGH-ON-TEES. — House Surgeon. Salary, £100 a year, with lodging, board and washing. Candidates must be possessed of a Medical and Surgical qualification, recognised by the General Medical Council, and be unmarried. Applications to be sent to Angus Macpherson, Secretary, up to November 3rd.

ROYAL FREE HOSPITAL, GRAY'S INN ROAD.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

ROYAL LONDON OPHTHALMIC HOSPITAL, BLOMFIELD STREET, MOORFIELDS.—Assistant Surgeon. Applications and testimonials to be sent to the Secretary, on or before November 8th.

TARVIN UNION.—Medical Officer to the Tattenhall District, in succession to Mr. Thomas James Proudlove, deceased. Area, 24,293 acres. Population, 5,312. Salary, £40 per annum.

THE CANCER HOSPITAL, FULHAM ROAD, BROMPTON, S.W.—Honorary Surgeon, also an Honorary Assistant Surgeon. Candidates must be Fellows of the Royal College of Surgeons of England, and practising only as consulting surgeons. Applications, with testimonials, to be addressed to the Chairman of the Weekly Board, at the Hospital, on or before November 11th.

WYCOMBE UNION.—Medical Officer for the First District, in succession to Mr. W. Rose, resigned. Area, 6,730 acres. Population, 6,917. Salary, £80 per annum.

DEATHS.

BROWN, CHARLES BLAKELY, M.D. (Oxon), of 3, Hill Street, Berkeley Square, W., on October 22nd.

GIBB, ALEX., M.D., Inspector General of Hospitals, at 12, Windsor Street, Edinburgh, on October 21st.

GIBSON, HENRY, M.R.C.S., at 50, Prospect Street, Hull, on October 19th, aged 71.

LUKE, JOSEPH, M.D., of Oak Lodge, Green Lanes, Finsbury Park, N., at 4, Beulah Villas, Clive Vale, Hastings, on October 22nd, aged 66.

ROGERS, N., M.D., at 16, The Strand, Exmouth, on October 27th, in his 77th year.

SHEEHY, W. H., L.R.C.P., at 39, Great Percy Street, W.C., on October 24th, in his 65th year.

NOTES, QUERIES, AND REPLIES.

Dens Sap, South Kensington.—There is no such title as "L.D.S., F.S.S., of the R.C.S." Another correspondent states that the circular is widely distributed in Wimbledon and its neighbourhood.

A Provincial Teacher.—At the corresponding period last year there were 129 candidates examined for the diploma of the Royal College of Surgeons; this year 125, of which number thirty-one were referred for six months, and eighteen for three months, making a total of 49.

COMMUNICATIONS RECEIVED—

Dr. J. MATTHEWS DUNCAN, F.R.S., London; Dr. CLIFFORD BEALE, London; Dr. TIRARD, London; Dr. NORMAN CHEVERS, London; Dr. HERMAN, London; Dr. STURGES, London; Dr. D. MACALISTER, Cambridge; Mr. JAMES DIXON, Dorking; Dr. RAYNER, Hanwell; Prof. SCHNITZLER, Vienna; THE DIRECTOR-GENERAL OF THE ARMY MEDICAL DEPARTMENT, London; Messrs. NEVILL, London; Mr. J. T. BACOT, Seaton, Devon; THE HON. SECRETARY OF THE ODONTOLOGICAL SOCIETY OF GREAT BRITAIN, London; THE SECRETARY OF THE SCOTTISH NATIONAL CONSTITUTIONAL ASSOCIATION, Edinburgh; Dr. WM. EWART, London; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; Mr. G. S. JOHNSON, London; Mr. KINGZETT, London; Mr. WYNTER BLYTH, London; Mr. WAGSTAFFE, Sevenoaks; Dr. HEBB, London; Mr. STONE, Wimbledon; OUR DUBLIN CORRESPONDENT; THE HON. SECRETARY OF THE MEDICAL SOCIETY OF LONDON; Dr. MARKHAM SKERRITT, Bristol; THE REGISTRAR-GENERAL, Queensland; THE REGISTRAR-GENERAL, London; THE REGISTRAR-GENERAL, Edinburgh; Mr. J. H. MORGAN, London; OUR VIENNA CORRESPONDENT; Mr. H. P. DUNN, London; THE HON. SEC. OF THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, London; Mrs. CAMERON, London; THE SECRETARY OF THE ROYAL INSTITUTION, London; THE SECRETARY OF THE OBSTETRICAL SOCIETY, London; Dr. R. G. DAUNT, Campenas, St. Paulo, Brazil; THE SECRETARY OF THE PATHOLOGICAL SOCIETY OF LONDON; THE EDITOR OF THE PHILANTHROPIST, London; THE REGISTRAR-GENERAL, Dublin.

BOOKS RECEIVED—

England to the Cape of Good Hope, &c., by A. Wilmot, F.R.G.S.—The Spitalfields Genius, by J. Fayle, B.A.—Handbook of the International Health Exhibition on the London Water Supply, by Col. Sir Francis Bolton, C.E.—Real-Encyclopädie der Gesammten Heilkunde—Biographisches Lexikon der Hervorragenden Aerzte Aller Zeiten und Völker — Dental Caries, by Henry Sewill, M.R.C.S., and L.D.S. Eng.—Handbook of Midwifery for Midwives, by J. E. Burton, M.R.C.S., L.R.C.P. Lond.—Subcutane oder intravenöse Infusion als Behandlungsmethode der Cholera, von Prof. Dr. Samuel—Lehrbuch der Physiologie, von Dr. A. Gruenhagen—Diphtheria Spread by Adults, by A. Jacobi, M.D.—Our Medical Charities, and the Working Classes, by Sampson Gamgee, F.R.S.E.—Observations in China, by Fortescue Fox, M.B. Lond.—A Descriptive Catalogue of the Pathological Museum of the Middlesex Hospital, by J. K. Fowler, M.A., M.D., and J. B. Sutton, F.R.C.S.—Some Practical Remarks on Dietetics in Disease, by William Pepper, M.D., LL.D.—Madness and Crime, by Clark Bell, Esq.—The Adaptation of Bible Religion to the Needs and Nature of Man, by the Rev. W. G. Blaikie—Transactions of the Clinical Society of London, vol. xvii.—Ueber Ptomaine, von Prof. Dr. L. Brieger—The Encyclopædic Dictionary, Part 10.

PERIODICALS AND NEWSPAPERS RECEIVED—

APPOINTMENTS FOR THE WEEK.

Friday, October 31 (*this day*).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday, November 1.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, November 3.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Medical Society of London, 8.30 p.m.—General Meeting. Mr. Edmund Owen, on "Lancing the Gums;" Dr. de Haviland Hall, on "A Case of Surgical Scarlet Fever."

Odontological Society of Great Britain, 40, Leicester Square, 8 p.m.—Casual Communications, by Messrs. Ackery, A. S. Underwood, Storer Bennett, and Morton Smale. Paper, by Mr. F. Newland Pedley, "Some Points in Connection with Fracture of the Lower Maxilla."

Tuesday, November 4.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Pathological Society of London, 8.30 p.m.—Dr. Hale White, on "Coarctation of the Aorta;" Drs. Hobson and Lanchester, on "Caseous Pneumonia Simulating Empyema;" Mr. Barker, on "Removal of Upper Jaw for Epithelioma;" Dr. Percy Kidd, on "Cardiac Aneurysms;" Dr. Howard Tooth, on "Lympho-sarcoma of the Liver in a Child;" Dr. Carrington, on "Cancer of the Liver and Adrenals with Melanæmia, &c.;" Dr. Acland, "Two Cases of Ulceration of the Intestines in Paraplegia."

Wednesday, November 5.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Medico-Psychological Association, Bethlem Hospital.—Quarterly Meeting at 4 p.m. Dr. A. H. Newth, on "The Value of Electricity in the Treatment of Insanity." Council Meeting at 3.30 p.m.

Obstetrical Society of London, 8 p.m.—Dr. Graily Hewitt, on "The Severe or so-called Uncontrollable Vomiting of Pregnancy;" Dr. Potter, on "A Case of Retained Product of Conception." Specimens will be shown by Mr. Lawson Tait and others.

Thursday, November 6.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Friday, November 7.

West London Medico-Chirurgical Society, 8 p.m.—Mr. Bernard Pitts, "Foreign Body in the Air-passage, Abscess of the Lung—Recovery;" Mr. Maitland Thompson, "Case of Retention (24 hours)—Catheter Fever—Death;" Mr. Noble Smith, "The Objects of the Medical Sickness, Annuity, and Life Assurance Society;" Dr. Chas. Good, "Gastric Ulcer—Rupture—Sudden Death."

Contents.

THE REVIVAL OF OVARIOTOMY, AND ITS INFLUENCE ON MODERN SURGERY.[1]

By SIR SPENCER WELLS, Bart.,

Late President of the Royal College of Surgeons of England.

MR. PRESIDENT and GENTLEMEN, MEMBERS of the MIDLAND MEDICAL SOCIETY,—

Next to the satisfaction which attends the fulfilment of the first duty of our calling—the relief of suffering and the prolongation of human life, which the Roman orator said raised the giver of health to man nearer to the Divine Giver of life—I know of no higher privilege than that of being permitted to address educated minds,—of endeavouring to influence for good, medical thought and opinion and practice—whether by the aid of the art of the printer—that "magic which embalms the thought"—or by addressing such an assemblage as this, with the knowledge that what may be said before you (after as much careful preparation as the too scanty leisure of a very active life permits) will be carried as far as our language is read or translated. The honourable privilege, as rare as it is enviable, of addressing a great gathering of fellow-workmen, of corresponding pursuits and tastes, from whom one may confidently expect a sympathetic hearing and active response, can hardly be over estimated. Much or little as we may know of each other, we are all united by the strong tie of professional interest; by the ambition to do well our daily work; and, I hope, by the desire so to make use of the meeting as to fuse temporary contact into durable friendship. I know that I see before me an assembly of no average intellectual standard. In days gone by, in this favoured district of our fatherland, there were "mighty men which were of old men of renown,"—the generations who have helped to make Birmingham what it is—the Areopagus of the Midlands. So to-day, the men who still kindle its enthusiasm, still direct its energies, and are the masterspirits of its industry, its patriotism, its loyalty, are aided and influenced by a residential doctorate equal to the task of keeping such a population sound in body, sound in mind, and of thus economising the vast financial interests depending on its sanitary condition. The members of this society now take the place, as a protective educational power, which was formerly filled almost entirely by the priest. Perhaps in many cases you do for the bodily health what is done by the rector or the nonconformist teacher for the moral direction of the parish. You are ready and willing to fulfil your high vocation, guiding your course of action as a beneficent, irrigating stream in the midst of a people whose bodily and mental welfare is entrusted to your charge.

[1] Inaugural Address of the Session 1884 of the Midland Medical Society, delivered at Birmingham, November 5th, 1884.

What to say to such an audience is of course the first question. Of local affairs you know more than I do. Medical politics and controversial topics must be avoided. I have been told that you would probably be disappointed if I did not tell you something more of my own work—of what I have done and how I did it—why I did it—of my successes and my failures—how mistakes have become less frequent and progress more certain—than can be learnt from anything I have yet published. Acting on this hint, and knowing that in the minds of many of you my name is more closely associated with the practice of ovariotomy than with any other surgical question, I would first ask your attention to one phase in the history of the development of the operation—that which has been well termed the

Revival of Ovariotomy in England.

There are not many here who can carry back their reminiscences so far as mine go. Without being formally apprenticed, I had all the advantages of the old apprenticeship system under an unusually able and worthy man, the late Michael Thomas Sadler, of Barnsley, in Yorkshire. For one year I lived with one of the parish surgeons of Leeds, attended the lectures of Hey and Teale, and saw much practice in the Leeds Infirmary. In 1837-38 I was in Dublin, under Graves and Stokes, Crampton, Beattie, Harrison, Apjohn, and Jacob. In 1839–40 I worked hard in St. Thomas's Hospital under Green, Travers, and Tyrrell. I obtained the prize for the fullest reports of examinations of the bodies of patients dying in the hospital during that period. But neither in the dead-house, nor in the wards or out-patient room of St. Thomas's, nor in Dublin, nor in Leeds, nor during my pupilage, can I remember ever having once seen a case of ovarian disease. I never heard a lecture upon the subject. Very little was said about it in any of the text-books; and the way in which it was introduced showed that it was not thought of sufficient importance for the attention of students to be drawn to it.

I very much doubt whether it ever formed any part of the examination at either the College or the Hall. We now know that, though Morgan, Key, and Bransby Cooper at Guy's Hospital, in 1839 and 1840, and Phillips at the Marylebone Workhouse in 1840, each operated once, the matter was not in any way brought under the notice of the medical students of that time. I have no doubt that the operations at Guy's were done under the influence of Blundell, who had been lecturer on obstetric medicine in that hospital. In the edition of his "Obstetrical Medicine," published in 1840, there is a chapter on ovarian dropsy very far in advance of the general knowledge of the day. To illustrate the routine treatment of the disease, he relates a characteristic saying of Abernethy, who, consulted on a case where tapping was useless on account of the viscid character of the contents of an ovarian cyst, said, "It won't do to go on boring holes in the belly." Probably Sir Astley Cooper's famous story of a case of "dry tapping" may be explained in the same way.

But I had not seen Blundell's book, and it was not till many years afterwards that I even heard of the name of McDowell, or of any of the fourteen cases of ovariotomy done in Great Britain between 1825 and 1839. It was not until I had myself written on the subject that I learnt what William and John Hunter had thought and suggested, or that John Bell had so lectured as to inspire McDowell with the determination to do what he afterwards did. In fact, I believe that most teachers and students of that day knew as little or cared as little about the subject as I did.

Very soon after becoming a member of the College of Surgeons in 1841, I entered the Royal Navy as Assistant Surgeon, and for some six years served in the Naval Hospital at Malta. In addition to naval practice, I saw many patients, both male and female, and did many operations, in consultation with resident practitioners in Malta. But I can only recollect one case, which I now believe might probably have been a case of ovarian tumour, but which at that time was a puzzle to us. My old friend Dr. Waters, of Chester, has lately reminded me that he and I had conversed on the subject of ovariotomy in Paris in 1848. But he spoke with knowledge acquired in Edinburgh under Hughes Bennett—I in complete ignorance. Still it is curious that we both came to the conclusion that, upon the facts as they then stood, ovariotomy was not a justifiable operation.

It was not until after settling in practice in London, which I did in 1853, that I ever saw a patient whom I knew to be suffering from ovarian disease. In 1854 I joined the Samaritan Hospital—at that time a dispensary for the diseases of women—a subject of which I knew less than of any other special division of our profession. In my young days I had done an unusual amount of midwifery, but latterly my practice had been almost exclusively surgical, with a strong tendency towards ophthalmic surgery. In 1853 or 1854 I became acquainted with Baker Brown. He occasionally came to the Samaritan Hospital, which he wished to join, and I two or three times saw patients with him at St. Mary's. In April, 1854, I and my friend Nunn, of the Middlesex, assisted Baker Brown in his eighth case of ovariotomy. This was the first time I had ever seen the operation attempted; and it certainly did not encourage me to look favourably upon ovariotomy. The patient died, and her death discouraged Brown. He, Nunn, and I talked the matter over, and I well remember Brown's saying, "It's the peritonitis that beats us." His first three cases died, the fourth recovered, his fifth and sixth died, the seventh recovered, and the deaths of the eighth, in 1854, and of the ninth, in 1856, led him to cease operating for more than two years and a half, and again to advocate treatment by pressure and iodine. He did not perform ovariotomy between March, 1856, and October, 1858.

When the Crimean War broke out, I left London, served in the Army in the East, and of course lost sight for a time of all the diseases of women. Any impression that I had received as to ovariotomy was certainly not favourable; but I did see cases of abdominal wounds which taught me that the peritonæum would bear much rougher handling than I had previously believed permissible. I had written about hernia, and had advocated division of the stricture without opening the sac whenever possible, simply to avoid the danger of admitting air or blood into the peritonæal cavity. But I learnt in the Crimea that a man's abdominal wall might be lacerated by fragments of shell, his intestines protruding and covered with mud, so remaining for several hours; and yet, that after careful cleansing of the cavity and accurate closure of the wounds, complete recovery was possible. When I returned to London in 1856, I was certainly much less afraid than before of abdominal wounds. I took up my work at the Samaritan Hospital again, but saw very few cases at first of ovarian disease. The first made a very painful impression upon me. Snow Beck tapped a very fine young woman, and injected iodine, he thought, into the cyst; but he really injected the peritonæal cavity. He had not taken the precaution of passing a long catheter through the short canula of his trocar; the emptied cyst slipped off the canula, and several ounces of tincture of iodine passed directly into the peritonæal cavity. Beck was grievously distressed; but the case did not so much deter us from the use of iodine as awaken us to the necessary precautions as to the mode of injection. But we had very few

cases of ovarian disease, and it was not till December, 1857, that I made my first attempt to perform ovariotomy.

A tolerably full report of the case was published at the time, and reprinted in 1865. Baker Brown was present, and strongly dissuaded me from going on with the operation, on the ground that, as the tumour was behind the intestines, it could not be ovarian.

It is not easy to estimate correctly the part played by Baker Brown in the progress of gynæcology. In the minds of many, his really great services have been overshadowed by the errors of his later practice. Some who fully acknowledge and admire what he did to popularise the operations for the cure of ruptured perineum and vesico-vaginal fistula, and who now recognise the great success which attended his adoption afterwards of John Clay's suggestion of dividing the pedicle of an ovarian tumour by the combined action of strong compression or crushing with the actual cautery, forget, or never knew, that when Brown assisted me in the case which I have just referred to, and in another which I am about to mention, his own early experience of ovariotomy had led him rather to oppose than encourage the repetition of the operation. At my second attempt, my first case of completed ovariotomy, Brown again assisted me, and in my first and in all subsequent reports of the operation I have fully acknowledged his zealous assistance. But it was not until after I had had three successful cases that Brown himself began to operate again, after an interval of more than two years and a half. At this third case Tyler Smith was present. He was greatly surprised at the successful result, and it induced him not only to cease the opposition he had formerly offered to Brown's practice, but to operate himself, which he did with great success.

I think it would be difficult to imagine a position more disheartening than that in which I was placed when making my first trials of ovariotomy. The first attempt, as I have said, was a complete failure, and strengthened, not only in the minds of others, but in my own mind, the fear that I might be entering upon a path which would lead rather to an unenviable notoriety than to a sound professional reputation. And if I had not seen increasing numbers of poor women hopelessly suffering, almost longing for death, anxious for relief at any risk, I should probably have acquiesced in the general conviction—have been content with palliative tapping, or making some further trials of incision and drainage, or of iodine injection, or of pressure, rather than have hazarded anything more in the way of ovariotomy. It may be forgotten now, but it is true, that at that time everything was against the venture. The medical press had denounced the operation, both in principle and practice, in the strongest terms. At the medical societies the speakers of the highest authority had condemned it most emphatically. The example of the men who had practised it was not followed; some of them had given it up. Only once had a successful result been obtained in any of our large metropolitan hospitals, that by Cæsar Hawkins, at St. George's, in 1846—and he never undertook it a second time. Every other attempt, at Guy's by Morgan, Key, and Bransby Cooper, at St. Thomas's by Solly, had ended in death.

This was how we stood at the end of 1857. It was in February, 1858, that I completed the operation for the first time. I need say no more about it now than that it led to my being congratulated by Dr. West upon "complete success," and, with other evidence, to his thorough conversion from his previous condition of conscientious and determined opposition to a state of warm support both in public and private. Let me read to you part of a letter written by my friend Keith, of Edinburgh. In the *British Medical Journal*, in 1873, Keith wrote: "Few watched more eagerly than I did the history of this operation, and few know so well the details of the early cases. Till 1858 I could find nothing whatever anywhere to encourage, but everything to deter one from attempting it. Ovariotomy was then as an operation simply nowhere, and had the practice of using Dr. Clay's long intra-peritonæal ligatures been continued, it would have yet been nowhere. Up till that year Mr. Brown had lost seven out of his nine patients, and had ceased operating for upwards of two years and a half. Surely there was nothing for anyone to learn from such results, except, perhaps, what there might be to avoid." Keith was one of the first to follow me, and did more than anyone else at that time to assist in the revival of ovariotomy. I had done eight cases when he began, and ever since we have gone on side by side, very friendly rivals, assisting each other, comparing notes, not always running on the same track, but always equally anxious to perfect the operation. You all know how wonderful his success has been. Some of his later cases of the removal of uterine tumours are unsurpassed as surgical achievements. He concludes the letter, part of which I have just read, by asserting as others, both before and since, at home and abroad, have also done, and which it is my highest pride and pleasure to feel was not due only to their friendly feelings, but because it is true, that the period of progress, "the revival of ovariotomy," began when the results of my earlier operations were made known, and the confidence of the profession was obtained by the publication of every case, whether successful or not.

Anyone who will look over the reports of my early cases, will see the names of the men who sent me the patients—West, Rigby, Watson, Acland, Hare, Stokes, and Oldham—of those who, as well as my colleagues, Savage, Priestley, Graily Hewitt, assisted me, or were present at the operations, among whom I may mention Paget, Fergusson, Tyler Smith, Bowman, Seymour Haden, Pirrie, Baker, Grimsdale, Bickersteth—who discussed with me various questions which arose as to pathology and treatment, Aitken, Richardson, Ritchie, Hutchinson, Frank, Druitt, Robert Lee, Churchill, Beatty, and Simpson—who for their personal assurance, like Nélaton, Worms, Demarquay, De Mussy, Péan, Courty, came from France; or De Roubaix and Boddaert from Belgium; or from Germany, as Schuh, Billroth, Esmarch; from Italy, as Porta, Vanzetti; or from America, as Gross and Marion Sims—will find no difficulty in understanding that we have now reached a turning-point. Some of these timely allies have finished their course; some remain ripened and matured by years of experience—not yet worn out, but finding their greatest happiness in their daily work, and in friendly association with their fellows and juniors. When I can name such men as not only having witnessed and sanctioned the operation, but becoming convinced, by following up the cases, that it was at least as successful as other serious operative proceedings, and when I add that many of these men soon began to perform the operation themselves, and publicly to advocate it—no one, I say, who considers all this will be surprised at the rapid rise and progress of ovariotomy between 1858, when it was revived, and 1864, when it was very generally accepted as a legitimate operation, and was not long afterwards cited as a triumph of modern surgery.

If I were to select from the books and pamphlets (most of which I have carefully preserved) published during these six years, any one work which contributed more than others to form professional opinion, to awaken interest, and to instruct those who had before not thought upon the subject, it would be the tables of cases most industriously collected by your own townsman, John Clay, and published as an appendix

to his translation of Kiwisch's "Clinical Lectures on Diseases of the Ovaries." The tables are now of far more value than the lectures. One of Clay's chief merits is the example he set of obtaining all the information possible as to every recorded case of ovariotomy, completed or attempted, from the first up to 1860. He collected such a mass of facts, and arranged them for reference or study so conveniently, that he supplied us with fuller and more trustworthy information than had ever before been gathered together upon any surgical question, and I think he may be said to have done more than helped in starting what is now called the "Collective investigation of disease."

From these tables as arranged by Clay, and from a perusal of the works published about that time, we can now see how fully the principles and many of the practical details concerned in the matter had been discussed. What may be called the ethical or moral side of the question had been fully argued. The fears and forebodings as to the physical and physiological effects of the removal of an ovary—such as the abnormal accumulation of fat, the development of masculine type, and the restriction of the sex of infants—were dispelled and falsified. The causes of death in fatal cases had been investigated. Many of the mistakes of the earlier operators had been corrected; and, far above all other things, the profession had gained confidence in the accuracy and completeness of the facts laid before them. The old plan of operating in a hot moist chamber, and keeping the room over-heated for days afterwards, was soon abandoned. The semi-recumbent position of the patient was exchanged with great advantage for the horizontal. Safer anæsthetics than chloroform were used. Simple bandages for keeping the patient quiet supplied the place of an objectionable crowd of assistants. Precautions, never before thought much about, were taken for protecting the patient from any infectious disease; by obliging every visitor intending to be present to declare that he had not made a *post-mortem* examination, nor been into a dissecting room, nor attended any case of infectious disease within a week; by the utmost attainable purification of the house, room, bedding and clothing, sponges and instruments—in fact, of everything brought near the patient—and all this was insisted on with a pertinacity which often gave offence. A great deal was gained by shortening the incision in the abdominal wall, by emptying the cyst before drawing it out, or by lessening the bulk by breaking down the septa of multilocular cysts; by extreme care in preventing the entrance of ovarian fluid into the peritonæal cavity, or by very carefully cleansing the cavity from any blood or fluid which had entered it—a process christened by Worms the "toilet of the peritonæum." Sir Benjamin Brodie long ago remarked with regard to lithotrity, that success depended upon attention to a number of minute details. So with ovariotomy. No one of the details which I have just alluded to may be alone of any great importance, but taken together they did a great deal towards preventing failure and securing success. Other modifications of more or less importance were soon made. The old vegetable material for ligatures and sutures, coarse whipcord or twine, was abandoned. After many trials of silver, iron, or platinum wire, horsehair, fish-gut, and other materials, we settled upon pure silk as the most useful and trustworthy, and proved that, after a few weeks' retention in the animal body, it entirely disappeared. The mode or process of its removal by the insinuation of white-blood corpuscles between its fibres, a sort of untwisting or solution, was watched stage by stage, and long before the treatment of the pedicle in this manner was seriously proposed, we learnt that silk ligatures, and portions of omentum secured by them, might safely be left within the abdominal cavity. Nathan Smith was the first to treat the pedicle in this way, but he made his ligatures from a leather glove. Tyler Smith was the first to revive the practice, using silk. A story has been very generally believed—probably some of you may have heard it—that Tyler Smith's first trial was accidental; that he cut off the ends of the ligatures inadvertently, forgot all about them, and was surprised to find that his patient recovered. But on inquiring of his former assistant, Dr. Edwards, who is still in practice in London, I am assured that there is no ground for this story. The operation was performed in June, 1861. Dr. Edwards writes: "Previously to this operation I had strongly advocated the advisability of dropping the pedicle and cutting short the ligature, and it was at my initiative that it was done. In fact, I did it myself."

The mode of treating the pedicle became a subject of anxious discussion. The evils which attended the use of the long ligatures were soon found to outweigh any advantage obtained by their service in drainage. The extra-peritonæal method was simplified by Hutchinson's introduction of the clamp, and for a long time it was only in cases where the clamp could not be used that any other method was sought for. I had hoped much from the écraseur, but only used it once. Others had spoken of crushing the pedicle and twisting off the cyst. I had an instrument made for tearing through it—a rough bluntish saw. But all these plans, without much trial, gave way before that combination of crushing and cauterizing for which surgery will be for all time indebted to your own Clay. Used at first by him for dividing omentum, both he and I suggested that this might be a good mode of dividing the pedicle in ovariotomy. Baker Brown was the first to carry out this suggestion in practice, and with immediate improvement in the results he obtained. Keith followed him, and, with occasional intermissions, has continued the practice. I also had very good results in thirty cases, and have sometimes blamed myself for not having given it a more extensive trial. I did not give it up, however, until I thought I had proved the ligature to be more trustworthy in cases of short pedicle. What is called the complete intra-peritonæal ligature—by which we mean the transfixion of the pedicle, tying it in two or more portions, cutting off the ends of the silk close to the knots, and returning them with the tied stump after cutting off the cyst—was by no means a common practice until long after the date of which I have been speaking.

The mode of closing the opening in the abdominal wall was one of the first things to attract my attention, and no one before me seems to have cared whether the peritonæum was included in the sutures or not. A very few still maintain that it is a matter of no consequence, and Kœberlé still asserts that it is better not to include it. I have not time now to trouble you with a thrice-told tale of how, by examination of patients who died after ovariotomy, and by experiments on animals, I convinced myself that by passing the sutures through the whole thickness of the abdominal wall, including the peritonæum, at such a distance from the divided edges as to permit two surfaces of the serous membrane being brought into contact when the sutures were tied, instead of merely bringing the edges together, a more permanent and complete union was obtained, and that one source of immediate danger was avoided—I mean the oozing into the abdominal cavity of blood, or serum, or fat from the divided tissues. So, too, we got rid of the inconvenience which patients who recover sometimes suffered from the adhesion of omentum or intestine to the abdominal wall.

I need not say much about the mode of dressing the

wound, but I think it is of some importance to note that from the first I was very careful to keep the wound as dry as possible. I had become convinced in my naval and military practice that water dressings and other moist applications (without going into any discussions as to the cause of pyæmia) were far inferior to dry dressings. For several years I used pads containing Skinner's mixture of calcined oyster-shells and oil of tar, covered with layers of cotton-wool, and supported by the gentle pressure of a flannel bandage; and the only modification made of late years in these dry dressings has been the substitution of the elegant and comfortable pads devised by your townsman, Gamgee, for the antiseptic and absorbent powder of Skinner.

The chief improvement made in the after treatment was in greatly diminishing the amount of opium. Large doses had often injured the patients, and I thought might have been the cause of death in some of the earlier cases.

By careful consideration of all the sources of danger, and by successive improvements in practical details, the mortality of ovariotomy became less excessive; and it was soon felt that the mortality after other surgical operations, both in London and provincial hospitals, as well as in private practice, was excessive and ought to be diminished. It was some years after Southwood Smith, Edwin Chadwick, and William Farr had begun their attempt to impress the importance of a knowledge of sanitary science upon the people of England, that its influence was much felt either in hospital practice or in domestic life; and I doubt whether the attention of surgeons was ever fully awakened to the possibility of reducing the mortality of great operations before Sir James Paget, at the meeting of the British Medical Association in London, in 1862, delivered his memorable address upon the study of the large group of diseases confounded under the name of "pyæmia."

Two years afterwards, at Cambridge, I addressed the association upon the same subject; and, after alluding to many sanitary measures, called attention to the bearing of the then recent researches of Davaine and Pasteur, and to the value of Polli's experiments upon the use of sulphurous acid and the alkaline and earthy sulphites in the prevention and treatment of many of the infectious and contagious causes of excessive mortality after operations. We were on the dawn of that phase of modern surgery when the so-called laws of sanitary science were tested in the laboratory by physiological chemistry and experimental pathology, and were afterwards acted upon by Lister and his followers.

During this time of reaction and activity in abdominal surgery, there was a corresponding development of the literature of the subject. It appeared in all shapes, and came from all quarters. The names of men who have since become celebrated were ushered in with their first contributions. Essays and records of cases abounded in periodicals. Pamphlets fell thick upon the public, and books were published which, though more or less incomplete, showed how fast material was accumulating for the future composition of elaborate treatises.

A review of all this matter poured out by the press, both English and foreign, on the question of ovariotomy, a few years before and after the date of 1865, enables us in a measure to gauge the extent of the interest the operation had excited, the change of opinion in reference to it, the success that had attended it, and to trace the indications which the reports contained of the spreading eagerness of the profession to seize every opportunity of giving to humanity the benefits which the practice was capable of conferring. But that which most forcibly strikes the attention in reading this literature is the contrast furnished by its tone and tendency with that which preceded and made way for the revival. Previously all that had been written was sceptical, doubting, speculative, or even prohibitory. Wavering expectation was modest in its demands, timid in its forecastings. There was more of fear than hope for the future. That future came, and with it the revival. Then, instead of the vague prophetic inspirations of the Hunters, the moving exhortations of Bell, the qualified and cautious encouragements of Blundell, the passive admissions of Astley Cooper that ovariotomy might be done—the conscientious shrinking, in an exalted reverence for the sanctity of human life, from the realisation of what seemed so desirable and within the compass of daring power—the pathetic wailings over sufferings unrelieved and deaths unresisted, and the despondency of professional inaction—we had reports of accomplishment which proved, by the wideness of their sources, their numerical importance, and the character of their authors, that the revival was assured. The question now changed from one of possibility to one of improvement, and reports of cases merged into discussions of practical details of operative and therapeutical interest. These, from their precautionary or conservative bearing, gave good augury of the vast ameliorations which we have seen within the last twenty years, and have brought us at the present time to nearly certain success when a careful surgeon operates in a favourable case. One may truly affirm that in all these outpourings of the revival period there was nothing vainglorious, boasting, presumptuous. As contributions to science they were serious, candid, plain, aiding further progress, informing to the profession, and useful to mankind. They bore upon them the signs of a wise resolution to advance circumspectly upon the path now open; and if tinged with a glow of the personal satisfaction which flows from a sense of duty in part fulfilled, and brightened with a gleam of the complacency reflected from the visible evidence, now so constantly before the public in the living, healthy survivors of the operation, that the profession as a corporate fraternity was equalling in its philanthropic energy that which had made the reputation and had been the pride and solace of its older "men of renown"—I can only say, not that it was excusable or admissible, but that this gratulation was no more than the circumstances prompted, or than may justly be felt by all who join in working, with a right mind and to a good issue, for the welfare of their fellow-creatures.

And here with 1865 I may end this retrospect of the revival of ovariotomy—of a rapid revolution in opinion and practice in less than ten years. Before 1858, the operation, like all good things, had been of slow growth. One hundred years ago, it was but a germ that might be descried in a lecture by John Hunter. Ten years later it was seed that fell from the hand of Bell. In little more than another decade it germinated as a living vitalising reality in Kentucky. Sixty years ago it was transplanted to the land of its philosophical conception. In twenty years more we find it a sapling on English soil—growing slowly at first, and up to 1858 looking as if it might prove no more than a withering gourd. But by 1865 its root had struck firm, its stem stood erect, its branches were wide and strong, known and sought as a refuge by the sick and dying. That it was no withering gourd has been proved by all that the world has since seen. Thousands of perishing women have been rescued from death; many more thousands of years of human life, health, enjoyment and usefulness have been given to the race; and to all future victims of a malady before inevitable in its fatality, it gives consolation, hope, and almost certainty of cure.

And passing over another twenty years—advancing

*

from 1865 to 1884—we can rejoice that in all our metropolitan and most of our provincial hospitals, and from the best teachers on both sides of the Atlantic, medical students of to-day may hear of the good already done—may see for themselves how success is attained, and possibly, by the establishment of some new fact, or the discovery of some new device, they may increase our power over disease, and carry on the work to our successors.

I must leave it to others to speak of our great hospitals and important schools. But I cannot close this part of my address without one word of hearty congratulation to my successors at the small hospital where, with seldom more than six or eight beds at my disposal, in twenty years I completed 408 cases of ovariotomy, the deaths having diminished in successive periods of 5 years from 1 in 3 to 1 in 4 or 5, and in the last two years to 1 in 10. In six years, 1878–83, my three successors among them had 496 cases—some 90 more than I did alone in 20 years—the deaths falling from 1 in 5 in 1878 to 1 in 18 in 1883. And the recent publication of my colleague Doran adds to the satisfaction I feel in seeing my operative work so efficiently continued, the pleasure of noting how happily he is supplementing the opening of his career as an operator by the intellectually higher distinction of being acknowledged as a penetrating investigator and clear expositor of the obscure subject of ovarian pathology, to which he is devoting his philosophical earnestness. On this centenary of Hunter's Lecture we may truly claim that his example is followed, his foresight verified, and our exertions rewarded.

(*To be continued.*)

CLINICAL LECTURES ON THE TREATMENT OF DISEASE.

Delivered in King's College Hospital,

By J. BURNEY YEO, M.D., F.R.C.P.,
Physician to the Hospital.

Lecture IV.

Catarrhal conditions of the Respiratory Passages.—Chronic Bronchial Catarrh.

(Continued from page 606).

In those cases in which the expectoration tends to become fœtid, cases of so-called *putrid bronchitis*, it is of the greatest importance, as I have already said, that our treatment should be directed to preventing or arresting the decomposition of the bronchial secretion. Inhalations of antiseptic agents which act also as expectorants are specially indicated, such as turpentine, tar, creosote, carbolic acid, &c., after the manner already described. In such cases the inhalation of a spray of a two to four per cent. solution of carbolic acid is exceedingly useful. We should also give turpentine, creosote, or tar internally. In such cases it is also advisable to combine tonic remedies with our expectorants, so as to maintain the general strength; we should also see that the patient has a nutritious and generous diet. The patient's apartment should be well ventilated and the air disinfected; for this latter purpose nothing is more agreeable than oil of eucalyptus. A mixture of one part of eucalyptus oil to six parts of rectified spirit may be diffused through the air by means of an ordinary hand spray, or by dipping cloths in it and suspending them in the room. An atmosphere so charged with eucalyptus vapour has a decidedly soothing and soporific effect, a real advantage in many cases.

The following combination is an excellent tonic and expectorant in these cases:—

℞ Ammoniæ Carbonatis, gr. xl.
Tinct. Nucis Vomicæ, ℥ lxxx.
Tinct. Cinchonæ Comp., ℥ j.
Spiritus Chloroformi, ℥ clx.
Infusi Senegæ ad ℥ viii.

M. ft. Mist.

Two tablespoonfuls three times a day or oftener.

Or when a more decidedly bracing tonic is required we may give the following:—

℞ Tinct. Ferri Perchloridi, ℥ clx.
Liquoris Strychniæ, ℥ xl.
Spiritus Chloroformi, ℥ clx.
Aquæ ad ℥ viii.

M. ft. Mist.

Two tablespoonfuls three times a day.

In those cases of chronic bronchial catarrh with very profuse secretion, cases to which the term bronchorrhœa is properly applied, the indications for treatment, as we have already seen, are

(1) to prevent the formation of the muco-purulent secretion, and
(2) to promote its expulsion.

Now besides the remedies directed to these ends which I have already referred to, there are others to which we may have recourse. Some authors advise the direct application of astringent remedies to the mucous membrane of the air passages in the form of *sprays;* fluids pulverised by means of a Siegle's spray producer, containing in solution such astringent substances as acetate of lead (five grains to the ounce), tannin (five to ten grains to the ounce), alum (five to ten grains to the ounce), perchloride of iron, Rhatany, &c.

These remedies have been found useful in the after treatment of cases of bronchorrhœa and putrid bronchitis. After the fœtor of the sputa and the decomposing processes in the bronchial tubes upon which it depends have been arrested by antiseptic inhalations, these astringent sprays are useful to remove the swelling, serous infiltration, hyperæmia and engorgement of the bronchial mucous membrane.

In addition to the other stimulating expectorants to which I have alluded as useful in these cases, I must not forget to mention senega, a medicine deservedly held in high repute in the treatment of chronic catarrhal conditions of the air tubes.

The following is an excellent stimulating expectorant in cases of chronic bronchial catarrh with profuse, stringy, adhesive secretions such as is often met with in aged people. The combination of carbonate of ammonia with senega is found to be very efficacious:—

℞ Ammoniæ Carb., gr. xl.
Sodæ Bi-carb., gr. xl.
Tinct. Camphoræ Comp., ℥ iv.
Spr. Chloroformi, ℥ clx.
Infusi Senegæ ad ℥ viii.

M. ft. Mist.

Two tablespoonfuls every five or six hours, with two tablespoonfuls of hot water.

The addition of hot water materially increases its expectorant power.

It will be noted that this mixture contains a small quantity of opium (in the compound tincture of camphor), but it is a very small quantity, only one-eighth of a grain in a dose; and this leads me to make a remark which is of the greatest importance in the management of cases of chronic bronchial catarrh, with profuse secretion, in the aged: be very cautious in the use of narcotics, and especially of opiates, in such cases. They are extremely badly borne, for by diminishing the sensibility of the bronchial mucous membrane, the

efforts of coughing are diminished, and the patient may fall asleep, sometimes never to wake again ; for in this sleep the mucus accumulates in the air passages, the access of air to the air cells is more and more interfered with, carbonic acid accumulates in the blood, and the patient dies poisoned by it. It is essential always to bear this in mind in treating the coughs of aged persons.

I must also not forget to mention the value of an occasional emetic in those cases of chronic bronchial catarrh with profuse suffocative secretion. The mechanical compression which the lungs undergo in the act of vomiting, not only tends to the expulsion of the mucus accumulated and retained in the air passages, but it also relieves pulmonary engorgement by simultaneous compression of the blood vessels.

Gerhardt has strongly recommended the application of manual compression to the chest and abdomen in cases where it is difficult by ordinary means to procure free expectoration and unloading of the air passages of the morbid secretions accumulated in them. He maintains that manual pressure on the external surface of the thorax and abdomen, applied during expiration, leads to the following good results :—

(1) Elevation of the diaphragm and a consequent reduction of the pulmonary dilatation.

(2) Increase of vital capacity.

(3) Diminution of the frequency of respiration.

(4) Promotion of expectoration.

Cases in which the air passages are occluded by viscid secretions, which the feeble muscular power of the patient is unequal to expel, are specially adapted to this mechanical treatment. The expiratory effort is directly strengthened by the associated manual pressure from without, and expectoration is also, indirectly, promoted by the more vigorous muscular activity, resulting from increased supply of oxygen. Gerhardt mentions the case of a patient with large bronchiectatic cavities in the lower lobe of the left lung, in which by inhalations of turpentine he soon succeeded in removing the odour of the sputa, but the expectoration was small, and physical examination showed that the cavities remained for several days together constantly filled. He then endeavoured to promote and increase the expiratory effort mechanically by placing the patient on his right side, and daily employing manual pressure, by which means he succeeded in preventing the retention of the sputa.

Stokes estimated highly the effect of counter-irritations and revulsive treatment in cases of chronic bronchial catarrh, and my own experience quite confirms his view. Stokes used to order a large portion of the chest to be sponged daily with a liniment composed of spirit of turpentine and acetic acid, so as to keep out an erythematous state of the skin. Stokes thought that besides the counter-irritation thus produced some of the ingredients were absorbed by the surface.

No doubt the vapour of the more volatile constituent (turpentine) may be inhaled and thus act locally on the bronchial mucous membrane. Patients themselves learn the value of these embrocations, and when once they have used them ask that they may be renewed.

The Linimentum Terebinthinæ of the B. Pharmacopœia is a useful form, to which I occasionally add, in the cases of scrofulous children, a drachm or two of tincture of iodine to the ounce.

The Linimentum Terebinthinæ Aceticum (B. P.) is also very valuable, it contains equal parts of oil of turpentine, acetic acid and camphor.

The Linimentum Crotonis is also useful, as a revulsive, in some obstinate cases of chronic bronchial catarrh; the disadvantage attending its use is that it brings out an unsightly eruption of the skin, especially if the liniment be used of the full strength of that in the Pharmacopœia ; but when diluted with twice its bulk of Linimentum Saponis there is little objection to its employment.

The following is the formula for Stokes' embrocation :—

℞ Spiritus Terebinthinæ, ℥ iii.
Acidi Acetici, ℥ ss.
Vitelli Ovi, j.
Olei Limonis, ℥ j.
Aquæ Rosæ ad ℥ vj.

M. ft. Embroc.

I must now consider, very briefly, the value of alterations of atmospheric pressure in the treatment of chronic bronchial catarrh. This "pneumatic" method of treating chronic catarrh of the air passages is much more common in other European countries than in our own, and most of the large cities on the Continent and many of the popular health resorts possess "pneumatic institutions" for the treatment of pulmonary affections by alterations of atmospheric pressure.

Various portable apparatus, notably one devised by Waldenberg and another by Schnitzler, are also in common use in Germany and Russia for this purpose.

The "pneumatic chamber," into which the patient enters bodily and remains for some time, is chiefly employed for inspiration of compressed air ; but by means of suitable arrangements, he can be made to *inspire* compressed air and *expire* into rarefied air. So, also, by means of the portable apparatus I have mentioned he can either *inspire* compressed or rarefied air, or *inspire* the former and expire into the latter.

It has been found that chronic bronchial catarrhs, even when obstinate and of long standing, are favourably influenced by pneumatic treatment. The pressure which compressed air exerts upon the swollen and hyperæmic respiratory mucous membrane, lessens the calibre of its vessels and reduces the afflux of blood, while it promotes the efflux of blood and the fluids of the tissues, and in this way diminishes the swelling.

This diminution of the flow of blood to the mucous membrane and promotion of the efflux of fluids from it lessens the amount of secretion and widens the lumen of the tubes, giving freer passage to the inflowing air, and thus increasing the amount of air that can enter and leave the air cells, and greatly aiding pulmonary ventilation.

If there is but little secretion in the bronchi, and expectoration is difficult, while the tubes remain permeable to compressed air, then this air of higher tension rushes into the partially collapsed air cells beyond the tubes and thus imparts increased expulsive power and facilitates expectoration.

Expectoration is also promoted by expiration into rarefied air, as by a simple physical process it removes hindrances to the outflow of air from the air passages. I cannot enter now more fully into the theory of pneumatic treatment, but those who have had the largest opportunities of watching its results maintain that its beneficial effect in the majority of cases of chronic bronchial catarrh is permanent, that the catarrh is often entirely cured, and even in incurable cases, dependent on some more deeply seated pulmonary lesion or cardiac affection, it is greatly alleviated.

Those who suffer habitually from bronchial catarrh in the winter should, if possible, pass that part of the year in a climate where they may be exposed as little as possible to sudden changes of temperature, to chilling fog and mist and to cold winds, and where they can get, without danger, a certain amount of exercise in the open air with plenty of sunshine.

The choice of any particular place is often determined by considerations of convenience, expense or society. In our own country the best wintering places

for most cases of chronic bronchial catarrh are Torquay, Penzance, Bournemouth, the Undercliff in the Isle of Wight, and St. Leonards.

But a drier and warmer winter climate than can be obtained in this country is advisable in many cases, and for these we can choose from the various resorts on the Western Riviera or, if we consider the climate of the Riviera too exciting, we may select Algiers or Tangiers, or if we wish a very dry climate there is Egypt and the Nile.

Madeira, Huelva, Malaga, Ajaccio, Palermo, Corfu, and many other places, offer also suitable winter quarters for the catarrhal subject.

You are perhaps aware that in France it is very common for sufferers from chronic bronchial catarrh to be sent during the summer months to go through a course of sulphur waters at one or other of the sulphur spas which are numerous in that country, especially in the Pyrenees.

The French physicians are fond of dividing their catarrhal cases into three classes :—the scrofulous, the arthritic, or rheumatic and gouty, and the dartrous. By the "dartrous" they mean constitutions prone to cutaneous eruptions. This classification has always appeared to me somewhat artificial, but they found upon it indications for the application of their different mineral springs to individual cases.

The arthritic or gouty cases are sent to Eaux Bonnes, Cauterets or St. Sauveur in the Pyrenees, or to St. Honorè in the Department of Nièvre ; or if the catarrh is irritative and congestive to Mont Dore, La Bourboule, or Plombières. Mont Dore is also especially adapted to the treatment of cases of chronic bronchial catarrh complicated with asthma.

The scrofulous are sent to Barèges in the Pyrenees, to Aix in Savoy, or the adjacent Challes, or to Uriage, the mineral waters of which contain chloride of sodium as well as sulphur, or to St. Gervais.

The "dartrous" or "herpetic" are sent to La Bourboule or Royat. But, as I have already said, this classification, both in theory and practice, is a little artificial.

The German physicians on the other hand consider those mineral springs which contain chloride of sodium in small quantity or, still better, chloride of sodium combined with carbonate of soda and containing some free carbonic acid as specially suitable to the treatment of chronic catarrh of the air passages.

Ems is pre-eminently the spa for this purpose as it contains both chloride of sodium and carbonate of soda in small quantity. *Soden*, near Homburg, is also the type of a weak chloride of sodium water, containing free carbonic acid, and it enjoys a great reputation in Germany in the treatment of these cases.

These courses are often followed advantageously by a few weeks passed in the moderately elevated mountain resorts of the Black Forest or Switzerland.

When chronic bronchial catarrh occurs in obese, plethoric middle-aged people who are free livers, a course of some more active mineral spring is indicated, and such patients often derive advantage from a few weeks' treatment at Kissingen, Marienbad or Carlsbad.

In all these health resorts the various kinds of baths available enable the physician to submit his patient, if he considers it desirable, to those "repeated energetic sweatings" of which Niemeyer speaks so highly in these cases. Powerful revulsion to the skin is undoubtedly an efficient means of relieving bronchial congestion.

As I have already said, if the bronchial catarrh is dependent on or associated with the existence of some other disease or constitutional state we must not lose sight in our therapeutic efforts of the original disturbance.

In the case of scrofulous children, we must look carefully to the general nutrition, give cod-liver oil, enjoin residence at the sea-side, the use of salt-water baths, free exercise in the open air in suitable weather, and mix some iodine with our embrocations.

If there is a well-marked syphilitic taint, we should of course employ iodide of potassium.

When chronic bronchial catarrh is a complication of heart disease, we must enjoin strict repose in a warm but well-ventilated apartment, we must give supporting food and medicines ; and some form of alcoholic stimulant, whatever the bigoted advocates of total abstinence may say to the contrary, is of great value. In cases of mitral stenosis digitalis will be helpful and in feeble anæmic cases, it may be combined with iron.

It is especially necessary in these cases to obtain free and regular evacuations from the bowels, for by unloading the intestines, the descent of the diaphragm is facilitated and any derivation of fluid from the portal venous system tends, indirectly, to relieve the engorgement of the right side of the heart. I think I have now touched on all the chief points to be considered in the treatment of chronic bronchial catarrh ; their application in the management of individual cases must be left to your own sound judgment and discretion.

THE COMMA-SHAPED BACILLUS A ZYMOGENIC, NOT PATHOGENIC, ENTITY.

By GEORGE WATERS, Surgeon-Major Indian Medical Department.

Professor of Pathology in the Grant Medical College, Bombay.

On reading in the *Journal of the British Medical Association* Dr. Koch's interesting and careful report on his investigations on Indian cholera, it occurred to me that I had already seen such organisms as are figured in his diagrams, in material other than is associated with that disease. I then set to work on the microscopical examination of mucus from the small intestines of persons who had died from ordinary affections, and found curved bacilli identical in shape, size, and appearance with *komma-bacillen* in all, or nearly all. These bacilli, it is true, are to be found much more plenteously in the flaky mucus so commonly met with in the ileum after death from cholera than elsewhere in the digestive tract or in this part of the bowel under other circumstances. But I have found identical organisms in neutral or slightly alkaline urine in similar abundance ; and the ordinary mucus, even of cholera, shows not many more bacilli than are to be seen in the mucus of the small intestines of persons who have died from other causes. Ordinarily, indeed, both as regards cholera and other affections, the intestinal mucus examined under the microscope shows very few curved bacilli, and a great number of straight, large, putrefactive bacteria, micrococci, singly, in zoogloea, and in chains, and spirilla. In human urine I found curved bacilli within five minutes of its being voided from the bladder. Some six hours later the same urine shows a slight increase in these organisms ; and this slow multiplication goes on till the urine becomes neutral or slightly alkaline, when they are to be seen in numbers such as are only elsewhere to be found in cultivations from the flaky mucus already mentioned. I think it unnecessary to give a diagram of the curved bacilli to be seen in abundance in neutral or slightly alkaline urine, as most medical men must by this time be familiar with those faithfully pourtrayed by Dr. Koch ; and then anyone can examine

them for himself with little or no trouble. The method of examination I adopt is as follows :—A drop of urine from the surface is placed on a glass slide, which is then heated slowly at the flame of a spirit lamp till evaporation is complete, and after a few minutes the dried residue is covered with a few drops of an alcoholic solution of gentian violet. Five minutes afterwards the excess of colour is washed off with distilled water, and the slide again heated over the flame of the spirit-lamp. I found this second heating absolutely necessary to kill the organisms, many remaining still alive after the first heating and the removal of the excess of colour, showing thus a most remarkable tenacity of life. The preparation may now be studied with a $\frac{1}{12}$th immersion lens, oil or water. A specimen mounted in Canada balsam can be very well studied with a $\frac{1}{8}$th object-glass and No. 2 eye-piece. Latterly I found that methyl blue gives a better result than gentian violet, for though not so bright in colour as the latter, it somehow defines the micro-organisms more distinctly. It is to be noted, however, that the process of staining is much slower with the methyl blue than with the gentian violet. Quite recently I got excellent results from using a mixture of equal parts of the two colours.

It would appear, then, that curved bacilli are not specifically connected with cholera, at all events not in the light which the head of the German cholera commission would have those organisms regarded. They are nevertheless an indubitable pathological feature of that disease ; but this, I think, will soon be shown to be something more in the shape of a consequence than a cause of the malady. An experienced and reliable observer like Surgeon-Major Lewis testifies to the presence of *komma-bacillen* in healthy saliva. They can be seen by anyone in healthy urine, and in the mucus of the small intestines of those who have died from ordinary diseases, and are thus presumably discoverable throughout the mucous tract under most circumstances. This leads me to the expression of an opinion that has been gaining ground in my mind for some time, which is, that the organism in question should be regarded more as a physiological than a pathogenic entity. Dr. Koch's own careful observations lend a measure of support to this supposition. He noticed that a colony of *komma-bacillen* in cultivation to a certain extent dissolved the sterilised proteids on which they were nourished ; presumably, the proteids were thus converted into peptones. He noticed also that for some days these organisms multiplied to the exclusion of all others in the flaky mucus of cholera kept on linen in a moist atmosphere, and then gave place to those characteristic of putrefaction. Now, this is exactly what I find in the case of urine ; until it becomes markedly alkaline, or perhaps I should say, till decomposition commences, it shows myriads of curved bacilli to the exclusion of all other organisms ; whilst beyond this point large straight putrefactive bacteria predominate. Indeed, the former are seldom to be found in decomposing urine. This would appear to indicate the small *komma-bacillen* to be fermentive, and the large straight bacilli, putrefactive organisms. And the fact that curved bacilli are found under varied circumstances in different regions of the mucous tract surely points to the probability of their performing a certain set normal piece of work in the animal economy. In urine we have seen that their life history is closely associated with the pre-putrefactive or fermentive stage of the change which this secretion undergoes. Now we either know or suspect that fermentation plays a part in the digestion which takes place in the lower portion of the small intestine, but hitherto, we have failed clearly to identify the agency by which it is accomplished. And here, I think, some light has been shed by Dr. Koch's observation that growing colonies of *komma-bacillen* liquefy in their immediate neighbourhood the proteids on which they grow. We have it on good authority that the bacillus butyricus is commonly found in the stomach and intestine of herbivora ; and the fact that this organism has the property of decomposing cellulose at once explains its importance in the digestive process of such animals. Why then should a similar zymogenic function not be attributed to an organism like the comma-shaped bacillus which seems to have its normal habitat in the presence of mucous membrane in the human body? Indeed I should not be surprised to find it conclusively proved that the comma-shaped bacillus is specially concerned in nitrogenous fermentation. Dr. Koch has drawn much more momentous inferences from arguments of a not less speculative character, and that, too, in the face of experiments, the negative result of which went to disprove his own hypothesis. And if I say that a superabundance of comma-shaped bacilli is found in the small intestines of cholera victims, because it would appear that whatever gives rise to that ailment brings about exalted fermentation in that part of the alimentary canal, I shall at least have as much logic in my assertion as he had in declaring that these organisms must bear a causal relation to the disease.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

LONDON TEMPERANCE HOSPITAL.

TWO CASES OF INTESTINAL OBSTRUCTION.

(Under the care of Mr. A. PEARCE GOULD.)

Acute Intestinal Obstruction—Laparotomy—Death.

E. E., aged 55, was admitted into the London Temperance Hospital under Mr. Gould's care on February 27th, 1884. He was a stationer by trade, and had never been a very strong man. For the last four years he had been subject to attacks of colicky pain across the belly, which were always relieved by a hypodermic injection of a small quantity of morphia. These attacks were not accompanied by constipation ; the size and character of the motions passed were natural. On the morning of February 23rd, on getting up, he was seized with pain of the same character across the belly, but this time accompanied with retching. The usual dose of morphia failed to give any relief, and in a few hours violent vomiting set in. These symptoms continued until admission. The vomited matters were at first bilious, then light yellow in colour, and later on dark brown, with a distinctly fæcal odour. There was no passage of fæces or flatus after the early morning of February 23rd. Since February 25th, patient had not passed more than half a pint of urine. The treatment previous to admission to the hospital consisted of opium and belladonna by the mouth, and the repeated administration of large enemata by a long rectal tube ; no motion had been brought away.

On admission, the patient was found lying on his back, with thighs drawn up, with a very haggard expression of face, and complaining of severe pain across the umbilicus. The skin was cold ; temperature in axilla 97·6°, pulse small, compressible, 75. He was constantly retching and occasionally brought up some dark fluid with a distinct fæcal odour. The tongue was dry

with a thin yellow-brown fur; the belly was uniformly but moderately distended, and there was neither dulness nor tumour to be made out in it. There was no external hernia at any of its usual or unusual situations; examination per anum showed the rectum to be empty and did not reveal any abnormal condition. It was decided to perform laparotomy at once.

Operation.—Under the carbolic acid spray, and with full antiseptic precautions, Mr. Gould made an incision two inches long in the middle line of the belly, about two inches below the umbilicus. Having divided the peritonæum upon a director, he passed his forefinger into the right iliac fossa and at once felt an "internal hernia." Falling into the pelvis were some coils of contracted intestine in marked contrast to the distended bowel all around it, and these were felt to be fixed to the cæcum by a narrow tight cord or band. The wound was slightly enlarged downwards, and then after some difficulty this band was brought into view and a double chromicised catgut ligature was passed beneath it and tied. The cord was then divided between the ligatures and at once Mr. Gould felt the contracted coil of gut fill out. The wound was closed with deep and superficial sutures, and dressed. A strip of iodoform gauze was placed next the skin, over that some carbolic charpie, and outside all the usual carbolic gauze dressing. The man was carried back to a warm bed, and was ordered to be kept very quiet, to have only icè to suck or iced water to drink, and to have opium if in pain. His pulse after the operation was 84, rather fuller than before. When seen five hours later, he was found complaining of severe pain in his back, having lost his old pain in the belly. He had vomited a little since the operation; there was hiccup. Temperature 98·8°, pulse 120. Respirations quick, but abdominal. A quarter of a grain of morphia was given under the skin. His pulse became feebler, the breathing quicker and entirely thoracic, and delirium set in, and he died eight hours after the operation. The only other treatment adopted, was the application of a sinapism to the præcordia and the hypodermic injection of half a drachm of ether twice.

Autopsy.—On opening the belly the small intestine was found to be slightly adherent, and the peritonæum was dull and congested. The vermiform appendix was found to have been divided about half-an-inch from the cæcum, and its other end was found adherent to the mesentery by firm old adhesions; the two ligatures were holding the divided ends of this structure securely. A coil of the ileum about two feet from the cæcum bore marks of having been constricted, and was still adherent in the form of a knuckle but was quite patent; this length of the intestine was greatly congested, but was not gangrenous. The intestine below this constricted part was full of flatus. When the two ends of the divided vermiform appendix were held in apposition, it was quite evident how the coil of ileum had been strangulated.

Chronic Intestinal Obstruction—Right Colotomy—Death.

E. W., a widow, aged 62, was admitted to the London Temperance Hospital under the care of Mr. Pearce Gould, May 20th, 1884. She stated that she had always enjoyed perfect health until three years before, when she had an attack of obstinate constipation with tympanites, vomiting and abdominal pain; this was relieved by internal remedies and enemata. Since that time the motions had been normal in appearance, but passed only once in two days. Her bowels had not been open since May 7th. For the first few days she experienced only a sense of nausea. On May 13th she noticed pain and rumbling in the belly, and that the belly was swollen. This swelling gradually increased up to the time of admission. On May 18th, immediately after an enema had been administered, she vomited about a pint of brown fluid with a fæcal odour, and this relieved the pain. Next day she vomited about two pints of very fœtid fluid with lumps of fæces in it. The patient walked to the hospital. She was emaciated, with a somewhat anxious expression, but not one expressive of much suffering. The tongue was moist with a thin brown fur on the dorsum; the woman asked for solid food. The belly was distended, measuring at the level of the umbilicus 34½ inches. The bulging of the right flank was distinctly more marked than on the left side. The veins of the surface were enlarged. There was no external hernia, and no tumour was to be felt through the tense abdominal walls; the belly was everywhere tympanitic. The rectum was dilated, empty, no stricture felt in it; the uterus was found to be enlarged, and quite filling the brim of the pelvis; it was freely movable; the left ovary was also enlarged. A good deal of flatus was passed from the bowel. Temperature 99·2°, pulse 100. The house surgeon ordered an enema containing castor oil, croton oil, and turpentine. Two pints were administered, but returned without any fæcal matter; he then applied leeches to the belly, followed by hot fomentations, and gave opium and belladonna by mouth. She was placed on spoon diet.

May 23rd.—There was more pain in the belly; slight nausea, no vomiting since admission. Mr. Gould found that the left flank was less tympanitic than the right; he ordered the simple enemata, which had been given from time to time without avail, to be discontinued.

May 25th.—Vomited beef-tea and milk; in the afternoon she vomited about 1½ pints of distinctly fæcal matter on two occasions. Mr. Walsham kindly saw the patient and when she was under the influence of chloroform, passed his hand into the rectum and sigmoid flexure, but could not detect any obstruction. It was accordingly decided to open the right colon.

May 26th.—8 a.m. Mr. Gould opened the ascending colon in the right loin and liberated about four pints of liquid fæcal matter exactly similar in appearance to the material the patient had vomited. During the course of the operation, the peritonæum was wounded, and so the finger was introduced into the abdominal cavity, and the line of the peritonæal reflection was exactly ascertained; the aperture in the membrane was then nipped up and surrounded by a catgut ligature. The patient was considerably collapsed after the operation; she recovered somewhat in the afternoon, but gradually sank and died 22 hours after the operation. Up to the time of death there was a free discharge of fæcal matter from the artificial anus.

At the *autopsy* a stricture of the middle of the transverse colon was found. It was 1½ inches in length, extended all round the bowel, and just admitted the forefinger; the omentum was puckered in, and the walls of the bowel were considerably thickened and indurated at the seat of the stricture. There were no secondary deposits in lymphatic glands or in any of the viscera. The peritonæum was perfectly smooth and glistening. There was a little clear serum in the pelvis; intestines somewhat congested. There was a fibroid tumour of the uterus the size of a child's head, and enlargement of the left ovary. There was atheroma of the aorta and of the aortic and mitral valves, hypostatic congestion of both lungs, with old pleuritic adhesions on the left side.

Remarks.—These two cases may be usefully studied together as presenting in a marked manner the contrast between acute and chronic intestinal obstruction, or rather between strangulation and simple obstruction. In each case the onset of the "obstruction" was sudden, but in the one was complete, and in the other incomplete, flatus being freely passed. In the one case

vomiting set in within a few hours, speedily became fæcal, and was urgent throughout the course of the malady; in the other vomiting was delayed for eleven days, and was subsequently absent entirely for six days, during which liquid food was freely taken. In the one case the abdominal distension was slight and uniform; in the other it was very great and less marked in the left than the right flank. In the one case collapse was an early and a marked symptom, while in the other it was absent until the time of operation, the patient being well enough to walk to the hospital a fortnight after the commencement of the illness, and rather resenting being confined to bed and placed on spoon diet.

The previous attacks of colic in the case of acute strangulation by the vermiform appendix are of some special interest. Such a history is not rare in cases of intestinal strangulation by band, and a question naturally arises as to their cause. It is impossible to think that they are due to the bowel slipping beneath the band, especially as in this case they were not accompanied by constipation. More probably they were due to some traction exerted on or by the band, and hence the relief obtained from morphia. The only treatment which offered any prospect of success was that which was ultimately adopted, and it is a matter for regret that operation was not resorted to earlier, when the chances of success would have been greater. So far as the operation itself was concerned, by following the suggestion of Dr. Kingston Fowler, the seat of strangulation was at once found, but it was a matter of considerable difficulty to expose the band, and then to ligature and divide it without injury to the distended coils of intestine all around it. Death in such a few hours after the operation, and from peritonitis, suggests a serious question. All the known precautions were used to render the operation aseptic; a steam carbolic spray was used throughout; the abdomen and the operator's hands and instruments were all carefully cleansed in five per cent. carbolic lotion, and the rapidity with which the inflammation set in excludes septic influences spreading in from the dressing. The question I would put is this. Is not the division of the vermiform appendix attended with danger of the escape of septic mucus, &c., into the peritonæal cavity? It is a mucous canal, continuous with the cæcum, and even when a double ligature is placed upon it the substances lying in the tube between them have free access to the cavity when the section is made. It is hardly open to doubt that the cause of peritonitis in this case was some *materies morbi* introduced into the peritonæal cavity at the operation, and it seems reasonable to think that it escaped from this mucous canal when cut across. If so, what is the right line of practice in any similar case? Clearly the band must not be left or the strangulation may recur; even were it possible to bring the divided ends to the surface and stitch them in the wound this would leave a double possibility of internal strangulation occurring. Two alternatives suggest themselves. One plan would be to attempt to detach the tube where adherent at its extremity by the division of solid fibrous adhesions, from which no septic extravasations would ensue. The possibility of this would depend upon the position, and mainly upon the character of the adhesion. Were it impossible the only other plan would be to divide the tube, and endeavour to render the parts beyond the ligatures aseptic by covering them with finely powdered iodoform.

One fact of interest in connection with the second case is the vomiting of very large amounts of distinctly fæcal matter at long intervals; that vomited in the hospital was indistinguishable from the matter which escaped from the colon when opened. It would have been far better if in this case, too, the operation had been performed earlier, when the patient's strength was fair, but the absence of all acute symptoms for some days after admission to hospital induced me to delay, and the result was that the patient never rallied from the shock of the operation. The case affords a remarkable confirmation of the views of Mr. H. O. Thomas in the fact that vomiting had first occurred immediately after an enema had been administered. The subsequent attacks of vomiting were not excited by similar causes. Both these cases were previously under the care of my friend, Dr. F. A. Hill, of St. John's Wood, who kindly placed them under my care.

Medical Times and Gazette.

SATURDAY, NOVEMBER 8, 1884.

The outbreak of cholera at Nantes seems to be a more serious affair than was at first supposed. While the epidemic is completely arrested in the South of France, it seems to be disseminating its germs abroad, and reaching points hitherto not infected. The first case which occurred at Nantes, in an hotel, on the 24th October, was of the type called "foudroyant." From the 24th October to the 1st of November the number of cases amounted to 36; from the 1st to the 2nd of November the number rose to 25; from the 2nd to the 3rd 10 deaths are recorded, the number of cases not being stated. The latest statistic is 13 fresh cases and 6 deaths.

The population of Nantes, one of the most prosperous maritime and commercial cities of France, exhibits a much higher moral tone than the inhabitants of Toulon and Marseilles, when the epidemic broke out. The temper of the two principal maritime races of France, the Bretons and Provençaux, is thus brought into vivid opposition. Although all the sea coast of France furnish men to the navy, still, more than two-thirds of French seamen are either from Brittany or from Provence. Without disparaging the eminent qualities of the Southern race, it must be confessed that the Breton has a higher sense of moral dignity, and is better able to look danger coolly in the face, not only upon the field of battle, but under the more dispiriting form of an epidemic disease. There were many instances of heroic conduct at Toulon, at Arles, and at Marseilles, and many a valuable life was nobly sacrificed; but the mass of the population simply ran away, disseminating the germs of disease on its road. At Nantes no panic has taken place, no shops are shut, no streets are empty. The city retains its usual animated appearance. A wooden hospital has been set up in the vicinity of the Hospice St. Jacques, an establishment situated outside the town. To these "baraquements" choleraic patients are sent. An observation ward has been put up at the Hôtel Dieu. One case of fatal cholera has occurred at Paimbœuf, close to Nantes.

In spite of the differences of opinion as to the propriety of the course of action pursued by Dr. Rabbeth in risking his own life on the slender chance of saving

that of one of his patients, adverse views were conspicuous by their absence at the meeting held at King's College, to consider the best means of raising some permanent memorial to his act of self-sacrifice. In fact it was felt that some recognition was indispensable and the questions raised were merely as to the scope and the form of the memorial. Both in King's College, and in the Royal Free Hospital permanent record was desired, but Sir William Gull introduced a new factor in proposing, as he suggested in a letter to a contemporary, that the best way of allowing the non-medical public to show their appreciation, would be to endeavour to raise funds for a medal to be given annually at the University of London. As will be seen from a letter from one of the Secretaries which we publish on another page, harmony was ensured by forming a large committee from both hospitals, and by securing Sir William Gull as one of its members. The ultimate form of the memorial must obviously remain uncertain, until all who admire an act of self-sacrifice in the practise of medicine have had their attention drawn to this effort, but the composition of the committee shows that the threefold object will be kept in view. In other words, it is hoped that this may be a *public* memorial, not merely one raised by those members of the profession who knew and esteemed Dr. Rabbeth.

Last Tuesday's meeting of the Pathological Society was not so well attended as the first meeting, but the programme contained several specimens of unusual interest. Drs. Lanchester and Hobson brought forward the specimen which gave rise to the best discussion, in the shape of a consolidated lung, which during life had given rise to all the symptoms and signs of empyema, with the single exception of not yielding pus to the aspirator. A free opening had, however, been made in two places, and a drainage-tube inserted in each, but without much benefit. The authors regarded the case as one of caseous pneumonia, and some of the speakers were inclined to agree in this view; others, however, thought it bore more resemblance to some form of new growth, such as lympho-sarcoma invading the lung throughout. Ultimately the specimen was referred to the Morbid Growths Committee. Dr. Percy Kidd read an account of four aneurysms of the heart he had met with at the Brompton Hospital. They all occurred in males; one was probably congenital, and the others appeared to be associated with rheumatism and endocarditis. Dr. Hale White showed a specimen of coarctation of the heart and aorta. Want of time prevented Dr. Acland from bringing forward his cases of ulceration of the intestine in connection with disease of the spinal cord with such completeness as to enable us to form any opinion as to the soundness of his views, but seeing that it is admitted that under the influence of nervous lesions nutritive changes may take place in the skin, bones, and joints, there is nothing impossible or even very improbable in similar nutritive disturbances being found in the intestine as a result of disease of the nervous system. Dr. Howard Tooth exhibited what appeared to be a diffuse lympho-sarcoma of the liver in a child, and Mr. Barker recounted a case of what he believed to be epithelioma of the superior maxilla, but the only two speakers who followed him did not agree either with him or with each other as to the nature of the tumour. Mr. Victor Horsley exhibited in the ante-room the body of a monkey which had died that day, exactly fifty-four days after the removal of its thyroid gland, and which presented a sufficient number of the signs of the disease to justify his calling it a case of artificial myxœdema. Should his further investigations in this direction be followed by like result, they will confirm the views of Kocher, which have more than once been expounded at the Clinical Society, as to the important part played by the removal of the thyroid in this strange disease.

The monthly meeting of the Obstetrical Society was held on Wednesday. The usual number of specimens was exhibited. One gentleman was in so great a hurry to show a new instrument (or rather a trifling modification of an old one) that he had not even waited till the instrument maker had completed its manufacture, but exhibited it "in the rough." While admiring the activity of this gentleman, we nevertheless think aspiring inventors will gain more credit for their contrivances and more profitably occupy the time of the society if they will wait until they have tried their instruments in practice before bringing them down to exhibit. The greater part of the evening was occupied by the reading of a long and elaborate paper by Dr. Graily Hewitt (illustrated by a printed table of cases which was distributed), on uncontrollable vomiting of pregnancy. Dr. Hewitt, as is known, thinks this vomiting is a result of flexion or version of the uterus; and his paper was an argument in favour of this view. Dr. Champneys and Dr. Galabin spoke adversely to the opinion defended in the paper; and then, upon the motion of Dr. Barnes, seconded by Dr. Hicks, the discussion was adjourned till the next meeting.

We have been requested to remind our readers that on Thursday next, the 13th, Mr. Jonathan Hutchinson, F.R.S., will deliver the first Bowman Lecture at the meeting of the Ophthalmological Society, when the meeting will commence at 9 instead of at 8.30, as usual. His subject will be "Diseases of the eye which appear to be in connection with gout," and we have no doubt that there will be a very large attendance of members and visitors, not merely because they will have the pleasure of listening to a masterly address, but also as a compliment to the distinguished man of science in whose honour the lectureship has been founded. The lecture will appear in our pages in an early number.

In reply to the petition of the Association of Members of the Royal College of Surgeons, praying for the direct representation of the medical profession in Parliament, Mr. Gladstone has written, as might have been expected, that he does not think that particular proposition would commend itself to the judgment of Parliament. He would gladly welcome the presence of more members of the medical profession in the House of Commons, but in his opinion this can

only be secured by the means which are at present open to all other professions. He is further unable to admit the contention that other learned professions are directly represented in the Legislature. There, we suppose, the matter will end. Meanwhile, in another part of the kingdom, some equally ill-advised politicians are doing their best not only to oust from the House of Commons one of the few men who are thoroughly versed in medical problems, viz, Sir Lyon Playfair, but also to bring the representation of Universities into discredit. One of the strongest arguments in favour of retaining the University seats is that less political rancour enters into the choice of the representatives than in ordinary parliamentary elections. The conservative graduates of the Universities of Edinburgh and St. Andrews, by pitting the Dean of Faculty, Mr. Macdonald, Q.C., against their present representative, Sir Lyon Playfair, are not only acting ungratefully to one who has been a faithful servant of their Universities, but are giving an additional handle to those reforming politicians who would dearly love to make an end of University representation for good and all.

On Saturday last the life-sized portrait in oils of Sir William Mure Muir, K.C.B., M.D., who lately retired from the Directorship of the Army Medical Department, was presented to Lady Muir in the name of the Officers of the Medical Staff serving in all parts of the British Empire. Owing to the serious illness of Sir William Muir it was with much regret found necessary to dispense with the deputation which it was intended should formally present the portrait, and the proceedings were, therefore, strictly private. The portrait, a three-quarter length, by Mr. W. R. Symonds, is a most striking likeness, and elicited warm commendations as a work of art, not only from the recipient, but also from all who had seen it at the artist's studio. The original (of which this is a replica by the same artist) adorns the walls of the Medical Staff Mess at Netley, forming there not only a permanent memorial of the lately retired Director-General, but also a lasting testimony of the high appreciation by the Officers of the Medical Staff of the pre-eminent services rendered by him to the Department.

The work of the Medical Schools, University and Extra-mural, writes our Edinburgh correspondent, has fairly commenced for the winter. The numbers are not made up yet, but the matriculation register, we understand, shows no signs of falling off. Most of the introductory lectures in the University showed a healthy spirit, partly no doubt the result of the Tercentenary Celebration, partly the outcome of more suitable environments. It is to be hoped that the stimulus, however derived, will have an enduring effect and that increased opportunity will result in extended accomplishment.

We observe with pleasure the announcement by the Professor of Pathology that the laboratory will be open to a limited number of graduates and senior students for the prosecution of research. We have little doubt that good work will follow this step, and we feel assured that it will be no fault of the able and popular assistant (Dr. Sims Woodhead) if our full expectations are not realised. His contagious enthusiasm must influence in the highest way the work of such a laboratory. We look in vain for a similar announcement regarding the physiological department. At the first meeting of this class in the new buildings, the professor went out of his way to describe in elaborate detail the appliances and purposes of upwards of a score of apartments devoted to the prosecution of physiological teaching and research. Great expectations of the foundation of a School of Physiology in our University were thereby naturally raised. Certainly no place was ever better adapted for such a purpose, and the possibilities of doing good work are practically unlimited. Up to the present any hopes in this direction have not been realised. No such invitation as that issued by Professor Greenfield comes from the physiological side ; nor, apart from the mere routine of teaching, is there much sign of active life. Surely it is time to look for some indication of vitality in this department. Can circumstances more favourable for earnest and valuable work be conceived ? Here we have accommodation and appliances unrivalled in completeness, seventeen hundred students and many graduates to supply workers, and a professor in the prime of life, luxuriously paid and provided for, to act as organiser. And as yet—*vox et præterea nihil.* Have the public not a right to ask, Why all this money spent on magnificent laboratories ; when is the work to begin ; is all this accommodation needed for teaching purposes only ? What wonder if they hold their hand in spite of the pressing appeals of Chancellor and Lord Provosts ?

The General Council of the University, at their meeting on Friday, awoke to the fact that a reformer had come in. A recent acquisition in the form of an M.B. had been advertised for some days previously as the propounder of certain propositions in the form of motions, which if carried into effect would have turned medical teaching in Scotland to chaos, and converted the schools into working models of Pandemonium. All the motions were withdrawn save one, which proposed an extension of the course to five years, and 22 as the minimum age for graduation. After half an hour's discourse by this gentleman, read from a manuscript, the Vice-Chancellor suggested that the *reading* of speeches in the Council was an innovation and a dangerous precedent, whereupon this "Cleanser of Augean Stables" sat down. Unluckily for the beneficent efforts of the new Hercules he was followed by Dr. Heron Watson whose annihilation was polite, thorough and satisfactory. We might suggest that during the coming year he might devote some of the hours snatched from the calls and cares of busy practice to the maturation of his ideas, and the committal of his expression of them to memory, and let him come again "with his hair just grizzled," and he will doubtless have a warmer welcome and a better hearing.

The inaugural address for the present session at the Mater Misericordiæ Hospital, Dublin, was delivered

on Friday, October 31, the lecturer being Dr. M. A. Boyd, one of the physicians to the hospital. His Eminence Cardinal MacCabe presided. The lecturer dealt chiefly with the subject of the development of therapeutical science. "What would be the surprise," he asked, "of a practitioner of the old Therapeutic School if he could rise from his tomb and see his most cherished remedies, his Lares and Penates, shattered and broken, the Iconoclasts rushing in on all sides and from every country, to share in the work of demolition? How much would it surprise him if he saw a victim to angina pectoris of the present day, with staring eyeballs and torture-wrung pallid face, getting the blood brought from the choked vessels of his heart, and his face made to suffuse with a crimson glow, after inhaling a few drops of nitrite of amyl, his pain ceasing, as the remedy began to exercise its physiological action? Or the garrotted asthmatic, relieved almost magically by equally potent inhalations of iodide of ethyl, or the victim of acute rheumatism—that *bête-noir* of the poorly clad and badly-housed dwellers in this humid clime—quickly relieved by the many compounds of salicylic acid and of salicine? Still more would it surprise him to see a joint or the abdominal cavity laid open fearlessly by the surgeon of to-day, under an antiseptic atmosphere, or a chest tapped by aspiration, and fluid that pressed injuriously upon the lungs or heart withdrawn, with none of the untoward results of a bygone surgical time, when such operations would be looked on as certain to lead to a fatal result."

At the Meath Hospital and County Dublin Infirmary, Professor Rawdon Macnamara was the protagonist of the occasion on Monday morning, the 3rd instant. The chair was taken by the Right Hon. William Meagher, M.P., Lord Mayor of Dublin, who was supported by the President and Vice-President of the Royal College of Surgeons in Ireland. The address was sound and practical, and met with a hearty reception at the hands of the students who were present in large numbers. *The* feature of the morning's proceedings was, however, a highly characteristic speech from the Rev. Dr. Haughton, S.F.T.C.D., who *inter alia* said he took exception to the professor's eulogium on "Truth," for he thought that a proverbially dull world would be much duller were it not for an existence of a good deal of Fiction as well as Truth. In the evening the annual dinner of Old Meath Hospital men took place at the Shelbourne Hotel, the chair being occupied by Dr. William Moore, Ex-President of the King and Queen's College of Physicians.

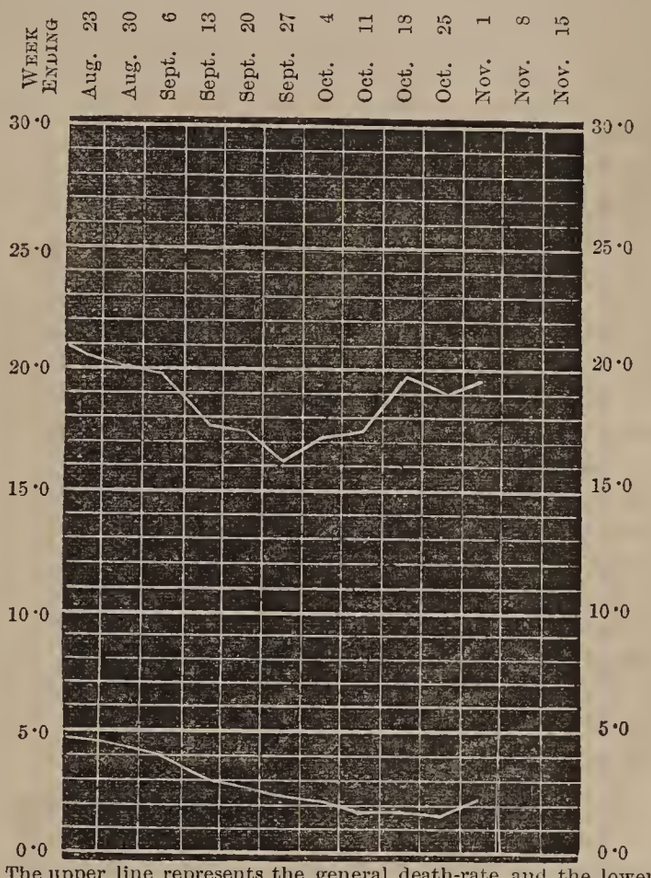
The winter session, writes our Belfast correspondent, commenced here upon Tuesday last, when the professors in the various class rooms opened their courses of lectures at the Queen's College. Professor Redfern, whose opening lecture has always attracted numbers of his old pupils from year to year, and taxed to the utmost the accommodation in his commodious lecture room, was listened to as usual with the deepest interest and keenest appreciation. The session at the Belfast Royal Hospital was inaugurated by an opening lecture delivered by Professor Cuming, President of the British Medical Association, who, after some words of advice to the men of various years as to the best way of spending their time in hospital work, plunged into the serious business of the session. Inaugural addresses in Ireland have never been the rule at the hospitals, not because the Irish student of medicine can in any way be said to be lacking in appreciation of oratory, but perhaps on account of the hospitals often not being complete schools of medicine in themselves, as is always the case in the metropolis. Owing to the regulations of the late Queen's University, whose examinations in arts and medicine always occupied a considerable portion of the month of October, many of the professors had to be in Dublin at that time, and the winter session accordingly has always commenced in November. One result of this arrangement has been, that just about the time the student is settling seriously down to work, the Christmas recess comes, and the majority find themselves really beginning the session about the end of the first week in January. The North of Ireland student is one of the hardest-working and most industrious of his class, and were it not for this fact, the lateness of the session would seriously tell against his progress, and would ultimately injure the prosperity of the school. Another serious drawback attending the *late* system, and one which tells particularly against the teachers, is the rapidity with which the summer session follows upon the heels of the winter's hard work, leaving the hospital staff no opportunity for relaxation. Too often the physicians and surgeons begin the spring course fagged out with the six months' clinical work in the wards. Doubtless, in a short time the new Royal University will enforce such regulations regarding certificates to be accepted by it, as will force the colleges and hospitals to abolish this relic of a bygone age.

The entries at the Belfast Medical School this winter will be scanned with unusual interest by the teaching staff and past students (of the late University) who have been closely watching the effects of the recent legislation which has so seriously told upon the prospects of the Queen's College and Belfast Royal Hospital. For the few years preceding the annihilation of the Queen's University, the average number of students attending classes in the Medical Department of the Belfast Queen's College amounted to almost 350. The Professor of Anatomy and Physiology lectured to a class containing nearly 300 men; but immediately after the new university sprang into existence, demanding a longer medical course and insisting upon a preliminary art's examination of considerable difficulty, the numbers attending medical classes fell very considerably. The late University fully met the wants of the North of Ireland and enabled the sons of its not over wealthy farmers and gentlemen to obtain a cheap degree in medicine within the short period of three and a half or four years. The Royal University, with its longer, and, of course, proportionally more expensive curriculum, is out of the reach of some who would have availed themselves of the M.D. of its predecessor. There is also, unquestionably, a deep and wide felt feeling of insecurity and unrest in this

part of the empire about the question of university education which of necessity has arisen upon the destruction of a comparatively young and vigorous institution. A considerable time must elapse before even the thinking minds in the community can realise that the new University may not soon be set aside in some new experimentation or tinkering with what must be acknowledged to be a very difficult question.

It is with these difficulties that the Belfast Medical School has been contending for the past three years. with what success remains to be seen. It will require at least another year before the immediate effects of the new university change can be fairly judged of. Last winter the first and second year classes were very materially thinned ; this year it will be the third year classes, and after 1885 the full operations of the Royal University will be evident. During the interval the standard of education has been decidedly improving, and it is evident that the facilities for the training of students in every department of medical science and practice can hardly be said to be inferior to those of any school in the kingdom. The hospital arrangements are most complete and extensive, as we showed in a tabular statement some time since. In spite, however, of the most complete teaching arrangements, and notwithstanding the great strides that the school can make in giving the student the best opportunities for pursuing his clinical studies, it must expect to find its growth, to some extent, crippled in the future. In our columns we have of late pointed out the great change in the relative popularity of the provincial and metropolitan schools of medicine, and we have pointed out that the increasing numbers of men who turn their faces to the provinces do so clearly not on account of the clinical teaching being better there, but because of the greater facilities for obtaining a degree in medicine. If the London schools are to preserve their supremacy it is only by meeting the want, and placing within the reach of the student a reasonably cheap and respectable degree instead of the rather expensive diplomas which, after all, do not confer upon him the coveted title of "Doctor." It is evident that no school can flourish long with its teaching at low water mark, but there are other factors in the growth of a medical school besides its good teaching ; and the large school of medicine in Belfast must content itself with the reflection that if its members shall not continue to increase with their former speed, its efficiency and thoroughness have never stood upon so high a platform. We regret that it will be impossible to form an estimate until next week of the numbers attending the medical classes this winter, owing to the lateness of the session, but they are expected to show a substantial increase upon those of last year.

During the past week 1,503 deaths were registered in London, giving a slightly higher death-rate than that of the previous week. But the death-rate of the present quarter so far, compares very favourably with that of its immediate predecessors. There were 21 deaths from small-pox in London, as defined for registration purposes, and in addition 16 deaths of London residents in Metropolitan Asylum Hospitals outside the above area, thus giving the large total of 37 cases. Measles and diphtheria claimed 22 victims a-piece, whilst scarlet fever is credited with a total of 28. Whooping cough was the cause of death in 13 instances, all children under five years of age, seven of them being under one year. The mortality from diseases of the respiratory system rose from 274 to 348, a high figure, but still below the corrected average. Nine infants under one year died from suffocation, and



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past eleven weeks.

strange though it may appear, the deaths under this head are slightly below the average. Only three deaths occurred from small-pox in the remaining 27 great towns of England. Glasgow last week had the very high zymotic death-rate of 5·7 ; this is accounted for when we learn that there were 17 deaths from scarlet fever, 12 from diphtheria and 8 from measles. The sanitary authorities in that quarter must have their work cut out for them.

The discussion on the pollution of the Seine, writes our Paris correspondent, was continued on Tuesday week, at the Academy of Medicine. The assembly voted the conclusion of Professor Brouardel's report, stating that it would be desirable to prevent the refuse of manufactories from being thrown into the river, but that time would be required to effect such a sweeping reform, while, on the contrary, immediate measures ought to be taken to prevent fæcal matter from mixing with a stream, the water of which is so largely used for drinking purposes. If the existing habits are at all to be modified in this latter respect, it will be necessary to carry matters with a very high hand. Experience has taught us that, as a rule, when people have dirt upon their premises, their sole object is to get rid of it, at any price and in any manner, without paying

the slightest regard to the convenience or health of their neighbours. With respect to the influence of water contaminated with fæcal matter upon the dissemination of cholera, Professor Le Fort remarked, that the inhabitants of Versailles have constantly been preserved from any visitation of the epidemic, although Versailles is supplied with water from the "machine de Marly." This costly mechanical structure was erected under Louis XIV., to supply the new city with water drawn from a then pure and unpolluted part of the Seine. But things have changed since that distant period, and the inhabitants of Versailles certainly now drink water polluted by the refuse of Paris. Their preservation from cholera is attributed by Professor Le Fort to the fact that they have no wells, these being, he says, the chief cause of the propagation and dissemination of the disease.

On the proposition of Professor Ball, the Paris Academy of Medicine has voted an address expressing the deep regret of the French Medical body at the destruction by fire of the palace of Christiansborg. The address was directed to Professor Panum, the President of the Copenhagen International Congress, it being contrary to etiquette for academies and scientific bodies to enter into direct communication with crowned heads. The Academy of Medicine has received with deep regret the announcements of the death of Dr. Rufz de Laviser, the author of several well-known works on the diseases of tropical countries; and of the severe illness of Dr. Fauvel, the celebrated hygienist, who is affected with inflammation of both lungs.

The question of the lady medical students at Paris has entered into a new stage. The right of taking a part in the competitive examination for the post of house surgeon and physician (interne) to the Paris hospitals had hitherto been denied to the fair sex; it is now asserted that M. Poubelle, the Préfet de la Seine, with whom the matter rests, will grant the permission. The force of logic is irresistible, and if ladies are allowed to become house surgeons, they will, in process of time, claim to be hospital physicians, and even raise their ambition higher; and some of these days, a Professor's Chair at some of the French Medical Faculties may be held by a lady, as in former times a prominent place was filled by the celebrated Vittoria Colonna, in an Italian University. Whether the medical profession will gain or lose by this infusion of the female element, is a question which the test of experience alone can solve.

Dr. Julius Althaus writes to us as follows: A committee has been formed in Germany from amongst the friends and pupils of the late Prof. Cohnheim, whose premature death a few months ago has been most deeply and widely lamented throughout the medical world, for the purpose of erecting a suitable monument over his grave. To the profession generally, Cohnheim was only known for his great scientific attainments, and uncommon originality of research, but to a large circle of friends and pupils, who came to study under him from all parts of the world, he had greatly endeared himself by the charm of his manners, and the large and warm-hearted sympathy which he freely gave to all those who were, like him, striving to cultivate the fascinating field of experimental pathology. I have been requested by Prof. Wagner, of Leipzig, on the part of the committee, to acquaint, through the medium of your columns, Cohnheim's friends and old pupils in England and the United States with the object of the committee; and I shall be happy to receive and transmit any contributions towards the fund which is now being raised, to the treasurer, Prof. His, of Leipzig. The list will be closed at the end of the year, after which a statement will be forwarded to all subscribers.

There are a few papers of medical interest in the November magazines, but none which it absolutely behoves one to read. The most important is Mr. Sydney Buxton's article on "Over-pressure," in the *Nineteenth Century*. As might have been anticipated, Mr. Buxton disagrees with most of Dr. Crichton Browne's conclusions, and is very sceptical as to his premisses. He thinks that doctors see only one side of the question, and that the worst; and he maintains that the opinions of the faculty have never yet been given on really medical and scientific grounds, and that, therefore, they are no better than the opinion of a layman who is practically conversant with the subject of education. Mr. Buxton has evidently not taken the trouble to read the series of letters from hospital physicians which we published a few weeks ago. The opinions there given were, so far as they went, distinctly medical and scientific, and were such as no layman could possibly have the means of forming. As we have before pointed out, it is absurd to argue that a doctor has no right to an opinion on the subject unless he is familiar with the working of the Code. The doctor merely gives evidence of facts which have come under observation, and the only logical way of meeting such stubborn arguments, is to prove that they do not exist. It is no answer to contend that the system is such that the facts cannot possibly exist, though that is the only answer that has yet been vouchsafed to the medical allegations. Dealing with the suggestions of the doctors that a systematic medical inspection of schools and scholars should be introduced and that a register of each child's physical condition should be kept, Mr. Buxton declares that they would be unworkable. "Elementary schools were intended simply for the education of children during a few hours of the day, and were not intended to supersede all parental responsibility, nor yet to be the happy hunting ground of doctors and scientific observers." The question, however, is surely not what the schools were intended but what they ought to be. The rest of Mr. Buxton's paper is devoted to a consideration of the working of the Code, but nowhere throughout his remarks does he allude to the modest but important suggestion made by medical critics, viz.: that the whole subject should be submitted to the consideration of a commission of enquiry. The same number of the *Nineteenth Century* also contains a chatty article on Karlsbad, by Mr. Fraser Rae, which is hardly up to the usual standard of papers in this magazine.

In the *Fortnightly Review* there is an article on Moderation and Total Abstinence, by Mr. Sutton Sharpe, whose account of the history of the famous "Medical Declaration respecting Alcohol" will probably produce some rejoinders. The whole article is written in the worst of taste, and will injure rather than benefit the cause of moderation, which it favours. *Blackwood*, in a rather common-place article on Outlying professions, has some remarks, scarcely worth reading, on the prospects of the young doctor in this country, in the colonies, and upon the sea. Dr. C. M. Campbell contributes to the *National Review* a telling indictment of our system of Poor Law Medical Relief of the rural poor. He suggests by way of reform that (1) the medical officer should be obliged to devote his whole time to his public duties, (2) that his salary should be fixed on a uniform system proportioned to the mileage of the district and the average number of cases treated, and (3) that all medicines should be supplied to and not by the medical officer, and should be of proved purity. He further suggests that every district should be provided with a cottage hospital. For the arguments by which these innovations are supported, we must refer our readers to the article itself, which we have been no less surprised than gratified to find in a journal of the conservative proclivities of the *National Review*.

The two most important educational journals both express themselves strongly this month as to the necessity for a systematic enquiry into the "Over-pressure" question. The *Journal of Education* says that, "to establish a *primâ facie* case of over-pressure, the method of agreements adopted by Dr. Crichton Browne was sufficient, and this was all that a private individual could hope to do. To determine the amount of over-pressure, resort must be had to the method of differences, and for this we must look to a commission of experts, partly medical and partly educational, and we have little doubt that the pressure of public opinion will compel the Government to appoint such a commission." The *Educational Times* believes that "no final verdict is yet possible, for no reliable evidence has yet been produced either in support of it or in contradiction to it. Accurate investigation is therefore required, and considering the extent and seriousness of the consequences involved, an open, thorough, impartial, and adequate enquiry should be commenced at once. Now that Parliament is assembled, it is to be hoped an hour will be found to give authority to a regularly constituted Commission of Enquiry."

We stated some time ago that there was a likelihood that the pathological laboratory organised in connection with the Health Exhibition would be established as a permanency, and endowed out of the surplus of the exhibition. We are glad to see that the Executive Committee have been bold and far-seeing enough to propose this mode of getting rid of some part of the moneys left on their hands. In their final report, signed by the Duke of Buckingham, they recognise that "the maintenance of the laboratories would ensure a means of sanitary research and teaching for the future which England has not had in the past. In these laboratories, studies could be carried on, and teaching could be given of a kind similar to that which is afforded by various foreign institutions which have been established in the interests of the public health. These studies have a direct bearing on the solution of health problems, which not only affect the well-being of communities, but exercise an important influence on agricultural and commercial interests." This proposal awaits the approval of the Prince of Wales. The interest His Royal Highness has recently shown in the kindred work of the Marine Biological Association should augur well for his decision in the present matter. If the laboratory is allowed to go on, it will be another singular instance of our funny roundabout English way of collecting money for objects which people do not sufficiently care about to endow directly. If the visitors to the exhibition had been told that a farthing out of each of their entrance fees would go to keep up a scientific workshop, most of them probably would have been inclined to ask to be excused the contribution.

Under the head of the celloidin process, we casually mentioned in a recent number the fact that pure anilin is capable of clearing up sections, and that it is not a solvent of celloidin, and that in consequence, oil of bergamot may be dispensed with in the celloidin process. As oil of bergamot has a very bleaching action on the colours of sections, and as pure anilin has no more tendency to remove the staining than oil of cloves, pure anilin has a distinct advantage over bergamot. And not only in this respect, but also in price, for commercially pure anilin can be purchased retail for sixpence an ounce, and this answers quite as well as the chemically pure, which is five shillings an ounce. In using pure anilin as a clearing agent, one point requires particular notice, and this is that the section must be very carefully dried before it is mounted, or else the balsam will slowly assume a brownish hue, and when this change reaches the section, the colour becomes slowly discharged. Since the discovery of the clearing property of anilin made a few weeks ago by Dr. Hebb, of the Westminster Hospital, trial has been made of its action on various colouring matters, and it is found that pure anilin heightens the effect of logwood staining, and seems to have little or no tendency to absorb the anilins. Now, assuming the reader's knowledge of the fact that pure anilin is now much used as a mordant in the anilin stains for bacilli, we need scarcely point out that it was but a short step to the conclusion that this method might serve to bring out micro-organisms with more distinctness and with less trouble. This is found to be the case.

The *New York Medical Record* for October 11th, states that during October the application of the New Civil Service Regulations to medical matters comes into force, as vacancies in the Hudson River Hospital for the Insane will be filled by competitive examination, all graduates of reputable medical colleges being eligible. In future the medical officers of hospitals, the superintendents of asylums, vaccination

and sanitary inspectors, and all others in the health department who require medical education and experience will only be able to obtain their appointments in this way. Matrons, nurses, and hospital servants in general will have to undergo a similar ordeal. The examinations are to be conducted by one of the three examining boards, appointed by the mayor and composed of three citizens. Besides requiring evidence of physical and moral qualifications, it will include the following points, with the relative weight given to each, viz.: medical knowledge, 50; experience, 20; efficiency and accuracy in work, 15; character for maintaining discipline, 15. By a curious regulation candidates are not obliged to produce a diploma, a certificate from some reputable institution of having studied for two years, or one from a professional man of having studied for three years sufficing. Here, the *Record* observes, is a possible opening for the "politicians" to get their friends in who have not been regularly qualified. However, our contemporary is of opinion that if the measure be carried out thoroughly, it will no doubt assist to raise the character of the profession. When we observe how the examiners are to be appointed, this seems a somewhat sanguine expectation.

THE RABBETH MEMORIAL.

We are glad to see that every effort is being made to commemorate in a really worthy manner the act by which the late Dr. Rabbeth sacrificed his life. The letter from Dr. Curnow, which we publish in another column, will go far to show that the movement has been taken up in no outburst of hysterical enthusiasm, but with a grave determination to give a tangible expression to that mixture of deep admiration and deeper regret which the profession and the public have felt for the heroic impulse which has cost us the life of one of the most promising of our younger members. If Emerson's definition of the hero is a just one, there are surely none who have a better claim to the title than those dead and living brethren of ours who, dominated by a rare and noble impulse, have cast behind them all considerations of self, and have risked their life to save that of their patients. No one can possibly grudge them the universal thrill of emotion with which their act is greeted. We can indeed enter into the feelings of those who, like Mr. Chatto (see his letter in another column) are anxious that the example of Dr. Rabbeth should not be made a rule of professional conduct, but they need have no fear that Dr. Rabbeth will find many imitators, with whatever enthusiasm and admiration we commemorate the manner of his death. And we are sure that it would be as unwise as it would be ungenerous for anyone to seriously attempt to baulk that admiration of its due expression. With whatever laurels we cover Dr. Rabbeth's grave, no one need feel that he has failed in professional duty, if he refuses to pit his own life against that of his patient. The public will certainly not blame him, composed as it largely is of men like that one who recently tried to punish his medical advisers, because they asked him to do for his own child the very thing that Dr. Rabbeth freely did for the child of a stranger. But to honour an ideal is not necessarily to enforce it. The tendency amongst us now-a-days is to unduly prize intellect at the expense of the far rarer gift of character. The intention of those who are organising the Rabbeth memorial, is, if we read it aright, quite as much to commemorate a life of generous and noble ideals, as to perpetuate the memory of a death which was but of a piece with it. It would be to the everlasting dishonour of the profession if, by showing luke-warmness in worthily commemorating Dr. Rabbeth's act, they should make it evident that they had ceased to reverence that high ideal of conduct which is so much the more worthy of reverence, because so many of us must feel that we should ourselves be unable to rise to it. The profession that no longer cherishes the memory of a hero, confesses thereby the degradation of its own ideals.

THE MEDICAL SUPERVISION OF ELEMENTARY SCHOOLS.

The statement lately published by the Chairman of the London School Board is not calculated to lessen the attention which is being so generally and so deservedly directed to the alleged physical results of our compulsory educational system. It is some source of pride that the metropolis provides an education for more than half a million of its juvenile population; and if Board Schools are the institutions in which this most desirable end can best be attained, it is satisfactory to know that three-fifths of that number of children receive instruction under this system, with an average accommodation of about 900 children to each school, although the attendance on any given day does not exceed eighty per cent. of all the names on the register. Even a rate of eightpence in the pound, with some probability of its yet further increase in the not distant future, will be grudged by few if it can be shown that education in its truly valuable sense is being imparted to those who may be trained into orderly and capable citizens, or allowed to degenerate into a lawless and indolent *canaille*, according to the treatment of their earlier years. Educationalists, however, can never afford to forget that children are something more than machines which have merely to be got into working order. The character, the social position and requirements, the inherent capacity of the individual are all important factors in the problem, and they cannot be fixed or regulated by Act of Parliament. The imposition of the specific requirements of the Educational Code upon the untutored minds of some 300,000 children drawn from classes in the earlier stages of intellectual evolution, and too often hampered by the worst possible surroundings and actual bodily starvation, must act, to say the least, unequally in very many cases; and in how many it will act disastrously can be imagined only when we realise that what is now, sometimes inconveniently, called "over-pressure" is simply an evident inability to withstand strain, and that the strain in any given case will be the outcome of even moderate force brought to bear upon a weak material, just as certainly as when excessive force is imposed on that of average

strength. Take into consideration all the elementary schools in the country, instead of those in London only, and it is plain that the total amount of immoderate mental wear thus entailed must be very considerable indeed.

But there is another point of view from which this question may be regarded, and it is one which helps us to estimate the antecedent probability of mischievous results. The brain of the school child and the peculiar difficulties with which it has to struggle are not the exclusive property of the School Board; and evidence obtained from other quarters may be of value in determining the likelihood of similar results following similar causes with at least equal frequency in Board Schools. In the large public schools, and in the best of our private schools, for instance, it must be remembered that, while the educational standard is high, the intellectual capability of the educated material is also above the average. The less capable candidates for admission have been strained out by some process of preliminary examination, which is usually sufficiently severe to make the effects of "over-pressure" felt in the first instance in the preparatory schools, and to relegate the obvious dunce to an educational environment of less exacting character. And yet, even in great and well managed schools, such as those now under consideration, over-pressure claims its victims. In spite of their richer heritage of intellectual endowments, in spite of the care lavished on their well-being from earliest infancy, and all the advantages of good food, warm clothing, and healthy surroundings, boys and girls fall out in the course of the struggle more often than people know or are willing to believe, and would break down oftener still but for the care with which the earlier signs of failure are attended to. For even from its earliest stage this part of the process which secures the survival of the fittest has not been altogether unwatched or unguarded. In the walks of life from which such children are drawn medical attention is not the last thing thought of, and, though too often delayed, the recognition of physical and mental inaptitude is more early and much more generally provided for than can be the case with those whose parents necessarily lack much of the appreciation of and sympathy with its earlier symptoms, and for whom no regular medical supervision is officially provided while at school. Having regard, then, to the inherent probability of its development under those conditions, as well as to the considerable and rapidly accumulating evidence as to its actual widespread existence, it is not satisfactory to find that all Mr. Buxton has to say on the subject of over-pressure is that the Board, after careful enquiry, "had failed to find any proof of mischief, except of occasional want of judgment of teachers."

Whether the over-pressure which, in one shape or another is practically admitted, be directly traceable to the too rigid requirements of the Code, or to the misdirected ambition of school managers and masters, or whether it is "the over-pressure of poverty, drunkenness, and starvation," its effects are visible in the physical deterioration of the children who suffer from it. It is allowed that the work demanded of the teachers is so arduous that all but those of naturally strong constitution break down under its strain; and it is not fair to the children, to the schools, or to the teachers themselves to lay upon the latter the onus of at once preventing, recognising, and curing such cases of over-pressure as may arise amongst their pupils. Teachers should be quick to appreciate the earlier signs of failing health of mind and of body; but if in doubtful cases—and, in their beginning, all such cases must be doubtful to the mind destitute of special medical training—appeal has to be made to the teachers' own "judgment"—naturally biassed in favour of "results"—the chances are that errors, when made, will seldom be on the safe side. It would be different if the teacher could apply for guidance to a recognised medical authority. Such a plan would relieve the teacher of a harassing responsibility; it would guarantee to the scholar a safeguard something better than the hazardous guess of an amateur's diagnosis, and in the avoidance of present misery and the maintenance of future health, it would secure a return far beyond its cost. In short, it is only by the adoption of a simple and effective system of medical supervision that the operation of a compulsory educational system can be safeguarded against its otherwise inherent dangers. This view has already taken practical shape in the form of certain resolutions recently adopted at the late meeting of the German Public Health Union. They state decisively that school hygiene can only be properly taught and studied by means of discussions conducted by medical men who have practical experience of schools, and recommend that all the hygienic rules required in educational establishments shall be submitted to medical correction, and that no alteration of them shall be attempted without medical sanction. With respect to the administration of hygienic rules, they provide that all teachers should receive special instruction, and should at all times have the assistance of a properly qualified medical officer.

Although the evils of brain-driving are now most prominently before the public and have just been alluded to in this connection, other risks attend the crowding together of large numbers of young people. To the question, How may infectious diseases be most easily spread in civilised communities? the answer, By means of day schools, would be the most comprehensive of any that could be given. And the conditions present in the case of most elementary schools,—the herding together for hours at a time of numerous children, many of them coming from squalid, insanitary, over-crowded homes situated in disease-haunted districts, unused to habits of cleanliness, and insufficiently nourished—are peculiarly adapted to the realisation of such results. As the first step towards lowering the disease and death-rates in such neighbourhoods, and one whereby the temporary closure of the school with all its attendant loss and drawbacks might often be avoided, and as a means of early getting at the starting point of a potential epidemic in the home or homes of the children first attacked, the prompt recognition of cases of infectious illness is a matter of the first importance. Again, less fatal than the exanthemata, but even more embarrassing because so comparatively frequent and so commonly neglected, are those contagious diseases of the skin, for instance, which are to be found so often and which spread so

easily in schools of this class. What, for example, are the statistics of ringworm as it occurs in the Board Schools of London; and, if we admit the existence of this malady in any given case to be in itself an indication of ill-health, what further conclusion does its frequency imply? How many of the 330,000 children now on the London register are "dullards," simply because they are sickening with some form of specific illness, or poisoned by insanitary home surroundings, starved for lack of both food and air, or unwritten martyrs to imperfections of sight or of hearing? How many of them at the present moment are not merely in danger as regards their own bodily health, but centres of dangerous infection to all the homes represented by their fellow scholars?

To such questions—on which even the Inspectors have unanimously agreed to differ—it is utterly unreasonable to demand from the "judgment of teachers" an answer which must be prompt and reliable in order to be of value, as each case presents itself for consideration. A medical officer appointed to, say, the four or five thousand children attending the schools within his district, would serve as the authority to which the teacher could, and would be expected to, appeal from his or her own suspicions or belief. By such means individual cases of over-pressure could be stopped in time, and the cause of trouble—the point where the shoe pinched—enquired into and set right; epidemics would be oftener stamped out, not from the schools only, but in the homes from which the schools are filled, and the average level of general health, and with it the permanent value of the educational work accomplished, would be proportionately raised. The medical officer should also have the right of visiting his schools when and at such hours as he might think fit from time to time. The post would not be an arduous one, and would demand little more than the time required for the diagnosis of the cases submitted for opinion; the details of treatment devolving on the District Medical Officer, in conjunction with the Medical Officer of Health in cases of infectious disease. Under these circumstances, the salary attached to such a post might be moderate without being unremunerative. It is only too certain that any proposed addition to the expenses of School Board administration would encounter opposition. In this instance the cost need not be great, and would be no measure of the advantages secured. It has been well said that education means to the children of the poor more than it does to those of the rich. That is all the more reason that care should be exercised in the process. Amidst all the agitation on the subject two facts stand out very plainly—the country is committed to a system of compulsory education, and the country will have to pay for it. If future generations are to reap an adequate return, we must use a watchful diligence that part of the price be not paid in such a deterioration of physical and mental vitality as would go far to neutralise the blessings of an otherwise priceless boon.

Iodoform Collodion.—An iodoform collodion is well spoken of for wounds in an exposed situation. It consists of iodoform 10 parts, and collodion 90 parts. To be applied with a camel's hair pencil, the edges of the wound being held together until it dries.

ESSAYS ON MEDICAL CLASSICS.

I.—INTRODUCTORY ARTICLE.

Among the immense number of books, manuals, monographs and periodicals that are daily produced for the enlightenment of medical students and practitioners, the standard works of bygone times are apt, unfortunately, to be overlooked and forgotten. And yet if it should be their fate to become totally neglected, we should suffer a serious loss, for many of them are worthy to live and flourish for ages, some few perhaps for as long as medical science shall be studied, for they have that within them which keeps them alive and fresh, and capable of producing impressions which no quantity of common literature can possibly excite. What it is that constitutes this superiority it is impossible to define, or to do more than indicate. It may sound contradictory to say that most of the additions that are constantly being made to the sum of our knowledge do not constitute a real increase of knowledge, yet in one sense this is true, for we may be "ever learning and never able to come to a knowledge of the truth." Whilst we hunger after facts and fractions of facts, and in a measure satisfy our hunger, we may not be acquiring therewith a corresponding degree of insight to realise their significance, or of comprehension to arrange and understand them. And even while we are getting, we may be forgetting equally. Bacon said that medical science made no progress whatever, but that all movement was in a circle, returning again and again to the starting point. This is rather an unjust, though perhaps not altogether unreasonable, criticism; at any rate it is not likely to obtain acceptance nowadays. But if we investigate the matter closely, we shall find that onward steps in medicine have not been always made by means of accidental discoveries, whether small or great, but by the occasional appearance of a genius who has devoted the power he possessed to the investigation and more perfect comprehension of what was previously only vague and wrongly understood, and whose merit it has been not so much to gain for us increase of territory, as to throw increase of light upon what was already in our possession. The writings of such men must ever remain of value as records of what they have done, and as lights and guides for the future. It is this species of writing that retains its freshness in spite of the lapse of years, and deserves to live and to be repeatedly studied. It constitutes what De Quincey called the "literature of power," in contrast to the mere "literature of knowledge." Its office is to inspire, animate and suggest ideas; not merely to fill the mind, but to prepare it for the reception and retention of experience; to put us in the way to observe and attain a broader view and better apprehension of the things we see, and to encourage a habit of reflection, which is essential, though it should not be predominant, in medical pursuits; and lastly, to serve as an example of the right method to pursue in our enquiries. We do not for a moment wish to imply that all old writing is

of equal value, or that all new writings are equally ephemeral. In former times, undoubtedly, there was much ephemeral literature also, which has long ago fallen out of sight and memory; and there are we hope books a-making nowadays which will deserve to go down to posterity side by side with the classics that have come down to us. Our present business is, however, with the latter.

The old authors are sometimes taunted with being "metaphysical," but no system of philosophy can exclude that which lies beyond the limits of the senses; and inasmuch as it is vain to regard medicine as an exact or "positive" science, and as it was, is and must be inextricably involved in a large proportion of mystery, it must be admitted that a reference to metaphysics need not be out of place, and it may even be that the older form may be better suited to the humour of the subject than the new. Further, the old language is thought to be vague and unmeaning: on the contrary, it is for its purpose the best possible. For the materialistic terms of the exact sciences are too often inapplicable and misleading, a metaphorical mode of relation often approaching nearest to the truth. We should simply be acknowledging our own dulness if we assumed that the older authors intended their phrases and comparisons to be taken as literally true, or as more than tentative and provisionally useful. Although we depend more than formerly on special instruction and acquisition in separate departments, yet the end served by the higher class of literature (though of course books are not meant to replace, but only to assist experience) can never become antiquated, and a familiarity with it aids us in the appreciation of what is good amongst the new. Several circumstances tend to hinder the completeness of medical knowledge at the present time: there is the universal taste for "minute philosophy" in all branches of science, partly aided by the number of departments into which practice has been broken up, and each of which may be conducted by routine on a certain fashionable pattern; then there is the excessive attention paid to the subsidiary sciences—physiology, chemistry, morbid anatomy, &c.—or rather to the theories arising from them; which, instead of being merely subordinate to the main ends of medicine, are apt to be regarded as ends in themselves, so much so that physiology has almost become divorced from medicine, and pathology bids fair to be the same. All these errors were seen and avoided by the great men of the past, who kept their faces turned steadily to the one great end for which the profession exists, and thereby attained a depth of knowledge which is unchanged by passing customs and fashions. For these reasons we think that the greatest works which have been created should be preserved and kept out of obscurity, and that they should still be used to discipline and strengthen the mind. Whether read seriously or out of curiosity they are interesting in affording a comparison between the present and the past. We propose in future articles to briefly examine a few of the works which have made the greatest mark in our medical literature, and which, in spite of the number and multiplicity of their successors, have stood the tests both of time and of comparison.

N. H.

REVIEWS AND NOTICES OF BOOKS.

Handbuch für Madeira; von Professor Dr. Paul Langerhaus. Berlin: August Hirschwald, 1884. Sm. 8vo., pp. 206.—Whether there is anything in the climate of Madeira which acts as a direct incentive to the making of books we cannot say, but the fact remains that few, if any, places have been so much written upon and be-handbooked. Few people, we fear, have read that earliest and quaintest of all the monographs of the island—Fructuoso's *Sandades da terra*, from which so many later writers have borrowed their information, but almost every visitor consults White's "Madeira," which, in spite of the date of the publication, still remains the best handbook in the English language. But in German, as far as we know, only two general accounts of the island are in circulation, those of Mittermaier and Dr. Schultze, both of which are somewhat out of date, and as a considerable number of *poitrinaires* of that nationality annually seek in Madeira a more genial climate than their own, the present work will doubtless be welcome to many. Many of the chapters, such as those on the history, geography, zoology, and like subjects, are necessarily more or less compilations from the works of former authors, but in his account of life in Funchal and directions to invalids, Dr. Langerhaus has allowed himself more scope, and some of his remarks should be laid to heart by those who in the presence of the constant summer of Madeira are too apt to forget that they are there for the sole purpose of getting well. In cautious mountain rides, where the patient seeks out the very variations in temperature which he came to the island to avoid; excessive exercise, and above all "that wretched lawn-tennis;" all these are justly condemned, but are nevertheless as much the rule as the exception, and a strong argument in favour of the advice that young people should not come out alone. In two chapters on the condition of the peasants and the mode of government, Dr. Langerhaus has striven to evoke an interest in subjects which are for the most part entirely ignored by the visitor. A knowledge of the value of *benefeitorias* and the exact working of the *metayer* system is perhaps not an absolute necessity for the healing of a diseased lung, but we venture to think that its acquirement is preferable to the *far niente* so characteristic of the climate which is not unfrequently accompanied by a state of depression to the last degree prejudicial to an invalid. The chapter on the meteorology of Funchal is carefully written and full of interest. It is most curious to note the variableness of the rainfall. Thus in 1867, no less than 50 inches were registered, while in the following year but 13 inches fell. The mean of the last ten years was found to be rather over 25 inches, but preceding observers have given the average rainfall as somewhat higher. The number of days on which rain falls averages between 70 and 80, but as few as 39 were registered in 1882. The mean, therefore, is greater than at Cairo or Algiers, but less than that of Pau or Palermo. But it should be borne in mind that even on the most rainy days there are almost always some hours when it is possible to go out, the rain having more of the character of violent April showers than of our continuous November drizzles. It is difficult to account for the loss of popularity from which Madeira has suffered and even now seems to be but slowly recovering. An unvarying temperature, most beautiful scenery, first rate hotels, and good English society combine to make it one of the best, if not the best of all the known health resorts. Almost everyone who has written on it has sung its praises, and Dr. Langerhaus is no exception. But on one point he has done it a most cruel injustice. "The climate," he says, "is unquestionably windy." No more misleading assertion could possibly have been made, unless it is intended to refer to the island as a whole. The light land and sea-breezes that daily occur would not be characterised as wind at all by an Englishman, while from all northern winds Funchal is completely sheltered by the high mountain range in the centre of the island. The chief climatological characteristics of the city are the extreme evenness of the temperature, and the

absence of dust and wind. It seems hard that one of these advantages should be called in question by one who in other ways has nothing but words of praise for the beautiful Atlantic island.

Intestinal Obstruction; by H. O. Thomas, M.R.C.S. *Abdominal Hernia;* by Rushton Parker, F.R.C.S. London: H. K. Lewis, 1883.—The author of this book, better known to the profession as the inventor of the splint for hip-joint disease which bears his name, believes that the usual treatment of intestinal obstruction is faulty, chiefly by reason of the complete lack of any guiding principle. The first eighty-two pages are devoted to a review of the literature of the subject, in which the author fairly makes out his case. In Chapter IV. we get an insight into Mr. Thomas's own views; they may be summed up thus—Costiveness, constipation or the retardation in the progress of the intestinal contents is an infinitesimal degree of obstruction, and "when we have arrived at a correct knowledge of the natural method of resolution in this trifling ailment, we shall have grasped the true principles for treating obstructions in general." Constipation works its own cure by altering the proportion between the solids consumed, and the liquids imbibed—"the imbibition of liquids being increased by thirst, and the consumption of solids being decreased from loss of appetite, the two prominent signs of genuine constipation." Dr. Thomas has been led to these views by seeing how harmless constipation may be when care in diet is exercised, and hence he considers the selection and restriction of diet as all-important in the treatmont of all forms of obstruction. "Food can be restricted in quantity, and selected in quality, without seriously lessening the sufferer's stamina." "The vitality is economised by rest in bed; protected by warm clothing and the soothing action of medicine, he cannot starve within the period usually assigned to the disease." The dangers and ill effects of purgatives are well described. The action of belladonna, and its value in obstruction, are discussed from a novel stand-point. The chapter on Sedatives is equally interesting, and will be found to contain much that is not found in the classical works on obstruction. On the whole, we must fairly admit that Mr. Thomas's work is both original and suggestive, and we recommend its perusal as likely to prove useful to all surgeons who have much to do with cases of intestinal obstruction. Mr. Rushton Parker treats of abdominal hernia, and makes some very terse remarks on herniotomy and kindred subjects. As many of his cases have been published in our columns, we need not here again more particularly refer to them.

Phthisis: Its cause, nature, and treatment; by John Parkin, M.D. David Bogue, London. Pp. 113.—This monograph, dedicated to the Royal Academy of Medicine and Surgery, at Madrid, by one of its corresponding Fellows, is apparently intended by its author to furnish conclusive evidence of the worthlessness of the germ theory of disease. Koch's bacillus is nothing more or less than a mushroom which, under certain favourable circumstances, can be made to flourish in diseased human tissues. Tubercular tissues appear to suit it best, but it may be found in other morbid concretions at times. There are several forms of fungus, however, to be found in the very same places. Why, therefore, should it be assumed that Koch's bacillus alone is to blame for the conditions which their presence entails? These micro-organisms get into the body by way of the mouth, and ought to set up disease in proportion to their number and extent of concentration, and yet the Kalmucks and other races in uncivilised regions devour countless myriads of these noxious parasites and seem to enjoy the best of health! Having disposed of Koch and his theories by these and other equally cogent arguments, the writer states his own conviction that the true cause of consumption is "malaria." From examination of the statistics given by Louis and other authorities, he finds it "very difficult to understand how hereditary predisposition can exert any influence in the production of phthisis." The real exciting cause of the disease is the introduction of the poison into the blood. The different forms of carbon, and particularly the gaseous form, have the property of neutralising the poison termed malaria. Hence carbonic acid gas is the most appropriate remedy when the air passages are the seat of malarial disease. Dr. Parkin's views upon some of these points have been held by him for 50 years. While bowing with respect for theories of so long standing, we cannot suppress a feeling of regret that they should be thus compelled to appear in their old age, unsupported by a single prop of fact to protect them from the shattering force of the evidence afforded by the experimental pathology of to-day.

ABSTRACTS AND EXTRACTS.

PROFESSOR CHARCOT ON A CASE OF HYSTERO-EPILEPSY.

The following lecture, delivered at the *Salpétrière*, is reported in the *Gazette des Hôpitaux*, September 9th. I wish to show you to-day, Professor Charcot observed, a case of the greatest interest in relation to diagnosis and prognosis, and one which is only exceptionally met with in practice. It is that of a young woman, long since the subject of hystero-epilepsy, the attacks of which are characterised by the four ordinary phases—the epileptoid phase, the phase of contortions, the passional phase, and the phase of delirium. But what is specially remarkable in her case is the epileptiform or epileptoid attacks which succeed each other in series of paroxysms, lasting for several days and formidable by their number, so that one is led to ask whether these attacks are a transformation of hysteria or whether they are a complication of it—a fact which it is of the highest importance to clearly distinguish, the prognosis varying so much in its gravity. For, in fact, if we have to do with the epileptiform disease, whatever may be the number and duration of the attacks, we are able to say that they will terminate in a favourable manner; while, if we are in the presence of true epilepsy, with such a number and duration of attacks, the prognosis is that death may speedily ensue. The attacks, or rather each series of attacks, in this patient is separated by a more or less long interval, and each of them commences with the tonic phase to which succeeds the clonic phase, and then comes resolution of the limbs and the stertor, each being preceded by a kind of small initial cry. The clonic movements are especially marked on the right side, and neither ovarian pressure, nor frictions along the spinal region exert any influence on the attacks. This woman never bites her tongue, very rarely foams at the mouth, and never wets the bed during the attacks. Her paroxysms are grouped in series of thirty or forty, and sometimes even more, attacks without any interval, and terminating in quite a peculiar mode of waking up. This is, indeed, characterised, so to say, by the passional phase, the woman, bounding to the foot of the bed and hiding her head for some seconds under the bedclothes, returns at once to herself feeling more or less fatigued and complaining of being too hot—and that is all. After a few instants she regains a state of health which is nearly normal. These epileptiform crises present a most striking contrast to true epileptic fits, which always terminate in deep coma. These crises to which the patient is a prey date from the 4th September, when she had 113 attacks, and next day these increased in number to 230 in five series, while on the 4th there were 380 in nine series. Next day there were 700 odd in the twenty-four hours. The present crisis, of which you are witnesses, consists of 43 attacks without any interval between them. What is remarkable is not only the epileptiform character of the attacks, but also their disposition in series which are always preceded, not by an *aura*, but simply by a state of discomfort, marked by a little headache, some troublesome beating in the temples and a kind of hissing in the ears, the attack immediately succeeding. In this case, then, we have not to do with epilepsy but with a transformed hystero-epilepsy, a condition of disease which I have designated as *hystéro-*

épileptique épileptiforme. The diagnosis is here of great importanee, for while in epilepsy attaeks of a like duration eannot persist beyond a few days without a fatal termination, in this form of disease the issue is always favourable. The thermometer is an exeellent means of diagnosis; for, while in hystero-epilepsy we do not find the temperature exceeding 38·2° or 38·4° C, in true epilepsy, even from the second day, it reaehes rapidly 39° and then 40°, 41°, or even 42° on the following days—so great is the differenee between the two affeetions. It is now seven months sinee this woman was seized with these erises, the first one lasting fourteen days, during whieh the total number of the attaeks amounted to 4,516, when the crisis eame absolutely to an end. The seeond erisis had only continued four days when this leeture was delivered. All means of treatment have been tried without any effect, bromide of potassium in doses of from 12 to 14 grammes proving as useless as the rest. Professor Chareot has only met with three other eases, all exaetly resembling the one just described.

GYNÆCOLOGY AND OBSTETRICS.

The Spiny Pelvis and its Obstetric Consequences.—Dr. M. Hofmeier eontributes to a reeent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* (Band X., Heft. 1), an artiele on the "Staehelbeeken," a word which we have translated by its literal equivalent, the "spiny pelvis." It means a pelvis which has projeeting into its eavity, bony spines, nodules or edges, and was first deseribed by Kilian. These projections are found most eommonly at the insertion of the psoas parvus, where there is sometimes a tuberele; along the pubie crest, which is oeeasionally a sharp ridge, or a spine; or along the saero-iliae articulations or pubie symphysis, where there are sometimes little bony outgrowths. Dr. Hofmeier now deseribes a ease of labour in which deformity of this kind was present. There was synostosis of the bodies of the last lumbar and first saeral vertebræ. From the saeral promontory, below the synostosis, a sharp ridge of bone jutted out towards the symphysis, forming with the saerum an angle opening below. It narrowed the eonjugate to three-and-a-half inches. The patient's first labour had been followed by the formation of a vesico-vaginal fistula. In the second, extraetion of the ehild was with difficulty effected by turning, although premature labour had been brought on at the end of the thirty-sixth week. Death took place two-and-a-half hours after delivery, from eelampsia. It occurred to Dr. Hofmeier that it was remarkable, seeing that the bony ridge was behind, that the anterior part of the genital canal should have been injured instead of the posterior. Perforation of the posterior part of the vagina or eervix uteri, by pressure, is an aeeident of parturition of whieh little notice has been taken by systematie writers, Spiegelberg being almost the only writer who has given a detailed description of it. Dr. Hofmeier therefore examined carefully the posterior wall of the uterus and vagina, and found a eieatrix, with adhesions in Douglas's poueh, about half an ineh below the external os, a point just opposite to the site of the vesieo-vaginal fistula. He also relates another ease in his own practice, in whieh perforation of Douglas's poueh oeeurred, the patient reeovering. The practical eonelusion he draws is that perforation of the genital canal on its posterior surface is probably mueh more frequent than is thought; but that commonly adhesive inflammation is set up, by which the injured part is shut off from the general peritonæal eavity, and henee the symptoms are slight, soon pass off, and therefore are often unnoticed.

Ovarian Disease Complicated with Pregnancy—Ovariotomy — Porro's Operation — Recovery.—A successful ease of this nature has just been placed on record by Mr. George Fortescue in the *Australian Medical Gazette* for May. The patient was an unmarried girl, aged 21, who had suffered from pain in the pelvic region for two years, and had for some months noticed a swelling in the lower part of the abdomen. She eame under observation in September, 1883, and menstruation had then been absent a month. The physieal signs indicated an ovarian tumour springing from the right ovary, and a preliminary tapping gave some thin eolloid semi-fluid material, eontaining par-albumen. After the tapping, a smaller eyst could be reeognised extending to the left of the other one and upwards. In January the operation of ovariotomy was determined upon. The possibility of eoineident pregnancy was borne in mind, but seemed to be negatived after a eareful examination from that point of view. When the abdominal seetion was made, two eysts eame in sight; the larger one was punetured, and a large quantity of dark eoloured semi-fluid material evaeuated, and as the other cyst was in the way of the withdrawal of this one, it too was punctured, and a watery fluid eseaped. On withdrawing the trocar, however, there was tolerably free hæmorrhage. This was stopped by the pressure of the foreeps, and a more complete examination diselosed the faet that this second tumour was the pregnant uterus. The fœtus, placenta and membranes having been removed, it was deeided, seeing the somewhat rough handling the uterus had received, that it should be removed. This was aeeordingly done, the right ovary being removed with it. The peritonæal edges of the incision were applied closely round the pediele but were not sewn to it; a drainage tube was put in, and the wound dressed antiseptically. The antiseptie spray was not used, and the operation lasted about an hour and a half. The patient made an uninterrupted recovery.

Super-alimentation in the Vomiting of Pregnancy.—In the *New York Medical Journal*, Dr. Millard has detailed the ease of a primipara three-and-a-half months pregnant. Vomiting had been exeessive for two months, there was profound exhaustion, and the general eondition was so serious that the induetion of premature labour appeared advisable. Other modes of nourishment having failed, the use of Debove's tube and the introduetion of the prepared beef-powder was tried as a last resouree. At the end of fifteen days so mueh improvement had been gained that ordinary diet eould be resumed; in another three weeks the patient eould take enough food to maintain her strength and to go about the room. She has sinee remained quite free from nausea.

The Treatment of Retro-Uterine Hæmatocele.—In a paper published in a recent number of the *Archiv für Gynäkologie*, Dr. Paul Zweifel advoeates more frequent interferenee with these effusions than has hitherto been eonsidered good praetiee. It seems to us, however, that the faets he adduees do not strongly, if at all, support his eontention. He advises ineision per vaginam, under antiseptie preeautions, followed by frequent washing out of the eavity in whieh the blood has been eontained. He relates four eases of his own in whieh this praetice was followed; three got well and one died. He quotes from other sourees 24 eases treated by incision per vaginam, of which five died. In two of these eases death occurred by sudden eollapse following the washing out which Dr. Zweifel reeommends. As he thinks the washing out was not done in these eases in a proper manner, our author eliminates these two, and reekons, including his own, four deaths out of 26 eases, or a mortality of 15·3 per eent. In our view, however, the two omitted cases ought by no means to be lost sight of, for they prove that the washing out of sueh eavities is not a thing to be done with perfect eonfidenee in its safety. Our own impression is that most cases do just as well without it. Dr. Zweifel then adduces a eolleetion of 66 cases treated by puneture, with 10 deaths, or 15·1 per eent.: a result much the same as that gained by the praetiee of ineision. Bearing in mind the fatal eases of injeetion, puneture seems to be the safer praetiee. Lastly, Dr. Zweifel gives for comparison a eolleetion of 129 published eases treated on the expectant plan, with a mortality of 18·4 per eent. But it must be remembered that published eases availablo for comparison eontain an undue proportion of fatal eases, and of eases in whieh the hæmatocele discharged into a mucous tract; for it is only in such eases that (independently of treatment) the diagnosis is eertain. It is familiar to every gynæeologist that small pelvie tumours, aecompanied with the history and having the signs of hæmatoeele, are very common, and generally get soon well, the mortality among such cases (of

which the diagnosis, although not scientifically certain, is yet as sure as that of the cases calling for operation) being nothing like 18 per cent. We regard Dr. Zweifel's figures, combined with daily experience, as confirming the old rule, not to meddle with hæmatoceles unless urgent symptoms, either of pressure or pyrexia, are present. We agree with him that, if we do anything at all, a free incision is best; but the subsequent washing out adds a new source of danger, and, if free exit for discharge be maintained by a drainage tube, is not required. If an india-rubber tube will not keep open, a glass one can be used.

Scarlet Fever in Pregnancy.—Dr. Leale terminates a paper on this subject with the following conclusions:—(1) Scarlet fever may attack the fœtus in utero. (2) A large proportion of children born with scarlet fever recover. (3) Scarlet fever of the new-born child has the same manifestations as in later life. (4) It may attack the woman during pregnancy and also immediately after child-birth. (5) It is exceedingly fatal during pregnancy and parturition. (6) It rarely if ever attacks the parturient woman if she has had it previously. (7) It causes death by coma, exhaustion, or convulsions. (8) Being a self-limited disease, it is best treated by relieving dangerous symptoms, and in accordance with the rules of hygiene. (9) It only exceptionally occurs during the ages that women bear children, therefore the proportion of those liable to contract the disease during pregnancy and child-birth must necessarily be small. (10) Scarlet fever and septicæmia are distinct diseases, being unlike in many respects.—*Philadelphia Medical News.*

"Uterine Milk."—A recent number of the *Archiv für Gynäkologie* (Bd. xxii., Heft. 2), contains an article by Dr. Werth, of Kiel, on the so-called "uterine milk." It is chiefly a criticism of the observations of Hoffmann, which we noticed at the time of their publication (*Medical Times and Gazette*, 1883, vol. ii., p. 608). The appearances described by Hoffmann are, according to Werth, *post-mortem* phenomena. When he examined placentæ in the manner recommended by Hoffmann, some hours after birth, he found the account given by Hoffmann was quite accurate. But when he examined them in the same way *immediately* after birth, he did not find any of the bodies which Hoffmann calls "uterine milk globules." He, therefore, believes that these are of *post-mortem* formation. (Hoffmann, we may mention, in speaking of a "fresh" placenta, includes under that term one four hours old). Werth also disputes Hoffmann's claim to novelty, for he says that the fluid Hoffmann claims to have discovered had been extracted from the placenta by Klebs, in a way practically the same; and that the globules to which Hoffmann attaches so much importance had been already described by Langhans. He regards Hoffmann's view that these globules come from decidual cells as incorrect, because the decidua, after separation of the placenta, does not form so large a part of it as to be able to furnish the fluid and globules in such quantity. He believes he has ascertained their mode of production. They are formed in the epithelial cells which cover the villi, and they are extruded into the intervillal spaces by the bursting of these cells. He has seen the globules in process of extrusion, and the traces of rupture in the epithelial cells. They are, therefore, a *post-mortem* product of dead epithelial cells. Dr. Werth proclaims himself as in agreement with Kölliker, Langhans, and Leopold, in thinking that the intervillal spaces contain nothing else than maternal blood. Hoffmann's uterine milk he thinks is blood serum, mixed with the products of dead epithelium.

Dermoid Cyst of the Ovary with Long Pedicle.—The patient had an obscure mental and nervous affection following child-birth which had kept her in bed for three years, during which time there had been frequent retention of urine, necessitating the use of the catheter. On many such occasions a tumour had been felt, at times resting upon the bladder, at others in one or other lumbar region; it was repeatedly pushed up almost to the ribs, where it was for the moment suspected to be a floating kidney; for long periods it could not be found at all. The patient subsequently died of brain lesion. At the autopsy, the floating tumour resolved itself into a dermoid cyst of the left ovary, as large as the fist, with a pedicle nearly four inches long which allowed the tumour to be put in almost any part of the abdomino-pelvic cavity. It contained a wad of hair embedded in a mass of solidified sebaceous matter, and four small incisor teeth attached to an alveolar process connected with the wall of the cyst.—*Boston Medical and Surgical Journal*, August 7.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

Tuesday, November 4th, 1884.

J. W. Hulke, F.R.S., President, in the Chair.

Coarctation of the Aorta.

Dr. Hale White showed an example of this remarkable deformity. The specimen was taken from a man, aged 46, who during life had had a systolic murmur over the heart, and œdema of the legs. The aorta *post-mortem* was found so constricted opposite the site of the ductus arteriosus that it could only admit an ordinary probe. It was about the size of the subclavian beyond this, and the thoracic and abdominal aorta were small. The superior intercostal was large and convoluted, anastomosing with the first intercostal also very large. The posterior scapular branches anastomosed with the second, third and fourth intercostal arteries. The internal mammary arteries anastomosed with the aortic intercostal, the phrenic, and by their superior epigastric branches with the deep epigastric arteries. There were other minor abnormalities. The deformity was due to a faulty development of the part of the fourth left branchial arch, extending from the left subclavian beyond the ductus arteriosus. Both sides of the heart were much hypertrophied, and there was a patch of fibroid disease near the apex.

Caseous Pneumonia of the Entire Lung.

Drs. Lanchester and Hobson showed the lung and microscopical sections from this case. The patient died seventeen weeks after an acute attack of chest disease. The symptoms and physical signs were those of an empyema of the left side, including marked bulging and displacement of the heart to the right. Upon this diagnosis the chest was punctured in several places, and also incised, but with negative result. A drainage tube was, however, inserted into the wound, which continued to discharge sero-pus to the end. A spontaneous opening formed subsequently at the seat of one of the punctures in the axilla, and purulent fluid continuously drained through this. The surgical treatment was strictly antiseptic. A few days before death symptoms of tubercular meningitis came on. After death there was found to be no pleuritic effusion, but the whole of the left lung was solid, distended, and filled with dry, caseous material which, however, had softened down and left a cavity in the superficial parts of the upper lobe corresponding to the axillary opening. The artificial opening simply led into a blind channel in the lower lobe. The right lung was studded with miliary tubercles. There were also tubercles in the liver, which was fatty, in the kidneys and spleen. There were tubercular ulcers in the small intestines. The microscopical appearances in the affected lung showed thickening of pleura, a decided but not uniform increase of the alveolar walls, and the alveoli stuffed with inflammatory products in which epithelial elements could only occasionally be traced. As far as the experience of the authors went this case was unique. The sign which of all others was regarded by writers as diagnostic of *effusion* as distinct from *pneumonia*, viz., displacement of the heart and bulging of the chest walls, was present. The uniform consolidation and caseation of the entire lung, with an absence of a similar process on the opposite side, was also remarkable. The only cases which seemed at all parallel were those that have been described by Virchow, Wagner

and others as syphilitic pneumonia in infants. The possibility of syphilis in their case seemed out of the question.

Dr. Goodhart had seen a similar case. It was mistaken for empyema and tapped. The whole of the left lung was converted into a solid mass and there were tubercles. The disease was not rare in partial form; a solid cheesy mass was not uncommon in middle lobe of right lung. It certainly was not syphilitic, perhaps it was a diffused lymphosarcoma.

Dr. Duckworth said that clinically and pathologically such cases were rare. Caseous invasion from the bronchial glands was not uncommon, but in this case the disease enlarged the lung and the chest wall. The clinical history was one of tuberculosis, he thought, a good account of the microscopical appearances.

Dr. Percy Kidd thought he had seen several similar cases: the question of tuberculosis might be settled by an examination for bacilli.

Mr. Butlin recalled two or three cases tapped without result, in which the lung was solid.

Dr. Angel Money had seen two cases.

Dr. West said that a mistake between solid lung and empyema was almost unavoidable. His idea was that the tubes were occluded by secretion, or they might be pressed upon by new growth, and the consolidation be thus produced. He thought that the naked eye appearances were those of sarcoma.

Dr. Lanchester said that they could exclude syphilis. The bulging and displacement of the heart was most unusual. The structure was very hard; notwithstanding the treatment, the lung did not break down, which was unlike caseous pneumonia. He would be glad for a careful microscopical examination to be made. Specimen referred to the Morbid Growths Committee.

Epithelioma of the Left Upper Jaw.

Mr. Barker exhibited a specimen of this disease removed four years previously, the patient having been exhibited to the society in May, and having then no recurrence. The whole of the upper jaw had been removed, with the exception of the orbital plate and corresponding portion of the soft palate. The tumour was extensive but limited, and did not involve the glands. The growth was found after removal to be adenoid in structure, the groundwork consisted of a well-developed smooth fibroid tissue, in which large groups of cells were arranged like those of racemose and tubular glands in places. In the centre of these groups was a lumen, apparently the result of mucous degeneration. The cells were arranged without any regularity, they were smaller than ordinary glandular epitheliomata. The growth appeared to be identical with the multilocular epitheliomata described by Mr. Eve. The essential cells were somewhat smaller than those of epithelioma, but he nevertheless would refer them to that class.

Mr. Butlin thought that Mr. Barker had confused two diseases. This he believed was a carcinoma, or perhaps hardly passed into the stage of tumour. He had shown to the Society cases of epithelioma, but in all such, the case had shown great malignancy, but very little external swelling.

Mr. Cripps would call it a true adenoid growth. There were small spaces lined by epithelium; they were probably formed from a papillomatous growth with single layers of epithelium. In section it gave the appearance of cavities lined by epithelium. It was possibly innocent; that would depend on its mode of growth, and whether it was encapsulated.

The President asked if the lumina were as distinct at the outer margin as in the centre.

Mr. Barker believed the lumina were equally distinct throughout. The speakers had totally differed, and he suggested that the specimen should be referred to the Morbid Growths Committee.

Aneurysms of the Heart.

Dr. Percy Kidd exhibited four cases of this affection. The first was an aneurysm of the undefended space, obviously of congenital origin, and due to imperfect development of the membranous part of the ventricular septum. The dilatation of one sinus of valsalva which was present was doubtless the result of atheroma. The second and third cases illustrated the influence of the friction of pendulous vegetations against the cardiac walls, the resulting erosion of the endocardium being the starting point of an aneurysmal bulging. In both these cases there had been rheumatic fever, and great pain in the præcordial region was a prominent symptom during life. In the fourth case the aortic valves and aneurysm were the seat of a marked fibroid change, and there were no traces of endocarditis. The patient had frequently had chronic rheumatism, but it was doubtful whether he had had acute rheumatism. It was well known that aneurysm of the heart was dependent upon a gradual yielding of some diseased part of its walls to the intra-cardiac blood pressure. Three of his four cases were instances of aneurysm resulting from endocarditis, acute or chronic, of rheumatic origin, and all four patients were males.

Dr. Angel Money referred to a girl aged 5, who had died with febrile symptoms and a loud heart murmur. There was an aneurysm bulging into the right ventricle and opening up the laminæ of one of the flaps of the tricuspid valve. There was a gumma of the brain which probably caused the idiocy, and he thought that the heart affection might have been syphilitic.

Lymphosarcoma of the Liver.

Dr. Howard Tooth showed specimens of this disease taken from the body of a female child, aged 5, who had been losing flesh for six months and had suffered from diarrhœa and epistaxis. There was no history of jaundice. At the *post-mortem*, tubercles were found in the lungs. The spleen and kidneys were natural. The liver was uniformly enlarged, very pale and smooth on surface, weighing 48 ounces. Microscopically it was infiltrated with small round cells, more marked towards centre than at periphery. In the central part there was a good deal of fibrous tissue. The condition was uncommon, especially in so young a child. It might be taken for leukæmic enlargement, but there was no enlargement of spleen or lymphatics. The amount of connective tissue was small, and there was no history of jaundice or ascites, so that cirrhosis was excluded.

Paraplegia and Ulceration of the Bowels.

Dr. Theodore Acland brought forward two cases of this association. Both patients had had syphilis; in both the symptoms resembled simple softening of the cord, and ran a rapid course, one ending in three weeks, the other in a month. In both ulceration had been mainly confined to those parts of the bowel which had been most distended, in one occurring in the small intestine, in the other in the stomach and colon. The question naturally arose, whether the nervous lesion had any causal relation to the intestinal lesion. Tubercular, syphilitic, cancerous and typhoid ulceration were excluded. The appearances were those of simple loss of substance rather than of an inflammatory change. The temperature was never above 100°, and was mostly subnormal. The question was then, whether the ulceration was due to simple distension or whether it was the result of loss of nerve power and analogous to a bed-sore, due therefore to pressure in a viscus whose distension resulted from lesion of the nervous system. In support of this view it was shown that the lesion of the cord was in the dorsal region, which suggested a probable implication of the roots of the thoracic ganglia whence arose the splanchnic nerves.

Card Specimens.

Dr. Turner. Hæmatoma of the dura mater. Endocarditis with ulceration.

Mr. Victor Horsley exhibited the body of a monkey, showing the effect of the removal of the thyroid. There was commencing atrophy of the cerebral convolution, and atrophy of the right ventricle. There was a gelatinous, opaque condition of the connective tissue throughout the body, and swelling of the salivary glands.

SOCIETY OF PHYSICIANS OF VIENNA.[1]

FRIDAY, OCTOBER 17TH, 1884.

PROFESSOR V. ARLT in the Chair.

Case of Universal Favus.

PROFESSOR KAPOSI showed a unique case of "Favus universalis." He had never seen nor heard of such an interesting development of this affection. When the patient first came to him three weeks ago, his extremities and the greater part of his trunk were covered with confluent yellow points of the size of a pin's head, while his head presented large favus crusts. In the short interval that had since elapsed, the disease had spread extensively, the crusts had become very large, and new ones were constantly forming. They now covered the scalp and face, the trunk, and the extensor aspects of the extremities. The patient could only move his limbs with pain and difficulty.

Cocaine as an Anæsthetic in Ophthalmic Practice.

Dr. CHARLES KOLLER read a communication on this subject. The anæsthetic influence which cocaine exerts when applied locally to the mucous membrane of the tongue led Dr. Koller to try its effect on the eye. After referring to the publications of Schroff, Anrep and Freud, he made several experiments on animals in Professor Stricker's laboratory, from which he found that two or three drops of a two per cent. aqueous solution of chloride of cocaine, introduced into the conjunctival sac, rendered the cornea and conjunctiva quite insensible. If he scratched with a needle, or even perforated the cornea of animals so treated, or passed a strong electrical current through it, or touched it with caustic, the animals felt no irritation at all. As to the duration of this anæsthesia, he could obtain no idea from his experiments on animals. He tried to find out if cocaine had also an influence on the inflamed cornea. He first produced keratitis in animals by introducing a foreign body into the eye, and he found that the cocaine also acted as a local anæsthetic under these conditions. The success of these experiments on animals led him to try the effect of cocaine on the human eye, and he had obtained the following results:—(1) One or two minutes after introducing a few drops of a two per cent. solution of cocaine chloride, the cornea and conjunctiva were rendered completely insensible; he could seize the conjunctiva with hooked tweezers and exert considerable pressure on the cornea and the patient felt nothing, nor were there any reflex movements. The anæsthesia lasted from seven to ten minutes, and disappeared gradually. (2) Simultaneously with the anæsthesia, considerable dilatation of the palpebral orifice occurred, which he explained by the absence of the sources of irritation which otherwise affect the cornea and conjunctiva. (3) The ocular and palpebral conjunctiva became anæmie. (4) Fifteen minutes after introduction, mydriasis set in. It was never present in any great degree; after an hour it decreased considerably, and totally disappeared some hours later. During this period the pupil re-acted quickly. (5) Paresis of accommodation set in together with the mydriasis, and also disappeared with it. (6) When the application of the above-mentioned solution of cocaine chloride was continued, and repeated every five minutes, the anæsthesia of the cornea lasted from fifteen to twenty minutes, and the deeper parts of the eyeball became anæsthetic, its sensibility being much diminished on pressure. (7) The application of cocaine never produced any signs of irritation. Dr. Koller had further made therapeutic experiments with cocaine in Professor v. Reuss' clinic, and found that it was a good anodyne in diseases of the eye which were associated with pain. He obtained good results with it in various diseases of the cornea and conjunctiva, which were associated with pain and photophobia, as *e.g.*, syndesmitis lymphatica and erosions of the cornea; it was also of use in cases in which the touching of the eyelids with nitrate of silver would cause severe pain. He recommended the application of cocaine in cases of iritis and iridocyclisis where the contraction of the vessels must render good service. The application of cocaine as an anæsthetic in ophthalmic operations had excellent results in thirty cases of removal of foreign bodies from the cornea, in cases of tattooing cicatrices on the cornea, in two cases of operation for staphyloma in children, as well as in several iridectomies and operations for cataract. When the anæsthesia in these operations was produced according to the method which Koller had recommended, *i.e.*, with a five per cent. solution, the patients stated that they felt nothing of the corneo-scleral incision, while the seizing and excision of the iris caused them but little pain. In this respect he quoted an interesting case in which iridectomy was performed on a man who had suffered from "seclusio pupillæ," affecting both eyes; the solution was applied in the operation on one eye and omitted when the other eye was operated on a week later. The patient declared he felt no pain at all during the first operation, but his restlessness during the second operation rendered it difficult.

Dr. KOENIGSTEIN said that simultaneously with, but independently of, Dr. Koller he had made experiments with cocaine and as his results were much the same as those obtained by Dr. Koller, he would only mention those details which completed the communication of Dr. Koller or which varied from it on some points. He had begun his experiments towards the end of August last, at the suggestion of Dr. Freud and made them at first on himself, and the members of his family, and on his acquaintances, and subsequently on a considerable number of patients in the ward of Dr. Scholz in the General Hospital. A drop of a one per cent. solution of chloride of cocaine introduced into the eye caused a slight burning pain. A little later slight tension could be felt in both the eyelids; which induced him to rub the eye, and on this occasion he convinced himself that no reflexes were present on the touching of the conjunctiva and cornea, and further that they were insensible even on more violent manipulations. At the same time the palpebral opening grew wider, and the eyeball seemed to be protruded; in order to close the "cocainised" eye a greater effort had to be made than in the case of the normal one; all the ocular symptoms of "Basedow's disease" were present. The conjunctiva was exceedingly pale, the small vessels had disappeared, the larger ones were contracted. Ten minutes after the instillation a slight difference between the pupils was already noticeable; after twenty minutes the pupil was of medium size; it did not dilate any further, but presented reaction to strong light. The interference with accommodation was trifling. After about two hours the pupil contracted, and the palpebral cleft again became smaller, and after six hours all difference between the pupils had disappeared. Experiments with concentrated solutions gave more marked effects. The use of a ten per cent. solution of acid reaction was attended with no disagreeable effects except a very intense burning pain. If cocaine chloride were employed in the solid form, the effects were most intense, and it was interesting to observe that even the surface of the lids lost their sensitiveness. The susceptibility of individuals to this alkaloid varied considerably; moreover, when cocaine was repeatedly applied, the eye seemed to become more tolerant of it. The experiments on animals, on frogs, rabbits, dogs, pigeons and fowls, gave similar results. The conjunctiva and cornea were insensible to injuries and chemical irritants. Further experiments had been tried on curarised frogs as to the contraction of the vessels, which, by means of the ophthalmic micrometer, was found to occur in the tongue, whilst the contraction of the vessels of the intestine and the liver could be seen distinctly. Dr. Koenigstein believed he had also seen an effect from cocaine on the vessels of the human retina, but of this he could not speak with certainty. The indications for the use of cocaine in ophthalmic practice were obvious. It should be employed where operations had to be performed in the eye as in the removal of foreign bodies, and of granulations, &c. As an anodyne cocaine should always be tried when painful processes were going on in the eye, whether there were disease of the cornea, the conjunctiva, or of deeper parts of the eyeball. He (Dr. Koenigstein) had used it with considerable success in applying caustics to the cornea and conjunctiva, in painful erosions and phlyctenular and pustular

[1] Reported by our Vienna Correspondent.

processes, combined with blepharospasm and pain, also in a case of herpes zoster and kyklitis, and in supra-orbital neuralgia. In touching with caustics, cocaine diminished the pain for a short time, but according to the patient it was more severe afterwards. The power of cocaine in diminishing the blood supply was tried in one case of iritis; a strong solution was used and it was found that cocaine was as efficacious in this respect as atropin. The application of cocaine was found very useful in dilating the pupil, and slightly paralysing accommodation in examinations with the ophthalmoscope; the patient's sight was not impaired, and in this respect cocaine was superior to all other mydriatics. It might be suggested that cocaine acted through the peripheral nerves of sensation; the dilatation of the palpebral cleft, the protrusion of the eyeball, and the slight dilatation of the pupil, however, seemed to point to its acting through the sympathetic, on the irritation of which all the symptoms appeared as well as constriction of the vessels.

Professor v. Reuss confirmed the communications of Dr. Koller, as the experiments had been executed in his clinic. Their success was so striking that he would advise every oculist not to perform any operation without cocaine; but it must be applied exactly according to the method prescribed by Dr. Koller, for if this was not followed the patients suffered from pain. In the extraction of cataract cocaine proved so excellent that patients whom the speaker was afraid of operating upon were perfectly quiet and stated they felt no pain at all. He was quite convinced of the efficacy of cocaine; it might be that there existed here and there individual differences, but one was not entitled to condemn a medicament because now and then a patient felt pain on operation in spite of its employment. He also confirmed the observation as to the dilatation of the pupil and the paralysis of accommodation. There was another question which was exceedingly important from the practical stand-point. He wished to find out if cocaine could be applied as a mydriatic in glaucoma; but without any previous experiments he would have feared to employ it in such cases. The experiments had, however, shown that when myosis had been pushed to an extreme by the use of eserin, mydriasis did not occur after the introduction of a five per cent. solution of cocaine. The effect of the eserin was therefore not at all influenced by the cocaine; on the other hand, myosis occurred quickly after the introduction of eserin into a cocainised eye in which the pupil had been dilated. He would, therefore, venture to apply cocaine in a case of glaucoma.

Dr. Hock had also tried experiments with one per cent. solutions of cocaine, the results of which were very satisfactory.

HARVEIAN SOCIETY OF LONDON.

Thursday, October 15th, 1884.

G. P. Field, M.R.C.S., President, in the Chair.

Interstitial Keratitis.

Mr. Juler, in a paper on this subject, referred briefly to the well-known changes noticed in the tissue of the cornea, as a result of chronic inflammation, and dwelt upon the leading clinical features and upon the treatment of the affection. One eye was usually affected for two or three months before the disease extended to the other eye. Pain and photophobia were symptoms subject to much variations; photophobia, when present, generally pointed to the existence of superficial ulceration. Prognosis was favourable, the opacity ultimately clearing up completely, but the process of cure was slow. The systematic administration of grey powder and of tonics, and the local use of atropin were eminently successful. A congenital syphilitic taint could be traced in at least 90 per cent. of the cases, and, with this, marked anæmia was generally combined.

The President alluded to the frequency of interstitial keratitis in cases of diseases of the ear. In his experience girls were affected in a much higher proportion than boys.

Dr. James Thompson expressed his firm belief in the syphilitic nature of the affection and in its curability by mercury. Dr. Thompson called attention to a sign of congenital syphilis, never absent in these cases, and to which he had found no reference in medical literature. In syphilised children, instead of the clean frontal line formed by the healthy hair of the scalp, an irregular border of fine fluffy hair, about half an inch to one inch wide, is almost invariably present.

Mr. Hartridge referred to the persistence in the cornea (after apparently complete cure of the opacity) of fine lines or striæ due to the obliterated vessels of the "salmon-patch" of Hutchinson. A case was mentioned in which the keratitis was the outcome of acquired syphilis.

Dr. Buzzard wished to remind the Society that the great advances made in the pathology and in the treatment of the affection, were mainly due to Mr. Hutchinson's teaching. The syphilitic nature of the disease was no longer a matter of doubt and the propriety of a mild mercurial treatment could hardly be questioned.

Dr. Alderson gave the full details of a case which exemplified the insidious mode of onset sometimes observed; the patient recovered perfect vision under the administration of grey powder and quinine, with occasional purgatives.

Demonstration on the Mechanical Principles of Surgical Apparatus.

Mr. Noble Smith remarked that although the application of splints and their management in the treatment of ordinary fractures received a full share of attention in lectures and in text-books, the use of apparatus for orthopædic cases was seldom adequately dealt with, and the principles which ought to guide the surgeon in devising and in using such apparatus were almost entirely ignored. The student, left in ignorance of these matters, was obliged in after years to rely too much upon instrument makers, whose knowledge of surgery was necessarily incomplete. Mr. Noble Smith demonstrated by means of a lay figure the principles which he thought should be followed in applying a splint for hip-joint disease; he also explained, by means of diagrams, his views as to the successful use of apparatus in cases of diseased spine, of knock-knee, of bowed legs, and of other orthopædic affections.

Referring to some of the author's remarks, Dr. James Thompson stated that he had recently removed a plaster-jacket which had been worn for three years without any interruption. The skin presented no abrasions or marks of any kind, and the boy had felt comfortable throughout. There remained no trace of any spinal deformity.

Mr. R. Fitzroy Benham did not regard the model exhibited to be an accurate illustration of a diseased hip-joint. The pain stated to be produced by mere extension of the limb was not brought about by pressure of the fluid against the upper part of the acetabulum, but by contact of the opposed inflamed surfaces. He failed to see the difference between the apparatus exhibited, and the apparatus known as Thomas's splint. Mr. Benham did not consider a padded back-board to be the best means of support in Pott's disease, but preferred the poro-plastic jacket. Sayre's plaster-jacket, unless applied with great care, might be worse than useless. He did not agree with Mr. Noble Smith that in severe cases of genu valgum it was advisable to allow the patient to go about with walking instruments until the inner malleoli could be brought together by means of appropriate supports, rest, and above all, manipulation.

Acetum Opii.—This preparation is made of opium ℥ v, nutmeg ℥ i, sugar ℥ viii, and dilute acetic acid ℥ ji. It is the strongest liquid preparation of opium, viz., 75 grains to the ounce, or gr. j to ℥ vi ss. It is nearly free from the sickening smell of opium and less apt to nauseate. The nutmeg helps to prevent nausea, and there is almost complete absence of narcotine, the ingredient of opium which is most irritating to the stomach. In this the acetate equals deodorised opium. Dose, 5 to 10 minims. It is made still more pleasant and efficacious if given in aromatic vinegar.—*New York Medical Record*, August 2.

MEDICAL CONSULTATIONS.

No. II.

A BATTLE OF SYSTEMS.

SCENE—*The consulting-room of M.D., Oxon.*

DRAMATIS PERSONÆ.

M.D., OXON.—*A Professor Emeritus.*

M.D., LOND. } —*London medical teachers.*
M.D., EDIN. }

M.D., OXON. Well, there's an end to that business, thanks to your kind help. And now bring your chairs to the fire and let us have a talk. (*To* M.D., EDIN.) What sort of an entry have you at St. Anne's, this year?

M.D., EDIN. Wretched! Worse than it has ever been since I have known the place. However, I am not surprised. The fact is, a small school is a mistake.

M.D., OXON. If so, the remedy is obvious; make it a large one.

M.D., EDIN. The very thing we have been trying to do We have a hard working staff—I don't believe any staff in London toils harder. We have spent hundreds on our new school and yet ——. The fault is not in us, but in the system. We are like an orchestra, whose instruments have got mixed. You know Jones?

M.D., OXON. Very well. I think highly of him.

M.D., EDIN. Yes, so does everyone, as a physician, but he knows no more of modern physiology than a country surgeon, and so he has to lecture upon it. That is the most flagrant example but it is pretty much the same throughout. Brown, who is absorbed in skins, has to teach botany; Smith, a brilliant surgeon, holds the chair of forensic medicine, a subject he despises; while Robinson, pathologist and sceptic, has to lecture on drugs, his ignorance of which is only equalled by his distrust of them.

M.D., OXON. And you?

M.D., EDIN. O, my case is just as bad. I am an amateur like the rest—or rather, worse than an amateur, for mine is not a subject I love. A lecturer on comparative anatomy ought not to have a constitutional horror of frogs and lizards.

M.D., OXON. But you teach clinical medicine as well?

M.D., EDIN. Not at all, except in the out-patient room. That is another blot on the system. I should no more think of taking my class into the wards than I should think of levitating up your chimney.

M.D., OXON. For fear of black looks.

M.D., EDIN. Exactly; my experience of small hospitals is that they are nests of jealousy. Each member of the staff has his little circle chalked out for him, and, to say the truth, he is eager enough to take it on any terms. Well, so long as he keeps within it, all works harmoniously. But let him, through zeal or officiousness, once step beyond it, and every one of his colleagues is down upon him.

M.D., OXON. I am not sure that the colleagues would be to blame. What would happen to a watch, for instance, if one of its wheels took upon itself to make excursions beyond its orbit? I am inclined to think that the other wheels would have just grounds of complaint.

M.D., EDIN. Aye, but a school is an organism, and not a machine. If one of your organs is not up to its work, does not another step in and do it for it? There is no jealousy or complaint there.

M.D., OXON. (*Smiling*). Jealousy, perhaps not, though who knows? But complaint, certainly.

M.D., LOND. As for jealousy, I don't know that the small schools have a monopoly of it. A good teacher is naturally jealous, and quite properly so, of any encroachment on his province. In a well ordered school, however, there should be no occasion for jealousy. Each teacher has his students allotted to him, and in his own particular circle is beyond the reach of competition.

M.D., EDIN. Yes, and that is the very reason why I condemn the whole system. There ought to be jealousy; there ought to be competition, instead of the array of safeguards by which we in London protect the teacher from all possible rivalry. Any living teaching is impossible with such a system. You condemn the trades unions because they drag down their best men's work to one dull average, and yet you cling to a system which does exactly the same thing, which absolutely discourages a man from putting forth his best powers. Give me the Edinburgh system!

M.D., OXON. In London, with its widely distant schools, it would be unworkable.

M.D., EDIN. I don't see why. Of course it would be a tremendous innovation, but if London teachers knew their best interests, they would not rest until they had introduced it. If they wish to keep up their entries, they will have to do it sooner or later, and why not now? In the first place, they would have to abolish the lectureships in half the subjects at all the small schools. It is simply absurd to have eleven lecturers on anatomy, physiology, chemistry, botany, forensic medicine, and comparative anatomy, when three for each subject would more than suffice for all the London students. There would then be some chance of each lecturer taking up his subject as his life-work, instead of making it merely a secondary object, a means of eking out a narrow income while he waits for practice. How can you expect a man to lecture competently on forensic medicine, when he sees no forensic practice? There is enough work in London for perhaps two or three experts in medical jurisprudence. All the rest of the lecturers must necessarily be mere amateurs at their business——retailers of book-work.

M.D., OXON. On that point, I grant, your argument seems sound enough, but the subject is after all a small one.

M.D., EDIN. I only use it as an illustration. However, look at my second point. Take clinical teaching. As it is, there is absolutely no competition, no encouragement to a good clinical teacher to teach well. However well he teaches, he gets the same fees as the man who does not teach at all. He is followed perhaps by a larger class, but he is only able to draw his pupils from a single hospital. If I had my way, I would throw open the whole clinical teaching of London to every medical student, give him a clinical ticket which would allow him to attend any hospital and any teacher, and arrange that the man who attracted the largest class should be the best paid. Then you would have a really healthy competition, and it would become worth a man's while to devote his life to teaching, and so to become really an expert in it.

M.D., OXON. Your ideas are large, and like all large ideas have a certain momentum in argument. I doubt, however, if they could be carried into practice so easily as you think. To introduce them would be to disorganize a system which has grown up with time, and which, you will admit, has turned out as good men as any other. I wonder what our friend here thinks of them.

M.D., LOND. I admit that the ideas are large and attractive, but there is a great deal to be said on the opposite side. Of course I can only speak from my own experience, but I am inclined to think that the teaching of

special subjects to medical students by pure experts is less successful in practice than in theory. At St. Paul's, as you know, physiology is taught by a pure physiologist, pathology by a pure pathologist, chemistry by a pure chemist, and so on. We are pure throughout. But see what the effect is. The physiologist teaches physiology as though everyone of his pupils were destined to engage in pure research. The chemist sees before him not medical students, but the future directors of dye works and soap manufactories. The pathologist thinks that a medical education should centre round the *post-mortem* table and the microscope. Each teacher by eternally focussing his eye on a small field, loses the power of accommodating it to more distant objects, and in the end grows to look upon his own branch of science not as a piece to be fitted into a puzzle, but as the puzzle itself. I verily believe that medical students are better taught by men who are first of all practical physicians and surgeons, and teachers of special branches only in a secondary degree. At any rate, if you have all your subjects taught by specialists, you ought to have a strong central authority, whose duty it would be to co-ordinate the various subjects and see that they are kept in submission to the one purpose of his school—the training of medical practitioners.

M.D., OXON. Well spoken for the defence. Now let me have your views on the second point, and then as an impartial onlooker, if you will allow me, I will do my best to sum up.

M.D., LOND. Well, I admit that in respect to clinical teaching, my friend has a strong case. But he assumes too much. He assumes that the average medical student is perfectly competent to judge who is the best teacher, an assumption which I cannot admit.

M.D., EDIN. Why not?

M.D., LOND. For this reason. As a rule the student only knows which teacher coaches him best for his examination, and the fear is that if you introduce a system of competition you will convert every successful clinical teacher in London into an examination coach, and the higher clinical teaching, which has no attraction at all for the examination candidate, will simply die of inanition. I believe that in London with all our protective safeguards, as our friend calls them, we have better clinical teaching than in Edinburgh, for it is conducted from a pure love of it, and with little ulterior hope of gain. Then if you draft off all the students to a few teachers, you will not only overcrowd their wards and work their material to death, but you will take the heart out of all the less able teachers and render the beds at their disposal useless. Possibly a modified system of competition for picked students and practitioners might work, but for the average student who wants looking after and often driving into the wards, a system under which he was allowed to cater for himself would simply excuse him from ward work altogether. He would naturally go to the teacher who would sign him up most easily.

M.D., EDIN. Stay a moment. If you adopt my system you must sweep away the whole apparatus of schedules. Improve the examinations. Test a man's real knowledge, and let him get it where and how he will. In my opinion schedules are only a sop to lazy examiners.

M.D., OXON. Surely that question is too large to enter into. I really think I must rule it out of court. And now if neither of you has anything more to say, I will tell you the views of an old man, who has lived long, who has taught many, and thought much. Possibly you will call them commonplaces, but if so they are commonplaces for which no place is found in either of your systems. In the first place a good learner is of more moment than a good teacher. As the years have passed over me, I have become more and more inclined to the view that the best learning is that which a man gathers for himself, with willingness and pleasure, and the worst is that which is drilled into him by his teachers. And this is essentially true of medicine, which is the noblest of trainings, but the worst of "crams." So that the best system is that which quickens most and hinders least the desire of the pupil to learn, whilst of teachers he is the best who most excites that desire. And as no one can excite it but he who has felt it himself, so no one can teach a science but he who has studied it fully and lovingly. Therefore when we are canvassing the merits of these two systems, the question we should ask is not whether the teacher is an expert or not, for an amateur may love his subject as well as, if not better, than an expert, but whether he has enough interest in it to quicken his pupils therewithal. Or is he only doing journeyman's work for the wages that shall fall to him? Born teachers are rare, and we ought, by giving them due wages and due honour, to chain them to the task for which they were born. But the danger of highly remunerating the teacher is that thereby you tempt men to assume the office who have no calling for it except the calling of pounds and shillings. I think we hardly now sufficiently recognize this gift of teaching, this gift which makes its owner able to interest his pupils in the driest of subjects. I have listened to Hyrtl and Partridge in their prime, and I never left their lecture doors without feeling that the power which enabled them to hold their pupils spellbound while they quickened the dry bones of anatomy is one which of all gifts is that least honoured and recognized. Pardon an old man these digressions. To resume, a born teacher needs no competition; he is above it; and it is an ignominy to force mere crammers into rivalry with him. But real teachers, as I have said, are rare, and this fact is of itself sufficient to convince me, that the only way of vitalising the teaching in such subjects as you have mentioned is to abolish all unnecessary chairs, to reduce them in fact to such a number, that we might fairly expect to be able to fill them with men who have some inherent fitness for their office. As to competition I candidly admit my distrust of it. It is a modern idea, which, as one of you has pointed out, is constantly making unwarrantable assumptions. If you and I compete before competent judges, well and good; but how if the judges are incompetent? Were it not better for our own peace and our own culture that we had never entered into rivalry? With regard to clinical teaching the complaint is that a good teacher here may have three times too many students and a good teacher there three times too few to teach. Would competition mend this? The best solution would probably be a compromise between the systems you have severally vaunted. I would suggest, though with diffidence, that the clinical clerkships at each hospital should be thrown open to the whole of the London students, but that for clinical practice, apart from office, the students should be allotted to the different hospitals in proportion to the number of their beds. And I would further suggest that every hospital in London, from the royal foundations down to the poor law infirmaries and special hospitals, should be thrown open for clinical teaching, so that no hospital case in the whole metropolis should pass through its stage of sickness unobserved and unrecorded. Have I summed up fairly? I see that I have pleased neither. Ah! well, 'tis the best of compliments.

GENERAL CORRESPONDENCE.

THE MEMORIAL TO DR. RABBETH.

[To the Editor of the Medical Times.]

SIR,—A meeting was held this afternoon at King's College, at which many eminent members of the medical profession and other distinguished persons were present, in honour of the late Dr. Samuel Rabbeth, and I have been desired to ask your assistance in making its purpose known. A large Committee was appointed, including the Chairman and Vice-Chairman of each hospital, Sir W. Bowman, Sir W. Gull, Sir Joseph Lister, Dr. Priestley, Professors Johnson and Wood, the Rev. Dr. Stokoe, and Mr. F. J. Gant. This Committee, which will have for its Honorary President, the Archbishop of Canterbury, as visitor of the College in which Dr. Rabbeth was educated, will take into consideration the best means of commemorating the name and sacrifice of Dr. Rabbeth at the two hospitals with which he was connected, and at the University of London, of which he was a graduate. The Principal of King's College and R. Ruthven Pym, Esq., have been requested to act as Treasurers, and Messrs. Coutts and Co., have kindly consented to receive subscriptions.

I am, Sir, yours &c.,
JOHN CURNOW, M.D.,
Nov. 5th, 1884. One of the Secretaries to the Fund.

[To the Editor of the Medical Times.]

SIR,—It is not a very agreeable task to set oneself up as the critic of a burst of enthusiasm when called forth in recognition of instances of self sacrifice for the good of others. Examples of this always have and always will move the human breast to its inmost depths; and the last instance exhibited by the death of Dr. Rabbeth, who well knew the great danger he was incurring, is as much entitled to admiration as any of those that have preceded it. And there has been no absence of such recognition. Proposals have been made for memorials of the occurrence, and an influential correspondent of a contemporary has even suggested that subscriptions should be raised for the foundation of a medal, to be awarded in future by the University of London. In like manner, in Paris, where several deaths have taken place from a similar cause, the Municipality has affixed tablets in memory of these sacrifices in the hospitals within which they occurred. Now, I venture to suggest that we are here getting on dangerous ground, and that our sympathies are taking a wrong direction. If in place of only expressing our mournful regret that such a calamity had taken place, we are to meet it with encomiums and recognitions, what is this but to hold it up for imitation and approval? Nay, if such occurrences were frequent, a state of opinion might come to be entertained that a medical man had not done his full duty to his patient who had not had recourse to this extreme measure. These deaths ought never occur, for no man should be called upon to lay down his life for that of his patient, even if he were sure of saving him, which, in the class of cases under consideration, is highly improbable, and those in authority should deprecate such sacrifices in place of holding them up as fitting for imitation. These young men, often possessed of great acquirements and potentiality of future utility to mankind, and having more or less of family responsibilities attaching to them, should not be stimulated into the performance of actions which no professional duty calls upon them to undertake; and that perhaps in favour of an individual whose life is of comparatively little account. The unavoidable dangers which beset the medical profession, and which are always met with courageous devotion, are surely sufficiently numerous.

I am, Sir, yours, &c.
Royal College of Surgeons of England, November 3rd. JOHN CHATTO.

INVENTIONS AND IMPROVEMENTS.

GERTRUDIS SPRING MINERAL WATER.

THE Prince de Solm's Gertrudis-spring mineral water is one of great complexity of composition; it contains about 46 grains per gallon of sodic carbonate, 71 grains of calcic carbonate, 42 grains of magnesic carbonate, 132 grains of common salt, besides salts of lithia, potassium, barium, strontium, iron, and manganese. To this list of bases must be added bromine, iodine and chlorine, the whole forming a total of some 270 grains per gallon. The water is alkaline in reaction and is well charged with carbon dioxide; its taste is similar to, but a little more agreeable than, that of seltzer water. The amount of bicarbonate of lithia in the water is sufficient to have a therapeutic action, and it seems a water likely to do good in rheumatic, gouty and dyspeptic affections. Organically the water is of considerable purity.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members on October 30th, 1884, viz.:—

Daniel Henry Cullimore, M.D. Brussels; Edward Owen Daly, M.B. Oxford; Henry Maudsley, M.D. Lond.; James Oliver, M.B. Edinburgh; William Camac Wilkinson, M.B. Lond.

The following gentlemen were admitted Licentiates on October 30th, 1884, viz.:—

Daniel Elie Anderson, Robert Alexander Baillie, Herbert Bidwell, William Lyne Blight, Charles Knox Bond, George Byrne, Ralph Thomas Cann, Harry Cecil Chapman, John Hedley Crocker, Jenkin Davies, Harold Antoine Des Vœux, Domiuick Anaclete D'Monte, Charles Cartwright Ellis, Herbert Fox, Thomas Underwood Gray, Charles Thomas Griffiths, Henry Habgood, Alfred Richard Hall, Harry Harlock, Edgar Alfred Hughes, Charles Style Humphreys, Isaiah Henry Joues, Robert John Kerby, Maurice Koettlitz, Thomas George Laslett, William Leppingwell Livermore, Charles William Low, Robert Humphrey Marten, George Edward Miles, George Morgan, Philip Robert William Santi, Percy Richard Stevens, Benjamin Wilfred Thomas, Alexander Bishop Voisin, and Alfred James Weakley.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, October 30th, 1884:—

William Turnour Parker, 68, Lillie Road, Fulham; Charles Lane Sansom, Devonshire House, Anerley, S.E.; Edgar Brewitt Sugden, 13, Adamson Road, N.W.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW. *Triple Qualification.*—The first examinations under the Conjoint Scheme recently entered into by the above bodies, commenced at Edinburgh on the 16th ultimo, and the following gentlemen passed their First Examination:—

William Griffith Roberts, Carnarvon; Robert David Prichard, Carnarvon; Thomas Monies, India; Herbert Park Shuttleworth, London; Thomas Young, London; William Beecham, Wigan; James Mason, Arbroath; Theodosius Thompson, Belford; Walter Dowley Eddowes, Stamford; Alexander Drimmie Pithie, Aberdeen; Edward Regan Crofton, Roscommon; Robert Duckett Harman, County Down; David Lees, St. Andrews; Charles Stewart Phillips, Jamaica; Thomas Kensington James Fulton, Pondicherry; Edward Brooks, Lancashire; Maurice Michael Murphy, County Kerry; James Andrew Murray, Cork; Richard Ambler, Hemel Hempstead; Arthur Patrick Brown, Shropshire; William Walter Paterson, Inveresk; Edmund Herbert Corder, Birmingham; Thomas Augustus Davidson, County Down; George Thomas Birkett, Cumberland; James Joseph McEniry, County Waterford; Joseph McDowell, County Down; Arthur William Hogg, Middlesex; John Westwood, Birmingham; Ephraim Hilliard, County Kerry; Alexander Donald McLean, Edinburgh; Edward Faloon Hawkesworth, Cork; Francis Joseph Kenay, Calcutta; John Cotter, County Cork; William Charles Robinson, County Antrim; Thomas Bowser, Northumberland, and Ernest Rutherford Sims, Derby.

The following gentlemen passed their Second Examination, viz.:—

William John Morton, New South Wales; Peter Lynch, Victoria;

John Horatio Doake, Bucks; Thomas Young, London; William Beecham, Wigan; William Jackson Hooker Macgilvray, Glasgow; Robert Sydney Marsden, Sheffield, and Ernest Frederic Taylor, Yorkshire.

The following gentlemen passed their Final Examination, and were admitted L.R.C.P. Edinburgh, L.R.C.S. Edinburgh, and L.F.P. and S. Glasgow, viz.:—

George Armstrong, Edinburgh; Francisco Fernandes, Demerara; William Francis Fossman, Ontario; Clement Hope Greatorex, Madras; Thomas Theophilus Hamilton, Newry; William Henry Owen Mills, Cape Town; Thomas Young, London; Sidney Taylor Williamson, London; George de Bourboulou Watson, China, and Edward William Short, Madras.

Royal College of Physicians and Surgeons, Edinburgh. *Double Qualification.*—The following gentlemen passed their First Professional Examination during the October sittings of the Examiners, viz.:—

John Godfrey Nixon, Tralee; James William Fox, Edinburgh; Isidor Bernard Le Gentil, Mauritius; Richard Walton Long, County Cork; Moses Bernstein, Sunderland; William George Meade, County Cork; James Carnegie Figg, Boness; Hugh McCallum, Plymouth; Idriee Anni Goumany, Mauritius; George James Elliot Trotter, Durham; Montague George Robinson, Sedgebrooke; Oswald Herbert Edwards, Great Crosby, and James Wallace, Antieur.

The following gentlemen passed their Final Examination and were admitted L.R.C.P. Edinburgh, and L.R.C.S. Edinburgh, viz.:—

Henry Harris, Honolulu; John Macgregor, Perthshire; Thomas William Riee, Queen's County; Bernard Stevenson, Nottingham; William Langran, Dublin; John Jones, Anglesea; Emmanuel Portal, Mauritius; Charles Coehrane Diekson, Galashiels; James McCaull, Belfast; Charles Spurgeon Davies, Canada; William Davies, Manchester; Theophilus Edward Samuel Scholes, Jamaica; George Shepley Page, Cephalonia; Charles William Dean, Lancaster; Alfred Ernest Woodforde, London; Digby Patrick Fitzgerald Freneh, County Galway; George Arthur Herbert Woodforde, London; Montague George Robinson, Sedgebrooke; John Cram, Dollar; Arthur Fowell Turner, Wiltshire; Sewell Samuel McFarlane, Australia; Arthur Thomas White, Torquay; James Malcomson, County Down; William Hitson Clayton, Leeds; Walter Benjamin Garvin, Ceylon; John William Faweitt, Yorkshire; Ernest Black, Woolwieh; Peter Campbell, Argyllshire; James Curtin Sheehan, County Cork; Archibald Hood, Midlothian; James Innes Fullarton, Australia.

Royal College of Surgeons, Edinburgh.—During the October sittings of the Examiners, the following gentleman passed his First Professional Examination, viz.:—

Francis Philip Denman, Yorkshire.

The following gentlemen passed their Final Examination and were admitted Licentiates of the College, viz.:—

Charles Arundel Parker, Chatham; William Albert Ross, Ontario; Alexander McKillop, Ontario; Duncan Gow, Ontario; Dominick Anaelet D'Monte, Bandora; Charles Arblaster, Shrewsbury.

The following gentleman passed the First Professional Examination for the Licence in Dental Surgery, viz.:—

James Taylor, Lancashire.

The following gentleman passed the Final Examination, and was admitted L.D.S. Edinburgh, viz.:—

William Hopper Harrison, British Guiana.

Academy of Medicine of Ireland. — The second annual general meeting of the Academy of Medicine in Ireland was held in the Royal College of Surgeons, Stephen's Green, Dublin, on Friday evening, October 31st. There was a large gathering of Fellows. Dr. E. H. Bennett, President of the College of Surgeons, occupied the chair. The following officers were elected for the session 1884–5:—*President*—J. T. Banks. *General Treasurer*—Robert MacDonnell, F.R.S. *General Secretary*—Wm. Thomson. Medical Section.—*President*—F. R. Cruise, President of the King and Queen's College of Physicians. *Council*—J. Hawtrey Benson, George F. Duffey, J. Magee Finny, T. W. Grimshaw, Richard A. Hayes, Henry Kennedy, A. N. Montgomery, *Secretary*; J. W. Moore, Walter G. Smith, and H. C. Tweedy. Surgical Section.—*President*—E. H. Bennett, President of the Royal College of Surgeons. *Council*—Wm. Colles, C. Coppinger, Edward Hamilton, Edward Dillon Mapother, Edward Stamer O'Grady, W. Thornley Stoker, W. Stokes, *Secretary*; J. P. Hayes, H. R. Swanzy, and Kendal Franks. Obstetrical Section.—*President* — Lombe Atthill. *Council* — John A. Byrne, Professor Dill, Belfast; Andrew J. Horne, J. Rutherfoord Kirkpatrick, G. H. Kidd, Arthur V. Macan, Thomas More Madden, W. Cox Neville, *Secretary*; R. D. Purefoy, and Wm. J. Smyly. Pathological Section.—*President*—Arthur Wynne Foot. *Council*—Phineas S. Abraham, Wallace Beatty, A. H. Corley, Samuel Gordon, J. V. Lentaigne, T. E. Little, J. M. Purser, F. J. B. Quinlan, Wm. Stoker, and J. B. Story.

Faculty of Physicians and Surgeons of Glasgow.—At the October Annual Meeting of the Faculty the following list of office-bearers for the year was declared:—President—Dr. Andrew Fergus. Visitor—Dr. Henry Muirhead. Councillors — The President, *ex-officio*; The Visitor, *ex-officio*; The Treasurer, *ex-officio*; Dr. R. Scott Orr; Dr. Thomas Lapraik; Dr. James Christie; Dr. Robert Perry; Dr. James Morton. Board of Examiners—Dr. Alex. Lindsay, Chemistry; Dr. Hugh Miller, Midwifery; Mr. H. E. Clark, Anatomy; Dr. James Stirton, Midwifery; Dr. J. Wallace Anderson, Medicine and Materia Medica; Dr. P. A. Simpson, Medical Jurisprudence; Dr. James Dunlop, Surgery and Surgical Anatomy; Mr. David C. M'Vail, Physiology; Dr. Alexander M. Buchanan, Anatomy; Dr. H. C. Cameron, Surgery and Surgical Anatomy; Dr. William J. Fleming, Physiology; Dr. William Macewen, Surgery and Surgical Anatomy; Dr. Robert Perry, Chemistry; Dr. Samson Gemmell, Medicine and Materia Medica; Dr. Eben Duncan, Medical Jurisprudence and Hygiene. William H. Hill, Clerk; Alexander Duncan, B.A., Secretary and Librarian.

Medical Bursaries for the University of Glasgow.—Mrs. Monteath, of Glasgow, has placed in trust the sum of 1,000*l.* for the establishment of two bursaries to be awarded to students who gain the highest number of marks in the subjects of anatomy and physiology at the professional examinations in these subjects, held during the year. A bursary of the value of about 20*l.* will be awarded annually in November, and will be tenable for two years.

The Cambridge Sanitary Science Certificate.—The Syndicate appointed to superintend the examinations in State medicine have issued their tenth annual report, in which they state that fifteen candidates presented themselves for examination in the first week of the present Michaelmas term, all of them taking both parts. Thirteen were approved by the examiners, and received certificates of proficiency in sanitary science. In 1883 there were seventeen candidates, and sixteen passed the examination.

Professor Humphry.—Dr. G. M. Humphry, F.R.S. Professor of Surgery, at Cambridge, has been elected a Fellow of King's College in that university. Dr. Humphry was Professor of Anatomy from 1866 to 1883, when he resigned. On the establishment of the Professorship of Surgery in May, 1883, Dr. Humphry was elected, but at present there is no stipend attached to the Professorship. Professor Humphry is also an Honorary Fellow of Downing College.

Leeds School of Medicine.—A series of Special Clinical Lectures, at which the attendance of medical practitioners as well as students is invited, will be delivered during the ensuing winter and summer sessions, by Dr. Clifford Allbutt, Mr. Wheelhouse, and Mr. T. Pridgin Teale, at 12 o'clock noon, on the dates below specified:—November 19, 1884, Dr. Allbutt, Scrofulous Neck; December 3, 1884, Mr. Wheelhouse, Pent-up Secretions; December 17, 1884, Mr. Teale, The Surgery of Scrofulous Glands; January 7, 1885, Dr. Allbutt, Migraine; January 21, 1885, Mr. Wheelhouse, the Surgery of Epiphyses; February 4, 1885, Mr. Teale, Ether *versus* Chloroform: A word about Anæsthetics; February 18, 1885, Dr. Allbutt, Infantile Palsy; March 4, 1885, Mr. Wheelhouse, Recent Abdominal Surgery; March 18, 1885, Mr. Teale, the Sphincter and its Surgical Neglect.

Alleged Death from Over-pressure.—At a recent meeting of the Macclesfield Union Sanitary Authority, Dr. Smith, of Chelford, reported the death of a girl from alleged over-pressure at school. He stated that every time he visited her she was in a state of muttering delirium concerning school and lessons. He did not blame the teacher, but the system, urging that when a child came from school its evening hours should be spent in physical development. It was decided to send copies of Dr. Smith's

statement to the Education Department, Lord Stanley of Alderley, and Mr. Salt, M.P.

The Medico-Psychological Association. — At the quarterly meeting of this association, held at Bethlem Hospital on Wednesday, 5th November, under the presidency of Dr. Rayner, Dr. Julius Mickle exhibited cases of aneurysm, and Dr. Savage a case of localised brain disease. A paper by Mr. Bonville Fox, on Exaltation in Chronic Alcoholism, adjourned from a previous meeting, was then taken, and discussed in connection with the kindred questions of insanity arising from the use of opium and Indian hemp. Dr. Savage read a paper on Delirium Tremens, passing to mania.

The Index-Catalogue of the Library of the Surgeon-General's Office, Washington.—The fifth volume of this admirable and exhaustive publication has just been issued, supplying an enormous number of references to periodical literature, from Flaccus to Health. It is said to include 15,555 author-titles, 5,755 volumes, and 12,596 pamphlets; also 8,096 subject-titles of separate books and pamphlets, and 34,127 titles of articles in periodicals.

Malignant Pustule.—In a recent number of the *New York Medical Journal*, Dr. A. C. Griffin reports a case of malignant pustule occurring in a male, aged 35, of fair physique and a moderate drinker. While dining at a restaurant he was bitten on the left cheek by a common green-bottle or carrion fly; on the site of the bite—which was so deep as to draw blood—a pimple developed and grew so rapidly, that by the next day there was formed an indurated swelling, 25 mm. in diameter, extending through the whole thickness of the cheek, with a small, unhealthy central ulcer, and surrounded by a wide, angry, red areola. The cervical and submaxillary glands were enlarged and tender; pulse 120, temperature 103·2° F., tongue coated, violent headache, complete anorexia. The ulcer was at once cauterised with pure carbolic acid, and the patient put on full doses of quinine and alcohol. The induration increased so as to extend from lip to orbit; the sloughing also extended almost through the cheek; pain became intense, the temperature rose to 104·8°, and the prostration was extreme; by the sixth day but little hope of recovery was entertained. Aided, however, by repeated cauterizations, and free stimulation, together with quinine and morphia in large doses, the patient began to improve and ultimately got well with only a moderately sized cicatrix at the site of the ulceration. In the *Boston Medical and Surgical Journal*, for May 8th, Dr. W. S. Janney gives details of four cases of the disease. One patient, a farmer, aged 60, died 58 hours after first noticing on his right cheek a slightly painful pimple, which rapidly extended so as to involve the whole cheek, the lower jaw, the right ear, and the parotid region, nearly as far as the posterior median line of the neck. The second case was that of a healthy married lady, aged 32, living in the country, who died 72 hours after first noticing near the lower lip, on the right side, an itching papule which rapidly developed as in the preceding case. Another woman, married, aged 30, died on the fourth day after first noticing the papule on the right side of her chin; on the third day hyperæsthesia of the right side of the body was noted. A wool-merchant, aged 24, of previous good health, sought advice on account of cough, when a papule, as large as a small pea was noticed just below the right half of the lower lip. The patient had been recently handling wool, and suspicion as to the real nature of the supposed "pimple" was therefore excited. The papule developed as in the other cases; the swelling was incised, injected with pure carbolic acid, and poulticed with linseed tar and iodine. In spite of extensive sloughing about the face, the formation of an abscess in the leg, and two successive attacks (right and left) of pleuro-pneumonia, the patient, at the end of three months made a good recovery. In all these cases the medical treatment comprised quinine, ferric-perchloride, carbonate of ammonia, morphia and alcohol. In each case there appeared evidence that the disease extended through the poison being carried by the superficial lymphatics only. Four stages may be recognised:—(1) Incubation period—from a few hours to fourteen days, without prodromata. (2) The formation of papule, vesicle, and pustule, lasting from twelve to twenty-four hours. (3) The extension of the œdema and inflammation, occurring twelve hours after the formation of the pustule. (4) The stage of gangrene, occurring in from twelve to twenty-four hours later.

Sulpho-Carbol, the New Antiseptic.—M. Pierre Vigier, the able writer of the "Pharmaceutical Contributions" in the *Gazette Hebdomadaire*, giving an account (in the number for August 8) of a paper on a new antiseptic, read at the Société de Biologie, by M. Ferdinand Vigier, a *pharmacien* of Paris, observes that the fact of its author being his near relative is an additional security for his examining the pretensions of the substance to an important position. The substance in question is orthoxyphenilsulphurous acid, which may be more conveniently named *sulpho-carbol*, as more simply indicating a combination of sulphuric acid with carbolic or phenic acid. The antiseptic and antifermentative properties of this compound are remarkable, and it has the advantage over carbolic acid of being soluble in water in all proportions, and of being neither poisonous nor caustic. It is a syrupy, rose-coloured liquid, of a pungent odour, but no-wise disagreeable in solution. It is volatilized in a water-bath, and may be used for fumigation. It was discovered in 1841 by Laurent, and has since then engaged the attention of many chemists. Recently its properties have been investigated by M. F. Vigier, with the assistance and in the laboratory of M. Laborde, and its great antiseptic powers have been duly demonstrated. It may be given internally also, in syrup and water, in doses of from one to five grammes daily. Indeed, being an inoffensive product, its doses may be increased *ad libitum*, which of course is not the case with carbolic or salicylic acids.

Experiments with Typhoid Matter.—A correspondent, signing himself F. Wood, whose name however we do not find in the Medical Register, has taken the somewhat questionable course of communicating the results of his experiments to a lay paper, the *Scotsman*. A short time ago, he writes, not far removed from Penicuik, a case of sporadic typhoid fever occurred. The medical attendant, for the purpose of microscopical and chemical analysis, removed some of the dejecta. Being interested in the case, he sent me a small portion of the matter, which, from curiosity, I experimented with in the following manner, and with the following extraordinary results:—Into the jugular of a strong healthy dog I injected a minute quantity of the dejecta, with the result that in a very short time symptoms, decidedly typhoid, expressed themselves rapidly terminating fatally. From the intestines of this subject, especially near the ileo-colic valve, I scraped away a portion of the intestinal secretion. With this I experimented upon three rabbits in the following manner—Near the region of the temporal artery in subject No. 1, I injected a minute portion of a weakened solution; also into the stomach of No. 2, in the form of a pill, I passed another small portion. Both animals had been kept two days short of food, and in a temperature never less than 68° F. In subject No. 1, fæcal diarrhœa rapidly became expressed, with acute fever of the typhoid nature. Subject No. 2 showed little or no material derangement. In the small bowel of subject No. 1, I was struck by the quantity of fluid so characteristic of malignant cholera. To test this further, I procured subject No. 3, also a rabbit, which had been kept for some days in a state of semi-starvation, and in a temperature never less than 78° F., but otherwise healthy. Near the region of the trachea I injected a minute portion of this intestinal flux, removed from No. 1. In a remarkably short time fæcal diarrhœa, succeeded by distinct choleraic diarrhœa, was shown, with painful spasmodic cramps, embarrassed breathing, icy coldness over the body's surface, rapidly running into mortal collapse—the whole chain of symptoms being pronouncedly those of malignant cholera. The intestinal discharge was most markedly symptomatic, being of the flocullicated (*sic*) rice-water nature so characteristic of cholera. Without running into extreme or hasty decisions upon this matter, it does appear to me, along with many others, that cholera of the

malignant type may be developed from the septic poison of ordinary typhoid, given the conditions of a reduced state of the system with an elevation of temperature — more especially would this be the case when, under bad sanitary conditions, typhoid assumed an epidemic form; and also from the above experiments that in the lower animals, at least, cholera may be developed from the germs of typhoid without any marked transitional gradations indicating its developing course.

BISMUTH IN THE DYSENTERY OF CHILDREN.—Dr. Waxham speaks highly of the use of bismuth in rectal injection in dysentery as it greatly abridges the ordinary course of the disease. From 10 to 20 grains are administered with mucilage and water after each evacuation; and when not sufficing to control the frequent stools, a little laudanum is added.

THE RUSSIAN UNIVERSITIES.—The following are the figures relating to the Russian universities at the beginning of 1882: (1) St. Petersburg, 99 functionaries (of whom 48 were titular professors) and 2,052 students, the expenses amounting to 429,903 roubles. (2) Moscow, 103 functionaries (57 professors) 2,430 students, and 526,724 roubles expense. (3) Kiew, 105 functionaries (46 professors), 1,475 students, and 460,334 roubles. (4) Charcow, 89 functionaries (51 professors), 821 students and 367,944 roubles. (5) Kasan, 109 functionaries (47 professors), 776 students and 379,496 roubles. (6) Warsaw, 79 functionaries (45 professors), 1,003 students, and 293,106 roubles. (7) Dorpat, 65 functionaries (42 professors), 1,426 students, and 256,807 roubles. (8) Odessa, 52 functionaries (28 professors), 374 students and 252,929 roubles. There are also at the different universities from 1 to 14 per cent. of "free auditors" who are aided or supported by bursaries and subventions. The library of the Odessa University is said to contain 92,454 volumes, that of Kasan 103,170, Charcow 103,704, Kiew 145,032, Moscow 190,440, Dorpat 218,893, and Warsaw 363,250.

APPOINTMENTS.

ARMITAGE, E. H., M.R.C.S. Eng., L.R.C.P. Lond.—Resident Medical Officer to the Hulme Dispensary, *vice* J. B. Dreaper, M.R.C.S. Eng., resigned.

BROWN, WILLIAM PERRIN, L.R.C.P. and L.R.C.S. Edin., and L.S.A. Lond.—Medical Officer to the Skircoat District, Halifax Union, *vice* Mr. George Scholefield, resigned.

CÆSAR, JULIUS, L.R.C.P. and L.R.C.S. Edin., and L.S.A. Lond.—Medical Officer to the Workhouse and the Eastchurch District, Sheppey Union, *vice* Dr. Bland, resigned.

COLLIER, M. P. MAYO, M.B. Lond., F.R.C.S. Eng.—Assistant Surgeon to the North West London Hospital.

DREAPER, J. B., M.R.C.S. Eng.—Honorary Surgeon to the Hulme Dispensary, Manchester, *vice* A. J. Neale, M.B., C.M. Edin., resigned.

DURHAM, FREDERIC, M.B. Lond., F.R.C.S. Eng.—Senior Surgeon to the North West London Hospttal.

DWYER, F. C., M.D.—House Surgeon to the Mater Misericordiæ Hospital, *vice* F. J. Cruise, L.R.C.S.I., resigned.

GARMAN, JOHN COOPER, L.R.C.P. and M.R.C.S. Eng.—Medical Officer to the Brewood District, Cannock Union, *vice* Mr. C. T. Duce.

HARTRIDGE, GUSTAVUS, F.R.C.S.—Consulting Ophthalmic Surgeon to St. Bartholomew's Hospital, Chatham, *vice* Henry Power, F.R.C.S., resigned.

HAXWORTH, WALTER, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the West Breton and Crigglestone Districts, Wakefield Union, *vice* Mr. Arthur White, resigned.

HOOD, DONALD WILLIAM CHARLES, M.D. Cantab., M.R.C.P. Lond.—Senior Physician to the North West London Hospital.

JENNINGS, CHARLES EGERTON, F.R.C.S. Eng.—Assistant Surgeon to the North West London Hospital.

PEDLEY, FREDERICK NEWLAND, M.R.C.S. Eng., L.D.S.—Dental Surgeon to the North West London Hospital.

SHAW, H. C. C., M.R.C.S.—House Surgeon to the Richmond Hospital, Surrey, *vice* A. L. Copner, L.R.C.P., resigned.

SHAW, JOHN, M.D. Lond., M.R.C.P. Lond.—Senior Assistant Physician to the North-West London Hospital.

SHONE, WILLIAM JAMES, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the Twelfth District, Wycombe Union, *vice* Mr. W. G. Hayden, resigned.

TOMKINS, H. H., M.R.C.S.—Assistant Medical Officer to the Gloucester County Asylum.

TREVES, EDWARD, M.R.C.S.—Additional Honorary Surgeon to the Throat and Ear Dispensary, Brighton.

WILSON, G. J. M.R.C.S., L.S.A.—House Surgeon to the Radcliffe Infirmary, Oxford.

VACANCIES.

BASFORD UNION.—Medical Officer of Health. (*For particulars see Advertisement.*)

GATESHEAD DISPENSARY.—Resident House Surgeon. Salary, £210 per annum, with apartments (without attendance), coal, gas, &c. Candidates must possess the double qualification. Applications, and copies of testimonials, to be sent to Mr. Joseph Jordan, 2, Side, Newcastle-on-Tyne, not later than November 21st.

HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN SQUARE.—Resident Medical Officer. (*For particulars see Advertisement.*)

ROYAL LONDON OPHTHALMIC HOSPITAL, BLOMFIELD STREET, MOORFIELDS.—Assistant Surgeon. Applications and testimonials to be sent to the Secretary, on or before November 8th.

ST. ANDREW'S HOSPITAL, NORTHAMPTON.—Assistant Medical Officer of Health. (*For particulars see Advertisement.*)

THE CANCER HOSPITAL, FULHAM ROAD, BROMPTON, S.W.—Honorary Surgeon, also an Honorary Assistant Surgeon. Candidates must be Fellows of the Royal College of Surgeons of England, and practising only as consulting surgeons. Applications, with testimonials, to be addressed to the Chairman of the Weekly Board, at the Hospital, on or before November 11th.

WATFORD UNION.—Medical Officer for the Bushey District, in succession to Mr. George Augustus Hicks, resigned. Area, 8,228 acres. Population, 6,619. Salary, £85 per annum.

DEATHS.

BARCLAY, CHARLES, Surgeon-General (retired), at Clifton, on October 26th.

BURTONSHAW, THOMAS, M.R.C.S., at 43, De Beauvoir Road, N., on October 21st, aged 32.

KAY, ALFRED, L.R.C.P., L.R.C.S., of Louth, Lincolnshire, drowned at Mablethorpe, on October 21st, aged 34.

RIMELL, T. W., Surgeon, late R.N., at 75, Eardley Crescent, South Kensington, on November 3rd, aged 64.

NOTES, QUERIES, AND REPLIES.

J. Tremearne, Esq., Creswick, Victoria, Australia.—Letter and enclosure received with thanks.

APPOINTMENTS FOR THE WEEK.

Friday, November 7 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

West London Medico-Chirurgical Society, 8 p.m.—Mr. Bernard Pitts, "Foreign Body in the Air-passage, Abscess of the Lung—Recovery;" Mr. Maitland Thompson, "Case of Retention (24 hours)—Catheter Fever—Death;" Mr. Noble Smith, "The Objects of the Medical Sickness, Annuity, and Life Assurance Society:" Dr. Chas. Good, "Gastric Ulcer—Rupture—Sudden Death."

Saturday, November 8.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, November 10.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Medical Society of London.—Dr. de Havilland Hall, on "A Case of Surgical Scarlet Fever" (postponed); Mr. Rogers-Harrison, on "A Case of Spontaneous Amputation;" Dr. Carrick, on "The Manufacture and Uses of Koumiss in Russia."

Tuesday, November 11.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Anthropological Institute of Great Britain and Ireland, 3, Hanover Square, 8 p.m.—Francis Galton, Esq., F.R.S., on "The Anthropometric Laboratory at the late Health Exhibition;" H. O. Forbes, Esq., F.Z.S., "Ethnological Notes on the People of the Island of Buru."

Royal Medical and Chirurgical Society, 8.30 p.m.—Dr. Champneys, on "Expiratory Emphysema, that is, Emphysema of the Neck, occurring during Labour and during Violent Expiratory Efforts; an Experimental Enquiry."

Wednesday, November 12.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Epidemiological Society of London, 11, Chandos Street, Cavendish Square, 8 p.m.—The President will deliver an Inaugural Address on "Certain Rare Epidemics and Endemics."

Hunterian Society, 7.30 p.m.—Dr. Collie, "Observations on the Diagnosis of Small-pox;" Dr. Turner, on "Case of Suppuration of Simple Fracture of Rib, with remarks on the Ætiology of Inflammation." Council at 8 p.m.

Royal Microscopical Society, King's College, W.C., 8 p.m.—G. Massee, on "Life History of Milowia Nivea;" Prof. F. Jeffrey Bell, on "Structural Characters of Spines of Echinoidea, 1.—Cidaridæ;" T. B. Rosseter, on "the Gizzard of Larva of Corethra Plumicornis;" Dr. J. D. Cox, on "Structure of the Diatom Valve;" Lewis Wright, on "New Lantern Microscope."

Thursday, November 13.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Ophthalmological Society of the United Kingdom, 9 p.m.—Bowman Lecture by Jonathan Hutchinson, F.R.S., on "Diseases of the Eye in Relation to Gout."

Parkes Museum, 74A, Margaret Street, Regent Street, 8 p.m.—G. J. Symons, F.R.S., on "Meteorology and Hygiene." The Chair will be taken by Capt. Douglas Galton, R.E., C.B., D.C.L., F.R.S.

Friday, November 14.

Clinical Society of London.—Dr. Stephen Mackenzie, on "Cases of Dysentery treated by Voluminous Injections of Nitrate of Silver;" Mr. Morrant Baker, on "Three Cases of Joint Disease in connection with Locomotor Ataxy;" Dr. H. B. Donkin, on "A Case of Muscular Atrophy and Joint Disease;" Dr. Hale White, on "A Case of Tumour of the Frontal Lobe with very few Symptoms." Living specimens—"A Case of Favus," by Mr. Malcolm Morris; "Cases of Joint Diseases," illustrating Mr. Baker's and Dr. Donkin's papers will be present, and perhaps others.

CLINICAL LECTURES ON THE DISEASES OF WOMEN.

By J. MATTHEWS DUNCAN, M.D., F.R.S.

Physician Accoucheur to St. Bartholomew's Hospital.

I.—*On Lupus of the Pudendum.*

SEVERAL times in the course of these lectures I have introduced to you this remarkable disease, when speaking of vaginismus, of vaginitis, of irritable bladder; and now I devote an hour to it. The pictures on the table show you, at a glance, how various are the appearances in different cases, and yet you will easily discover how much the group of pictures of lupus differs from the group of pictures of epithelioma and carcinoma of the same parts. There is much mutual resemblance of this lupus and that of other parts, but I do not tell you that they are pathologically the same, as is generally believed.

The disease affects women chiefly during the child-bearing period of life. I have seen it in a child, but at that age it is extremely rare, and I may interpolate the remark that it does not occur in males, or, at least, is very rare in that sex. The disease is generally said to be very uncommon even in women, but that is not my opinion; we are seldom without several cases in "Martha" during a session.

We have been in the habit of speaking of cases that are in measurement small, as instances of lupus minimus; and of cases with great measurements, either of hypertrophy or of destruction, as cases of lupus maximus; and it is curious that we have never observed a case of the former to grow into one of the latter, or *vice versâ*. The case, for instance, that I described in my lecture on vaginismus, was for six years under observation and to the end it was one of lupus minimus. Little ulcers healed up, little ulcers came; a urethral caruncle appeared; the hymen became indurated and had little nodules on it; but after all it was always minimus. On the other hand, our most monstrous case, nine, or more strictly three, years under observation, has improved considerably, but has not in dimensions undergone much change. We have no good account of it as at one time minimus. I have, indeed, never had the good fortune to see a case grow from being minimus to being maximus; yet such growth must take place.

A case of lupus minimus may very naturally be classed, on superficial examination, with urethral caruncle, or eczema of the vestibule, or pruritus pudendi. A case of lupus maximus may be taken for one of tertiary syphilis, or of elephantiasis, or of cancer. Cancer is easily distinguished; and we have taken special care, in all our recent cases, to look for and consider any indications of syphilitic taint. I have no doubt that the

alleged rarity of the disease is to be accounted for by the mistakes I have referred to.

Lupus of the female genital organs is best known as a disease of the pudendum and neighbouring parts; and these are really far most frequently its seat, but it may spread over the adjacent parts of the thighs and the hips. It may attack the vagina and the urethra and rectum; it may attack the cervix and body of the uterus. I do not know of its affecting the tubes.

It is interesting to notice that the face and the pudendum in women are the favourite seats of this kind of disease; and any one familiar with the appearances in the face recognises some degree of similarity in cases of the disease in the pudendum. There are, so far as my observation goes, no tubercles to be seen in the pudendal disease. Why this should be so I cannot say. The moisture of the vulva may transform little tubercles into the little red spots seen there; but the disease affects parts of the pudendum that are not kept moist, and there I have not noticed tubercles.

The cases have a general outward similarity which has been recognised by many visitors to "Martha"; and there is a uniformity of structure as revealed by the microscope—no new or specific elements being found, but the presence of young or growing fibrous tissue with many leucocytes, these often grouped around the vessels. I pretend to no histological authority, and merely tell you what Dr. Thin has told me, after having examined many specimens sent to him from "Martha,"—that the disease is histologically unlike ordinary lupus, the morbid structure being diffused in the affected parts, not occurring in nodules or tubercles. Whilst in ordinary lupus the cells undergo a series of retrogressive changes, in the disease of the pudendum the cells are found either as simple white blood cells or as connective cells in various stages of development. In ordinary lupus the distinctive cells are associated essentially with destruction of fibrous tissue; in the pudendal disease they are associated with the formation of fibrous tissue. The disease has been said to have alliance with scrofula; but I have failed to trace, clinically, any such connection. No doubt in some cases it is a syphilitic disease, but this complication we have done our best to exclude from the cases which form the groundwork of description here. We have, indeed, only very rarely met with evidence of syphilitic taint. The women affected are often of fine healthy even blooming appearance. The disease has a peculiar history and such extraordinary changes or transformations as to separate it from every other.

This lupus is characterised by ulceration, lupus ulcerosus; by destructive ulceration, lupus exedens; by hypertrophy, lupus hypertrophicus. There may be no hypertrophy in one case and in another there may be no ulceration, or such destruction as is implied by exedens. I have never seen great hypertrophy without some ulceration, but often without marked destruction of parts; ulceration and ulcerative destruction without hypertrophy is not rare. Besides, you have discolouration often, and often inflammation of the affected parts, and of the neighbouring organs—the urethra, the bladder, the vagina, and the rectum. We had a case in which there was inflammation and stricture of each of the three passages.

The disease gets its name (lupus) from the ulcerative destruction which it frequently causes. The ulcers, whether exedent or not, secrete pus copiously, sometimes laudable pus, sometimes thin and watery. They may affect hypertrophied parts and have no destructive quality. They may cover a great area, the extent not being discovered until the parts are unfolded. They may burrow and be like abscesses, having small openings; or they may burrow far and wide, and form large empty caverns with large openings, potential caverns, for the sides mutually touch. They may be numerous. They may heal altogether or only in parts. They may bleed copiously. Their occasional gnawing quality is often wonderfully displayed in destruction, which may remove the whole ano-perinæal region, including the viscera there—the urethra, vagina, and rectum. When the uterus is affected the peritonæum may be perforated. In lupus minimus there may be only little red pin-head spots, which change, healing and re-appearing as months go on; or there may be a small scarcely ulcerated reddish patch; or a little ulcer on a urethral caruncular hypertrophy, or on a coriander seed hypertrophy on the hymen, or near it.

The hypertrophies vary as much as the ulcerations. I have never seen them so great in lupus of the face, or of any other part of the body. When great they are generally ulcerated and generally on their inner sides, or where they are in contact with other parts. Sometimes the hypertrophy of a nympha or of a labium majus, or of both, has no morbid appearance or feeling except size. The same is true of the masses sometimes observed around the anus. In the case of lupus minimus so often referred to, the left nympha was, at the end of six years, unexpectedly found in this state. It presented, on histological examination, nothing peculiar, and we would not have known it was diseased, had we not seen it previously like its neighbour, and now four times as big. Sometimes, as in one of our hæmorrhagic cases, there seems to be a new development of nympha, that part not terminating at the side of the vaginal orifice but encircling it posteriorly in a copious frilled healthy-like fold. The hypertrophy may extend over the hip with or without deforming it. It may, in the pudendum, result in the production of large irregularly lobed projecting masses. In one case we had a fantastic appearance, which I show you, several rounded white masses hanging suspended by long threadlike white stalks. A large hypertrophy is generally ulcerated somewhere, but I have never seen it destroyed by such ulceration or removed. There is no doubt that, in many cases, the urethral caruncle is merely one of these hypertrophies.

The colouration of ulcerated parts is always red, more or less pale, or more or less deep. Other parts may have a natural brownish or red tint, or may be deep red, especially if inflamed, or they may be pearly or ivory white.

Inflammation, as I have already said, is not uncommon, more common in the neighbouring mucous tracts than in the ulcerated and hypertrophied parts. In the mucous tracts the colouration is deep red, and the secretion of pus is copious. The inflammation frequently leads to stricture. Adjacent parts of skin, as between the hips, are sometimes intensely and chronically inflamed, copiously secreting pus, and this without any distinct ulceration, only a scarcely raw redness without defined edges.

The disease is often marvellously without symptoms, only the inconvenience of the hypertrophy or of the discharge, or of both. A woman with extensive ulceration may think she has only whites, and cohabit, and bear children; or she may not suspect she has any special disease till she is seized with copious hæmorrhage. But there are other cases where, without inflammation, and generally in minimus cases, the sensitiveness is extreme, and this great difference in cases has made me doubt the identity of the disease in them. When there is inflammation, the inguinal glands may be affected, and they may, though rarely, be affected without inflammation. Of course, when parts are inflamed we have the usual symptoms of that condition.

From cancer the disease is easily distinguished

histologically; but without resort to that evidence, you will know the malignant affection by its appearance, its history, and by the early enlargement of the inguinal glands if it affects the vulva. If the disease is altogether internal, you may have great difficulty in diagnosis.

Elephantiasis is a disease affecting the clitoris or labia only, a great hypertrophy of slow growth, sometimes curiously and regularly nodulated, as in this specimen, without the exedent ulceration of lupus. It is also distinguished by histological characters. I know little of it, for it is rarely seen in these countries.

There is a sort of elephantiasis seen in tertiary syphilis, of which I know very little. In cases I have seen the hypertrophy has been considerable, not at all like that of this lupus, nor like the enormous growths of elephantiasis. It is of a uniform dull leaden red colour, generally smooth on the surface, sometimes superficially ulcerated in mutually touching surfaces, sometimes fenestrated, and the inguinal glands are affected.

As the lupus varies in its characters with the lapse of time, so it is natural to expect that it should be regarded as amenable to treatment; and, no doubt, great gain may come from treatment, especially surgical interference. This consists in removing hypertrophic masses, and in cauterising ulcerations; and both these operations are best done by actual cautery; and when the galvano-caustic is available, I prefer it. I do not say you cure the disease by this means, but you have seen cases of great extent and severity very greatly ameliorated by it, the women going away believing themselves cured.

The mucous membrane inflammations are treated just as such inflammations are treated in other circumstances, but we have learnt to attach special value to mercurials, using chiefly the lotio nigra as a wash, or applied in strips of lint. Under favourable circumstances and treatment, it is interesting to notice the softening or even disappearance of strictures caused by these inflammations.

Constitutional treatment is not to be neglected. Regulation and maintenance of general health, the use of cod liver oil, of arsenic, and of iron.

Lupus is not a fatal disease, and few autopsies are recorded. They have as yet added nothing to our knowledge of the specialties of the affection.

THE REVIVAL OF OVARIOTOMY, AND ITS INFLUENCE ON MODERN SURGERY.[1]

By SIR SPENCER WELLS, Bart.,
Late President of the Royal College of Surgeons of England.

(*Concluded from page* 642.)

In asking you to consider the influence which the revival of ovariotomy has had upon modern surgery, I think we may not only assume the revival as complete by the year 1865, but that, in the words of Paget, "the influence for good was not limited by the increased success of ovariotomy, but extended to every department of operative surgery, and will always continue to be felt in the whole practice of surgery." And the rapidity with which the success of ovariotomy led, again using Paget's words, to "an extension of the whole domain of peritonæal surgery," is not less remarkable than the rapidity with which ovariotomy had advanced in professional opinion between 1858 and 1865. The first extension naturally enough was to the

Removal of Uterine Tumours.

At first, this was only done after a mistaken diagnosis. But before many years had passed it was done designedly, at first only in cases of pedunculated subperitonæal outgrowths; but latterly, under conditions most favourable, success has been obtained in a proportion of cases very surprising even to those who in their long experience have many times been astonished at their own success. Nothing in the whole history of surgery can be at the same time so gratifying and so astounding as the records of Keith's later cases of the removal of uterine tumours, collected and published by his son. Taken alone, they would almost justify a general law to the effect that no woman should be allowed to die of any innocent uterine growth without attempt to save her life by operation being made. When the earlier cases of Kœberlé were criticised in the French Academy by Boinet, Richet cautioned the audience against summary condemnation of an operation not dreaded more than ovariotomy was not long before. The question since that day has been decided by experience, and if a word of caution is now needed, it is only to warn surgeons of the future that they cannot hope for success unless they prepare themselves for operation upon the living body, by taking every available opportunity of practising upon the dead body, and by a conscientious determination to study rather the true welfare of the patient than, on the one hand, how to avoid responsibility, or, on the other hand, how to advance their own renown.

It is fortunate that in some of these cases of uterine tumour an alternative proposal ought to be considered. Both ovaries may be removed with the knowledge that this proceeding has been followed by atrophy of the uterine growth. This, on the part of Hegar, was the legitimate application of a principle, and the practice has often proved successful. In cases where removal of the tumour would have been impossible or exceedingly dangerous, removal of the ovaries and Fallopian tubes has led—with far less risk—to cessation of bleeding and more or less diminution of the morbid growth. But we must have further experience before we can arrive at a fair estimate of the relative value of the two courses of action. We have learned, however, that if the ovaries are not completely cleared away—if, having been adherent, they have been twisted or scraped away from their connections, and some small portions left—menstruation may afterwards recur quite regularly, even though both Fallopian tubes have been totally removed. I have more than once warned the profession against the capricious extirpation of the ovaries, because they are supposed to be the source of all womanly ills, and I repeat my caution, seeing to what wide-spreading evils its neglect may lead. I think it a charity to lay a checking hand on an erring judgment before it has gone too far, and I would fain save our profession from the public odium which must sooner or later be the penalty suffered by all, if a few indiscreet members of our body act without general sanction, or disregard general disapproval.

I have not time to enter upon the very important question of the excision of the entire uterus, either by the vagina or by abdominal section, nor of that substitute for the Cæsarean section known as Porro's operation, nor of the operative treatment of extra-uterine fœtation; and can only say a very few words about the next kind of abdominal tumour, the removal of which followed the ovarian and uterine—

The Enlarged Spleen.

I did not meet with a case which I thought justified the operation until 1865, although I had long before

[1] Inaugural Address of the Session 1884 of the Midland Medical Society, delivered at Birmingham, November 5th, 1884.

that been determined to do it in any suitable case. My second case was performed in this town, and I have only met with one since. I need not tell you that the example has been frequently followed by other surgeons, and there is every reason to hope that increased experience may be followed by diminished mortality.

And so with

Renal and Peri-renal Tumours.

Nephrotomy, nephro-lithotomy, pyelo-lithotomy, and nephrectomy, terms hardly entering into surgical literature twenty years ago, define operations which are now performed in increasing numbers, and especially to the physiologist, with a wonderful success. My colleague, Knowsley Thornton, can boast of ten nephrectomies, all by abdominal section, as well as four nephrotomies and three nephro-lithotomies—the whole seventeen cases successful. These cases, and seven successful cases of pyelo-lithotomy out of eight, as lately recorded by Anderson, can only be the effect of rigidly abiding by the observance of what we now know to be the rule and criterion of good work. So also with a variety of solid and semi-solid abdominal tumours, originating in the pelvic cellular tissue, or in the peri-renal fat, or in the mesentery, the appendices epiploicæ, the omentum, or the abdominal wall, extirpation is effected with a loss of life so small as would have been almost incredible a few years ago.

Already in several cases tumours formed by peritonæal hydatids have been successfully removed. I have not time to do more than barely allude to opening of the gall-bladder and the removal of gall-stones, the opening and draining of hepatic abscesses, of hydatid cysts of the liver, of pelvic abscesses, and of hæmatocele, to removal of the pylorus, gastrostomy, and opening the stomach and removing a large mass of hair. In one remarkable case Mr. Thornton removed a mass of hair weighing two pounds, which was moulded into the shape of the stomach. The incision across the greater curvature was five inches long, and fifteen deep, and fifteen peritonæal sutures were required to close it. The abdomen was closed, and the patient is perfectly well. Ten years ago such an account would hardly have been believed. With the exception of this and one successful case by Schönborn, in all other reported cases such masses of hair in the human stomach have only been found after death. But no one who has watched the progress of these operations, has considered the causes of death in fatal cases, and the details of the operative proceedings in successful ones, can come to any other conclusion than that one important element in the attainment of success is the scrupulous observance of the principles laid down as necessary to success in ovariotomy—not only as regards the hygienic precautions never omitted in modern surgery, but especially as to the importance of a very accurate and exact union, not only of the edges, but of the peritonæal surfaces of the viscera and of the abdominal wall. In gastrostomy, for instance, it is found that when the stomach is attached to the abdominal wall by a single ring of sutures, the weak attachment may give way, and risk of extravasation into the peritonæal cavity may be great. But when, after dividing the abdominal wall, the parietal peritonæum is sewn to the skin all round the opening, a broad surface of visceral and parietal peritonæum may afterwards be maintained in contact by a circle of sutures, forming loops, passed through the peritonæal coat of the protruding portion of stomach, and through the whole thickness of the abdominal wall, about half an inch from the edge of the incision. Smaller fine sutures being inserted between the larger ones, a very close and secure attachment of the stomach to the peritonæal lined opening in the abdominal wall, and complete occlusion of the peritonæal cavity are guaranteed. This done, we have an example of the carrying out in its integrity of one of the fundamental rules of practice in the operation of ovariotomy as regards the peritonæum—surface to surface, not edge to edge merely—and it is a fact not to be overlooked that in gastrostomy the result of the operation seems to depend upon it; the rule being that the cases in which it has been neglected fail, while those in which it is observed end satisfactorily. Thus the lessons learnt at an early stage of our experience in one operation have been the means of leading directly to the successful performance of the other.

This tracking of Paget's extension of the "domain of peritonæal surgery" has carried us a long way, and perhaps those who have entered upon their career at a late stage of the successive annexations may find it not easy to understand the fascination which the subject has for their precursors, who remember its dawning, who were pioneers in realising possibility, and who now live and are still pressing forward to the ever-receding horizon before us. Far as we have come on the way, and much as we have done, there is more to do and more to gain. If formerly we plumed ourselves on our triumphs over the peritonæum—or rather, as it really was, over our fears of the peritonæum—upon our ovarian, uterine, renal, and splenic victories, and put up trophies of all those organs in our museums, we now see our way to new conquests. In proof of this it is a satisfaction to refer to a series of cases and papers in some of the very latest English and foreign medical journals, showing how much more frequently than heretofore obstruction of the intestines is now successfully treated by operation, and that excision of the pylorus, and of parts of the intestines, is already a subject of careful experiment. This is directly traceable to ovariotomy, for one of the very earliest cases was my own union of the upper and lower ends after removing about three inches of small intestine invaded by cancer from an ovarian tumour. In Treves's paper on Excision of Intestine, you will see how firmly an operator of to-day is taking his stand on the true principles of abdominal surgery which we have watched emerging from their obscurity. He does not ignore the teachings from experiments upon animals. He supports himself by the nine successful resections of lengths of the intestines of animals made by Madelung. He traces the failures in many operations of the same kind on the human subject to faults in the details, such as want of perfect adaptation and insufficiency of sutures. And he lays down as rules for his own action that he must separate the peritonæum from the other tissues and introduce abundance of sutures after Lembert's method—bringing the two serous surfaces together, and avoiding the mucous membrane with the needle. A recent paper by Reichel informs us that already 121 cases of resection of intestine have been collected, the conclusion being that the two ends of the bowel should *not* be united at the time of the resection, but that an artificial anus should be established. This can be closed by a subsequent operation. You will probably soon see a report of a case not yet published, where Mr. Jessop, of Leeds, cured a fæcal fistula by separating the injured intestine from the abdominal wall, and uniting the upper and lower parts of the gut by suture. What I said with regard to practice on the dead body before operating on living women afflicted by uterine tumours is equally applicable to the resection of intestine. But here practice on the dead is not sufficient, and if we are not allowed to experiment on living animals in this country, we must either go abroad or practice on men and women. At my request a young surgeon, Mr. Jennings, from whom I hope and expect great things in the future, has recently cut away portions of intestines of dogs, uni-

ting the upper and lower parts so as to maintain the continuity of the canal. Some of the preparations may be seen in our College Museum, and they strongly confirm the conclusion that success depends upon complete union of the apposed serous surfaces.

If I were reviewing modern surgery in general, and not limiting myself to the influence upon it of the revival of ovariotomy, I should speak hopefully of pulmonary surgery, of the draining of cavities in the lung, of incising gangrenous lung, of resection of portions of ribs to obtain contraction and closure of the pleural cavity, and of excision of parts of the lungs, or of an entire lung—even of the surgical treatment of purulent pericarditis. But these are subjects to which I can barely allude as proofs that we do not yet know how far we may go with rational surgery, or what may be in store hereafter for surgical enterprise.

But while we modern surgeons congratulate our science on its liberation from the trammels of tradition; upon its working in an atmosphere cleared of the mist of superstition; upon the changing of its mode of action from a blind grappling with the phantom entities of disease to a study and manipulation of over-nourished or degenerating tissues; upon its having laws which can be understood, and rules of practice which can be followed, we ought not to overlook one fact, which perhaps is more evident to outsiders than to ourselves, standing as we do in the dust and turmoil of the arena of our work. I mean that that work, good and useful as it is, has too much the character of what is technically called "salvaging"—is too much in correlation with what is done by the lifeboat service. Is it there that we ought to stop? I know that we are gradually drawing on beyond that point, and that our investigations are turning in the direction of sources, causes, means of prevention, and outlets for avoidance. But before we can reach the same level of achievement in preventive medicine that we have arrived at in operative surgery—before we can arrest the formation of ovarian cysts instead of excising them—we must know and understand what we have to deal with. We must master the problems presented to us by the erratic developments and mortal decadences of the tissues and organs which we are now content to clear away. And we ought to have the means of accomplishing this task on a scale commensurate with the importance of the subject of pathology—the professional desire for original research—and the dignity of the College of which we are members.

Most of the University cities on the Continent have made provision for this necessity, with such a liberality and profusion of accommodation that the prosecutors of these studies are there at a great advantage. I have visited some of these establishments, and have been able to make comparisons which cause me to regret that so little of the like kind has been done here, and that we have been content to leave a matter which really touches the honour of the profession, and is of national concern, to almost unaided personal zeal and efforts. In England the jesting phrase that "science does not pay" is so common that we scarcely feel the reproach. The history of medical science gives us many instances of unfairly remunerated men (W. Farr, for example), and of the appropriation of the profits of their applied work, and it would be well if the authorities of our profession took the lead in forming an organisation which should aid the modest labourers of its foundations, protect their interests, and reward their industry. I have long desired to see this done by our College, and the munificent bequest of Erasmus Wilson, a man who estimated the value of money by the good that it could be made to do, now puts it in the power of the College of Surgeons to out-rival all other corporations, by setting up round the nucleus which Hunter left the most elaborate combination of all the means and appliances for physiological and pathological research, by concentrating the intellectual power which now runs to waste or is diverted to personal interests, and by guiding and directing all that can be done to the advancement of the purely scientific progress of medicine and science.

Last winter I was away from London for about six weeks. While staying at Würtzburg and Munich, I could note in the most recently erected pathological laboratories how far our German brethren are in advance of anything which I, at least, have seen in this country. At Rome again, and at Naples, I was both pleased and surprised to find how much our Italian brethren were doing. And during the meeting of the Medical Congress at Copenhagen, I was shown arrangements for the study and cultivation of micro-organisms, quite as complete as those which many of you may have inspected at the temporary rooms of the Health Exhibition in London, under the able and instructive guidance of Mr. Watson Cheyne. Now one may fairly ask why provision cannot be made to ensure the continuance of this work, and its extension, in a better and permanent abode?

Something of the kind I hope to see in Lincoln's Inn Fields. I concur completely in the project to make such additions to our noble building as our Council have long felt to be an absolute necessity, and for which they have already considered plans prepared by the eminent architect, Mr. Waterhouse. These constructions are intended to furnish better and more convenient arrangements for the examinations for our diplomas, to guarantee the uninterrupted use of the library, and to give us further facilities for the promulgation of the higher truths of surgical science. Unquestionably this will be in some degree a credit to our College and to British surgery. But I hope I shall not be misunderstood. I have no wish whatever to add to the duties of our College as a teaching institution. We are an examining body, acting for the protection of the public by testing the success of the teaching in the schools and hospitals, and vouching for the competence of our candidates for their calling, after proving to us that they have gone through the course of study we prescribe and possess the average skill and knowledge necessary to meet all the usual demands of practice. Perhaps, hereafter, we may take the higher position of sitting simply as a court of judgment upon the qualifications of those who present themselves for our diploma, irrespective of the mode and time and place in which their knowledge has been acquired—putting aside all interference with the routine and details of the course of study.

But I aspire to something more than success in securing the requisite skill in practical surgery in those who disperse themselves among the people as practitioners under our warrant and authority. I trust that we may go further; and, no longer trammelled by State interference and sensational clamour, that we may accomplish that which such men as are on our Council would probably have done long ago, had it not been for the restrictions placed upon them by financial considerations. Now the funds at their command give ample means for the carrying out of any schemes which the most enthusiastic devotee of original research could, in his most sanguine dreams, imagine. My ambition is that we should not merely be the source of honour to students, and the directors and approvers of schools and teachers, but that we should become the centre of medical research, the mainspring of all the developments of medical science. And now that we can do it, why should we not do it? Why should we not have buildings and accessories, imposing in their grandeur and adequate in their accommodation, laboratories, complete in their fittings, instruments and

*

materials, rooms for conferences, and proper places for the storing of records and results? Why should not our Fellows and Members who are moved with the desire to advance medicine and surgery, by enquiry and experiment, be presented with as great facilities as are to be found in any continental city or university —such as are so profitably enjoyed by Pasteur, Ranvier, Brown Séquard, and their colleagues and assistants—advantages hitherto unapproached on this side of the Channel, but which our transatlantic brethren are not slow to emulate? I feel that to support the honour of our profession, to fulfil our duties as the representatives of surgical science, justly to carry out the intentions of our late president and benefactor, we ought to be magnificent in architectural and constructive outlay, active in personal work, and liberal in the encouragement and help we proffer to those who come to make use of the opportunities which our College will give and promote the object for which we are all so deeply concerned and so heavily responsible.

I am encouraged to augur the completion of such a scheme as this for rendering original investigation in the future infinitely more easy, precise, and valuable than the surgeons of the past ever hoped for, and to believe in the accomplishment of its designs, when I think that the will of such meetings as this must be obeyed, and feel the conviction that the men of Birmingham will be among the first to avail themselves of it.

I have spoken to you of the past and the present. The future is in your hands; and I appeal to you as men typical of the thought and action of the profession, actuated by the highest moral sentiments, seeking and mutually guarding your honour as a body—chasing out, with instinctive repugnance, that which, ignominious in principle or practice, has accidentally intruded itself among you, and conscious that—by assuming the highest functions of your calling, in the investigation of national interests, in the promotion of public good by giving counsel to princes and legislators, by such a devotion of your energies, by such a sacrifice of personal consideration as is involved in bettering the condition of the people, in shielding them from disease, and in the prolongation of their healthy lives—you will add lustre and dignity to the private confidence, gratitude, and sympathy which the profession has already gained by its power over actual suffering and sickness, and by the skill, conscientious vigilance, and humane tenderness with which you make that power manifest.

"I speak as unto wise men, judge ye what I say."

ON SOME RARE EPIDEMICS AND ENDEMICS.[1]

By NORMAN CHEVERS, C.I.E., M.D.,
President of the Society and of the Health Department of the Social Science Association.

GENTLEMEN,—Since we last assembled in this place, death has taken from our association one who, although younger than most of us, was second to none as a man of science. The daily business of the life of John Netten Radcliffe was epidemiology, and when that life closed prematurely a few weeks ago, there was not in Christendom any investigator of disease to whom the title of "epidemiologist" was more justly due than it was to our late esteemed and lamented fellow-workman, an enquirer as honest as he was able, upon whose brief and by no means painless mundane existence the divine light of truth was bountifully shed.

Considering how few and brief our meetings are, I, at the opening of last session, submitted to you for discussion an epidemiological subject, as being more in accordance with the great objects of our society than an ordinary "presidential address," dealing with unpractical generalities.

I, however, have nothing to communicate didactically. As a seeker for knowledge, I lay before you a few somewhat obscure points in epidemiology which, I doubt not, it is within your power to elucidate.

I happened lately to meet with a citation of the following passage from the "Chronicon Angliæ Petriburgense," recording that, in the year 987, "*duæ pestes mortiferæ, Anglis antea ignotæ, Angliam invadunt; febris quædam et morbus, quem scitam*[2] *dicunt.*"

Without pausing to enquire how far the leech-craft lore of that early age was fully competent to decide whether the type of an epidemic was or was not absolutely new or old (seeing that we of the present day occasionally puzzle greatly over such questions), I, having lived at a time when the enteric fever of Jenner was not common in England, and when diphtheria was of rare occurrence in this country, India, and Australia, venture to think that you may not be unwilling to devote a little attention this evening to the consideration of certain epidemic and endemic diseases which are either positively of rare occurrence, or are, as appears more probable, so irregularly distributed over the earth's surface, and so uncertainly fluctuating in their occupation and transgression of their proper areas, and so changeful in their types as to appear new to the ordinary observer, and often to lead men of travel and reading to hesitate in declaring that they are old.

We may be led to call any given outbreak of disease which appears unusual to us "rare," (1) because we are imperfectly acquainted with the geographical distribution of disease. Thus, in a given case, upon our remark, "this type of disease is perfectly new to me," an American or Indian practitioner may say, "this is pernicious fever, with which I am well acquainted." (2) Few observers live long enough to see disease in all its constantly varying types. If London practitioners could now see the type of maculated typhus, with lung complication, which prevailed in this city in one of my years of studentship, they would doubtless call it "rare." Truly it was a rare type of that which was then one of the commonest diseases of these islands, but which is now far less prevalent. (3) Or again, it is within the range of possibility that there should occur any day in our midst an outbreak of disease, regarding the type of which many practical men might be quite at fault, until they were told by one who had lately read Hecker, "this is a re-appearance of the Black Death, which killed fifty thousand persons in London in the year 1347."

I think that I do not claim too much for the Epidemiological Society when I say that, constituted as it is of men who have studied disease in all its modern phases in every quarter of the globe, and who, in the library and in intercourse with their professional brethren, have made it the subject of life-long enquiry, it is at these serious but most friendly and pleasant conferences that the very fullest light may probably be thrown upon whatever still appears to be novel or rare in the characters of epidemic and endemic disease.

Bear with me while I lay before you, in the form of questions, the following subjects for discussion.

In his recently published invaluable work] "An

[1] Inaugural Address delivered before the Epidemiological Society at the opening of the Session, 1884–1885, November 12th, 1884.

[2] The name of this disease survives in the English vernacular. A looseness which is very prevalent among cattle in Natal is called "Skitters."

Epitome of Reports of Medical Officers of the Chinese Customs Service,"[3] our friend Dr. Gordon cites the following report :—"At Newchwang, during the winter of 1880–81, quinsy attacked nearly every foreign adult in the settlement. The majority of the patients had more than one attack ; in some instances the disease was very severe. The largest number of cases and the most severe occurred in the first half of the winter. After a considerable fall of snow, the cases decreased in number and severity." It is a common matter of observation that simple tonsillitis occurs epidemically. particularly in cold and damp weather, but epidemic quinsy is, I think, rare, and I seek reference to similar outbreaks.

Seventeen years ago, a healthy girl of four was brought from India to Cheltenham. Shortly after her arrival it was observed that she was jaundiced. This did not cause surprise as the season was very chill, and she had suffered much from heat and fatigue on the homeward route. It was then noticed that her brother, an equally healthy child, three years her senior, who had been more than two years at home, was also jaundiced. The attacks were unattended with evidences of constitutional distress, and were very transient. I have heard of similar outbreaks of simple jaundice among the children of a neighbourhood, but would be glad to obtain further data.

I have a tolerably fair acquaintance with the history of the epidemics and endemics which have occurred in the neighbourhood of Calcutta during the last half century, but I have only heard of one extensive outbreak of inflammation of the external meatus of the ear. This occurred in the rainy season of 1857. Thousands suffered, mostly along the north bank of the Hooghly, from otorrhœa, the mischief not unfrequently involving the structures of the tympanum. Have similar endemics been observed ?

In Calcutta, boils occur much more generally in some seasons than in others ; but we usually see cases after the hottest weather. The types of furunculi do not appear to vary greatly, but only in one of my twenty-four hot seasons was there an outbreak, very prevalent among children, of livid vesicular boils about as large as peas, which burst spontaneously, and discharged an abundant damson-coloured cruor, so that the child had almost always a bloody streak down its face. Assuredly furunculus is as essentially a constitutional disease as septicæmia is ; but our knowledge of its ætiology greatly needs extension.

At Howrah, there was an endemic of mumps among the children inhabiting a row of houses fronting a partially tidal earthen ditch, into which the excreta of the large gaol were voided. Two little European brothers were attacked with exudative laryngitis [diphtheria ?]. I am aware that cases of mumps, complicated with diphtheria, have been observed, but I am still in search for detailed histories.

About twelve years ago, while residing in Calcutta, and subject to malarious asthma, I suffered occasionally from another neurosis—a moderate colicy pain in the sigmoid flexure, lasting for an hour or two. On the morning of the day preceding my departure for England, I visited my college, breakfasted comfortably at a friend's house, and ordering my carriage for a round of calls, was told that my coachman (a Mahomedan whose mode of life was as different as possible from my own) was ill. I went to the man in anger, but at once perceived that he was in great agony with colic. I said that I would give him medicine, but before I had gone up a flight of stairs I was attacked with most excruciating colic, from which I suffered for hours. I remained subject to occasional recurrences of this neurosis for about two years, but this was by far the most severe attack. I do not think that I saw a dozen cases of colic in India.

I am confident that this was no mere coincidence. I had merely looked at the man, had asked a question or two, and had turned to leave him, when the pain struck me as if I had been shot through. Had this happened to a hysterical woman, I could have better understood it; but that the nervous system of a medical man, in charge of a large hospital, should be thus sympathetic is a matter which I have hitherto entirely failed to comprehend.

In January, 1883, the inmates of my house in Bayswater were ten in number. On the first of that month I noticed a large herpetic spot on the lip of one of them. This recurred on the 27th. I was then told that a servant girl had been suddenly attacked with painful swelling of absorbent glands at the back of the neck. I found that this was caused by a large blotch of herpes just below the hair, and immediately above the upper enlarged gland. On the twentieth of that month, Dr. G. H. Savage published in the *Lancet* a report on "Herpetic Fever," as it prevailed in London. I think that this point deserves further investigation.

Some of the conditions to which I have now alluded were undoubtedly *endemics*, rare, as far as my experience and reading go, which is admittedly not very far. In the classification of the others I solicit your assistance.

With regard to manifestations of disease on a more extensive scale, some *epidemic* outbreaks may only appear to us to be rare because we are imperfectly acquainted with the epidemic history of the sites in which they occur. Thus, it has not been proved that diphtheria appeared in India earlier than 1852, or in Australia before *cir.* 1853, or that yellow fever had been seen in Montevideo previous to 1857 ; still it is quite within the range of possibility that we may yet discover musty records of the fact that these were not the first appearances of the diseases in those localities. Thus, about five years ago, we were told by a competent authority that South Africa enjoyed immunity from true enteric fever. A few months later, we learnt that our troops in the Natal field force suffered considerably from this disease ; and our friend Inspector-General Lawson has lately informed me that he has found clear evidence of the presence of this fever at the Cape in 1827.

The evidence that certain epidemic diseases are rare in particular localities is unquestionable. So it is with cholera of the Asiatic type in these islands.

The last appearances of bubonic plague in England and in Southern France were respectively in 1665 and in 1720.

There is, at present, no evidence whatever to show that Beriberi fever had even extended to Southern Bengal previously to the year 1877. We have no record of the appearance of Pali plague in the plains of India since its first recognised outbreak in the Bombay Presidency in 1815, but its congener, Mahamari, has appeared at rare intervals in the hills, and its closely allied pest, Indian relapsing fever, has, happily unfrequently, committed terrible ravages in the North Western plains.

In a recently published chapter of my work on the "Diseases of India," I showed that a wave of influenza extended from India to England between the years 1824 and 1837. I then cited[4] accounts of the influenza which occurred in 1831 in Penang and Java, and in 1834 in Calcutta.

I have since learnt[5] that this disease also prevailed on the Continent of Europe and in England in 1831 and 1833. As we have no evidence of the recurrence of grave influenza since 1834 in Calcutta and 1837 in

[3] p. 179.

[4] *Medical Times*, vol. i., for 1884, p. 761.

[5] Hecker and Gordon.

England, we may, while admitting that epidemic catarrh, which is so common nearly everywhere, is a mild type of influenza, resolve to place grave influenza among rare epidemic diseases.

There is a disease, regarding the alleged epidemicity of which I am desirous to obtain your opinions. Scorbutus is stated by Hecker to have prevailed as an epidemic, more especially in Germany, in the year 1486, and with such severe and unusual symptoms the people were inclined to regard it as a totally new malady. He cites various authorities in evidence that, on several occasions in the fifteenth and sixteenth centuries, scurvy occurred as an epidemic in Europe. All Indian authorities concur in the observation that scorbutus is constantly endemic in certain districts, especially in Scinde and Behar. Such endemicity may be accounted for upon the supposition that, in such localities, the soil and water are faulty and that the food supply is defective in anti-scorbutic constituents; but various authorities, headed by Kenneth Mackinnon, have adduced facts which go far to show that in India, at least, scorbutus occasionally presents itself as an epidemic, in localities out of the domain of endemic scurvy, quite independently of any abnormality of climate or food supply.

Additional observations upon this point will be exceedingly valuable.

In my addresses delivered at our opening meetings in 1882 and last year, I made some allusion to the occurrence of dysentery in London. I then showed that the last prevalence of dysentery here occurred between the years 1840 and 1847. The details have been recorded by Dr. Baly, and that this malady was true dysentery I had convincing evidence in my own person. The almost complete subsequent immunity of London from this disease is proved by the fact that two distinguished hospital physicians, of middle age, have lately said to me, nearly in the same words, "I have never seen a case of dysentery originating in London." Nevertheless, the Registrar-General's returns, as cited in the public prints, give us to understand that—I quote one verbatim—"119 [deaths occurred during the week ending 18th August, 1883, in London] from *diarrhœa and dysentery*." In one week in the previous month of July, the newspaper gives 351 deaths from dysentery. Making due allowance for inaccurate citation by non-professional reporters, this assertion of the occurrence of a multitude of deaths from dysentery in a city whose physicians have never seen English dysentery, appears, to say the least, rather perplexing.

Undoubtedly the Registrar-General is as wrong in massing together cases of those perfectly distinct maladies, dysentery and diarrhœa, as an ornithologist would be if he classed the owl with the sparrow. I lately spoke upon this matter to a very high non-professional authority. He said that the anomaly probably arose from a prevalence of cases of "dysenteric diarrhœa"—a disease of which I now hear for the first time, and in the existence of which, either at present or at any other time, I confidently disbelieve, diarrhœa and dysentery being two perfectly distinct entities, always to be differentiated by observing the symptoms and washing the stools. Hence I venture to offer, for an expression of your opinions and for your future investigation, the questions—Has dysentery occurred in London of late years? Does it continue to occur? And what is the true nature of the destructive malady which is spoken of as "dysenteric diarrhœa?"

Not many minutes after writing the above, a few days ago, I met with the following expressions, used by a sound pathologist in describing a case of tropical liver abscess observed in London. We are told that the man "had been suffering for some time from *diarrhœa*," [the italics are mine] "with slimy motions" . . . . "There was a return of the *dysenteric* symptoms"; the "motions were loose, slimy and contained blood." Extensive dysenteric disease of the colon was found after death. The erroneous belief in the existence of such a disease as dysenteric diarrhœa probably arises from the fact that grave dysentery is not always attended with severe pain. Hence doubtless the fact mentioned in Rymer's "Fœdera," that the English soldiers fought at Agincourt "naked from the waist downwards because of the distemper" [dysentery] "which hung upon them." Had the poor fellows suffered as much as I always did in dysentery, they could not have fought at all.

I believe that a careful search for indigenous dysentery in London and its suburbs will probably lead to the discovery of genuine cases.

A year or two ago my friend Dr. John Macpherson told me that a typical case had occurred at Forest Hill.

Having now offered you, out of an overflowing budget of ignorance, more questions than can well be answered in the few minutes which remain to us, I will merely say that I am heartily rejoiced at being allowed the great privilege of greeting you here again; and that I am confident in the hope that, in the future as in the past, our quest for scientific truth will continue to be ruled by brotherly friendship and large-minded toleration.

CHOREA AND OVER-WORK AT SCHOOL.

By F. DAWTREY DREWITT, M.A., M.D. (Oxon).

Physician to the Victoria Hospital for Children, late Resident Medical Officer, Great Ormond Street Hospital for Sick Children.

HAPPILY, there seems to be a chance of the important question of over-pressure in schools not being allowed to degenerate into a party squabble, for that would inevitably put back for some time all hope of wise legislation on the subject.

Surely, just at this time of transition in all things social and political, any sensible person would regret to see the recent Acts of Parliament on popular education seriously interfered with. Few measures of such importance, both to the State and to the individual, have been undertaken of late years, and all the talk we used to hear of education unfitting men and women for physical work in after life, fortunately seems to be dying out. The Scotch, in spite of *res angustæ domi*, have always been in advance of us in educating their poor, who are consequently more capable than ours of intelligent physical work, and seem to have more of that especially British characteristic, fitness for undertaking posts of responsibility both at home and abroad. Still, there can be no doubt that children suffer from over-work, and it is clearly the duty of the State to keep such suffering at a minimum.

Of the definite forms of illness caused by over-work, chorea seems to be the most common, and the following short histories of 25 unselected cases of chorea, all in fact that I can at present lay my hands on, and all given me by the parents themselves, are probably typical of the general run of such cases which find their way to our children's hospitals.

The first six were brought up to the Great Ormond Street Hospital for Sick Children in 1879 and 1880. The remaining nineteen have been out-patients of mine at the Victoria Hospital for Children in Chelsea, in 1882–83–84.

Phœbe B., 15, Drury Lane, aged 11, has had chorea one month. Was working hard at Board-school from 9 till 12.30 in morning, and from 2 till 4.30 in after-

noon, and 3½ hours at Sunday school. She sits up reading school books till 10 or 11 at night. Her mother has often locked up her books; she has then borrowed other girls' books.

Jane W., Hudson Road, Plumstead, aged 8, attending school; no evidence of over-work. Present attack of chorea followed a fall on the back of her head. A previous attack followed a fright; saw her brother nearly run over by a cart. Has had rheumatic fever. Mother had chorea.

Charles B., Grange Road, Bermondsey, aged 11; chorea three weeks. Mind affected; tears up books, and has painted the school fire-place with red ochre; no recollection of it afterwards. Has a great dread of school; no evidence of over-work. Boy hit him on the head just before attack. Father had chorea and rheumatic fever. Mother, rheumatic fever.

Rose S., Burlington Road, Bayswater, aged 7. "Had been attending Westbourne Park Government school; very quick in learning. Makes rhymes like a grown person; very fond of drawing; works in the evenings by her own choice." Chorea came on gradually with mental change and delusions.

Florence C., Northampton Street, Clerkenwell, aged 11. Attending school; not over-worked; was much frightened by some stories about black bogies. Chorea followed; has had rheumatic fever.

James H., Blenheim Street, Chelsea, aged 10, attending St. Luke's Schools, Chelsea, when chorea began. Work 5½ hours a-day; Sunday school 2 hours. Very fond of books; worked at home-lessons every evening, and then read other books till 9 or 10 at night; trying to pass into 4th Standard. Has had rheumatic fever. Mother, chorea and rheumatic fever.

Roger R., Malcolm Square, Chelsea, aged 11; has had general chorea 7 months; attending St. Luke's Schools, Chelsea. "He is unlike other boys, he learns without being taught; likes his lessons, and has no difficulty with them; takes his books home and works at night. He is also teaching himself music;" has had rheumatic fever.

Rose D., Fulham Road, Brompton, aged 9. Second attack of chorea, following as did first attack, severe blow on head; extensive scar present. Sharp child, attending school, but not over-worked.

Emily H., Laurence Street, Chelsea, aged 7. Has chorea, left arm and face. It followed a fright at seeing a man in a fit.

Robert W., Cheyne Walk, aged 12. Chorea three months. "Is at the top of his school; is fond of it and works very hard. It's no trouble to him."

Jessie B., Chelsea, aged 10. Chorea four weeks. Goes to Christ Church School, Paradise Road. "High up in the school (4th Standard); takes her books home and works hard at them."

Agnes B., Wellington Street, Chelsea, aged 7. Chorea three weeks; going to Christ Church Schools. "Very fond of her work; is at school 6 hours a-day, and asks for books and her pencil as soon as she comes home. Sister had chorea."

Jane K., aged 10. Slight chorea 2 weeks. "Takes her books home to work; works hard at sums; does compound addition." History of rheumatism.

Henry H., Convent Gardens, Notting Hill. Chorea 9 weeks. Fell off roof of shed at school. Had concussion of brain; chorea followed. No evidence of over-work.

Maud C., aged 8, Battersea. Chorea 1 week. Goes to National School; not very quick at book-work. Teacher is severe with her, and punishes her by keeping her in.

Kate G., Italian Walk, Vauxhall, aged 9. Chorea 1 month; was frightened by a runaway horse.

Kate P., Church Street, Chelsea, aged 13. Was frightened while swinging. Her sister "kept on swinging her till she was sick; would not leave off." Chorea followed.

Ada C., Chelsea, aged 7. Goes to Christ Church School; works hard. "Goes through her lessons in her sleep, and begins with her slate and book before she is up in the morning."

Elizabeth B., aged 13. Chorea. Was frightened by boys at Parson's Green.

Emily M., Battersea. Chorea, following fright.

Henry B., aged 13. Severe general chorea 7 weeks. In 6th Standard, and works hard, but sleeps well and not over-worked. Saw a woman lying in a fit; thought she was dead; was much frightened.

Alice W., Kamballa Road, Battersea, aged 7. Chorea 1 month; attending school in Green Lane. Sometimes kept in over time, but is very fond of work; never has a "book out of her hand. Is always spelling."

Clara H., Frere Street, Battersea, aged 9. Chorea came on while working hard for Scripture examination at school.

Frederick H., Camera Square, Chelsea. Attending school in Park Walk, Chelsea; no evidence of over-work. Fell on his head a month ago; chorea followed, scar on head visible.

There is no doubt that many, perhaps all, of these children were predisposed to chorea either from rheumatism or hereditary tendency. The determining cause, however, in 12 out of the 25, was a fright, a fall, or a blow. In the remaining 13, there is more or less distinct evidence of severe school work.

But now comes an important point. The over-work in nearly all the 13 was due not to the over-zeal of the teacher, but to the child's own active mind; to over-brain work, as in the case of the child who borrowed other children's books when her own were purposely locked up, but not to over-pressure.

Out of the hundreds of out-patients which come to our children's hospitals, it is extraordinary how few complain of school, at least, that has been my experience; and those who do suffer from school work, soon get over it on staying away for a time. Even chorea, though sometimes a serious illness, is generally recovered from in a few weeks.

All the cases above mentioned, with the exception of one which happened lately, and is still under treatment, recovered completely. Still, there is no doubt that over-brainwork occurs. It exists among adults during University life, and in life afterwards, and it would be extraordinary if it did not exist among children who naturally have more enthusiasm, and less physical strength than their elders. Probably, the greater number of over-worked children do not become hospital out-patients.

Now what is the remedy? First, I should say some modification of the "payment by results" system.

Secondly, taking care that children only work in working hours. In our great public schools, over-work is I believe not much felt, and one of the reasons for this probably is that boys are taught to play as well as to work. As soon as the time for cricket or foot-ball comes, all thoughts of vulgar fractions and irregular verbs vanish, but it is not the same with the poor. Playgrounds certainly have been provided by the School Board, but there are not enough of them, and the children are too much inclined to go home and sit down in close rooms, or at best spend their time in the open air, making mud pies over the street drain, or stuffing up the broken bell-trap in the back yard with tea-leaves and cabbage stalks. They ought to be taught to play games as well as to read books, and I can see no harm in making out-of-door exercise almost compulsory, perhaps in providing a dancing master, and professional teacher of cricket. At all

events quick children require some physical work to act as a check to book-work, and keep their over-active brains at rest. For I think the preceding scanty notes are enough to show that every now and then harm is being done, and, unfortunately, it is the best material which is wasted, the willing horse which is over-driven.

Such a plan as this would, of course, if carried out, entirely prevent children being kept indoors to do impositions or extra work during play hours. That, however, would be an unmixed good. Schoolmasters who keep children in when they ought to be at play, or parents and schoolmasters who have little fits of sulks with children when they are naughty and refuse to speak to them for hours, only help to spoil a child's character; short and sharp corporal punishment is far better. The ever to be remembered Dr. John Brown, the author of "Rab and His Friends," had the courage to write on this subject in a popular magazine some years ago, and concluded, if I remember rightly, with a paragraph to the effect that corporal punishment besides warming their little bodies had a direct tendency to "warm their little hearts."

CASE OF THE RESTORATION OF THE NATURAL COLOUR OF HUMAN HAIR AFTER HAVING BEEN GREY FOR SEVERAL YEA

By VANDELEUR C. ISDELL, L.R.C.S.I., L.M. Dub.

In conversation with Dr. George Hailey, F.R.S., of London (during his homeward voyage from attending the recent meeting of the British Association in Canada), regarding the changes in colour which occasionally take place in human hair, I mentioned a curious circumstance in connection with the restoration of colour with which I am intimately acquainted, from its having occurred in the case of my own father, Dr. James Isdell, of Dublin.

The main features of the case are the following:—

In the year 1861, when at the age of 62, both the hair of his head and beard were completely grey, whereas, in 1882, that is to say 22 years later, when he died at the age of 83, the hair of his head was of its original natural dark colour, the whole of it being quite dark with the single exception of a few grey hairs on each temple.

Unfortunately, as regards the condition of the beard at the time of his death I can say nothing, from his having shaved it off many years previously, and never allowed it to grow again.

I may mention that my father had been a teetotaller for upwards of 40 years, and that his mode of life had always been an exceedingly regular one. Moreover, no constitutional or other reason, that I am aware of, could be assigned for this strange freak of Nature in restoring to its natural colour my father's hair after it had become decidedly grey, and it is on account of authentic cases of this unusual occurrence being exceedingly rare, that, at Dr. George Harley's suggestion, I send you this brief history of the case as I think it may be useful to persons collecting data in connection with the anomalies of hair colouration.

Constipation from Lead.—A favourite prescription of Prof. Da Costa for the constipation of plumbism is one drop of croton oil, made into eight pills, of which one should be taken two or three times a day.—*Philadelphia Medical Report*, July 19th.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. MARY'S HOSPITAL.

A SERIES OF CASES OF URINARY TROUBLES.

(Under the care of Mr. EDMUND OWEN, F.R.C.S.)

(From notes taken by Messrs. Barton and C. Murray.)

Stricture—Extravasation of Urine—Perineal Section.

(1) A. H., 43 years of age, had led a rough life in Australia; for ten years he had had stricture of urethra. At the end of August a small catheter had been passed, and this operation was at once followed by retention of urine and a perineal abscess. For this he was admitted to St. Mary's Hospital. Under an anæsthetic, Mr. Owen performed perineal section (having failed to introduce a fine grooved staff). The perineal incision was prolonged forward through base of the scrotum and urethra, and a No. 12 (English) catheter was passed *per urethram* and into the bladder. Much offensive urine was drawn off and the bladder was then washed out. Five days later No. 14 was passed, and the sluggish wound in the perineum painted with compound tincture of benzoin with marked advantage. At the beginning of November he was discharged, having made arrangements to attend twice a week under the house surgeon, Mr. French, for the passage of a No. 15 catheter which entered the bladder easily. The urine passed *per urethram* and he had perfect control over it; he was looking well and strong.

Stricture—Phthisis—Acute Cystitis—Median Cystotomy.

(2) W. S., the wreck of a man who had been for years an asylum-attendant and afterwards an undertaker's porter, was admitted in the middle of September to the medical wards for phthisis; he had been a steady drinker. When he had been a few days in the ward he complained of pain above the pubes and of intense pain at the glans penis. The urine drawn off was so thick with pus and blood that at last it refused to flow through the eye of the catheter; the bladder was distended up to the umbilicus and the man was in a perilous condition. It was thought very possible that the pus and the blood in the urine were the result of tubercular ulceration of the bladder.

The patient was then transferred to the surgical wards, and Mr. Owen, having examined him, proceeded to perform median cystotomy on Buchanan's rectangular staff. Much offensive urine, pus and blood escaped, and the bladder was then and on every day for a month afterwards treated by free irrigation. The finger could detect no ulceration on the lining membrane of the bladder. From the time of the operation the patient improved in every way. No. 12 catheter is passed occasionally, and the man is preparing to leave the hospital.

Traumatic Rupture of Urethra—Pelvic Abscess.

(3) J. G., a boy of 8, whilst "doing Blondin" in Hyde Park on September 28th, fell astride the top bar of an iron railing. A few hours later he was brought to St. Mary's Hospital with retention of urine. Under chloroform, Mr. French was able to pass No. 6 silver catheter, drawing off much urine slightly stained with blood; with Mr. Owen's concurrence he then deeply incised a large blood tumour in the perineum. No urine escaped from the wound, but next day, as the

catheter could not be introduced and the boy was suffering from retention, Mr. Owen opened the urethra by an incision from the apex of the prostate forwards. The catheter was then passed and the bladder emptied; for the next three weeks the instrument was passed every other day, and all went on well. Then steadily his temperature ascended to 102°, he became pyæmic, and the hypogastric region grew hard and very tender though the urine came away clear. Leeches and fomentations were freely used, but as the hardness and tenderness increased and the boy was getting worse, a pelvic abscess was diagnosed which Mr. Owen attacked much as if he were about to tie the external iliac artery, except that he used the scalpel but little, and the grooved director a great deal. In this way about four ounces of pus were liberated from the sub-peritonæal region, the finger introduced being able to feel the back of the recti abdominis, the front and summit of the bladder and the fold of peritonæum reflected from the bladder. The finger was passed across behind the two recti and a counter opening was made in the opposite inguinal region, the large cavity was washed out with hot water tinged with iodine, a large drainage tube was passed through the two openings and iodoform was insufflated; pressure was firmly applied and the boy was made to lie prone. Immediately his temperature came down to and has remained at normal, his aspect improved and his appetite returned; no suppuration followed and in a few days the small drainage-tube was taken away. In every respect the boy is going on well, and though still in the hospital (Nov. 12) he is convalescent.

Remarks by Mr. Owen—These cases form but a part only of a highly interesting series of cases which have recently been under my care at the same time, and they have afforded excellent material for clinical remarks, of which the following have perhaps been the most important:—

(1) A hard swelling suddenly appearing in the perineum is most likely abscess; the pus is bound down too tightly to allow of fluctuation; it must be freely incised in the middle line. "Incontinence" in the adult means a bladder brimming over. A No. 9 or 10 catheter does not efficiently dilate the adult urethra. A man with stricture should learn to pass a full-sized bougie for himself, and it is highly expedient that he become a teetotaller.

(2) Median cystotomy is a simple and comparatively bloodless operation—it is one of dilatation rather than of cutting—it affords immediate relief to acute and obstinate cystitis and allows a digital examination of the interior of the bladder. The aphorism "a man is as old as his kidneys" is excellent; so far as the surgeon is concerned some men are old at 40.

(3) Rupture of the urethra entails the advent of a traumatic stricture; the patient must be made to understand this and keep himself under constant and prolonged supervision. Pelvic abscess must be treated on the principles which guide us in dealing with abscess in any other situation, for though deeply placed the pus is easily accessible. Pressure on sensory nerves causes elevation of temperature through the sympathetic system, and a belief in the germ-theory of disease should never imply a neglect of the important influence of that system.

Benzoin in Chaps and Frost-bites.—At a meeting of the Philadelphia Medical Society, Dr. Seiler called attention to the value of tincture of benzoin in the treatment of chapped hands and frost-bitten feet. He has used it in a number of cases with great success, simply painting the skin with it. The stocking may be prevented from sticking by rubbing some oil over the benzoin.—*Philadelphia Medical Report*, July 19th.

Medical Times and Gazette.

SATURDAY, NOVEMBER 15, 1884.

A private and informal meeting was held a few days since, at a house in Mayfair, to discuss the desirability of forming a "Teaching University" in London. Several eminent members both of our own and other learned professions were present, and the scheme was so well received that a small committee was elected to give a detailed consideration to the question. We hear that the medical profession, in both its branches, is extremely well represented on this committee, as indeed it well deserves to be, considering that it is by medical students that the want of a university is most felt. What we require is (1) A come-at-able degree, and (2) Organisation of teaching; and no scheme for founding more resident colleges and university professorships will be acceptable if these two desiderata are neglected.

A general meeting of the Association of Fellows of the Royal College of Surgeons was held on Saturday last, the 8th instant, to consider the recommendations of their Sub-committee on the proposed alterations in the Charters of the College, a provisional scheme of which we published a fortnight ago. Only very slight and unimportant alterations were made in the sub-committee's proposals. The meeting was presided over by Mr. Pollock, and about 150 Fellows, either by their presence or by sending letters of approval, signified their assent to the recommendations.

Our Paris correspondent writes:—The cholera has made its appearance here, a fact with which the daily papers have of course made the public acquainted. The present state of things was preceded during a few days by an epidemic at Aubervilliers and Pantin, on the outskirts of Paris, among the *chiffonniers*, or rag-gatherers, who congregate in wooden huts in these suburban localities. The huts were evacuated and burnt, the population removed, and the local epidemic arrested; but on the 3rd of November, an undoubted case of Asiatic cholera broke out in the Rue Coquillière, in the business centre of Paris. The person affected was a young married woman in an advanced state of pregnancy. The case soon proved fatal. Four deaths from cholera took place the next day, and the usual process of dissemination set up. On Sunday, November 9th, from midnight to midnight, 186 cases and 51 deaths were reported. On November 10th, within the same limits of time, the number of cases registered was 153, out of which 33 proved fatal.

The infliction is impartially disseminated throughout the various quarters of Paris, the Arrondissements chiefly affected being the 11th and 7th. In this latter section of the capital, a local epidemic, of unusual severity, has occurred in a poor-house, kept by Sisters of Mercy, for the aged and infirm paupers of the

district. The house is situated in the Rue de Breteuil. When the visitation occurred, the disease made fell havoc among the old, disabled and unresisting population. Twenty-eight paupers died on the 9th, and seventeen on the 10th. It is owing to this local outbreak that the 7th Arrondissement exhibits so large a death-rate from cholera, the other portions of the district being comparatively free. The general attitude of the population is excellent. The necessary measures had long ago been taken, an invasion of cholera having been daily apprehended since last July. Two hospitals (Mariniers and Bichat) have been set aside for cholera patients; and in all hospitals and lunatic asylums a special quarter is put apart for the same purpose. Disinfecting processes are applied by a trained body of special agents, and rapid interment is enforced. Several cases have occurred in the garrison of Paris, especially among the *chasseurs*, and it is intended to station the troops, as far as possible, outside of the city.

A very remarkable fact, to which no one seems to have drawn attention, is that the outbreak of cholera was preceded, during the end of September and the whole of October, by a strongly marked epidemic of influenza. During six weeks, half the population of Paris was afflicted with coughs and colds, with sore throat and loss of voice, and many cases occurred of fatal bronchitis and pneumonia. Now, the contagion of cholera was certainly imported into Paris from the very beginning of the epidemic in the South of France. Several sporadic cases were observed in travellers coming to Paris from Perpignan and other infected localities. Two such patients died at the Hôpital Bichat, in the wards of Dr. Gougenheim, in whom the *post-mortem* appearances were exactly those of Asiatic cholera. The seed was therefore sown broadcast, and yet it did not prosper, the receptivity of the population not being carried to its proper pitch. Then, the epidemic of influenza comes "to manure the soil," after which a paltry epidemic among rag-gatherers (probably caused by the importation of soiled rags from the South) breaks out at Aubervilliers, and in an instant the whole capital is on fire. Is it not probable, therefore, that something more than the comma-bacillus, something more than pollution of rivers and wells, is required to set the fiend free?

Dr. Fauvel, the illustrious hygienist, died just in time to escape witnessing the downfall of his predictions. He was carried off by pneumonia, at the age of seventy-two. His health had long been failing, and the moral shock of recent events aggravated his situation. He was Vice-president of the Academy of Medicine, Inspector-General of Sanitary Sciences, Professor at the Medical School at Constantinople, and Honorary Member of the Consultative Committee for Hygiene. In former years he took a very active part at the International Congresses held at Vienna and Constantinople for the regulation of quarantine and the organisation of sanitary measures for the abatement of the plague.

Mr. Mundella, as we anticipated, is determined to have no official enquiry into the working of the Education Code, and lives in the hope that a partial and more or less private investigation by the London School Board will be sufficient to silence all complaint. Mr. Stanley Leighton, in the House of Commons, last week, appears to have asked for more than the most extreme believer in the existence of over-pressure had ever demanded, viz., a commission of enquiry composed entirely of medical men. Such a commission, we fear, would as little satisfy Mr. Mundella, Mr. Fitch, and the rest of the Education Department, as a commission nominated entirely by the department would satisfy medical men. The *Medical Times*, as Mr. Storr has pointed out in the leading journal, was the first to advocate an enquiry, and it never asked for more than a mixed commission. We are glad to see that Mr. Mundella recognises the advantage of an enquiry being "assisted by impartial and thoroughly qualified medical experts"—we shall be curious to see whom he regards as experts in this particular matter—and testifies to the benefits that have followed the public discussion of the question. Not the least of these benefits is that the discussion has evidently brought Mr. Mundella into a more statesman-like frame of mind than when he hurled his famous "boomerang."

The debate on the Indian Medical Service raised in the House of Commons, in July last, has brought forth good fruit with unhoped for promptness, and in unlooked for fulness. On that occasion the tone of the Under Secretary of State for India, Mr. Cross, was uncompromising and unsympathetic. He stoutly denied that the junior officers of the Service had any grievances at all to complain of. The Service had been over-manned and promotion was unquestionably slow; but all that was a matter of luck, and the Government of India had nothing to do with it. Mr. Cross' bark was hard and defiant, but at the conclusion of his speech he softened so far as to express some sympathy with the junior officers, who, according to him, had no grievances; and to assert that he should be delighted to help them could he do so consistently with his duty; and he promised that the whole matter of the debate should be placed before the Government of India. On Thursday sen'night Mr. Cross showed that his action in the matter in question has far exceeded the promise of his speech. Mr. Gibson asked whether any, and if so what, steps had been taken by the Indian Government to lessen or remove the grievances of the Indian Medical Service; and in reply Mr. Cross stated that the measures taken to reduce the number of the unemployed medical officers had been efficacious. The Government of India had telegraphed that there are now only two unemployed officers in Bengal; and they will report how many are still unemployed in Madras and Bombay. Further, it has been decided to place all surgeons of the Indian Service, not holding executive charge, on precisely the same footing, as respects pay, as Surgeons of the Army Medical Department similarly situated. The lower rate of pay hitherto termed "unemployed pay," will for the future be called "grade pay," and will be given only when

an officer is in receipt of staff salary in addition to his pay. Thus, all the most real and serious grievances of the Indian Medical Officers have been quickly and effectively remedied, a clear proof that had a little extra forethought and care been exercised they would never have existed. Cure is good, but prevention would have been much better.

It appears that the new regulation requiring Surgeons-major to undergo an examination for promotion to the rank of Brigade-surgeon is to be made retrospective, and to apply to even very senior officers. In reply to a question by Sir H. Fletcher on the subject, the Secretary of State for War stated that there are several Surgeons-major over fifty years of age who will have to pass an examination before being promoted to the rank of Brigade-surgeon. Lord Hartington did not suppose that any precedent could be found for such a proceeding, but in no other Service was it so difficult to arrive at the grounds of selection for promotion; and the examinations were determined on at the suggestion of the Director-General. Previous Directors-General of the Army Medical Department must, presumably, have had to undertake the responsibility of selecting officers for promotion to the administrative ranks of the Service; and it would not seem too much to ask the present Director-General to bear the burden of that responsibility for a while rather than to compel officers who have served for twenty or five and twenty years, or even longer, to submit to an examination for promotion.

Those who are anxious that the College of Surgeons should take the place as a national institution to which its coming wealth and the numbers of its members well entitle it, will read with real pleasure the career sketched for it by Sir Spencer Wells in the concluding portion of his Birmingham address, published in another column. We are glad that the scheme of establishing a pathological institute, which we believe we were the first to advocate, finds favour in the eyes of one so influential at this College as Sir Spencer Wells.

At the Medical Society, on Monday last, Dr. de Havilland Hall read a paper on so-called Surgical Scarlet Fever, his reason for doing so being that "the connection between surgical operations and scarlatina is unknown to many students and practitioners, *probably on account of the text-books on surgery most in vogue ignoring the subject.*" This is certainly a curious reason to give for bringing forward such a subject. Since the authoritative expression of opinion made at the International Congress that so-called surgical scarlet fever is nothing but the ordinary fever occurring after operation, it seems to us to be regretted that the old and obsolete term should be revived. Nevertheless, an interesting debate occurred on Dr. Hall's paper, in which, after relating a typical case, he summarised the published cases, the most generally accepted views, and added a bibliography up to date. The paper when published will be a valuable addition to the Medical Society's volume. We cannot agree with him, however, that the *surgical* text-books are responsible for the ignorance of the subject which he so much deplores Surely the medical text-books are the most suitable places to discuss such questions. On turning to the latest work on "Diseases in Children," by Dr. Eustace Smith, we find it spoken of as "the form of scarlatina which occurs sometimes after surgical operations." Dr. Hall's calling attention to the subject will be the means, let us hope, of having any deficiency in the text-books put right. In the discussion which followed, most of the speakers accepted Dr. Hall's view that the disease was ordinary scarlet fever, that it might be followed by the usual sequelæ, and would affect other persons exposed to it. Other forms of disease were also mentioned as liable to attack surgical patients: such as erysipelas, chicken-pox, gout, as well as non-specific erythematous rashes. The influence of anæsthetics in bringing out "rose rashes" was also alluded to. Altogether it was an interesting and profitable debate, which, if it did not bring out any new facts, will certainly serve to draw professional attention to the need of careful supervision and strict isolation of all cases in which rashes follow on surgical operation.

At the Medical and Chirurgical Society, on Tuesday, the 11th, before a very small gathering of the Fellows, Dr. Champneys read a paper on Expiratory Cervical Emphysema, occurring during labour. The final conclusions were quite lost sight of in the elaboration of detail with which the paper was over-weighted; partly in consequence of this, and of the nature of the subject, there was little or no discussion. The chief point, however, which followed from Dr. Champneys' experiments, was to show that the "weak spot" on the anterior surface of the root of the lung, that is to say, that in violent efforts of expiration, when the lung ruptures, the rupture occurs at the root, and not, as one would have thought, along its free margins. The accident occurs only about once in two thousand labours, and seems always to end favourably, hence the condition is not one of any great clinical importance.

The Bowman Lecture which was delivered before the members of the Ophthalmological Society on the eve of our going to press, will appear in full in our pages next week. Suffice it to say at present that the members and visitors present, by their numbers, testified to the esteem in which Sir William Bowman is held, not only amongst men engaged in his own line of practice, but in all classes of the profession. Mr. Hutchinson, who had been selected by the Council to give this, the first, lecture, chose the relation of Diseases of the Eye to Gout, a subject in which his interest has already been amply evidenced by numerous writings. The lecture was obviously the result of clinical experience and observation, and was mainly devoted to an endeavour to extend the limits at present set upon the influence of gout on diseases of the eye, the lecturer dwelling especially on two conditions in which he believed that gout played an essential part, viz., a form of very destructive iritis, occurring first in one eye and then in the other, and usually attacking young people. The other affection for which he claimed a gouty connection was neuritis; and this, too, was supported by clinical evidence, one case especially afford-

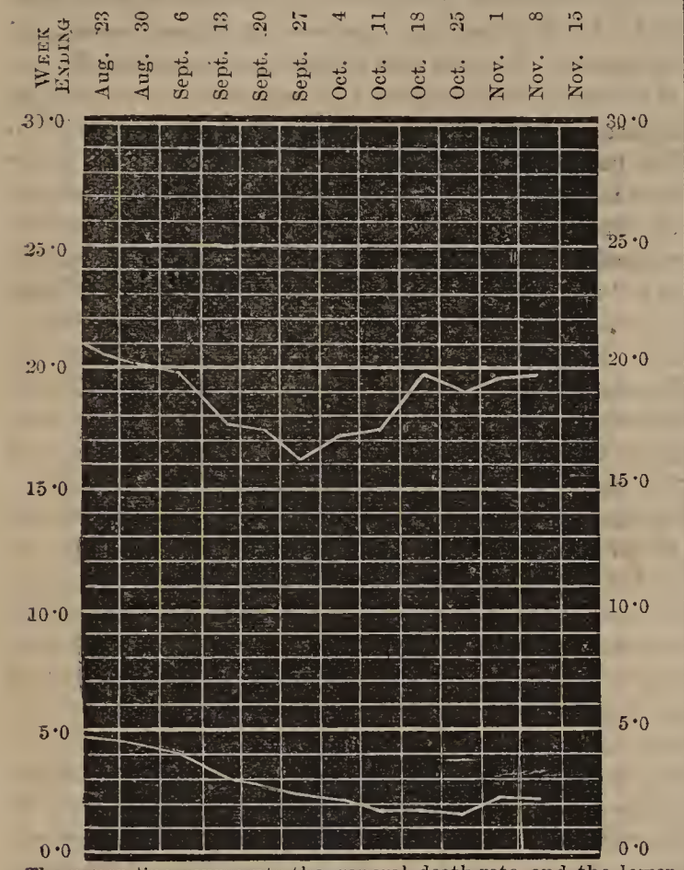
ing strong support to the assumption that neuritis of the optic nerve might be of gouty origin.

An interesting discussion on Intestinal Obstruction has recently occupied the Liverpool Medical Institution during two evenings, those, namely, of October 23rd and November 6th. The discussion, which was exceptionally well attended on both occasions, was opened by Dr. Greves and Mr. Pughe, who narrated a successful case which had been under their joint control at the Children's Infirmary, and which closely resembled one of Mr. Gould's cases published in our columns last week. The obstruction, occurring in a child, was diagnosed to be a band in the region of the cæcum, and on the failure of mechanical means, Mr. Pughe, under the strictest antiseptic precautions, opened the abdomen. He found that the obstruction was caused by an adherent vermiform appendage tightly constricting a loop of intestine. The appendage was ligatured in two places and severed between the ligatures. Relief was immediate, and the child was shown to the audience in perfect health. Twenty-one physicians and surgeons took part in the debate, including the majority of the hospital physicians and surgeons of the city. About the medicinal treatment there seemed to be very little difference of opinion, it being generally admitted that complete rest, starvation, and large quantities of opium formed the most reliable measures. Mr. H. O. Thomas opened the discussion on the second evening and reiterated the opinions he has so ably practised and preached for the last twenty years and more. The physicians claimed great results from medicinal treatment; but, as Mr. Paul showed, their general statements were not supported by statistics. Whilst he was pathologist to the Royal Infirmary, eighteen cases of intestinal obstruction were admitted. Ten of these reached the *post-mortem* room, several of which, Mr. Paul showed, might have been saved by timely surgical interference. Dr. Rich, the present pathologist, said his experience was very similar. Of the cases cured by medical treatment, a considerable number, according to several speakers, were cases of colic and constipation, which would have got well under any treatment.

Most of the physicians admitted abdominal section to be useful as a *dernier ressort* in intestinal obstruction, but held that the mortality from it only justified its being used as such. The surgeons replied that the mortality was due to the operation being performed too late. Generally, when the physician handed the case over to the surgeon, it was more fitted for the *post-mortem* than the operating theatre, and the operation instead of being a *dernier ressort* only hastened the end. They maintained that the surgery of the abdominal cavity was now almost perfect, that the diagnosis was chiefly at fault, and that the subject under discussion suffered from belonging to the physician first and to the surgeon afterwards. The surgeon ought to have such cases from the beginning. He could easily manage the medicinal treatment as well as the physician, and the necessity for a correct diagnosis, *upon which he might have to act*, would sharpen his diagnostic powers; besides, he could have all the details for a surgical operation arranged, and would not have to operate hastily and perhaps without suitable assistants and precautions, as he often has to do when called in after the patient has begun to sink. It was evident, from the case referred to by all the speakers, that the experience of each was extremely limited, and that cases of intestinal obstruction are comparatively rare. Hence individual experience is limited, and no one has extensive opportunities of perfecting the diagnosis and treatment of such cases. The patient, taken ill suddenly, is narcotised by the nearest medical man, and every symptom seems for the moment improved, until, when death threatens, a surgeon is sent for to find a distended dying man. Many surgeons asked why the physicians did not treat external hernia in this way; to which the physicians replied, that they would not thus treat internal hernia, if it could be diagnosed as such, but that the difficulties of diagnosis were so great, the causes of intestinal obstruction so various, and the operation of abdominal section so hopeless, that they were rather disposed to trust at present to the medicinal than the surgical treatment, except in cases such as that described by Drs. Greves and Pughe. The grand results claimed by antiseptic surgery in dealing with this disease were founded, according to the physicians, rather upon anticipations of the future than on cases hitherto cured by it. It was generally agreed by all that starvation, rest and opiates should be tried at the beginning, when strenuous efforts to establish a diagnosis should be made by careful watching and analysis of symptoms, and that preparation for surgical treatment should be made, to be applied whenever the pulse began to seriously fail, the prostration to increase, the tongue to become dry and brown, and the vomiting to continue more than four times in the twenty-four hours. Aspiration was spoken of highly by some as a palliative and sometimes a curative proceeding. Purgatives were universally, and enemata generally, condemned, except to start the bowels after the symptoms had completely passed away. Inflation by air or fluid was only recommended in the very early stage of intussusception. The discussion was a very successful one, and has somewhat cleared the atmosphere around an obscure region of diagnosis and treatment.

During the week ending last Saturday, 1,516 deaths were registered in London, including 167 from the zymotic diseases. Of the latter, small-pox accounted for 22 victims, 10 of whom were unvaccinated, whilst there was no statement as to vaccination as regards 8. The deaths from measles and scarlet fever numbered 32 from each, both, but especially the latter, being considerably under the average. Diphtheria caused 17 deaths, whilst 19 were attributed to whooping-cough. The mortality from diseases of the respiratory organs continues to be much below the corrected average, a fact no doubt partly due to the extraordinary amount of sunshine we had last week, no less than 21·4 hours having been registered, whereas the average of the preceding five weeks was not quite 12·4 hours. Nearly one fourth of the total number of deaths, viz., 354,

occurred in infants under one year of age, and our readers will probably be as much surprised as we were to learn that 19 of these were carried off by tabes



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past twelve weeks.

mesenterica. Of the 28 large towns, Preston again heads the list with a death-rate of 31·5, Cardiff being second with 27·4; the zymotic death-rates being 6·3 and 7·3 respectively in these towns.

By the death of Professor Fawcett the Lord Rectorship of the Glasgow University has become vacant, and the appointment must be made by Saturday the 15th instant. The students have arranged among themselves that an understanding should be made between the Conservatives, Liberals and Independents by which they may unanimously choose a gentleman to fill the vacancy. Mr. Robert Browning, who was first unanimously selected by the students, telegraphed his thanks for their kindness, but at the same time declined the honour. Mr. Matthew Arnold is now spoken of, but whether he will accept the honour is not certain. At one time it was arranged that the usual party selection should be made, and the names of the Marquis of Salisbury, Lord Hartington and Mr. Trevelyan were mentioned. The time being so very limited the usual demonstration will of course be out of the question. At the meeting which was held last week in the University, for nominating candidates for the Lord Chancellorship, the Marquis of Bute and the Earl of Stair were ultimately the two noblemen who seemed to divide the suffrages of the meeting. A poll was therefore decided upon and voting papers were issued, but in the interval the Marquis of Bute wrote to the Principal of the University, thanking him and all those who desired to confer the honour upon him, at the same time declining it, and stating that he had been proposed without his knowledge, as otherwise he would not have allowed his name to have appeared on the list. The supporters of the marquis, however, will not take a denial but are determined if possible to return him at the head of the poll, and as it were, compel him to accept or at any rate to place the Earl of Stair in the awkward fix of being a defeated candidate. This is to be regretted, for the Marquis of Bute, it is certain, will not allow himself to be placed in the position which he in his letter to the Principal most positively but courtcously declined.

Last Sunday being the second Sunday in November, was set apart as in previous years as "Hospital Sunday" in Dublin. Fortunately, the weather was beautifully fine and large congregations assembled in most of the two hundred and thirty Protestant Churches in which the collection was made. It was the eleventh annual appeal on behalf of the Dublin Hospital Sunday Fund, the first having been made in 1874, since which year 40,060*l.* have been collected, and 37,559*l.* distributed among the participating hospitals. Circulars distributed previously to Hospital Sunday showed that the hospitals on behalf of which this appeal is made, receive annually within their walls upwards of 11,000 patients, attend upwards of 3,000 lying-in women at their own homes, treat as extern patients upwards of 8,000 accidents, and relieve many thousands at their dispensaries; they contain nearly 1,200 beds, many of which unfortunately cannot be used for want of funds. The work done by these hospitals costs about 40,000*l.* a year, of which about 10 per cent. is supplied by the collections on Hospital Sunday, but a great deal still remains undone in consequence of the limited incomes of the institutions. It was further pointed out that in a well-managed hospital the annual cost of maintenance (exclusive of management) per bed is about 25*l.* and as each bed on an average accommodates 18 patients in a year, this 25*l.* will relieve about 18 sick persons; 30*s.* will, on the average, provide for one patient during his stay in hospital; 2*s.* 6*d.* will maintain a patient in a Dublin hospital for one day. Every one who contributes half-a-crown to the Hospital Sunday Collection may thus provide for one poor sick person for one day. So far as the returns have as yet come in, the collection of the present year appears to be well up to the average.

In the characteristic address which he delivered at Meath Hospital last week, Professor Macnamara bitterly complained that he had been dubbed a "fossil," and gave a long and amusing demonstration that the term had been misapplied. For ourselves, when listening to the discussions of the Medical Council, we have been tempted to wish that Mr. Macnamara were anything so silent as a fossil. The term appears to have been applied to him because he does not believe in the carbolic spray; and he is no doubt glad to believe that, if that is sufficient to constitute a fossil, he is not the only one in the profession. He does not believe in the spray, because if it effectually destroyed the germs which favour suppuration, it would have to be

of such a strength that it would also destroy the tissues to which it was applied. A little later in his address Mr. Macnamara stated, "in justice to Dr. Koch," that in the two last invasions of Dublin by cholera, he found the premonitory diarrhœa more controllable by astringent mixtures containing sulphuric acid than by other remedial measures. "Contrast this clinical experience with Dr. Koch's statement as to the action of acids in destroying the vitality of his microbes, and I think we may attach to it some importance." Surely if Mr. Macnamara believes that one germ can be killed by an acid solution which only braces up the stomach, he ought not to be so sceptical as to the effect on other germs of another acid solution which can be used many times as strong. "There are germs and germs," would probably be Mr. Macnamara's answer; to which our rude reply would be, "There are Professors and Professors."

A distinguished physician who has had ample experience of both the English and Scottish systems of medical education, has been prompted by our last week's colloquy to write to us as follows:—I quite think with you that, to compete with Edinburgh, it is necessary to concentrate our teaching, more especially in Anatomy, Physiology and other preliminary subjects. It is also, I think, most desirable to make more of the great clinical field in London. The clinical teaching wants stimulating. If we elected one or possibly two clinical lecturers or professors at each hospital, and made those appointments open to all physicians, London and provincial, taking care that the professors or lecturers devoted a certain time *daily* to clinical teaching, we should effect a great revolution, and should gradually improve the clinical teaching, without in any way interfering with the gradual rise by rotation of the hospital staff. Many men who cannot teach can observe, though the best teaching and the best observing usually, I believe, go together. The same method of appointing all lecturers would, I think, be an improvement, but it is especially in the clinical field that London can easily beat Edinburgh, or at least ought to do so. There, there are often two clinical clerks to a bed, and many men well able for hospital work cannot get even assistant physician appointments.

An anti-vaccinator, who during the period of his imprisonment for non-compliance with the requirements of the law had been made acquainted with the discomforts of the plank-bed, has protested against what he regards as a specially illegal addition to an unjustifiable punishment; and his indignation assumes the very tangible form of an action for damages. Whether in this instance the application of a salutary law has been technically strained, may form the subject of a very pretty legal argument, on which a decision will in due time, no doubt, be reached. The production of the charge, however, reveals the existence of such a personal appreciation of the importance of dis-ease as we might scarcely have looked for amongst those who profess themselves persistently careless of the evil results which the practice of their own peculiar theories is only too likely to entail on others. Did the present state of society admit of its impartial application, it is possible that herein might be found the most efficient means of meeting the "arguments" and of silencing the clamour of many misnamed reformers. A great deal might be advanced in favour of adopting something of the *suus cuique mos* principle in dealing with the perpetrators of wanton injuries to the person. If, for instance, the dynamitard knew that his certain fate, on capture and conviction, was to be seated on a valise stuffed with his favourite explosive, with its fuse connected with the mechanism of a "peep-o-day" time-piece placed a few feet in front of him, so that he would watch the clock-hands slowly traversing its face towards the hour of his doom, the drawbacks attendant on his trade would be decidedly increased, and that by the prospect of just such suffering as he was prepared to inflict on others, and the number of its members lessened in proportion. On the other hand, and supposing the subject were in all other respects new to us, it is probable that we should not think a few nights on the plank-bed, even if that couch possessed the power of obliterating all natural prominences, effacing all rotundity, and rendering the sleeper's countenance as plane as that of an inhabitant of "Flatland," was unmerited by the man who, in the face of overwhelming evidence and of repeated warnings, had deliberately chosen to expose the members of his own family together with those of his neighbours to an indefinite extent, to the ravages of a disease which is always loathsome, often disfiguring, and not seldom fatal.

An interesting statistical report has just been published by the Administration of Public Assistance of Paris. The total number of beds, in the various establishments which depend upon its resources, is stated at 16,462. The following are the figures mentioned:—

Hôtel Dieu	559
Obstetrical Clinic (females)	130
,, (children)	53
Pitié	719
Lariboisière	706
St. Antoine	621
Tenon	825
Necker	418
Beaujon	422
Cochin	249
Bichât	200
Laënnec	628
Salpétrière (pensioners)	3,821
,, (lunatics)	720
Bicêtre (pensioners)	1,658
,, (lunatics)	738
Enfants Malades	562
Trousseau (children)	427
St. Louis	843
Midi (venereal)	336
Lourcine	243
Maternité	316
Dubois	351
St. Anne (lunatics)	917
Total ..	16,462

The population of Paris, according to the last census, amounted to 2,240,000. The proportion of the number of hospital beds to the population will, therefore, be

found to be larger than in most European cities. It must also be remembered that a very large number of the poor receive "home assistance," and that in all these hospitals and in the "Bureaux de Bienfaisance" gratuitous consultations are given, including, in many cases, the gratuitous supply of drugs. It is even said that the Paris apothecaries seriously complain of the loss which this state of things entails upon their trade. It will, therefore, easily be understood how large a drain upon the public purse is entailed by this vast and complicated system of official relief to the poor, and how dependent the Administration must needs be upon the Municipal Council for the necessary supplies.

The *Société de Chirurgie*, containing nearly all the surgeons of Paris hospitals, met the other day to discuss the claims of lady students to the situation of *internes* or house surgeons. The ladies were blackballed by 23 votes to 4. Soon after, the *Société Médicale des Hôpitaux*, which comprises nearly all the physicians of Paris hospitals, met for the same purpose, and voted against the ladies by 64 voices to 4. After this signal defeat, the ladies will find it difficult to carry their point.

An influential Committee has been formed in Stockholm, under the presidency of Professor Axel Key, for the purpose of carrying on the work of collective investigation in Sweden, in connection with the International Committee. A similar Committee has been formed, on Professor Runeberg's proposition, in Finland. The recommendations of the Sub-committee as to the lines of enquiry to be followed, are now under consideration by the International Committee.

As an illustration of the oppressed condition of educational and medical matters depicted by "Stepniak" in the *Times*, we may mention that the Centenary Festival of the Obuchow Hospital, founded 100 years since by the Empress Catharine II., which had been announced, has been prohibited. And yet the hospital, as the *St. Petersburg. Med. Wochenschrift* (October 25th) shows, has something to be proud of. The 200 beds provided at its foundation have risen to 1,000, and on emergencies have been increased to 1,300. In one year as many as 3,600 cases of typhus have been received; and during the worst period of the cholera in 1878, it received 123 cases daily, the number for the year amounting to 16,730. There was a time when it was always a recommendation to a practitioner if he had served in this hospital, and much good work has been done there. To cite but one example, the researches made there on Recurrent Fever may be said to have assured to this disease its "academic rights," so to say, of being one of the scourges of mankind. Within its walls, too, sixteen practitioners have lost their lives through their attendance on the inmates.

We hear with regret that many of the volumes in the library of the Royal College of Physicians are not in such a good state of preservation as might be desired. This may probably be traced to a want of proper hygienic conditions, for books require air and exercise to keep them sound, almost as much as human beings. The library is a spacious and airy room, but the books are kept locked in glass cases, and many of them are probably not often disturbed from their rest. Damp has affected many of them to such an extent that some —especially amongst those advanced in years—are considerably damaged; the pages have become deeply stained and can only be separated with difficulty. The leather bindings too are said in many cases to be so softened that the backs split and the covers break off on the tenderest handling. The worst of it is that the books which are most likely to go to ruin are those which are most valuable from the scarcity of copies of them at the present time. If all these allegations are well founded, we are sure that the officials of the College will be grateful to us for calling attention to them, and will not lose a moment in putting things right.

An American physician has added to the groaning pile of Shakespearian literature yet another tome, under the title of "Shakespeare as a Physician," in which is supposed to be recorded "every word which in any way relates to medicine, surgery, or obstetrics found in the complete works of that writer, with criticisms and comparison of the same with the medical thoughts of to-day." The volume consists of nine chapters, under the several headings of obstetrics, psychology, neurology, pharmacologia, ætiology, dermatology, organology, chirurgery, miscellaneous. A reviewer notes the omission of separate chapters on gynæcology, laryngology, and otology.

Turning over the pages of Mr. Stuart Reid's new life of Sydney Smith, the other day, we came across the following in a hitherto unpublished essay by the famous wit, entitled "A Little Moral Advice." It deserves quoting in full:

"When you are in a melancholy fit, first suspect the body, appeal to rhubarb and calomel, and send for the apothecary; a little bit of gristle sticking in the wrong place, an untimely consumption of custard, excessive gooseberries, often cover the mind with clouds and bring on the most distressing views of human life. I start up at two o'clock in the morning, after my first sleep, in an agony of terror, and feel all the weight of life upon my soul. It is impossible that I can bring up such a family of children, my sons and daughters will be beggars; I shall live to see those whom I love exposed to the scorn and contumely of the world!—But stop, thou child of sorrow, and humble imitator of Job, and tell me on what you dined. Was not there soup and salmon, and then a plate of beef, and then duck, blanc-mange, cream cheese, diluted with beer, claret, champagne, hock, tea, coffee, and noyeau? And after all this, you talk of the *mind* and the evils of life! These kind of cases do not need meditation, but magnesia. * * * * I recommend lights as a great improver of animal spirits. How is it possible to be happy with two mould candles ill snuffed? You may be virtuous, and wise, and good, but two candles will not do for animal spirits. Every night the room in which I sit is lighted up like a town after a great naval victory, and in this cereous galaxy and with a blazing fire, it is scarcely possible to be low-spirited, a thousand pleasing images spring up in the

mind, and I can see the little blue demons scampering off like parish boys pursued by the beadle."

It is curious to think that this was written by a churchman close upon eighty years ago.

Nature's anachronisms are always full of interest. It is not rare to hear of persons who are rightly described as having been born before their age; and now and again we meet with those whose birth, having been accidentally omitted some centuries ago, has placed them, mentally if not physically, a few hundred years behind the present time. Such an individual recently forwarded to the Editor of one of our contemporaries an interesting communication from which we quote the following—"for what it is worth." "When I state that after the death of a dog or person who has been bitten by a poison snake, on examination P.M., there will be found attached to the liver a snake of the same species as the one that bit the dog or person, and if the dog has been bitten twice there will be two snakes, and in one instance the snake put out its tongue, nobody who has never seen it or heard of it will believe it. Yet such is the fact. This is why a person or dog who has been bitten with a snake feels the influence every year, at the time snakes awake up from their dormant state." Anyone, we think, may be pardoned for not believing in that which "he has never seen or heard of," and in the present instance the most generous critic might be excused for carrying his incredulity to even further limits. Judging from the internal evidence afforded by the statement itself, it may be surmised that the writer is a confirmed adherent of other ancient faiths, as, for instance, the cure by "a hair of the dog that bit you," and this possibly according to its more modern rendering.

Dr. Collingridge's report as Medical Officer of Health for the Port of London for the first half of the present year is before us. In view of the possibility of an invasion of cholera, very great attention has been paid to the hygienic condition of all vessels lying in the Port. Cleanliness has been insisted upon, ventilation has been provided, drinking water looked after, bilges cleaned out, and everything that could be thought to have any bearing upon the health of the seamen has been carefully attended to. One of the great difficulties that he has to contend with is the introduction of unsound meat, which, owing to the extent of the trade in frozen meat, is taxing the resources of his slender staff severely. As instances of what they are doing in this direction we note that about eight tons of semi-putrid herrings were destroyed from one ship, and in another case 933 frozen sheep, equivalent to 26·5 per cent. of the whole consignment, were condemned as unfit for human food. The meat so condemned is destroyed under the supervision of the Inspectors, having been first thoroughly disinfected to avoid the possibility of a nuisance. The compulsory notification of infectious diseases is practically in force and works well. The report gives details of each instance in which infectious disease came under the notice of the sanitary authority.

A series of lectures delivered by the well-known Dr. Schutzenberger, the last Professor of Medicine in the Medical Faculty of Strasbourg, between the years 1834 and 1870, were, in conformity with a wish expressed before his death, collected together and published by Masson in 1879, under the title "Fragments de Philosophie Médicale." The work, consisting of lectures on medical philosophy and clinical medicine, furnished an excellent exposition of the doctrines and practice of the Strasbourg School of Medicine, and was much prized by attached pupils of Schutzenberger as a momento of happier days. It is not a little startling, therefore, to find the *Gazette Hebdomadaire* publishing in its last number an article, in which it shows in great detail that a translation of this work into Spanish has been published, as his own, by Dr. Encinas, of the Madrid Medical Faculty. His work of 700 pages is represented to be no mere imitation or adaptation of that of Schutzenberger, but simply a translation, of which proof is furnished by printing a large number of passages of the two works in parallel columns. It is not a little singular that the only portions of Schutzenberger's work that have not been included in the translation are those which relate to Medical Confraternity, Professional Relations, and Professional Morality.

The want of a biographical dictionary, giving details of the lives and labours of those who have contributed to the advancement of medicine, has long appeared to us as one of the most important desiderata in medical literature. We have just received—from Germany, of course—the first part of a work which promises to adequately fill the gap. It is edited by Professor Hirsch, of Berlin, with the assistance of Dr. A. Wernich, and a goodly list of contributors. In this list, which contains some of the best known names in Germany, we notice with regret no representative either of England or France. The United States are adequately represented by Dr. Billings, while Austria, Hungary, Belgium, Holland, Denmark, Italy, Greece, and Spain have all some one to look after their interests. We have no right to complain, for no one has shown a greater neglect of past English medical worthies than their successors. Out of 440 works from which the present dictionary is compiled, there are only three of purely medical biography, viz., the well known works of John Aikin, Dr. Munk, and the late Dr. Forbes Winslow. The first part of the dictionary only carries us as far as Albers, but in that short alphabetical division the English school is not badly represented by such names as Abercrombie, Abernethy, and Addison, besides many others of less celebrity. The biographies in each case appear to have been carefully compiled, and if equal thoroughness is shown in the subsequent parts the whole will be a work for which we cannot be too grateful to German enterprise and research. We cannot quite agree with the editors that "the just appreciation of our predecessors is the only thing that keeps us from an irreverent nihilism, and frees us from the fetters of authority;" but we candidly admit that there is much to be learned from the lives of others of our great predecessors than the two worthies Harvey and Hunter, on whom the

backward glances of English panegyrists are wont to be exclusively bent.

Professor Humphry, in the recently issued number of the *Journal of Anatomy and Physiology*, has given us what we may consider as part of the first-fruits of his investigation into the health of aged people, in the shape of a paper relative to the repair of wounds and fractures in them. As he observes, it seems rather a paradox to say that in the aged wounds, if they do not slough, have a tendency to heal rapidly, more so than at an earlier period of life. This is contrary to what might have been expected, and the professor apparently has not been able to frame any theory entirely satisfactory to his own mind, and so he offers no explanation, but calls attention to what seems even more remarkable still, and that is, that the stump left after the separation of the parts in senile gangrene often heals with unexpected quickness. In the fracture of the bones in old people the same thing is seen, there being either an utter failure to produce the uniting material, or the union takes place at a comparative early date. He reminds his readers that the true cause of the non-union in cases of fracture of the neck of the femur in the aged is not on account of any tendency in such persons to non-union, but is owing to the difficulty of keeping the ends of the fragments in apposition, and because the ends of the bones are constantly bathed in synovial fluid.

A phantom brain of colossal dimensions—not the offspring of the Psychical Research Society, but a histological model—has been lately constructed by Buechi, of Berne, under the supervision of Professor Aeby, for an American museum, for the purpose of demonstrating the course of the cerebral fibres, and their relation to the several nuclei and to the spinal cord. Its dimensions are 125 centimetres in height, and 70 centimetres in width, or about 4 feet by 2½ feet. The different cortical areas are represented by numerous small corks distributed in systematic order. The larger basal nuclei occupy appropriate positions. The medulla and the upper part of the spinal cord are made up of ganglia and wires of different colours. The several columns of the cord, each distinguished according to its function by a special colour, lead to their appropriate ganglia of corresponding tint, or to the areas in the cortex marked by similarly coloured corks. Thus, in the anterior and lateral columns the motor fibres can be traced to the anterior and lower portion of the medulla, where they decussate, through the pons to the internal capsule, where, between the optic thalamus and the caudate nucleus of the corpus striatum, they radiate to the cortex; here they are seen to originate chiefly from the convolutions about the fissure of Rolando; from a point where a red ball is situated, a red motor fibre descends to the anterior or lateral column. Each column of Türck is shown in relation with the posterior part of the lateral column of the opposite side. The posterior columns, coloured blue, are represented as forming the posterior third of the internal capsule, and passing to the corpora quadrigemina and optic thalami, also coloured blue, as the great centres of sensation. The external portion of the lateral columns, coloured green, lead to the cerebellum, decussating near its superior surface. The yellow fibres place the basal nuclei in communication with the cortex; the white fibres forming the corpus callosum are purely commissural. The columns in the cord are thus represented in precise correspondence with the arrangement given by Flechsig and endorsed by Charcot and Hammond. A model of this kind, and on such a scale, would doubtless prove useful to the student, who often experiences no small difficulty in obtaining, from piecemeal dissection and reading, a satisfactory grasp of the structure, function, and relationship of the several paths and centres of the cerebro-spinal system.

COMPROMISE OR CONFLICT?

In March last the President of the Royal College of Surgeons called a meeting at the College "to report to the Fellows and Members the alterations in the Charters proposed by the Council, and to receive from them any suggestions or recommendations with respect to them, or *any other alterations* in the Charters which they have to offer for the consideration of the Council." (The italics are our own.) The ill grace with which the "other alterations" offered by the meeting on this occasion were subsequently received will be still fresh in the recollection of our readers. Largely in consequence of this, and as the outcome of a general feeling of dissatisfaction which has been slowly but surely springing up, Associations of the Fellows and of the Members were formed with a view to protest against this irresponsibility of the Council as at present constituted, and to take such further steps as would secure for their opinions more consideration from the Council, and give them a more direct share in the management of the College. The Association of Fellows was quickly organised, and besides having the good fortune to secure Mr. Pollock as president, it soon numbered within its ranks some of the most active of the younger Fellows, both metropolitan and provincial, and obtained a large amount of tacit support, even from within the Council itself. A sub-committee was formed to consider the present Charters, and to propose such alterations in them as seemed called for by the spirit of the times. A fortnight ago we were enabled to publish the result of their labours, and this week we have the pleasure of recording that their recommendations have, with a few unimportant alterations, been enthusiastically adopted by the Association at large. It is also not improbable that the Members' Association have been at work on somewhat similar lines, but all the sign of activity they have yet given, has been an ill-advised and entirely gratuitous petition to Mr. Gladstone for the parliamentary representation of the medical profession.

We have already expressed our opinion that the new recommendations are good in themselves, and that the mode in which it is proposed to carry them out is at once conciliatory and constitutional. To make the office of president even more honourable and more coveted than at present, should not find disfavour even with the most conservative Council, and as long as they (the Council) nominate their chief

it is surely but a slight concession to grant that the Fellows shall elect him. Of perhaps greater moment to many existing councillors will be the proposal that the president should be eligible for re-election five times. This will, of course, lessen each man's prospect of the prize, but the honour when conferred will be enhanced in the same ratio. The president will not be bound to accept nomination more than once, and thus if the next few presidents—at present simple members of Council—feel deeply on this point they can defer to the wish of the Fellows at large by accepting their recommendations, and, at the same time study their own and their colleagues' feelings by declining to serve as president for more than one year. In a very few years all those councillors who have been elected under the old *régime* will have passed the chair, and gradually the new system of election by merit and re-election on account of special aptitude, will take its place among the traditions of the college. While hoping to secure the president's services for a longer period than has hitherto obtained, the Association recommend that ordinary Members of Council shall seek re-election more frequently, and instead of the three senior members vacating office, it is proposed that the six seniors shall retire, being of course eligible for re-election as at present. In this manner an indirect control of the Council is secured, for members will know that their re-election depends on their not persistently voting counter to the expressed wishes of the constituents whom they represent. As a set off, certain undignified procedures in connection with election to the Council are to be abolished, and henceforth, should these recommendations become accomplished facts, surgeons of eminence will not have to go round, or send others round, to get their requisition papers signed as to their fitness for office. In all this there looms, doubtless, a change which is thoroughly, but not violently, radical; indeed, we can hardly compliment the sub-committee too warmly on the completeness as well as the inoffensiveness of their report. To attempt to further emphasise the value of the proposed changes, or to advise their acceptance by the present Council would be but to repeat what has been said often enough in these pages already; to go further, would bring us within a measurable distance of language which, though by some called "warning," might by others be regarded as "menace;" while we much prefer to leave the subject to those whom it concerns to quietly work out its own effects.

The growth of the principle of direct and responsible representation of the masses in the government of the country has been slow but steady; and the present political crisis shows the hold which it has gradually taken on the people. If irresponsible control is bad for the country at large, it is bad also for individual corporations. Moreover, as surely as a country or a corporation falls foul of its subjects, so surely will evil result, whether good be ultimately gained or not. On these questions of domestic reform, the profession, we must admit, has appeared singularly indifferent, but in this matter as in others, it is the law-abiding quality which distinguishes the Anglo-Saxon race, rather than indifference to the subject matter that has been at the bottom of their quiescence. Besides, the very nature of the calling we all exercise renders combined action difficult of inception and individual effort both thankless and ineffectual. Now, however, the stone has been set rolling, and organisations have been called into existence which are determined by combination to secure that which individual effort failed to accomplish. In the very fact, however, that there are two distinct reforming bodies at work, lies a source of weakness. For it implies divided and diverging interests. The Members' Association have not yet given much sign, and it is not possible therefore to say what they are aiming at. The Fellows, following precedents which were inaugurated when the higher grade was first started, jealously reserve to themselves not only the right to sit on the Council, but also to elect the Council. They concede to the Members the somewhat meagre right of attending the annual meeting; but Fellows alone, who number scarcely one thirtieth of the entire corporation, are to be trusted with college management, while Members are quite excluded. It is true that the Fellows number among themselves most of the best surgeons in the country, that the fellowship represents a higher standard of surgical attainment, and that our chief hospitals wisely exact this standard as a qualification for office. But surely this is no reason why the great bulk — twenty-nine thirtieths—of the body corporate should be absolutely excluded form all active and direct participation in college management and representation. To be a good surgeon is one thing, but to say that because a man is not a Fellow therefore he is unfit to manage the lay concerns of his college is another. The college was formerly managed by its Members entirely, and it was the Members who instituted the fellowship "in order more effectually to promote and encourage the *study* and *practice* of the said art and science of Surgery." The earliest Fellows were self-elected, and so late as the last Council there were two honorary fellows in office whose names stand high even among the foremost. No better proof could be given that it is not the diploma but the man whom we must chiefly honour.

The present Council will doubtless take ample time to consider the recommendations which will soon be formally presented by the Association of Fellows; they certainly ought not to stir in the matter of the Charters until the Fellows' recommendations have been further discussed, it may be in public meeting. Meanwhile, if the Members will bestir themselves, let us hope that, in drawing up their recommendations, they will act with as much energy, but with as much moderation and good sense as the Fellows. We have dealt chiefly with the foregoing points, the constitution of the Council, as the corner stone of the whole movement. The appointment of a treasurer, for instance, or of the examiners, or the concession of an annual meeting, are minor details as compared with the mode of election, and the tenure of office of the Members of Council. Given a responsible instead of an irresponsible Council with a president elected by a general vote, for a term of years, instead of for one year and by rotation, and the rest will follow as a matter of course. This is not the time or place to vindicate the right of the Members to a seat on the Council of the College;

but we may express a hope that the two associations will work harmoniously together, and that the now more powerful because more compact and less scattered body of Fellows will use the privileges from which in times past they ousted the Members with a due consideration to the prosperity of the profession, and not for the advancement of personal interests.

DR. KOCH AND HIS CRITICS.

Dr. Koch has published a reply to some of the objections which have been raised by his statement that he has "discovered the cause of cholera" in the so-called "comma-bacillus." Dr. Koch endeavours to deal with the objections of those who point to the fact that he is false to the principles laid down by himself in so many words at an earlier period of his career as a bacteriologist. Dr. Koch *formerly* stated (and all men of a scientific habit of mind must agree with that statement) that no micro-organism could be justly declared to be the cause of a disease, until the organism had been "purely cultivated" and the disease had been produced by the inoculation of a healthy animal with this "pure culture." Dr. Koch *now* calls those persons who hold this reasonable doctrine "sceptics," and in a somewhat flippant manner states that he hopes to convince them by experiments which he is *now* (too late!) conducting similar to those of Professors Reitsch and Nikati.

It is too late for Dr. Koch to convince any true scientific sceptic. The man who has rashly committed himself to such public assertions with regard to the cause of a phenomenon, cannot be subsequently accepted as a witness in his own favour. As soon as Dr. Koch publicly declared on insufficient data that he had discovered the comma-bacillus as the cause of cholera, and without any reserve insisted on using his authority and position to force upon the public a mere hypothesis as though it were a demonstrated or even a highly probable conclusion, then and there Dr. Koch put himself out of court as a witness of new facts in support of his contention. Others may produce the record of experiments in order to establish Dr. Koch's hypothesis, but he himself is so terribly involved in the issue that we cannot accept his judgment on such delicate experiments as those which he now is anxious to quote in favour of his view. *Vestigia nulla retrorsum*!

In reply to Dr. T. R. Lewis, Dr. Koch apparently wishes us to believe that he knew all along of the common occurrence of "comma-bacilli" in the mouths of healthy human beings. It is difficult to believe that Dr. Koch would not previously have mentioned these normal comma-bacilli and have pointed out how they differ (if they do differ) from the cholera comma-bacilli, had he been acquainted with them. Dr. Koch states that the normal comma-bacilli of the mouth differ from those of cholera in regard to the conditions favourable to their artificial cultivation. *When* did he discover this? He reproaches Dr. Lewis with not having made such artificial cultivations. *When* did Dr. Koch make such cultivations of the comma-bacilli of the mouth himself? Surely it was *his* business to show that the hypothetical cholera comma-bacillus was distinct from the closely similar comma-bacillus of the mouth. Yet we find no allusion whatever to the comma-bacilli of the mouth in Dr. Koch's reports or in the address to the Special Medical Congress in Berlin. Either Dr. Koch did not know of the existence of the comma-bacilli of the mouth or he suppressed all mention of them when he endeavoured to obtain credence for his extraordinary assumption that a comma-bacillus is the cause of cholera.

There will be no difficulty in producing experiments *now*, which will seem to prove that the cholera-comma and the normal mouth-comma behave differently. It will not be difficult to produce symptoms like those of cholera, by injecting cholera-commas into guinea-pigs or rabbits. This kind of experiment is so delicate that it may easily be allowed to take a course favourable to the views of a prejudiced experimenter. That is the pity of it. Dr. Koch has sacrificed for a momentary notoriety the irrecoverable position of a trusted scientific observer. He *must* be for the future (he has so willed it) a prejudiced experimenter. He has the fearful responsibility on his shoulders of his premature claim to a "discovery," of his unfortunate attempt to force his shadowy hypothesis of the comma-bacillus upon Europe as a solid result of scientific method, and this must render all his work on this subject for the future rightly liable to suspicion and doubt. Though we may credit him with perfect sincerity, we can never regard him as otherwise than hopelessly biassed.

MEMORIAL AND MANIFESTO.

A memorial is always in some sense a manifesto—an utilisation of a particular and concrete circumstance to emphasize a general and abstract belief. The monuments in Westminster Abbey, the statues sprinkled about our streets are quite as much embodied creeds as memorials of individual excellence; indeed they are to us of value in direct proportion to the modern acceptance of the belief they represent. The groans with which a certain tableau in Monday's pageant was here and there received, incline one to believe that nowadays a monument to Wat Tyler would in most quarters be regarded with much more sympathy than a statue of the loyal Lord Mayor who killed him. Every subscriber, then, to a memorial which he wishes to be lasting, should ask himself not so much whether the act or the life which he would commemorate is worthy of commemoration, as whether the emotion and admiration it has aroused in him are such as belong to all time and to all humanity, or are only incidental to a gust of passion which even he may live to smile at. Applying this criterion to the memorial by which it is proposed to perpetuate the memory of Dr. Rabbeth, we think we may safely say that neither the subscribers nor their posterity are ever likely to condemn as sentimental or ephemeral the feelings which are prompting that memorial. At no period in the world's history has there been a time when self-abnegation has failed to arouse admiration, and it will be a sad day for the human race when it ceases to be applauded. In fact, it is the universal validity of this feeling which is the main justification for commemorating the

noble but by no means unique, example of self-sacrifice which has recently occurred in our ranks. That there are many young men and old in the profession who have done over and over again what Dr. Rabbeth did, without incurring death, and without even thinking that they were doing anything particularly heroic, does not at all detract from the moral value of our dead comrade's act, or justify us the less in worthily commemorating it. And this is clear enough if we realise that in subscribing to the memorial we are paying our devotions quite as much to the inward grace of self sacrifice as to the outward manifestation of it by Dr. Rabbeth.

This view of the case has been already put forward by Sir William Gull, both in his letter to a contemporary and in his remarks at the meeting which was held at King's College last week, and it is one which, we believe, will be universally welcomed by the medical profession. Accepting it, they will see in the memorial a timely opportunity of emphasizing both for themselves and still more for the public the ideal they have of the spirit in which the medical practitioner should approach his work. That many of us, perhaps most of us, often fall short of this ideal is no reason why we should not seize the opportunity of making a confession of our faith. An ideal is never, and is perhaps not meant to be, universally acted up to. If it were it would cease to be an ideal. An ideal must necessarily be above the reach of ordinary human nature; but the higher the ideal, the higher will be the average of individual excellence. It is the pride of our profession that, almost unknown to the public, there are so many amongst us who do reach, or fall but little short of, the ideal. Every medical practitioner must always be ready to risk his life at the call of duty, and the proportion of them who show themselves willing to go further, and to encounter risks beyond those which strict duty entails, is happily not small. Every day almost brings us intelligence of medical men who have fallen at the post of duty. Here, for instance, are two examples, selected from this week's cuttings :—"The *Gazetta Med. Lombardia* states that out of one hundred and thirty practitioners working under the Red Cross Society during the recent epidemic of cholera at Naples, twenty fell victims to the disease." "The *St. Petersburg Med. Wochenschrift* records the death of Dr. Gussew, a young Moscow physician, from diphtheria, contracted whilst examining the throat of a child suffering from that disease. The child coughed some diphtheritic *débris* into his face, and though he washed it away carefully, he was seized with fever on the same day, and on the third day after died from well-marked diphtheria." The public forget or ignore these risks, and the spirit of self sacrifice which leads them to be cheerfully encountered. They are ready enough to cry out upon us if we ask what appears to them too much in the cause of science and humanity, but they have no eyes for the merits of those who surely according to their own showing give too much in the same causes. Who can blame us then, if in testifying to our esteem for a dead colleague, by founding a memorial of him, we at the same time make it a manifesto of the ideal which we strive after and which we not seldom reach?

REVIEWS AND NOTICES OF BOOKS.

A NON-CONTAGIONIST ON CHOLERA.

Dr. Chapman's article which while purporting to be a review or criticism of a number of works on the subject is in reality a mere reiteration of the writer's peculiar views on the pathology of cholera, which he holds to be a neurosis, directly produced by excessive stimulation of the ganglionic system of nerves and for which the only rational treatment is the ice bag. Whatever may be thought of the taste displayed in the choice of a non-medical quarterly for the discussion of pathological questions and in the frequent and obtrusive mention of "my discoveries" and the like, our main quarrel with Dr. Chapman is that he misrepresents the opinions of others and then holds them up to ridicule. We know that some Indian medical officers of high authority do not believe in the communicability of cholera, and that the official positions that several of them occupy at the present time give prominence to their views; but while many others of at least equal scientific standing hold strongly by the opposite opinion, it is to say the least unfair to ignore them. On the other hand, it is really unpardonable to represent the recent panic displayed by the populations of Italy and southern France, the *cordons sanitaires* and absurdities of fumigations and quarantines as the logical consequence of the views held by nearly all English and German, and not a few of the highest French authorities. Instead of attempting to explain away the accumulated evidence of the transportation of cholera, he says "it is *dogmatically* affirmed to travel from one district or from one country to another," and so on, whereas in India he tells us "the clothes of such patients are not burnt or even fumigated; and all persons are free to go in and out of cholera districts without let or hindrance." So they are, and so we may remind him the natives crowd in the houses of small-pox patients, and appropriate their clothes without fear but not without the natural consequences.

Dr. Chapman's theory of cholera, briefly stated in his own words, is that "all the symptoms are due to a simultaneous and abnormal super-abundance of blood in, and excessively præternatural activity of, both the spinal cord and the sympathetic nervous centres," that "so far from those related to the intestines being profoundly depressed or exhausted, they are in a state of the most extreme and tumultuous activity," and he quotes Dr. G. Johnson to the effect that the profusion of epithelial cells in the evacuation "can only result from a very active vital effort." These phenomena he attributes to stimulation of the cerebro-spinal nerves, while he explains those of the algid stage by an excessive constriction of the entire arterial system through extreme stimulation of the sympathetic; and lastly, the *post-mortem* contractions of the muscles and the early advent of rigor mortis by the return of the blood to the muscles consequent on the exhaustion of the sympathetic centres. All this is very ingenious,

[1] "The non-contagiousness, causation, and scientific treatment of cholera."—By John Chapman, M.D. The "Westminster Review," October, 1884.

but even admitting it to be a full and satisfactory explanation of the immediate cause of the phenomena of cholera, it is but a statement of the *modus operandi* of the essential cause of the disease, not of the cause itself. In fevers in which the existence of a material cause is indisputable. cerebral muscular and other phenomena are manifestly due to the action of the poison circulating in the blood on and through the nervous system and we cannot assent to the assertion that "mental emotion exerts no influence on the progress and termination" of these diseases, notably typhus.

Dr. Chapman maintains that heat *per se* is the immediate and most potent cause of cholera and diarrhœa, in virtue of the stimulation it exerts on the spinal and sympathetic nerves. But if so, why is cholera still unknown in Australia where the heat of summer is intense; and how can we explain the prevalence of cholera in Russia far into the winter, though both facts are easily explicable by the theory of a material poison? Why, again, does cholera never break out on board vessels at sea in the tropics or in the passage from England through the Red Sea, the hottest spot in the world? Surely it is far more reasonable and simple to assume that high temperatures set up changes in the organic pollution of the soil which favour the development of the causes of diarrhœa and of cholera if that be introduced from abroad. One is almost ashamed to waste words in combating such a hypothesis, but the way in which Dr. Chapman presses the well-known story of the Southwark and Lambeth Waterworks into his service is even more ridiculous. If the imbibing of foul water increased the sensitiveness of the nervous centres of Londoners to the effect of heat, why did the immediate consequences in the shape of cholera appear only on two occasions and not in seasons equally hot? If Dr. Chapman would be content to work out his theory as a contribution to the pathology of cholera, he might earn our thanks, but the attempt to elevate it into a *causa vera et sola* lands him in absurdities and worse.

Transactions of the American Surgical Association. Edited by J. Ewing Mears, M.D. Philadelphia: Blackiston, Son and Co., 1883, pp. 568.—This is the first volume of the transactions of an Association founded in 1881, the object of which is to unite into one harmonious whole such of the 60,000 medical men in the United States as practice and teach surgery proper. The book before us contains the names of the founders of the Association, the lists of officers nominated at the first and subsequent meetings, and the addresses which are usual at such preliminary meetings; wherein are detailed the objects of the Association, and the lines on which it is proposed to work it. That the Association has prospered there can be no doubt, in presence of the volume before us, and that it has a good *raison d'être* will be admitted when the large questions in surgical pathology and practice, which are still unsettled, are borne in mind. The volume contains 32 essays on various subjects, with the discussions to which the papers, when read, gave rise. The authors are thoroughly representative of the various medical schools in America, and among them are included some of the best known names in surgery. Listerism is discussed from several different standpoints; it appears to have obtained a firm footing, and to be largely adopted throughout the entire continent. There is an admirable monograph extending to 100 pages, on "Intra-capsular Fracture of the Femur," with special reference to bony union, by Dr. Senn. He unites all the evidence both for and against the possibility of bony union, and shows that "the number of well authenticated specimens has been gradually increasing, and the knowledge derived from clinical observation and experimental investigations on this subject during the last few years, can leave no further doubt pertaining to the production of bony callus in intra-capsular fractures." Such a conclusion is of great importance in the interests of patients suffering from this accident; for it will induce surgeons, even more than at present, to be anxious to secure that co-aptation of fragments which is of course the *sine quâ non*. Dr. Senn concludes his article by a section on "Treatment." He suggests the following points: (1) Immediate reduction and co-aptation of the fracture under an anæsthetic. (2) Fixation with a plaster of Paris splint. (3) Lateral pressure. (4) Direct fixation of fragments by bone pegs. This section is full of interesting detail, to which we must refer our reader, as it is incapable of useful abridgment. Another interesting subject worked out in the same spirit—that of testing the correctness, or incorrectness of generally accepted doctrine on given points in surgery—is that of "Foreign Bodies in the Air Passages: a Study of 1,000 cases to determine the propriety of bronchotomy in such accidents," by Dr. Weist. The author considers as one of the evidences of the advancement of surgical science "that its *dicta* no longer emanate from an individual, but are formulated from the united experience of the profession." This study has taken several years. Not content with recorded cases, the author issued a circular to the profession in America and Europe, asking for particulars of any unpublished cases. It is in this manner that Dr. Weist was able to get together the unprecedentedly large number, 1,000 cases, on which to formulate his conclusions. The outcome of this study goes to upset the usually accepted doctrine "that the presence simply of a foreign body in the air passages determines the necessity of bronchotomy." And that "in many cases where it is certainly known that the trachea or bronchus contains a foreign body, the patient will be more likely to recover if trusted to the chance of spontaneous expulsion than he will be if subjected to operation." We must acknowledge ourselves as "persuaded against our will," and therefore of the "same opinion still," Dr. Weist's conclusions and statistics notwithstanding. In the first place, the death-rates of operated and non-operated cases are not strictly comparable. Dr. Weist tells us that in a given number of cases spontaneous expulsion of the foreign body occurs. Well and good, there is an end to the matter as regards these cases. Of the remainder however an operation is performed and 73 per cent. recover—a goodly percentage surely! The remainder die (27 per cent.). In order rightly to estimate this latter percentage we ought to know the cause of death, and whether death was due to, or in any way accelerated by, the operation: further, whether the *foreign body was got out* at the operation, or whether (as in a case mentioned by one of the speakers in the subsequent discussion) it was left behind; and if left behind, whether its position was accurately determined. To leave behind a foreign body, "moving during the act of respiration and appearing at the opening," is not a surgical proceeding, and cannot be used for purposes of surgical argument. We still feel, therefore, that in all cases where a foreign body is known to have penetrated the air passages, and not to have been spontaneously expelled, the correct practice is to open the trachea and endeavour to get it out. If the surgeon is unsuccessful, we do not think that the case will have been materially complicated by the operation. The space at our disposal will not permit us to enter into further detail, or to notice any of the other equally interesting papers. The volume is well published, and if its successors are equally good, they will form a valuable addition to our surgical literature.

Manual of Diseases of the Ear, for the use of Students, &c., &c.; by Thomas Barr, M.D. Glasgow: James Maclehose and Sons.—There is no lack of text-books for the student desirous of studying diseases of the ear. Another has been added to the list in Dr. Barr's work. This book will take its place with the other standard works on the

subject. For those wishing to obtain a general knowledge only of aural surgery, Dr. Barr's book is too voluminous; but those wishing to study the subject more fully, will find it a very valuable treatise. The book is divided into four parts. In the first part the opening chapter on the method of examining the ear is exceedingly well written, giving the fullest instructions very clearly and intelligibly, and we consider it the best part of the book. Chapter II deals with the causes of ear disease, and Chapter III with affections of the nose and throat in their connection with diseases of the ear. In this chapter the author treats more fully of the relation of naso-pharyngeal catarrh to ear disease than is usual in English text-books of aural surgery. The relation of adenoid vegetations in the roof of the pharynx to chronic deafness in children is very much overlooked, even by many practitioners well acquainted with diseases of the ear, and Dr. Barr has done good service in forcibly drawing attention to the subject. Cases have frequently occurred in which even well known surgeons and physicians have assured anxious mothers that the children would "grow out of their deafness" as they grew stronger, where subsequent examination by those skilled in rhinoscopy has showed well-marked adenoid vegetations in the naso-pharyngeal cavity. The next chapter is devoted to methods of treatment, and while acknowledging the very valuable information therein contained, we question the advantage of discussing such subjects as "application of vapours or fluid to the middle ear," "paracentesis of the membrana tympani," "operative treatment of aural polypi," &c., in a separate chapter, rather than under the heading of those diseases which require such treatment. Again, the author, by describing at length the anatomy of the various parts of the ear, increases the bulk of his book without, in our opinion, adding to its value. Parts II and III treat of the diseases of the external and middle ear, and call for no special notice, except a word of praise for the very lucid manner in which the different methods of treatment are handled. Our knowledge of diseases of the inner ear is so unsatisfactory, and the differential diagnosis of pathological conditions so obscure, that this part of the work is of necessity more or less a compilation. In conclusion, we must still express a fear that the book is too exhaustive for the ordinary reader.

Tropical Trials: a Handbook for Women in the Tropics; by Major S. Leigh Hunt and Alexander Kenny, M.R.C.S., pp. 461. W. H. Allen & Co.

On Duty under a Tropical Sun., pp. 192. Second edition; by the same authors.

Both of these useful little books are intended to counteract many of the petty annoyances and personal discomforts attendant upon residence in tropical climes. The smaller volume, which has already reached a second edition, devotes over a hundred pages to diseases of tropical countries, the range of these including the commoner forms of accidents and their appropriate treatment. This volume is intended especially for the use of men. In their larger volume, "Tropical Trials," the authors address themselves mainly to women, and give much valuable information for the guidance of women in the tropics. One chapter is devoted to practical suggestions on clothing and outfit, numerous hints on many of the small items essential to comfort finding a place under this heading. Other chapters give notes on travelling by land and by water, general remarks on diet, and hints on domestic economy. As in their previous book, the authors devote more than half their space to more purely medical topics, the maintenance of health and the treatment of simple maladies being allowed nearly 200 pages; thorough and practical on all points, we venture to think that this chapter will prove of the utmost usefulness. The authors are careful to guard against the indiscriminate use of powerful remedies, their remarks on the abuse of chloral being especially to the point. For sea-sickness they recommend the use of bromide of sodium in certain cases, but are emphatic on the effect of moral control or a "pinch of resolution." These books are both written in cheerful simple language, they possess the advantage of a careful index, and we feel confident that any one resorting to them for directions in emergencies will find safe guidance for the treatment of the slighter ailments, and clear instructions as to the management of the sick room. In books so obviously intended for general use it is extremely satisfactory to find the following in italics—"*Always be sure that what you do is in strict accordance with the instructions of the medical man who is attending the case.*" "*Never administer a medicine without first reading the label.*" These two sentences sufficiently indicate the sound common sense and excellent healthy tone of the two volumes.

The Technics of "Massage;" by Albert Reibmayr. With 126 woodcuts. Vienna: Toeplitz and Deutieke, pp. 136, 1884.—The little book before us is an excellent, if brief, treatise on the art of "Massage," a remedy which, though old as the hills, has not yet had an English name given to it. "Massage," however, seems likely to come once more into vogue, together with the practice of gymnasties, which are now so largely patronised, and have been carried out on such a splendid and really anatomical scale in Sweden and elsewhere. Nor, in moderation, can anything be better adapted on the one hand to keep the body healthy than gymnasties, nor, on the other, to restore suppleness to a limb or a joint that has been diseased than well-directed massage. Our author more than once adverts to the necessity of a suitably trained person to carry out massage with satisfaction to a patient. It is not every hand which can be taught; it requires a special faculty, as well as a special training. The book before us is admirably illustrated. It will prove thus useful even to those who cannot read German. The method of treating each part of the body is figured, so that there need be no difficulty, even with beginners, provided they bring the special *tact* to bear, which appears to be the *sine quâ non*. We cordially recommend the work to our readers, and could wish that it might even be presented to them in an English dress.

ABSTRACTS AND EXTRACTS.

MEDICINE.

Hay Fever.—In a recent number of the *New York Medical Journal*, Dr. J. O. Roe, treating of the pathology and radical cure of this malady, states that the first thing is to determine, by careful exploration of the nasal chambers, the exact conditions which have been the exciting cause of hyperæsthesia. Every sensitive spot should be located and thoroughly treated, until the peculiar "hay-fever sensation" is no longer experienced by the patient when these regions are touched. This sensation is unmistakable, for on touching one of these spots, however lightly, a burning sensation is felt in the nostril as though the probe were heated, and is attended by the usual reflex phenomena. When the turbinated bodies are hypertrophied, or are hyperæsthetic, sufficient tissue should be removed by Jarvis' snare or the galvanic cautery, to destroy the diseased and sensitive nerve terminals, and to obliterate the enlarged blood vessels. All obstructions to the nostrils, and all abnormal conditions of the passages, hypertrophic or otherwise, should be corrected. It is especially important that there should be no point of contact between the turbinated bones themselves or between them and the septum. Projecting bony spiculæ often exist in this region—more often between the middle and superior than between the inferior turbinated bone and the septum—and they are apt to excite irritation and thickening of the opposed mucous surface. When all offending tissue has been removed, local medication should be made to the nasal passages until the parts are healed, the chronic rhinitis cured, and the special irritability has disappeared from every portion. These radically curative measures are best instituted at a time when the patient is free from the affection, and in time to allow of a thorough healing of the parts before the date of the expected attack. It is also advisable to examine the patient from time to time during the hay-fever season, in order to discover whether any portion of the nasal mucous membrane has been overlooked, and has become

irritable—in which case the diseased tissue should be promptly and thoroughly removed. The details of treatment, &c., in four recent and successful cases are given; and the author concludes that the cause of a vast amount of annually recurrent suffering is to be found in the nasal chambers; that it can with care, patience, and perseverance be entirely removed; and "that in those cases in which we fail at first to give our patients entire relief, we know that our work has been incomplete, and that by perseverance our efforts in every instance will be crowned with success."

Elevation of Temperature in Chlorosis.—In the number of the *Lyon Médical* for May 25, Dr. Mollière gives an account of a continuation of some investigations which he has already laid before the Lyons Society of Medicine. He here summarises the results of a close examination of 30 cases of chlorosis, these being all the cases of that affection which have been admitted into his hospital service. The temperature in all these has been taken in the rectum, and without exception has been found to exceed the normal, the temperature rates having been taken morning and evening for a month or two, and even as long as eight months. The mean curve has oscillated between 37·8° and 38° C. during the persistence of the symptoms, to descend a degree as the cure approached. Occasionally there have been elevations as high as 39° or even 40° C. on the occurrence of febrile exacerbations, unconnected with other intercurrent diseases. Dr. Mollière has never met with the lowering of the temperature below the normal mean noted by Professor Peter, and this he attributes to the fact, that while his own observations were always taken in the rectum, those of Professor Peter were always taken at the surface. As Dr. Dieulafoy observes in noticing these results obtained by M. Mollière, they would almost justify the revival of the name given to chlorosis by the ancients—*febris alba virginum*. In all these cases the diagnosis has been most rigorously established, and where any suspicion of phthisis has arisen, the case has been eliminated; and in proportion as the symptoms were well marked the elevation of temperature was found to be higher. On the administration of quinine the temperature has diminished as in ordinary pyrexia, except in some cases when the temperature had been only slightly raised.

Hyper-pyrexia.—This term, says Dr. Goodridge, in the *Practitioner*, for July, includes other conditions besides fever, viz.; excessive heat-production, arrested heat-discharge, and deficient heat-regulation. As an instance of what he believes to have been a case illustrative of this last mode of origin, he quotes the case of a young man who, during an apparently mild relapse of acute rheumatism, was carried off by a hyper-pyrexia of nine hours' duration. There was no evidence in this case of special heat-retention, or increase of heat-production, and failure of heat-regulation is consequently regarded as the main cause. The patient had suffered from several debilitating influences, such as want of sleep from joint pain, chorea and impaired action of the heart. Supposing all these causes of exhaustion to act upon the centre for regulating the production of heat, the result would be an excessive production of heat such as was actually observed, and this theory would well explain its occurrence.

Movable Kidneys.—In the *Birmingham Review* for July, Mr. Lawson Tait takes the opportunity to reply to those who have expressed dissent from the views which he put forth on this subject in the pages of a contemporary a few months since. He disbelieves in a floating kidney as a thing of any pathological importance, chiefly because the cases, thirteen in number, which have come under his own observation where this diagnosis had been made have turned out seven times to be distended gall bladders, four were cases of ovarian cystomata, and two were tumours of the pancreas. The literature of the subject is for the most part not based upon *post-mortem* experience, whilst of the few cases that have been recorded some were instances where it had not been suspected during life. He is very sceptical too about a floating kidney being painful, and observes with much truth that the meso-nephron, which is the cause of the kidney being movable, is a congenital condition, and does not therefore offer any reason for such a kidney being painful.

Can Locomotor Ataxia Be Cured?—In a paper bearing this title (*New York Medical Journal*, August 30th) Dr. G. M. Hammond, after quoting cases of obvious recovery from alleged tabes; and others in which—death having supervened in the course of distinct ataxic symptoms—the *sectio* revealed congestion of the cord without any sclerosis of the posterior columns; and others in which recovery from ataxia had followed dry cupping, and the application of Junod's boot, concludes:—(1) The loss of patellar tendon reflex in locomotor ataxia is not always due to sclerosis of the posterior columns. (2) Sclerosis of the posterior columns may exist unaccompanied by the ordinarily prominent symptoms of ataxia. (3) Congestion of the posterior half of the spinal cord may give rise to most, if not all, of the symptoms of locomotor ataxia. (4) It is impossible during life to make a differential diagnosis between posterior spinal sclerosis and posterior spinal congestion. (5) Posterior spinal congestion is curable. (6) There is no evidence to show that sclerosis once existing in the spinal cord has ever been removed. (7) Those cases of so-called locomotor ataxia which have been cured are simply cases of spinal congestion more profound in the posterior half of the cord.

Transmission of Phthisis.—At the late meeting of the Hygienic Congress at the Hague, two important communications were read on this subject. In the first of these, Prof. Corradi, of Pavia, draws the following conclusions—(1) That the contagion of pulmonary phthisis is possible. (2) Prolonged cohabitation is one of the principal conditions of its occurrence. (3) Debility and all causes which diminish the power of organic resistance render it more easy. (4) The possibility of transmission through the medium of clothing, goods, &c., has not been sufficiently proved. (5) It is also doubtful whether the milk or flesh of tuberculous animals can give rise to the transmission, especially after culinary preparation. (6) That, at present, regulation of cohabitation is the only prophylactic measure that can be had recourse to. (7) Investigations should be continued in different countries, with the aid of a uniform formula. The other paper was a report from M. Vallin, on the "Danger of alimentation by means of the flesh and milk of tuberculous animals," of which these are the conclusions—(1) The tuberculosis of animals is specifically identical with human tuberculosis. (2) It has been proved that the ingestion of raw tuberculous matters may engender tuberculosis. (3) The injection under the skin, or into the peritonæum, of the blood or muscular juices of phthisical animals, is capable of determining phthisis. (4) The ingestion of the raw flesh of phthisical animals is capable, in certain cases; of transmitting the disease, and especially abdominal tuberculosis. (5) The inoculability of tubercle is not destroyed, except by a notably higher temperature than that attained by the central portions of roasted meats. (6) The milk of phthisical cows may transmit tuberculosis, and is especially dangerous when the mammary glands are tuberculous. (7) Boiled tuberculous milk is harmless. (8) In order to guard against all danger, we should, at all events provisionally, prohibit the use of meat of animals the subjects of confirmed generalised tuberculosis, with commencing emaciation. (9) The habit of eating underdone meats should be discouraged, and as a matter of security, milk should always be boiled. (10) Attempts should be made to diminish the frequency of tuberculosis in animals by choice in breeding, improved stalling, isolation of infected animals, disinfection of contaminated stalls, &c. (11) Tuberculosis of horned cattle should be ranged among contagious diseases affecting them, and submitted to the laws applicable to these. (12) Assurance societies against tuberculous cattle should be encouraged, in order to indemnify the proprietors for losses from this cause.—*Progrès Medical*, September 13.

Bright's Disease of Malarial Origin.—Dr. Atkinson, Professor of Pathology in the University of Maryland, terminates a paper bearing this title with the following conclusions:—(1) Transitory albuminuria is not uncommon in the course of malarial fevers, and is due to the intense visceral congestions characteristic of these affections. It may be present only at the height of the congestion and

recur with each return of this, or it may persist in the intervals, in which case the congestion approaches to the condition of acute inflammation. (2) In a proportion of cases, varying with locality and type, inflammation of the kidney occurs, accompanied by dropsy and the usual symptoms of nephritis. (3) The usual form of malarial nephritis is the tubal and diffuse variety, the inflammation seeming to be most intense in the vicinity of the glomerula. (4) Contracted kidney may occur from long continued or frequently repeated attacks of malarial fever, but it is quite improbable that this form ever occurs primarily as purely interstitial nephritis. (5) These changes may be induced by any form of malarial fever, though they more commonly follow chronic intermittent fever. (6) The tendency of the disease is towards recovery, but from the persistence of impaludism or intensity of the inflammation, structural changes may be produced characteristic of chronic Bright's disease from whatever cause. (7) Treatment should be directed primarily against the malarial intoxication, especially in recent cases; and a correction of this will often be followed by a gradual but complete subsidence of the nephritis. Even in chronic cases this is the point primarily to be attended to, the disease then to be treated as ordinary Bright's disease.—*American Journal of Medical Sciences*, July.

Hypertrophic Cirrhosis of the Liver.—The characteristic features of this disease are said to be that the liver is invariably enlarged, and that there is an intra-lobular growth of connective tissue. Its identity as a separate disease has not yet been established, and in the American *Journal of Medical Sciences* for July, Dr. Atkinson adds his protest against its claim to the distinction of a separate place in our nosology. The apparently new development of ducts, on which a good deal of stress has been laid, has been shown to be present also in other affections. Intra-lobular changes similar to those seen in this disease are found in some cases of congenital syphilitic cirrhosis, so that from a pathological standpoint this disease cannot be clearly separated from others. And the same holds good in regard to the clinical aspects; enlargement of the liver and spleen, and jaundice are the only constant symptoms, and these present nothing distinctive.

The Pitch of the Percussion Sound.—Most writers make no mention of the matter, and of the few who have compared the two sides, the majority say that both are exactly alike in pitch, intensity, and quality in the infra-clavicular regions. Trante and Gretmann state that the pitch is generally higher on the left side; Flint, Da Costa, and Seitz that it is higher on the right. As the result of an examination of 200 subjects, all between the ages of twenty and forty, and all being in good general health, and having symmetrical thoraces, Dr. Leonard Huntress found in 72 cases, or but little more than one third of the whole number, no difference between the two sides; in 71 the pitch was slightly higher on the right side; in 26 it was slightly higher on the left; it was markedly higher on the right side in 23, and markedly so on the left in 8 cases. It may therefore be inferred that, while it is much more significant to find the left lung showing dulness at the apex than the right, yet this is by no means proof of disease.—*New York Medical Journal*, June 14th, 1884.

Quinsy.—At a meeting of the New York Academy of Medicine, Dr. F. H. Bosworth, in the course of a paper on the Structure, Function, and Diseases of the Tonsils, said that he had long believed that quinsy was not an inflammatory process involving the tonsil; he regarded it rather as an acute cellulitis of the areolar tissue of the fauces, the red and angry appearance sometimes presented by the tonsil being always secondary and arising from its proximity to the phlegmon. From an analysis of a hundred and thirty-three cases he establishes strong grounds in favour of the old doctrine of the association of quinsy and rheumatism, arthritic or muscular. This connection was further evidenced by the frequency with which cases of quinsy aborted on the early administration of the salicylates. He recommends the use of 15-grain doses of salicylate of soda every two hours. In several cases in which the quinsy-habit had existed he had found that this remedy, employed with the earliest symptoms, had completely arrested the disease. In the course of discussion Dr. Bosworth remarked that the connection between the tonsils and quinsy was purely an incidental one, depending on the location of the former. Patients whose tonsils had been removed were quite as liable to have quinsy as those in whom the operation had never been performed.—*Philadelphia Medical News*, Oct. 11, 1884.

Tannate Injections in Cholera.—Professor Cantani, of Naples, has obtained excellent results by the early treatment of cholera with enemata of warm solutions of tannic acid. (*Centralblatt für die Medicinischen Wissenschaften*, No. 44, 1884). He used the solution in strength of 5 to 10 grammes of the acid to 2,000 of boiling water, with a little mucilage and laudanum. To ensure success he generally made the injection as high up in the bowel as possible, but found that even with an ordinary syringe the treatment was valuable in the early stages of the disease. It was especially effective during the period of premonitory diarrhœa, which was at times completely checked even after a single injection, a period of rest following of from eight to ten hours, and further attacks being cut short in a similar way. The tannate injections seemed to prevent the excessive loss of fluid by the bowel, to permit the continuance of the flow of urine and so to stave off the typhoid state and altogether to prevent the onset of the algid period. The exact mode of action of the tannic acid must remain as yet undetermined. Amongst other possibilities, Professor Cantani suggests that it has a directly destructive or abortive influence upon the comma bacilli. In furtherance of this view he made direct experiments upon artificially cultivated bacilli and found that, although not destroyed by the acid, the micro-organisms were checked in their reproduction and in their mobility for a period of from twenty-four to thirty-six hours.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, November 11th, 1884.

George Johnson, M.D., F.R.S., President, in the Chair.

On Expiratory Cervical Emphysema, that is, Emphysema of the Neck, occurring during Labour, and during Violent Expiratory Efforts—An experimental enquiry.

Dr. Champneys said his present enquiry was complementary to the previous one dealing with emphysema of the anterior mediastinum after tracheotomy ("Medico-Chirurgical Transactions," vol. lxv., 1882, pp. 75–86). Healthy fœtuses were used (with two exceptions) in all the experiments. Frequency.—The accident occurred in about 1 in 2,000 labours. Ætiology.—It was generally agreed that it was caused by bearing down, which is only another name for violent and prolonged expiratory efforts. It occurred during the second stage of labour, and generally appeared first at or about the suprasternal notch, from whence it might extend in all directions. Clinical course.—It was never accompanied by pneumothorax, was all absorbed within a week or so, and seemed always to end favourably. Pathological theories.—It had been attributed to rupture of the (1) bronchi, (2) trachea, (3) lung. Three autopsies supporting the third theory were given; the others seemed to be unsupported by facts. Mode of experiment.—Tracheotomy was performed, and the trachea connected by means of T tubing with a mercury manometer, leaving an open tube for inflation. Seventeen experiments were performed, some with the lungs *in situ*, others with the thorax open, others with the lungs removed from the chest. In one an attempt was made to trace the course of the air by means of a coloured gelatine mass. The conclusions from the experiments were the following: (1) The cause of emphysema of the neck during labour is rupture of the lung tissue, the air escaping near the root of

the lung, passing beneath the pulmonary pleura into the anterior mediastinum, and so beneath the deep cervical fascia into the neck. The route thus marked is the same by which air passes into the anterior mediastinum after tracheotomy (see "Medico-Chirurgical Transactions," vol. lxv., 1882, p. 75, *et seq.*, and p. 85). (2) The weakest parts of the lung are opposite the pleural reflections (*i.e.*, the spaces between the lobules and the fissures between the lobes), and especially the anterior surface of the root of the lung. (3) Pneumothorax, when it occurred during experiment, had nothing to do with the production of emphysema of the neck. The healthy bronchi and trachea are able to resist the greatest possible expiratory efforts. (4) The lungs and pleura, when quite air-tight, are freely permeable to fluids. (5) The usual rules of practice, to restrain bearing down and accelerate labour after the production of emphysema of the neck, are sound. (6) The accident would seem to be noted in about 1 case in 2,000, but it is not improbable that slight cases are overlooked. (7) The air emerges from the thorax along the great vessels, but may not become superficial till it has travelled higher up. (8) The emphysema of the lower part of the trunk, usually connected with rupture of the uterus, belongs to quite a different category and is generally associated with a fatal result.

Dr. ANGEL MONEY regarded toughness of the pleura as the reason why extravasated air took the course it did. He had been much struck with this toughness, and the pericardium possessed the same quality.

Mr. GODLEE asked what reason the author had to assume that the anterior mediastinum was more compressible than other surrounding parts. The only reason he could suggest was that the whole mass might be pushed up slightly through the upper aperture of the thorax. Given a rupture of the lung, he thought, on anatomical grounds, that the air would take the course it did, independently of other causes. Would it not be well to repeat the experiments on the adult body?

Dr. POWELL questioned the propriety of the term "pleural reflections." As to the "weak spot," had not Dr. Champneys in his experiments used a pressure which was far beyond anything that could occur during life? His subjects, too, being fœtuses, were the results, he would ask, comparable with normal expiratory effort?

The PRESIDENT asked whether as chloroform diminished muscular effort, the accident might not be altogether avoided by anæsthesia.

Dr. O'CONNOR asked whether there were any other weak spots.

Dr. SYLVESTER felt indebted to Dr. Champneys for his paper. He had come chiefly to learn whether it was possible by any voluntary effort for a person to inflate his own body. He believed certain lizards could do this. The question interested him in connection with his own experiments and trials to save life from drowning. But he had not got much help from the paper, which he regretted. He feared that there was not any prospect of a satisfactory answer in this direction.

Dr. CHAMPNEYS replied at some length, in answer to the President, that anæsthesia would probably ward off the accident, but it occurred, unfortunately, unexpectedly and accidentally. He had used fœtuses in his experiments for the simple reason that they were more easy to obtain than adult bodies.

Dr. CAYLEY showed a preparation illustrating gangrene of the base of the lung, in a case of cancer of the lower end of the œsophagus and adjoining part of the stomach, which had ulcerated through the spleen and diaphragm into the lung. Mr. Gould, in consultation with Dr. Cayley, had opened and drained this cavity, with considerable relief of symptoms.

The Society then adjourned.

ELECTROLYSIS IN NÆVUS.—In all but cases of very large and invading erectile tumour, Dr. Delore, of Lyons, considers that electrolysis is by far the most preferable method of treatment, acting as it does with great precision and certainty, and leaving only slight cicatrices. The best apparatus for its application is that of Chardin.—*Compte Rendu Général*, October 1.

MEDICAL CONSULTATIONS.

No. III.

OUR HANDICAPPED HOSPITALS.

SCENE.—*A room at the Sydenham Club.*

DRAMATIS PERSONÆ.

F.R.C.P.—*A Consulting Physician.*

F.R.C.S.—*A Teacher of Anatomy.*

And subsequently,

M.R.C.P.—*A Medical Lecturer.*

F.R.C.S. (*Coming in.*) Ah! this is fortunate. I scarcely thought to find you here. I called at your house this morning, just after you had left, and they told me you had a country journey.

F.R.C.P. True, I was to have gone down to Lord A——, had in fact already taken my ticket, when a telegram was handed me stating he was dead. I had put off my other engagements, and here I am, stranded. Fortunately, it has given me the rare pleasure of a talk with you. You called on me?

F.R.C.S. Yes. I am very anxious to obtain your support for a movement in which I and other hospital teachers are deeply interested. We have at last made up our mind that if London is to maintain its position as a centre o medical education, we absolutely must be able to offer our students a fair chance of getting a degree. Our present idea is to petition the University of London to modify their medical examinations.

F.R.C.P. Lost labour, my dear friend!

F.R.C.S. Well, we are not very sanguine. But we have decided that that channel must first be sounded before we try others, and we hope that your influence with th Senate, if you would be good enough to exert it, would go a long way towards obtaining what we want.

F.R.C.P. Possibly; in fact, more than possibly. But it would be assuming a great responsibility.

F.R.C.S. You are not unused to responsibility.

F.R.C.P. Yes, that is very true; but one does not court it.

F.R.C.S. I hardly think you would wish to avoid it, if you saw things from our standpoint. The question is a most momentous one.

F.R.C.P. O, come now, there you surely exaggerate. A mere question of titles, a matter of leather and prunella, eh?

F.R.C.S. Indeed, we feel it to be a most pressing matter, not merely for our own interests, which are a secondary consideration, but because it nearly touches the welfare of medical education in this country. We are losing our students steadily. The yearly entries are declining and our senior men are constantly tempted away to Edinburgh, to Aberdeen, to Newcastle to finish their curriculum. Surely it cannot be to the interests of the students themselves to lose the benefit of the best clinical talent in the country—that of your own successors for instance.

F.R.C.P. True; but are not my successors a little to blame? In my time no student thought of going away for his degree. To have been taught by us outweighed in his mind the attraction of any title. I cannot help thinking there is something a little artificial in your agitation. Why is it burst upon us so suddenly?

F.R.C.S. Why? Because our students are beginning to find out that it will pay them to have a degree. But perhaps I had better read you this rough draft of an address to the London Senate.

F.R.C.P. Pray do.

F.R.C.S. (*Reading.*) "We, the past and present teachers at the London hospitals, beg most respectfully to draw your attention to the difficulties under which medical education in London is at present labouring. At no time, we believe, have the appliances and organisation for teaching been more complete, or the zeal of the teachers more manifest. But, in spite of this, the entries of new students, so far from increasing, show a steady diminution. We think it may be fairly concluded that the main, if not the sole, cause of this decline is connected with our inability to promise the majority of our students a fair chance of obtaining a medical degree, and with it the title of "Doctor." While freely admitting the inestimable services that your University has rendered to the cause of medical education, the high character of your examinations, and the unquestioned ability of your medical graduates, we humbly beg to point out that the conditions under which your medical degree is granted are such that not more than a very inconsiderable percentage of London students can hope to obtain it, while of the remainder an ever increasing proportion leave the well-found clinical schools of the Metropolis to finish their education elsewhere. The average number of students who annually obtain your M.B. degree is about forty. Assuming that thirty-five of these come from London schools, and that the average annual entries at those schools are less than 600, it is obvious that only six or seven per cent. of our students, at the outside, will be fortunate enough to graduate in medicine at your University. We would further point out that during the years 1875–1882, while 1,511 students entered for the preliminary scientific examination, only 252, or less than 16 per cent., succeeded in passing the 2nd M.B. In the meanwhile other universities are offering increased facilities and we believe that the proportion of English students who obtain a part or the whole of their medical education away from London is certain to undergo steady increase, unless an arrangement is made whereby they can obtain a degree in London. Under these circumstances, we beg to submit the whole question to your earnest consideration."

F.R.C.P. A very politic address. And you wish me to add my signature?

F.R.C.S. We should be glad of it, of course. But we hoped for more from your personal influence with the members of the Senate.

F.R.C.P. Really, I have hardly thought out the question. I cannot promise anything now, but I will see, yes, I will see. At present, your movement strikes me as a little artificial. I am, I admit, somewhat old-fashioned in my views as to the title of "Doctor." I think it ought to connote a really learned man, a man of culture and erudition. It should not be distributed broadcast to every student who has lounged through a medical curriculum. Let us beware of Americanizing our institutions.

F.R.C.S. Unfortunately we have to deal with facts. Others will distribute the M.D. broadcast if we do not. As it is we are heavily handicapped, and are daily dropping behind in the race.

F.R.C.P. I am grieved to hear that. But are you sure that you are making the best of your advantages, or are you, pardon me for the comparison, only unskilful workmen quarrelling with your tools? I cannot but think that if you London teachers really made the most of your unrivalled opportunities and your unquestioned abilities, you would have no reason to fear the rivalry of anyone. Why should not the boast "I am a London man" be able to outweigh any title that Edinburgh or Manchester can give? I should be inclined to call yours a door-plate policy.

F.R.C.S. We do not wish to make every student an M.D. All that we contend is that the London University, by modifying its examinations, should open its degree to a much larger proportion of students than at present, say to sixty instead of six per cent., so that any student of average application and ability might fairly hope to obtain one. Of course, if the University insists on keeping its doors closed, we shall have to try elsewhere.

F.R.C.P. Well, well, I will think over it and see how I can help you. (*To* M.R.C.P., *who has just come in.*) How d'ye do. We are talking of a question on which I am sure you will have something to say. Our friend here wants to convert the sour grapes of the London M.D. into sweet-water ones, to pull down the boughs within the reach of men of low stature. That is a mission which will just suit a root and branch reformer like you.

M.R.C.P. Yes, I have strong views on the question, as F.R.C.S. knows, but I think that he and his friends are entirely on the wrong tack. They will get nothing from the London University, and it is waste of time to try. We can apply no pressure to it, and this is a question where nothing will be gained without pressure. Its medical graduates elect a member of the Senate once in, say, ten years, and even then cannot make sure of his vote. I would give the University of London a long rope, and set to work on bodies who can be made more amenable. I am heartily in favour of a practicable London degree, but I would get it from the Colleges. There the London teachers can apply pressure. Why if they were only united they could elect a President and Council at each College pledged to the lips to get the necessary powers from Government. If they are in earnest they should stand no nonsense from the Colleges, but insist on their doing what they wish. Never mind the woman difficulty, let the women have the degree as well, and welcome.

F.R.C.P. My good friend! Would you make the whole policy of the Royal Colleges turn on a paltry question of a degree? What! risk ruining two time-honoured institutions that a few score boys may have handles to their names? As the Germans say, in emptying the bath, you risk spilling the baby. You would burn a house to grill a pork chop. But I knew we should have something incendiary from you.

M.R.C.P. You no doubt can afford to look upon the matter frigidly, but to us it is likely to turn out a question of vital importance. It is not so at present, but it will become so; and we who look far ahead cannot contemplate the prospect of empty lecture-rooms, of diminishing fees, and lessened opportunities of good work without dismay. Five years hence, you will see, everybody will think as we do. Why wait till half a dozen London schools have closed their doors, before taking action? We do not ask for much. We only ask that London shall have what every other capital in Europe has. Why should we lose our livelihood because a bevy of old gentlemen in Burlington Gardens have decided that a man shall not get their degree unless he can work a torsion-balance or dissect a cockroach? Their system is ridiculous. Going up for their examinations is for all the world like climbing a greased pole; if you fail to touch the top even by a few inches, you slip right down to the bottom and have to wait a year before you can try again. We should not mind a stiff examination in purely medical subjects, but what we do object to is to see men fruitlessly wasting, on collateral sciences, time and energies which are all wanted to make them decent practitioners. We must and will have a degree, and if the London University stands in our way, so much the worse for it. We cannot apply pressure to it directly, but we can advise our students not to go up to it.

F.R.C.P. Ah! my dear friend, if you London teachers were united, what is there you could not do? But you know you are not, and all you attempt will come to nothing.

Take an old man's advice, and don't threaten until you are sure that you can perform.

F.R.C.S. You must not judge us London teachers by the past. Circumstances are at last forcing us to be united, but we threaten nothing. M.R.C.P. represents our extreme wing, but I assure you that, as a whole, we shall do nothing rash. For my own part I believe that the Colleges will never consent to apply for fresh powers, but they may yet find a way of meeting our wishes. I, for instance, see no reason why they should not let their licentiates put "Dr." on their door-plates. Or they might even come to an arrangement with Durham, by which its degree would be given with the combined licence, on condition that three months, or less, should be spent at Newcastle, and perhaps a part of the examination conducted there. There are many ways of getting round the difficulty without threats or bluster. Who can tell, for instance, that the whole subject may not be taken out of our hands, and a real teaching university be founded in London which would fully meet our requirements? The great thing is to know what we want, and to be united in our resolve to have it.

F.R.C.P. There you speak like a sensible man. Remember this, that in our profession if you want anything, to use threats is exactly the way not to get it. We are conservative, and detest change. We are sensitive and resent the very whisper of coercion. But we are, withal, careless and easy-going, and yield before silent, persevering, united effort. As for the London University, if you take my advice, you will not waste time upon it.

GENERAL CORRESPONDENCE.

THE PHYSIOLOGICAL DEPARTMENT AT EDINBURGH UNIVERSITY.

[To the Editor of the Medical Times.]

SIR,—I am sorry to observe that your Edinburgh Correspondent, in your issue of October 11th, and in that of to-day, has furnished your readers with several misrepresentations regarding me, and the department of the University which I direct. I might treat his communications with the contempt they deserve, but I prefer to expose their injustice.

With reference to the resignation of my late assistant, Dr. Gibson, he says: "It is not satisfactory to find that one who proved himself a capable and popular teacher, and who promised well as a physiologist, should have had so little encouragement to stay among us as he appears to have met with. Under circumstances like this, the foundation of a school of physiology in Edinburgh seems a remote possibility." The frequent changes in my staff of assistants has been a misfortune to this school, in so far as able young teachers have been removed from it just when they had attained to some considerable experience. Professor Stirling, of Aberdeen; Professor De Burgh Birch, of Leeds; Professor Hayecraft, of Birmingham; and Professor Anderson Stuart, of Sydney, were successively my assistants during my first eight years as professor here. I suppose no other school in the country can claim to have sent out four young trained professors of physiology within eight years. My late assistant, Dr. Gibson, who was with me during the two past years, received last July an invitation to accept a chair of physiology in a Canadian University, which he declined. Shortly afterwards, he was virtually offered a valuable lectureship on physiology in London, which he would have accepted, had private influences not induced him to return to Queensland, his native country. Your correspondent ought to feel gratified that physiologists educated in Edinburgh are so much in demand in the medical schools of this country, and its colonies, and in place of his uncalled for sneer about "so little encouragement to stay among us," he might condole with me on the consumption of my time required in educating physiologists for other schools. Of course, it is a source of gratification to me to see my assistants gain independent and important positions, and to feel that although they are no longer helping the Edinburgh School, they are now representing that school and continuing its methods of tuition elsewhere.

The mean attempt of your correspondent (Oct. 11) to incite my students to worry me about writing a text-book, has not yet produced the result he seems to have hoped for. Your correspondent contrives to make it appear that of the many teachers here, I am the one who seems disposed to do little to help my students, and yet I question if any other teacher here has been so generous in helping his pupils. Ten years ago, although I was then almost totally devoid of the necessary means, I spent a thousand pounds in providing them with the appliances necessary to help them in their studies. For several years I willingly sacrificed my private comforts in order to help them in the above manner. I believe the professor of chemistry and myself have invested more of our own means in teaching and research appliances than any other of our colleagues. Your correspondent's sneer about the "public" having a "right to ask why all this money spent on magnificent laboratories" strikes me as very strange when I think of my sacrifices in former years.

Your correspondent is gratified that the professor of pathology has "announced that his laboratory will be open to a limited number of graduates and senior students for the prosecution of research," but "he looks in vain for a similar announcement regarding the physiological department." It is true, that I have not announced any "advanced class" for laboratory work with a special fee attached, but your correspondent might have read in the calendar and on annual placards that my laboratory is always open for research. It has been in the past few years, and it will be for a good many years to come, difficult to get many workers, firstly, because of the Vivisection Act, certificates for experiments to be done in my laboratory having been twice refused by the Home Office. Consequently, most young men go to the Continent to do physiological research that implies experiments on animals. Secondly, physiology has not that direct bearing on practical medicine which pathology and therapeutics have. Consequently, it is difficult to get young men to work at physiological research, unless they are supported by fellowships and scholarships.

In my laboratory during the past session Dr. Yonnan, a Vans Dunlop scholar, did an excellent research on "The Structure of the Vitreous Humour," which was published in the last number of the *Journal of Anatomy and Physiology*. Dr. Noel Paton, who holds a research fellowship of the University, has been engaged in solving the difficult problem of "The Effect of Hepatic Stimulants on Excretion of Urea and Uric Acid." Dr. Hunter some months ago assisted me in investigating the effect of corrosive sublimate in preventing decomposition of the urine, the results of which will presently be published. Dr. Dyce Fraser continued his work on "The Cause of Scarlatina."

Dr. Gibson began a research on "Development of Blood Corpuscles," regarding which he published a paper in the *Lancet*, and of which more would have been heard but for the unfortunate refusal of a certificate by the Home Office. All the above subjects were suggested by me, and given to the researchers, who received from me all the help I could give, and who in no case paid anything save a small sum for necessary expenses. Dr. Alexander Bruce has also been conducting a research on the "Development and Pathology of the Human Brain," for a whole year, with apparatus belonging to the Physiological Department. During the past ten years I have personally done more research than any of my colleagues, and the amount could have been far greater than it has been but for the extraordinary labour thrown on me for a period of four years by the rapid growth of our medical schools.

When your correspondent says that "at the first meeting of my class at the new buildings, I went out of my way to describe in elaborate detail the appliances and purposes of upwards of a score of apartments for the prosecution of physiological teaching and research," he does, indeed, display a most acrimonious spirit. I was at infinite pains

and trouble to supply to the architect designs and measurements of every room and its contents down to the minutest detail in my department. My colleagues have all been equally painstaking in their efforts to make our new buildings supply the wants of a great medical school for centuries to come.

The remainder of the money needed to finish the teaching departments of the new buildings was rapidly coming in until eighteen months ago, when the Edinburgh newspapers suddenly became pervaded with violent attacks on the university and its professors, made by members of the Extra-mural School of Medicine, who had suddenly become seized with the delusion that university professors were attempting to stifle the Extra-mural School by means of the Medical Bill. Unlimited abuse about *text-books*, lectures, practical classes, examinations, &c., was levelled at our heads, and the immediate effect was an almost complete stoppage of the subscriptions to our new buildings. Members of the Extra-mural School have since then admitted that they had been under a misapprehension. The mischief they wrought, however, has not been undone. Comparatively little money has been obtained for the buildings since their attacks. Now, however, it appears from your correspondent's notes of to-day, that the idea he would like to insinuate is that the public hold their hand because a sufficient amount of work is not being done in our laboratories. This is, indeed, the addition of insult to injury.

What is required in all the Scottish Universities for the development of research is large sums of money to endow research scholarships, to pay for the materials and appliances required. In Edinburgh University, at all events, I think we require no more money to assist students, but much more to assist researchers, and it was to appeal for a Research Fund that "I went out of my way" to show that I had done all in my power in designing a laboratory in which a Research Fund could produce valuable results.

Regretting to have trespassed so much on your valuable space,

I am, Sir, yours, &c.,
University of Edinburgh, WM. RUTHERFORD.
8th November, 1884.

A HOME WITHIN A HOSPITAL.

[To the Editor of the Medical Times.]

SIR,—With the kind aid rendered by the Press, the Bolingbroke House Pay Hospital was established, and has been able to carry on its useful work for years, but so important a change has just been made in its administration that in the interest of the great lower middle class public I hope you will allow me to make it known. The funds for the establishment of Bolingbroke House were provided by those who wished to give to sick persons the advantages of hospital treatment and nursing, with home surroundings, upon paying such a reasonable fee as their means allowed, and so relieve the great free hospitals. Hitherto six gentlemen have acted as a medical staff and treated all cases, but as this was believed to limit the usefulness of the institution, they very considerately withdrew, to enable any qualified practitioner to send in a patient under his own special care and treatment. Trained nursing with proper sanitary surroundings and hospital treatment generally in the best air within the four mile radius are such obvious advantages to patient and doctor alike in serious illness, that now that Bolingbroke House is available to any qualified practitioner we may expect all its beds to be constantly occupied. It meets the special need of those who fall sick in lonely lodgings. It is a home within a hospital, and it gives a helping hand to those who in time of sickness are willing to help themselves. The Honorary Secretary, Mr. J. S. Wood, Woodville, Upper Tooting, S.W., will send a prospectus to anyone writing for it.

I am, Sir, yours &c.,
J. ERSKINE CLARKE,
Nov. 8, 1884. Trustee.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Thursday last, 13th instant. The resignations of Messrs. Forster, Savory, and Hulke, as Examiners on the Court of Examiners were accepted, to take effect from the completion of the Fellowship Examination, which will be held this month. Mr. Hulke will alone offer himself for re-election. It was agreed to proceed to the election of Examiners in Anatomy, in Physiology, and in Midwifery, under the new scheme of the two Colleges, at the next meeting of the Council; and it was referred to the Nomination Committee to advise and report upon candidates. It was further agreed that the candidature for examinership in Anatomy and Physiology should no longer be restricted to Fellows of the College, but should be open also to Members. It was agreed that the new Board should be employed to carry on the first professional examination of those even whose studies commenced prior to the date from which the new conjoint scheme takes effect. The examination for the Fellowship will as heretofore be conducted solely by those who have obtained that diploma. The present Court of Examiners, until otherwise ordered, are to be constituted Examiners of Surgery under the New Board. A communication from Mr. Pollock, to the effect that Mrs. Hawkins was about to present to the College a bust of her husband, Mr. Cæsar Hawkins, was received with much satisfaction. The matter arising out of Mr. Heath's motion as to the mode of election of the President was considered. The following resolutions:—(1) That the office of Vice-President be for the future held for one year only by the same person; (2) That the President be elected annually by the Council from among its Members, and that no President hold office for longer than five years, were referred to an Extra-ordinary Meeting of the Council to be held on Wednesday next, November 19th, at 4 p.m. A series of recommendations from the Association of Fellows was received, and ordered to be considered at this Extra-ordinary Meeting after the other business had been completed.

UNIVERSITY OF CAMBRIDGE.—At a congregation held November 5th, the undermentioned Degrees were conferred:—*Doctor of Medicine* — Herbert Tyrell Griffiths, Trinity. *Bachelor of Medicine*—Charles Arthur Morris, Caius.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — At a meeting of the Council, held yesterday (Thursday), Mr. Jonathan Hutchinson, Cavendish-square, Diploma of Member dated May 21st, 1880, student of the London Hospital, who passed his examination in November, 1883, was admitted a Fellow of the College.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, November 6th, 1884:—

William Peard Barrett, Bunwell House, Cheltenham; William Howard Bell, 27, Myddelton Square, E.C.; Trevor Augustus Dagg, St. Bartholomew's Hospital; Ernest Farr, Gloucester House, Barry Road, East Dulwich; Herbert Charles Walter Jones, St. Bartholomew's Hospital,

The following gentleman also on the same day passed the Primary Professional Examination.

Herbert Josiah Jones, The Middlesex Hospital.

THE INTERNATIONAL MEDICAL CONGRESS.—Mr. Henry Morris has received a communication from Mr. Audley Gosling, Her Majesty's Chargé d'Affaires at Copenhagen, to the following effect:—"I beg to inform you that the King was graciously pleased to receive me to-day in private audience for the purpose of delivering to his Majesty the address, signed by the English, Scottish, and Irish members of the International Medical Congress, recently assembled here, expressing their profound regret at the loss sustained by His Majesty and Denmark in the destruction of Christiansborg Palace on the 2nd ultimo. The King

seemed fully to appreciate the graceful tribute of sympathy, and commanded me to convey to its authors his 'heartfelt thanks.'"

THE EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—At a meeting of the Medico-Chirurgical Society, held on the 5th instant, the following gentlemen were elected office-bearers for the ensuing year:—President, Dr. Henry D. Littlejohn. Vice-presidents, Dr. David Wilson, Dr. J. Batty Tuke, and Dr. John Duncan. Councillors, Dr. George Hunter, Dr. James Jamieson, Dr. Graham Brown, Dr. J. M. Cotterill, Dr. Rattray, Dr. A. Moir, Mr. Johnston Symington, and Dr. Maebride. Treasurer, Mr. A. G. Miller, 11, Walker Street. Secretaries, Dr. MacGillivray and Dr. James. Editor of Transactions, Dr. William Craig.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—The following Fellows have been appointed Examiners for the Membership for the year 1885:—In *Principles of Medicine*, *Medical Anatomy*, and *Medical Chemistry*, Dr. J. M. Finny and Dr. Walter G. Smith. In *Practice of Medicine* and *Principles of Public Health*, Dr. C. J. Nixon and Dr. F. J. B. Quinlan. In *Clinical Medicine*, Dr. G. F. Duffey (Vice-President) and Dr. J. M. Purser.

ACADEMY OF MEDICINE IN IRELAND.—The following officers of the subsections of State Medicine and of Anatomy and Physiology, have been appointed. Subsection of State Medicine. Chairman—John William Moore, M.D., F.K.Q.C.P. Committee — Charles A. Cameron, Fellow and Vice-President, R.C.S.I.; E. MacDowel Cosgrave, M.D.; Thomas Wrigley Grimshaw, M.D., Registrar-General for Ireland: E. Dillon Mapother, M.D., F.R.C.S.I.; John Byrne Power, M.K.Q.C.P.; and H. J. Colpoys Tweedy, M.D. Honorary Secretary—H. J. C. Tweedy, M.D. Subsection of Anatomy and Physiology. Chairman—D. J. Cunningham, M.D. Committee—Phineas S. Abraham, F.R.C.S.I.; Francis T. Henston, M.D.; John Freeman Knott, F.R.C.S.I.; John Stephen McArdle, L.R.C.S.I.; John Mallet Purser, M.D.; and John Alfred Scott, L.K.Q.C.P. Honorary Secretary — (Not yet appointed).

LONDON HOSPITAL MEDICAL COLLEGE—CLINICAL SURGERY.—As Emeritus Professor of Clinical Surgery, Mr. Jonathan Hutchinson, F.R.S., will deliver a course of six lectures in the anatomical theatre on subjects of interest to house surgeons and dressers, at 3 p.m. each day, as follows:—Monday, November 24th, "On the art of note-taking, and other matters." Wednesday, November 26th, "On the surgery of the receiving room." Monday, December 1st, "On head injuries, hernia, and other matters." Wednesday, December 3rd, "On dislocations and fractures." Monday, December 8th, "On the treatment of wounds, &c." Wednesday, December 10th, "On retention cases, injuries to viscera, &c." Members of the profession will be admitted on presentation of their address cards.

CHARITABLE BEQUESTS.—Mr. Graham Moore Robertson has left 250*l.* each to St. Mary's Hospital, Paddington; the London Hospital, Whitechapel; and the Hospital for Sick Children, Great Ormond Street.

SIR ERASMUS WILSON.—Mr. Thomas Brock, A.R.A., has received a commission for a colossal bronze statue of the late Sir Erasmus Wilson, to be erected outside the Margate Infirmary, which owes so much to that physician. He will be represented clad in his robes of office as President of the Royal College of Surgeons.

PROSECUTION UNDER THE DENTISTS' ACT.—The British Dental Association recently instituted a prosecution in Edinburgh against William Robertson, for representing himself as registered to practise dentistry when he was not so registered. The defendant was fined 5*l.* with the alternative of seven days' imprisonment.

ANTHROPOLOGICAL INSTITUTE.—At a meeting held on Tuesday last, Professor Flower, F.R.S., President, in the chair, Mr. Francis Galton described the object, method, and appliances of the late Anthropometric Laboratory, at the International Health Exhibition, reserving the statistical results, which were not yet fully worked out, for another occasion. He established it to show with how little expense an elaborate course of measurements might be made, and how popular such a system of measurements would be The result was that 9,344 persons passed through the laboratory, each of them being measured in 17 distinct particulars for the sum of 3*d.* in a compartment only 6 feet wide and 36 feet long. The popularity of the laboratory was so great that its door was besieged by far more applicants than could be admitted, and many persons made repeated attempts and waited long for their turn, but at last gave it up as hopeless. So many applications have been made abroad and at home for duplicates of the instrumental outfit that it was advisable that any suggested improvements in them should be considered before they became established in use. The present paper was to invite discussion. An identical set of instruments to those used at the Exhibition have been set up by Mr. Gammage, optical instrument maker, at 172, Brompton Road, assisted by Mr. Williams, who between them conducted all the measurements at the Healtheries. They make a moderate charge for measuring, and keeping a register of the results. Mr. H. O. Forbes read a paper on the people of the Island of Burn.

THE PARIS NIGHT SERVICE.—Dr. Passant, in his report for the quarter ending Sept. 30 (*Gazette des Hôpitaux*, October 25), states that the number of calls amounted to 2,446 (as compared with 1,659 for the same quarter in 1883), or 28·58 per night. Of these visits 880 (32 per cent.) were paid to males, 1,256 (55 per cent.) to women, and 310 (13 per cent.) to children under three years old. The affections for which these visits were made, were as follows —(*a*) Anginas, croup pertussis, &c., 143. (*b*) Asthma and affections of the heart and lungs, 163. (*c*) Gastro-intestinal affections, strangulated hernia, retention of urine, &c., 928. (*d*) Metritis, uterine hæmorrhage and abortions, 157. (*e*) Labours, 209. (*f*) Affections of the brain and nervous system, and alcoholism, 371. (*g*) Rheumatism, fevers, and hæmorrhages, 213. (*h*) Wounds, contusions, fractures, dislocations, and burns, 164. (*i*) Poisonings, 30. (*k*) Suicides, 6. Sixty-five patients were dead on the arrival of the medical attendants.

VACANCIES.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—Resident House Physician. Salary, £65 per annum, with board, lodging and washing in the Hospital. Candidates must be duly registered. Applications with qualification and testimonials to be sent to the Secretary (from whom further particulars can be obtained), on or before Decr. 9th.

GATESHEAD DISPENSARY.—Resident House Surgeon. Salary, £210 per annum, with apartments (without attendance), coal, gas, &c. Candidates must possess the double qualification. Applications, and copies of testimonials, to be sent to Mr. Joseph Jordan, 2, Side, Newcastle-on-Tyne, not later than November 21st.

GREAT NORTHERN CENTRAL HOSPITAL, CALEDONIAN ROAD, N.—House Surgeon. (*For particulars see Advertisement.*)

HOLLINGBOURN UNION.—Medical Officer for the Fourth District, in succession to Dr. Edward J. Barry, resigned. Area, 16,199 acres. Population, 3,628. Salary, £60 per annum.

LIVERPOOL EYE AND EAR INFIRMARY.—House Surgeon. (*For particulars see Advertisement.*)

NORFOLK AND NORWICH HOSPITAL.—House Surgeon. (*For particulars see Advertisement.*)

ROYAL FREE HOSPITAL, GRAY'S INN ROAD.—Senior Resident Medical Officer. (*For particulars see Advertisement.*)

THE BIRKENHEAD EYE AND EAR HOSPITAL AND DISPENSARY.—Honorary Surgeon. Applications, stating qualifications, &c., to be sent to the Honorary Secretary. on or before November 22nd.

WESTERN OPHTHALMIC HOSPITAL, 155, MARYLEBONE ROAD, W.—Surgeon. Candidates must be Members or Fellows of the Royal College of Surgeons of England, and have attended Ophthalmic Practice for twelve months. Applications to be sent to the Secretary at the Hospital, on or before November 22nd.

DEATHS.

CHILCOT, JAMES, M.R.C.S., at Wardell, Richmond River, New South Wales, on September 11th, aged 37.

HUNTER, R. H., M.R.C.S., at Isleworth, on November 11th, aged 46.

KIDD, LEONARD, Deputy Surgeon-General, Army Medical Staff, at Hamilton, Bermuda, on October 31st, in his 55th year.

RANSOM, P. P., M.R.C.S., L.S.A., at North Elmham, Norfolk, on November 4th, aged 64.

RIDSDALE, G., M.D., at 26, Endsleigh-gardens, Gordon-square, N.W., on November 11th, aged 69.

SIMPSON. MAGNUS, M.B.C.M., at 15, Inverleith-row, Edinburgh, on November 11th, aged 32.
VEITCH, J. T., M.D., of Brahrang, Warrington-road, Ipswich, on November 10th, aged 67.

COMMUNICATIONS RECEIVED.

DR. CLIFFORD ALLBUTT, F.R.S., Leeds; Dr. GEORGE HARLEY, F.R.S., London; Dr. ISAMBARD OWEN, London; Prof. RUTHERFORD, Edinburgh; Miss YATES, London; THE SECRETARY OF THE MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH; THE SECRETARY OF THE PARKES MUSEUM OF HYGIENE, London; Mr. NOBLE SMITH, London; Dr. J. W. LANGMORE, London; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; THE HON. SECRETARY OF THE BOLINGBROKE PAY HOSPITAL, London; Mr. EDMUND OWEN, London; Dr. JAMES NIVEN, Manchester; Mr. T. P. TEALE, Leeds; THE REGISTRAR-GENERAL FOR ENGLAND, London; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; THE HON. SECRETARY OF THE MEDICAL SOCIETY, London; THE SANITARY COMMISSIONER FOR THE PUNJAB, Lahore; Mr. EDWARD RAY, London; THE SECRETARY OF THE SANITARY INSTITUTE OF GREAT BRITAIN, London; Dr. EWART, London; OUR LIVERPOOL CORRESPONDENT; Dr. CHOLMELEY, London; Mr. CHATTO, London; Dr. CLIFFORD BEALE, London; Mr. SHIRLEY MURPHY, London; Mr. R. W. PARKER, London; Mr. STEVENS, London; THE DIRECTOR-GENERAL OF THE AMERICAN EXHIBITION, London; THE SECRETARY OF THE MEDICAL DEPARTMENT, LOCAL GOVERNMENT BOARD, London; THE WARDEN OF THE LONDON HOSPITAL MEDICAL COLLEGE; THE SECRETARY OF THE BALLOON SOCIETY OF GREAT BRITAIN, London; Mr. HENRY MORRIS, London; THE SECRETARY OF THE PATHOLOGICAL SOCIETY, London; THE EDITOR OF THE TEMPERANCE RECORD; THE SECRETARY OF THE SOCIETY OF ARTS, London; THE SECRETARY OF THE ANTHROPOLOGICAL INSTITUTE, London; Mr. LAWSON TAIT, Birmingham.

APPOINTMENTS FOR THE WEEK.

Friday, November 14 (*this day*).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY OF LONDON.—Dr. Stephen Mackenzie, on "Cases of Dysentery treated by Voluminous Injections of Nitrate of Silver;" Mr. Morrant Baker, on "Three Cases of Joint Disease in connection with Locomotor Ataxy;" Dr. H. B. Donkin, on "A Case of Muscular Atrophy and Joint Disease;" Dr. Hale White, on "A Case of Tumour of the Frontal Lobe with very few Symptoms." Living specimens—"A Case of Favus," by Mr. Malcolm Morris; "Cases of Joint Diseases," illustrating Mr. Baker's and Dr. Donkin's papers will be present, and perhaps others.

Saturday, November 15.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, November 17.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

MEDICAL SOCIETY OF LONDON, 8.30 p.m.—Dr. Carrick (postponed) on "The Manufacture and Uses of Koumiss in Russia;" Dr. Markham Skerritt (Clifton), on "the Conduction of Physical Signs in Diseases of the Lungs;" Mr. Noble Smith will show a Case—Cured Meningocele.

Tuesday, November 18.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

PATHOLOGICAL SOCIETY, 8.30 p.m.—Dr. Percy Kidd, on "Fatal Hæmoptysis from Bronchial Ulceration;" Dr. Carrington, on "Addison's Disease, with Cancer of the Liver and Supra Renal Capsules;" Dr. Norman Moore, on "New Growths in stomach of a Child;" Mr. Sutton, on "Uterine and Ovarian Disease in Animals and Birds;" Mr. Knowsley Thornton, on "Hydronephrosis caused by Papillary Growth and Calculus;" Mr. Hopkins, on "Bones from a case of Ataxia;" Mr. Treves, two specimens of Tumour of the Soft Palate; Mr. Lane, Fracture of first Rib (card).

Wednesday, November 19.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

SOCIETY OF ARTS.—Opening Address, by Sir Frederick Abel.

Thursday, November 20.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Friday, November 21.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, ADAM STREET, ADELPHI, LONDON, 7.30 p.m.—Meeting. Mr. Alfred Spencer, on "Noxious Trades."

ON THE RELATION OF CERTAIN DISEASES OF THE EYE TO GOUT.

BEING

THE BOWMAN LECTURE,

DELIVERED BEFORE THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM,

Thursday, November 13, 1884,

By JONATHAN HUTCHINSON, F.R.S.

GENTLEMEN,—At the request of your Council I have the honour this evening to deliver the first Bowman Lecture. This lecture has been instituted with the design of gratefully commemorating the services of Sir William Bowman to science, and more particularly those which he has rendered to this Society in his capacity as its first president.

It is intended that the lecturer shall on each occasion undertake the investigation of some special subject in connection with ophthalmology.

I do not think that any more appropriate method could have been devised by which to pay respect to one of our very foremost workers. For myself, I can only say that I feel deeply the responsibility of the yet very agreeable duty which has devolved upon me, and could heartily wish that your Council had selected some one more capable of doing it justice. Having made this personal apology, I feel, however, that I shall best honour the name of Bowman by trying to imitate the example of his life, and proceeding at once, to the best of my ability, to deal with the subject in hand.

I take for the subject of my lecture the relations which exist between certain Diseases of the Eye and Gout. We shall have to classify several different forms of disease—for the most part, but not exclusively, inflammations of the iris—to describe their peculiarities and to examine the evidence which is forthcoming as to their real connection with gout. The enquiry is an important one, for a gout taint is of extremely common occurrence in a large proportion of the British population. The investigation is also in many of its ramifications one of great intricacy and difficulty. Certain facts we shall, I trust, be able to establish with clearness, but respecting many others we shall not be able to get further than the stage of more or less confident inference. I had at one time intended to bring before you a good deal in the form of attempted proof — that is, of statistical or tabular statements of fact. I have found, however, in the preparation of the lecture that the time at my disposal will not permit of more than a brief sketch of the whole subject, and I shall therefore, on compulsion, spare you much of the detail. It is, however, only just, both to you and to myself, to state that my arguments and assertions this evening will be based upon the careful examination of a lengthy series

of recorded cases. A large part of these will be found given at length in Volumes VII. and VIII. of the Ophthalmic Hospital Reports, and the remainder I have in type before me, although not yet published.

Definitions of Gout and Rheumatism.

Before we proceed to enquire whether gout may be deemed to be the cause in some instances of such diseases as hæmorrhagic retinitis, recurring iritis, glaucoma, and others, it may be well to state that I wish to keep a clear distinction between gout and rheumatism. This distinction is in practice often very difficult and sometimes quite impossible to draw, but for all purposes of accurate clinical pathology we must insist upon its existence. By gout I shall mean all states of health which are, whether directly or remotely, connected with the accumulation of lithate of soda in the blood, as the result of overfeeding or defective assimilation.

Under the laws of inheritance of morbid tendency it may easily be the fact that a person may feel the effects of this condition in his parents, who may yet himself never exhibit it. We may have a form of inherited gout which is not associated in the patient with either lithiasis or lithæmia. Hence, as I shall have to show presently, some very peculiar forms of morbid action.

Thus it may perhaps be conveniently laid down that there are two fundamental conceptions of what gout is. They are not antagonistic, but rather in mutual co-existence. In practice the two methods of influence constantly modify each other.

What I may call the primitive conception of gout regards it as due to a state of the blood induced in part by errors in feeding, and in part by defects in assimilation and depuration. It has regard to the food, the digestive power, the habits as regards exercise, and the integrity of the kidneys. In this form of dietetic or humoral gout the stage of lithæmia is essential, and the final product of deposit of urates in the tissues almost equally so. We must, however, seek a wider vision than this. As an introductory stage let us imagine the condition of a man who many years ago was subjected for a long period to the ordinary causes of primitive or humoral gout, but who for a considerable series of years has carefully avoided them. In such a person it is easy to see that although his blood may have been long kept free from excess of urates, yet, as the consequence of conditions of long duration in the past, his tissues may have received modification, and may be prone still to suffer in a peculiar manner when exposed to the ordinary exciting causes of disease. In particular they may be liable to grow old on a peculiar type. Not only are his tissues in general modified, but those of his nervous and vascular system have probably been especially influenced. Hence the power of control over any process of inflammation, by whatever cause it may have been initiated, is peculiar and defective. If such a man sprains a joint it will not recover in the way it would have done had he never had gout, yet the joint may nevertheless be very far from assuming a typical gouty state. There may be no tendency whatever to the deposit of urates. Now let us take another step in the attempt to give reality to our conceptions of the hidden influences under which the every-day phenomena about us are produced. Let us imagine that such a person as we have supposed, one who has suffered severely and through many years from humoral gout, becomes a parent. His offspring will inherit his tissues, his tendencies as regards digestion, kidney excretion, skin elimination, and all the rest. These will, no doubt, give a greatly increased proclivity to common typical gout should the causes of it come into play. They may, however, do much more than this. They may render their subject liable, quite independently of exciting causes, or with but little help from them, to forms of inflammation or of degraded nutrition, which are not unequivocal gout, but which are yet the direct consequence of it in predecessors. The modification which is here inherited is, I repeat, of the tissues and not of the blood, though it is obviously very easy that the two may complicate each other. The subject of tissue modification from inherited gout may easily become the victim of humoral gout as well.

Inherited Gout.

It is clear from this argument that we must be prepared to see inherited gout assume very different forms from those in which we are so well accustomed to recognise the primitive type. Permit me now to suggest that it is the clinical, or rather the social, fact that a not inconsiderable proportion of the well-to-do classes of the British population are born under the conditions which I have been supposing. The number of those who are the descendants of parents who have suffered from humoral gout is very large indeed, and, especially in our large towns, it is by no means restricted to the educated classes. We must be prepared, then, to encounter, not unfrequently, peculiar types of morbid action which derive their peculiarities from this association. It is the duty of the clinical investigator to carefully examine the evidence which is forthcoming as regards each before he admits its claim. Certain diseases of the eye for which this claim is with more or less confidence put forward will form part of our topics for discussion this evening. It may, perhaps, facilitate matters if I express at this stage the belief that most of the varieties of what is called rheumatic gout stand in this relation to true gout. The list would include lumbago, sciatica, neuralgia, crippling rheumatism, arthritis deformans, osteo-arthritis, many forms of iritis, and many cases of glaucoma. I by no means wish to suggest my belief that any one of these is in all cases in some degree dependent upon the inheritance of gout. Some of them are doubtless in not a few instances purely rheumatic, and this admission renders it desirable that I should say two or three words as to what our conception of rheumatism ought for the most part to be. Let me hint that from our primitive idea of rheumatism I should like to exclude all causes having reference to food or assimilation, and to count only those which regard climate and weather, and especially exposure to cold and damp. The rheumatic diathesis, like that of gout, may become ingrained, and at the same time modified by hereditary transmission, and in this connection it is easy to overlook its original causes and even to believe that it may begin spontaneously, or in consequence of other influences than the true ones. The hereditary diathesis of rheumatism (arthritic susceptibility to weather) may easily co-exist with that of gout (arthritic susceptibility to diet), and each of them or both together may combine in endless variety with other forms of morbid tendency. It follows that we have to study many hybrid or mongrel types of disease in more or less close connection with them.

"Hot Eye," Irritable Eyes, Quiet Gout, &c.

There is a condition to which, for want of a better name, I have for long been in the habit of recognising as Hot Eye. It is one of the many curious phenomena which attend quiet gout. I use the term quiet gout as distinct from acutely paroxysmal gout. In families liable to gout, for one person who becomes the subject of acute attacks of podagra, what is known as unequivocal gout, there are often half-a-dozen who are the subjects of minor symptoms which denote a similar tendency. In them the tendency never rises to sufficient height to induce a severe and characteristic paroxysm. They are nevertheless liable, after taking beer or wine injudiciously as to quantity or quality, to experience slight pricking pains in joints, attended by lithic acid

in the urine and other unmistakable signs of the diathesis. In many, these symptoms occur in such invariable association with the causes suggested, that it is not possible to doubt as to their nature. The liability varies with the weather and time of year, and it often ends, unless precautions are taken, in a sharp attack in the great toe. The terms suppressed gout, or better, undeclared gout, are often used in reference to it, but since it is simply a minor form of the disease not in any way suppressed, and certainly not to trained observers undeclared, I prefer the term quiet. Amongst the frequent occurrences which denote its presence are repeated short attacks of congestion of the eye. Usually one only is affected, but sometimes both. The conjuctiva becomes red, and the eyeball feels hot, and pricks, as if sand were in it. The attack may come on within half-an-hour of the meal which has disagreed, and it may last a few hours, or a day or two. Sometimes, owing to interference with the ciliary muscle, vision is slightly dim, and all attempts at accommodation are usually painful. Those who are liable to hot eye, not unfrequently in the end suffer from iritis; indeed it is not unfrequently an introductory stage to that disease. On the other hand, many are liable for years to very frequent attacks of it without apparently any risk of its assuming more serious proportions. In the intervals of the attacks, the eye is usually quite well, and it is indeed its definitely paroxysmal character, its sudden development, and very complete and rapid disappearance, which especially mark its arthritic relationship.

In connection with this subject it may be noted, that not unfrequently those who suffer from unequivocal gout, experience shoots of sharp pain in the eye-balls, the nature of which they well understand. A man, William B., aged 51, who had suffered much from gout, and whose father and four of his father's brothers had all had it, complained much of this kind of pain, yet he had never had iritis. When he was gouty, he said he frequently had "darts of pain through the middle of each eyeball," and occasionally across the bridge of the nose.

A further practical note I must ask leave to make. It is to the effect that many cases of irritable hyperæsthetic and easily tired eyes in young persons are in association with inherited gout. I feel sure that in some of these cases we are in the present day in danger of pushing the recommendation of spectacles to an excess. Some slight degree of hypermetropia may be detected, and it is assumed to explain the irritability of the eye. Yet glasses do no good, and in fact only increase the irritation. In such cases, very often, the real malady is inherited gout.

Transverse Calcareous Bands of the Cornea.

I must admit, in the commencement of our investigation, that little or no evidence exists as to the deposit of urate of soda in any of the structures of the eye. I doubt whether it has ever been proved in any single case, although several observers have suggested its presence. I trust, however, that we are long past the stage of belief which regards such deposit as essential to a gouty inflammation. The nearest approach to proof of gout deposit has been made probably in the case of what are known as the transverse calcareous bands in the cornea. Sir William Bowman, in the year 1848, was, I believe, the first to publish cases of this kind, but the earliest case had been observed by Mr. Dixon. Valuable information respecting the disease has recently been collected and studied by Mr. Nettleship. I believe I may fairly sum up the present state of our knowledge by saying that no one has yet proved that the salt deposited is that of gout. It is usually calcareous. The disease occurs in persons very likely to suffer from gout, and sometimes with a gouty history, but we are not as yet justified in holding that this earthy deposit is in direct connection with that diathesis.

Arthritic Iritis.

It will be admitted without dispute from anyone that there are several forms of *Iritis* which are arthritic in their origin. In other words, they occur to those who are liable to attacks of inflammation of joints, and the inflammations of the eye occur under conditions similar to those which excite the inflammations of the joint. Both are in some cases prone to occur in an acute but transitory attack. Both are very apt to recur after periods of complete immunity, whilst in other cases both may assume a chronic, persisting and destructive form. With such features of similarity we are justified in assuming, as indeed is done by all authors, that they are due to the same causes. The problem which I have to consider to-night is whether these causes belong to gout or to the rheumatic class; whether they are sometimes the one and sometimes the other; and lastly, whether they are not in some cases of a hybrid or mixed nature. Permit me briefly to state some of the peculiarities which are to be observed in different types of arthritic iritis; and to ask respecting each what evidence we possess which would connect them with the tendency to gout. Let us take first the common form in which the iritis occurs in acute transitory paroxysms. Of this, good typical examples will be in the memory of us all. Its subjects are usually men, and often of vigorous health, and past middle life. The iritis scarcely ever affects both eyes at the same time, but occurs first to one and then to the other, sometimes keeping to the same eye during several successive attacks and then leaving it to assail its fellow. The attacks are often acute, beginning very suddenly, and attended with great pain. When they subside they subside completely, and leave the eye without the slightest degree of irritability. The duration of the severity of an attack may vary greatly at different times in the same patient. The tendency to form adhesions is extremely great. It is very remarkable how in most cases of this class the disease restricts itself to the iris and shows no tendency to disorganise the globe. Thus a patient in whom, in consequence of repeated attacks, the pupils may be occluded, with the exception of mere pin-hole apertures, may yet continue to enjoy very fair sight. I by no means wish to imply that this is usually the case. The case of Dr. Curry, as recorded by himself in the Medico Chirurgical Transactions, is a good type form of this disease. Dr. Curry had suffered much from true gout. I may cite, however, as another good type illustration of this class, that of a gentleman whose friendship I had the privilege to enjoy during a long period of my early life. He was a florid, fair complexioned man, of vigorous habits, a large eater, and through life accustomed to drink beer. He inherited rheumatism but there was no known history of gout. He had suffered in boyhood in consequence, as he believed, of too free bathing when hot, from rheumatic fever. When I knew him first he was about five and forty, and from that time onwards to his death, at the age of sixty, he had a variety of arthritic complaints—lumbago, sciatica, chronic arthritis of the knees and other joints, and recurrent iritis. Both his pupils were closed with the exception of very small apertures, through which, however, he still continued to see enough to follow an occupation in which everything depended on good sight. I attended this gentleman year after year, usually in the early part of February, for most severe attacks of iritis, never affecting both eyes at once. He was benefited by large doses of iodide of potassium, and the free use of blisters. At length his attacks ceased to occur and during the ten years preceding his death I believe

he had not had any. I made a *post-mortem* examination of his body, and found no proof of gout. His knees contained loose cartilages, and there were patches where the articular cartilage was wearing away, but there was no urate of soda.

I have the record of a considerable number of cases in which the liability to these recurrent forms of iritis occurred in those who were the subjects of unequivocal gout. But there were a far larger number in which the concomitant symptoms were of rheumatic arthritis and not of true gout. The question remains, however, whether this form of rheumatic gout, although unattended by lithate of soda deposit, be not in reality a hybrid disease possessing, in addition to an unquestionable share of rheumatism, an admixture also of gout tendency. The infrequency of the disease in women, the age, the habit of body and the mode of life of those who are usually its subjects seems to me to strongly support this view. So does also the extreme severity of the attacks, and their rapid and complete subsidence when once the point is turned. When this form of iritis does occur to women it is never, I think, so acute or so paroxysmal as in men; and it almost always happens to those whose relatives have suffered from gout.

Various Forms of Arthritic Iritis.

Next to this form of recurrent iritis, and including perhaps some of its examples, I have to mention the iritis which occurs in connection with gonorrhœal rheumatism. All observers will admit, I think, that iritis associated with ordinary rheumatic fever is infinitely rare. So also is it in connection with that type of arthritis to which the name of crippling rheumatism may be given. In other words, iritis in association with either acute or chronic rheumatism is a thing that we scarcely ever observe. In men, however, the rheumatic affections, whether acute or chronic, which are induced by gonorrhœa are not unfrequently accompanied by iritis. This iritis is less distinctly paroxysmal and much more liable to persist and be destructive than is the case in the form which I have just described.

My explanation of this is easy. The reason why gonorrhœal rheumatism so often causes iritis is because it occurs usually to the subjects of inherited gout.

A third form of arthritic iritis is one which affects women more frequently than men, which not unfrequently attacks both eyes at once, which is apt to spread to the ciliary region and choroid; to persist and to prove destructive. In a very considerable proportion of the women who suffer from this form there is a history of gout in former generations.

Another group of arthritic iritis might be constituted of cases in which the malady happens to young patients, and proves but slightly, if at all, liable to recur. These single attacks of iritis without history of gonorrhœa or syphilis, and occurring in young persons, usually, I think, affect the male sex and almost always there is the history of gout in relatives.

I must just mention, in order to complete my classification, although it is but of little clinical importance, the group of cases in which iritis occurs in association with glycosuria. In these, according to my experience, the patient is almost always the subject of gout also.

To sum up then, I would say, that although in many individual cases of arthritic iritis there may be no proof of liability to gout in either the patient or his relatives, yet the tenor of the evidence in general is in favour of the conclusion that when iritis occurs there is in reality some gout complication. The more purely and definitely is the case one of rheumatism, the less the probability that iritis will happen. When iritis occurs the complications are almost invariably those which suggest what we call rheumatic gout, rather than rheumatism pure and simple; that the smaller joints are often affected and nodi digitorum present, whilst sciatica, lumbago, and neuralgia are frequent complications. I have elsewhere tried to prove that gonorrhœal rheumatism occurs in nine cases out of ten to those who inherit a gouty constitution and that it is chiefly this inheritance that gives the proclivity to it. I cannot stop now to recapitulate the evidence on which this belief rests, but if it be trustworthy it offers an explanation of the fact that iritis is so frequently met with in association with this type of rheumatism.

In certain cases of iritis with arthritic associations a very peculiar condition is observed. I allude to the filling of the anterior chamber with a soft gelatinous jelly-like mass. This material, which produces an appearance most alarming to the uninitiated, concealing the pupil and suggesting entire destruction of the cornea, is susceptible of very rapid absorption, and may, in the course of a very few hours, clear right away. I believe that in some cases of syphilitic iritis this peculiar form of appearance has been noticed, but if I were to speak from my own experience I should cite it as a symptom very strongly indicative of gout. I would make the same remark, though with less confidence, respecting the rare cases of iritis complicated with hæmorrhage.

Statistics as regards Arthritic Iritis.

My report on arthritic iritis, published in the *Ophthalmic Journal* of 1872–74, contains the narrative of 104 cases which are suitable for our present purpose; for various reasons I omit a few on account of doubts as to their nature or imperfections as to the details. The report comprises cases of all varieties in which either rheumatism or gout, or the two together, were supposed to have been the causes of inflammation of the eye. They were collected from my note-books, both from hospital and private practice, up to the date mentioned. It is right to state that at that time, my opinions as to the influence of true gout were less advanced than they are at present, and that my knowledge as to the means of recognising it was also less. The notes of many of the cases had been taken some years before they were published, and thus certain enquiries which I should now carefully make were unfortunately omitted. On this account I have no doubt that we must consider that the report does not show the influence of gout so strongly as it would have done had the cases been taken with better knowledge. Out of the 104 cases, I find a positive history of gout having occurred in the patient in only 18 cases, and only in 29 was there the history of positive gout in near relatives. It is to be observed, however, that these numbers take cognizance only of what has been termed "unequivocal gout," namely, of those in which an unmistakable attack of inflammation in the great toe or other single joint had unquestionably occurred. It omits altogether the much larger number in which the gouty tendency had remained undeclared or had been manifested only in what we may term its quiet form. Any one who will examine for himself the narratives to which I refer, will, I feel sure, agree with me in this opinion. In a very large proportion there was, I think, good reason for believing that a taint of gout existed where the narrative mentions rheumatism only; the arthritis had constantly been of the chronic type, and had very frequently presented exceptional conditions. If we may count such maladies as sciatica, lumbago, neuralgia, nodi digitorum, gonorrhœal rheumatism, rheumatic gout when affecting the smaller joints, as being for the most part indications of gout rather than of pure rheumatism, we shall then find that facts at any rate suspicious of gout are present in nearly all the cases. It is, I think, decidedly exceptional for rheumatism pure and uncomplicated to show

any tendency to attack the tissues of the eye. Iritis in conjunction with rheumatic fever of the ordinary form is almost unknown, and even in cases in which patients suffer from repeated attacks, as is sometimes seen, the eyes usually remain free. So soon, however, as changes of type occur, the disease showing a tendency to attack the smaller joints, or to affect only single joints, or to pass into the chronic form; then we get the liability on the part of the eye to suffer. On this point my own experience is quite in accordance with that previously expressed by an acute and zealous clinical observer, the late Dr. Fuller. Dr. Fuller in his first edition, speaking of rheumatic gout, stated that in 11 out of 101 cases which he had tabulated when Medical Registrar to St. George's Hospital, the eye had suffered more or less severely, and in 14 out of 193 cases which had subsequently been under his own care in the hospital. In a second edition, he stated that he had so far modified or developed that opinion, that he had come to believe that many, if not all, of the cases in which this complication occurs, were examples of obscure gout or else of gonorrhœal rheumatism, adding "this at least is certain, that since my attention has been specially directed to this question, I have been enabled to find a gouty or venereal (meaning, I think, gonorrhœal) taint in every case in which the eye has been inflamed in connection with presumed rheumatic gout." This is strong testimony, stronger certainly than I am prepared to give, but I doubt whether it much exceeds the truth. Among other authors who have distinctly recognised gout as a cause of diseases of the eye, and appear to have referred a considerable proportion of those diseases, when arthritic, to gout rather than to rheumatism, I may mention Dr. Jacob, Mr. Weller, Mr. Middlemore, Dr. Copland and perhaps Mr. Wardrop. Mr. Middlemore goes so far as to think that he has seen in one or two cases, the pupil occupied by calcareous concretion of a gouty nature. None of these observers have, I think, recognised any other special disease as connected with gout than recurrent iritis. Almost invariably I find sclerotitis put down as rheumatic.

Insidious and Destructive Iritis from Inherited Gout.

I must now enter upon one of the most important topics of my lecture. It is the attempt to prove that there is a very peculiar form of destructive iritis, occurring for the most part in young persons, which stands in all cases in direct relation with the inheritance of a gouty constitution. It does not occur to those who themselves suffer from attacks of gout but to their descendants.

It was in 1863 that I first saw, at Moorfields, a girl named Mabey. She was then about 18, tall, well-formed and florid. She was too florid, and the circumscribed areas of colour in her cheeks varied in tint from bright red to slightly livid, according to the coldness of the day. She was the subject at the same time of a most peculiar form of arthritis of the last joints of all her fingers, and of double iritis. Her right eye was lost and painful and I accordingly excised it. Her left was saved only by repeated iridectomies and finally by extraction of the lens. After the last operation she continued for five years to enjoy good sight and was free from relapses. Her fingers also got well. At the age of 26 she became the subject of phthisis and died, I believe, at about 30. I showed this patient at the Hunterian Society, and drew attention to the unusual features of her disease. Some one present, looking at her hands, remarked, "Surely this is gout." I took the hint, enquired into her family history and found that in all probability it was gout. Her father had suffered repeatedly from that malady in an unequivocal form, and he had tophi in his ears. I show you drawings of the state of the girl's fingers. In order to ascertain whether there were urate deposits in connection with the swellings, I cut into one of the largest and obtained only a soft jelly-like substance. When after some years the swelling subsided, the terminal joints were all left disorganised and the last phalanges were more or less displaced. There appeared reason to believe that a feeble state of the circulation combined in this case with the gout inheritance.

I have repeatedly mentioned Mabey's case in public and with it others which came under my notice subsequently and I must content myself on the present occasion with a short summary of the facts. In 1872 I gave a lecture at Moorfields on this disease and was able to cite four well marked examples of it. In 1880 I gave, at the London Hospital, a second lecture, in which I adduced seven additional cases, making eleven in all. Of these eleven patients four were females and seven males, but it happened that the most typical and severe forms of disease occurred in females, a fact which my subsequent experience has fully confirmed. In all cases both eyes ultimately suffered, but only in one were both affected simultaneously. In three instances last-joint arthritis, that is to say destructive inflammation of the last joints of the digits, occurred. In all the cases vitreous opacities as well as iritic adhesions were developed. In most of the cases the eye which was last attacked suffered most, and a decided tendency was shown for the disease to come to an end as the patient advanced in life. In several cases the eye was saved by repeated iridectomies, and in one or two change of climate seemed to be very beneficial.

In all the cases but one the family history of gout was clear and strong, and in the exception the patient was the son of a brewer's man, and his father had died early, so that it was very possible that his proclivities had not declared themselves. In several of the cases the patient had been reduced almost to blindness. In three one eye had been excised and in one both were quite lost. In all excepting two the disease had begun between puberty and the age of twenty-five, and it would appear to be the fact that the earlier it begins the more severe it is. Such then was the state of my facts in 1882 when I put my last lecture into print. I think you will allow that I was justified in avowing a strong belief that inherited gout was the real cause of this peculiar form of iritis.

That I may add a little more colour to my picture I will ask your permission to state briefly the facts of three cases which have come under my notice since the date referred to. They are all cases of great interest and two of them illustrate a fact which I had previously only once or twice noticed, namely, that there is a tendency to the formation of cataract.

The last case which I have seen is that of a Miss D., aged 30, the daughter of a surgeon in the country. She was brought to me with the left eye quite destroyed and the right nearly so. In the left an opaque lens had undergone spontaneous absorption and the iris was everywhere adherent to the opaque capsule. In the other the lens was half opaque and the iris extensively adherent. I was told that I had myself seen this patient ten years before and had then recognised only commencing cataract in both. The patient's father, an intelligent medical man, was astonished when I told him that there had been extensive iritis, and assured me that his daughter had never had any attacks of inflammation. The patient herself said that she had never noticed more than that the eyes had sometimes been red and hot and would prick a little. We have here then a good instance of the very insidious course of the disease. In the left eye there was no perception of light, and very probably the vitreous was affected. I found on enquiry that in Miss D's family there had been

*

much gout. She herself appeared to be in good health.

Mrs. O. is a young married lady who has borne three children and during lactation in each instance suffered from a chronic form of almost painless iritis. Both pupils are almost excluded. Her father has suffered gout, and several other near relatives. She is of feeble circulation and liable to chilblains.

I have kept one of my best cases to the last. Miss L., aged 22, is the youngest of a family of eight, and was born after the death of a father who had suffered much from "chalk gout." Her eldest brother has had both gout and rheumatism, and there is rheumatism also on her mother's side. Miss L. began to suffer in her eyes at the age of 12, and at first it was simply redness and irritability with "black specks," "balls," and mist. At the age of 14 she had a severe attack in both and was several months under Mr. L.'s care almost blind. From this she recovered, but at 18 a surgeon in Liverpool performed an iridectomy on the left on account of exclusion of the pupil. A little later Mr. C. did an iridectomy in the right. Neither of these operations resulted in any improvement of sight. In 1880 a surgeon in Leeds removed a soft cataract. The eye was lost and Mr. C. excised it a few months later. Miss L's. present condition is that with the one remaining eye she can just puzzle out $\frac{20}{200}$.

Could I possibly produce before you a more marked example of an insidious destructive disease, progressing in spite of the most highly skilled assistance to its melancholy end? Yet it is only a fair example of about half those included in my series.

Relapsing Cyclitis.

There is a peculiar form of chronic inflammation of certain parts of the eyeball which clinical observers have recognised under the name of *Relapsing Cyclitis.* It is a cyclo-kerato-iritis involving the ciliary region of the sclerotic, the adjacent part of the cornea, and the iris. Sometimes one of these structures suffers more than another but usually all are involved. It seldom damages the pupil itself much, seldom invades the centre of the cornea, or only very late in the disease, and it does not show much tendency to involve the choroid or vitreous. It usually begins in one eye and only affects the other after a long interval, and to the last one usually suffers more severely than the other. It may begin in early life but often does not do so till middle periods. When once it has begun it never wholly leaves its victim but continues either to persist with slow chronicity or recurs over and over again after intervals of health. It causes scars in the ciliary part of the cornea, thinning and discolouration of the ciliary region of the sclerotic, and ends either by inducing staphyloma or by making the whole cornea dull. It may occasionally become needful to excise the eyeball on account of the persisting irritability combined with great impairment. It affects, I think, women more frequently than men. It is a very peculiar type of disease, and it would not be difficult to place side by side a group of examples of it all exactly alike. I know of no treatment short of a complete change of climate which does much to benefit it. In this respect it is much like the form of iritis which I have been striving to prove to be a direct result of inherited gout. Yet I am by no means in a position to produce before you respecting relapsing cyclitis such evidence in reference to its gout origin as that which we have been discussing. I dare not indeed do more than suggest that it is very probable that in some cases the constitutional cause of this destructive and persisting disease may be gout. I have found a gout history in some of my cases but in others it has been absent. The last case which I have seen has been the one in which this suspicion was the strongest.

Miss D. is the daughter of a medical friend. She is now 40 and she has suffered all her life from her eyes. She was treated when two years old by Mr. McMurdo for what was then called strumous ophthalmia, which proved very intractable. Since then she has had numberless relapses, and in both eyes the cornea at its edges has become extensively opaque. Her left eye is the worst, and has recently been so troublesome that I was inclined to recommend its excision. It is by no means a blind eye but the cornea is so hazy that it is of little use. Now say that we have here a case in which strumous ophthalmia has persisted through life, let us ask what is the constitutional peculiarity which has conduced to this exceptional result. The lady has been well cared for all her life, she shows no other signs of struma nor are such present in any of her relatives. Her father is a robust man. Mark that both eyes have suffered and that in both it is the peripheral parts of the cornea which have been chiefly involved. Now this lady's maternal grandfather and two of her maternal uncles suffered severely from gout, her mother had an attack in her great toe, and even she herself has on one occasion had an attack of it. This strong gout history is certainly by far the most definite fact which I can obtain as explaining the peculiarities of her eye disease.

Can Gout cause Neuritis?

Although from time to time strong suspicions have been expressed as to the occurrence of gouty affections of the nervous system, I believe the question has seldom been definitely put, "does gout cause neuritis?" We know that gout can cause the tissues of a joint to inflame, and that œdematous effusion with cell proliferation, in fact the ordinary phenomena of inflammation, are its results. I shall be much disappointed also if it is not regarded as proved that it can cause the tissue of the iris to inflame in a precisely similar manner and with like results. Can it attack any of the structures of which the nervous system is composed? Can it cause inflammation of ganglia, of nerve trunks or of their investments, or may it indeed attack the central organs? Without venturing to suggest that any of these occurrences are common, it is yet difficult to deny a possibility or even probability in exceptional cases. We can understand the influences that are likely to localise gout; its exciting causes may come into play far less frequently in reference to the nervous system than to the joints; or even to such an apparently exposed part of the organism as the eye. Still, if we admit that in the gouty condition inflammations may attack the cellular tissue in any part of the body, it is difficult to suppose that the cell elements which enter into the formation of nerve trunks, for instance, will always escape. I am glad to note in the progress of neuropathology of the last few years that there seems an increasing tendency to recognise the possibility that not a few nervous affections may be due not to central disease, but to primary inflammation of the connecting trunks or of the peripheral organs. We know for certain that chronic neuritis, probably beginning peripherally, is a part of leprosy. It is highly probable that it is often a part of syphilis and quite possible that it occurs also in locomotor ataxy. How else explain many of the transitory forms of ptosis, etc., etc., which occur in the two latter diseases?

Gouty Neuritis of the Optic Nerve.

The question which I now wish to put definitely is: Are there any cases of inflammation of the optic nerve, or of any of the motor nerve trunks of the eyeballs. the direct cause of which is the existence of a gouty

constitution? The decision is of importance not only in reference to diseases of the eye, but because it would throw much light on certain other obscure affections met with in this disease. Is sciatica really a neuritis of the sciatic trunk or its sheath? Are any of the forms of gouty neuralgia really produced by gouty neuritis? If the optic nerve can inflame from gout why not the pneumogastric, or the phrenic? I am sorry to say that I have exceedingly little evidence to bring forward in answer to these important questions. I will mention briefly one or two facts which are suggestive, and which I hope will prove sufficiently so to induce a more careful investigation of the subject. In two or three cases I have attended young ladies, of families in which gout had been prevalent, who suffered from attacks of ptosis, with the other group of symptoms referable to paralysis of the third nerve, for which I could find no other more plausible explanation than that they were caused by gouty neuritis. In one of these the attacks were transitory and recurrent, several having occurred within a period of a few years. I must not venture to trouble you with details of these cases, but feel myself obliged to speak rather more at length concerning one in which the optic nerve itself was inflamed, there being, I think, fair reason to suspect that the cause was inherited gout. A young lady, of 16, was brought to me from Ipswich, on account of blindness of one eye in July, 1879. She had no other symptoms whatever, was florid and appeared to be in good health. The ophthalmoscope showed nothing but what was quite normal, and had it not been that her pupil dilated more widely when the other was covered, I might have suspected that she was feigning. A week later the changes were conspicuous, the disc being much swollen and its margin concealed. Under treatment by mercury combined with quinine, in the course of a few weeks the attack had passed away, but the disc was left pale. Four years later I saw this patient again with similar symptoms in the other eye, and I was now told that she had several times suffered from transitory attacks which always occurred during spring. Her health remained perfect. There was a strong history of gout in the family, both her parents having suffered repeatedly. It seems to me not at all improbable that these recurrent attacks of transitory neuritis were really of a gouty type. In saying this, I have regard to the entire absence of the more ordinary causes and concomitants of optic neuritis, to the recurrent nature of the affection, its want of symmetry, and the exceptionally strong family history, both parents and many other near relatives having suffered. I cannot call to mind any other case of recurring optic neuritis, with gout history, which I could at all fairly place side by side with this one. I have, however, several times seen optic neuritis occur in women who were of gouty family without any of its ordinary accompaniments and clear away entirely under treatment. In none of the cases of which I am thinking did any recurrence take place, and in most of them both eyes were simultaneously attacked.

Other forms of Gouty Neuritis.

Before quite taking leave of this important question as to the possible occurrence of gouty neuritis, I must trouble you with yet one other case. A lady, of 56, came under my observation in whom for several weeks the left facial nerve had been quite paralysed. I observed at once that she had had two large iridectomies done downwards and outwards, and on enquiry found that she was nearly blind. It was twenty-three years since she had first noticed cobwebs before her sight, and fifteen since she had last been able to read. The iridectomies had been done six years, with what object I do not know, for although she said that she had once had rheumatic inflammation of her eyes, there did not appear to be any adhesions. In each eye the lens was partially opaque, and in each there were extensive choroido-retinal changes with pigment deposits and waxy atrophy of the discs (a peculiar form of retinitis pigmentosa). Mrs. H., told me that she had a sister who also had "amaurosis." I persuaded her to bring her sister, and may now state the family history which belongs to them both. One of their brothers suffers not unfrequently from attacks of unequivocal gout, and a sister is crippled by rheumatism, but their parents died aged, and are not known to have suffered. The elder of the sisters, aged 69, has herself had gout, and describes her great toes graphically as having been swollen and red like tomatoes. This sister after her first confinement, aged 27, had an attack in her eyes which lasted several years attended by great pain and intolerance of light. Her recovery from it was very gradual, but finally it was almost perfect, and I could now find no material changes. For several years she has been very deaf and she has suffered severely from neuralgia and chronic arthritis of wrists and fingers. Once she was told by Mr. Critchett that she had "gout in the eyes." The younger sister describes ten years ago an attack of shoulder neuralgia attended by torticollis which kept her in bed six weeks and was accompanied by agonising pain, as if her arm were in the fire. She also has suffered most severely from neuralgia on many occasions.

Here then is a family so definitely gouty that a brother and sister have each had true gout and several other sisters are crippled by rheumatism; one sister has become almost blind with neuro-retinitis, and has suffered from neuralgia, torticollis, facial paralysis and an attack which was probably neuritis of the brachial plexus. Another sister is deaf, has been all her life liable to neuralgia, had a several years attack of pain in her eyes which was called "amaurosis," and in later life one which was named "gout in the eye." It seems highly probable that we have here an instance of gout affecting, at different periods of life in each sister, different parts of the nervous system, and attended by true neuritis of various nerve structures.

Glaucoma in Relation with Gout.

I had intended to have said a good deal as to the nature of glaucoma, and the evidence as to its connection with gout. The subject is, however, too important to be discussed hurriedly, and I have not time to attempt to do it justice. I must therefore content myself with the mere expression of opinion that in the production of this extraordinary disease a gouty tendency often takes a large share. More particularly would I suggest this in the exceptional cases in which glaucoma shows itself in early life, and I could, if time permitted, bring before you some important cases illustrating this point.

Retinitis Hæmorrhagica and its connection with Gout.

There is yet another definite and well characterised affection of the eye which claims conspicuous mention in connection with our subject.

Retinitis Hæmorrhagica is very rarely indeed seen excepting in those who are themselves gouty. It is a disease of middle life or of advancing years, and in its more typical forms is never seen in the young. It seldom happens to both eyes at once. It is attended by great swelling of the disc and adjacent parts of retina by such turgidity of the central vein that I was at one time tempted to believe that it depended primarily upon thrombotic phlebitis of that vessel. It is possible, however, that such is not its true pathology, and that the venous distension and stasis, perhaps in some instances thrombosis, are really secondary to the neuritis. If this be the fact and neuro-retinitis be the

primary condition, then we have in retinitis hæmorrhagica an instance in proof that acquired or humoral gout may become the cause of neuritis. It is not, I think, ever seen in association with the inheritance only of a gouty constitution, but is found with lithæmia in free livers who have usually experienced unequivocal attacks. The case which Jæger took for his beautiful plate in illustration of the disease was that of a tavern keeper of plethoric habit and bloated appearance. Nothing is said as to gout, but it is fair in such a man to assume that there was a tendency to it. In order to determine statistically, as far as practicable, the association of retinitis hæmorrhagica with gout, I have tabulated 24 cases, with the exception of the one of Jæger's all from my own note-books. In twelve of these, exactly one-half, the patient had suffered definite attacks of gout, and in five others there was strong presumptive evidence of a gouty constitution. In seven there was no proof of gout. This last group comprises two in which diabetes was present; one in which albuminuria existed, and two in which the retinitis was not very well characterised as of the hæmorrhagic group. If I had kept more closely to the type of cases illustrated by Jæger's portrait, I should have been able to make yet stronger statements as to the almost invariable association of the disease with gout. It may be of interest to state a few other facts deduced from my table. Thirteen of the patients were men and eleven women. The youngest was 45. In seventeen cases only one eye was affected, and in seven both. In some cases there were hæmorrhages only, with little, if any, evidence of neuro-retinitis.

Summary.

I must now bring my lecture to a close, and in doing so may, I think, venture to assume that it has been shown to be probable that there are many different forms of inflammation of the eye, or of parts of it, which are in connection with gout. Some of these are very peculiar and specialised types of disease, and have already been accorded distinctive clinical names; others quite as distinct are not as yet so well known, and of others we may say that they are to be distinguished from other inflammations of the same structures not so much by their features as by their cause. Of all we may assert that they are infrequent; some, if we confine ourselves to well-marked types, are distinctly rare. We have divided these different affections into two groups: (1) those which go with acquired, humoral or renal gout, and (2) those which depend upon the inheritance of structures damaged, or at any rate specialised, by gout in predecessors. It is needless to repeat that in almost all cases of acquired gout there is inheritance also, and that in many in which the disease is chiefly caused by inheritance, some modification and increase may have been derived from personal habits. Still, the difference between the two classes of affections is very marked. In the one attacks of a transitory nature are the rule, and these attacks are often acute and attended by much pain. In the second group, although a tendency to temporary recovery and recurrence is often observed, yet there is a great proneness to chronicity and persistence. The invasion is often insidious, but the disease is usually in the end destructive. In the former group we have placed hot eye, sclerotitis, recurrent iritis, and retinitis hæmorrhagica. All these are diseases of adult life. In the second group we have insidious disorganising iritis, relapsing cyclitis, certain forms of soft cataract, and perhaps some of primary optic neuritis. Not only are there clearly marked clinical differences between the two classes of affections, but the difference in treatment is equally marked. In the first the well-known measures against gout must be taken, a restricted regimen, alkalis, colchicum, and aconite, and liberal counter-irritation. In the second we must use tonics, and although counter-irritants are here also often valuable, we cannot trust to any measure as really curative short of complete change of climate.

On the Proofs of Gout.

It may be, perhaps, convenient to say a few words as to the kind of evidence which justifies a diagnosis of gout as the cause of any particular disease of the eye. In the case of humoral or acquired gout there ought to be the history of one or more definite attacks of joint inflammation usually of an acute character, and attended by redness and œdema, and followed by peeling; usually the great toe will have been the joint affected. Such patients will often state that they are very susceptible to the influence of beer and wine, and that malt liquor and some wines almost always cause indigestion, and make the urine muddy. These dietetic disturbances, to which as a test of gout attention was, I think, first claimed by Sir James Paget, are very important and valuable. If tophi are present in the ears or elsewhere they are of course conclusive. In a few cases we are justified in assuming the existence of humoral gout, although no paroxysm has ever occurred. If the dyspepsia be there, if the joints ache and prick after beer or wine, and if there be gout in relatives, we may confidently believe that it is present, although not yet declared. As regards the inherited form, we may take it as highly probable whenever parents or grandparents, or any one of them are known to have suffered definitely. If even uncles, aunts, brothers, or sisters, or cousins have suffered from true gout in early life, the belief that a family taint exists becomes very probable. The evidence must always be carefully sifted. It will not do to take the statement of the patient without first carefully informing him as to the scope of the enquiry. Patients will often confess to gout who do not know what the word means, and a far more numerous class will hastily deny its history, although the facts, when correctly obtained, may be most conclusive. If, however, proper care be taken, and the patient, after being instructed, be allowed time for consideration—above all, if the enquiry be repeated after an interval, or if several relatives be interrogated, then I believe that in most cases truthful data will be obtainable.

It may be enquired as to the value of certain affections which may be considered to belong both to rheumatism and gout, as symptoms of the latter. Permit me very briefly to repeat my creed. I believe that the subjects of gonorrhœal rheumatism are in a very large majority of instances the inheritors of a gouty constitution, and that all the conditions usually classed as rheumatic gout are really, in most instances, dependent in a large degree upon like inheritance. Thus, if a patient has had sciatica or lumbago, if he shows nodi digitorum (osseous, not tophi), if he has suffered from chronic rheumatism affecting the smaller joints, I should think it fair to allow considerable weight to these facts as pointing to a taint of gout. Even the strictly rheumatic disorders, acute rheumatism itself, if it happens to the relatives of those who have had gout, lends support to the theory of family tendency to gout. It is an observation as old as the days of Heberden, and confirmed I am sure by daily experience, that the children of the gouty are more liable than others to attacks of rheumatic fever. In this we see another proof of the inheritance of structural proclivities, rather, I think, than of blood disorder or tendency to it.

Conclusion.

And now, gentlemen, as my last word, I do not know whether I have to defend myself in the eyes of any of you from the charge of "seeing gout in everything." I am well aware that this diagnosis is a very easy one,

and seductively ready at hand for the idle prescriber. I submit, however, that it has not been exactly in that temper that I have brought before you the statements which I have made this evening. My desire has been to state the issues explicitly, and to keep close to facts. Where statistics were admissible and obtainable I have had recourse to them. I may assert that I have said nothing but what has been based not only upon clinical observation, but upon clinical note-taking, and the subsequent collation of cases. Nor, I contend, have I made any very sweeping statements. So far from my having exceeded the truth, my conviction is that when our clinical pathology shall be more advanced, and diseases more minutely classified, we shall in all probability recognise as gouty yet other maladies, and perhaps not a few beyond what I have claimed. It is a subject upon which scepticism is as irrational as credulity. That the gouty constitution exists, and is very common in our English population, that it is potent in the production of disease, and that it is remarkably hereditary, are facts which no one will doubt. In relation to the multiform diseases of the eye it must have a domain, and that an important one. To discover some of the extensions and limits of that domain has been the object of my best endeavours to-night.

THE SELF-EDUCATION OF THE MEDICAL STUDENT.[1]

By W. T. GAIRDNER, M.D., LL.D.,
Professor of the Practice of Physic in the University of Glasgow.

In the course of a visit to London, not many weeks ago, I had the opportunity of studying, with some detail, one of the most interesting and valuable of all the departments of that great and successful show and treasury of things new and old which, by a process of almost spontaneous evolution in the English language, has come to be designated by a new word—the Healtheries. There I found Mr. Watson Cheyne in the midst of his germ-culture—surrounded by test-tubes of gelatine and surfaces of carefully prepared material ready to receive, or having already received, those minute and careful inoculations of particles of living matter, which we are every day learning to recognise more and more as the seminal principles of many important and disastrous forms of disease, as well as the essential factors in fermentation, putrefaction, and all manner of decompositions of organic matter.

The peculiar feature of a modern laboratory of this kind, as most of you probably know, is that we seek to cultivate, out of the body and at will, those micro-organisms which it is most important for us to study in reference to the prevention or the treatment of disease—to determine the growth before our very eyes, and under conditions where their whole life history can be accurately followed, of those individual organisms which, occurring, as it were, by accident, and in spite of our best arrangements, do so much to mar the healing of wounds, the safety of surgical operations, &c., or which, by directly causing disease spontaneously, are immensely destructive of human or animal life. And in order to have these minute organisms separate and distinct from each other, the experimentalist strives to have what he calls pure cultivation — *i.e.*, cultivation only of one organism at a time, and this on a surface or in a medium previously sterilised artificially—*i.e.*, deprived of all accidental traces of such organisms growing there contrary to the express design of the operator.

It was while pondering over the wonders I had personally witnessed, under the guidance of Mr. Watson Cheyne, that it occurred to me that some figurative application of them might be made suitable as an introduction to the address you have called upon me to give you, gentlemen of the University Medico-Chirurgical Society, when thus gratefully acknowledging your kindness in having named me as your annual honorary president. The purpose of this address, which, I fear, must after all be very unequal to my intentions and to your goodwill, is to make a few reflections or suggestions as to what I have termed "self-education"—meaning thereby something outside the regular discipline of your curriculum, and yet not so entirely removed from your professional work as to be even apparently foreign to, and apart from, it : in other words, not the more general—moral, religious, ethical—discipline which is usually applied in "self-culture," as, for example, it has been admirably treated in a little book by my old friend Professor Blackie. To get an insight into this higher kind of self-culture I do not know that I could direct you better than by sending you to this small book on a great subject, or, if you would prefer to be instructed by a member of our own profession, to the exquisitely humorous and humane essays of another dear old friend, now lost to us—the author of the immortal tale of "Rab"—the late Dr. John Brown. No one can read the works of either of these authors without feeling the stirring within him of new impulses and new feelings, all of them in the direction, at least, of the best and largest wisdom—that wisdom which is even better than science.

My aim to-night is something short of this, and yet not without alliance therewith—to show you that, even in the midst of the medical education, so called, which is laid down for you in your curriculum, and which is therefore compulsory, and may be even felt by some of you as a bondage, there is a good deal over and above, which is really and truly a part of medical education, and which you can only do effectually for yourselves. And as the proper province of a society like this is precisely to strengthen and confirm such tendencies, and to make such "self-education" possible, or easier, to you, it will serve to limit the province of my discourse if I keep in view chiefly, but not exclusively, what I think this society may do, or may aid in doing, for all of you.

But to return to my simile. Is not all education, properly so called (as distinguished, at least, from mere erudition or cramming) a process more or less resembling that by which Mr. Watson Cheyne grows his minute organisms? You will be disposed at first to laugh at me if I liken the human mind, medical or other, to a cut potatoe or a lump of soft gelatine, and especially of sterilised gelatine. Well, I am not disposed to stand out for the comparison in this last particular; for, as I mean presently to affirm, it is impossible, however you may try it, altogether to sterilise the human mind. But this may at least be said, that the mind of man, from babyhood upwards, presents a fruitful soil on which you may grow almost anything you please, provided only that the thing in question is alive, or has the potency of life in it, as is the case with a seed or germ. And the true distinction between education, properly so called, and what I have termed mere erudition or cramming, is that the latter consists of putting into the mind lifeless or comparatively inert matter, not necessarily useless, inasmuch as it may make a good manure, but not seminal, and therefore not capable of growth ; while the former consists in a process of inoculation or insemination of the

[1] Part of an Address delivered to the Glasgow University Medico-Chirurgical Society, November 14th, 1884.

mind with principles which, being alive and fitted for growth, and finding there a fitting soil, inevitably tend to grow and develop into organisms. And if this is the essential nature of all education, properly so called, that it is a growth as of a seed into a plant within the mind, the argument is not invalidated by the fact that there may be, nay there must be, a bad education possible as well as a good.

The principles of evil, nay the seminal principles of disease, will grow in that fruitful soil of the human mind just as well as the principles of good, in some cases, perhaps, still more actively and irrepressibly. The one point in both instances which makes it an education is that it is a growth; that in the act of developing into an organism the seminal principle implanted or inoculated alters the very constitution of the mind itself as effectually as the yeast fungus changes the nature of a saccharine solution, or the septic organism disintegrates the nitrogenous elements in which it becomes developed. And to make the analogy still more complete, this education, or insemination, of the mind for good or for evil is, in reference to other minds, of the nature of a contagion or infection. A small, often an infinitesimal, inoculation of the results of education in one mind will be sufficient so to influence another, or even a multitude of other minds, as to give rise to a similar growth in them to an extent practically limitless, so that a single truth in science, a single principle of working in an art, a thought that breathes, a word that burns, may spread its influence through a family, a school, a profession, a nation, aye, it may be over the whole civilised world, as surely as the *torula cerevisiæ* will multiply in any number of saccharine solutions, or as the germs of anthrax, or of small-pox, or of cholera will spread through any number of flocks and herds, or of human beings, all over the world, if only they find a fitting, and, still more, an exhausted or virgin soil for their development.

Now, it is not necessary for my present purpose to carry this parable further, and I have already indicated one point in which, to my mind, the analogy breaks down. Mr. Watson Cheyne is enabled to ensure what is called a pure cultivation of the particular organism he is in quest of by successive inoculations of it in artificially sterilised soils—*i.e.*, in *media*, in which by the most careful manipulations he has secured in advance the absence of all other germs than the one he is pleased artificially to introduce. But it is extremely difficult, even with the command of all the resources of a laboratory, and a complete control of all the materials with which he is working, so to sterilise absolutely even a piece of cut potatoe. And in the much larger laboratory of educational activities which this world presents it may be looked upon as a practical impossibility to sterilise absolutely any single human mind. If you do not implant, or inoculate, the right kind of germs, or educational influences, in sufficient abundance, or if you do not place them in the necessary conditions for their growth, other influences will certainly occupy the field, and will grow there in spite of all your efforts, till the mind becomes, like the world in the eyes of the Prince of Denmark :—

> "An unweeded garden,
> That grows to seed: things rank and gross in nature
> Possess it merely."

As some theologian—I forget at this moment who—has expressed it, if you do not receive God's teaching Satan will be sure to insinuate an education of a different kind, the elements of which will not fail in our poor human nature to find a fruitful soil in which to luxuriate, till they end in having the whole field to themselves. Now, here is especially the province of "self-education," or self-culture, whichever you choose to call it. Not to pursue the higher aspects of the subject referred to in my last sentence, you may say that each one of you is or ought to be consciously educating himself throughout with the view to an ideal of professional and medical skilfulness, of complete equipment for the duties of life, which ideal ought to be kept steadily in view from the first.

Apart altogether from the mere technical curriculum, which, of course, is not to be despised or evaded, you will find that if you keep this ideal well in view there are qualities and accomplishments of mind and heart, aye, and of eye, and ear, and hand to be cultivated, and others to be sternly repressed; habits to be diligently learned and others to be unlearned; even small social usages, and apparently insignificant peculiarities of manner and conduct, which, through the sheer influence of association, may acquire such an ascendency as to make or mar the settled purpose of a life. Is it not worth while, then, to make all these things, while you are as yet young and immature, the objects of a deliberate self-education; to study carefully such examples as are presented to you of the fully-formed medical character, and to observe for yourselves how its best and most congenial elements may be cultivated and its defects avoided? The difficulty, of course, is first to find your ideal; next, to successfully strive after the realisation of it in yourselves. But this, at all events, may be said, that if you do not so seek and so strive there will be for you no chance whatever of even the most moderate success of a legitimate kind in your profession; whereas, if you do so seek and strive you may, indeed, fail of your highest aspirations, but you will in no case fail utterly and ignobly.

Let us try, then, to make note in succession, and in the briefest possible way, of those qualities or endowments which it might be reasonable to expect you at this stage of your career to cultivate, and by cultivating carefully and purely, to exclude as far as may be their opposites—qualities moreover which when possessed or cultivated in their highest degree go far to make up the ideal of a physician or surgeon, as the case may be. I do not think any of you will be disposed to quarrel at first sight with the following mere enumeration of them; although were it possible within the compass of an address, or at all events possible for me to say to you all that they imply, you might complain that the ideal is too high for you, or for any man, to compass successfully. But that you know is of the very essence or nature of all ideals whatever; so let us proceed boldly to present to you the mere outline of our ideal medical practitioner.

(1) He must be a careful and accurate, and at the same time a keen and quick, observer of nature.

(2) He must be able to connect his isolated observations of fact by rapid, and at the same time trustworthy, processes of reasoning.

(3) He must, in dealing with emergencies, endeavour to have always what the Greeks (and Dr. John Brown after them) called *ἀγχίνοια*—nearness of the *νοῦς*, *i.e.*, presence of mind.

(4) He must as a surgeon or accoucheur have much deftness of manipulation—manual dexterity, as we call it; or, perhaps still better, ambidexterity.

(5) He must treasure in his memory, and be constantly increasing from day to day, large stores of various reading in his own and other languages, in order that not only all past observations, but also the vast field of scientific progress in its relation to his art may be constantly before him, or at least freely accessible when wanted.

(6) He must be able to write, at the very least in his own native language, with vigour, compactness, and lucidity.

(7) He must have a soul above mere money-grubbing; must on no account degrade his profession into

a trade, but must be, as far as is possible to human nature, the disinterested friend, the companion, the good genius I had almost said, of all his patients.

(8) For this reason, if for no other, he must in every case have in him the distinctive essence of what is called a gentleman ; and if his practice is, or is ever to be, among what are called the upper classes, he must be a gentleman not only in principle, but in detail ; not necessarily what is vulgarly and falsely often styled a fine gentleman, but a gentleman in outward manner as much as in the inner spirit.

(9) He must be a man endowed with a deep sense of moral responsibility, so as to beget confidence and unfailing trust in him on the part of his fellow-men. Responsibility, therefore, to them in the first instance ; but, underlying that, and sustaining it as surely as the root and the stem sustain the flower—a deeper and more latent responsibility to Him who is the source of all good, and, therefore, of all moral principle and moral responsibility whatever.

[The remainder of Dr. Gairdner's address consisted of a more detailed treatment of the first two headings of the above ideal, with brief remarks on the others].

THE ACTION OF HYDROCHLORATE OF COCAINE ON THE EYE.

By GUSTAVUS HARTRIDGE, F.R.C.S.

Ophthalmic Surgeon to St. Bartholomew's Hospital, Chatham, and Assistant Surgeon to the Royal Westminster Ophthalmic Hospital.

I HAVE recently been making some observations on the action of hydrochlorate of cocaine on the eye.[1] On placing a single drop of a four per cent. watery solution into my own eye, it produced anæsthesia of the cornea and conjunctiva in about half a minute, so that the finger could be passed over them, or the conjunctiva taken hold of with forceps, without any unpleasant sensation. The anæsthesia remained for six minutes, and then gradually disappeared. The pupil became dilated in about twenty minutes from the time of the instillation, together with slight paresis of accommodation. Gradually these effects passed off, so that in four hours the pupil was of the same size as in the other eye ; in twelve other eyes similarly treated the same results ensued. This four per cent. solution was also tried in the following :—

Five cases of foreign bodies on the cornea. In each the foreign body was removed, without the least pain or flinching of the patient, in about one minute after a drop of the cocaine had been instilled.

Ten cases of ulcers of the cornea, with great photophobia. In many of these immediate relief was given to this distressing symptom, and in some the relief was permanent ; in others the instillation had to be repeated.

Two cases of abrasion of the cornea, with much photophobia. Great relief was at once given by a drop of the cocaine solution.

Case of cataract, on which Mr. Power was about to operate, had five instillations of two drops each, at intervals of five minutes. The opaque lens was then removed without an iridectomy. The patient gave no indication of pain, and said that the operation did not hurt in the least.

Case of iridectomy for glaucoma. The operation was done after two instillations, with an interval of five minutes between each. The patient complained of much pain both when the incision in the cornea was made, and the segment of iris was snipped off.

Case of needling for opaque capsule. After two drops with an interval between each, a speculum, fixing forceps, and needle were used without any unpleasant sensation.

Case of entropion of the lower lid, requiring the excision of a piece of skin. Two drops of the cocaine solution were injected by means of a hypodermic syringe beneath the skin about to be excised ten minutes before the operation ; one drop was also placed between the lids. A good deal of pain was felt on the removal of the skin. Two drops were also injected into a small pigmented growth near the external canthus of another patient. The growth was then removed. It was doubtful if the pain of the operation was at all relieved.

Case of obstructed nasal duct. Two drops were instilled at a short interval five minutes before slitting up the canaliculus without any diminution of the pain usually felt.

From these experiments the following deductions may be drawn :—

First, that hydrochlorate of cocaine is of considerable value as a local anæsthetic in the following cases : (*a*) In diseases of the cornea where photophobia is a prominent symptom. (*b*) For the removal of foreign bodies from the cornea. (*c*) In all operations affecting the cornea and conjunctiva only. (*d*) In cases of cataract extraction, where it is undesirable to give ether or chloroform.

Secondly, that it is of little or no value—(*a*) in operations involving the skin ; (*b*) in operations on eyes suffering from glaucoma, even if considered advisable.

Further observations are needed to confirm these experiments and to determine the strength of the solution which produces the best results, together with the most satisfactory mode of applying it, whether in a watery solution, in oil (in which it is readily soluble), in vaseline, or in discs, and if frequent applications at short intervals produce a greater effect than a single drop. I hope on some future occasion to be able to give some more observations bearing on these points.

[1] Cocaine is the alkaloid derived from Erythroxylon coca.

A CASE OF SUB-ASTRAGALOID DISLOCATION OF THE FOOT.

By FREDERICK W. KIRKHAM.

Surgeon to the Royal West India Mail Company.

ON September 4th, 1883, J. W., a seaman in the employ of the Royal Mail Company, fell from the foreyard to the spar deck of the *Don*. He was picked up in an unconscious state from which, however, he quickly recovered. Upon examination he was found to have fractured his right humerus, and to have incurred an injury to his right foot. This injury presented the following characters. The dorsal surface of the foot appeared abnormally short, and presented a well defined rounded prominence over the scaphoid bone. Viewed from the inner side the foot appeared somewhat extended, shortened from the ankle joint to the end of the toes, whilst the heel was abnormally prominent. By manipulation the prominence before mentioned was made out to be the head of the astragalus resting on the superior surface of the scaphoid bone, the inner surface of the former being in an almost direct vertical line with the tuberosity of the latter. A little limited movement was obtained

in the ankle joint, free movement being prevented by the contraction of the muscles of the calf, and, as far as could be ascertained, the articular surfaces of the tibia and fibula were in apposition with the trochlear surface of the astragalus.

The injury was diagnosed as a case of sub-astragaloid dislocation of the foot backwards.

Chloroform was administered, and reduction attempted. After a lengthy and ineffectual trial by manipulation, division of the Tendo Achillis was performed, which enabled the dislocation to be quickly and easily reduced. The leg was put up on a flat posterior splint, with a foot-piece with two side splints, and pressure was applied by a pad over the astragalo-scaphoid articulation. The splints were retained for six weeks, after which passive motion was allowed. The patient did extremely well, and when last seen, six months after the accident, complained only of a little weakness in the foot; at that time the measurements of the bony prominences of the foot which had received the injury corresponded accurately with those of the left or uninjured foot.

The fractured humerus did well also.

Medical Times and Gazette.

SATURDAY, NOVEMBER 22, 1884.

We have from time to time made our readers acquainted with the precautions that have been taken during the last twelve months or so, in view of the approach of cholera; but as these measures were described in detail in the House of Commons on Monday last, by the President of the Local Government Board, in answer to a question on the subject by Mr. Moore, it may be useful to re-state them here. The "precautions against the infection of cholera" at our various ports constitute our first line of defence. Regulations have from time to time been issued against the admission of rags from infected countries; and the orders respecting rags from France and Italy are still in force. The Local Government Board have sent Dr. Blaxall and Dr. de Chaumont to examine into the sanitary condition of the principal English ports, with special reference to their preparedness against cholera; and inspection of this kind will be repeated. The Board have made enquiry into each rumoured case of cholera on board ships coming to English ports, and in every instance it was found that the sanitary authorities were taking proper precautions against the importation of the disease. The duties and powers of Officers of Customs and Port Sanitary Authorities in the matter were defined in regulations issued in July last year, and were accompanied by an explanatory circular, and by a memorandum prepared by the Medical Officer of the Board; and all these precautions are still in force.

As regards London, special reports have been made to the Board, by Sir F. Bolton, on the condition of the water supplies. The Metropolitan Asylums Board have been taking steps for the provision of hospital accommodation, and the Medical Officers of Health, with the Vestries and the District Boards, have been consulting as to the most practicable and efficient preparations, and the best course of action should cases of cholera appear. Last year a Committee was formed by the Local Government Board for the special purpose of conferring as to the best practicable measures for the prevention of an outbreak of cholera, and the most prompt and effective means of meeting it should it occur. This Committee includes the Medical Officer of the Board, Dr. George Buchanan, who, we may remind our readers, had considerable experience of the disease during its outbreaks in England in 1854 and 1865; Sir William Jenner, Sir Joseph Fayrer, Sir Lyon Playfair, and representatives of the Foreign Office, the Home Office, the Customs, the Metropolitan Asylums Board, and the Local Government Board. The Committee has not been called together this year as yet; but a conference was lately held between representatives of the Metropolitan Asylums Managers, Members of the Medical Staff of the Local Government Board, and Sir Charles Dilke as to the fitness and readiness of arrangements to deal with any cases of cholera that may occur. It may be added that, if needed, further and more stringent regulations can be issued under the Diseases Prevention Act, 1855, and the Diseases Prevention Clauses of the Public Health Act, 1875.

The cholera here, our Paris correspondent writes, seems to be rapidly decreasing, as far as figures can be trusted. In an official communication read before the Municipal Council, M. Poubelle, the *Préfet de la Seine*, gave the following statements:

November	4th . . .	2 deaths.
„	5th . . .	1 „
„	6th . . .	14 „
„	7th . . .	14 „
„	8th . . .	33 „
„	9th . . .	69 „
„	10th . . .	98 „
„	11th . . .	89 „
„	12th . . .	86 „
„	13th . . .	75 „

On the ensuing days, official statements give the following figures:

November	14th . . .	56 deaths.
„	15th . . .	72 „
„	16th . . .	44 „
„	17th . . .	36 „
„	18th . . .	41 „

It cannot be doubted that the authorities sincerely endeavour to state the truth; but it would require the calculating powers of a Babbage or a Leverrier to reconcile the contradictory statements of the *Préfecture de la Seine*, and the *Préfecture de Police*, neither of which coincide with the figures of the *Bulletin Municipal Officiel*. That these contradictions do not arise from falsification of the real truth, but rather from "stupid honesty" is self evident; but I cannot attempt to give the daily number of cases, a point at least as interesting as the daily number of deaths, on account of these discrepancies, which it would be insincere to overlook, and arbitrary to conciliate. It seems, however, from all reports, (1st) that the epidemic is decreasing; (2nd) that its severity, as tested by the

proportion of deaths to the number of cases on record, is less intense than on former occasions. These results may fairly be attributed to the sanitary precautions taken, and perhaps to the cold weather and frost which have recently set in. At Nantes, the disease is slowly fading away; and a small epidemic has recently broken out at Melun.

It is sincerely to be feared that, after travelling all over Europe (cases are reported in Spain), the cholera will settle down as a naturalised inhabitant of Western Europe, like small-pox, measles, and scarlet fever, which were unknown to the Roman world, and were imported into the Western world by the Mussulman invaders of the 7th and 8th centuries. The importation is already an accomplished fact in some parts of Russia; but from these points a vast expanse of territory separates us, and the current of trade runs in other channels. If cholera settles in Europe, there will be an end of quarantines, and sanitation will be the only safeguard against future outbreaks of the epidemic.

"It is an ill wind that blows nobody good," says the old proverb; and the invasion of cholera may have proved instrumental in solving one of the difficulties of modern physiology. Dr. Pouchet has ascertained the existence of biliary acids in large proportions in the blood of cholera patients. Now the functions of the liver seem during cholera to be momentarily suspended; the stools are white, and the gall-bladder is empty. The secretion of bile recommences during the last, or typhoid, stage of the disease. It is well known that, according to certain physiologists, the principles of bile exist ready formed in the blood, and that the liver only excretes them, just as the kidneys excrete the materials of urine. According to the opposite school, the liver really secretes bile, just as saliva is secreted by the salivary glands. Now the experiments of Dr. Pouchet would seem to resolve the problem in favour of the doctrine of *excretion*, not *secretion*. Dr. Pouchet has also found in the urine of these patients an extractive substance, which possesses highly poisonous properties. This substance is distinct from *cyanurin*, which we know to exist in large quantities in the urine of subjects affected with cholera.

In order to prove the non-contagiousness of cholera, Dr. Bochefontaine has tried upon himself a dangerous experiment. He collects five cubic centimetres of the liquid fæces in the bowels of a female just dead from cholera; he makes them up into pills with lycopodium and gum arabic, and swallows them. Although the fæces were ascertained, by microscopic inspection, to contain a large proportion of microbes, including the comma bacillus, yet Dr. Bochefontaine experienced no trouble beyond slight anuria, fever, and nausea. He, therefore, boldly concludes that cholera is not contagious, and that there is no danger in drinking water polluted by the fæces of patients. To this it might be replied, that cholera, like other infectious diseases, only attacks those who, from unknown causes, are predisposed to contract them. The *receptivity* of the subject is a factor of as great importance as contamination itself.

The meeting of the Clinical Society on November 14th was very numerously attended. Two subjects only were presented for discussion. The first of these, the treatment of chronic dysenteric diarrhœa by means of large injections of nitrate of silver, was introduced by Dr. Stephen Mackenzie, who gave a detailed account of a series of cases in which he had obtained some very successful results. So successful indeed has the treatment been in his hands, that it is probable that it will shortly be put in practice to a far greater extent than has even yet been the case. Beyond the production of local pain, it did not appear that any evil results had ensued upon what at first sight appears a somewhat heroic procedure. That chronic ulceration of mucous surfaces is best treated by local astringents, or even by caustics, is a well-known fact, and although the necessarily blind injection of three pints of fluid, containing a drachm of nitrate of silver, into the bowel would seem to be a very indefinite mode of application, still, the results on record speak most strongly in its favour.

The second paper, read by Mr. Morrant Baker, brought forward the subject of the joint lesions in cases of locomotor ataxia, concerning which a great deal has already been said in this and other societies. That much remains to be decided before the disease can be definitely accepted as an individual affection, there can be no doubt. The discussion, however, tended to show that the view is gaining ground that the original opinions of Professor Charcot are correct. The different clinical history of these cases when compared with that of chronic arthritis, and the remarkable fact that among the very numerous cases of arthritis in the workhouses and asylums there are no cases of locomotor ataxia to be found, are strong points in favour of this view. The debate was adjourned to the next meeting of the Society, on November 28th, when it is possible, however, that arguments may be urged upon the other side. The Hon. Secretaries of the Society ask us to state that before the adjourned discussion there will be the usual opportunity for exhibiting living specimens at 8 p.m., and the Society will be grateful to any of its members who can show illustrative cases, more especially examples of typical rheumatoid arthritis, combined with ataxia, or typical Charcot's arthropathy without ataxia. We may add that Professor Charcot has promised to send over for the occasion a series of preparations from his own private collection to illustrate the disorder and its specific characters.

A correspondent writes, with regard to the discussion:—"The Clinical Society has committed itself to a scholastic disputation upon Mr. Morrant Baker's thesis of the essential identity of rheumatoid arthritis and tabes dorsalis. That the debate will awaken fresh interest in many points of these maladies, and that a good deal of useful miscellaneous information will come to the surface next Friday is very probable. That any

solid result will be forthcoming from so premature a discussion is hardly to be looked for. To discuss the truth of the proposition $x=y$ with but a faint glimmering of what x represents, and no knowledge whatever of the value of y, is an exercise more philosophical than scientific. We have traced locomotor ataxy and its attendant symptoms up to a certain lesion of the spinal cord; so far we have progressed, but very little further. The origin of the spinal lesion is still wrapt in obscurity. As for the pathology of rheumatoid arthritis, it is not too much to say that we know nothing whatever about it, except in its effects in the morbid anatomy of the damaged joints. To the cause of the damage, whether to seek it locally, in the blood, in the vessels, in the trophic nerves, in the trophic nerve-centres, or where else, we have as yet scarce the barest clue. In our present state of knowledge it is a patient search for facts that is needed; the time for speculation will come in due course.

At the Medical Society, on Monday last, Dr. Markham Skerritt, of Clifton, read a paper on the Conduction of Physical Signs in Diseases of the Lungs. It was universally recognised, he said, that the lungs acted as a conducting medium for physical signs in heart lesions, but it was not so fully appreciated that the physical signs of diseases of the lungs themselves might be detected at a distance from the spot where they originated. He argued (1) that physical signs due to disease of a limited portion of lung were liable to be conducted by the adjacent tissue so as to be recognised at a distance from the site of the lesion—as in front when the disease was at the back, or over the sound lung where one lung only was affected. (2) That it was therefore as important to trace to their origin the physical signs dependent upon lung disease as it was to follow out those of a cardiac lesion. Instances were given of the adoption by a consolidated lung of the signs of pneumothorax derived from the other side, the transmission to the sound side of the tubular breathing of pneumonia, the interchange of physical signs between the affected side and the unaffected in pleuritic effusion, the conduction of the physical signs of phthisis from one apex to the other, and the conveyance throughout the pulmonary region of sounds having a strictly localised origin. The physical signs, he said, which were most liable to be conducted were those of auscultation, and chiefly *râles*, and altered breathing. In the localisation of a conducted sign in lung disease the process was the same as with a cardiac lesion. In conduction a physical sign retained its special quality, but lost in quantity in proportion to the distance from its source. The readiness with which a sound was conducted was also of value, he argued, as an indication of the state of the transmitting tissue. At the same meeting, Mr. Noble Smith exhibited the child who was shown last year with a meningocele, which he had since successfully treated by subcutaneous injections of the iodo-glycerine solution. The sac, situated on the occipital bone, was originally as large as a walnut; it was now no larger than a small marble, and was quite hard and solid, while the child was in good health. Mr. Smith had injected the fluid into the subcutaneous tissue of the scalp, and not into the sac. Apart from the rarity of the lesion, the success of this treatment is most gratifying.

At the meeting of the Pathological Society, last Tuesday, the most important communication was that of Mr. Sutton on behalf of the Committee on Comparative Pathology, in relation to a study of uterine and ovarian disease in all species of wild animals including, as he somewhat humorously said, the human female. The result of this investigation showed that ovarian disease was more commonly present in animals born in confinement than in those more strictly wild. Cystic disease of the ovary, due as he believed to dilatation of the tubules of the parovarium, was discovered in no less than two-thirds of fifty mares chosen at random. Dr. Percy Kidd showed a specimen of perforation of the pulmonary artery from bronchial ulceration, the result having naturally been a sudden and fatal hæmoptysis. The bronchial ulceration appeared to have been due to pressure of an enlarged gland. Dr. Kidd spoke of it as an extremely rare occurrence; we believe that it is less rare in the child than in the adult. Dr. Carrington showed a case of gastric ulceration associated with ulcerative endocarditis. Dr. Norman Moore exhibited a case of what must be admitted to be a most rare occurrence, namely of carcinoma of the stomach in a girl of 13. We should hardly be prepared to attach so much importance as he did to the fact that the child's paternal grandmother had died of carcinoma of the colon. Mr. Knowsley Thornton brought forward a specimen of hydronephrosis, and Mr. Hopkins some bones from cases of locomotor ataxy. There were several card specimens.

The subject of nephrectomy will be brought before the Royal Medical and Chirurgical Society on Tuesday next, November 25th, in a paper by Mr. Henry Morris. An interesting discussion is expected to follow, in which, besides others, Sir Andrew Clark, Sir Henry Thompson, Mr. Savory, Mr. Bryant, and Mr. Hulke will probably take part.

At the opening meeting of the Pathological Section of the Academy of Medicine in Ireland, on Nov. 7th, there were two papers of considerable interest which gave rise to some discussion. The first of these was by Mr. Kendal Franks, and related to a case of intussusception of the small intestine. The symptoms were very obscure, and he was only able to surmise before operating that the obstruction was situated in the small intestine. When the abdomen was opened the intestine was found to be almost gangrenous, and it was quite impossible to draw out the intussuscepted portion. The patient died a few hours after the operation. The debate turned mostly on the question of diagnosis and of operative interference, one speaker suggesting that probably the changes which had taken place in the intestine indicated the natural process of cure by sloughing and separation of the intussuscepted portion of intestine. The second paper related the case of a girl, aged 19, operated upon by Mr. Wheeler (who made the communication to the Society), for a hypogastric tumour which had originated behind the recti abdominis muscles, and had some connection with the periosteum of the pubic bone. The tumour

was removed and proved to be a spindle-celled sarcoma; there was an enlarged gland in its vicinity, also exhibiting sarcomatous characters. The patient died some five weeks after the operation, but the exact cause of her death did not transpire.

The second annual dinner of the Guy's Hospital Universities' Graduates Club was held, under the presidency of Dr. Galabin, at the Holborn Restaurant, on Monday, November 17th. A goodly number of graduates of the Universities of Oxford and Cambridge at present connected in various capacities with Guy's Hospital were present. The club is essentially intended for the social union of present students and teachers at the hospital, but by a wise elasticity of its rules, the presence of former members of the club will be permitted at future meetings. The very large increase in the entries of medical students at the older Universities has given rise to the establishment of several University Clubs of late and will tend to unite all former graduates at their respective hospitals in a manner which will materially improve the general social tone of those institutions.

The Council of the College of Surgeons have made but little progress at present with the important questions of procedure which are now under their consideration. Considering their importance, the wide ground they cover, and that they involve traditions almost sacred to the College authorities, we are not surprised at the delay. The Ordinary Council, doubtless, after discussing them, referred these questions to an Extra-ordinary Council, which, in their turn, have referred them to the Committee on Charters and By-laws. Meanwhile the Councillors have time to study the charters, and to turn the questions at issue over in their own minds; nothing is more likely to reconcile them to the proposed changes, or to impress on them the incongruities and the short-comings of the present system on which the College is worked. We trust that the present crisis will be solved in a manner which, while supporting the dignity of the College as a public institution, will secure for its body corporate that voice in its affairs and management which their number, their education, and social status give them the right to expect.

It is not altogether surprising to find that the lately effected union of the two London Colleges is not regarded with universal approval in the provinces. From the point of view of the provincial schools there are only two objects to be aimed at in any alteration of the existing system. Either the present mode of examining and granting diplomas should be rendered more convenient and less expensive, or some new plan should be devised by which a better class of qualification can be obtained for the same amount of trouble and money. Under the provisions of the scheme, as sanctioned by the General Medical Council, it is by no means clear that a saving of inconvenience will be effected, and certainly there will be no relief from expense. The relative value of the double qualification can only be determined by its ultimate popularity. Perhaps the most important consideration to the country candidate is the question of cost. College fees are in some cases formidable enough, without the additional burden of an enforced residence in London for a week or ten days, for the purpose of attending an examination which does not occupy as many hours. It is, of course, essential that due time should be allowed between the paper work and the *vivâ voce*, in order that the examiners may not be hurried in forming their estimate of every candidate's papers. There does not appear, however, any adequate reason for the present custom which obliges all candidates to come to London for the purpose of writing these papers. No great inventive effort is necessary to devise a scheme whereby provincial students might be enabled to write their examination papers within the limits of their own school buildings, or even at special local centres, under the most impartial supervision. Their attendance at the London centres for the purpose of *vivâ voce* examination might then be limited to a few hours if necessary. We are glad to learn that a petition is about to be presented to the Colleges of Physicians and Surgeons respectively, bearing the signatures of the Deans of the more influential provincial medical schools, praying that an arrangement of this kind may be embodied in the new scheme of Conjoint Examination. The granting of this petition would greatly add to the popularity of the new double qualification and might indeed serve to turn the scale of the balance in which the scheme is now being weighed, and by which in some quarters it has already been found wanting.

Here is an item of intelligence not calculated to raise the depressed spirits of our London teachers:—"The returns from the tutors show that 111 medical students have entered the University of Cambridge this term as freshmen. This number may be increased after the December previous examination, as some students postpone making up their minds as to medicine until this examination (the preliminary required for registration) is passed." In 1882 the number of entries, according to the medical registrar's returns, was seventy-six. That is to say, in two years the number of students commencing their medical education at Cambridge has increased by over 50 per cent., and the Cambridge School has leapt into the position of the second largest medical school on this side the Border. Another point worth noting is, that the large majority of these 111 students will succeed in getting their degree, whereas, if they had been so foolish as to compete for the London degree not more than twenty at the outside would have succeeded in passing the Second M.B., and the rest would have had to be content with a simple diploma. There yet remains a third point for comment, which is this—the policy of the Cambridge School is controlled by men who are active teachers. At the London University, on the other hand, there is hardly a single medical member of the Senate who is still employed in teaching, and very few who are thoroughly *en rapport* with the present lecturers at the medical schools. The Annual Committee of Convocation contains three or four medical teachers, but it is only a consultative body, which has very little influ-

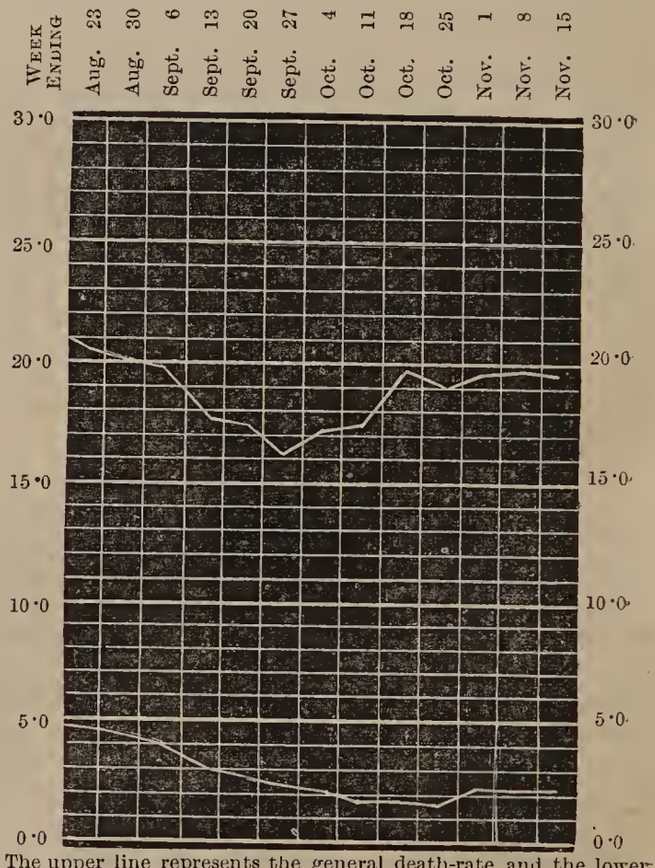
ence on the decisions of the governing committee. It is high time for the Senate of the London University to wake up from its complaisant dreams of its past successes, and to adapt itself to its altered environment.

To look at the matter from the meanest point of view. One hundred and eleven students this year begin their medical education at Cambridge (intending, no doubt, to finish it in London); forty-nine students having begun it in London have gone this year to finish it at Newcastle (Durham); in all 160 students. Of these we may fairly estimate that 100 would have taken their complete curriculum in London if they had seen a reasonable prospect of capping it with a degree. Put the fees that go into the pockets of Cambridge and Newcastle teachers at twenty-five guineas for each student—a low estimate—and it is obvious that London teachers are losing 2,625*l.* yearly, because there is no practicable London degree. Next year, if we are not mistaken, this figure will go up to 4,000*l.*; and where will it be the year after that?

We have looked forward to the Registrar-General's report for the third quarter of the present year with some interest, as the season with which it deals was one of quite exceptional character, and it was difficult to predict exactly what effect a long period of heat and drought would have upon the distribution of disease. Last summer was the first really hot one that we have had since sanitary activity became general throughout the country, and there is probably nothing which finds out the weak places in our armour like continued drought. The mean temperature of the quarter was 3·0° above the average in the preceding 112 years, and that of August was as much as 4·4° above the average. The rainfall of the quarter was 2·87 inches below the average. As a result of these meteorological conditions we find a general death-rate for the whole country (19·7 per 1,000), 1·1 above the average; but while the death-rate of the 28 great towns was 2·3 and that of the towns generally 1·3 above the average, that of the rural districts only exceeded the average by 0·5. On turning to the zymotic death-rate we find it in excess of the average by 0·55 per 1,000, an excess almost exclusively due to the greater fatality of diarrhœa; for the deaths from scarlet fever, whooping-cough and fever were below the average, while those from measles, small-pox and diphtheria were only slightly above it. The diarrhœa death-rate for the whole of England and Wales was 2·72 per 1,000, or 0·81 above the average; but it was 3·9 in the 28 great towns, and 3·2 in 50 other towns; whereas in the rural districts it was only 2·0, and in many counties only 1·0 per 1,000. In 12 of the great towns it was over 5·0 per 1,000; in 4, namely, Norwich, Nottingham, Preston and Leicester, it was over 6·0, mounting in the last two towns to 8·3 and 9·1 respectively. Both of these centres, however, have a high diarrhœa death-rate almost every summer, their average for the last ten years being 6·4 and 7·1 respectively.

It is curious to trace the rise in the diarrhœa death-rate in correspondence with the rise in the thermometer. The chief heat occurred during the first three weeks in August, and the average diarrhœa death-rate of the 28 great towns accordingly reached its maximum in the weeks ending August 23rd and August 30th. In London, however, the death-rate reached its maximum in the third week in July, as the result of a hot spell with a temperature 5·2° above the average, which terminated on July 11th. In the August heat, when for eighteen days the mean temperature was 5·9° above the average—on one day, the 8th, it was as much as 10·4° above it—the diarrhœa death-rate in London remained comparatively low, being more than 3·0 less than the average in the 28 towns. This is well shown in a table given by the Registrar-General, from which we see that of the 28 great towns only one, London, had its maximum death-rate from diarrhœa in the third week of the quarter, and only 2, viz., Leicester and Derby, in the fourth week; while in the case of all the other 25 towns the maximum occurred after the August heat, viz., in 2 in the seventh week of the quarter, in 12 in the 8th, in 7 in the 9th, in 5 in the 10th, and in 1 in the 11th week. There must be some cause for such different conduct on the part of the different towns, but what it is we are at a loss to say.

The Registrar-General has again this week a favourable return to make, both the general and zymotic death-rates being about the same as last week. The total deaths registered in London last week were 256, the deaths from zymotic diseases 85, and the deaths from respiratory diseases 86, below the ten years' averages. The mortality from small-pox unfortunately continued to increase, 49 deaths of London residents having occurred in the week; the admissions



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past thirteen weeks.

into hospital, however, fell from 233, the number of the previous week, to 199. The deaths from the rest of the common zymotic diseases, except diphtheria, were considerably below the average, those from measles, scarlet fever, and whooping-cough, taken together, being nearly one hundred fewer than usual at this period of the year. But there were fourteen deaths from puerperal fever, the average being six. The mothers, however, took their revenge, exactly the same number of infants (fourteen) having died from suffocation, in most cases, probably, from being overlaid. The average zymotic mortality of the 28 great towns was exactly the same as that of London, but their average general death-rate was 1·3 above that of the metropolis. Glasgow had a higher zymotic death-rate than any of the large English towns, except Cardiff, where measles is raging.

The increased prevalence of small-pox in London and elsewhere during the summer months has aroused the vigilance of our transatlantic cousins against a possible invasion of epidemic variola; and it has brought to light the existence of some exceedingly useful regulations which are intended to provide against the spread of the disease through the medium of schools. During a previous epidemic, the Illinois State Board of Health, issued a School Vaccination Order, which was then acted upon with the most satisfactory results. At the time when it first came into effect, Jan. 1, 1882, nearly sixty-nine per cent., or over 490,000, of the school children in Illinois, were either entirely unprotected against small-pox, or had again become susceptible through failure to re-vaccinate at the proper time. Within sixty days, that is by March 1, there remained less than 6 per cent. of unprotected and susceptible amongst those in attendance; and the frequency of small-pox and varioloid among public school children had been reduced by more than a third, while the rate of mortality amongst the children attacked had fallen from 16·5 to 3·3 per cent. During the four years 1880–83, the small-pox returns for the whole State showed that the deaths among un-vaccinated school children were at the rate of 48 in every 1,000 attacked; amongst the vaccinated school children the death-rate was only ·9 per cent. of those attacked. These figures certainly present a strong argument for the "necessity of a thorough enforcement of proper and successful vaccination as a pre-requisite to admission to the public-school room."

It is pointed out that this School Vaccination Order is permanent and continuous. Not only so, but the Attorney General has decided that it is the duty as well as the right of the State Board of Health to issue such orders for the preservation of public health; that these rules and regulations, when promulgated, have the force and authority of law; that the local authorities may exclude from school those children whose parents refuse to comply with such requirements; that if any School Board or managers refuse or neglect to carry out such orders, they may be proceeded against for neglect of duty; and should any such Board be prosecuted for enforcing the provisions of the order, they may defray the expenses of counsel, &c., for defending them out of any school funds of their district not otherwise specifically appropriated. Allow as much as we may for the abstract theories of the matter, the "liberty of the subject" always reaches its vanishing point when its further exercise would infringe the requirements of public health. A great step such as this in the direction of practical school hygiene might be adopted by us with national advantage.

Nothing can be more gratifying to the professional mind than to find the Science of Medicine received with open arms and unquestioning faith by the lay public. The German Government, above all others, should command our admiration in this respect. Attention has of late been prominently called to the exemplary manner in which, anticipating Dr. Klein, they have figuratively "swallowed" Professor Koch's bacillus. In a no less thorough and impetuous fashion did they receive the more important teachings of Sir Joseph Lister in respect of the antiseptic treatment of wounds, but their faith in this particular has lately led to a judicial decision of somewhat more than ordinary importance. Early in the present year a man was stabbed in the chest with a knife, and the wound thus inflicted was treated by a fully qualified surgeon, who did not employ any antiseptic precautions. Blood-poisoning ensued in course of time, and the patient died. The surgeon has recently been put upon his trial for mala praxis and has been convicted on the ground that he had not observed the well-recognised rules prescribed by modern medical science for the treatment of such cases, and that he must have known by ordinary observation that his own treatment would be followed by death! On an appeal to a superior court this remarkable judgment was confirmed and, although a further hearing has yet to take place before a third tribunal, the whole transaction suggests unpleasant thoughts of what might possibly arise in our own country if this example of the Teutonic method were to find followers on the English Bench.

The *Allgemeine Medicinische Central-Zeitung* reports the case of a Berlin doctor who was recently summoned to a police court for having practised deception. A person residing at Rostock having written to him asking him whether he could undertake the treatment of varices from which he suffered, received a reply that he could cure these completely and rapidly. After fifteen marks in advance had been forwarded, the treatment was commenced, but as this was attended with no success, the patient summoned the doctor for having practised a fraud upon him. The defendant maintained that no fraud existed, as the medicine sent was only preparatory, and the patient had received full instructions as to the course he was to pursue. The court, however, ruled the deception as proved, as the defendant must have known that he was making false representations when he stated that the varices would be completely and rapidly cured; and he was fined a hundred marks or ten days imprisonment. The two experts who were called, Professor Liman and Dr. Israel, both agreed

that "treatment at a distance" was always most objectionable, but added that the accused might not necessarily have been guilty of wilful deception, for as the intellectual condition of practitioners is so various, it is possible he might have believed in the efficacy of his remedies, which, however, they themselves regarded as of only temporary utility. To our mind, the decision of the magistrate seems in this case to have been far more praiseworthy than the shuffling of the experts.

Mr. Armstrong's report for the year 1883 on the city and county of Newcastle-upon-Tyne, shows a general death-rate in Newcastle itself of 25·4 per 1,000, considerably above that of any of its seven immediate predecessors, and nearly 4 per 1,000 higher than the average of the 28 large towns, according to the Registrar General's Report. The actual number of deaths was 3,792, whilst there were 5,482 births. Amongst the infectious diseases the mortality from measles was excessively heavy, no fewer than 209 deaths being attributed to this affection ; of these 30 were in infants under one year, exactly ten times as many as occurred from it at this age in 1882. There would appear to have been an extensive epidemic of scarlet fever during the year, as 1,152 cases were notified with a mortality of 10·8 per cent. There were 493 cases of small-pox with a death-rate of 12·2 per cent., 216 cases of enteric fever with a death-rate of 20·0 per cent., and 90 cases of typhus with a death-rate of 24·8 per cent. The compulsory notification of infectious diseases has been in force during the year, and Mr. Armstrong says that thus far it has worked smoothly and given satisfaction to all parties. The urgent need for better accommodation for infectious cases will be obvious when we state that only 13 cases of scarlet fever seem to have been admitted into the Fever Hospital during the year. Maps of the town are appended showing the distribution of cases of scarlet fever, small-pox, enteric fever and typhus, the fatal being distinguished from the non-fatal cases.

A large and annually increasing number of American medical men are in the habit of leaving their own country for the purpose of studying at some of the more famous European schools. The Students' Number of the *New York Medical Journal* contains, under the head of "Medical Study in Great Britain, France, and Germany," a very full account of the methods in vogue at the different centres of medical education, with particulars as to the courses given by the various professors, the scale of fees, the cost of living, and much useful advice as to the method by which the student may utilise the time at his disposal to the best advantage. As an outline programme for the student about to leave the States, but uncertain where to go first, the following plan is recommended: "Make a short stay in London to see the best men, and obtain an idea of English methods. If, by contrast later with German men and methods, they appear preferable, the student can return to England ; if not, he will have a longer time for work on the Continent. Go next to Germany, and select one of the smaller university towns for the first three months' work. Here, whatever time is not occupied in acquiring the language can be spent in the study of pathology in a laboratory whose director will be able to give his instruction to the beginner in his own language. Strasburg, Heidelberg, or Leipsic may be chosen for this purpose. As soon as the first semester is over, go to Vienna for obstetric work during the vacation, and while there obtain whatever information is desired regarding the special study which is to be pursued. Both the specialist and the general student will find one semester in Vienna indispensable, and will probably desire to take a second one. The second vacation may be passed at Berlin, Leipsic, or Munich, where special courses are to be obtained between the semesters. From Germany go to Paris, so arranging one's plans as to spend the months of April to July in that city. If French is not understood it can be learned in Germany during the preceding winter, or a competent teacher can be obtained in Paris at the International Society of Teachers in the Rue Royale. If one's time is very limited, spend it all in Vienna. If it is unlimited, visit as many Universities as possible, but do not spend less than an entire semester in each, for little good will be obtained from hearing but half-a-dozen lectures from any one man. Above all, remember that it is less the actual knowledge obtained than the new methods of acquiring knowledge which are to be prized and utilised. If the student returns imbued with the French enthusiasm combined with the German thoroughness, his medical trip will be a permanent source of congratulation."

There is to be held in London, in 1886, an American Exhibition of the Arts, Inventions, Manufactures, Products, and Resources of the United States of America. An immense Council of Welcome has been formed, comprising all the celebrities of the day ; a list of which has been published with an epitome of the achievements of each ; as for instance :—

GEO. BUCHANAN, Esq., M.D., F.R.S., London, Poet, Author and Dramatist ; Author of "Undertones," "North Coast Poems," "The Land of Lorne," also of "A Madcap Prince," "A Nine Days' Queen," "The Shadow of the Sword," "Lady Clare," etc. ; Member of the Executive Council of the International Health Exhibition, London, 1884.

THE BOWMAN LECTURE.

The series of Bowman Lectures instituted by the Ophthalmological Society of the United Kingdom was most happily inaugurated last week by Mr. Jonathan Hutchinson, whose lecture we publish to-day. After a short and graceful introduction, the lecturer points out that the subject chosen, Diseases of the Eye in relation to Gout, is an especially important one to us, from the frequency of the gout taint in the British population. He insists upon the existence of a clear distinction between gout and rheumatism, while admitting the difficulty, and even in some cases the impossibility, of actually drawing this distinction in practice. By *gout* he means "all states of health which are, whether directly or remotely, connected with the accumulation of lithate of soda in the

blood, as the result of overfeeding or defective assimilation." From the primitive idea of *rheumatism*, he would exclude as causes all that have reference to food or assimilation," and would "count only those which regard climate and weather, and especially exposure to cold and damp." Now, the primitive type of each of these diseases becomes much modified by inheritance, *e.g.*, a form of transmitted gout may exist, "not associated in the patient with either lithiasis or lithæmia." Again, the primitive type of the one disease may be associated with an inherited form of the same disease or of the other; while an inherited form of both may co-exist in the same individual. The intricacy of the investigation is therefore manifest and becomes almost hopelessly so when we are told that "strictly rheumatic disorders, acute rheumatism itself, if it happens in the relatives of those who have had gout, lends support to the theory of family tendency to gout. It is an observation . . . confirmed I am sure by daily experience, that the children of the gouty are more liable than others to attacks of rheumatic fever." It will be sufficient, for the present, to look upon the hereditary diathesis of both diseases as manifesting *arthritic susceptibility*, and to bear in mind the terse, pithy definition of each given in the lecture, viz, "arthritic susceptibility to food," and "arthritic susceptibility to weather." Attention is drawn to the modification of tissues liable to be produced in the subject of acquired gout, and to the proneness of those tissues "to suffer in a peculiar manner when exposed to the ordinary exciting causes of disease." The offspring of such a person inherits his tissues, and his tendencies as regards digestion, &c., and therefore has an increased proclivity to typical gout if exposed to its usual causes. But besides this, he inherits, independently of exciting causes, a liability to "forms of inflammation or of degraded nutrition, which are not unequivocal gout, but which are yet the direct consequence of it in predecessors." We are thus logically introduced to the class of diseases forming the subject of the lecture.

"Hot Eye" is the term applied by Mr. Hutchinson to a condition associated with quiet, or as it is commonly called "suppressed" gout. This affection is characterised by repeated short attacks of conjunctival congestion, and a feeling of heat and pricking in the eyeball, and is liable to occur after taking injudicious diet. In connection with this affection, our attention is also directed to the occasional occurrence of sharp shooting pain in the eyeballs in persons suffering from unequivocal gout. The lecturer has done good service by drawing attention to the true nature of such cases, and to the definite course of treatment indicated. He next makes a most important note in reference to a form of asthenopia, occurring in young persons in association with inherited gout. Most ophthalmic surgeons are, we think, too apt to order glasses in slight degrees of ametropia with asthenopia, without considering the other possible causes of the symptoms complained of.

Nearly all cases of "arthritic iritis" are believed by Mr. Hutchinson to be really due to gout, either alone or in association with rheumatism. "It is, I think, decidedly exceptional" he says "for rheumatism pure and uncomplicated to show any tendency to attack the tissues of the eye." He points out, in support of this view, that iritis in conjunction with rheumatic fever of the ordinary type is almost unknown. He considers consecutively the different types of arthritic iritis, and enquires into the evidence we possess connecting each with the tendency to gout. First he takes the ordinary recurrent form, frequently called "rheumatic iritis," which occurs in acute transitory paroxysms of well known type. He finds that a considerable number of such cases occur in the subjects of true gout, but that in a much larger number of cases the concomitant symptoms are those of rheumatic arthritis and not of true gout. He argues that this form of rheumatic gout is "in reality a hybrid disease, possessing, in addition to an unquestionable share of rheumatism, an admixture also of gout tendency." This view is supported by its infrequency in women, and by the age, habit of body and mode of life of those usually its subjects. Secondly, he mentions the iritis occurring in connection with gonorrhœal rheumatism, and points out that, while iritis in association with acute or chronic rheumatism is very rare, it often accompanies the rheumatic affections induced by gonorrhœa. This peculiarity he explains by showing that gonorrhœal rheumatism occurs usually in the subjects of inherited gout. He describes two other distinct forms of arthritic iritis less frequently met with and both often associated with a history of inherited gout. He thus brings forward weighty evidence in favour of the general association of arthritic iritis with gout rather than with rheumatism, and his observation that gonorrhœal rheumatism nearly always occurs in those who inherit a gouty constitution is one of great value. He next introduces a strong array of cases to prove the existence of a peculiar form of destructive iritis always associated with the inheritance of a gouty constitution. That such a true "gouty iritis" undoubtedly occurs has now been taught for several years by Mr. Hutchinson, and his views have been extensively adopted in this country. In favour of *Relapsing Cyclitis* being of gouty origin, facts are still wanting. He merely suggests "that it is very probable that in some cases the constitutional cause . . . may be gout." The case here is evidently weak.

The next enquiry is, "does gout cause neuritis?" Such a question has manifestly most important bearings, not upon diseases of the eye alone, but upon pathology in general. Unfortunately here again little evidence can be produced in argument, but we trust that further attention may be directed to this matter under the stimulus of the cases now described. That gouty sciatica may be produced by an inflammation of the nerve or its sheath is at least plausible; and, if so, it is also possible that some forms of optic neuritis may really be due to gouty inflammation.

In reference to *Retinitis Hæmorrhagica*, Mr. Hutchinson expresses the belief that it is "very rarely seen excepting in those who are themselves gouty." This is, in our opinion, much too sweeping an assertion, yet we feel considerable diffidence in thus casting doubt upon it after the lecturer's vindication of the wide-spread nature of the gouty malady and of the multifarious aspects under which it may be encountered.

In recapitulation, Mr. Hutchinson shows how the

different gouty eye affections may be divided into two groups, according as they are associated with (1) acquired, or (2) inherited gout. In the former group the attacks are generally acute, transitory, and painful, and the patients are adults; here he places hot eye, sclerotitis, recurrent iritis, and retinitis hæmorrhagica. In the second group the attacks are prone to be chronic and persistent, often insidious, and usually destructive; here we find the true gouty iritis, relapsing cyclitis, and certain forms of soft cataract. Indications as to treatment are afforded by the nature of the gout in the two groups. Altogether, this, the first Bowman Lecture, is a brilliant example of Mr. Hutchinson's masterly power of generalisation from carefully recorded observations made on a large number of cases. Even where it may not be convincing his argument is always fruitful in fresh ideas, and deserves our careful consideration and with it our gratitude.

CLINICAL PAPERS.

XVI.—Tracheotomy in Diphtheria.

Tracheotomy is the one operation of vital importance which any practitioner may find himself called upon to perform, and when we reflect how very few students on commencing practice have had the opportunity of doing it or even of seeing it done, it is easy to understand why the majority regard it with such dread. And yet there is really, in most instances, but little difficulty in the operation, and with proper assistance such difficulties as there are entirely vanish, provided always that the case is not of such urgency as to demand a swift and masterly operation. The difficulty is often inherent rather in the diagnosis than in the treatment. In cases where membrane is or has been present on the fauces, or where there is presumptive evidence of infection from clear instances of diphtheria having occurred in the same house, the diagnosis will be open to little doubt. In other cases where no evidence of this nature is obtainable, the mode of onset of the attack must be carefully enquired into, and the liability of the patient to previous attacks of hoarseness duly taken into consideration. Too much weight, however, should not be attached to a history of frequent attacks of croup, for we all know that those who are subject to tonsillitis are at least as liable as others, if not more so, to contract pharyngeal diphtheria, and the same argument may be applied without much forcing to the case of the larynx. The present writer remembers a case in which a child was admitted into hospital for croup, the parent stating that he had had many similar attacks. On the strength of this history, tracheotomy was deferred until too late to save life, while ample evidence of the presence of diphtheria was ultimately obtained. The presence of albuminuria in a given case affords valuable evidence in support of the theory of diphtheria, but its absence must not be allowed much weight in the contrary sense.

As regards the indications for the operation in the absence of clear evidence of diphtheria, the most reliable sign is the character of the breathing, together with the colour of the patient. So long as there is no recession of any part of the chest wall or of the suprasternal or supraclavicular region during inspiration, we need not feel much alarm; it is this sign which gives the best information as to the amount of laryngeal or tracheal obstruction. Auscultation of the lungs will probably reveal at this stage an impeded entry of air with perhaps a dry stridulous kind of râle. The presence of abundant moist râles, more or less fine, would indicate that another factor was entering into the causation of the dyspnœa in the shape of blocking of the small tubes probably with that semifluid mucus which often seems to precede the formation of membrane, and the presence of which renders any operative interference futile. If, in spite of treatment by means of inhalation of steam or medicated vapour, a supporting diet, and appropriate internal remedies, the dyspnœa, increases, and the lips and face become gradually more livid, nothing will be gained by delaying the operation. We are alluding more especially to the case of children in whom it is decidedly exceptional for membranous casts of the trachea or bronchi to be coughed up. Chloroform should, as a rule, be administered, unless the asphyxia has already reached the stage of unconsciousness. A very small quantity usually suffices, and its administration requires more than ordinary care, but it enables the operator to proceed with much more deliberation, a point of no small importance.

A good light is essential to success, and if the operator has any doubt as to whether there is sufficient light he will do well to provide himself with artificial illumination before commencing the operation, as afterwards there will be no time to wait whilst it is being obtained. The shoulders and neck should be supported by a little pillow, so as to throw the head back and put the neck on the stretch, and great care should be taken that the shoulders are square in order that the operator may have no difficulty in finding the middle line of the body. The incision should commence just below the lower margin of the thyroid cartilage, and be continued downwards for over an inch; it is better to have too large an incision than too small a one. After dividing the skin, each side should be kept back by an assistant holding a retractor in each hand, and taking care to maintain an equal tension on each. The less the knife is used in the subsequent steps until the trachea is reached the better, though, of course, if the patient should have stopped breathing no time must be lost in dissecting down to the trachea, which must be boldly opened at once. The safer plan for the operator, if time permits, is to push aside with two pairs of forceps the various structures that he meets with, or to tear them through with his forceps, or if any fibrous layer should prove too tough, it may be divided with a scalpel on a director. The isthmus of the thyroid should be pushed down, or if absolutely necessary the operator may cut through it, but it is far better to avoid doing so if possible. Meanwhile, the assistant with the retractors should successively grasp and hold aside the tissues beyond which the operator has passed, his great object being to keep an equal traction on the two sides;

otherwise he would encourage the operator to dissect to the side of the middle line, and so the trachea might never be reached at all. In many of those unfortunate cases that will happen to young surgeons who perform tracheotomy without bringing any relief to the patient, and learn next day in the *post-mortem* room that the trachea has never been opened, the blame belongs really to the assistant.

As soon as a sufficient length of the trachea has been laid bare (the first two rings or so) an incision should be made through these from below upwards in the middle line and a pair of Trousseau's dilators inserted without loss of time. The violent coughing which immediately follows the opening of the trachea is one of the most pleasant sounds an operator can wish to hear. He should be at once on the alert to remove any pieces of membrane which may be coughed up into the orifice in the trachea in order to prevent their being sucked back at the next inspiration. Hitherto the operator has been, in spite of himself, perhaps, in more or less of a hurry; it is of great importance, if ultimate success is to be obtained, that he should not hurry over the remaining steps. Keeping the trachea well open with the dilators he should pass feathers moistened either in warm water or in some weak alkaline or antiseptic solution, according to his prejudices, down the trachea and into the bronchi and by twisting them round before withdrawing them, endeavour to remove any membrane that may happen to be lodged there. He should then do the same to the larynx, passing the feather upwards from the wound. If necessary, he might also pass a soft flexible tube, or some apparatus of like nature, and attempt by aspiration to remove any membrane that may be blocking the air passages. When he is satisfied that he cannot remove more membrane by any of these methods, the ordinary silver tracheotomy tube, of the largest calibre that the child's trachea will admit, should be inserted and the patient put back to bed again. The accident of which one so often reads of the tube getting blocked with membrane directly it is put in and obstructing the breathing is one that never ought to happen; it shows that the operator has not thoroughly finished his operation. With the return of the patient to bed the operation may be considered to be over and the after treatment then begins, a subject our space does not permit us to deal with at present. Φ

REVIEWS AND NOTICES OF BOOKS.

Brain: A Journal of Neurology; London: Macmillan & Co., October, 1884.—The current number of *Brain* is worthy of the good reputation that this periodical has so thoroughly established. The first article is by Professor Obersteiner, of Vienna, and deals with the "Cerebral Blood-Vessels in Health and Disease." Especial attention is called to certain histological changes that occur in the vessels of brains which are in all other respects healthy, and are not connected with any disturbance of function; such as calcareous deposit, fatty degeneration of the muscular coat, connective tissue degeneration, and dilatation of the adventitial lymph-sheath. Professor Pitres, of Bordeaux, contributes a paper on the "Early Occurrence of Ankle-Clonus in Hemiplegia," in which he points out that this phenomenon takes place probably much earlier in many cases than is usually believed, and quotes a few instances in which it was noticed eleven and fifteen hours respectively after the occurrence of the apoplectic seizure. He states his opinion from his own experience that the cases which show this phenomenon early remain permanently and more or less completely hemiplegic, with late rigidity of the affected leg; so that he considers the elicitation of ankle-clonus during the first few hours or days of the attack to be an almost certain sign of an incurable paralysis. If this view be correct, and it seems *à priori* probable from the little we know about the import of ankle-clonus, we have doubtless a very definite and useful additional aid to prognosis in these practically important cases. More observation, perhaps, is wanted as to the non-occurrence of ankle-clonus in cases which recover before Professor Pitres' dictum is accepted as absolutely as he makes it, but it seems likely that in cases where the lesion in the motor tract is sufficiently grave to affect the control of the so-called reflexes perfect recovery would not ensue. This paper is valuable too as emphasizing the point that ankle-clonus is only in certain cases due to lateral spinal sclerosis, it being probably quite as often caused by cerebral as by spinal conditions. It is clear that in the cases of Pitres, lateral sclerosis is out of the question. In an interesting paper on Cases of Tumour of the Corpus Callosum, written with his usual clearness and accuracy, Dr. Bristowe points out that growths in the median portion of the structure do not give rise to characteristic symptoms, but that the symptoms which are presented in these cases are due to an extension of disease to the hemispheres. From these negative and positive grounds it is possible to make a diagnosis, the progress of such a case being probably first headache and vague symptoms of progressive cerebral disease; second, the gradual onset of more or less marked hemiplegia; third, the appearance of some such similar symptoms on the opposite side of the body, and, fourth, the coming on of dementia, with drowsiness, loss of speech, difficulty in swallowing, and want of control over rectum and bladder. Dr. Bristowe thinks that, though attention has not been specially directed to such cases as these, they are examples of a class which are not unlikely to be met with in practice. Dr. Radcliffe Crocker's paper on Lesions of the Nervous System Ætiologically Related to Cutaneous Disease consists of a *résumé* of the main facts and views in relation to this interesting subject, with which the name of Weir Mitchell will always be connected. Although there is nothing very new in this paper, it is valuable for its conciseness, and will be useful for reference. The series of original articles closes with one by Dr. Charles Mercier, who by his writings in various periodicals is rapidly making good a claim to be considered one of the ablest and clearest of our neurological thinkers. A devoted though independent professor of the creed of Mr. Herbert Spencer, as edited by Dr. Hughlings Jackson, Dr. Mercier in the present paper acts most usefully to the medical profession as an interpreter of his predecessors in this line of thought. We have nowhere seen such a clear and aptly-illustrated account of what is meant by the term "Nervous Discharge" as we find here set forth. It must be read *in extenso*; we will not attempt to give it in abstract. The subject is one of obvious difficulty, and the terminology by means of which it is expounded is of necessity somewhat metaphorical; but Dr. Mercier has succeeded in making a maximum use of "terms of the known" in his explanation with a little, and that a decidedly brilliant use of the scientific imagination. Much, however, as we welcome this paper, which will doubtless be most valuable in clearing up the minds of many thinkers on the subject, we can scarcely agree to Dr. Mercier's "Experienced Alienist" (see the first page of his essay), who rejected the existence of a nervous discharge, because he thought it was of the nature of a discharge of pus, being adduced in evidence of any necessity of enlightening such a mind as his. Probably the most superficial student has always in view the analogy of the *electrical* discharge on hearing this term, and this alone would be ample justification for Dr. Mercier's most lucid exposition of the *real* nature (if we may be excused the paralogism) of the supposed nervous discharge. But the alienist

who confused himself about the word was probably suffering more from alienism than ignorance, and, like many of his patients, was beginning to be caught by the analogies of "empty words." For him we would counsel a short detention, and we sincerely hope that Dr. Mercier's compassion for his aberrant friend will never induce him to lower his standard or style of writing which is so admirably suited to his legitimate purpose of expounding and contributing to philosophic neurology.

Surgical Handicraft; by Walter Pye. H. Kimpton, 1884. — This might be expected to be a work on manipulative surgery pure and simple, but it is intended to be something more, for it is a manual also for "other matters connected with the work of house surgeons and dressers." The meaning of this is not quite clear. We have looked for any account of house surgeon's duties, responsibilities or privileges, but there is nothing that we can find in the work that answers to this. Similarly, as to dressers, we find no instructions as to duties, what to observe or how to observe it, none as to the instruments he should possess, none as to case taking or the performance of *post-mortem* examinations. Then if the manual should be intended for students beginning the practical work of surgery, we have looked in vain for how to make the simplest of common applications, a poultice, or how to apply it. The preface leaves one as vague as the title page on the object of the book. It states that the author's endeavour has been "to describe the details of surgical work as it appears from the point of view of house surgeons and dressers in surgical work." We have been thus critical because of our inability to see the author's aim, and we have examined the book with care as coming from a surgeon of recognised ability. The subject matter is good, and if we can divest ourselves of the idea of its being a manual of elementary practical work for dressers, or other than a handbook of minor surgery, bandaging and splints, with special chapters on surgical emergencies, practical surgery and anæsthetics, we shall find in it much to speak highly of. But even as such we should have been glad to see a helping description of how to tie a ligature properly, how to take off ordinary strapping best, how best to remove a plaster of Paris or similar splint. These are omissions which no doubt will be rectified in future editions, for a student should not require an infinity of instruction books, and these points may fairly be looked for in a work on surgical handicraft. But in the chapters which treat of minor surgery, practical surgery such as fractures, wounds, &c., and especially in that which treats of joint diseases, the information given is of great value to student and practitioner alike. The illustrations to the text are very abundant and useful, and in the treatment of fracture or disease by means of splints, illustrations of splints properly applied are of great use to the student and save lengthy description. One section on surgical emergencies is of great practical value to advanced students and practitioners, for it contains short chapters on retention and extravasation, hernia and intestinal obstruction, fits, drowning and other forms of suffocation, and on poisons. And a chapter on anæsthetics by Mr. Mills is good and likely to be referred to by the reader for practical information. There is a useful chapter on the extraction of the teeth by Mr. Hayward and another on some points in the practical management of aural cases by Mr. Field. The book has convenient marginal references and is well printed.

ABSTRACTS AND EXTRACTS.

SURGERY.

The Micrococcus of Gonorrhœa.—Dr. Sternberg contributes a paper on the ætiological significance of the micrococcus which is so frequently found in gonorrhœal pus. He concludes that the organism *is* connected with the infective virulence of this discharge; but this "gonococcus" does not present any distinctive morphological character as claimed by Neisser and some other observers, according to Sternberg. "Pure cultures" of this organism, carried to the *fourth* generation, have shown its infective qualities; but Sternberg thinks that to absolutely ensure all exclusion of the original material, or of micrococci still infected with it, cultivations should be carried further. He discusses their varying characters under cultivation, and does not attach much importance to them. His observations lead him "to think that they are subject to the modifying influence of changes in their environment as well as the higher plants"; and he does not the less regard them as the essential feature of these discharges because similar organisms are found in other kinds of discharges.—*The Philadelphia Medical News*, October, 1884.

Subcutaneous Ligature of the Brachial Artery, followed by Primary Union.—Dr. Canizzaro relates, in *Lo Sperimentale*, for June, the following case: Messina, 22 years of age, during a struggle, 10th April, 1882, received a wound from a dagger on the anterior surface of the right forearm, three fingers' breadth below the bend of the elbow, the weapon issuing at the posterior part of the arm, having wounded the ulnar and interosseous arteries. Violent hæmorrhage ensued, which was arrested by compression applied by means of snow. The bleeding repeatedly recurred at intervals notwithstanding the compression and digital compression of the brachial; and after a vain attempt at tying the divided ends of the vessels it was resolved, several days after the accident, to tie the brachial. Esmarch's bandage was applied and the skin of the arm forcibly drawn externally, so that the incision into it should not correspond with the spot where the brachial was tied. The ligature of the artery was easily effected. Union readily took place, and by the fourteenth day the pulse could be distinctly felt in the radial artery. The original wound took some time to heal, but six months afterwards all effects of the accident had disappeared.

A Second Attack of Syphilis.—In the *Philadelphia Medical Times* for August, Dr. Engel records a case in which a man had two attacks of syphilis. He was first called to the patient for an epileptic seizure. When the patient had recovered from this, Dr. Engel learnt that eight months before he had had a chancre, for which he had been treated by a homœopath who had pronounced him cured when there was still a bubo left. A few months later he had sore throat, followed by an eczematous coppery eruption of which he still bore traces. He was at once put upon the line of treatment to be subsequently described. For five years he continued under treatment. Seven years after the epileptiform seizure he came back to Dr. Engel with a Hunterian chancre. This healed in three weeks, and he was then lost sight of for three months when an eczematous eruption similar to that he had had before made its appearance. At the same time, he began to suffer from pain beneath the sternum, and when seen, eleven days after the onset of these symptoms, he was very ill, and the physical signs led Dr. Engel to diagnose inflammation of the aorta. He was at once put upon the treatment by mercurial inunction and rapidly began to improve. Dr. Engel then proceeds to discuss the diagnosis, and he points out that this could not be considered a relapse of the previous manifestations, because he had a typical chancre after the second infection. Again, the time which elapsed between the first manifestations and these later ones was much greater than is ever seen. Other points which he mentions are that when once the internal viscera have been attacked by syphilis the skin eruptions cease to appear, excepting gummata and rupia. Another point too he notes is, that syphilitic patients hardly ever get the same form of skin eruption twice. On the second occasion the patient had a perfectly typical chancre, nor were the secondary symptoms in any way modified by his former attack. From this Dr. Engel concludes that the cure of his syphilis must have been quite complete in the first instance seeing that the second attack was in no degree milder than in an ordinary attack. The treatment is by mercury in the first instance, the patient beginning with a grain of calomel daily; at the

end of three days this is increased by one third of a grain a day, and in three days more a like amount is added, and so on till the patient is taking three grains daily. If the inunction treatment is adopted, a drachm of the mercurial ointment is daily rubbed into some part of the body, the patient not being allowed to change his underclothing more than once a week. This plan is continued until salivation has set in and is not then stopped until the gums commence to ulcerate. When the effects of the salivation have passed off, a mixture of bark and iron is administered, under which the patient rapidly regains the flesh he had lost under the mercury. At the end of a week iodide of potassium is given in increasing doses, from five grains daily up to sixty grains a day. If any manifestation of syphilis reappears at this time, this dose is still further increased until no sign of syphilis is present. The maximum dose is then continued for a week longer, and it is then gradually diminished. Change of air at this time is generally recommended, and after two or three weeks the patient is ordered a hot bath every other day and takes a decoction similar to Zitmann's decoction. If any sign of syphilis should still be present, the patient goes through the whole course from the commencement again. If the patient is quite free from syphilitic manifestations, he takes for four weeks one-fourth of a grain of yellow iodide of mercury; then for four weeks one-sixteenth of a grain of corrosive sublimate; then for four weeks the same dose of binoxide of mercury; then for four weeks iodide of potassium as before; then the same round again until seventeen months are past, during the last two of which he also takes some bark and iron. For the next eighteen months, every three months the patient passes through a three weeks' course of iodide of potassium; beginning at five grains a day, and altering the dose every four days up to twenty grains and down again. At the end of this period he is recommended to take a short course of iodide of potassium twice a year for the rest of his life.

Conical Stumps.—During a discussion on this subject at the Société de Chirurgie (*Union Méd.*), Professor Verneuil observed that conicity of the stump has no dependence upon the mode in which union has been effected. He is not in the habit of healing his stumps by first intention, and he in general obtains most excellent stumps, while in the exceptional instances in which he has obtained union by first intention he has had conical stumps. This accident in fact occurs only in cachectic individuals in whom the stump has become atrophied, or in those in whom it has become inflamed. Conicity is not met without such inflammation, or unless the patient is suffering from a bad general condition, which, by impairing nutrition, produces atrophy of the soft parts of the stump. "Everything which favours *antiphlogistie*, to use a neologism, is a means of preventing conicity of the stump."

Injections of Ether and Iodoform In Cold Abscess.—Professor Verneuil obtains a rapid cure in almost all his cases of cold abscess, abscess from diseased bone, or from congestion, &c., by ethereal injections of iodoform of the strength of one in twenty. The abscess is first emptied by means of Potain's aspirator, and then receives from 100 to 300 grammes of the iodoform solution. By not exceeding this quantity (*i.e.*, five to fifteen grammes of iodoform) no fear of accidents need be felt. The liquid penetrates into all the anfractuosities and diverticula of the abscess, the ether becoming absorbed or evaporated, and the antiseptic agent being deposited uniformly on the pyogenic membrane, the action of which it modifies. This simple means, so exempt from danger and so easy of application, has proved highly successful, very large abscesses having yielded to three or four injections.—*Revue de Thérapeutique*, August 15.

New Method of Treating Large Bone-cavities.—Dr. F. Lange (*New York Medical Journal*) has applied Neuber's system of deep canalization to the treatment of large cavities in the lower end of the femur in adults. An anterior flap is formed from the soft parts covering the front of the lower end of the femur: the whole of the anterior wall of the cavity is removed, and the abruptness of its lower edge is removed by an oblique section, which substitutes for it a smooth inclined plane. The whole bone-cavity is thoroughly scraped out and disinfected: for this purpose the application of a strong carbolic spray is recommended as being specially efficient. Then the dorsal flap, whose length must correspond to the extent of the cavity, is depressed towards the bottom of the cavity, and fastened there by a nail or needle. No sutures are applied. The raw surfaces above the edges of the flaps heal by granulation: and the flap itself becomes gradually raised to the level of the rest of the wound, by a new formation of apparently bony tissue beneath it. Cases in which this procedure was successfully adopted are given in detail.

Carbolic Acid Injections in Hæmorrhoids.—Dr. Washburn, commenting on the statement of Dr. Matthews, of Louisville, that this is a dangerous practice, observes that it is so only when the proportion of acid used is too large. He has employed it in numerous cases without any ill results having been produced. If the pile is external he always returns it, even if an anæsthetic has to be resorted to for this purpose, before examining it by a bivalve speculum, and especially before treating it. If he wishes to slough out a tumour, he uses but one part of acid to two of sperm oil, but if he wishes to secure absorption only, he employs one to four. If the patient is very sensitive to pain, only from five to fifteen drops of the solution should be injected, and this may have to be repeated two or three times before complete removal of the tumour. To prepare the injection, the acid is dissolved by heat and measured with the oil into a phial, which is then placed in a water-bath. The water is brought to about boiling point, after which the acid and oil will not separate. Before operating the bowels should be thoroughly moved and washed out, so as not to want moving again for 24 hours, and if the patient is very susceptible, a dose of morphia may be given to keep him quiet and allay pain. The needle should be inserted so as to deposit the fluid in as nearly the centre of the tumour as possible. In some cases inflammation will follow, but generally the patient can at once go about his affairs. Only one tumour, especially if large, should be treated at a time, the remainder being operated upon at intervals of two weeks.—*Philadelphia Medical Reporter*, August 16.

Treatment of Carbuncle by Compression.—In a clinical lecture on carbuncle, delivered at the Hospital of the University of Pennsylvania (*Philadelphia Medical Times*), Prof. Ashhurst observed that some peculiarities which occur in the ulceration of a carbuncle have not been understood until lately. The ulceration causes a sieve-like appearance of the surface, owing to its being set up at several distinct points. Why it should thus manifest itself has been recently shown by Dr. Collins Warren, of Boston, in his examination of the skin at the back of the neck, where he found little processes or tubes of fat connecting the deeper tissues with the surface, and which he calls *columnæ adiposæ*. It is along these columns that the pus of the carbuncle, which originates as a phlegmon of the deep cellular tissue, begins to make its way to the surface. The slough, commonly called the core, which is the result of sloughing of the deep cellular tissue, protrudes through these openings. Prof. Ashhurst states, that in regard to the treatment, he now always resorts to a modification of compression by adhesive plaster, as first recommended by Mr. O'Ferrall, of Dublin, finding it a much more simple, and far less painful and dangerous procedure than crucial incision or cauterization. On suppuration occurring, Mr. O'Ferrall cut a hole in the plaster for the discharge of the pus, but Prof. Ashhurst prefers adhesive strips applied concentrically, as in the treatment of swelled testicle. They are first applied at the margin and gradually brought more and more inwards, leaving a space in the centre to allow the slough to come out. From the time of application the spreading of the carbuncle is arrested, and the pain is greatly relieved. The carbuncle rapidly diminishes in size, and over its centre a small poultice is applied, which after a while is changed for resin or zinc ointment.

Suture of Nerves.—M. Chaput, from an elaborate research into the particulars of the cases hitherto published, arrives at the following conclusions:—(1) Suture of nerves is an absolutely harmless operation; (2) It may be

followed by immediate reunion and with a return of almost all the functions of the nerves; (3) Suture has been successful at least in a proportion of 66 per cent.; (4) Primary and secondary suture have furnished nearly similar results, but somewhat to the advantage of the latter.—*Archives Générales*, September.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 14TH, 1884.

Sir ANDREW CLARK, Bart., M.D., President, in the Chair.

Chronic Dysentery treated by Voluminous Enemata of Nitrate of Silver.

DR. STEPHEN MACKENZIE read a paper on this subject of which the following is an abstract. The author alluded to a former series of cases he had brought before another Society, and stated that extended experience had strengthened his belief in the value of large enemata of nitrate of silver in the treatment of cases of chronic dysentery or dysenteric diarrhœa. The mode of procedure he adopted was as follows:—The quantity of nitrate of silver to be used was dissolved in three pints of tepid water in a Leiter's irrigating funnel, which was connected by india-rubber tubing with an œsophageal tube with lateral openings. The patient was brought to the edge of the bed and made to lie on his left side, with his hips well raised by a hard pillow. The terminal tube, well oiled, was passed about eight or ten inches into the rectum, and the fluid allowed to force its way into the bowel by gravitation. The injection rarely caused much pain, and often none. It usually promptly returned, but when long retained it was advisable to inject chloride of sodium, to prevent absorption of the silver salt. Various strengths had been used, from thirty to ninety grains to three pints of water, but usually one drachm of nitrate of silver was employed. The treatment was based on the view that, whatever the nature of dysentery, whether constitutional or local, in the first instance, the later effects were due to inflammation or ulceration of the colon, which was most effectually treated, as similar conditions elsewhere, by topical measures. Sometimes one, sometimes two, injections were required, and in some cases numerous injections were necessary; but in all the cases thus treated, many of which had been unsuccessfully treated in other ways previously, the disease had been cured. In most cases other treatment was suspended, but in some Dover's powder or perchloride of iron, which had been previously administered, was continued or subsequently prescribed. The cases narrated were—1. In which the disease had lasted several years on and off; two injections were used, and the case was cured in six weeks. 2. Second attack, duration uncertain; four injections used; cured in five weeks. 3. Duration two months; two injections used; cured in three and a-half weeks. 4. Duration five years; one injection used; cured in three weeks. 5. Duration eighteen months; two injections used; cured of dysenteric symptoms, but remaining under treatment for diabetes. 6. Duration fourteen months; one injection used; cured in seven weeks. The treatment, which laid no claim to novelty, was brought forward to elicit the experience of others who had tried it, or to induce others to employ it in suitable cases.

Dr. CARRINGTON, while congratulating Dr. Mackenzie on the success of his series of cases, expressed some doubt whether such good results would be obtained when the treatment came to be more widely practised. It had been tried at the hospital at Greenwich without any remarkable effect, but the injections had not been so voluminous as those used by Dr. Mackenzie, which might, perhaps, explain the fact. He could not help observing that to anyone familiar with the extent of the local lesion in dysentery, the almost immediate cure by the nitrate of silver injections seemed almost phenomenal. The colon was usually capable of holding six pints of fluid, and the three pints used in some of the cases might possibly have failed to reach the affected parts. He should employ the method, however, when an opportunity occurred.

The PRESIDENT observed that large injections of astringent fluids into the bowel had been practised since the time of Hippocrates. He was not sure what the opinion of Indian physicians had been upon this subject, and suggested the possibility that a marked difference might exist between these cases and those occurring in the tropics.

Dr. CULLIMORE asked Dr. Mackenzie whether he would advocate the use of injections in all cases, irrespective of the presumed seat of the lesion? He referred to cases previously recorded, and showed that in many instances the patients had been suffering from recurrent attacks, and had only recently returned to England after long voyages from the tropics. The good influence of complete rest and of suitable food might have been the really essential point in their recovery. Absolute rest was a most important factor. He gave his own experience of the treatment of chronic dysentery in Indian gaols, by means of rest and milk diet. The average duration of the illness was two months. In one case, where he had used an injection of forty grains of nitrate of silver in two pints of water, the chief result was the production of great pain. He mentioned a case which had been apparently caused by starvation, and referred to the common Indian experience of dysentery following famine. He had tried other forms of injection, but with no marked results. Krameria appeared to be useful in some cases. Iodoform only had the effect of checking fœtor.

Dr. DUCKWORTH had only used the nitrate of silver injection in one case, and that without any very striking result. He thought that it was frequently forgotten that a very large number of conditions were apt to be classed together under the label of "dysentery." Purging and the presence of ulceration in the large intestine were the main clinical and pathological phenomena characteristic of the disease. Cases might, however, vary very greatly in their ætiology, and especially in the idiosyncrasies of individual patients. The constitutional state of the patient was a most important consideration in all cases of tropical disease.

Dr. BERNARD O'CONNOR mentioned the case of an Indian physician in whom recurrent dysentery had been cured by a voluminous injection of hot water.

Dr. STEPHEN MACKENZIE, in reply, pointed out that he had purposely used the term "chronic dysenteric diarrhœa" to express the various forms that are met with. He described the clinical course of such cases as seen in hospitals, and quoted the experience of many former physicians of the Seamen's Hospital as to the inefficacy of any of the ordinary forms of treatment. In the very advanced cases, where the bowel was fairly rotten, he did not believe that any treatment could be of service, but in the less severe cases he thought the injection treatment would prove most effective. He would, however, employ sedative treatment at first. The ordinary remedies had been tried, and had failed in all the cases in his series. With respect to the size of the injection, he thought that more than three pints would be liable to stretch the intestine too severely.

Three Cases of Joint Disease in Connection with Locomotor Ataxy.

Mr. MORRANT BAKER contributed the above. The patients were two males, aged respectively 45 and 56; and a female, aged 54. In all, the symptoms of locomotor ataxy were well marked, the disease having existed in one case for about 2 years, in another for a few months, and in the third for 20 years. In two cases (male) the joint chiefly affected was the right knee-joint; in the female the right elbow-joint and both hip-joints, with incipient disease of the left elbow-joint. In all the cases the disease of the joints was apparently a typical example of the affection usually termed Charcot's disease. The joints were much enlarged, the articular surfaces greatly mis-shapen, and the ligaments weakened or destroyed. There had been very considerable

wearing away of the articular ends of the bones—one or other condyle and a large portion of the head of the tibia in the case of the knee-joints, and apparently nearly complete disappearance of the heads of the femora in the case of the hip-joints. The joints were loose and flail-like; although in the case of the diseased elbow-joint, and in those of the knee-joints, the patients retained considerable power of voluntary movement. Mr. Baker remarked that he had brought the cases before the Society chiefly in order to add to the record of facts regarding a rare and not well-understood disease; but he thought a discussion might well be raised in connection with them on the following points:—(1) Whether the disease is actually new? (2) What are its alliances, if any, with rheumatoid arthritis? (3) If connected with the last-named disease, is its occurrence in conjunction with locomotor ataxy a mere coincidence? or do these stand in the relation, one to the other, of cause and effect: and (4) If connected pathologically both with rheumatoid arthritis and with locomotor ataxy, should not all cases of rheumatoid arthritis be considered of neurotic origin, whether accompanied or not by symptoms of locomotor ataxy? There was still another theory possible, even if Charcot's disease and locomotor ataxy and rheumatoid arthritis were all connected in pathological origin. It was conceivable that all arose from some antecedent diseased condition of which the result was expressed in pathological changes, sometimes in the cerebro-spinal nervous system, sometimes in the joints, and sometimes in both.

Dr. Buzzard thought that the views expressed by Mr. Morrant Baker would greatly add to the better appreciation of this disease. But the disease itself was not by any means a new one. He had recently found in Dr. Graves's work, written before the days of Duchenne, an account of a case of typical gastric crises, which were manifestly a part of locomotor ataxy. The symptoms in this case began as long ago as 1823. Since that time a far larger proportion of the population had come under medical supervision owing to the spread of the out-patient system in hospitals. The main point at issue was the connection between Charcot's joint disease and rheumatoid arthritis. He reminded the Society that Charcot first brought up the subject in the year 1868 as an affection of the joints only. Five years afterwards a case was shown in which the joint changes were accompanied by fracture of the long bones, and it was at that time believed that the bone lesion was the principal feature of the disease. Tioville described certain cases of a similar kind. An analysis of the chemical composition of these bones was made by Regnard, who found that a marked reduction in the mineral substances had occurred, the proportion of fat being much higher than normal. He (Dr. Buzzard) would suggest to surgeons the advisability of testing the specific gravity of the bones entering into the diseased joints in these cases. He had found no record of this having been done in Dr. Adams's work on the subject. Bones should be taken for the purpose from each variety of bone disease. With respect to the discrepancy between the experience of Professor Charcot and that of Dr. Moxon, he pointed out that it was valueless as an argument. The peculiar circumstances which enabled the former to see and examine such vast numbers of cases are not present in the practice of the London physician. With his own personal experience of many hundred cases of locomotor ataxy he could point to hardly any cases of joint disease. Such cases did not come to the physician. After seventeen years' experience among large numbers of all forms of nervous disease he had seen a very few cases of swelled joints, but in every instance they occurred in association with locomotor ataxy. Why should other diseases of the nervous system be free from this connection? He thought that these cases of joint disease contrasted most strongly with those of rheumatoid arthritis. The latter might go on slowly for years, and did not break down rapidly as was the case with Charcot's diseases. Chronic arthritis was best seen in workhouses and asylums, and in such institutions he had sought and found numerous examples of it, but not a single case of locomotor ataxy among them all.

Mr. A. E. Barker related particulars of a case shown by him in 1881 of a railway porter who first sought his aid in consequence of a difficulty in micturition, associated with frequency, and some straining. He also suffered from vomiting and epigastric pain at intervals, with much gastric distension, and nausea at other times. Numbness and pain in one foot was also complained of, and on examination a perforating ulcer was diagnosed. A careful examination of the case by Dr. Gowers failed to detect any symptoms of ataxia at that time. A second ulcer developed in the foot, but these improved under treatment. A year later the patient was seen again, and it was ascertained that the return of pain and ulceration in the foot was always synchronous with the occurrence of the gastric symptoms. At the beginning of the present year the same symptoms were observed, coupled with quivering of the muscles of the thigh, and at times sudden and extreme weakness of them. At the present time there was evident commencing disorganisation of the knee-joint, the tibia being partially dislocated backwards, and slightly inwards. Throughout the course of the illness there had been no ataxic symptoms present, and there is still an ordinary knee-jerk. The periodical gastric symptoms have somewhat improved. There had been occasional pains in the legs. No ocular symptoms had been noticed. The patient was exhibited to the Society.

Dr. Duckworth thought that the Society was much indebted to Mr. Morrant Baker for the philosophical views that he had expressed with reference to this subject. He was one of the few surgeons who had not been content to regard the occurrence of the joint disease and the nerve symptoms as merely coincident. For himself, he was satisfied that there was a joint disease in these cases quite distinct from rheumatoid arthritis, and he thought that the clinical features alone would serve to distinguish it. In some of the cases there appeared to be recovery, but in others the disease seemed to run riot and to cause disintegration of the joint with a rapidity and violence not seen in the ordinary cases of arthritis. It seemed hardly likely, moreover, that a physician of Dr. Charcot's position, and with such a vast field of experience, should fall into error in this matter. He admired the philosophical tone of Mr. Baker's remarks as to the possibility of the joint and spinal lesions being both manifestations of a single disease, and pointed out the fallacy of the supposition sometimes indulged in in the deadhouse, that identity of pathological lesions proved the similarity of the processes that have led up to them. He believed that it was not possible to distinguish from the bones alone between Charcot's joint-disease and rheumatoid arthritis.

Dr. Hale White referred to a statement made by Dr. Moxon at a previous meeting, that in thirty consecutive cases of locomotor ataxy he had not met with a single example of the joint lesion, and contrasted it with Charcot's experience in which the cases occurred in the proportion of one in every ten. He thought such a discrepancy as this was remarkable. Many opportunities of observing these joint changes occurred in the dissecting room, and he had lately had the opportunity of seeing one case in which osteo-arthritic changes were present in the larger joints, whilst the temporo-maxillary articulation showed alterations precisely identical with those in Charcot's cases. Such a case formed one of many connecting links between the two conditions. No case had as yet been shown in which a patient with osteo-arthritis was suffering simultaneously from locomotor ataxy. The absence of such a case rendered it difficult to accept the explanation so frequently given, that these joint lesions are simple forms of disease occurring in cases of locomotor ataxy.

On the motion of the President, the debate was adjourned to the next meeting of the Society.

The following living specimens were exhibited:—

A case of Spina Bifida, shown by the sub-committee appointed to investigate the subject, and sent by Dr. Maude, the patient, aged 19, having been under the care of Dr. McLean, of Portland, Dorsetshire.

A case of Spina Bifida, by Mr. R. W. Parker.

Favus, by Dr. Malcolm Morris.

Charcot's disease, by Dr. Buzzard, and Messrs. Turner, Barker, Bowlby, and Morrant Baker.

A case of Muscular Wasting, in illustration of his paper, postponed till the next meeting, by Dr. H. B. Donkin.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, NOVEMBER 18TH, 1884.

J. W. HULKE, F.R.S., President, in the Chair.

Fatal Hæmoptysis from Bronchial Ulceration Perforating the Pulmonary Artery.

DR. PERCY KIDD showed a specimen taken from the body of a girl, aged 15, who died suddenly from profuse hæmoptysis. At the *post-mortem* examination the body well nourished but extremely blanched. Traces of blood about nose and mouth. Main passages contained blood throughout. Both lungs marked with patches of inhaled blood, and studded with small hard nodules. The left apex contained a large cavity; there were also a few small cavities in the lower part of the upper lobe, and the small bronchi were generally thickened and slightly dilated. A large firm *post-mortem* clot filled the left main bronchus and the secondary bronchi. The bronchial tube to the upper lobe, about half an inch beyond its origin from the main bronchus, had been perforated by ulceration, which implicated this branch and the neighbouring parts of the main bronchus. The ulceration of the bronchus had extended into a secondary branch of the pulmonary artery lying in front of it, the opening in the artery being as large as a hempseed. A little below and internal to this point there was another perforation of the bronchial wall leading into an irregular space containing a crumbling cretaceous bronchial gland. The bronchial ulceration was soft and ragged, and had merely the ordinary characters of scrofulous or tubercular ulceration. The other lung contained no cavities. Bronchial glands generally cretaceous and slightly enlarged. The stomach contained two pints of blood, but was healthy. The intestines showed slight scrofulous ulceration. The mesenteric glands were enlarged and calcareous, and the liver was slightly amyloid. Other organs normal. The hæmorrhage in this case was clearly due to perforation of the pulmonary artery, by the bronchial ulceration, which in its turn was set up by the pressure of an enlarged calcareous gland. The case was an extremely rare one.

Ulcerative Endocarditis.

Dr. CARRINGTON showed this specimen. The patient, aged 23 years, had suffered from acute rheumatism, of three months' duration. He had a soft blowing systolic murmur at the apex, which subsequently became louder and very harsh, and albumen appeared in urine with blood. There was pyrexia throughout. At the *post-mortem* there was extreme ulceration of the mitral valve with rupture of many of the chordæ tendineæ. The spleen contained infarcts. The kidneys showed acute nephritis and contained many infarcts. The stomach contained 15 ozs. of clotted blood, it was dotted with hæmorrhages. Projecting inwards at the posterior wall, near cardiac end, was a hemispherical mass, formed by a false aneurysm into which the splenic artery opened. There was no induration round the ulcer, some recent clot was found in the walls of the stomach round it. The case was interesting because ulceration of the stomach in cardiac disease was rare, and although this was a strong argument against the embolic theory of gastric ulcer this case illustrated one mode of the formation. The three stages seemed to be indicated by the condition of the duodenum without ulceration, and the superficial and deep ulcers in the stomach. Probably the pressure of the effused blood caused local anæmia, and permitted gastric solution. Another point of interest was that an aneurysm seemingly cured might bleed between the sac wall and its contents. The sudden increase in intensity of the bruit had enabled a surmise of rupture of the chordæ tendineæ to be made.

Carcinoma of the Stomach in a Child.

Dr. NORMAN MOORE showed sections of the stomach taken from a girl, aged 13 years, who was brought to the hospital with extreme anæmia and slight anasarca of the face, hands, and legs. Her heart's action was very feeble and she had a loud systolic murmur, audible at the left base. Her pulse was of very unequal beat, and a systolic thrill was to be felt over the whole cardiac area. She had no albuminuria. Besides her anæmia, her chief symptoms were repeated attacks of cardiac distress. She never vomited blood, but two days before her death complained of pain in the abdomen, and was slightly sick once or twice. An enlargement of her spleen was felt. She died five weeks after admission. *Post-mortem*—A new growth of which sections were shown, was found at the cardiac end of the stomach close to the œsophagus. The mass was about three inches across. Its periphery arose from the mucous membrane, and was of the same colour, but its central parts were ragged, dark coloured and very tense. On section, it was red with paler stripes. The outer part of the growth was adherent to the liver, but did not penetrate it. There was a little recent peritonitis apparently due to a slight tear at the periphery of the growth. No glands, and no other organs were infiltrated. There was a very old, and perhaps congenital dislocation of the right hip joint. The heart was greatly dilated. It contained several adherent, softened, *ante-mortem* clots, and there was an adherent thrombus in the left jugular vein. The microscopical characters of the growth were those of a carcinoma with somewhat wide trabeculæ, with extensive mucoid degeneration of the cell contents, but no degeneration of the trabeculæ, and with hæmorrhages into several parts of the growth. Three distinct stages were visible in the growth. In the least degenerate, numerous cells of an epithelial type were collected in large alveoli. In another, advanced mucoid changes were observable in the epithelial cells and in some cells the nuclei had disappeared. In the most degenerate parts almost all the nuclei had disappeared, leaving a mass of mucoid material intersected by traces of the cell boundaries. In all three parts the fibrous trabeculæ of the carcinoma remained unaltered. The early age of the patient was a remarkable feature of the case: it was one of the earliest, if not the very earliest example of cancer of the stomach (with microscopical determination) hitherto recorded. The cancerous mass was less dense than such new growths in the gastric wall usually were but resembled many such cases in the absence of secondary deposits. The child's paternal grandmother died of carcinoma of the descending colon at the age of 53, in 1878, and was examined *post-mortem* by Dr. E. D. Wallis, of Leiston, Suffolk. The growth was not examined microscopically, but there could be little doubt that it was a true carcinoma, and his case might be regarded as an example of the law of heredity that peculiarities tended to appear at an earlier age in the progeny than that at which they occurred in the ancestor.

Mr. HENRY MORRIS referred to a woman with cancer of the breast operated upon, who died, and some months later the mother also had cancer. It was a striking instance of the tendency of the disease to occur at an earlier period in the offspring.

Mr. EVE said that cases of cancer of the stomach were usually cylindrical, in this case the cells were spheroidal.

Mr. CRIPPS disbelieved in the hereditary theory of cancers. According to Dr. Moore's theory, how was it that cancer was still a disease of old age? It ought by now to appear immediately after birth.

Mr. HUTCHINSON thought there was little doubt as to the law. In cases occurring early in life, there was a strong history of cancer in the family as a rule, but not in cases occurring late in life.

The PRESIDENT referred to the case of two sisters who suffered late in life from cancer, the parent having died from cancer in early life.

Mr. BUTLIN thought that in this case there was no evidence of strong tendency to cancer. The Collective Investigation Committee were about to issue a card enquiring especially into the question of heredity of cancer.

Dr. NORMAN MOORE, in reply, thought the law was well established in reference to certain varieties of structure, and it might apply to certain varieties of epithelial structures.

Uterine and Ovarian Disease in Amphibian Birds and Mammals.

Mr. J. BLAND SUTTON exhibited a series of specimens which served to show that flexions of the uterus were not

confined to the human race. The first was an example of retroflexion in a macaque monkey; the second specimen showed acute anteflexion in a bonnet monkey; the third, acute lateral flexion of the uterus to the right side, also in a monkey. In the last two specimens, the pelvis was considerably distorted, as a result of rickets. Two other specimens, illustrating anteflexion of the uterus, were taken from deer; one hyomoschus, which had, a short time previous to its death, given birth to a young one; the other from a molucca deer. The pressure of the anteflexed fundus in the last case had caused atrophy of the anterior wall of the uterus. The uterus of a kangaroo was shown, in which both Fallopian tubes had become greatly distended on account of the accumulation of caseous material in their interior, due to some obstruction of their openings into the uterine cavity. Some of the contents of the tubes had probably leaked into the peritonæal cavity, and had given rise to fatal peritonitis. Mr. Sutton stated that ovarian disease was not uncommon in animals born in confinement, but seemed to be very rare in "wild animals." He observed that it had long been shown that some cysts in the broad ligament frequently arose from abnormal distension of the tubules forming the "organ of Rosenmüller" (the parovarium). He had made an investigation with a view to determine how far the notion of cystic dilatation of functionless tubules held good. The results, briefly stated, were, that male toads possessed the remains of Müller's ducts in a well marked degree; and it was no uncommon thing to find these ducts, which in the male toad were functionless, dilated in their lower third into cysts, some very small indeed, but others of considerable size, and affording indisputable testimony to the origin of cysts from a pre-existing duct. About two hundred and fifty frogs and toads were examined to test the point, and about ten well marked examples of the cyst were found; they were, as a rule, arranged symmetrically. In birds, as in frogs and toads, upon the Müllerian ducts devolved the duty of conveying the ova from the abdomen to the outer world. In the embryo chick, there were normally two oviducts; but the left duct alone persisted, whilst the right one usually disappeared, though now and then a small rudiment of the lower end, from a quarter of an inch to an inch long, remained attached to the cloaca. It might become the seat of cystic change, and in some cases assumed considerable proportions. The occurrence of these cysts was by no means unfrequent; and their presence was injurious, for a cyst might become detached, and set up fatal peritonitis. A curious fact, first pointed out by Hunter, was occasionally noticed; a hen-bird would lay aside the sober plumage of her sex, and take on that of the cock. This fact had been attested by several naturalists of eminence; and Mr. Sutton exhibited a drawing of a hen golden pheasant now living in the Zoological Society's Gardens. Two years ago, she assumed the resplendent dress of the male bird; the only difference being, that there was no white rim to the pupil and no spurs. She lived quite happily with her mate, and they did not fight. This singular change was always associated with disease of the ovaries or the oviduct. In mares, cysts in the meso-salpinx were so frequently found, that in fifty old mares, taken at random, two-thirds possessed cystic ovaries, the cysts varing in size from a grape to an orange, and in number from three or four to a dozen. Careful examination of these cysts had convinced him that they arose by dilatation of the tubules of the parovarium, brought about by the increased blood-supply to the ovary in old age, due to the dilatation of the ovarian veins, much as was seen in the prostate of men advanced in life. Among other animals, he had met with cystic ovaries in a tiger who was born in this country and lived in confinement for twelve years. The cysts were small, numerous, and pedunculated, resembling the incipient cysts so frequently seen about the ovary and Fallopian tubes in virgins. Cystic tumours were also shown from a cat, a goat, and a tree-porcupine. He had brought these facts before the Society, not as mere curiosities of disease occurring in animals, nor as interesting in that they illustrated truths which might *à priori* have been anticipated, but because they demonstrated, unquestionably, that there was a strong tendency for functionless ducts to dilate into cysts.

Mr. Doran said that removal of the ovaries in the young human female was not necessarily followed by loss of feminine character. A large number of thin walled parovarian cysts sprang from the hind part of the parovarium. Papillomatous cysts were sometimes found in these cases, and he asked whether Mr. Sutton had found any such growths. Gaertner's duct was frequently persistent though not always patent. These did not always lead into the urethra, but had been traced sometimes into the vagina near the cervix uteri.

Dr. Drewitt thought that the hen bird taking on male plumage was usually ascribed to old age, but he would ask if disease of the right tube really interfered with and spoiled the function of the left ovarian tube.

Mr. Eve referred to a case in which cyst of Müller duct caused a large tumour. He agreed with Mr. Doran in his view of the cyst behind the ovary. True parovarian cysts had a fluid of low specific gravity, and had no albumen, a point of diagnostic importance.

Mr. Sutton said that the cysts contained albumen; he had not met with any papillary cyst. Such might, however, be developed from the remains from the Wolffian bodies. Gaertner's duct, when patent, often became the seat of cysts. In reply to Dr. Drewitt he said that disease on the right side did not interfere with the function of the left side.

Hydronephrosis from Papillary Growth.

Mr. Knowsley Thornton showed the specimen and drawing taken from a female, aged 32, with cystic abdominal tumour. She had had pain in right loin, colic, and hæmaturia nine years previously. Under the anæsthetic the diagnosis of hydronephrosis was made, and an operation performed by right lateral incision. Three pints of urine, sp. gr. 1011, trace of albumen, were drawn off from tumour during operation. A papillary growth, backed by a calculus found overlapping orifice of the ureter. Probably the papilloma was congenital, and the calculus had formed subsequently. The communication with the bladder was shut off. The left kidney was felt to be enlarged at the time of the operation. The patient recovered.

Bones in Tabes Dorsalis.

Mr. Hopkins showed specimens from two cases of this disease. In the first there was an old fracture of the neck, with changes identical with those of rheumatic arthritis. The patient had presented well marked symptoms of tabes, but no gastric crises; bulbar symptoms appeared towards the close. The right hip joint was too freely movable, and the right knee joint contained an excess of fluid. Left optic neuritis and contracted field of vision had been noticed. In the second case the patient had well marked tabes; there was effusion into the right ankle joint, and also a spontaneous fracture of the left femur. Optic neuritis was observed, and bulbar symptoms had been present. The femur and articular ends of the bones forming the knee and ankle joints presented irregular cartilaginous surfaces, due to ulceration and wearing down of the cartilages. A ring of new cartilage, in part ulcerated, had formed round the head of the femur. The fracture had firmly united.

Card Specimens.

Mr. Knowsley Thornton—(1) Cystic kidney removed by abdominal section. (2) Scrofulous kidney removed by abdominal section.

Mr. Hutchinson, F.R.S.—A drawing of a case of gangrene of the finger in a case of diffuse morphœa.

Dr. Hale White—(1) Ulceration of trachea after tracheotomy. (2) Primary encephaloid cancer of liver.

Mr. W. Arbuthnot Lane—Fracture of sternum.

Dr. W. B. Hadden—Bacilli with cancer of the liver.

Dr. F. C. Turner—Traumatic aneurysm on renal artery.

Mr. Godlee—Extensive fracture of skull, with great separation, and corresponding laceration of brain opening latent ventricle.

Mr. Davies Colley—Synostosis of vertebral spine (living specimen).

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, November 5th, 1884.

H. Gervis, M.D., F.R.C.P., President, in the Chair.

The following specimens were shown :—

Tubal fœtation—Dr. Sydney Jones for Mr. Lawson Tait.

Fibroid uterus with two cystic ovaries, removed by operation.—Mr. Thornton.

Fibroid of uterus with cystic degeneration, removed by operation—Dr. Aveling.

Retroverted and adherent uterus with two prolapsed and adherent ovaries—Mr. Walter Griffith.

Hagedorn's surgical needles and holder—Dr. Bantock.

Double intra-uterine tube—Dr. W. Duncan.

Greenhalgh's spring pessary with glycerine pad—Dr. Godson.

A plea was raised for the revival of toughened glass specula by Dr. Heywood Smith.

On the severe and so-called "Uncontrollable" Vomiting of Pregnancy.

A contribution on this subject by Dr. Graily Hewitt was read. The author's object was to investigate the question as to the influence of morbid conditions of the uterus in giving rise to the disease. The facts and cases published and available for discussion of this question were now arranged and tabulated and analysed. The first series of cases were 32 in number, and included all cases the author had been able to collect in which the condition of the body of the uterus was noted and observed in cases of severe vomiting in pregnancy. In a second series of cases, 13 in number, the condition of the os and cervix uteri was particularly noted and described. These two series of cases constituted the clinical data available for use in the discussion of the question as to the influence of the condition of the uterus itself in causing the vomiting, and they included 10 cases observed by Professor Horwitz, of St. Petersburgh, 8 recorded by the author, 7 by Dr. Copeman, 2 by Stoltz, 2 by Dance, and single cases recorded by other authorities. In the series of 32 cases there were 28 cases of a very typical description, in which sickness of an intense degree of severity was present in the course of the first half of pregnancy. In the majority of these 28 cases the vomiting was so severe that the question of artificial abortion arose. In 23 of these cases the uterus was in a state of decided anteversion or anteflexion, and in 12 of these 23 cases, there was impaction of the anteverted or anteflexed uterus in the pelvis. In one case the uterus was anteverted slightly, but had been considerably anteflexed shortly before the pregnancy occurred. In 4 of the 28 cases, the uterus was retroverted. It thus appeared that out of the 28 cases in question, the uterus was decidedly altered in shape and position in 27 cases, and in the one case remaining was anteverted slightly. The cervix was thickened and unduly hard in 3 of the 32 cases, and much thickened in 6 cases. In the other series of 13 cases, the cervix was described as very hard in 4 cases. In 2 cases (of the 32 series) pus was found between uterus and decidua after death. Excessive sensitiveness of the uterus was present in most of Horwitz's cases, and in four or five what Horwitz termed parenchymatous inflammation. The remarkable feature in the series of 32 cases was that in all the cases where attempts were made to raise the uterus from its displaced position, and when this attempt was successful, the vomiting ceased; whereas, when the attempt failed, the vomiting continued, and the patient died, the exceptions being those in which artificial abortion was induced, and one in which abortion occurred naturally. In some of the cases, artificial abortion was had recourse to as a primary procedure. Of the 32 cases 11 died, 20 recovered, in 1 result not known. The 20 recoveries included 6 after induction of artificial abortion, 1 natural abortion, 7 after manipulative treatment and replacement of uterus; 6 following positional treatment, rest, anti-inflammatory remedies, &c. The second series of 13 cases were, with one exception, cases in which the new treatment suggested by Copeman was carried out, and in which no record was given as to the state of the body of the uterus. In these 13 cases recovery took place. The author concluded: (1) That the cases in which the disease is due to some other organ than the uterus are so few in number (only 1 in the series of 32) that they may be almost excluded from consideration. (2) That in the large majority of cases the disease presents itself during the first half of pregnancy. (3) That the evidence points to interference with the normal expansion and growth of the gravid uterus as the condition of the production of this dangerous affection, and that this is most frequently brought about by or in connection with retention of the bulk of the uterus in the bony pelvis, in 88 per cent. the uterus being anteflexed or anteverted, and in 12 per cent. in a state of retroversion, the other conditions met with being hardness, resistance or unusual rigidity of the os and tissues of the cervix. (4) There appear to be two factors to be considered capable of interfering with the expansion of the uterus (*a*) incarceration with flexion or version; (*b*) undue hardness, and rigidity of os and cervix. These may be conjoined in a given case. It appears to be borne out by the facts recorded that the incarceration is the more important of the two factors, as a rule at least. The facts appear to point to the occurrence of embarrassment in the expansion of the uterus very early in the pregnancy, such as might be expected to be occasioned by a previously flexed state of the uterus or by a congested indurated state of the cervix, or by the two conditions combined. As the pregnancy advances, the congestion and swelling are intensified, and the resistance to expansion thus increased. It appears probable that the particular cause of the sickness observed is the compression of the nerves situated in the tissues which are especially exposed to compression, viz., those around the cervix uteri, and especially those near the internal os. Copeman's success in the treatment of severe sickness by dilating the internal os is evidence in this direction. The importance of the flexion element has been denied, one principal objection being that sickness is not always present when the uterus is flexed. But the case is the same in the non-gravid uterus; severe sickness is not seldom due to flexion of the non-gravid uterus, while flexions are observed without sickness. Corroboration of the author's views are contained in Gehrung's recent paper. As a rule, severe sickness is limited to the first half of pregnancy, in a very few cases it persists longer; in these rare cases, the cause may be rigidity of the tissues round the internal os, persisting to a late period. As regards treatment, the first indication is to secure the normal upward movement of the fundus uteri, to relieve the incarceration of the uterus, when present, if that be possible, and to prevent its occurrence by a properly arranged method of treatment. Absolute rest in the supine position if anteversion be present or on the face or side if retroversion be present, and the use of the knee-elbow position will be required. These measures suffice in many cases. If the uterus be fixed, gentle continuous pressure must be applied internally by the fingers, or by an air-ball, and the position maintained by a suitable pessary. These measures failing, Copeman's procedure of dilating the cervix should be employed. The last alternative, induction of artificial abortion, will, it is believed, be rendered unnecessary if the other less severe measures are applied sufficiently early.

[The discussion, which was adjourned soon after its commencement, will be given in the notice of the next meeting].

The Female Internat in Paris.—The projected permission of women to become *internes* of the Paris hospitals, which the new Préfet is, it would seem, about to grant, excites great opposition on the part of the medical officers of the various hospitals. At a meeting of the Paris Hospital Medical Society (composed exclusively of these officers), called expressly to consider the question on the 5th November, after a warm address on the part of Professor Verneuil in favour of the ladies, and a brilliant reply by Professor Trélat, the meeting almost unanimously pronounced against the project, there being only four votes in its favour.

GENERAL CORRESPONDENCE.

OVER-PRESSURE IN SCHOOLS.

[To the Editor of the Medical Times.]

SIR,—A somewhat important point in connection with this question has lately come under my notice, which should, I think, be clearly understood and duly regarded by all who are concerned in the present controversy as to the existence or the prevention of over-pressure. Dr. Crichton Browne has given evidence, and it is apparent from the recent manifesto of the school teachers themselves, that a large body of teachers believes that over-pressure exists. Mr. Fitch, the apologist of the Code, practically maintains that the danger of over-pressure is fore-stalled by the vigilance of the teachers on this point, and that their desire that children who are in their opinion unfit should be "exempted" or withdrawn from the examinations constitutes a safety valve which may be trusted to regulate the prescribed pressure. Mr. Fitch says in his now notorious memorandum, that on a visit paid by him and his assistants last year to schools containing upwards of 40,000 children, "the exceptions desired by the managers and teachers had been almost always freely sanctioned, except in cases of truancy and unexplained absence." The Code, moreover, provides as follows for this matter of exemption. (Art. 109, *e.* 6). "The following, amongst others, will be considered reasonable excuses for with-holding a scholar, or not presenting him in a higher standard; *delicate health* or prolonged illness; obvious dulness or defective intellect, temporary deprivation, by accident or otherwise, of the use of eye or hand, &c." It would thus seem that if this rule were strictly carried out (and it would only be strictly carried out, especially as regards the words I have underlined, by means of some kind of medical inspection) the evil of over-pressure might be reduced to a minimum if indeed it did not disappear altogether. Now it is obvious that if the teachers' "exemptions" are to be relied on as in any sense a practicable safety valve, such as Mr. Fitch apparently considers them to be, the principle on which they are made is all-important to the question at issue. A recent visit to two large Board schools gave me considerable insight into the matter, and I have reason to believe that the conclusion to which I came would be applicable to every school under the Code. I was asked by a manager to visit certain Board schools with him, in order to indicate, if possible, the children who, from reasons of ill-health, should not be pressed for the forthcoming examination. I found on arriving, that from most of the classes, in expectation of my visit, several children considered to be proper subjects for "exemption" were picked out by the teachers for my inspection. In nearly every case these children were dullards, or "very backward"; some of them indeed obviously from their conformation and physiognomy deficient in intellect, most of them stupid, but scarcely any in such a condition of ill-health, nervous or otherwise, which need have prevented them learning the little all that it was possible for them to learn. The obvious and indeed freely avowed principle on which the teachers had placed these exceptions before me was, that the children could not learn, and therefore could not pass the examinations. In one class only were two orders of "exceptions" placed before me. In this instance a highly-intelligent male teacher had put aside as usual a group of dullards, but also a group of children whom he said he thought would suffer from being pressed, but whom he should be obliged to press against his will if they were not exempted. These children were all intelligent enough, but some were obviously very delicate, and others had been but a short time at work — one regulation of the Code is, that a child who has been in regular attendance during half a school year, should be presented with those who have had the whole year's work. With pressure, the teacher said, which he himself thought harmful, these children would pass well enough. This, however, was the only case in which a teacher seemed to have any notion whatever of making an exception for the child's sake rather than his or her own. The sole object of the teacher's exemptions is to keep up their percentage of passes, for on that their credit, and, indirectly, their position depend. It is clear that the cases on which the regulations of the Code are likely to press most hardly are such as are not likely to be detected by most teachers with the best intentions, but would often be a source of vexation to the teachers' souls if they were withdrawn, for many of them would be bright and industrious enough to do their schooling credit. The teachers are of course in no way to be blamed; they must do their work in the best way they can; but it must be clearly understood and loudly proclaimed that if over-pressure can take place under the Code, the teachers' exemption principle as urged by Mr. Fitch is no safety valve whatever. They do not except the cases which would be harmed, while but little harm could be done by any educational Draco to most of those whom they wish to withdraw.

It may perhaps be conceded to the defenders of the Code that it is suitable to the average child who is well fed, housed and cared for, and subject to no hereditary disease, but the grave question in many London districts at least, is how many children do not come up to this desirable average. That a very large number do not it requires no medical eye to see, and from experience gained elsewhere in addition to my recent visit to these two schools I am sure that, in the East of London at least, there are very many children ill-clad and ill-fed enough to render the question of any educational pressure at all in their cases sadly out of place, and almost grotesque.

I am, Sir, yours &c.,
H. B. DONKIN.

[To the Editor of the Medical Times.]

SIR,—The following was unfortunately omitted from the list of short histories of chorea cases, which you were good enough to insert under the above heading last week:—Nellie L. P., aged 6. "Has always been a sharp child; quick in learning; works hard when at home; always spelling."

I am, Sir, yours, &c.,
F. D. DREWITT.

THE PHYSIOLOGICAL DEPARTMENT AT EDINBURGH UNIVERSITY.

[To the Editor of the Medical Times.]

SIR,—I observe that some notes of mine in previous numbers of the *Medical Times* have called forth a long and angry letter from Professor Rutherford, which appears in your issue of Saturday. Will you permit me to reply to his strictures as briefly as I can?

In the first place he goes back to a remark of mine in your number of October 11th, with reference to Dr. Gibson's resignation, and waxes indignant because his departure was deplored, and regret expressed that he seemed not to have met with sufficient encouragement to induce him to stay among us. Now, I would ask Professor Rutherford to note that no blame was attached to any particular person in connection with this matter, and certainly it was neither expressed nor understood by me that he was in any special way answerable for his assistant's resignation. What I meant to indicate was, that there must be some fault in a system which permitted the withdrawal from our school of so many able physiologists just at a time when their training as teachers was more or less completed, and when we should be justified in expecting their real work as investigators and superintendents of laboratory work to commence. From the way in which Professor Rutherford supposes the blame directed to him and the elaborate defence he thereupon proceeds to make, one would almost suppose that some element of personal unpleasantness had entered into the circumstances of Dr. Gibson's resignation. With evident complacency, Professor

Rutherford gives a list of former assistants who during the past eight years have been withdrawn from our school in order to fill chairs in various home and colonial schools of medicine. He evidently seems to regard this result as in every way satisfactory, and certainly no one admits more readily than I do that it is a compliment to the school of physiology here. But I would ask Dr. Rutherford whether, admitting an unexampled capacity on his part for training professors of physiology, he will undertake to say that the teaching of physiology in the university has gone on without hitch in spite of the frequent changes of *personnel* in his staff which have occurred during the past eight years. It is all very well and proper to train physiologists for chairs in other schools, but is it not Professor Rutherford's first duty to see to the efficiency of his own? Is it right that the status and emoluments of the senior assistant in what is probably the largest physiological department in the world, should be such that the first vacancy in any provincial or colonial school at once attracts him to compete for it? Does he suppose that the assistant working directly under him, doing all or nearly all the practical teaching in his department, influences physiological teaching less than the occupant of a chair in Leeds or Sydney? Would the gentlemen holding these appointments not have found a better outlet for their energy as teachers and investigators as senior assistant in such a department as we have here, and would not the benefit to physiology have been greater than as matters are? If Professor Rutherford would apply himself to improve the position of his assistants so as to induce them to remain longer with him, his time in training them might be saved, his energy directed to greater advantage, his department enhanced in efficiency, and physiology both as regards teaching and investigation greatly benefited. I do not mean for a moment to assert that Professor Rutherford is in any way specially answerable for the state of matters as they stand at present, nor did I suggest such a thing, but I unhesitatingly affirm that a condition of things which permits a biennial change of the official in his department next in importance to himself is deeply to be deplored. Nothing which Professor Rutherford's letter contains proves the contrary.

Professor Rutherford next refers to some remarks of mine regarding the matter of a text-book. He suggests that I attempt to induce his students to "worry" him about writing a text-book. I believe that it is the almost unanimous wish of his students that he should write a text-book, and I certainly suggested that they were quite within reason in asking him to complete either his text-book or his "Notes" begun last year. It may enable you readers to understand the state of the case if I make the following statement. It is supposed to be a special feature of the medical faculties of the Scottish Universities that they recognise the lectures of other teachers besides their own as qualifying students to appear for examination. Thus, theoretically, a certain amount of free-trade is introduced into the teaching for the M.B. While this is nominally so, there is on the other hand, rightly or wrongly, a deeply rooted opinion among students, that it is well for them to be more or less familiar with the expressed opinions of the professors who act as chief examiners as well as teachers. This can only be accomplished in one of two ways. Either the student must attend the professor's class, or else read a text-book of which he is the author, or one which accurately reflects his teaching. In 1880, Professor Rutherford published Part I. of a "Text-book of Physiology" which covered about an eighth part of the course. From time to time during the past three years the second part has been announced by the professor himself, but has been as frequently deferred for some reason or another. Last session, as the result of considerable pressure on the part of his students, he published a small volume of 160 pages, entitled, "Notes of Lectures on Physiology. Fasciculus I." This contained notes on part of the physiology of the blood, the physiology of respiration, and part of that of digestion. They were, so far as they went, admitted to be excellent, and of great value to his students. In a note prefixed to this volume, Part II. of the text-book was again announced as likely to appear this year. I need hardly say that the hopes so raised have not been as yet realised. I may further state that Professor Rutherford has a peculiar way of ending the parts of his books somewhat after the manner of the serial stories in the weekly "dreadfuls." Let me quote the concluding sentences of both his books so far as completed. The test-book ends thus: "By transferring the actual vibrations of the muscle by resonance to a strip of flexible metal, Helmholtz proved that the note actually produced by the——" and the "Notes" thus: "Fig. 16 shows a fairly constant normal secretion of bile, falling during the later hours of the experi——"

I would ask any of your readers if they know any method more calculated to whet the appetite for Part II. than this mode of closing Part I.? It is hard enough for the reader of the weekly serial to have to stop in the middle of a murder; what would he think if he were compelled to stop in the middle of a sentence, let alone the middle of a word? And yet Professor Rutherford says his students "worry" him if they ask him to relieve the suspense of four years!

Professor Rutherford then deals with the subject of research in his laboratory. He states that his laboratory is always open for research, and then proceeds to explain why it is so empty of researchers. First, he says, on account of the Vivisection Act, and, secondly, because of the comparative want of a direct bearing of physiology on medicine. I always thought that in order to understand morbid processes we must first be acquainted with the normal ones, and I should consequently have supposed that the bearing of physiology on medicine was *specially* direct; but since Professor Rutherford says it is not so, I must, I presume, take his word for it.

Next he details the results of the work during the past session. All I can say on reading these is, that they are even less than I had supposed; and if Professor Rutherford thinks they are worthy of the department over which he presides, most men will admit that he has the virtue of being easily pleased. He certainly does not flatter his colleagues when he says he has done more research during the past ten years than any of them, but that is their matter. If more men cannot be got to work than there are at present, what in the name of wonder was the purpose of building such an establishment? And if research-fellowships are necessary in order to induce men to devote themselves to physiology, would it not have been wiser to devote less money to the multiplication of rooms, and have employed the rest for the payment of some men to come and work in them? Professor Rutherford says he has devised laboratories which will serve for centuries to come. Would it not have been better to let the "centuries to come" take care of themselves, and contrive to accomplish a little work in the present one?

Professor Rutherford occupies a distinguished and privileged position. He need not complain if his distinction exposes him to criticism, and his privilege involves obligations. He has practically the monopoly of the teaching of physiology in a gigantic school; the generosity of the public has provided him with unsurpassed accommodation. He admits that he is responsible to "the minutest detail" for the extent and design of the laboratories he governs; have not the public a right to demand that he assumes the responsibility of employing them to the best advantage? The same remarks apply to all his colleagues; they will certainly be required to give an account of their stewardship. They are the guardians of public property; the public have given ungrudgingly, and will unquestionably claim the right of enquiry as to its administration.

I have the honour to be, Sir,

YOUR EDINBURGH CORRESPONDENT.

Edinburgh, November 17th, 1884.

[To the Editor of the Medical Times].

Sir,—Professor Rutherford, in his attempt to answer the charges of your Edinburgh correspondent has wandered into side issues which have little to do with the main question, but which show that he is still sore on the defeat his party sustained in the University in connection with the Medical Bill of last year. He talks of the "delusions" entertained by members of the Edinburgh Extra-mural

School regarding the attitude of certain professors to that school. Does Professor Rutherford really mean to assert that there were no good grounds for the so-called "delusions?" Does he forget the determined fight he and his party made to maintain the extraordinary preponderance of votes given to the Universities, and to Edinburgh University in particular, on the proposed Medical Board? Has he forgotten the letter which appeared in the *Scotsman* of Thursday, May 17th, 1883, under the signature of "Justice?" Does he imagine that it was not well known in Edinburgh that that letter, with its unjust attacks on Edinburgh teachers, and unmanly references to "disappointed" and "rejected" candidates for University chairs emanated from a University source, and was written by a professor? Truly if professors ever managed to dissemble their love they did it then. Professor Rutherford's answer about his late assistant is insufficient. Without doubt private influences may have induced that gentleman to return to Queensland, but there is no doubt here that Dr. Gibson himself was under the impression that he had been treated with scant courtesy by certain of the professors, because of the active part he took in trying to improve the status of university assistants. I do not know who your Edinburgh correspondent is, but there is no doubt he represented a state of feeling that is very prevalent among the younger members of the profession here.

I am, Sir, yours &c.,

AN EDINBURGH GRADUATE.

THE ENGLISH CONJOINT EXAMINATION.

[To the Editor of the Medical Times].

SIR,—I fear the new examination scheme of the English Colleges of Physicians and Surgeons will, unless modified, tend to perpetuate one of the weak points of ordinary English medical education. In almost every other country instruction in Science precedes instruction in subjects purely medical, and in our universities the examinations are so arranged that the student is encouraged to acquire a knowledge of Chemistry before he commences to study Physiology. But it seems that according to the new scheme the student's first examination is to include Chemistry as well as Anatomy, Physiology, and Materia Medica, and he will thus be led to attend lectures on the first three of these subjects simultaneously as heretofore. This combination is objectionable on several grounds. An average first year's student cannot give due attention to all these subjects at once, and Chemistry is habitually neglected, as most lecturers at medical schools know only too well. Again, some knowledge of Chemistry is essential to the due comprehension of lectures on Physiology, but how can this knowledge be secured if instruction in the two subjects commences simultaneously?

Lastly, the combination of Chemistry with Anatomy and Physiology leads students to enter a medical school at an earlier age than they would if attendance on Chemistry were made to precede studies purely medical. Education is hardly advanced enough in England for all the examining boards to insist on such preliminary instruction in Science as is required abroad, but surely a movement in the right direction may now be made by *allowing* students to pass the examination in Chemistry and Chemical Physics before commencing their strictly medical work. They would thus be encouraged to attend a course of Science in the year preceding their entrance on the study of Physiology and Anatomy. If the present combination of subjects is made compulsory, students who take such a course will be placed at a disadvantage, since the examination in Chemistry will be separated from the antecedent instruction by more than twelve months.

I am, Sir, yours, &c.,

D. J. LEECH.

The Owens College, Manchester, November, 1884.

INVENTIONS AND IMPROVEMENTS.

MEAT PREPARATIONS FOR INVALIDS.

MR. GEORGE MASON, of 417, King's Road, Chelsea, has entered into competition with other well-known makers in the preparation of meat essences and other specialties for the use of invalids. We have examined his essence of beef, his concentrated beef-tea in skins, and his savoury meat lozenges, and have found them to be pure and of good flavour. The beef essence, which is the form best suited for medical cases, is especially worthy of recommendation.

MEDICAL NEWS.

THE ROYAL COLLEGE OF SURGEONS.

AN extraordinary meeting of the Council was held on Wednesday last, to discuss Mr. Heath's resolution relative to the election of President and Vice-Presidents, and for other business. In Mr. Heath's unavoidable absence, through indisposition, Mr. Thomas Smith took charge of the first motion: "That the office of Vice-President be for the future held for one year only by the same person."

This was seconded by Mr. Allingham. After a discussion the motion was lost. Six members voted for, fourteen against it, three members were absent, and the President did not vote. The minority included Mr. Thomas Smith, Mr. Allingham, Mr. Holmes, Mr. Cadge, Mr. Lawson and Sir William MacCormac. The majority included Mr. Erichsen, Mr. Marshall, Mr. Savory, Mr. Lund, Mr. Wood, Mr. Power, Mr. Hutchinson, Sir Spencer Wells, Sir Joseph Lister, Mr. Bryant, Mr. Hulke, Mr. Croft, Mr. Hill and Mr. Durham.

The second Resolution, "That the President be elected annually by the Council from among its Members, and that no President hold office for longer than five years," was then moved and seconded, and finally withdrawn by permission of the Council; whereupon Mr. Cadge moved as a substantive motion, "That the President be elected annually by the Fellows in a manner to be hereafter agreed upon by the Council." To this an amendment was moved by Mr. Marshall, seconded by Mr. Wood, and carried *nem. con.*, "That the subject of the election of President be referred to the Committee on Charters and By-laws, to report thereon to the Council." This was also carried as a substantive motion. This Committee consists of Sir James Paget, Mr. Erichsen, Sir Spencer Wells, Mr. Marshall, Mr. Lund, Mr. Cadge, and Mr. T. Smith, together with the President and Vice-Presidents, *ex officio*.

It was also resolved, on the motion of Mr. Marshall, seconded by Mr. Holmes, and carried *nem. con.*, that "The communication from the Association of Fellows, and the accompanying recommendations be also referred to the same Committee to report thereon to the Council."

UNIVERSITY OF LONDON.—M.B. Examination:—

First Examination—George Elliott Caldwell Anderson, Guy's Hospital; Frederick William Bennett, Owens College and Manchester Royal Infirmary; William Henry Bowes, Guy's Hospital; Edmund Percival Cockey, St. Mary's Hospital; Edgar March Crookshank, King's College; John Roberson Day, University College; Harry Lord Richards Dent, King's College; John Philip Glover, St. Thomas's Hospital; William Ayton Gostling, B.Sc., University College; Charles David Green, St. Thomas's Hospital; Charles Gross, Guy's Hospital; Frederick David Irvin, University College; Frederick William Caton Jones, St. Bartholomew's Hospital; John Hervey Jones, Owens College and Manchester Royal Infirmary; Arthur Hamilton Nicholson Lewers, University College; Langton Philip Mumby, Westminster Hospital; Francis George Penrose, University College; John Joseph Powell, University College; Frances Helen Prideaux, London School of Medicine for Women and Royal Free Hospital; Charles Edwin Purslow, Birmingham School of Medicine; Ernest Septimus Reynolds, Owens College and Manchester Royal Infirmary; Rolla Edward Rouse, St. Thomas's Hospital; Frank Rushworth, St. Bartholomew's Hospital; Herbert Ritchie Spencer, University College; William Thorburn, B.Sc., Owens College and Manchester Royal Infirmary; Alfred Jefferis

Turner, University College; John Foster Vince, Queen's College and Hospital Birmingham; Frederick Womack, B.Sc., St. Bartholomew's Hospital; Henry Robert Woolbert, University College.

Second Division—Joseph Rosamond Adie, University College; Daniel Elie Anderson, B.A., B.Sc., University College; Hugh Reeve Beevor, King's College; Letitia Caroline Bernard, London School of Medicine for Women and Royal Free Hospital; Samuel Ferguson Bigger, University College; James Grierson Brown, Liverpool Royal Infirmary; George Frederick Cooper, St. Thomas's Hospital; Joseph Dobson, Leeds School of Medicine; William Arnold Evans, Owens College and Manchester Royal Infirmary; William Wadham Floyer, Guy's Hospital; Robert Garner Lynam, King's College; William Herbert Lister Marriner, St. Thomas's Hospital; Charles Joseph Parkinson, Owens College and Manchester Royal Infirmary; John Raglan Thomas, St. Bartholomew's Hospital; Theodore Thomas, Universities of Aberdeen and Edinburgh.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, November 13th, 1884:—

Alfred Naylor Darlington, Queen's College, Birmingham; David Davis, King's College; Joseph Jewitt Dickinson, Cambridge and London Hospital; Alfred Dudley Edginton, St. Bartholomew's Hospital; Albert Ernest Foster, Leeds School of Medicine; Ernest Humphry, St. Bartholomew's Hospital.

King and Queen's College of Physicians in Ireland.—The following Licentiates in Medicine of the College, having complied with the By-Laws relating to membership, pursuant to the provisions of the Supplemental Charter of 1878, have been duly enrolled Members of the College, viz.:—

Henry Lionel Smith, Lic. Med., 1869, Kirkwall, Orkney; Thomas F. Young, Lic. Med., 1877, Bootle; Frederick Joshua Roberts, Lic. Med., 1878, Enniscorthy.

At the usual Monthly Examinations for the Licences of the College, held on Monday, Tuesday, Wednesday and Thursday, November 10, 11, 12 and 13, 1884, the following candidates were successful, viz.:—

For the Licence to practise Medicine:—

Robert Abraham, Aughnacloy, County Tyrone; John Martin Coates Cole, Clones, County Monaghan; Eugene Crowley, Bandon, County Cork; Ignatius P. Doyle, Dublin; John J. Gaynor, Roxboro', County Roscommon; Daniel Kenny, Ballyconran, County Wexford; Patrick Joseph Kiernan, Dysart, County Westmeath; Annie McCall, London; John McGuiness, Dublin; James Longheed Rowlett, Dublin.

For the Licence to practise Midwifery:—

Robert Abraham; John Martin Coates Cole; Eugene Crowley; Ignatius P. Doyle; Thomas Frizell, M.D., R.U.I., Dungannon; John J. Gaynor; Charles Hayden, M.D., R.U.I., Carrick-on-Suir; Daniel Kenny; Patrick Joseph Kiernan; Marcus Moore, London, M.D., R.U.I., Myroe, County Derry; Matthew McAulay, M.D., R.U.I., Castlewellan, County Down; Annie McCall; John McGuiness; James Longheed Rowlett; Hugh Smith Morrison, M.D., R.U.I., Garvagh, County Derry; William Alexander Wadsworth, M.D., R.U.I., Brookeboro', County Fermanagh.

Royal College of Surgeons.—Mr. William Scovell Savory, F.R.S., Vice-President of the College, will deliver the annual "Bradshaw Lecture" on Thursday the 4th proximo. This lecture was founded by the widow of Dr. William Woods Bradshaw, F.R.C.S., some time Mayor of Reading, in memory of her husband. The lady left 1,000*l.* each to the Royal Colleges of Physicians and Surgeons for that purpose.

M. Pasteur.—It is stated that M. Pasteur is about to proceed to Rio Janeiro in order to study the yellow fever.

University of Cambridge.—Professor Humphry has been elected to represent the University in the General Medical Council for a further period of five years. Dr. Michael Foster has been elected President of the Cambridge Philosophical Society.

Edinburgh Royal Infirmary.—Several thousand pounds have been recently bequeathed to the infirmary, subject to certain life-rents.

The Hospitals Association.—The programme of papers to be read at the general meeting of the Association, to be held during the winter, has been prepared. The following subjects, amongst others, will be discussed:—"On Hospital Ships," paper by P. Murray Braidwood, M.D. "A Re-discussion of the Out-patients Question," paper by J. S. Bristowe, M.D., F.R.S. "On Horse Ambulances in connection with Hospitals," paper by Captain William Joyner, Chairman of the Northern Hospital, Liverpool. "The relation of the Provident Dispensary to the Hospital," paper by C. J. Radley. The opening meeting will be on the 6th December, but it will take the form of a soirée, and will be held at the rooms of the Medical Society of London, No. 11, Chandos Street, Cavendish Square, when the members will be received by the Council of the Association. We are asked to state that Mr. J. S. Wood, Secretary of the Chelsea Hospital for Women, and Hon. Secretary of the Bolingbroke House Pay Hospital, has been elected a member of the Council of the Hospitals Association, and that he has also joined Mr. J. L. Clifford-Smith as Hon. Secretary of the Association.

Glasgow University.—The election of a Lord Rector of the University to succeed the late Mr. Fawcett took place on Saturday morning. The proceedings were conducted in the Bute Hall. The unanimous selection of Emeritus Professor Lushington by the various clubs deprived the occasion of the interest and excitement connected with past rectorial elections, and the great bulk of the students did not turn out at the early hour of 9 a.m., knowing that the proceedings would be purely formal. This is the only occasion on which a Lord Rector has been unanimously elected by acclamation and without a contest. A torchlight procession took place in the evening in honour of the event, and a holiday was allowed on Monday by the Senate. A holiday in connection with the election of Lord Rector is generally given at the solicitation of the Lord Rector himself, but on this occasion the Senate were willing to draw a distinction, as the Principal said. It may be stated that the new Lord Rector, Edmund Law Lushington, LL.D., was for the long period of 37 years Professor of Greek in the University of Glasgow, a general favourite with his students, and as many said he not only "spoke Greek but thought Greek." The Lord Rector is a brother-in-law of Lord Alfred Tennyson, Poet Laureate. It was intimated last week that there was a likelihood of a request being made to Mr. Matthew Arnold to allow himself to be proposed for the vacant honour, but at the meetings which took place amongst the students, it was found that the desire was not unanimous. Dr. Lushington was then proposed and carried unanimously. He accepted, and was duly elected.

APPOINTMENTS.

Adams, Matthew A.—Analyst for the County of Kent. Re-appointed for one year.

Blumer, W. P., F.R.C.S.E.—Honorary Surgeon to the Monkwearmouth and Southwick Dispensary, *vice* James Murphy, M.D., resigned.

Calwell, W., M.D.—House Surgeon to the Belfast Royal Hospital.

Chadwick, Alfred, M.R.C.S. Eng., L.R.C.P. Edin., and L.S.A. Lond.—Medical Officer to the Heap District, Bury Union, *vice* Mr. James Henry Worsley, deceased.

Cufande, Frank, M.R.C.S. Eng., L.R.C.P. Edin.—Medical Officer to the Aele District, Blofield Union, *vice* Mr. W. H. Cufande, deceased.

East, C. H., L.S.A.—Assistant House Physician to King's College Hospital.

Fraser, T. A., M.B., C.M., M.R.C.S.—House Surgeon to the North Riding Infirmary, Middlesbrough.

Galpin, George Luck, M.R.C.S. Eng., L.S.A. Lond., M.D. and Mast. Surg. Queen's University, Dublin.—Assistant Medical Officer and Dispenser at the Asylum of the Central London Sick Asylum District, *vice* Mr. Edward Davis, resigned.

Gibb, W., M.B.—House Surgeon to Barnhill Hospital, Glasgow, *vice* Thomas S. Dunn, M.B., resigned.

Grimsdale, T. B., B.A., M.B., M.R.C.S.—Assistant Medical Officer to the Children's Infirmary, Liverpool.

Hall, W. W., M.B., C.M. Edin.—Resident Medical Officer to the Kilburn General Dispensary.

Harris, T., M.D. Lond., M.R.C.S.—House Physician to the Radcliffe Infirmary, Oxford.

Hasell, E. S., L.S.A.—Physician Accoucheur's Assistant to King's College Hospital.

Heaton, Frederic Luxmore, M.B., M.R.C.S., L.K.Q.C.P. Dublin, —Medical Officer to the St. Asaph District and of the Workhouse, St. Asaph Union, *vice* Mr. L. Lodge, resigned.

Hewitt, F. W., M.B. Cantab., M.R.C.S.—Administrator of Anæsthetics to Charing Cross Hospital.

Hodges, Herbert Chamney, M.R.C.S. Eng., and L.R.C.P. Lond.—Medical Officer to the Fourth District, Hertford Union, *vice* Mr. Herbert Busy Hodges, resigned.

Hodgson, G. G., M.R.C.S., L.S.A.—Physician's Assistant to King's College Hospital.

Hughes, Edgar A., M.R.C.S., L.S.A.—Assistant House Accoucheur to King's College Hospital.

Hutchinson, Samuel John, M.R.C.S. Eng., and L.D.S.—Lecturer on Dental Surgery and Pathology at the Dental Hospital of London, *vice* Coleman, resigned.

Jacomb-Hood, C., M.R.C.S., L.S.A.—House Surgeon to King's College Hospital.

LANE, ALEXANDER, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the Presteigne District, Knighton Union, *vice* Mr. Richard Harding.
LITTLEWOOD, J. O., L.R.C.P., M.R.C.S.—Consulting Surgeon to the Walsall Cottage Hospital.
MENZIES, J. H., M.R.C.S., L.S.A.—House Surgeon to the West London Hospital.
MOLONY, J. L.K.Q.C.P., F.R.C.S.I.—Resident Medical Superintendent of St. Patrick's (Swift's) Hospital for Lunatics, Dublin.
OAKES, HENRY, L.R.C.P. Edin., L.F.P.S. Glasgow.—Medical Officer to the Loppington District, Wem Union, *vice* Mr. J. G. Wilson, resigned.
PARKINSON, SIDNEY GEORGE, M.R.C.S., and L.S.A.—Medical Officer to the Second District, Wimborne and Cranbourne Union, *vice* Mr. W. Wyke-Smith, resigned.
PEARSON, SILVESTER, M.D., M. Ch.—Professor of Materia Medica in Queen's College, Cork, *vice* Prof. O'Keefe, deceased.
PENNY, FRANCIS, M.R.C.S., L.S.A.—House Surgeon to King's College Hospital.
REID, FRANK, M.R.C.S. Eng., L.R.C.P. and L.M. Edin., and L.S.A. Lond.—Medical Officer to the Sixth District, St. Saviour's Union, *vice* Mr. J. Tunmer, resigned.
RUNDLE, EDMUND, L.K.Q.C.P., L.M., L.R.C.S. Irel.—Medical Officer to the Sitluey District, Helston Union.
SHEARS, C. H., L.R.C.P., M.R.C.S.—Assistant Surgeon to the Liverpool Eye and Ear Infirmary.
STEWART, A. H., M.R.C.S.—Resident Medical Officer of the Male Lock Hospital, Dean Street, Soho.
TRIMMER, HENRY B., M.D., M.R.C.S., L.S.A.—Medical Officer to the Third District, St. Neot's Union, *vice* Dr. Walker, resigned.
TURNER, N. H., M.R.C.S.—House Surgeon to King's College Hospital.

VACANCIES.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—Resident House Physician. Salary, £65 per annum, with board, lodging and washing in the Hospital. Candidates must be duly registered. Applications with qualification and testimonials to be sent to the Secretary (from whom further particulars can be obtained), on or before Decr. 9th.
ALSTON WITH GARRIGILL.—Medical Officer for the Second District, in succession to Dr. Walter R. S. Jefferies, resigned. Area, 24,000 acres. Population, 2,333. Salary, £8 per annum.
ASHBOURNE UNION.—Medical Officer for the Calton District, in succession to Mr. James B. Hall, deceased. Area, 12,171 acres. Population, 1,638. Salary, £18 per annum.
BOROUGH OF NOTTINGHAM.—Medical Officer of Health. (*For particulars see Advertisement.*)
BRENTFORD UNION.—Medical Officer to the Sixth District, in succession to Dr. Hunter, deceased. Area, 2,920 acres. Population, 8,086. Salary, £60 per annum.
ERPINGHAM UNION.—Medical Officer for the Northrepps District, in succession to Mr. Arthur E. Fluder, resigned. Area, 4,916 acres. Population, 1,170. Salary, £24 per annum.
GREAT NORTHERN CENTRAL HOSPITAL, CALEDONIAN ROAD, N.—House Surgeon. (*For particulars see Advertisement.*)
KING'S COLLEGE, LONDON.—Chair of Materia Medica and Assistant Physicianship. (*For particulars see Advertisement.*)
NORFOLK AND NORWICH HOSPITAL.—House Surgeon. (*For particulars see Advertisement.*)
ROYAL CORNWALL INFIRMARY.—House Surgeon. Salary, £120 per annum, with furnished apartments, fire, light, and attendance. Candidates must be legally registered to practise both in medicine and surgery, and unmarried. Applications, stating age, with testimonials to be sent to the Secretary, Royal Cornwall Infirmary, Truro, before November 27th.
ROYAL FREE HOSPITAL, GRAY'S INN ROAD.—Senior Resident Medical Officer. (*For particulars see Advertisement.*)
ST. MARY ABBOTT'S, KENSINGTON.—Analyst for the Parish, in succession to Mr. E. L. Cleaver. Salary, £50 per annum, and 5*s.* for each analysis.
THE BIRKENHEAD EYE AND EAR HOSPITAL AND DISPENSARY.—Honorary Surgeon. Applications, stating qualifications, &c., to be sent to the Honorary Secretary, on or before November 22nd.
WESTERN OPHTHALMIC HOSPITAL, 155, MARYLEBONE ROAD, W.—Surgeon. Candidates must be Members or Fellows of the Royal College of Surgeons of England, and have attended Ophthalmic Practice for twelve months. Applications to be sent to the Secretary at the Hospital, on or before November 22nd.
WEST LONDON HOSPITAL, HAMMERSMITH, W—Assistant Ophthalmic Surgeon. Candidates must be Fellows of one of the Royal Colleges of Surgeons of London, Edinburgh or Dublin, and not practising Midwifery or Pharmacy. Applications and testimonials to be sent to the Secretary by November 27th.

DEATHS.

BOWMAN, H. T., M.D., at 22, Windsor Terrace, Newcastle-on-Tyne, on November 13th, aged 30.
CARROLL, WM., M.D., at 37, Lady Lane, Waterford, on November 8th, aged 81.
LANGSTAFF, CHARLES, M.D., of Bassett, near Southampton, at Havre, France, on November 9th, aged 51.
MOSELEY, W. A., M.D., at Cheltenham, on November 14th, aged 31.
RAINEY, GEORGE, M.R.C.S., of St. Thomas's Hospital and Brixton, on November 16th, in the 84th year of his age.
SALL, W., M.D., Deputy-Inspector of Army Hospitals, &c., at Munster Terrace, Fulham, on November 15th, aged 73.
SEWELL, J. J., M.R.C.S., L.R.C.P., at Guy's Hospital, on Nov. 10th.
WILSON, JOHN, Surgeon-General, Madras Army, retired, at Lonsdale, Newton Abbot, on November 13th, aged 56.
WRIGHT, THOMAS, M.D., F.R.S., at 4, St. Margaret's Terrace, Cheltenham, on November 17th, aged 75.

NOTES, QUERIES, AND REPLIES.

VITAL PROCESSES IN ADVANCED LIFE.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—In your last number you quote Professor Humphry's statement that wounds in the aged heal more rapidly than at earlier periods of life and the same remark applies to the union of fractures, and you observe that the professor apparently has not been able to form any theory entirely satisfactory to his own mind and so he offers no explanation. I would suggest that these results admit of explanation as it is a well recognised fact that wounds or ulcers do not heal, or the process of repair in fractures commence while inflammation be present. In early periods of life the circulation is vigorous and the nutritive functions are in activity and inflammation in consequence more apt to follow injury. These attendants of youth are absent in age, therefore the healing processes are not disturbed by inflammation, indeed there may be so little energy that sloughing may result in cases of wounds or disunion in cases of fracture. In the same number of your journal, I observe a communication of a case where the person was grey at the age of 62, and the original colour of the hair was restored when he died at 83. I think it would be worth while to enquire how long he was dyeing before he departed this life.

I am, Sir, yours &c.,

M.D.

"*Querist*,"—1. If the Guardians elect a duly qualified and resident District Medical Officer the appointment is valid without ratification by the Local Government Board; but no salary can be legally paid to the Officer unless it has been previously sanctioned by that Board. If the Medical Officer appointed is not fully qualified, or does not reside in the District, the Guardians can only employ him for such period as the Local Government Board approve. 2. You can obtain it as a subscriber, but it is cheaper to obtain it as a Member.

Royal College of Surgeons.—Essays for the Jacksonian Prize, awarded by this institution, for the present year must be sent in on or before Wednesday the 31st proximo. The subject for this prize for the ensuing year is "the Diagnosis and Treatment of such affections of the Kidney as are amenable to direct surgical interference."

APPOINTMENTS FOR THE WEEK.

Friday, November 21 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Society of Medical Officers of Health, 1, Adam Street, Adelphi, London, 7.30 p.m.—Meeting. Mr. Alfred Spencer, on "Noxious Trades."

Saturday, November 22.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, November 24.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Medical Society of London, 8.30 p.m.—"A Discussion on Anæsthetics"—(1) Paper by Mr. Woodhouse on "The Brain" Discussion opened by Mr. G. H. Bailey.

Tuesday, November 25.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Anthropological Institute, 8 p.m.—Dr. J. G. Garson, "Exhibition of a Prehistoric Skull from the Island of Antiparos;" Dr. W. H. Coffin, "Note on the Abnormal Dentition of a Hairy Boy from Russia;" Miss A. W. Buckland, "Facts suggestive of Prehistoric intercourse between East and West;" Mr. Horatio Hale, "On some Doubtful or Intermediate Articulations;" Mrs. Erminie A. Smith, "Remarks on the Customs and Language of the Iroquois."

Royal Medical and Chirurgical Society, 8.30 p.m.—Henry Morris, M.B., F.R.C.S., "A Successful Case of Lumbar Nephrectomy for Renal Calculus."

Wednesday, November 26.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operatious), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Hunterian Society, 8 p.m.—Dr. Goodhart, on "Water on the Brain;" Dr. Herman, on "The Number of Persons who Suffer from Headaches;" Mr. Charters J. Symonds, on "The Spontaneous Disappearance of Nævi."

Thursday, November 27.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Parkes Museum, 74A, Margaret Street, Regent Street, 8 p.m.—Lecture by Dr. Alfred Carpenter, "On Progress and Co-operation in Sanitary Work."

Friday, November 28.

Clinical Society of London, 8.30 p.m.—Adjourned discussion on Mr. Morrant Baker's Paper, "On Cases of Charcot's Joint Disease." Living cases will be exhibited at 8 p.m., as well as some illustrative specimens sent by Professor Charcot. If time permit, a "Case of Tumour of the Frontal Lobe, with few symptoms," by Dr. Hale White, will also be read.

Quekett Microscopical Club, University College, Gower Street, 8 p.m.—Ordinary Meeting. W. F. Bates, "On the supposed Sexual Threads in Zygnemacea.

CLINICAL LECTURES ON THE DISEASES OF WOMEN.

By J. MATTHEWS DUNCAN, M.D., F.R.S.

Physician Accoucheur to St. Bartholomew's Hospital.

II.—*On Endometritis.*

Having no supreme central authority to define terms and punish deviation from proper use of them, we have much to suffer. Who can tell what anyone means by endometritis? Often its use is the parent or the child of ignorance and confusion; often it is a cloak of ignorance and confusion.

In beginning this lecture I must make it clear what I do not mean by it and what I do mean by it. It is not chronic cervical catarrh or "ulceration," a disease which is sometimes called cervical endometritis. The uterine cervix is a different organ from the uterine body, and endometritis is inflammation of the corporeal endometrium, that is the mucous membrane of the body of the womb. Those who speak of cervical endometritis speak of this as corporeal endometritis. Time is too precious to permit the survival of such long names as "corporeal endometritis." Further distinction has been made of inflammation of a part of the corporeal endometrium, that of the fundus uteri, fundal endometritis; and this I cannot adopt, in the meantime at least. No doubt a part, not the whole, of the corporeal endometrium may be inflamed, partial endometritis, but that is a very different matter from describing as a distinct disease an endometritis of the fundus.

Inflammation of a part or of the whole of the corporeal endometrium I shall call endometritis, and in so doing I believe I concur with the best literary examples.

I may, in passing, mention to you the occurrence of endometritis in pregnancy—decidual endometritis. Sometimes a hypertrophic endometritis is seen in abortions, sometimes a croupous, sometimes a catarrhal, with or without accumulated hydroperione. Exaggerated hypertrophic endometritis is occasionally observed in abortions after fever, and I have seen it well developed after ordinary typhoid. With or without syphilitic infection you may have decidual endometritis, affecting the vera, and producing projecting masses or little tubera, or affecting the serotina and resulting in the production of fibrous tissue and sometimes consequent adherent placenta. Then you have catarrhal inflammation of the vera,

often seen in advanced pregnancy, and often the cause of the hydrorrhœa gravidarum.

Again, you have endometritis of the puerperal state, sloughing or diphtheritic, seen in *post-mortems*. Rarely you have purulent endometritis after delivery, with very copious flow of laudable pus; often you have catarrhal endometritis, with copious flow of thin, and generally blood-tinged, serous fluid—lochial catarrh.

Then you have, after the puerperal state has passed, it may be long passed, and this whether the delivery was a mere abortion or at the full time, a purulent endometritis, the discharge being very copious and often fœtid, and all produced by a retained, often a putridly decomposing, bit of decidua, or of placental tissue. This disease you will not cure otherwise than by removal of the retained mass.

These various examples of endometritis have all connection with pregnancy, and are not, in ordinary medical writing or speaking, thought of when this disease is the subject.

The endometritis of elderly women, that is, of women after the menopause, is seldom heard of, but it is a true endometritis, not extremely rare, and we have had it illustrated in our work in "Martha." I call it the endometritis of elderly women because I have never seen it except in such. Here is a museum specimen of it, as observed in a case of cancer of the cervix. The internal os uteri had become closed—acquired atresia—and the body expanded into a globe as big as a small orange, its walls somewhat thinned (they were distended by pus), its internal surface lined by a thin pyogenic membrane. When an elderly woman has occasional or constant bloody, or blood-tinted, discharge, or purulent discharge, and still more when the discharge is fœtid, it is natural to entertain the gravest suspicion that she has cancer of some of the internal genital organs; and yet it may be only a senile vaginitis or an example of the endometritis of elderly women. Several such cases I have seen diagnosed as hopeless cancer of the uterine body and yet they were easily cured. No doubt this is rare good luck, and it is important to know it. In this disease there is generally little or no pain, the woman notes only the new and alarming discharge. If you dilate the uterine cervix by tangle tent, and this must be done carefully, you find the uterine cavity somewhat expanded. Instead of having practically only two dimensions, it has three, or is more or less globose. Your finger passed into it may feel nothing peculiar, or it may feel a portion of the mucous membrane slightly elevated, and softer than the rest, and this is plainly the diseased part. It is cured by local applications, and the cure may be effected after the disease has lasted for years. In the few cases which I have observed, a 10 or 20 grain to the ounce solution of nitrate of silver has been used, injected through a hollow probe; or powdered nitrate of silver has been passed in Lallemand's port-caustique. But, alas, in most such cases you are doomed to failure. Good may come from your cauterisation, but the disease persists. It is a commencing epithelioma, not an endometritis. It is only in the earliest stages of commencing malignant disease that you are liable to this confusion, and I know of no way of diagnosing except retrospectively. If it is cured it is an endometritis. Retrospective diagnosis is not of much value to your patient. It is prognosis that you desiderate.

The next endometritis that I mention is the pseudo-menstruation of fever and of rheumatism. It is known to be an endometritis, for, after death in such cases, the mucous membrane is found in a catarrhal condition, swollen, red, and bleeding. The ovaries also are found to be affected simultaneously. In another place, indeed, speaking of ovaritis, I have pointed out its frequent association with corporeal endometritis; and pseudo-menstruation.

Now, at length, I come to what would be in the present day called the real (the common!) endometritis; and I know nothing more unsatisfactory. I often hear of it, but very rarely do I find any evidence of its existence. Much is said of it, and I remind you that many authors delight in long descriptions of what is little known or not known. There is, truly, little to be said of what is known. If you go back to the French journals and elsewhere to read the first and starting descriptions of this disease, you will be very much disappointed—little else than verbiage. The disease is often called granular; but who has seen or knows anything about these granulations? No doubt a granular condition, seen after death, has been described, and this is very valuable; but in the case whose *post-mortem* description I remember, there were no symptoms during life. In reading and in conversation I often met with a granular condition observed during life, but all the time I am inwardly most sceptical. I have looked for it carefully and often, but I have never seen it or felt it. Then it is said, Oh! take a curette and scrape it out, and then you have the diseased tissue in your hands. But the scrapings are very small and you would get the same by scraping a healthy uterus. There is, indeed, nothing more unsatisfactory.

Yet I have no doubt there is endometritis; and, if it has any symptoms, they are very ill-defined, or unknown as yet. The disease is suspected by finding menorrhagia or a prolonged secretion of thin bloody fluid. A great writer says the fluid is glairy, but this is a mistake. The cervix is more or less patulous. If the cervix is dilated by tangle tent the body of the uterus is found to be expanded, its cavity having three dimensions, or being globose, and its surface very soft, or feeling villous. Two cases with all these characters we have recently had in "Martha," and I would not consent to founding a reliable description of a disease on two cases. These cases we treated by ergot and painting the uterine cavity with tincture of iodine. If this dilatation and painting is thoroughly done, you may bring your patient into more danger and disease than resulted from the original malady. You must, therefore, be very careful and circumspect. Of course the local remedies can be applied without dilatation, in a somewhat hap-hazard fashion; for without it your diagnosis is imperfect.

To give you an idea of the rarity of the disease, or of anything like it, I may tell you what I did one winter. You know what a large number of cases come to the out-patient department and how they are attended to by Dr. Godson. Well, I secured his special attention to

finding for me cases of endometritis that we might specially study them that winter. We got not one.

Endometritis with copious secretion of pus, or of thin, watery, or blood-tinted fluid, is not rare in connection with uterine fibroids; and this is perhaps partly explained by the liability of these tumours to all degrees or kinds of inflammation. I show you here a museum specimen of a uterine fibroid, in which the uterine cavity was dilated and filled with pus.

Then membranous dysmenorrhœa is generally supposed to be the result of inflammation of the menstrual membrane—menstrual endometritis. The mucous membrane gets hardened, blood is effused at the junction of its superficial and deep layer, and so the superficial layer is separated, and then it is thrown off in large flakes, or rarely even unbroken, and is discharged on the first or second day of the flow. The discharge of small soft thin flakes of the superficial layer is common in healthy menstruation. It is the discharge of the entire membrane (very rarely) or of large patches, as thick as a shilling or thereabouts, that constitutes this disease. The dysmenorrhœal pain accompanying the discharge is not of the greatest, not such as is seen in a case of dysmenorrhœa spasmodica. You distinguish the disease from monthly abortion, the membrane in this case being much thicker and richer than the dysmenorrhœal membrane and the disease being cured by celibacy. You will find it hard to do any good in a case of membranous dysmenorrhœa. I cannot tell you any treatment that is likely to even ameliorate the condition. Yet, of course, you regulate the general health and you may try iodide of potass or corrosive sublimate. In the virgin, I meantime advise you to abstain from local treatment.

Chronic endometritis is described as sometimes ending in atrophy of the mucous membrane and complete arrest of function. The mucous membrane is said to be replaced by a thin layer of fibrous tissue, from which the gland tubes have disappeared, its surface covered not by cylindrical but by flattened or scaly epithelium.

Nothing has given such an impulse to this subject as the paper of Olshausen, published a few years ago, on what is called fungous or tuberous endometritis, and you may wonder why I have put off to the end of my lecture such an important disease of the mucous membrane of the cavity of the body of the uterus. The reason is that I do not regard it as an inflammatory disease—not an endometritis. You would not call a myxomatous polypus an inflammation. Neither would I so call this. It is a general myxomatous hypertrophy of the mucous membrane, and a similar condition is, I believe, not uncommon in the nose. It is not spontaneously separated and discharged. It is, in my experience, a rare disease. We have had one good case in "Martha," and I have seen lately two good cases in private practice.

The disease has no distinctive symptoms. There may be pelvic malaise; there may be anæmia from loss of blood, for generally there is profuse menorrhagia with more irregular and less severe metrorrhagic loss; or rarely a thin watery discharge may flow, frequently more or less blood-tinted. I have seen the disease only in married women and it entails sterility.

When you examine, you find the uterus, including the cervix, bulky. The latter is pale and may be excoriated. The cervical canal is enlarged, and the swollen mucous membrane of the body I have, in one case, seen as a red mass hanging into or almost through it. This is very deceptive, and you are pretty sure to say to yourself—Oh, here is a clear case, a mucous polypus hanging in the cervix, a simple matter. You seize it with volsella, and it is so soft that you get no real hold. You seize it with forceps and it is compressed and almost disappears between the blades. Now you will perhaps suspect the real nature of the case, retrospectively remarking that there was nothing like a pedicle to the red mass. Then you dilate the cervix by tangle tent; and, passing your finger through it, you feel the enlarged uterine cavity filled with soft tissue, uniform in surface, or hanging in looped up or curtain-like folds. Then, with a curette such as I show, you scrape out this myxomatous tissue, or you may, with uterine forceps, pull it off in masses. You may get away one or two teaspoonfuls of it; and its bulk is small now compared with its bulk *in situ*, for it is an œdematous tissue and the distending fluid has run out. The removed masses are more or less hyaline and almost bloodless, or they may be firmer and distinctly blood-tinted.

This proceeding may cure the patient if the scraping has been complete, but the disease returns and returns, and you may have to scrape again and again. Besides scraping you may try caustics, such as nitric acid; and you may administer ergot to try to induce uterine retraction.

The masses removed by curette present, under the microscope, the characters of ordinary mucous membrane of the body of the uterus, little altered. The adenomatous malignant outgrowth from the endometrium is scarcely liable to be confused with this; it is much larger in mass, more solid in structure, continuous in increase, and has special histological characters.

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.
President of the Health Department, Social Science Association, and of the Epidemiological Society.

(Continued from page 538.)

Cretismus.[54]

Wherever Bronchocele is extremely prevalent in India, Cretinism may be found.

Our local medical literature contains a considerable amount of observation upon this disease.

Writing in 1859, Mr. McClelland stated that in one locality alone, during a halt of a few hours, Mr. Nicholson, of Bubnowlee, in the Goruckpore District, collected numerous children — *bowkuts*, or cretins — from an adjoining village for his inspection, as examples of the condition of the people in large tracts of country in

[54] I have thought it well to place Bronchocele and Cretinism together.

his neighbourhood. He found that ten per cent. of the children of the villagers where goitre prevails are *bowkuts*, or idiots. Many are deaf and dumb; their limbs weak and feeble; their features large and without expression; the eyes dull and vacant. They seldom live to attain adult age. Cretin children in these districts are generally, but not always, born of goitred parents. Sometimes one parent has goitre; more rarely the parents are free from the disease. Cretinism begins to show itself at a very early age; the goitre comes on later. Both forms of the disease sometimes go together in the same individual; but there are many instances of cretins without goitre. Mr. McClelland's remarks on the association of goitre and cretinism in Kemaon[55] deserve close attention. He considered that these diseases are intimately connected. He observed that, in the little hamlets where goitre prevailed to a great extent, the people were characterised by a want of enterprise and bodily vigour, as compared with their immediate neighbours, who were free from the disease. "In Goseragong the people are generally affected with goitre, yet there are no cretins among them. The same may be said of Deota; but in the villages of Salmora, Oliel, Goraght, Tomilly, and Ager, which contain 138 inhabitants, 78 had goitre, and 42 were cretins; while there was not one of the latter class to be found in any of those villages that were exempt from goitre. Hence it appears that, in a population in which goitre prevailed to the extent of rather more than 50 per cent., 30 per cent. were cretins; while, in the remaining portion of the people, amongst whom goitre did not extend to above 9 per cent., there were no cretins."

In that variety of goitrous disease which occasions cretinism, the patient is invariably seized before the age of five years, and the disease continues uninterruptedly throughout adolescence. During this time there is a depraved action of the absorbent system, shown in the monstrous development of certain organs; while the natural growth of others is proportionately suspended.

Hence the limbs are short and crooked, the spine distorted, the head often of enormous size, the features bulky and idiotic, and glandular swellings are common on various parts of the body, and seldom entirely absent on the neck. The cretins are not, in general, so imbecile as natural-born idiots. They retain at least some glimmering of reason acquired in childhood, which enables them to perform many useful offices. Cretins are sometimes seen without any great enlargement of the thyroid gland, but such cases are rare, and they are generally much deformed, so as not to be mistaken for congenital idiots. Tumours on the elbows, knees, and other joints, as well as along the course of the lymphatics, are common with the cretins of Ager and other villages in Kemaon.

In writing upon the diseases of Nepaul,[56] Dr. D. Wright notices that, in that country, cretinism, as usual, is an accompaniment of goitre, but the cases seen in Nepaul are by no means very numerous in proportion to the number of goitrous people that are met with."[57] Writing eleven years earlier, Dr. Wright's predecessor, Mr. John Brown, observed that "In the Valley of Nepaul and its vicinity, goitre and in many instances, cretinism prevails to a large extent." He adds that the towns of Deopatun and Nunksal "are affected with goitre and cretinism to a large extent." In his valuable "Observations on Goitre as seen in Oude," my friend Mr. H. M. Greenhow[58] maintains, apparently with too much confidence, that cretinism "is quite unknown throughout the Himalayan regions, and that, according to his own experience in Oude, it is equally unknown there." Out of his 300 cases of goitre he only met with one individual who showed the least sign of weak intellect. This was a boy who was not deformed in body in any way, but whose mind was evidently imbecile. He urges that it is not surprising that, in such a number of persons brought indiscriminately together, one should be found of less than ordinary capacity. Those he examined were generally as healthy and strong in mind and body as are the country people in any part of India he has visited. It will be noticed that, while stationed for a winter at Secrora, Mr. Greenhow "sent his servants and other agents out into the bazars of the town, to bring to him any goitred persons whom they might encounter; and in this manner he soon brought together 300 cases." Doubtless these were mostly sufferers of exceptional vigour anxious to obtain relief by medicine, while their torpid cretins remained inactively at home. At any rate, a special search for cretins by medical men who may travel through that district appears desirable.

Dr. Coates stated, in 1880,[59] that Chumparun is a peculiarly goitrous district. Goats and sheep, dogs and horses suffer from the disease. Cretins (*bods*) are frequently met with in goitrous villages.

In his paper on "Goitre," which I have cited in my notes on that disease, in speaking of the great prevalence of bronchocele in the districts about Motiharee, Segowlee, Bethiah, and on to Goruckpore, indeed, along the whole line of the Himalayan Teraie, Dr. Mouat says; that, in reply to the question "Have you seen any cases of goitre patients whose intellect was affected by the disorder? Captain Cunningham, who had treated some 25,000 cases of goitre, replied, "I have seen many cases of goitre patients whose intellect was decidedly affected by the disease, as, after the goitre was reduced, they appeared much more intelligent, and like rational creatures, which they were not before." He added, "However, there are so many idiots about this part of the country only slightly afflicted with goitre that it would be difficult to say whether idiotcy was actually induced by it, or the symptoms increased in those whose intellect was naturally defective."

Between London and the Snowy Range, Dr. J. Fleming saw many cases of goitre, but few cretins.

Surgeon-Major Ross[60] found goitre very prevalent in Kashmir, especially in the Sind Valley. It almost exclusively affects females. "Some cretins are to be seen."

In a paper on the Medical Topography of Orissa, published in No. X of the "Indian Annals," Dr. Shortt makes bare mention of the fact that "cretins are met with in many parts of the Hill Districts."

I am not aware that the above remarks by Brown, Wright, Greenhow, and Mouat have led to any systematic enquiry into the subject of cretinism in the Sub-Himalayan Districts. I shall be grateful for further information upon this important subject from brother officers who may visit those localities. Late research having shown that cretinism may attend congenital deficiency, or acquired disease of the thyroid, and may follow its ablation, it will be well to learn something regarding the mental condition of those innumerable native patients in whom goitre has disappeared under the use of biniodide of mercury ointment. In conducting such enquiry, valuable data may be looked for in the observation by Professor Kocher and Dr. Lardy, of Berne[61] who declare that a progressive cachexia, designated by Kocher *cachexia strumi priva*, is very liable to be induced by extirpation of bronchocele.

This they find to be characterised by great anæmia, tumefaction (especially of the face), and a diminution of intellectual activity, furnishing a display of symptoms resembling those of cretinism. Dr. Lardy adds that a remarkable feature in these cases is "the brutalized countenance these unfortunate persons assume, while they become incapable of executing any employment that demands intelligence." We are told that Professor Billroth, who has himself performed thyroidectomy 120 times, entirely denies that this condition is liable to follow the operation.

The experience of M.M. Jaques Louis and Auguste Revertin[62] confirms the observation of M.M. Kocher and Lardy. They noticed torpor of intellect, puffiness of the face and extremities, which, however, did not pit on pressure, and an alteration in the complexion, a whitish yellow colour, not that of anæmia or albuminuria, but similar to what is seen in some cretins. It is added, "These symptoms closely resemble some of those noticed in cases of *myxœdema* which have been recorded by Ord, Hadden and others, and the similarity is especially noteworthy from the atrophy of the thyroid gland which has been observed." A very important discussion on the association of cretinism and myxœdema with changes in the thyroid gland took place at the Pathological Society on the 23rd of November, 1883, and it is understood that the society will appoint a commission for the investigation of this question.

Although bronchocele is not endemic in the Delta of the Ganges, many cases present themselves there. I did not see cretinism or myxœdema in Lower Bengal.[63]

Diabetes.

Glycosuria is frequent among rich elderly natives in Calcutta, many of whom are fat and indolent and immoderately fond of sweetmeats. I heard of several fatal cases of carbuncle in such diabetic patients.[64]

Writing in 1871,[65] the Editor of the *Indian Medical Gazette* remarked that he believed that "among the upper and middle classes of natives in Calcutta, almost every family had lost one or more of its members from diabetes." Baboo Satcory Dutt had informed him that, in one of the most respectable and influential native families in Calcutta, No. 1 died of acute diabetes at the age of 65; No. 2, his eldest son, of chronic diabetes; No. 3, his third son, had chronic diabetes; No. 4, his fourth son, died of acute diabetes; No. 5, daughter of No. 1, now aged 65, has diabetes; No. 6, eldest son of No. 2, grandson of No. 1, died of chronic diabetes; No. 7, second son of No. 2, has diabetes; No. 8, eldest son of No. 4, has diabetes. In addition, the wife of No. 3 died of diabetes.

I saw, in India, three European gentlemen suffering from this disease. These cases were very chronic. Two of their number attained advanced ages. The third, a Bengal civilian, was found to be diabetic, by one of our best authorities, about sixteen years ago. As he is now a very robust man in green old age, it appears likely that the glycosuria was due to a transient cause. This case is probably explained by Dr. Wilks's observation that, in young diabetic patients, the tendency is sooner or later towards a fatal termination; whilst, in the old, the presence of sugar in the urine is often found in those who are suffering from mere dyspepsia or gout. Cases of diabetes have frequently been detected in India by noticing that flies and trains of large black ants visit the utensil. Morehead gives an account of six cases of saccharine diabetes in natives, all the instances of that disease of which he had personal knowledge in India.

Dr. Cayley relates[66] a case of removal of a scrotal tumour in a native which terminated successfully, although diabetes appeared three weeks after the operation, and recovery was retarded by repeated attacks of secondary hæmorrhage. In 1874, when the milk system in glycosuria was much under discussion, I showed, in the *Indian Medical Gazette*, that, in his Phthisiologia, or a Treatise of Consumptions, Dr. Richard Morton, who died in 1698, gave histories of milk treatment in diabetes.

I did not see *Purpura Hæmorrhagica* in India, and I have met with very few recorded cases.

In a report upon the health of H.M's. 54th Regiment in the Madras Presidency, Mr. Hamilton noticed[67] that six cases of purpura hæmorrhagica had been under treatment, one proved fatal; the immediate cause of death was effusion into the thorax after a very tedious illness. Two men were invalided for this disease. In the treatment, more decided benefit was derived from the use of quinine, with liberal diet and moderate use of wine, than from any other means.

There is[68] a very full report by Dr. Gamble of a case of purpura occurring in a private of the K. O. R. at Bellary, Madras Presidency. There were considerable ecchymosed spots on some and vibices on other parts of the body. There was also hæmoptysis. Two ounces of pure blood of arterial hue were spat up daily. There appear not to have been any febrile symptoms. On the fourth and seventh days there was profuse epistaxis. On the twelfth there was considerable hæmatemesis, followed by melæna. Oranges were then allowed. Slight epistaxis recurred from time to time, but he was convalescent in less than three weeks. According to the practice of the time, V.S. to eight ounces was employed on the twelfth day after the "considerable hæmatemesis." We are told that "the blood drawn separated after a few hours almost entirely into serum; the crassamentum consisting of a mere scum occupying the whole surface of the bleeding cup, of a dark sooty colour."

Mr. Raleigh[69] treated, in 1834, a stout well-made sailor, aged 21, who, having come from America in 123 days, had been about two months in Calcutta. On the voyage he had been fed principally on salt provisions, but since coming into port, had been liberally supplied with fresh meat and vegetables. He had invariably been in good health at sea, and during his last voyage "had been perfectly free from scurvy" or other complaint. When he had been about a fortnight in port, a "red rash" appeared, without any accompanying indisposition, on his face, chest, arms and thighs. The spots became daily more numerous, larger and darker for six weeks. Three days before his admission, "copious bleeding took place from the mouth, from which a constant draining of blood had continued." The reporter does not precisely indicate the source from which he considered that this hæmorrhage (the stools frequently contained large quantities of blood) proceeded, but perhaps the explanation appears in the following paragraph: On the dorsum of the tongue were five black *elevated* spots of the size of a pea, and on the inside of each cheek were two others of the size of a sixpence with irregular edges, the soft palate and uvula were thickly

speckled with petechiæ, the gums were *not* ulcerated." He had no contraction or stiffness about the joints. The face, chest, and trunk generally, but particularly at the sides, over the shoulders and nates, were thickly covered with spots, varying in size from that of a pin's head to the circumference of a large pea, and of various shades of colour, between bright purple and dark brown, not elevated. On the forearms and nates were several large vibices in stripes, as if produced by the lash of a large whip; these were very black, and irregularly raised so as to feel rough. His countenance was rather sallow. He declared, on admission, that he experienced no uncomfortable sensations or pain. His appetite was good and he slept well. In the first ten days of his treatment, there was occasional mention of feverishness and headache. There was considerable bleeding from the mouth for four days in hospital. From the fourth to the sixth day, much blood passed by the urine, which, for the first two of these days, was loaded with mucus. Upon the principle which then ruled practice—that hæmorrhage indicates V.S.—he was bled eight times from the arm during the first nine days "and lost at least 120 ounces of blood, independent of the enormous quantity which flowed from the mouth and was voided by the stools and urine. He took a powerful cathartic daily." On the sixteenth day after admission, he was reported "perfectly recovered, a little weak." It is added, "he was never so much reduced by the treatment as to be confined entirely to his bed. I found him daily walking about the hospital, and he always walked to the door or window of a morning, in order that I should examine the eruption."

My friend Dr. Herbert Baillie recorded[70] the case of a male infant to which he was called when it was nearly exhausted by hæmorrhage from the gums which he had lanced five days previously. The bleeding was with difficulty stopped by the application of nitrate of silver. There was the peculiar flea-bite appearance seen in purpura over the body and limbs. Dr. Baillie then recalled the fact that, during the two preceding months there had been an occasional appearance of maculæ on the trunk. There would appear a little lump under the skin nowise discoloured. In two or three days the swelling increased and was accompanied by an erythematous blush, which in a few days more extended, and became of a deeper hue, leading to the belief that suppuration was about to take place, when, in another day or two, being then larger in circumference than a rupee, the place became bluish, then green, and disappeared gradually like a bruise. The decline of these patches closely resembled the changes seen in cases of erythema nodosum, which it also resembled in the presence of fever. The house being low and damp, the family removed the child to a boat on the river, and to Calcutta, where recovery was speedy.

In 1878, Mr. Harden reported a fatal case of purpura hæmorrhagica in a Hindoo boy of 10. There was dry gangrene of both feet.[71]

The gaol returns for 1881 give the death from purpura of a prisoner in the Bombay Presidency, and three admissions of soldiers' children, all in the Bengal Presidency.

THE NUMBER OF PERSONS WHO SUFFER FROM HEADACHES.

By G. ERNEST HERMAN, M.B., Lond.,
Obstetric Physician to the London Hospital &c.

ONE point which is incidentally raised in the controversy between Dr. Crichton Browne and Mr. Fitch, relates to the frequency of headaches in children. Dr. Crichton Browne went into some schools, and asked those children who suffered from headache to hold up their hands; and he adduces the large proportion who did so as some evidence of the existence of over-pressure in those schools, quoting Sir Richard Owen to the effect that if more than five per cent. of children suffer from headaches, there must be something wrong. Mr. Fitch thinks enquiry to be answered by the holding up of hands a very rough and uncertain way of ascertaining the facts. But it seems to me that as the conclusion that headaches were excessively frequent in the schools under examination is drawn from comparing with Sir Richard Owen's estimate the number of headaches ascertained in answer to enquiry, a much more important fallacy lies in the assumption that Sir Richard Owen's opinion is correct. I have not seen any account of the evidence on which it is founded; and it is plain that its value entirely depends upon what steps Sir Richard Owen took to find out what proportion of children in general suffer from recurrent headaches.

I was led to make some enquiry into this point when commencing the study of the diseases of women, because I found headaches so frequently associated with these diseases, and, in works upon the subject, so commonly described as reflex effects of uterine disease. It seemed to me that before we could put down headache as a regular reflex effect of uterine disease, we ought to know whether headache is more frequently associated with uterine disease than with disease of other kinds; and whether it is more common in women suffering from uterine disease than in women of the same class who consider themselves in their ordinary health.

To get information on this point, I, in 1876 (when engaged as Medical Registrar to the London Hospital), went round the general medical wards, both male and female, and enquired of each patient whether *before the present illness* he or she had been subject to headaches. Those patients who said that headaches had come on with the illness for which they entered hospital I excluded altogether, putting down their answers neither as negative nor affirmative. I also excluded those patients, chiefly men, who said that they had had headaches after getting drunk, or in connection only with some equally definite occasional cause, and also those who entered hospital for some cerebral disease of which headache might be regarded as an early symptom. With these exceptions, I took every patient without any selection. As my object was only to get an approximate idea of the frequency of headache for my own guidance, and not to make a complete investigation of this intricate subject, I did not carry my enquiry very far. I regret now that I did not enquire of larger numbers. But as I can find no other numerical estimate of the frequency of recurrent headaches, I think even these small figures worth publication. It is well known that recurrent headaches are extremely common. Dr. Liveing says "there are few people who have not some acquaintance with it, either in themselves, their families or friends."[1] I enquired of 67 women, and 95

[1] "Megrim, sick headaches and allied disorders," 1873, p. 5.

men. Of the 67 women, 44 said they were subject to headaches; 23 were not subject to them. Of the 95 men, 25 said they were subject to headaches, while 70 did not so suffer. I have notes in some cases of the age at which the headaches began. I am sorry they are so few in number, but I give them for what they are worth. Of the 44 women, 16 said they had suffered from them as long as they could remember; 1 mentioned 7 as the age at which they began; 6 said they began at 15 or 16. Of the 25 men, 5 had had them as long as they could remember, 1 said since boyhood, 1 since the age of 12, and another since the age of 22.

The proportion of men to women suffering from headaches agrees fairly with the estimate formed by other investigators. Liveing,[2] basing his statement only on 53 cases, finds them slightly more common in women than in men. He quotes Labaraque, Calmeil and Lebert to the effect that headaches are much commoner in women, and Symonds, who found that out of 90 patients so suffering, 76 were women.

With regard to the age at which the headaches begin, all agree that they most commonly begin in early life. Symonds found that half his patients had suffered from them as long as they could remember; Liveing found that 11 out of 49 assigned a similar duration to their trouble, and that 16 out of 49 had begun to suffer before they reached the age of 10.

Out of my total of 162 patients 42·6 per cent. suffered more or less from recurrent headaches. Of the total number questioned 12·9 per cent. had suffered from headaches as long as they could remember, but information as to the age at which the headaches began was only obtained in less than half the cases. Taking the lowest enumeration, that of Liveing, as representative, it would seem that a third of the people who suffer from headaches begin to do so before they reach the age of 10. Applying this to my percentage, it would seem that, taking boys and girls together, about 14 per cent. of all school children might be expected to suffer from headaches. This estimate may or may not be correct, but I can find no other attempt to form an estimate based upon facts. I may point out that as the figures I use were collected from adults in the year 1876, School Board regulations could only have affected a few of them, and those not early enough for the blame of their attacks of headache to be attributed to the Board school.

It may be added also, that Liveing estimates that in half the cases these headaches are hereditary. It is of course well known that the attacks of headache are often excited by emotional disturbance, anxiety, or mental strain of any kind, and it must be admitted that a child subjected to undue educational pressure is liable to have inherited headaches thereby intensified in severity and increased in frequency. But before the mere fact of a number of children suffering from headache can be regarded as any evidence that educational over-pressure exists in a particular school, we need to know that headaches are more frequent in the children of that school than among children in general; and we need to know also the number of such children that inherit from either or both parents a tendency to recurrent headaches. And the same caution should be used in judging of the connection between headaches and uterine disease. That the catamenial period may provoke an attack of headache, and that uterine disease may cause headaches to be more severe and frequent, I think cannot be denied; but before setting down headache as simply a reflex result of uterine disease, we should enquire as to the patient's previous history as regards headaches, and also as to her family history on the same point.

[2] Op. Cit., p. 22.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

WESTMINSTER HOSPITAL.

A CASE OF CHOREA—DEATH, WITH SYMPTOMS OF ACUTE MANIA.

By H. B. DONKIN, M.B., F.R.C.P. Physician to the hospital; and
R. G. HEBB, M.D., Pathologist to the hospital.

(For the notes of the progress of this case we are indebted to Mr. T. SWAIN, House Physician.)

A. G., a girl aged 20, a cloth-sorter, was admitted into Westminster Hospital on July 30th, 1884, suffering from general and well-marked choreic movements, and manifesting also great excitability, knocking down a nurse soon after admission into the ward, and running downstairs screaming. She soon, however, quieted down and was got to bed.

The history of the case showed that the girl had been "very delicate" up to 14 years of age, but with the exception of having had scarlatina at four years old, had never been laid up. There had never been any symptoms of rheumatism. The father of the patient had suffered frequently from delirium tremens, and had much alarmed her mother two months before patient's birth. Just two months before admission, the patient was much frightened by being detained all night in an excursion train, which, by reason of some accident, was delayed in a siding. She complained immediately afterwards of numbness of the legs, great "nervousness," headache, loss of appetite, and of gradually failing sight. On the 26th July, she was first noticed to drop things, and the speech became affected, general chorea rapidly ensuing.

On admission a well-marked systolic bruit was heard over the præcordia, loudest at the apex. The heart's action was irregular, and the respirations jerky.

July 31.—During the previous night the patient was very restless, but appeared rational. She complained of palpitation and a feeling of a "ball in the throat." During this day she took food well, but was very talkative and did not sleep at all.

August 1.—No sleep last night. Menstruation began at four a.m. Patient talked nonsense all night, and continues to do so to-day. Fancies her mother is dead, and in the next room. Is very excited, and alternately shrieks out and has fits of crying. In the evening she was still more excited and incoherent, refused to take some chloral that had been ordered her, became furious, jumped out of bed and assaulted the nurse. At ten p.m. she had a hypodermic injection of morphia, and another in two hours afterwards.

August 2.—At two a.m. (two hours after the second hypodermic injection) the patient fell asleep for two and a half hours, then awoke suddenly and became almost unmanageable. At six a.m. the fury suddenly ceased, and she slept again for two hours. On awaking, the choreic movements were very violent, but otherwise the patient was tractable. About three p.m. she became again suddenly violent, turned the nurse out of the room, locked herself in and began breaking the furniture. The door was forced open, and the patient was with difficulty restrained from doing harm to herself and others. A hypodermic injection of morphia was given, but she continued to rave for about two hours.

Then she became exhausted and fell asleep. About six p.m. the nurse noticed a sudden change in her respirations, and going up to the bed found her dead. The temperature was immediately taken and found to be 107° F. In the morning it had been 100°, and had previously ranged between 97·8° and 99·6.°

Post-mortem examination made 36 hours after death. Body well-nourished. Rigor mortis nearly passed off. There are the usual signs of *post-mortem* decomposition, but though there is much blood-staining of the tissues, and considerable evolution of gas, there are no holes in the viscera. Brain 50 ozs. Dura mater adherent to the bone throughout; with this exception the meninges and their blood vessels seem fairly normal. The brain is of a green colour, and is very soft, especially in its anterior third, where, in places, it is almost fluid. The walls of the ventricles, although their cavities did not seem to contain any excess of fluid, were greatly disintegrated. There was nothing noteworthy in the cerebellum. The spinal cord, reserved for microscopical examination, was fairly firm except towards the lower end of the cervical region. The right pleura was adherent throughout; left pleura normal. At the apex of both lungs was a patch about the size of a bean, of caseation, encapsuled in a fibrous sheath and surrounded for a short distance by a net-work of old and quiescent tubercle. The mediastinal glands were much enlarged, one, the size of a pigeon's egg, being caseo-calcareous. The pericardium was normal. With the exception of the deep-staining of the endocardium, and the softness of its muscular tissue, the heart was quite normal. Careful examination was made of all the valves, but no trace of structural alteration could be detected. At the root of the aorta were several very small patches of commencing atheroma. There was nothing noteworthy in the liver, the spleen, the gastro-intestinal tract or the bladder. The pyramids of the kidneys were of a dark purple colour, while the cortices were pallid and relatively large; their weights were $4\frac{3}{4}$ and 5 ozs. The uterus was normal in position, its cavity was bathed by a thin sanious fluid; the left ovary contained a recent menstrual follicle. There was partial prolapse of the anterior vaginal wall. Hymen circular. Microscopical examination of the spinal cord was made from sections of the cervical, dorsal and lumbar regions. The sections show abnormal anatomical conditions. Throughout its extent, the anterior fissure is merely indicated by the presence of a small blood vessel, which in some places does not extend half-way to the commissure. This defect, most noticeable in the dorsal region, has produced an agglutination of the anterior columns, and apparently owing to the traction on the commissure, a triangular mass rises up between the anterior cornua, giving the appearance of a third or middle cornu. This pseudo-cornu seems to be composed of vertical and transverse nerve fibres with coarsish connective tissue and blood-vessels. In consequence, or rather as part and parcel of this condition of things, the central canal is not only much dilated in some places, but distorted into various curious shapes in others. The distortion is most marked in the dorsal region, the dilatation in the cervical. As this forward traction has been made unequally, the halves of the cord are asymmetrical, the asymmetry being most marked in the cervical region. In the lateral columns of the cervical enlargement and immediately adjacent to the posterior roots, the connective tissue has an almost fibrous appearance, and this fibrosis is almost limited to the side of asymmetry. In the lumbar region the peculiarities alluded to, although present, are but slightly noticeable. The blood vessels of the cord generally are large, tortuous, and very frequently unusually placed. Finally, the presence of bacilli would be expected from the condition of decomposition of the body, but how far the numerous micro-organisms in this particular case are to be considered putrefactive must be left an open question. Within the blood-vessels of the cord,

Fig. 1.—Cervical Region.

Fig. 2.—Dorsal Region.

The asymmetry, so marked in the cervical region, is unfortunately but little noticeable in the plate.

advancing along their coats, large numbers of rod-like bodies were detected. Within the vessels their position is irregular, and they are fairly uniform in size, while in the coats of the vessels they are seen as long filaments of unequal length, and lying parallel to the long axis of the vessel. Yet it must be added that a few were seen scattered about outside the vessels. The chief points to remark in this case seem to be as follows:—

(1) *The healthy condition of the valves of the heart: though there was a well-marked mitral murmur.* In this context we would quote another case (also unconnected with rheumatism) with a mitral murmur, in a child of five years old, whose death from other causes during chorea afforded an opportunity of examining its heart. The valves were carefully inspected, and found to be perfectly normal.

(2) The possible connection of the cerebral symptoms with the changes indicated after death. The brain was too far gone for microscopical examination, but the anterior part, as has been shown, was disproportionately softened. The temperature was found to be 107° just after death, and there was a remarkable number of bacilli in the blood-vessels of the cord.

(3) The abnormal condition of grey matter in the spinal cord. This faulty organisation may perhaps be considered in connection with the above-mentioned fright, sustained by the mother while pregnant, and with the unstable nervous condition of the patient as evinced by her history and symptoms. But, regarded by itself as an example of abnormal development, it seems worthy of record.

(4) The oncoming of the nervous symptoms, headache, failure of sight, &c., two months before admission, immediately after a great fright which seemed completely to upset her. (In this case there was no suspicion of rheumatism, either personal or hereditary.) It is unfortunate that her recurrent violence and her short life in the hospital made a thorough clinical examination of her nervous system quite impossible.

Medical Times and Gazette.

SATURDAY, NOVEMBER 29, 1884.

THE profession has suffered a serious loss in the death of Dr. Mahomed, the intelligence of which has been received by all who knew him, and still more by his personal friends, with feelings of the sincerest regret. We have given in another column as full a sketch of his career and character as our space allows, but may repeat here that the profession can ill afford to lose a man of such marked enthusiasm, industry, courage, and determination as Frederick Mahomed. His loss will be most severely felt at Guy's Hospital, where the influence of his earnest and unselfish enthusiasm upon the students, and the impact of his strong personality upon their minds, have been warmly appreciated by all his colleagues. The profession has also suffered considerable loss this week in the death of Leslie Maturin, of Dublin, who forms the subject of our second obituary notice. He, too, died of a zymotic disease, contracted in the course of his daily work. These two mournfully premature deaths, added to that of a London student, who died last week of small-pox, caught from a patient, should still further impress upon the public the serious character of the risks which daily threaten the life of the much-abused medical practitioner.

A CRY has been lately raised against the *bona fides* of the competitive examination through which candidates obtain, or fail to obtain, commissions in our naval and military medical services. It seems that Irish candidates have been rather markedly unsuccessful at these examinations of late, and, not unnaturally, perhaps, this is held in some quarters to be only a new instance of "injustice to Ireland." Nothing less than that could explain the failure of the candidates from the Irish medical schools! It was in expectation, it may be supposed, of finding some proofs of the suspected misdealings of somebody connected with the Burlington House examinations, that on Thursday se'night, Mr. Sheil asked the Secretary of State for a return of all the marks gained at the last two examinations for the Army Medical Department. Lord Hartington replied that, for obvious reasons, it is not the practice in any examinations to give the marks obtained by unsuccessful candidates, unless they can be designated by numbers; and in the examinations for the Medical Staff the candidates are not known by numbers. He stated that the vacancies had in all cases been filled by the candidates who obtained the highest aggregate of marks in the compulsory subjects of the examination, without failing to, at the least, reach the standards in all of them; and he added that marks in the voluntary subjects have value only in determining the place of a candidate who is already in the list of those who have succeeded in virtue of the marks gained by them in the compulsory subjects. We especially republish this part of Lord Hartington's reply, as it is of great importance to candidates, and though it is in accordance "with the published terms of the competition," we suspect it is very often overlooked or forgotten. Lord Hartington further said that he did not see why an unsuccessful candidate should not, on application, be informed of the marks he gained, and that therefore he should give directions accordingly; the more willingly as he understood such information can be obtained in the case of the Naval Medical Department.

THE Authorities of the War Office have determined that the regulations as to examinations for promotion to the rank of Brigade-surgeon shall be put in force at once. Lord Hartington stated in the House of Commons last week that vacancies in that rank have not been filled up since the issue of the circular of August 1st as to those examinations. The senior Surgeons-major who have to be examined are serving in all parts of the world, and no promotions are to be made till all their examinations have been held, and been considered. The home examinations are fixed for the 27th and 28th of the present month; those for the colonies on December 1st; and those for India as soon as the necessary arrangements can be made. The promotions made will be ante-dated to the time when the vacancies severally occurred, so that the officers promoted will not suffer by the delay. As the officers concerned will have had but very little time to prepare for the new ordeal it cannot be supposed that the examination will be a severe one; and as it seems probable, to say the least, that some of the officers affected must, in India and the colonies, be in stations where there are no medical officers of higher rank than themselves, it must be supposed that in such cases the examination will consist solely of paper work, in answer to prescribed questions. But it does not appear that any question was put to Lord Hartington upon this subject.

A DISCUSSION on anæsthetics was expected at the Medical Society on Monday last, but it was a signal failure. Mr. Woodhouse Braine contributed a very interesting paper on the subject—an abstract of which appears in another column—and as many specialists were present, some, we believe, by invitation, an instructive debate was expected. Thanks, however, to the intrusion of irrelevant subjects, such as vivisection, experiments on dogs, &c., there was a little beyond the opening paper, and some remarks by Mr. Bailey and

Mr. Eastes, a valuable evening was thus thrown away. Mr. Braine's paper was full of suggestions and valuable hints for the general surgeon, as well as for those who take up the subject of anæsthetics as a specialty. In this as in other topics there seem some broad differences of opinion ; but as to the greater safety of ether as compared with chloroform, there was complete unanimity. Mr. Bailey rather criticised the opening paper, in which nothing had been said about the dangers of anæsthetics when asphyxia is threatened. The best plan, he thought, was to rely upon vigorous artificial respiration; nitrite of amyl was of little good. He never gave bichloride of methylene, because of its uncertain composition and variable results. He did not think chloroform was so dangerous, when properly managed, as was generally made out ; and he thought a Clover's bag was the safest mode of administering it. He rather deprecated special anæsthetists, and thought every surgeon should be properly taught, and should be able to administer all anæsthetics whenever they were necessary. In country practice it was not possible always to get a specialist. Mr. Eastes thought that Clover's bag was far the safest way of administering chloroform, and that the next best method was that by Junker's apparatus, which was specially serviceable, when used with the small tube, in lengthened operations about the nose, mouth or palate. But he considered chloroform unsafe for adults, from its action as a cardiac depressor. For ordinary practice he strongly advised the use of the A. C. E. mixture. The exhilarating effects of the three parts of ether in the compound antagonised the depressing effects of the two parts of chloroform. But for safety he considered nitrous oxide gas and ether, the former alone for small operations, and the two combined for longer cases, the best form of anæsthetic for adults yet discovered. Mr. Eastes also referred to the methods of relieving patients threatened with syncope, and made some remarks on the preparation of the patients for anæsthesia ; he advocated, like all sensible men, that the anæsthetist's whole attention should be concentrated on his own work.

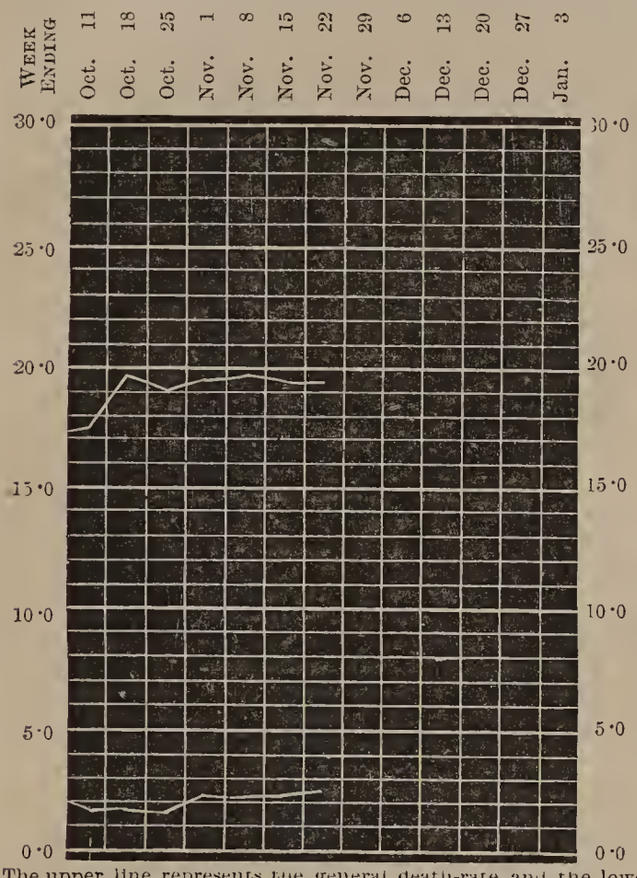
The Society of Medical Officers of Health received a notable accession of strength at its meeting on Friday the 21st instant, in the election of the unprecedented number of twenty-eight extra metropolitan members, besides four associates and five honorary members, viz.: Col. Sir F. Bolton, Capt. Douglas Galton, Professors Koch and Pasteur, and Mr. Trendell, the literary superintendent of the Health Exhibition. A paper on Noxious Trades was read by Mr. Alfred Spencer, whose official position under the Metropolitan Board of Works has given him an unusual acquaintance with the subject and practical experience of the best means for the prevention of nuisances arising from these manufactures. The paper, which was followed by a long and not uninteresting discussion, had been kindly contributed by Mr. Spencer, at the request of the secretaries, in place of one by a member on small-pox hospitals, the reading of which it was thought advisable to postpone until the decision on the Darenth case, judgment in which was not expected to have been given so soon.

The second dinner of the Oxford Graduates Medical Club was held at Limmer's Hotel, on Thursday, November 20th, when members had the privilege of introducing guests belonging to their own or to the sister University. There were present more than fifty members and about twenty guests. The chair was taken by Sir Henry Acland, one of the vice presidents, and he was supported on his right by Dr. Fincham, president, and had on his left Professor Humphry of Cambridge. Besides these, there were present Professor Burdon Sanderson, Mr. Pridgin Teale, Dr. Corfield, Dr. Fowler, secretary to the Cambridge Medical Graduates Club, Dr. Griffin of Weymouth, and many others both from the country and from London. A general meeting was held at which several new members were elected, and after dinner when the usual loyal toasts had been drunk, that of the Club was proposed by the chairman and was responded to by Dr. Fincham, who paid a warm and kindly tribute to the secretaries, whose exertions had been so satisfactorily rewarded by the success of the Club ; he concluded by proposing the health of the guests, coupling with it the name of Professor Humphry, who made an eloquent speech in reply, touching with great tact and delicacy upon the different systems of medical education pursued at the two Universities. The health of the chairman was proposed by Dr. Andrew, and after his reply, a very pleasant evening was thoroughly enjoyed by the members and their guests.

The London School Board, after a debate extending over several weeks, has at last decided, by a majority of twenty-four to twenty, to enquire into the subject of educational over-pressure ; but it has rejected, unwisely, we think, Sir E. H. Currie's carefully worded proposal that "the Committee be *authorised* to request the Presidents of the Royal Colleges of Physicians and Surgeons to name three medical practitioners whom the Committee *may* invite to report for the information of the Board upon the medical aspect of the question." As it is, we can see no guarantee that the Committee will be either willing to give due weight to, or able to duly appreciate, the medical evidence which, after all, much as it has been scouted in some quarters, is almost the only evidence worth taking on the question. We have all along contended for a commission or committee partly composed of medical men, and we see grave reasons to distrust, even in advance, the report of any committee of laymen. Justice, dealing with a single individual, often admittedly fails because there is no means of providing the judge with a medical assessor ; and here is an enquiry involving, according to the indictment, the life and happiness of thousands of individuals, and the decision is entrusted to a handful of laymen, many of whom have plainly manifested their bias against all scientific evidence.

The Registrar-General reports that 1,521 persons died in London last week, 816 being males. Of the total number, 333 were under the age of one year. The deaths from zymotic diseases numbered 176, being 69 below the corrected average, and giving a rate of 2·3 per 1,000. Small-pox counted 46 victims amongst

Londoners, a very high figure, especially when it is seen that there were no deaths from small-pox recorded in the other 27 great towns in England, and none in the 8 principal Scottish towns. The total number of cases under treatment at the end of the week was 768, the new cases having been only 149, or 50 less than the new ones last week. Scarlet fever had 36 victims,



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past seven weeks.

the same number as last week, whilst diphtheria claimed 31 deaths, the same number as in the first week in September, on which occasion the Registrar-General called attention to the fact that it was the highest figure ever reached. Of these 31 deaths, 18 occurred in children under 5 years of age, and 11 in persons between the ages of 5 and 20. Whooping cough was fatal in 24 instances; with one exception, the victims being all under the age of 5 years. The deaths from bronchitis numbered 203, exactly 100 below the corrected average. Our readers will probably not be surprised to learn that there were 3·5 hours of sunshine during the week; on no less than three days no sunshine at all having been recorded. There were 19 deaths from measles in Glasgow, and 16 from scarlet fever in Dublin.

The Conservative Graduates of the Edinburgh and St. Andrews Universities, if they have done nothing else, have, by bringing forward a candidate of their own way of thinking, succeeding in extracting a most interesting speech from Sir Lyon Playfair, the sitting Member. The speech, delivered on the 20th instant, drew together a large audience, comprising most of the Edinburgh professors and leading practitioners. Indeed we are rejoiced to see the medical profession giving such almost unanimous support to a representative, from whose political opinions many of them admit their dissent. Sir L. Playfair began by deprecating the introduction of politics into the contests for University seats, pointing out that such a procedure would lay those seats open to radical attack. He then made an eloquent appeal for the more liberal endowment of the Scottish Universities by the State, showing that the 38,000*l.* a year, by which it was proposed in the last University Bill to endow the four Scottish Universities, was less by 2,000*l.* than the sum granted annually to a single German University, Leipsic. Germany spent large sums in this way, because it knew that such expenditure was most reproductive. Sir L. Playfair then passed to the subject of Medical Reform, and defended the line he took in connection with the last Medical Bill. "I acted in the interests of a higher education for a noble profession, and I intend to act in the same way again. But I hope to see a much simpler Bill introduced next Session A Bill of three clauses instead of seventy-two clauses like that of last Session would suffice, and would give peace to a much agitated profession. Instead of a dead level of uniformity, as hateful in education as it would be in nature, that differentiation of aids and methods in training medical men would, under such a Bill, be continued by the Universities and corporations, which have already done so much to raise medicine to the rank of a learned profession. This cry for uniformity did not arise in Scotland; it arose in England. The hospital schools in England are excellent in their way, but they have not the requisite resources for the development of practical scientific teaching. It is, therefore, with great pleasure that I see a movement for a true teaching University of London, which may become a worthy competitor of our medical school in Edinburgh." We may here interject that the cry for uniformity arose in England, because it is in England that we have most reason to deplore the low standard of the Scottish Corporations.

Sir Lyon Playfair next passed on to show what he had done in respect to the Vaccination and Vivisection questions, in the latter of which he truly said that the well-intentioned benevolence which throws itself into opposition to ascertained experiences in the progress of medicine, is misled by its ignorance of the motives and the objects of science. On the over-pressure question, he said that he at once accepted Dr. Crichton Browne's evidence that there are, in poorer schools in England, children who are physically and mentally unable to grapple with the standards to which they are put. But he contended, and brought forward figures to prove, that on the great mass of school children our educational system had not only had no deteriorating influence, but a powerfully ameliorating one. "The general result at which I have arrived, by a careful consideration of this question, is that we must be guided by medical experience in bringing charitable influences to bear upon the condition of ill-fed and ill-clothed children, so that the ordinary mental exercises, which are not too much for the great mass of our young population, may not bear too heavily on the feeble frames of the sickly and nervous weaklings." The speech was on the whole an admirable one, and as

admitted by Professor Mecklijohn, who seconded the vote of thanks to Sir L. Playfair—proposed by Professor Turner, and carried with applause—it was equally admirable for what it omitted as for what it contained. It was a model of a lucid unpartisan statesmanlike address.

The Hospital *Fête*, organised in connection with the recent visit of the Sanitary Institute of Great Britain to Dublin, and the Sanitary Exhibition at Ball's Bridge, in that city, has brought in a sum of between 400*l.* and 500*l.*, after payment of all expenses, Accordingly, 30*l.* will be handed to each of the twelve large clinical hospitals of Dublin, and 8*l.* to each of the smaller and special hospitals. The only pity is that the amount has to be divided and sub-divided to such an extent, owing to the multiplicity of the participating institutions, that no one hospital will be materially benefited by the donation.

On Saturday morning, November 22nd, an arrest was made in Blackhall Place, Dublin, under the provisions of the Pubtic Health (Ireland) Act, 1878, and upon a committal warrant, signed by one of the divisional police magistrates for Dublin. The prisoner, Alicia O'Brien, was conveyed to Grangegorman Prison, where she will have to remain for a period of two months, unless an alternative fine of 5*l.* is at once paid. The fine was imposed for contempt of a magistrate's order in reference to the insanitary state of some house property in the prisoner's possession. More arrests were expected to take place during the week under the same Act.

The correspondents of the daily press fall into curious errors, through want of care and information, in reporting on medical subjects. The correspondent of the *Standard* in recording Dr. Koller's successes in procuring local anæsthesia of the eye, states that "a single drop of cocaine, the extract of the coca leaf, if dropped into the eye renders it totally insensible." A "drop of the extract" also produces the same effect on the larynx, "a point of the utmost importance in diphtheria and other grave throat diseases." He further states that Dr. Schrötter has made use of it "in operating on an old polypus." We should imagine the correspondent's idea as to who or what an old polypus may be is as hazy as that of the writer who recently informed the world that Dr. Klein had swallowed a microbe. If the lay journals think it necessary to keep their readers *au courant* with medical progress, they would do much better to rely on the medical writers on their own staffs, or to give extracts from the English medical journals. There would then have been no necessity for the *Standard* to publish "Blinkstein's" letter, for it would have known that English ophthalmic surgeons have been exciting themselves over cocaine for weeks.

Another item for the despondent medical teachers of the Metropolis! The Brussels' correspondent of the *Daily News* writes—"In proof of the renown of the Brussels University abroad, and the esteem in which its teaching is held, I may observe that since 1864, 157 British physicians and surgeons have obtained the degree of M.D. (of these 29 passed last year), besides 20 unsuccessful candidates." The correspondent is of course wrong in his deduction. The renown and teaching of the University have nothing at all to do with the numbers of its British medical graduates, everyone of whom would have preferred a British degree many times over, if he could have got one on reasonable terms. A system which compels a man like the late Dr. Mahomed to go abroad for one degree and subsequently to spend scores of hours in the railway train to obtain another, stands self-condemned, and sufficiently excuses us for going out of our way to publish the following apt lines, sent us by a correspondent :—

"Dura Mater."

There was a wise lady—initials L. U.—
She had so many children, she knew not what to do;
What others had taught them she yearly assessed,
Passed one out of six and got rid of the rest.

The Local Government Board has recently issued three reports (to be obtained of Knight and Co., 90, Fleet Street) of enquiries made by its inspectors into the conditions favouring the outbreak of zymotic disease in three different agricultural towns, viz., St. Albans, Huntingdon and Godmanchester. The St. Albans enquiry was conducted by Mr. Shirley Murphy and had reference to an outbreak of enteric fever in May and June last. It forms a sort of sequel to the report on the outbreak of the same fever in North London last year, which was traced by Mr. Murphy to the milk supplied by the same farm which he now arraigns as the cause of the St. Albans epidemic. The reports on the sanitary condition of Huntingdon and Godmanchester, rendered necessary by the fatal prevalence of diphtheria in these two adjoining towns, are the work of Dr. Franklin Parsons. The three towns dealt with in these reports provide, so far as their sanitary condition is concerned, a striking example of the three degrees of comparison. St. Albans, a town of 11,326 inhabitants is in a fairly good sanitary condition. It is mainly supplied with water of good quality from deep wells, but less than a fourth of the houses enjoy a constant supply. It has a recently constructed sewerage system discharging into a sewage farm, but at the time of the fever only half the houses were connected with the sewers. The outbreak, however, was not traced either to sewer defects or polluted water; indeed the 610 houses still supplied by private wells showed a considerably smaller proportional incidence of fever than those supplied by the water company.

On coming to enquire into the milk-supply as a possible source of infection, Mr. Murphy, after a long and laborious investigation, succeeded in tracing the fever to the milk of a certain farmer Z. He found in fact that of the houses supplied directly or indirectly with Z.'s milk 21·1 per cent., but of the other houses only 0·14 per cent. were invaded by the outbreak. On investigating the conditions at Z.'s

farm, however, Mr. Murphy could form no idea as to the condition which gave Z.'s milk its infective quality. The faulty conditions found at the farm last year had been remedied, and Mr. Murphy admits that the milk was now produced under circumstances of reasonable cleanliness and healthiness. We would, however, remark that it is really a stretch of courtesy to assume that it is only the water used for washing the pails that comes in contact with milk in most dairies, and that even if the passage of fæcal matters from the cesspit to the well could be satisfactorily excluded from consideration in this case, it is by no means improbable that the chamber slops and the water in which the sheets and soiled linen of the earlier cases had been washed may have been thrown on the ground in the vicinity of the well. We are surprised that this alternative did not suggest itself to Mr. Murphy, for it is only in towns that such slops are usually discharged into the drain, and the limited capacity of the iron substitute for a cesspit would in a rural locality make the readier disposal of slops in the open more likely. The moral that Mr. Murphy draws from his investigation is obvious, viz., that "English people should adopt as their invariable rule in the use of milk the custom usual among many continental nations of boiling all milk as soon as they receive it into their houses." To obtain this, however, as a general custom, you must first explode the fallacy almost universally held amongst the poor, that "milk boiled is milk spoiled."

If the sanitary condition of St. Albans may be described as fairly good, that of Huntingdon must be classed as indifferent, and that of Godmanchester as distinctly bad, not to say villainous. Dr. Parsons inspected both towns in 1880, and his recent inspection was made partly with a view to ascertain how far the improvements he then recommended had been carried out, and partly with reference to the prevalence of diphtheria in both towns in 1883. At Huntingdon, some attention has been paid to his recommendations; at Godmanchester none. At the former town while there is evidence of sanitary progress having been made, "there is still much need for further improvement, especially in substituting the town water for that of the dangerous shallow wells, and cleanly closets for filthy cesspit privies; in a better system of scavenging; and in systematic action for the discovery and remedying, or still better for the prevention, of conditions dangerous to health before they occasion disease." At Godmanchester, on the other hand, the town council have taken no steps whatever to remedy the unwholesome conditions pointed out by Dr. Parsons in 1880, and the following *précis* of his report in that year is equally applicable now: "a mere village, in a low-lying damp situation, subject to floods. Cottages old, dilapidated, ill-ventilated, and overcrowded. Sewers of defective construction. Water-supply from shallow wells liable to pollution; some houses unsupplied. Offensive midden and cesspit privies very close to houses. Great accumulations of filth. No proceedings taken for the abatement of nuisances. No public scavenging, byelaws, or hospital accommodation." As to the causation of the outbreaks of diphtheria, Dr. Parsons has to confess that he is unable to form any definite opinion.

The following *Jeu d'Esprit* is going the round of the Brazilian journals. It should be explained that the last page of the Thesis for the Doctorate in the Faculties of Rio de Janeiro and Bahia is dedicated to twelve *Aphorisms* of Hippocrates chosen by the candidate which he has to sustain before the examiners. The names introduced, some baptismal, others patronymic, are those by which certain of the professors are commonly known. *Baro* in No. 8 is a titled professor much given to the analysis of Aphorisms. "Cunea," in 12, must be understood as *protection* and *solicitations* of powerful patrons, an important element in deciding the results of examinations in Brazil, though now on a much less scale than formerly.

Examinis Aphorismi.

(1) Natura examinatorum est principium studii. (2) Scientia longa, studium difficile, tempus breve, examen fallax. (3) Si Hilarius Magnus, Cyprianus, Barataque in examinis mensâ intraverint, malum. (4) Si, autem, Benitius, Nunusque, vel Caetanus examinarent, bonum. (5) Dies examinis, si frigoris fuerit, bonum, si pluviæ, melius. (6) In examine clinicæ, questiones faciles bonum. (7) Quos Souza Lima non salvat, eos Nunus salvat; quos Nunus non salvat, eos Benitius salvat; quos, vero, Benitius non salvat, simplificatos existimare oportet. (8) Si thesis in mensâ fuerit Baro, aphorismos cognoscere oportet. (9) Si, quod Deus avertat, unus ex nostris reprobatus erit, in Bahiâ refugium quærere oportet. (10) Si, autem, in Bahiâ, Ludovicus Alves, Braga, Demetriusque in examinis mensâ intraverint. malum; et in Rio ficare, melius. (11) Studiosus, si in cerebro scientiam gestat, coloratior est, si ignorantiam, minus coloratus. (12) Ad extremos rigores, extrema cunca exquisite optima.

Dr. Blaxall's report to the Local Government Board for the year 1882 on Emigration and Immigration from and into the United Kingdom, has lately been placed in our hands. He shows that as regards disease prevention, notwithstanding all that has hitherto been done, matters are still unsatisfactory, and that infectious disease frequently follows in the wake of emigrants from one port to another, and is by them introduced on board ship. With but few exceptions no steps are taken to prevent this latter catastrophe. If the passengers exceed 50 in number they are required to undergo an examination by an officer of the Board of Trade when at the point of leaving the country, but there seems to be no adequate provision for dealing with the case of emigrants coming from the Continent to embark in English ships, when the infectious disease has declared itself. At most of the ports there are infectious hospitals to which a patient can be removed, but until the disease has actually declared itself there appears to be nothing to prevent a person from mixing with others and spreading the disease wherever he goes. Dr. Blaxall considers that there is a great need for a better regulation of the passenger traffic, so as to protect the public, the emigrants and other countries

against the spread of infectious disease, due regard being had to the other interests concerned in emigration. Sanitary measures should not be vexatious or cause delay in the traffic.

Certain facts have recently been brought to light with respect to an outbreak of cholera in Constantinople in the year 1874, which possess more than ordinary interest at the present time, although hidden for so many years within the unfathomable recesses of the Turkish official conscience. During the month of August, 1871, an epidemic of cholera was rampant in the city, and, owing to the want of accommodation, a certain number of patients were lodged in an old disused and condemned building known as the "Hôpital de Maltépé." In one particular ward, it is stated, the mortality was very great. At the close of the epidemic the old hospital was pulled down and a new stone building erected in its place. From motives of economy, however, the same ground plans were employed for the new hospital, so that the various wards were placed on the identical areas of the former wards. In the case of the room which had been so peculiarly fatal at the time of the epidemic, this identity was so exact that it was not thought necessary to take up the old flooring or in any way to alter it. Two years later, at a time when there were no cases of cholera in or about the city of Constantinople, or indeed in any other part of Europe, one of the male nurses in attendance on the sick in this same ward was suddenly seized with all the symptoms of Asiatic cholera, and died in six hours from the onset of the attack. Two other cases occurred in the next twenty-four hours with equally rapid and fatal results. Energetic measures were then taken by the medical officer in command (whose name, Macridi Bey, has a somewhat English ring about it), and the whole of the contents of the infected ward were rendered innocuous, the flooring which had undoubtedly harboured the infective material being completely burnt. Within a short period the ward was again fit for occupation, and has been continued in active use to the present time. The secret of this remarkable outbreak, however, has only lately been acknowledged, and is published in a semi-official communication to a Vienna medical journal. The story is instructive in many ways, and especially in showing the liability of wooden floorings to retain infective materials for so long a period in a virulent form. The daily scrubbing of old and absorbent boards keeps them in precisely that condition which appears most favourable to the spread of cholera.

We lately noticed the useful and voluminous advice contained in the students' number of an American journal, on the subject of study abroad—*i.e.*, in the different English and European Schools of Medicine and Surgery. A later number of the *New York Medical Journal* contains an article on the same subject—"from a moral standpoint," with the object, apparently, of providing the antidote to such poison as the careless, the wicked, or the weak might possibly be able to extract from its previous utterances. It is pointed out that the fact of a man's having "studied abroad" is nowadays of but little account with either the profession or the laity, unless he can give proof not merely of time spent in study, but of time well spent. A small minority go abroad knowing what they wish to do; they do it; and they are generally heard of again. Others start with the mistaken ambition of covering the whole field of medicine in their study; and a yet larger number have little or no definite idea of what they wish to undertake. To the last class, and to the failures and the disappointed among the second class, the dangers are neither few nor slight. There is danger, while broadening his professional knowledge, that such a man will lose in moral tone, in delicacy of feeling, and in tenderness towards suffering; against which the acquisition of a superficial *politesse* or polished indifference, is no adequate set-off. To the man who does not start with the instincts of a gentleman, or who fails to maintain them in full and vigorous exercise, there is danger in the lax moral atmosphere of the great continental cities, notably Vienna; in the light regard in which woman is held, in the absolute subjection in which patients are kept, and in the cold-blooded way in which they are too commonly treated. Again, there is far less of that responsibility to society which exercises a beneficial and restraining influence on young men at home; he needs, in short, to be "an individual of strong character and absolute devotion to a high ideal who returns as clean a man as when he went." All this is truth, and truth as old as medicine or as humanity. The physician falls as far short of his ideal—of the perfection which it should be his not merely to gain but to exercise—on the one hand if he be not a thorough gentleman, as he does on the other, by limiting his professional usefulness, if he has failed to seek, to seize and to apply his opportunities of acquiring knowledge. And knowledge can be gained to real advantage only after an orderly fashion. The advantages which undoubtedly exist "abroad" for the acquisition of special knowledge are comparatively useless to the student who has not learnt how and what to learn at home; he is but a sorry builder who would commence the superstructure without having laid the foundations; and for all practical result, might as well attempt the building of his house from the top to begin with.

"The treatment of snake-bite by the Explosive Cautery" does not refer to that instance of cool courage recently reported from India and noted in our columns, where the possessor of a cobra-bitten finger had the presence of mind to amputate the injured member by the prompt discharge of his gun. It is somewhat less heroic in conception and more tedious in application. A surgeon of the United States Army quartered in the Indian Territory has been curing snake-bites (the particular kind of reptile is not stated) by covering the site of the fang-puncture with gunpowder, igniting it, scarifying the wound, and repeating the operation with more gunpowder burning, finally dressing the wound with a linseed poultice and laudanum. This cautery is said to be "rapid, painless, and thorough, and, if quickly applied, appears

to afford the best chances for recovery." We think that this treatment, or something very like it, has been heard of before, but under a less imposing title. Titles, however, of all kinds, have, undoubtedly, a curative value of their own.

On Tuesday last, at the hospital for epilepsy and paralysis, Regent's-park, a tumour was successfully removed from the substance of the brain. The case is under the care of Dr. Hughes Bennett, who, having diagnosed an encephalic morbid growth of limited size, and localised it in the upper part of the Fissure of Rolando, requested a surgeon to trephine the skull over the suspected region: this was carried out by Mr. Rickman Godlee. A mass of glioma, the size of a walnut, was extracted from under the grey matter of the upper part of the ascending frontal convolution. Up to the present time the patient has progressed favourably in every respect. We shall be interested to learn the future progress of the case.

THE DRUG OF THE DAY.

For the next few weeks the medical journals will no doubt be full of the praises of cocaine as a local anæsthetic. Ophthalmic surgeons are trying it almost universally, and every enterprising practitioner who has to deal with any painful or excitable mucous membrane within reach of the brush or the syringe, will no doubt ere long be following in their wake. Whether cocaine is destined to share the fate of the hundred and one drugs that have gone up like a rocket amidst universal plaudits, and come down like its stick amidst universal neglect, time alone will show. But the character and variety of the evidence before us seems to give fair promise that in a certain number of applications the drug will prove a really valuable addition to our therapeutic resources. So long ago as 1860 Dr. Albert Niemann, of Goslar, who was the first to give the name of cocaine to the alkaloid extracted from the leaves of the *Erythroxylon Coca*, observed that it left a transient numbness upon the tongue when tasted, followed by a sensation of cold. But this observation remained unfruitful until Dr. Charles Koller, incited by the researches of Freud, commenced a series of experiments in Professor Stricker's laboratory at Vienna, on the local action of cocaine on the eyes of animals. His earlier results were communicated somewhat prematurely to the Heidelberg Ophthalmological Congress in September last, in order to secure to himself the credit of priority of discovery. A more complete communication on the subject was read before the Vienna Society of Physicians on October 17th, and a *resumé* of it was published in the *Medical Times* three weeks ago. At the same meeting Dr. Königstein, who had made experiments independently of Dr. Koller, stated that he had obtained practically the same results. These two investigators dealt only with the effect of cocaine on the eye, but at a subsequent meeting of the Vienna Society on October 24th, a report of which we publish in another column, Dr. Jelinek gave an account of his trials of the drug in producing anæsthesia of the pharynx and larynx. These were conducted in the wards and on the patients of Professor v. Schrötter, who together with his colleague Professor Störk bore witness to the ease with which difficult manipulations could be undertaken within the larynx, when previously anæsthetized by means of cocaine. At the same meeting, Dr. Königstein, who had been continuing his experiments on the ophthalmic applications of the drug, stated that he had been able to remove the eyeball of a dog, previously cocainized, without the animal feeling any pain. Meanwhile observers in this country have not been idle, though their researches have been necessarily confined to experiments upon themselves and their patients. Mr. Bader and Mr. Hartridge have made successful trials with cocaine in ophthalmic practice which fully corroborate the claims put forward for it by Dr. Koller; while Dr. Felix Semon and Dr. Prosser James have used it in laryngeal operations, with a success which quite bears out the assertions of Schrötter, Störk and Jelinek. Mr. Lucien Howe, an American ophthalmologist, has also carried out a series of trials on animals and patients, the latter in the clinics of Professors Schöler and Schweigger at Berlin, and has published a concise account of his results in the *Lancet*. While fully recognising that in the first trials of an apparently useful drug the judgment is apt to be warped by ardent enthusiasm, Professor Howe thinks the belief justified "that cocaine is destined to rank as one of the most valuable agents in ophthalmic surgery."

Pure cocaine occurs in the form of colourless transparent prisms, without smell, but with a slight bitter taste. The hydrochlorate or muriate of cocaine, with which most of the experiments have been made, is a white crystalline powder, which is sparingly soluble in water, but readily soluble in alcohol, ether, oil and vaseline. In the case of the eye, a two per cent. aqueous solution of the drug is sufficient for all practical purposes, and acts almost as well as a solution of double that strength; the throat however requires a stronger solution, and Dr. Jelinek recommends a dilute alcoholic solution of ten or twenty per cent. For the former strength the proportion of alcohol to water should be as one to four; for the latter as two to three. When one drop of a four per cent. solution (and the same is true of much weaker solutions) is introduced into the eye, a slight burning sensation is felt. A minute or two later, the cornea and conjunctiva become anæsthetic, and lose all reflex excitability; the finger can be passed over them, and the conjunctiva taken up with the forceps without causing any unpleasant sensations. At the same time there is a feeling of tension in the lids, and the eye seems protruded, as in a case of Graves's disease. The conjunctiva becomes exceedingly pale. These phenomena last for about ten minutes and gradually disappear. In from ten to fifteen minutes the pupil begins to dilate, and there is slight paresis of accommodation. Mydriasis is never present to any great degree, but it lasts for some hours after the anæsthesia has disappeared. Dr. Königstein thinks that these effects are mainly due to the influence of cocaine upon the sympathetic, and the facts that the

vessels generally, including, probably, those of the retina, are contracted by it, that the pupil is dilated and the eye protruded seem to give some warrant for this belief.

With regard to the clinical uses of cocaine, it serves the purpose both of a local anæsthetic and a local anodyne. It may be applied in all cases attended with pain in the eye and photophobia, in painful erosions, phlyctenulæ, injuries, &c., and its power of causing contraction of the vessels seems to indicate it in cases of inflammatory congestion both of the conjunctiva and deeper structures. Professor v Reuss even recommends it as a mydriatic in glaucoma. As a local anæsthetic, preparatory to operation, it has been used in many operations on the conjunctiva and cornea, in removing foreign bodies from the latter and in tattooing cicatrices upon it, in touching it with caustics, &c. As to its reliability in deeper operations, as iridectomy, operations for cataract, for squint, and on the skin of the eyelids, the evidence is conflicting; but Dr. Köller has pointed out the importance of applying it with systematic thoroughness, and probably some of the failures that have been recorded may be traced to a too ineffectual instillation or to a too hasty operation. Dr. Koenigstein indeed states that even the surfaces of the eyelids entirely lose their sensitiveness when cocaine hydrochlorate is applied in the solid form. For most operations it appears to be sufficient to introduce a drop of a two per cent. solution at intervals of two minutes. The maximum effect, according to Mr. Lucien Howe, is reached in fifteen minutes, but earlier according to other observers.

Fewer experiments have been made with regard to the application of cocaine to the larynx, but there can be no doubt that it has considerable power of diminishing the sensibility to pain and controlling reflex excitability. A ten per cent. or twenty per cent. solution is used according to the sensitiveness of the parts and the seriousness of the projected operation. It should be applied three or four times at intervals of ninety seconds, and the anæsthesia lasts for about a quarter of an hour, *i.e.*, quite sufficient for the majority of endo-laryngeal operations. The solution must be applied systematically with a brush or mop to all parts of the pharynx or larynx which the operator is liable to touch in the course of his manipulations, and the epiglottis must therefore be anæsthetized with special care. The most successful case yet placed on record is one in which Dr. Schrötter removed some warts from the larynx of a child of seven, without experiencing any difficulty on the part of the patient. As an anodyne in painful affections of the pharynx and larynx it is possible that cocaine may entirely supersede the use of morphia, and become a valuable means of promoting the euthanasia in those dolorous cases of laryngeal cancer and tuberculosis, the progress of which is perhaps the most trying that the physician has to witness. The drug will also be found useful in facilitating examinations with the laryngoscope, in all cases where there is much reflex irritability of the soft palate and pharynx. In such cases it need only be applied to the parts with which the laryngeal mirror is likely to come into contact.

There are many other functions which cocaine will no doubt be called upon to fulfil, presumably with some measure of success. It might be employed to facilitate difficult catheterism, and by its injection into the bladder to remove the painful contractions met with in obstinate cases of catarrh. It will also probably be applied, with more or less success, in painful affections of the vagina and rectum; and it may be presumed that it would be of use in cases of vaginismus, though its transient effects will of course considerably limit its utility. It would also be worth trying in those incorrigible affections, pruritus ani and pruritus pudendi, and it may possibly be of use in some forms of gastralgia. Whether it would be found efficacious in allaying the painful irritation in appropriate cases of eczema is doubtful, but it will be worth a trial. The only disadvantage connected with it is, as Dr. Jelinek observes, its costliness. It is at present purchasable for about ninepence a grain, and it has been estimated that to secure a painless and easy endo-laryngeal operation costs several shillings. There is at present probably little chance of a diminution in the price, and if, as is quite possible, the market has been interfered with by some enterprising wholesale firm, the cost may run up to a point which would seriously limit the application of the drug. If it should sustain its popularity, however, a powerful impulse will be given to the growth of coca—a plant which is at its best when carefully cultivated—and a new opening will be provided for capital and industry. But it will take long before such operations make any impression on the market price of the alkaloid.

In conclusion we may state our belief that the claims of cocaine to a valuable use in a limited series of applications, though put forward with all the confidence with which new drugs are wont to be ushered in, are supported by much better evidence, both of reason and experience, than those of many of its predecessors which, having been convicted of taking in the profession, have finally met with the treatment deserved by all impostors.

RENAL SURGERY.

A most interesting and instructive debate on Renal Surgery took place at the Royal Medical and Chirurgical Society on Tuesday last. It was raised by the reading of a paper by Mr. Henry Morris, which is elsewhere reported. The successful issue of his case is somewhat lessened by the fact that the ablated kidney was perfectly healthy in structure, although it did contain, embedded in it, a calculus as large as a hazel nut. This fact possesses an equal interest for the physiologist and for the surgeon; and it should make the latter especially careful in recommending the removal of the organ for a disease which cannot be actually diagnosed, as in the present instance, until it would have been too late to remedy the mistake. Mr. Hulke related a case and many others are on record where "well marked symptoms of renal calculus" have been present during life, which after death have been proved to be dependent on other causes by the absolute integrity of the kidneys. One of the speakers regarded Mr. Morris's success as a near

escape from a "surgical calamity;" while another characterised it as "success founded on a misfortune." We must not, however, judge individual cases on general principles; each one must be taken by itself, and in this particular instance, Mr. Morris may be congratulated on the result of the operation, and on the correctness of the diagnosis, which led him to recommend it to his patient. Besides this point, another of more purely surgical interest was raised, viz., the relative merits of the lumbar and the peritonæal methods of operating. Mr. Morris, Mr. Bryant, and Mr. Hulke supported the former; except in special cases, it was *the* incision for by far the large majority of cases. Among other advantages secured, besides sparing the peritonæal cavity, drainage was more easily obtained through the lumbar incision. Mr. Thornton was the chief advocate of the abdominal incision, for which he claimed the advantage that it enabled one to see, and to examine, *both* kidneys carefully with little or no disturbance, thus making sure that a second kidney was present, and in a healthy functional condition. We cannot but feel that there is right on both sides; in the hands of such an exceptionally successful peritonæal surgeon as Mr. Thornton, abdominal nephrectomy no doubt will prove successful, while in the hands of other surgeons less experienced in this mode of operating, the lumbar incision is the one they should adopt in most cases. For the drainage of pyo- and hydro-nephrotic kidneys, lumbar incision appears to have answered admirably for a while, though further measures have subsequently been needful, for the contraction which takes place after the fluids have drained away facilitates the removal of the organ, even should it be determined to proceed by the abdominal method. Sir Spencer Wells agreed with Mr. Thornton that more details are necessary than we at present possess, to enable us to say that *this* or *that* method of operating shall be done. He inclined to the abdominal method for the removal and drainage of large tumours. It is most gratifying, however, to find that surgeons have found such comparatively safe and satisfactory methods of dealing with disease in an organ like the kidney, and we cordially re-echo Dr. George Johnson's congratulatory remarks to those who have worked at the subject. With the sufficiency for healthy existence of a single kidney, clinically as well as experimeneally demonstrated, with the possibility of removing tubercular kidneys, cancerous kidneys, and calculous kidneys, future generations will escape some ills and dangers which but a few years ago rendered the life of many patients intolerable, and brought discredit on medical art.

Trichinosis.—An inspector of meat has been condemned at Halle to a year and a half's imprisonment in consequence of his careless inspection of some pork, in consequence of which ninety persons, inhabiting the village of Strenz-Naundorff, became affected with trichinosis, twelve of the number dying. He had reported the pork in question as free from trichinæ, while he had only examined six of the thirty specimens submitted to him, and these very carelessly, so that a subsequent examination proved that they were infected.

REVIEWS AND NOTICES OF BOOKS.

EUSTACE SMITH ON DISEASE IN CHILDREN.[1]

Few will be found to quarrel with Dr. Eustace Smith for having accepted the responsible task of writing a complete treatise "On Disease in Children." The task, he tells us in his preface, was undertaken not without hesitation, on account of the length of time required to complete it, and especially the knowledge that many manuals of varying merit were already in the field. "Encouraged, however," he continues, "by the reflexion that the author's opportunities for studying these complaints had been abundant, that in the course of more than twenty years he had acquired a mass of valuable material, and that of existing books few dealt with more than a part of the subject, he thought himself justified in believing that a treatise which undertook to discuss the whole subject of disease in early life, and to deal with the matter from a clinical standpoint, might not be without its uses." Few also will be likely to find fault with the New York firm of publishers, at whose invitation the book was written, for having selected an author, already favourably known, both in this and foreign countries, through his "Wasting Diseases of Children," and who could bring the rich experience of twenty years, spent in the study of the diseases of early life, in the out-patient room and wards of one of the largest of our children's hospitals. Surely no one in this country has a greater justification for the task.

There can be but little room for doubt as to the difficulties encountered in writing a really practical treatise on the diseases of children. Few general physicians, in this country at least, have good opportunities of gaining the necessary experience all along the line, say, for instance, on the diseases incident to birth, or are able to take into their wards infants under two years old, or children suffering from scarlet fever, measles or whooping cough. How many have gained what knowledge they possess of the morbid anatomy of infants, from *post-mortems* made in garrets in the slums and back streets, under circumstances anything but favourable to scientific investigation? It is then hardly surprising that much that has been written on diseases of children has passed from book to book, and that the works themselves have been well padded with superfluous matter, which had nothing to do with their real subject. Thus one recent book on diseases of children devotes nearly two pages to describing the various tests for sugar in the urine! No one can accuse the author of the book before us of either lacking the necessary experience for writing a book on diseases of childhood, or of filling his pages with redundant or superfluous matter; for it bears evidence on every page of the practical knowledge and wide experience of the writer, and his possession of the happy faculty of putting his facts clearly and concisely before his readers.

---

[1] On Disease in Children. By Eustace Smith, M.D., F.R.C.P., Physician to the East London Children's Hospital, and to the Victoria Park Hospital for Diseases of the Chest. London: J. & A. Churchill.

The introductory chapter with which the book opens deals with the peculiarities of disease as it occurs in children, the methods of examining infants, the pulse, temperature, bathing, therapeutics, &c., and contains much useful information well put and to the point. In Part I. are included, the acute infectious diseases which are perhaps not as fully described as some other groups of disease, yet on the whole their clinical features, diagnosis and treatment are ably dealt with, and the chapter on whooping cough is exceedingly good, the author's favourite treatment for this troublesome affection being a mixture of sulphate of zinc and atropine in the spasmodic stage and alum during the period of decline. He has apparently more faith in atropine than Henoch and some recent writers. In scarlet fever when the temperature is high, he recommends the cold bath (70° F.) the child being kept in till his teeth begin to chatter. We confess that we should not often be tempted to follow this advice on account of the depression of the heart that it is apt to produce, but should certainly prefer the milder measures he refers to later on, namely, sponging with cold water and the wet pack. The paragraph devoted to the morbid anatomy of scarlatinal nephritis is meagre and is apparently founded on Dr. Klein's observations contained in the Report of the Local Government Board for 1876. These observations, which have done duty on several occasions in recent text-books, were made on kidneys taken from patients dying early in the disease, and were examples of the septic or interstitial form which, as Friedlander has shown, is perfectly distinct from the post-scarlatinal form occuring during or at the end of the third week and accompanied by blood, casts, &c., in the urine. In describing the symptoms of nephritis, the author refers to cases which are seized, sometimes suddenly, with dyspnœa and which are often rapidly fatal. These cases he explains as being due to an interstitial œdema of the lungs. We confess to grave doubts as to this explanation being the true one ; we can hardly believe in an œdema which affects the interstitial tissue of the lungs and not the air-passages and alveoli, but think these cases are in reality cases of cardiac failure, the heart being found at the *post-mortem* with both sides dilated and its walls pale and flabby ; the fatal results being brought about by the giving way of an ill-nourished heart, over-worked by the obstruction encountered in driving the blood through the capillaries and arterioles.

Parts II and III include the general and diathetic diseases, the most important chapters being devoted to Rickets, Rheumatism, Scrofula, Tuberculosis and Syphilis. All these subjects are treated in a masterly manner, the description of the last being very full and exhaustive. Part IV is devoted to the Diseases of the Ductless Glands and Blood. The chapter on Hodgkin's disease, illustrated as it is by cases occurring in the author's practice, is extremely interesting and forms an important contribution to this rare and obscure disease. The chapters on Convulsions and Epilepsy are full of practical hints and information based upon the author's experience. Among the various causes given for convulsive seizures in infants, he instances lead-poisoning. He remarks that "infants are very susceptible to the influence of lead given internally. I have long since ceased to make use of this remedy in the treatment of the diarrhœas of young children, as I have several times seen convulsions follow its employment and the attack has seemed to me in some cases to be directly excited by the use of this agent." A case is given which came under the author's care for convulsions at 11 months of age, apparently connected with an attack of erysipelas, but the fits continued after the inflammation had subsided and the child, who remained under observation till 12 years of age, became a confirmed epileptic. The author has much faith in strychnine and belladonna in the treatment of epilepsy, but gives a large dose of the bromides at night. He also speaks well of borax.

Otitis and its consequences, including purulent meningitis, are very fully treated of, as is also tubercular meningitis, but we must demur to the latter part of the following statement, that "in this disease examination by the ophthalmoscope, if it can be managed, shows a congested state of the retinal vessels and discs, and sometimes small bodies like grey granulations *can be seen projecting from the sides of the small retinal arteries.*" Surely the miliary tubercles when visible in the fundus are situated in eth choroid ?

It need hardly be said that, in the chapters on Infantile Atrophy and the disorders of the gastro-intestinal tract, the author shows himself to the greatest advantage. The symptoms, diagnosis and treatment of these affections are described in detail and with the minutest care, yet in simple and forcible language. His directions for the general treatment and dietary of infants under all conditions of health and disease are so complete and full, as to leave nothing to be desired. His prescriptions are always simple and if he has not supplied as rich a formulary as some writers on children's diseases, it is because those given are sufficient for all practical purposes, and have the merit of having stood the test of a long experience. With so much that is excellent, it would be ungenerous to lay much stress on omissions and in a first edition we suppose that printer's errors must not be too severely dealt with. Another edition may probably see a short chapter on mediastinitis, diabetes mellitus and insipidus—which we cannot agree with the author in saying present the same characters in the child as in the adult—and a fuller reference to acute yellow atrophy of the liver, which is hardly so rare in children as the author seems to suppose and has more than once been mistaken for tubercular meningitis. Of printer's errors uncorrected there are not a few, especially with regard to the names of authors, thus, for example, Jaccould, Fagg, Samson, Creighton Browne, Macuna, to say nothing of Pyerian glands, jejunum and ilium and a week mustard poultice. Finally we need hardly say, we have the highest opinion of the value of the book as a practical guide to Disease in Children. Written as it is from a clinical stand-point, faithful in its description of the symptoms of disease, and especially strong in diagnosis and treatment, it will take its place as a thoroughly trustworthy work on the diseases of early life, and one on which the already high reputation of its author may safely rest.

Surgical Emergencies. Twelve lectures, delivered at the University of Leipzig, by Dr. von Lesser. Translated and revised by Dr. Frederick Lyons. Bermingham's Medical Library. New York, 1883, pp. 215.—The work, we are told by the translator, "treats of subjects that have been left untouched by the few short and imperfect works on surgical emergencies that have appeared, and which in general treatises on the surgical art are so encumbered by the mass of other matter that they are inaccessible." On turning to the contents, a little curious as to what these subjects can be, we find a medley of subjects, not a third of which can at all appropriately be discussed under "surgical emergencies" (the equivalent to which, in the original German, is "surgical aid in cases of pressing danger). We do not pretend to know what is generally taught in Leipzig, or in the American schools; but if such subjects as are found in this book are "not included in theoretical lectures on surgery," it is very well that they should be taught in some other way. Such an omission ought at once to be reported at head-quarters. Among the subjects we find—transfusion for loss of blood; impediment to the supply of air, and tracheotomy; obstruction of the bowels; gastrotomy; congenital malformations; effusions to chest and pericardium; injuries to brain and skull; and a chapter on generalities, including first aid to the sick and wounded in war. Surely these subjects have all been adequately discussed in the standard works. The author's expressed consciousness "of the imperfections of this little work" though due in a measure to the lack of the "requisite leisure to put the finishing touches to every detail," spares us the necessity of saying anything else concerning these "surgical emergencies."

Photographing the Larynx; by Thomas R. French, M.D., Brooklyn. (*Archives of Laryngology*, No. 4, 1883.)—Dr. French gives an account of the efforts and difficulties which have attended his attempts to obtain useful photographic representations of the healthy and diseased larynx. Having failed to obtain satisfactory results by bringing the patient to the camera, he succeeded in producing some fairly clear impressions by bringing the camera to the patient, reducing the whole photographic apparatus to the size of a cigar-box, which formed, as it were, the handle of the laryngeal mirror. Although it cannot be said that his results so far are calculated to throw new light upon the subject of laryngeal disease or even adequately to illustrate the knowledge which we already possess, still they may fairly be expected to pave the way to more complete demonstrations in the future.

Lectures on General Nursing; by Eva C. E. Lückes. London: Kegan Paul, Trench and Co., 1884.—This little book contains a dozen lectures addressed by Miss Lückes to the probationers at the London Hospital at the commencement of their training. They deal only with general topics, and Miss Lückes has evidently been at no small pains to avoid trespassing on the ground of the medical man in her lectures. We have read these lectures with a great deal of interest; they are pleasantly written, and so far as we can judge they forestall every question which could suggest itself to the mind of a beginner, though of course they will not teach a person to become a nurse, nor does Miss Lückes suggest in any way that they should take the place of practical experience. The book is sure to be popular.

What to do in Cases of Poisoning; by William Murrell, M.D. Fourth Edition. London: H. K. Lewis, 1884.—This diminutive little volume contains in a condensed space a great deal of information on the subject of poisoning. The fact that in such a short time it should have reached a fourth edition speaks volumes for its popularity, and we need not say anything further in praise of it than that it has evidently supplied a felt want.

ABSTRACTS AND EXTRACTS.

LARYNGOLOGY AND OTOLOGY.

The Use of Cocaine in Dysphagia.—The following striking example of the successful use of cocaine in overcoming painful deglutition was related by Dr. Jelinek in a paper read before the Vienna Society of Physicians, which has been published in full in the *Wiener Medicinishe Wochenscrift* (No. 46), and a *résumé* of which appears in our report of the Society's meeting in another column. The patient, a male aged 45, was suffering from tubercle. There was extensive swelling, and brawny infiltration of the epiglottis, but only moderate dulness and slight crepitation were discoverable at the apex of the right lung. He had been treated as an out-patient in the clinic of laryngology for three months, and iodoform and morphia had been daily blown into his larynx, and he had constantly taken ice. In spite of this treatment he affirmed that for close upon two months he had only been able to swallow milk in the minutest quantities. He was extremely wasted, incapable of work, scarcely able even to walk, and tortured by continuous pain and thirst. Before applying the cocaine solution Dr. Jelinek made him drink some water. He had hardly swallowed a drop before he started up in the greatest pain, while the water returned through his mouth and nose. Dr. Jelinek then carefully painted the lingual and part of the laryngeal surface of the epiglottis, and the valleculæ, with a ten per cent. solution of cocaine, and a minute afterwards told the patient to drink again. The man anxiously took a small mouthful, for a moment looked around in astonishment, and then, to the surprise of all, greedily swallowed the whole glassful at a single draught. Tears of gratitude filled his eyes, and he could scarcely find words to express his thanks. The next day he related that on reaching home, an hour after the application, he had, to the astonishment of his wife, made an excellent meal (the first he had had for two months) without any difficulty, but that soon after the pain reappeared, and three hours after the painting was as bad as ever.

Successful Extirpation of the Thyroid Gland.—Under this title Dr. F. W. Rockwell describes (*New York Medical Journal,*) a case of ablation of the enlarged right lobe, from a female patient, aged 18. The tumour was first noticed at the age of 3 years, and had grown slowly and steadily until September, 1883, when a similar growth appeared on the left side of the trachea. Both tumours then increased rapidly so as to greatly interfere with respiration and deglutition; there were also repeated attacks of vertigo and paroxysmal dyspnœa. Various local and constitutional measures having been employed without benefit, the patient was etherised on February 11th, and the enlarged right lobe carefully enucleated through an incision reaching from the hyoid bone to the sternal notch. Aided by the systematic employment of forci-pressure and of temporary catgut ligatures, the dissection was accomplished with the loss of not more than two ounces of blood. As the dissection had invaded the infra-clavicular space, a button-hole was made below the incision, and a drainage-tube led through this up into the bottom of the wound, and secured with a horsehair suture. Two long catgut sutures, one leading to a large vessel in the isthmus of the gland, the other to the inferior thyroid, were left as guides in case of secondary hæmorrhage, their ends being brought out of the opening alongside the drainage-tube. The wound was irrigated with corrosive sublimate solution (1 in 1,000), closed with horsehair sutures, and covered with a pad of naphthalised sawdust and a gauze bandage. Antiseptic precautions, with the exception of the spray, were adopted throughout the operation, which lasted nearly two hours and a half. The left lobe, as it was but slightly affected, and as its removal would have involved further tedious dissection, was not interfered with. The drainage-tube and all but four of the sutures were removed on the third day. The wound was entirely healed by March 2nd, and on the 14th the patient resumed her duties as domestic servant, the left

lobe being apparently reduced in size since the operation, and there being a complete absence of symptoms of the former trouble. Dr. Rockwell strongly deprecates the method of operating by "attempting as rapidly as possible to reach the pedicle of the growth and secure the principal vessels," in view of the profuse and paralysing hæmorrhage which such an attempt must often incur. From Dr. Paul Liebrecht's work he quotes the following list of recorded operations:—by German, Austrian, and Swiss surgeons, 226; by French, 34; by English, 30; by American, 16; by Italian, 10; by Prussian, 3; by Belgian, 2; by Swedish, 1: giving a total of 322. Of this number 250 were cured, 64 died, 2 were not completed, and in 5 the result was uncertain. Adding to these a series of 34 cases with 5 deaths we reach a grand total of 356 cases, with a mortality of 69, or 19·39 per cent. The actual mortality from causes incident to the operation itself appears not to exceed 8·75 per cent. This estimate nearly agrees with that of Watson, of Edinburgh, who maintains that operations conducted on the plan of careful dissection and enucleation prove fatal in only about seven per cent. Under these circumstances Dr. Rockwell considers the operation of thyroidectomy undeserving of the condemnation which it has received at the hands of most prominent surgical authorities of recent date.

Tracheotomy in Croup.—Dr. Jennings in the *Archives of Pediatrics*, for September, fails to see any distinction between membranous croup and diphtheria; the conditions are identical. He recognises, however, three grades of severity, one in which the disease is confined to the larnyx and trachea, as regards its local manifestations at any rate, another in which the pharyngeal disease is mild, and a third where the pharyngeal or naso-pharyngeal disease is severe and would be dangerous apart from the croup. Only a small percentage of cases, he says, recover after tracheotomy out of this last group, but to our way of thinking such divisions are too artificial. He considers that the general condition of the patient and the tendency of the disease have more influence over the result than the age of the patient. His youngest successful case was an infant of nineteen months. He advises that chloroform should be given, on which point we agree with him, though we cannot agree that the low operation is to be preferred; the reason for this, viz., that one is more likely to get below the membrane, is, in our opinion, wholly insufficient and would certainly not counterbalance the increased difficulty and danger of the operation. In the after-treatment he mentions the use of a feather to remove any membrane or mucus, but does not insist upon its systematic use at the time of the operation, a point, as we believe, of the greatest importance. No tube ought to be put in until the operator has done his best to clear not only the trachea but the larynx of any membrane that may be there; to omit this precaution is to run a great risk of deriving little or no benefit from the operation. With all that he says about keeping the tube clean in the after-treatment we entirely agree, and we have learnt to consider the degree of discolouration of the outer part of the tube as a reliable guide for prognosis; the more speedily the outer part of the tube, that in contact with the wound, becomes blackened the worse the prognosis.

Rhinolithiasis and Pharyngolithiasis.—The patient (*New York Medical Journal*, July 26th) had suffered from chronic catarrh in the head for several years, with periodical attacks of right hemicrania. There was a copious flocculent discharge from the nostrils, great vascularity and thickening of the nasal mucous membrane generally, and marked obstruction of nasal respiration on the right side. Palpation revealed the presence of a hard, grating substance, occupying the floor of the right nasal fossa, which was supposed to be necrosed bone. It being found impossible to dislodge the foreign body anteriorly, it was pushed backwards into the naso-pharynx (the patient having been cautioned not to take a deep breath or to swallow during the manipulation) whence it was speedily spat out. It proved to be a calcareous mass, almost black in colour, and conoidal in shape, measuring 1·5 by 1·25 c.m., and weighing exactly a gramme and a half. Embedded in the mass was a cherry stone; but the patient, a gentleman forty-nine years of age, could not recall any incident of his childhood to account for the presence of the cherry stone. Free nasal respiration was fully restored. The literature of the subject is not extensive. Störk (who had seen but one example), Demarquay, and Ponisot, have written upon it. The determining cause is, almost invariably, the presence of a foreign body which forms a nucleus for the deposition of lime salts. The gouty diathesis may be a predisposing cause. For the expulsion of rhinoliths, sternutatories (Fränkel), a stream of hot water injected through the opposite nostril, strong pressure made through the posterior portion of the nose and throat, extraction by a loop of iron wire which is rotated to tightness upon the stone, and breaking up the concretion by drilling it in various directions by means of the dental engine, have been recommended. In a previous number of the same journal are recorded two instances of what was at first supposed to be glandular tumour of the neck. After the evacuation of pus, a sinus was, in each case, found extending upwards behind the jaw; a probe could be passed for several inches, until its extremity was felt at the outer side of the tonsil, just beneath the mucous membrane. After the discharge of small calcareous masses, the tract finally healed. The course of events was considered to be, old inflammation of the tonsil with calcareous degeneration, and subsequent burrowing of pus to the side of the neck.

Concretion in the External Auditory Meatus.—A lady, aged 45, had suffered from a fœtid discharge from the right ear since an attack of scarlet fever in childhood. The watch was heard on contact only. The meatus was found to be occupied by a firm gritty substance which was at length removed, *en masse*, by means of strong straight forceps used with considerable force. The canal was then seen to be much ulcerated, bathed in pus and blood; there was a perforation in the postero-inferior quadrant of the tympanum. After cleansing the middle ear the watch was audible at five centimetres. The cast of the meatus which had been extracted was about 12 mm. long, dirty grey in colour, closely resembling an ordinary pebble, and of a very offensive odour. It consisted essentially of cretaceous particles deposited around and amongst distinctly recognisable cotton fibres. The patient was positive that cotton wool had not been introduced into the meatus for more than twenty years.—*Boston Medical and Surgical Journal*, August 21st.

Mumps as a Cause of Sudden Deafness.—Dr. Connor, in the *American Journal of Medical Sciences* for October, relates an example of this, and from it and abstracts of thirty-one of the cases which he has collected arrives at the following conclusions: (1) mumps does in some rare cases produce complete deafness; (2) it is usually attended with all the evidences of disease of the labyrinth; (3) these show that it sometimes begins in the cochlea, but more frequently in the semicircular canals; (4) owing to the lack of early observations and treatment it is impossible to say that it is not transmitted through the middle ear from the parotids to the labyrinth; (5) the histories of some of the cases would seem to suggest that such an origin was possible; (6) this possibility renders it very important that every case of deafness during an attack of mumps be at once carefully examined, so as to settle the question; (7) this possibly offers the only hope for the successful treatment of these cases, so as to prevent deafness. Thus, if there be a middle ear disease, we might hope that revulsive and counter-irritant treatment would arrest the disease and save the labyrinth; (8) as to treatment of the labyrinthine disease, nothing has thus far been devised that has produced any satisfactory result.

Earache from Irritation of the Jaws.—Dr. Sexton, of the New York Eye and Ear Infirmary, brought under the notice of his class accounts of several cases that had been treated at the clinic, and in which even when otalgia was very severe no signs of hyperæmia or inflammation had been detected in any part of the ear; and he showed that among the poor earache is in many instances due to dental caries. In other cases of chronic or acute inflammatory processes of the ear, very great exasperation is manifestly produced by these reflex agencies. Very often a cure is effected in these cases by the extraction of

the diseased teeth. Dr. Sexton also alluded to the frequent attendance of females with aural trouble through sympathy of the nerves, as compared with men. "In reference to the treatment of these cases, it was believed that since dentistry had become such a popular business, and dead and diseased teeth had been so carefully retained, especially among better-to-do people, nervous diseases of the head were becoming alarmingly common. The very general custom of wearing false teeth attached to vulcanite rubber, celluloid, and other plates was also an evil of vast proportions. Indeed, he sometimes thought that the evil done through ill-advised dentistry was greater than the possible good arising from the work of the more capable dentists." —*New York Medical Journal*, October 4.

Chromic Acid in Papilloma of the Larynx.—Dr. Jarvis recommends chromic trioxide as a local application to these growths as being safe, reliable, effectual, and self-limited in its action; its use is not necessarily attended with pain or spasm. It is best applied by means of a special instrument, consisting of a tube provided with a trigger and a spring, the force of which can be accurately regulated, in order to limit the action of the caustic to the growth to be removed, and to surprise the larynx. Since, according to Mackenzie, 67 per cent. of the tumours of the larynx are papillomata, and Cohen has found forty-eight out of sixty-six tumours of this character, the field of action open to this agent appears to be an extensive one.—*Boston Medical and Surgical Journal.*

Complete Paralysis of Left Vocal Chord in Extreme Abduction Resulting from an Incised Wound of the Neck.—The wound, which was suicidal, and was made from behind forwards, severed the sterno-cleido-mastoid muscle, and was deepest just in the track of the pneumo-gastric nerve. There had been complete aphonia ever since the injury (which was inflicted in November, 1883); the left vocal band was found immovable in a position of extreme abduction, while the right band was normal. In forced inspiration the latter did not go out so far as the left one constantly remained. No explanation is given as to the method in which the injury operated.—*Boston Medical and Surgical Journal.*

Unilateral Paralysis of Laryngeal Abductors.—At the Annual Congress of the American Laryngological Association, Dr. Delavan related the case of a patient, æt. 69, who suffered from cerebral hæmorrhage with paralysis in 1877; although all the other paralytic troubles had long since disappeared, the unilateral paralysis of the abductors still persisted. According to Nothnagel (Ziemssen's Cyclopædia) this condition is exceedingly rare. A similar case, in which the unilateral paralysis was the only injury resulting from falling down stairs and striking the head, was also mentioned.—*Boston Medical and Surgical Journal.*

The Vapour of Glycerine in Obstinate Cough.—Professor Trastor, of Nantes, employs the vapour of glycerine with great advantage when a cough becomes distressing or fatiguing. Fifty or sixty grammes are placed in a porcelain capsule and evaporated over a spirit lamp. An enormous amount of vapour is disengaged. In phthisis and various other affections much relief is gained in this way.—*Revue Médicale.*

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, November 25th, 1884.

George Johnson, M.D., F.R.S., President, in the Chair.

A Successful Case of Lumbar Nephrectomy for Renal Calculus.

Mr. Henry Morris read a paper on this subject, of which the following is an abstract:—A labourer, aged 35, who had suffered from well-marked symptoms of renal calculus of the right side since the end of 1881, and had been under the care of Dr. Douglas Powell at the Middlesex Hospital, came again under treatment in October, 1883. In November, 1882, Mr. Morris had explored his kidney digitally and with the probing needle, but did not detect the stone. On October 24th, 1883, the exploration was repeated, but again failing, the kidney was removed through the lumbar incision. The patient made an uninterrupted recovery, and at the present time is at hard work as a charcoal burner, "is as well as ever he was in his life, and able to work without the slightest inconvenience." The kidney excised was of normal size and appearance, and its secreting structure was found by Dr. Coupland on microscopical examination to be quite healthy. The organ, however, was harder and tougher than usual, and contained a rounded rough calculus about the size of a marble. Careful daily examination was made of the urine by Mr. Paul both before the nephrectomy and for more than six weeks after the operation, so that the rapidity and power with which one kidney can take on the whole of the excretory function is shown in a table which forms part of the paper. The results are equivalent to those of a simple physiological experiment, because a healthy kidney (so far as its excreting substance went) was removed, and a healthy one was left behind. A comparison was made between the lumbar and the peritonæal methods of nephrectomy. The author endeavoured to show that the arguments which have been used in favour of the peritonæal operations are more theoretical than practical, and that, if logically followed out, they are likely to lead to pernicious results. The conclusion arrived at was, that lumbar nephrectomy, as a rule, is the better operation, though there are exceptional circumstsnces and certain diseased conditions in which the abdominal method is preferable. In nephrolithotomy the lumbar incision, and that only, ought to be employed. In judging of the condition of the opposite kidney to the one to be removed, we have to depend upon the general symptoms of the case and upon the amount of urea daily excreted. But it is not correct to infer that the kidneys are diseased because they excrete a daily average quantity of urea *even less than half the standard quantity.* Persons who have long been living an invalid life, and who have lost much flesh, may with perfectly sound kidneys eliminate not more than from ·8 to 1·8 per cent. of urea, and only pass from 30 to 35 ounces of urine a-day.

The President, in inviting discussion, congratulated surgeons on the successful manner in which they now treated these diseases of the kidneys; it made physicians envious to see them thus radically deal with disease.

Mr. Bryant said it was pleasant to hear the President speak so encouragingly of these cases. The paper demonstrated in the first place an interesting physiological detail, that one kidney sufficed for the purposes of both, and could do all that was necessary to health. In the second place, the difficulty in diagnosing calculus, even after prodding with a needle, and manipulation was shown; a small calculus was so lost and so buried, that it escaped detection even when present. This should teach that, in all cases, operations could at best but be considered exploratory. In the present case it was regretable that the stone could not be found, for then the kidney itself would not have been removed. In all cases the kidney should be explored through the pelvis, and a careful search made before the organ was removed. He considered the lumbar operation as the proper one for calculus; probably in the case to-night, the stone could not have been detected even had the abdomen been opened. Speaking generally, he was in favour of the lumbar as against the abdominal incision, believing that surgeons would get all they required from the former. In cases of large tumour it would be different: these peritonæal operations had been discovered, so to speak, accidentally, while surgeons were looking for ovarian tumours; nevertheless, we must be grateful. In pyonephrosis and hydronephrosis, drainage through the loin led to contraction and withering of the sac, with great relief, and at worst a discharging sinus in the loin; under such circumstances he questioned whether the more extensive and more serious operation through the abdomen were warranted.

Mr. Hulke, like Mr. Bryant, had never removed a

kidney, but had cut into many. Both his own clinical experience and his reading alike convinced him that the lumbar incision was the better, and especially so for drainage. Unless very large, even when it was desirable to cut the tumour, the lumbar incision sufficed; and in cases where there was pus or secretion in the perirenal tissue the lumbar incision was by far the better. In a few exceptional cases the abdominal incision could be adopted. In reference to diagnosis, he referred to a case in which calculus had been diagnosed by several leading men, and on one occasion, in consequence of the severity of the symptoms, it had been decided to operate, and all the preparations were complete when the patient, a physician, finally declined to submit; a while afterwards he died of some other disorder, and on making a *post-mortem* examination not the least sign of a calculus or any other disease was found. He also related a case of perirenal abscess, which discharged a quantity of pus through the loin, the patient recovering. Any attempt, he thought, to drain such a cavity through the abdomen would have been most hazardous.

Mr. Thornton, as regarded the case under discussion, joined his congratulations to those of other speakers, but at the same time he could not help feeling that Mr. Morris had just escaped a surgical calamity. The removal of a healthy kidney was not a light matter; in not cutting into the organ before removing it he had neglected an advantage which he himself claimed for the lumbar operation. As to the ureter, he thought there was nothing to fear in the majority of cases. Like the ovarian pedicle, it withered; if inclined to slough, one place was as good as another. Coming to the other question raised, the abdominal operation as against the lumbar, he felt he might be in a minority of one. At present, however, there were not sufficient details on which to arbitrate; it was impossible to lay down hard and fast lines. In one successful operation by the abdominal method he had felt the stone quite easily, and then made an opening through the loin at the most convenient spot, through which the calculus was removed. Moreover, he had examined the opposite kidney, had made sure of its presence and of its healthy condition. As to the danger to the peritonæum, he personally, had no fear of it; he would fear to wound many other tissues of the body more than the peritonæum, which was remarkably tolerant when properly treated. He had drained kidneys through the loin, but subsequent operation, in his experience, was necessary.

Mr. Barwell referred to a case of loose kidney, which he had operated on through the loin.

Mr. Larkins referred to a paper which he had read while a student before the Guy's Physical Society, in 1869, on some experiments made on rabbits, which showed that they recovered from the operation and remained well after extirpation of the kidney.

Sir Spencer Wells was a little surprised that the value of diagnosis by means of the hand in the rectum had not been referred to. He agreed that it was impossible as yet to say which operation was the right one; for large tumours and for draining he thought the abdominal incision the better.

Mr. Macnamara asked Sir Spencer whether diagnosis had ever been successfully made this way.

Sir Spencer Wells replied that among other surgeons he had himself done so.

Mr. Baker was about to have asked the same question. He had heard rumours of injury and dangers to the peritonæal cavity. He rather inclined to agree with Mr. Thornton in his views on the operation. He enquired as to the value of the plan of enucleating the kidney from its capsule; he had himself tried the plan which he thought offered certain advantages. With regard to drainage, all the cases in which he had operated, had finally required the major operation subsequently. It seemed as if one kidney sufficed for the needs of the body; perhaps, however, this was only in health; he had had a case in which the patient got on well while in health, but having been attacked by some febrile condition, death rapidly supervened.

Mr. Barker thought it made all the difference whether a healthy kidney was incised through the loin or a diseased one; in the former case it was probable that a sinus would continue to discharge; while, owing to the contraction which takes place in a diseased one, a sinus did not remain long open.

Mr. Morris replied.

The meeting (which had been specially prolonged) then adjourned.

A number of very interesting pathological specimenss illustrating surgical disease of the kidneys, from the Museum, of Guy's and the Middlesex Hospitals were shown.

MEDICAL SOCIETY OF LONDON.

Monday, Nov. 24th, 1884.

Arthur Durham, F.R.C.S., President, in the Chair.

Anæsthetics and their Administration.

Mr. Woodhouse Braine contributed a paper on the above subject. He began by contrasting the relative merits of the various anæsthetic agents now in vogue, saying that we had yet to discover an anæsthetic which was absolutely safe: nevertheless, he thought it incumbent upon us to select some agents in preference to others for the reason that they were safer than others. Anæsthetics might be divided into two classes—(1) Those which produced death through the lungs as well as through the heart; this class included chloroform, bichloride of methylene, dichloride of ethidene, and many others of the chlorine series; (2) Those which produced death through the lungs alone, the heart's action continuing for some time after respiration had quite ceased; this class included ether and nitrous oxide. In the fatal cases under chloroform death was usually instantaneous in the great majority of cases, and began at the heart; when the heart once thoroughly stopped, nothing served to ward off death, while, when respiration stopped, even for a minute or two, with artificial respiration there were good chances of recovery. In choosing an anæsthetic there were three factors to be considered—(1) The nature of the operation; (2) The amount of insensibility necessary; (3) The length of time during which insensibility had to be kept up. In ovariotomy, for instance, we frequently gave bichloride of methylene; for after the first incision there was little if any pain, and the smallest degree of anæsthesia sufficed. Of all anæsthetic agents, the quickest and safest, but the most difficult to administer really well, was nitrous oxide; to get its full effect it should be administered pure, all air being rigidly excluded: deep snoring and an insensitive conjunctiva were the best signs of insensibility. Pregnant and suckling women took gas without any deleterious consequences; children, even those who suffered from chorea, or epilepsy, took it well; great age was no bar, he having given it on one occasion to a woman aged 94. From experiments made on himself, he had learnt that just before the loss and the return of consciousness, the hearing power was greatly intensified, and he warned surgeons to be careful in their remarks, and advised the room to be kept as quite as possible. As regarded ether, he said the chief reason against its making its way lay in the difficulty of its administration; in unpractised hands there was generally considerable struggling. His usual practice was to induce complete insensibility by means of nitrous oxide, and then to quickly change the face piece for the Ormsby or Dublin inhaler. This ought to be done very rapidly, so that the nitrous oxide which the patient gets rid of by the first subsequent expiration, passes through the sponge and becomes charged with ether for the first inspiration. The cold produced by the rapid evaporation of the ether is often very great, and the sponge becomes frozen into a solid mass, which gives off very little ether vapour. To prevent this the inhaler should be warmed, or the sponge should be wrung out in hot water. The ether then comes off rapidly, very little is required, and, moreover, the patient is quickly under its influence. After complete anæsthesia has been produced in this manner, the sponge may be removed, and the insensibility may be prolonged by allowing the patient to breathe from the india-rubber bag, admitting fresh air only as required.

Ether has one great advantage over those anæsthetics which depress the heart's action; for the vessels bleed so freely as the operation proceeds that the surgeon is obliged to tie a much larger number, hence there is seldom secondary or even any subsequent hæmorrhage to interfere with healing. Chloroform tends to produce syncope; whenever this appeared imminent a few whiffs of nitrite of amyl furnished the quickest means of restoring the heart's action. The anæsthetist besides this drug ought always to be provided with a pair of tongue forceps, and the instruments necessary for tracheotomy. Among the more general points referred to, Mr. Braine spoke of the sickness which follows anæsthetics; that after ether was often caused by large quantities of flatus, and generally took place suddenly and forcibly, that after chloroform was preceded by more faintness and nausea, and took place more quietly. Hiccough was best relieved by a cup of tea without either milk or sugar. Although a great advocate for having the stomach empty, he never would allow a patient to become faint for want of food. If the operation was arranged for about 9 a.m. no food should be taken, unless the patient was *in the habit* of having a small cup of cocoa or something, then this might be allowed, for its privation might cause the patient to feel faint. It was a bad practice to give the breakfast before the usual time, for the stomach, not accustomed to it, failed to digest the unusually early meal. It was always well to examine the organs of respiration and circulation; this examination allowed you to get on good terms with the patient, and it gave him confidence, or, in other words, additional cardiac power. Artificial teeth, especially small plates, should always be removed; whole sets were less likely to be swallowed. It was best to ask the patient to open his mouth, and to look for oneself. To avoid after-sickness, it was very essential that the patient should not be shaken when being lifted from the operating table to the bed. Except in cases of special debility, the nurse should be instructed not to give any kind of food for three hours. Warm food, he said, kept up the nausea; hence it was better to give all nutriment quite cold until the following morning. He summed up his remarks as follows:—It was well to avoid all anæsthetics which tend to depress the heart's action. (2) For short operations nitrous oxide is the best agent. (3) For longer operations, except where it is desirable to avoid hæmorrhage, as in some eye operations, or when the cautery was used, ether answers perfectly. (4) The best time for operating is the early morning. (5) The nasal tubes are of little use. (6) Nitrite of amyl is the best cardiac stimulant.

SOCIETY OF PHYSICIANS OF VIENNA.[1]

FRIDAY, OCTOBER 24TH, 1884.

PROFESSOR BILLROTH in the Chair.

The Use of Cocaine in Throat Affections.

AFTER cases of interest had been exhibited by Professor Billroth and Dr. Königstein, Dr. JELINEK called the attention of the Society to the Use of Cocaine as a local Anæsthetic and Anodyne, when applied to the Mucous Membrane of the Pharynx and Larynx. He first briefly reviewed the various methods hitherto employed to diminish the sensibility of the pharynx and larynx, viz., the painting with solutions of morphia, advocated by Türck, the ether spray of Rossbach, painting with tannin, bromide of potash, &c. Türck's method, as modified by Schrötter, had found numerous adherents, and was very commonly used. The pharynx and larynx were painted twelve times with chloroform, and after the lapse of an hour an equal number of times with a concentrated solution of morphia. This was done on the evening preceding the day of operation. The next morning the sensibility of the larynx was found so diminished that operations could be performed without distress. The disadvantages of this method were obvious. The preparation lasted twelve hours, and the patient had to be watched during the whole night, as there was a possibility of narcotism. Further, the painting with chloroform caused disagreeable sensations to the patient. Dr. Jelinek now employed the hydrochlorate of cocaine to produce anæsthesia of the pharynx and larynx. This drug seemed to have been long known to French physicians; Fauvel mentioned it as a tensor of the vocal cords. Its practical employment as an anæsthetic and anodyne, however, had hitherto, strange to say, been unknown. Hydrochlorate of cocaine was a crystalline powder which dissolved easily in ether and alcohol, but less easily in water, and which had a neutral reaction. When the powder itself or a concentrated solution was applied to a mucous membrane it was followed by diminished sensibility to touch and to heat, comparative insensibility to pain, and diminution of reflex excitability. When applied on the mucous membrane of the tongue the sense of taste became impaired. For practical purposes the power possessed by cocaine of lessening sensibility to pain and controlling reflex excitability were most important. At the clinic of Professor v. Schrötter, Dr. Jelinek had had a good opportunity of making experiments on the action of cocaine when applied to the larynx. He used dilute alcoholic solutions of ten per cent. and twenty per cent. which were at first clear, but which after some days became turbid, owing to the alcohol evaporating, and some of the cocaine being precipitated. It then became necessary to add a few drops of alcohol. Hydrochloric acid should not be used in preparing the solution, and it should not be filtered. In slight operations, where little reflex action and only moderate pain were present, the ten per cent. solution sufficed; but where the larynx had to be rendered anæsthetic for more serious operations the twenty per cent. solution must be employed. To the pharynx the solution should be applied by means of a little mop; to the larynx by means of a thick soft camel's hair pencil. The application must be repeated every minute and a half, if necessary. The anæsthesia lasted ordinarily from ten to fifteen minutes, and disappeared totally after twenty minutes. All those parts with which an instrument might come into contact—the margin, the lingual and laryngeal surface of the epiglottis, the palleculæ, and so on, must be painted, as reflexes might occur wherever a part had remained untouched by the solution. Dr. Jelinek then mentioned some cases in which polypi and papillomata had been removed from the larynx by Professor v. Schrötter with considerable success, after making use of his method. The author next passed on to consider the use of cocaine as an anodyne, and drew attention to cases of tuberculous perichondritis, in which deglutition was so painful that the patients refused food, and were in danger of perishing from inanition, though the process in the lungs was not very advanced. The application of hydrochlorate of cocaine rendered good service to these patients, and in similar cases equally good results had been obtained. The diminution of pain sometimes lasted for three hours; it was necessary to seek out all the implicated spots, and to paint them thoroughly. In these cases only aqueous solutions had been used. He further pointed out that cocaine diminished the swelling of a mucous membrane where present, lessened its secretions, and, according to Fauvel, tightened the vocal cords. No local or general disturbance had been observed after its employment. It only had one disagreeable quality, namely, that 1 gramme (15 grains) of it cost from 5 to 6 florins (from 9 to 11 shillings).

Professor v. SCHRÖTTER said that Professor Störk and he had succeeded in preparing patients for operation by means of the above treatment in from three to eight days, so that they became quite indifferent to endolaryngeal manipulations. He added that Türck's method of producing local anæsthesia of the larynx had unjustly obtained the name of "Schrötter's method." This was not right, as he had only modified the method. He attached great importance to the employment of cocaine. The method of Türck, however, was not dangerous, it was only very disagreeable for the patients. He had that very day removed papillomata from the larynx of a child aged 7 years, after having painted it a short time before with cocaine hydrochlorate. The child did not feel anything, the manipulations were quite easy, and there was no trouble on the part of the patient.

[1] Reported by Our Vienna Correspondent.

The use of cocaine was quite free from danger, and it would totally supersede the local application of morphia. Pain was also removed by treatment with cocaine, and though morphia inhalations did good service in cases of perichondritis, the effect of cocaine was still better, according to the statement of the patients. The experiments with cocaine were not yet concluded, but, judging from what he had seen hitherto, he thought it a very valuable drug, and could promise a good future to it.

Professor STÖRK remarked that he had employed a twenty per cent. solution of hydrochlorate of cocaine in order to remove a polypus of the vocal cord, and as to its efficiency he could in general confirm the communications which had been made on this subject. The local sensibility was diminished, but the reflex excitability was not entirely removed.

In connection with this discussion, Dr. KÖNIGSTEIN said that he had performed enucleation of the eyeball on a dog after the application of cocaine, and the animal did not feel anything of the operation. First he rendered the conjunctiva anæsthetic, then he made an incision, and injected into Tenon's capsule a one per cent. solution of cocaine, after which he completed the operation without any trouble.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, NOVEMBER 6TH, 1884.

H. POWER, Esq., M.B., Lond., F.R.C.S., Vice-President, in the Chair.

CLINICAL EVENING.

Movable Kidney.

DR. SYDNEY PHILLIPS showed a boy, aged 9, presenting a lobulated, elastic mass situated chiefly in the umbilical and left lumbar regious; the upper edge of the mass reaching half-way between ensiform cartilage and umbilicus, the lower edge half-way between the latter and Poupart's ligament. The tumour could be pushed downwards as far as Poupart's ligament, and was movable to a less exteut iu other directions. There was a marked hollowness and concavity in its left lumbar aspect. The tumour had been noticed after an attack of whooping-cough, when the boy was seven months old; it had gradually increased from the size of a pigeon's egg to its present dimensions, but for the last two years had not altered. During a period of observation of eighteen months his urine had been normal and there had never been hæmaturia. The boy's health had been fair, but he had suffered paroxysmal attacks of pain about the tumour. Dr. Phillips believed the tumour to be a displaced kidney which had undergone some change, possibly cystic, accounting for its increased size. It was not a double kidney as the right kidney could be felt in the normal position.

Dr. STEPHEN MACKENZIE briefly discussed the case and pointed out that the tumour was not typically kidney-shaped, and that the abdominal walls were not abnormally lax; these were important reasons for doubting that the case was one of movable kidney.

Dr. CHAMPNEYS considered that diagnosis in a case such as this should be based upon a process of exclusion. Had the patient been a female the existence of a dermoid cyst rising from the pelvis might have been strongly suspected. Against the hypothesis that this was an instance of movable kidney the following facts might be urged:—(1) as pointed out by Landau the subjects were generally adults; (2) they were most commonly women; (3) in a large majority of cases a movable kidney was situated on the right side. The supposition of malignant disease was set aside by the long history of the tumour which was first observed at the age of seven months. The complication of strangulation was negatived by the observation that for a long period the size had remained constant. With regard to the mobility of the mass, Dr. Champneys had noticed that the centre of movement appeared to coincide with the summit of the iliac crest, in other words with a joint perceptibly below the axis of the normal kidney. The final inference remained that this was a solitary and therefore a hypertrophied kidney, and that it was slightly displaced, although not an instance of the malposition known as horse-shoe kidney which was the result of a congenital blending of both organs.

Mr. GANT, in commenting upon the case, gave his reasons for believing that its nature was an open question of diagnosis.

Mr. JOHN MORGAN remarked that he had not long ago had a boy under his care who presented a very similar tumour in the abdomen. The patient remained under observation for more than a year. The swelling, which was freely movable, lay to the left of the umbilicus, was round, smooth, painless, and did not increase in size while under observation. In the case before the Society he thought that the size of the swelling, the absence of any abnormal condition in the urine, together with the great rarity of such a condition in boys, were against the probability of this being a movable kidney. On the contrary, he fancied that fluctuation could be detected on deep pressure, and if so might it not more probably be some congenital cyst of the peritonæum or of some other abdominal organ?

Dr. MAIR referred to several cases of movable kidney which had come under his observation. Judging from his experience of these cases he hesitated to admit that the slight movement which he had detected in the mass was sufficient to justify this diagnosis. His examination of the patient rather led him to believe that the tumour was at some point or other fixed.

Two Cases of Lichen Planus in which the Eruption was Distributed along the Course of Cutaneous Nerves, with Remarks on the Influence of the Nervous System in the Disposition of Cutaneous Eruptions.

This formed the subject of a paper by Dr. STEPHEN MACKENZIE. The author narrated the case of a woman in whom Lichen planus was arranged round one-half of the back and abdomen in belt form, like Herpes zoster, for which the eruption had been mistaken. Later the eruption became generalised. There was intense itching of the skin, and white patches on the buccal mucous membrane. In the second case, also that of a woman, the eruption was confined to a track down the inside of one arm corresponding with the internal cutaneous and ulnar nerves, with intense itching in the area of the eruption. Dr. Mackenzie proceeded to point out that these cases were deviations from the ordinary type of Lichen planus, which was characterised usually by marked symmetry. He next drew attention to other cutaneous diseases which were distributed along the course of nerves, as Herpes zoster, morphœa, neuropathic papillomata, purpura, &c. He next considered the anatomical evidence explaining such neurotic eruptions, and by the kindness of Mr. McCarthy, was able to show to the members a microscopical specimen of the spinal ganglia of a case of retroceding zona. He then dealt with the significance of such eruptions, indicating his belief that the local lesions of the nervous centres merely determined the localised eruption, and that there was some other factor which decided its nature. He instanced some observations of Dr. Moxon, in which the local development of tubercle, cancer and pleurisy, were determined by local affections of nervous centres. He then passed in review the circumstances which occasioned symmetry of eruptions, showing that local tissue peculiarities could not be left out of consideration, and that asymmetry rather than symmetry was characteristic of eruptions directly due to local diseases of the nervous system. He thought that symmetrical eruptions like Lichen planus and psoriasis were due to some general nerve influence, or diathesis, the symmetry in such diseases being in part due to local tissue influences; and that cases such as he had narrated did not support the view that the ordinary symmetrical distribution was the direct outcome of nervous influence.

Dr. MALCOLM MORRIS said that cases of localised Lichen planus, like zoster, were very rare. He referred to a communication in the *New York Medical Record* by Dr. Robinson, in which Lichen planus and Lichen ruber were described as two diseases, the former being the most localised. Mr. Morris thought on the whole that Lichen planus was probably neurotic and not a blood disease, as it often developed in persons who were severely depressed. He

mentioned the case of a lady, aged 50, whose husband died suddenly abroad. On her return to England she was, after a few days, attacked with general Lichen planus, accompanied with intense irritation and other nervous symptoms. She gradually recovered as the depression passed off, under the influence of arsenic and complete rest. This pointed to the disease being a nerve storm like megrim, with cutaneous manifestations.

Dr. COLCOTT FOX remarked that modern researches had accumulated a mass of evidence to show that the nervous system played a very prominent part in the evolutions of skin diseases, either directly through trophic nerves or through the agency of the vaso-motor system. From anatomical considerations it was evident that if a morbid influence was exercised through the vaso-motor nerves, the areas occupied by the eruptions would correspond with the areas of blood supply. It was difficult to resist the conclusion that the corymbose patches of eruption seen in a great many affections of the skin were thus caused. It was still more impossible to resist the conclusion that the patches of shingles were developed on the trajectory of a nerve, and indeed this had been placed on sure ground. From the mass of evidence to hand he might point to the evidence of nævi, both blood-vascular and papillary, in relation to nerve distribution, and this brought him to speak of continuous lines or narrow bands of eruption which were usually ascribed to nerve influence though more difficult to account for at first sight. Such bands he had described in 1880 as occurring in slight asymmetrical cases of Lichen planus, and these were now confirmed by Dr. Mackenzie. As to the ætiology of Lichen planus, he had been schooled in the theory that it was a neurosis, from the constitutional symptoms present, and his experience led him more and more to adopt this theory.

In reply Dr. STEPHEN MACKENZIE said that he quite agreed with Dr. Colcott Fox as to the neurotic nature of Lichen planus as had been so well pointed out by the late Dr. Tilbury Fox. The gist of his paper had been to show that the affection of the nervous system was of a general kind, but that the distribution of the eruption was not so much determined by nervous agency as was supposed. Where the direct influence of the nervous system was undoubted, the eruption tended to have an unusual or unsymmetrical distribution.

Cases of Painful Mamma in Young Girls.

By Mr. JOHN H. MORGAN. A well made girl, aged 11½, had suffered from severe pain in the left mamma for some time, which had become more acute lately. The gland was very little enlarged, and showed no symptoms of inflammation but was the seat of great pain and was very tender to the touch. The pain was continuous, with exacerbations. There was no history of injury, the catamenia had not appeared. Shortly afterwards the right mamma became affected in an exactly identical manner. Neither local nor general treatment afforded relief. After some weeks the pain began to intermit, and at length gradually disappeared.

Notes were read of six other similar cases, in five of which the left and in one the right mamma was the seat of pain. The children were between 10½ and 12 years old; none had menstruated, and in none was treatment either local or constitutional of much benefit. It was suggested that this pain was not due to inflammation, but to some developmental changes in the gland, in sympathy with changes in the ovaries and in the organs of generation.

Mr. H. POWER, alluding to a statement by the author, remarked that such cases had not remained unnoticed in medical literature, and referred to an article by Erb, dealing with this subject, in a volume of Ziemmsen's Cyclopædia, which he had translated.

Mr. GANT, corroborating Mr. Power's observations, alluded to a chapter in his own work on Surgery. This painful affection presented four well marked characters (1) hyperæsthesia; (2) wide distribution; (3) superficial nature of the pain, and (4) paroxysmal exacerbation. It might be looked upon as a pseudo-mastitis. In many cases it was probably the outcome of depraved habits. He also referred to the subject of irritable breast in the adult.

Dr. CLEVELAND, believing in the neuralgic character of the pain suggested that the hypodermic use of morphia might be expected to yield the same relief as in other neuralgiæ.

A New Antiseptic Vaporiser.

Mr. R. F. BENHAM stated that some antiseptic agents, carbolic acid foremost, did not become converted into vapour at ordinary temperatures; hence the objections to most inhalers. The apparatus exhibited, which was of small size and inexpensive, consisted of a closed chamber, heated by a spirit lamp, for the reception of water and of the disinfectant, provided at its upper part with a vent-hole of only sufficient size to allow the steam to escape under some pressure. On the principle of Hero's engine, a narrow horizontal tube, open at both ends, and at its middle point, and balanced on a pin projecting from the top of the boiler, was made to revolve with considerable rapidity by the steam issuing from its extremities and became the means of diffusing steam and antiseptic in a state of perfect mixture. This invention was originally brought out by Mr. Benham twenty years ago, and as a mechanical toy enjoyed considerable popularity, but had never been brought before the notice of, or utilised by, the profession, although, on a larger scale, it had been employed to disinfect and to perfume the Agricultural Hall.

Dr. CLEVELAND submitted that he could discover no essential difference between the vaporiser and Maw's Eucalyptus Globe.

Mr. BENHAM replied that the latter instrument being of recent date he could lay claim to undoubted priority of invention.

Improved Surgical Syringe.

Mr. BENHAM exhibited a syringe which differed from ordinary patterns mainly in the addition, in lieu of the nozzle, of a coned plug terminating in a transverse tube open at both ends for connection with india-rubber tubing through which the flow was regulated by a T tap. By this means the fluid might be aspirated or driven in alternating directions with great ease. The apertures of inlet and outlet being in a line instead of at right angles as in the ordinary stomach pump, it was impossible for one aperture to be open before the other had been completely closed. Loss of time in syringing was avoided, inasmuch as even when a small nozzle was used the flow of fluid in refilling the syringe was not impeded thereby; the nozzle, once *in situ*, did not require to be shifted during the whole operation; the absence of any valve obviated the danger of obstruction or corrosion; and lastly, the attachments might be readily applied to any of the existing syringes by adapting instead of their nozzles a screw of the same thread as that of the plug, whilst other fittings, such as a cannula and trocar, could be added at will.

Retroversion of the Gravid Uterus.

Dr. AMAND ROUTH read details of five cases of retroversion of the gravid uterus, two of which, when first seen, were complicated with resulting retentions of urine; the bladder in these cases exactly simulating the objective signs of unilocular ovarian cyst. Seventy ounces of urine in the one case, and fifty ounces in the other, were drawn off. Reduction was easily effected in all the cases without subsequent abortion occurring, and with immediate relief of the symptoms of backache, nausea, and frequent micturitions. The importance of early diagnosis and treatment was insisted upon.

Dr. CHAMPNEYS remarked that whereas in general outline cases such as those described were made up of combined flexion and impaction, none of the symptoms special to flexion or to impaction were present. Sometimes considerable difficulty was experienced in replacing the uterus. In such cases the pressure of water or of air was a valuable means of treatment. Dr. Champneys to a case recently seen by him, in which an indiarubber bag was introduced into the rectum and distended with water under a pressure of four feet, with excellent results.

Enlarged Prostate in a Dog.

Mr. T. W. CARMALT JONES not being present to read his paper, Mr. J. E. LANE exhibited the specimen and read a few notes on the case.

GENERAL CORRESPONDENCE.

SHIP-SURGEONS.

[To the Editor of the Medical Times.]

SIR,—Looking over the back numbers of the *Medical Times* for this year, I have just read your article commenting upon Dr. Domett Stone's letter to the *Times*, of last December, upon ship surgeons.

May I be allowed to make a few comments upon the subject though so long a time has elapsed since it was mooted. It is unnecessary to say I agree in the main with all that was said, but I think the question will bear looking at from somewhat another point of view. In the Royal Mail Steam Packet Company, as in others, the surgeon's pay is scandalously low, being the same as that of the steward and cook, and not only is the pay extremely low but surgeons of this company, like those of the Peninsular and Oriental, are compelled to insure their lives for a certain amount in an Insurance Company whose premium is absurdly high and whose directors are, curiously, many of them directors of the Peninsular and Oriental and Royal Mail Companies. This may, however, be only a coincidence. And the result of this low pay is deplorable; the service is simply made a convenience of by junior practitioners to enable them to make a voyage or two before settling down in practice, very few ever entering it with a view of remaining in it any length of time. This is of course extremely pleasant as far as they are concerned. They obtain an appointment, make one or two voyages, and then, being tied down by no specified length of service, they leave when they please. But let this be looked at from another light. How many of these men have ever seen a case of yellow fever, of bilious remittent fever, of dengue, of beriberi, of dysentery or of cholera? And grant that they may be able to diagnose these diseases by their book knowledge, would it not be the height of absurdity to say their treatment would be as successful as that of some of their senior colleagues who have seen and treated many such cases?

And again. How many of these men know anything of naval hygiene? Many perhaps have studied or passed an examination in public health on shore, but that will not avail them much at sea. It is a notorious fact that the majority of surgeons in the Mercantile Marine know absolutely nothing of the construction of the ship they sail in, and as little of the various modes of ventilating and disinfecting it. And it is on such men as these that the lives and health of large crews and numbers of passengers are dependent. No wonder the rate of mortality at sea is so high. The Royal Navy recognises the necessity of their surgeons having a special knowledge of naval hygiene, ought not the Mercantile to do likewise?

This is the existing state of affairs and will continue so to be till the time comes when shipping companies will pay their surgeons sufficiently well to enable them to adopt the sea as a permanent field for practice. In the present depressed state of trade, when all shipping companies are striving their utmost to make both ends meet, it would not be fair to ask them to do much by way of increasing pay, but it would not be asking much if it were suggested that surgeons should be paid on the same scale as chief engineers, and that they might be allowed to charge first-class passengers for attendance on some specified scale. The Royal Mail Company have issued a regulation against passengers being charged for attendance though they modify the severity of it a little by adding that they have no objection to surgeons receiving fees voluntarily offered, but this is a bitter piece of sarcasm, for, of passengers, not one in five ever thinks of offering more than his card and thanks for any service done him.

I firmly believe that, were the large Mail Companies to give their surgeons better pay, were they to allow them to charge first-class passengers for attendance, and were they to insist on their signing for a certain period of service, and passing an examination on naval hygiene before entering, they would procure the services of many excellent men and we should see a department of medicine, which is now unfortunately in such a deplorable state, sought after by those who would fill it with credit not only to themselves but also to the companies who employed them. In conclusion I may say I write this letter in no repining or malicious spirit against the Company which I have more particularly mentioned and from which I must say I have always received extreme kindness and courtesy.

I am, sir, Yours, &c.
F. W. KIRKHAM.
Surgeon to the Royal Mail Steam Packet Company.

PODONYCHOTOMY: A NEW OPERATION.

[To the Editor of the Medical Times.]

SIR,—Amongst some MSS. recently left to me by a venerable nonagenarian member of our profession was the following paper which appears to have been written for some society. No date is appended to it, and the writing is somewhat illegible, but I have not had much difficulty in copying it. I cannot find that the paper was ever published, and I therefore venture to send it to you.

I am, Sir, yours &c.,
A. S. L.

"On the Operation of Podonychotomy."

"Several reasons have induced me to bring this subject before you to-night, but amongst them I will only name these—That I have paid no particular attention to it myself, and that if others happen to be in the same position, the discussion, after I have read my paper, will probably lead to suggestions conducive to one adopting proper methods in the performance of this important operation. Neither have I any theory of my own to advance upon the subject. Not long ago it is true that all practitioners undertook this operation which seemed rightly to fall, if we may judge from the writings of the last generation, within the domain of all, rather than in that of the pure surgeon, but now things have changed, and while at that time every practitioner carried a pair of seissors in his pocket, that simple instrument has now given place to the onychotome. Steadily has the two-bladed weapon fallen into disuse, and various special instruments have been elaborated by the surgeon for the performance of this operation. But to sigh over the cenotaph of the scissors, and to make epitaphs on the Hirudo, save we can say with Horace, "Nisi plena cruoris," for they both occupy the same cold tomb, is to give no answer to the question why the operation of podonychotomy is now so rarely performed. Have the toe-nails become permanently shortened by a process of evolution, or does the increasing prosperity of the profession, and the growing obesity of its members place the toe-nails out of ordinary reach? This last speculation is worthy of attention, and seems to throw some light on the scientific acumen of those great surgeons who lived before us, and with whom it must have been both a pleasure and a profit to dwell.

"It has often been remarked that the toe-nail, if unimpeded in its growth, will continue to increase in length and thickness, and following the bent of its own inclination, perchance cause pressure on the delicate structure of the adjoining cutis. Hence are prone to arise shortness of temper and a sense of irritation which are extremely annoying in old age, and which, even in early life, have given rise to diarrhœa, convulsions, and eczema. I am ready to admit that in such cases removal of the superabundant growth might have given instant relief, but I think that the cart must have been often put before the horse. How has the general public gained an insight into this strange pathology, and how can this society best remove the source of so much evil? To compare the practice of cutting the toe-nails with that of cutting the hair, though both hair and nails are developed from the same embryonic blastoderm, is to throw ridicule on the whole science of surgery and to degrade the noble art of the surgeon to the same level as the cheap trade of the advertiser. Perish the thought!

"There is one special disease of infancy which is apt to be

overlooked by those who see in over-growth of the toe-nail, the source of every evil; I refer to measles. It is frequently impossible to say when the poison of measles has been received into the system, but we should not content ourselves with the assumption that onychial irritation arises from this cause. Coincidences are the bane of young men, and, indeed, of all logic in medicine. The growth of the nails is a simple physiological process, handed down from father to son, from mother to daughter, and of the many ills to which flesh is heir, few are due to the exercise of this normal function. Atavism at any rate finds no support from it.

"Then to pass to the nail itself. What are the various conditions which call for use of the scissors, and demand a return to one good remedy out of fashion? When the matrix is healthy, and the nail is growing, it may be unnecessary in early life to perform any operation, for the infant may feed on its own toe. This is very common after the morning baptism. Does one then find it red and swollen, we know the cause, and I have never found any occasion for the use of the onychotome, although I always have one with me in my cigar case. Doubtless there are toe-nails which need removal. Who sees them? Who removes them? Do the physicians? God forbid! Do the family practitioners of whom I see so many around me; or do members of the society and of the general public cut their own toe-nails, abdominal obesity being the only obstruction? Lastly, I should like to hear from the society whether its members are in the habit of ordering Rochelle salts or Gregory's powder after this operation, or whether they allow the eliminative channels to have their full natural play? What are the dangers to be avoided in the conduct of this operation, and can those who have been under the care of the chiropodist give us the benefit of their experience?"

THE REVIVAL OF OVARIOTOMY.

[To the Editor of the Medical Times].

SIR,—I have just heard with very deep regret that Dr. Charles Clay, of Manchester, at the age of eighty-three, is stricken down with paralysis, I therefore hasten to take up a matter which concerns him, namely, the claim made by Sir Spencer Wells concerning the revival of Ovariotomy. Sir Spencer Well's address recently delivered before the Midland Medical Society was announced with the brief title "Modern Surgery," but on its appearance in print this title is enlarged to "An Address on the Revival of Ovariotomy and its Influence on Modern Surgery," and in it he practically makes a claim of having revived Ovariotomy between the years 1858 and 1865. Such a claim as this cannot in the least degree be substantiated when the facts of the case are fully examined. So far as has yet been discovered the first ovarian tumour removed in England was by the hands of Dr. Charles Clay, on September 27th, 1842, all others, with the exception of one by Houston and another by Lizars in Scotland, were clearly parovarian cysts. In 1843, Mr. Aston Key removed both ovaries, and Mr. Bransby Cooper also tried the operation in that year, but it was not till 1844 that there was a successful case in London operated on by Dr. Frederick Bird, followed by one in the practice of Mr. Lane. In the provinces, however, many successful cases had been done. In June, 1848, Dr. Charles Clay published a series of 32 cases with 10 deaths, and in 1857 he had completed 77 cases with 24 deaths. He operated continuously for many years till he had 395 cases, with 101 deaths, his total mortality being fractionally above 25 per cent., a mortality which I may remind Sir Spencer Wells is almost identical with that (25 per cent.) of his own 1,000 cases. At the same time the operation was being performed frequently in the large provincial towns of England, but particularly in Manchester, by Southam and others with great success. The only revival therefore of Ovariotomy which Sir Spencer Wells can lay any claim to is after its temporary decadence for two and a half years in London in the hands of Mr. Baker Brown, and even upon this point the evidence is by no means satisfactory. But if it is to be contended that from the time of McDowell till 1857 there was nothing being done in Ovariotomy, and that the revival took place in that year at the hands of Mr. Spencer Wells, I say it may as well be claimed for him that he revived the moon. To Dr. Charles Clay is due the credit of having established Ovariotomy in England and of having carried it through its early struggles. His practice was a mistaken one in the use of the long ligatures, but its results were certainly no worse than those obtained by the clamp. Dr. Clay unfortunately did not know of the results obtained by Nathan Smith from the use of the short ligature. Had he done so, abdominal surgery would have been half a century in advance of its present position, for then it would have been impossible for the clamp ever to have made its appearance. Baker Brown re-introduced Nathan Smith's principle and Keith brought it to perfection.

I am, Sir, yours &c.,

LAWSON TAIT.

Birmingham, November 24th, 1884.

OBITUARY.

FREDERICK A. MAHOMED, M.B. Cantab., F.R.C.P.

WITH profound regret we find it our duty to record the death of Dr. F. A. Mahomed, which took place on Saturday, November 22nd, at his residence, No. 24, Manchester Square, W. He had been attacked with rigors twenty-three days previous to his death, and the ordinary symptoms of typhoid fever followed in due course. Pursuing a plan of treatment agreed upon by himself and his colleague and friend, Dr. Cayley, he passed through the earlier stages most favourably. About the beginning of the third week a moderately severe hæmorrhage took place, with a somewhat alarming fall of temperature. On the day previous to his death he became collapsed, and never fairly rallied. He retained consciousness almost to the last, and still felt confident of recovery at a time when his friends could see only too plainly that hope was gone. He leaves behind him a widow and several children. The circumstances of his death recall to mind with painful clearness the loss which the profession sustained exactly a year ago in the death of his colleague Dr. Fagge. In both cases a bright prospect of future success had enabled them to enter upon practice in the West of London, and both have passed away at a time when their intellectual vigour was at its highest point.

Frederick Mahomed was born at Brighton in 1849, and commenced his medical life at the Sussex County Hospital in 1868. Entering as a student at Guy's Hospital in 1869, he obtained prizes at the end of his first and second years by examination, and was also awarded the prize for the best paper at the Pupils' Physical Society in 1870–71, for which he took the Sphygmograph as his subject. Becoming qualified in 1872, he was appointed resident medical officer at the London Fever Hospital, at which institution he has since succeeded to the posts of assistant physician and physician. He held the post of pathologist and medical tutor to St. Mary's Hospital School until his appointment as medical registrar at Guy's Hospital in May, 1877. A year after the retirement of Dr. Habershon he succeeded to the post of assistant physician, and shortly afterwards became demonstrator of pathology in association with Dr. Goodhart. In the meantime he had obtained the degree of M.B. at Cambridge, and had been elected a Fellow of the Royal College of Physicians, where he was recently nominated as the Bradshawe Lecturer for next year. As secretary of the Collective Investigation Society, his work has become known far and wide; and none can forget the vigorous manner in which, in conjunction with Dr. Burnet, he laboured to ensure the success of the late testimonial to Messrs. Bower and Keates. His unselfish efforts on behalf of them, and of the cause which they represented, will not be overlooked now that occasion has arisen for their practical recognition. The stimulus which has of late been given to the practice of anthropometry may, in a large degree, be attributed to the influence of Dr. Mahomed. In association with Mr. F. Galton he suc-

ceeded in formulating the science into a more practicable shape, and would doubtless have carried it to a point of real usefulness had his life been prolonged. He held an appointment as medical officer to an assurance company, in addition to his multifarious labours in hospital and private practice, and in scientific investigation.

Throughout each phase of the career outlined in the foregoing sentences, Dr. Mahomed exhibited in a most striking manner the quality of pure enthusiasm. Whether in the investigation of a new line of thought, or in the improvement of some old method of practice, he was equally enthusiastic and equally confident of ultimate success. And in this confidence there was no taint of self. With a new theory or a fresh belief fairly established in his mind, he did not hesitate to put it forth for the benefit of friends and students alike, thinking only of the purely scientific aspect of the question, and anxious only to enrich the common store of knowledge. Those who knew him but little have sometimes been led to think that he allowed his enthusiasm to overstep the bounds of reason. Among his students especially, there was at one time a tendency to look upon him as a visionary diagnostician, haunted by ever present phantoms, which showed him renal disease in everything. But no one held such an opinion for long. The most prejudiced person could not fail to recognize the value of such enthusiasm as this after a short acquaintanee with Dr. Mahomed. It was in the highest degree contagious, and its effect may be noted in the energy and success with which all those schemes have been conducted with which he was associated at the onset.

With a remarkable ingenuity and a singular aptitude for happy suggestion he united the still more valuable quality of indefatigable industry. To whatever kind of work he set his hand, he invariably entered into it heart and soul, with a single-minded determination that nothing should be wanting on his part to carry it to a successful issue. No better example of his indomitable energy can be cited than the manner in which he obtained his degree at Cambridge. Finding that residence within the precincts of the University was insisted upon by the authorities, he obtained permission to absent himself on certain days of the week, on condition that he slept at Cambridge. Without relinquishing any portion of his work in London, which was at that time most laborious, he travelled almost daily between the two places, employing the time on the journey in reading for his examinations.

From the first moment of his appointment at Guy's Hospital as Medical Registrar, he was for ever striving to add to the facilities for giving the most thorough praetieal education to students. By organising classes and demonstrations, and by improving the system of case-taking, he was able to introduce a sound practical knowledge of elinical medicine into many a brain that would have absorbed but little of itself. The extent of the loss to the Medical School can hardly be overstated. A vigorous and honest enthusiasm such as his, earried colleagues and pupils alike toward the fulfilment of higher aims. Of steady and industrious workers and of eultivated and powerful thinkers there is no lack, but of pure and single-minded enthusiasts there are but few in the profession. The element which such men supply is of inestimable value in the small world of a medical school. Apathy and agnosticism are the besetting sins which hinder the progress of medicine therein: but neither could long abide the presence of Dr. Mahomed.

Of his published work, by far the most important is to be found in the volumes of the "Guy's Hospital Reports," to which he contributed many papers on the subjects of chronie renal disease and albuminuria. Of his work upon this subject, and upon the teachings of the sphygmograph, it may be said that, like all his original labours, they are most suggestive, and will undoubtedly form the groundwork of future knowledge which others must now endeavour to supply. He was a frequent attendant at the Medical Societies, and took an active part in debates. A few days only before the onset of his fatal illness he was present at a meeting of the Clinical Society, and earned well-merited applause by the narration of a successful case in which, with characteristic energy, he had cured intermittent perityphlitis by means of operative removal of the foreign body which was giving rise to it.

With a thorough love of his profession as a scientific pursuit, Dr. Mahomed was by no means independent of it as a means of living, but in all his work he was never actuated by a shadow of an unworthy motive. In his endeavour to enlarge the range of medical science he worked for others and not for himself. In words which he himself was fond of quoting, he may well be "counted among the learned and the good who strive to make the future better and happier than the past."

The funeral took place on Thursday, November 27th, at Highgate Cemetery, in the presence of a large gathering of colleagues, friends, and students, many representatives being present from St. Mary's Hospital, the Fever Hospital, and the British Medical Association.

LESLIE MATURIN, M.K.Q.C.P., L.R.C.S.I., &c.

We deeply regret to record the almost sudden death of this talented and rising Irish physician, which occurred at his residence, Cork Street Fever Hospital, Dublin, on Wednesday, November 19th. Dr. Maturin died on the tenth day of an attack of scarlet fever caught under circumstances which strongly remind us of the sad death of Dr. Samuel Rabbeth some weeks ago. Six days before the symptoms of his fatal illness showed themselves, Dr. Maturin went with a brother practitioner to visit a little child lying dangerously ill of scarlatina anginosa. A large abseess near the tonsil endangered the child's life, and Dr. Maturin opened it. At the same moment the ehild coughed into his face. So conscious was he of the danger of this aceident that he returned to Cork Street Hospital, saying that he felt he was in for an attack. This presentiment proved only too well founded. He visited the sick child on Tuesday afternoon, November 11th, and the following Monday, November 17th, he was suddenly seized with shivering, vomiting, purging, violent headache, and pyrexia so intense that in a few hours his temperature rose to 105·4° Severe nervous (ataxic) symptoms quiekly set in, the throat became intensely painful and sloughy, and extreme dysphagia accelerated a deadly loss of strength. Then eame heart failure, and the end.

Leslie Maturin, whose life was thus untimely cut short at the age of 35 years, was the eldest son of Mr. John Maturin, of Newtownstewart, eo. Tyrone, a scion of one of the many old French Huguenot families which sought a refuge in Ireland after the Revocation of the Ediet of Nantes. From his student days his eareer was one of great promise. Even before he obtained his diplomas, in 1874-75, he was selected to fill the responsible post of Assistant-Accoucheur in the maternity attaehed to Dr. Steeven's Hospital, Dublin, wherc he had previously held the appointment of Surgical Resident Pupil for a lengthened period. Subsequently, he acted for some time as Surgeon-Superintendent of the Emigration Department, New Zealand Government. But these tame employments did not harmonize with Maturin's temperament, which was zealous, daring, and ambitious, and accordingly on the outbreak of the Russo-Turkish War in the summer of 1877, we find him volunteering as Surgeon to the Red Cross Society—the Russian Siek and Wounded Society under the administratorship of Dr. Humphry Sandwith, C.B. Through the trying campaign of the memorable winter of 1877-78, and through the still more trying horrors of the famous siege of Plevna and Rahova, and the battle of Gorney Dubnick, Leslie Maturin passed unscathed. He was second in eommand to Dr. Sandwith, who wrote in the highest terms of praise of his work and abilities.

On the conclusion of the war, Dr. Maturin returned home and served for some time as a dispensary medical officer, both in that *ultima Thule*, Achill Island, and also at Blessington, co. Wicklow. On the outbreak of small-pox in Dublin in 1878, he was appointed medical officer in sole charge of the Small-Pox and Fever Hospital of the South Dublin Union, at Kilmainham. This appointment he continued to hold until the hospital was elosed in 1882. While in charge he did excellent work, the results of whieh he published in the form of annual reports in the *Dublin Journal of Medical Science*. Early in 1883 he became resident medical officer and registrar to Cork Street Fever Hospital, Dublin,

where his kindness and attention to the sick, his ready resource and skill, often excited the admiration of the writer of this notice.

During his comparatively brief career, Leslie Maturin contributed many valuable papers to current medical literature. In the *Dublin Journal of Medical Science* he published several articles of interest and of scientific value. Among them we would in particular mention his reports of Kilmainham Fever Hospital, in which are included statistics relating to nearly three years' constant work in that institution, and a very important article on the "Use of Urari in Tetanus," as also one on "Vascular Hydrosis as a Prophylactic to Poisonous Absorption."

Dr. Maturin's death has excited wide-spread sympathy in Dublin, and the esteem and affection in which he was held received ample proof in the numerous and representative attendance of members of the profession and personal friends on the occasion of his interment at Mount Jerome Cemetery on the morning of the 21st instant.

MEDICAL CONSULTATIONS.

No. IV.—DIET.

SCENE—*The dining-room of a country house, after dinner.*

DRAMATIS PERSONÆ.

F.R.C.P.—*A physician from town.*

M.D., CANTAB.—*A provincial physician.*

L.S.A.—*A country practitioner.*

F.R.C.P. Absolutely a vicious dinner!

M.D., CANTAB. But pleasant and seductive, none the less.

F.R.C.P. Naturally. Vices, I have been informed, are commonly—I might say uncommonly—pleasant, until one confronts the penalty.

L.S.A. As Shakespeare says

"The gods are just and of our pleasant vices
Make instruments to plague us."

F.R.C.P. O, Shakespeare. Yes, exactly. But Shakespeare, marvellous fellow though he was, had not quite the experience of a London physician. He knew nothing, I take it, of gin-drinker's liver, of beer-drinker's kidney, of syphilitic brain or debauchee's spinal cord. Certainly he can have known little of those minor penalties of indulgence for which we have had to prescribe to-day, and from which we may infer the stronger digestions of his day were exempt. And why exempt, but that their dishes were more sensibly dressed, not tricked out with Frenchified sauces to spur on the jaded appetite, but sent to table with their natural flavour and their natural toughness? The jaws and the palate are the stomach's lawful guardians. With proper food the palate and the jaws are weary before the stomach. But if you circumvent palate and jaw, your stomach, with its lowly organised sensation, knows no more when to stop than that of a cow turned loose into a field of vetches; that is why I called our dinner a vicious one. The chances are that we have all eaten more than we can assimilate. Our hostess, I am sure, in spite of all our preaching, habitually does so.

M.D., CANTAB. I fear she does. And yet, on your own reasoning, her very sufferings may, like the aching jaw and cloyed palate, be the means of protecting organs whose integrity is more essential to life. Her grandmother would have had, not indigestion, but gout. If all they say is true, except in children, gross greediness is an obsolete vice. No one nowadays dies of a surfeit. When we go abroad, we make a single portion, which I take it is the index of the traditional appetite, serve for two or three.

F.R.C.P. Yes, but we have three courses where once they were content with one. Our ancestor who sat down and ate half a leg of mutton and then filled his pipe was greedy.

L.S.A. (*sotto voce*). "A joint of mutton and any pretty little tiny kickshaws."

F.R.C.P. But your modern gentleman who only eats moderately of soup, whitebait, salmon, sweetbread, filêt, saddle of mutton, game, sweets, ice pudding, and an assortment of fruits——

L.S.A. "A snapper up of unconsidered trifles."

F.R.C.P. Aptly quoted indeed! Your modern diner-out, I was going to say, is not greedy. O, no, he is *gourmet*, but not *gourmand*. For all that, however, he eats more than is good for him. Not more perhaps in the twenty-four hours than is necessary to replace his daily waste, but he crowds it all in at a sitting, and so he gets what I am in the habit of calling "one-meal dyspepsia." That is the modern fault.

M.D., CANTAB. It is not our fault hereabouts, as you would readily admit if you saw our hunt breakfasts and shooting luncheons. What you call "one-meal dyspepsia" is common enough among the mill hands who come to me at the hospital. They eat largely of meat at noon, and fill in with tea and bread and butter. But our upper classes and their servants, especially the servants, seem to me to be always eating. Their life is a "perpetual feast;" as for the "contented mind," well, the less said about it the better.

L.S.A. But, Dr. F., do I understand that you really attach more importance to restriction of quantity than regulation of quality?

F.R.C.P. Certainly I do. Regulation of quality is only important as a means of restricting quantity. In London, I have the reputation of being a starving physician, because I din it into the ears of all my patients that they eat too much. But I don't interfere with what they eat. In fact, I hold it to be unbecoming in a man of science to trouble himself with details of diet, and tell his patients what, if they are in their senses, they must know better than he. "Eat less" is the command I give, and I find it marvellously successful. An anxious mother brings me her fat hysterical daughter, "Dear doctor, she eats nothing—but *nothing*." "Eat less," and the next month she comes back a different creature. The most tiresome patients I have to deal with are ladies advanced in years, like our hostess, who firmly believe they must eat to keep up their strength, that the more they eat the stronger they will keep. It is a fixed idea which not the eloquence of all the physicians in the world would avail to remove, for there is nothing a woman fights against so much as the notion that her powers are on the wane.

M.D., CANTAB. As to dieting, I don't think I altogether agree with you. You will admit that one food is more digestible than another. Experiment has shown it to be so, and science has told us why. Who then can steer his patient safely through the shoals and rocks of a dangerous diet into the still waters of eupepsia, if not the physician who has taken soundings of them?

F.R.C.P. Your simile is a false one. Digestions vary, and are not framed on one pattern. *Quot homines tot digestiones.* Each man has his own rocks and shoals, and in avoiding them a grain of personal experience is worth a hundredweight of scientific doctrine. Besides, the more you interfere with quality of diet, the more you will have to interfere with it. If you begin by making things too easy for the stomach, it will end by making things too hard for you. It is an aphorism of mine that "a man

is as strong as his digestion," but then his digestion is very much what he chooses to make it. Forbid cheese, for instance, and the stomach will soon take it into its head that cheese is of all things the most indigestible; whereas if you had said nothing about it, the stomach would have taken it as a part of its day's work and said nothing about it either.

L.S.A. "Subdued to what it works on, like the dyer's hand."

F.R.C.P. There are more ways of pampering that dear organ of ours than distending it with dainties; and of the men who habitually think of it too much, I can hardly say which spoils it the most, the valetudinarian or the epicure. The question is, who shall be master, you or your stomach, and woe to you if you let it get the upper hand.

L.S.A. "By my penny of observation" I have come to the conclusion that if we only took indigenous diet, we should hear little of dyspepsia. Nearly all the foods that cause it are, I find, foods that are not native to this country. Item, tea imported from China. Item, potatoes imported by Raleigh from America. Item, cane sugar imported from the West Indies. Item, cucumber. Item, cheese, of which the most fatal kinds come to us from France and Switzerland, and must be putrid to be palatable.

M.D., CANTAB. And pray, my good L., what of the homely radish, the indigenous lobster, the salmon of our rivers, and the pastry of our cooks? What says your Shakespeare?

"Gets him to rest crammed with *distressful bread*."

L.S.A. O come, I protest. The bread was "distressful" because the poor fellow could not get anything better. Your gloss is entirely unsupported by the context.

M.D., CANTAB. I willingly bow to your superior authority.

F.R.C.P. For my part I believe that the idea of looking on almost every imaginable food as a criminal ready to work mischief on the slightest provocation, is quite a modern one, and doctors are greatly to blame for encouraging it. The real fact is, that science has not yet provided us with a generalisation as to admissible foods. All that we can say at present is that foods that can be chewed can be digested, provided always you do not take too much. Diet is a matter of common sense, not of science, whose interference with it has proved purely mischievous. Our peptonized foods, our pepsines, our malt extracts have worked more harm to the national digestion than all the tea and potatoes that were ever imported. Useful they may be to tide over a period of digestive languor; or in old age when the laboratory of life is failing. But for healthy men and women, whose powers can yet respond to natural stimuli, they are a fatal gift—a gift of over-meddlesome science.

L.S.A. Then how, pray, have you won your reputation for curing dyspepsia?

F.R.C.P. Easily. Because while other men have drowned their patients' stomachs with half the pharmacopœia, bismuth, alkalies, charcoal, acids, strychnine, iron, pepsine, hypophosphites, arsenic, mercury, and I know not what, my remedies have been but two—starvation and calumba. In the worst cases a course of rectal feeding and perhaps a blister on the pit of the stomach. Twice I think in my life I have prescribed a diet of asses' milk. Once I had the stomach washed out. But these were quite exceptional cases. In fact, I seldom order anything but two leisurely meals a day of crisp and toughish diet. If the patient rebels, I send him to the dentist. (*Rising.*) How goes the time?

L.S.A. I fear you ought to be starting. There is a long drive before you. A glass of sherry before you say good-bye upstairs?

F.R.C.P. Shall I? Thanks! Ah, that to practise were as easy as to preach.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—*Fellowship Examinations.* The following gentlemen having undergone the necessary examinations, on the 24th instant, were reported to have acquitted themselves to the satisfaction of the Board of Examiners, and when eligible, will be admitted to the pass examination, viz.:—

Messrs. William F. Taylor, student of Kingston, Canada; Henry D. Farnell, University College Hospital; Thomas M. Porter, Liverpool School; John C. Lamont, University of Edinburgh; and Frederick H. Taylor, London Hospital.

Seven candidates, having failed to acquit themselves to the satisfaction of the Board of Examiners, were referred to their studies for six months.

The following gentlemen passed on the 25th inst., viz.:—

Messrs. Clayton C. Harris, St. Bartholomew's Hospital; Gilford Hastings and Samuel W. Owen, Guy's Hospital; William Williams, St. Mary's Hosnital; and Alfred J. Gregory, London Hospital.

Four were referred for six months, making a total of eleven rejections out of the twenty-one examined.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, November 20th, 1884:—

Edward Thomas Gregory, Charing Cross Hospital; William Lees, University College; Arthur Smith Loftus, Charing Cross Hospital; George William Mullis, Guy's Hospital; Joseph Orlando Orr, Toronto University; Harry Winstanley Shadwell, St. Bartholomew's Hospital; Thomas William Thomas, University College.

The following gentleman also on the same day passed the Primary Professional Examination.

Theodore Albert Vores Ford, St. Thomas's Hospital.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 19th inst., the degree of Bachelor of Medicine was conferred on Oswald Auchinleck Browne, Trinity. Dr. Donald MacAlister has been appointed by the Senate an examiner at the third examination for the degree of M.B.

UNIVERSITY OF GLASGOW.—On the 21st inst., in the Bute Hall, a supplemental graduation ceremony took place under the presidency of Principal Caird. The degrees conferred were as follows:—

M.D.—William Broadfoot, Alexander Meighan, Charles Wilson.

M.B.C.M.—Robert Eaglesham, James D. Farquharson, Alexander M. Kinghorn, David Moffat, Robert L. R. Macleod, Tamiz Uddin.

PATHOLOGICAL SOCIETY.—Tea and coffee will in future be provided at the meetings of the Society from 8 to 9 p.m., instead of at the close of the meeting as heretofore.

THE Library of the Royal College of Surgeons will be closed for the purposes of the Fellowship Examinations, on Friday 28th and Saturday 29th November. Also, after 1 o'clock on Monday, December 1.

MIDDLESEX HOSPITAL.—The Princess Christian has consented to open the new building in connection with the Middlesex Hospital on Tuesday, Dec. 16, at 12.30 p.m.

BELFAST ROYAL HOSPITAL.—The annual report of this charity was submitted to the yearly meeting of its corporation on Monday last, 17th inst. From the secretary's statement it was seen that the institution commenced the financial year with a debt of over 700*l.*, and although every exertion was made to wipe this out during the year, it has steadily increased, until now it amounts to almost 1,800*l.* A bazaar, which opens in a few weeks with every prospect of success, is expected to more than wipe out this deficit. The cause of this state of matters was demonstrated by the figures in the medical report, which show that of the 15,000 patients treated during the year there was a surplus of 1,500 over that of many years' work done since the hospital was founded. Though this heavy debt hangs over the charity, the board of management and general committee are determined to turn away no deserving or pressing cases. It is thus yearly becoming clearer that the hospital will soon be unable to meet the demands of the population.

One of the causes for its limited subscription list was stated strongly to be owing to a dissatisfaction existing amongst some of the clergy about the want of facilities given to them of visiting patients of their own denominations while in hospital. A special meeting will be at an early date summoned to consider the question.

Newcastle-upon-Tyne Infirmary.—The Prince of Wales has consented to become patron of this hospital, an office that has not previously existed in connection with it.

Charitable Bequests.—The late Mrs. Willoby, of Hastings, has left 2,000*l.* to the Brompton Consumptive Hospital, and 1,000*l.* each to the London Cancer Hospital and the Sussex County Hospital at Brighton.

Compulsory Notification of Infectious Diseases.—Dr. Tibbits read a paper on this subject at a recent meeting of the Bradford Medico-Chirurgical Society. He said that it was only for the last 10 years that compulsory notification had seriously occupied public attention. He maintained that there was a tendency to over-legislation in matters pertaining to the public health, and dwelt on the different diseases which it was compulsory to notify. He contended that compulsory notification without provision for isolation was absurd, and dwelt upon the difficulty of diagnosing fevers from their early symptoms, instancing cases in which patients sent into hospital and alleged to be suffering from one fever were found to be suffering from another, and meantime infected other patients. To obviate these difficulties, he suggested (1) that quarantine wards ought to be provided for doubtful cases. (2) A large convalescent house for scarlatina patients should be provided. (3) All patients should first be sent to quarantine wards except in those cases where the diagnosis was absolutely certain. (4) In all cases of doubt, a consultation should take place between the medical attendant and the Medical Officer of Health, and if they could not agree, a third person should be called in as arbiter. (5) All Medical Officers of Health should be purely State Officers, and legislation of this kind should be imperial.

Chloride of Cocaine.—The *New York Medical Record* (October 18th), commenting upon communications from several correspondents concerning this new local anæsthetic, observes that we are in some danger of over-reaching the bounds of reasonable enthusiasm regarding its merits, so considerable have these proved when submitted to the severest tests by several well-known ophthalmologists. If its power to control pain in iridectomy can be established, the importance of the discovery of this anæsthetic will, in eye-surgery at least, rank second only to that of ether itself. The test for its still wider range of usefulness in surgery is yet to be made in ophthalmic practice. It is not reasonable to suppose that, even from the present aspects of the question, we shall stop here. It is quite certain that in those numerous cases in which local anæsthesia is necessary for minor operations in surgery, gynæcology, laryngology, otology, and even dentistry, this anæsthetic will be tested. Especially would it seem to be indicated in those parts of the body which are covered by mucous membranes and plentifully supplied with sensitive nerves. As yet we know little or nothing of its possibly poisonous effects in large doses, and it is to be hoped that no rashness will demonstrate them.

The Lord-Chancellorship of Glasgow University.—The voting papers issued to the members of Glasgow University Council, in reference to the election of the Lord-Chancellor, were on Thursday last summed up by the Registrar (Mr. T. Moir) in the presence of the proposers of the Earl of Stair and the Marquis of Bute. The result was declared as follows :—For Earl of Stair, 720; Marquis of Bute, 192; Lord Reay, 26. A great number of the votes were rendered invalid through the voter not having attached his signature to the voting paper; and of such rejected papers there were, for the Earl of Stair, 389; Marquis of Bute, 126; Lord Reay, 11. Principal Caird intimated the election of the Earl of Stair in the manner prescribed in the ordinances of the Scottish University Commission.

British Medical Temperance Association.—At a meeting of the British Medical Temperance Association held on Tuesday last in the Medical Society's rooms, it was announced that the President, Dr. B. W. Richardson, and the Council were now prepared to offer a prize of 100 guineas for the best essay on the Physical and Moral Advantages of Total Abstinence from Intoxicating Liquors, to be competed for by medical students in the United Kingdom. Dr. Heywood Smith subsequently read a paper on the Use of Alcohol by Parturient Women.

Hydrophobia in Vienna.—Hydrophobia is stated to have been rampant in Vienna for some weeks. There have already been some 80 cases and 11 deaths.

French and German Doctors in 1883.—During 1883, the six Faculties of Medicine in France conferred 662 diplomas of doctor of medicine, viz., Lille 20, Nancy 21, Lyons 43, Bordeaux 44, Montpellier 69, and Paris 465. During the same year 692 diplomas of doctor of medicine were conferred in Germany.

The Digitaline of the French Hospitals.—M. Laborde, who some time since exposed the worthlessness of the quinine employed in the French hospitals, has now taken their digitaline in hand. He stated at a recent meeting of the Société de Biologie that he had formerly examined samples of digitaline on sale of German and of French manufacture, and had found that the latter was of very superior quality. He has lately examined a sample of that used at the French hospitals, and has found it worse than any other as regards chemical composition and physiological action. Therapeutically, it may be declared to be inert; and this is why many hospital physicians have discontinued prescribing digitaline, or only use that which they bring with them.

Chronic Conjunctivitis.—A dram of balsam of copaiba to an ounce of white vaseline makes an ointment popular with New York ophthalmologists in treating chronic conjunctivitis.

Cheese Poisoning in Michigan.—At the recent meeting of the Michigan State Board of Health, Dr. Baker continued his reports on this subject. Seven outbreaks within the State had been reported during the year, 190 persons having been affected in all, but none fatally. The symptoms were very similar in all cases, consisting of pains in the stomach, muscular cramps, coldness of the extremities, and great prostration, with violent retching and purging for several hours. Specimens of the Lowell cheese had an acid reaction, and a peculiar strong odour, believed to be due to caprylic acid or caproic acid. Examined under a one-tenth inch immersion objective, the cheese was found to contain the mycelium of a mould, and to be swarming with several kinds of bacteria in active movement.

Arrangements for Dental Students in Dublin.—A largely attended meeting of the staffs of the Clinical Hospitals of Dublin was held in the Albert Hall of the Royal College of Surgeons, Stephen's Green, on Tuesday, November 25th, to consider a proposition by Mr. R. Theodore Stack, that dental students should be granted certificates for partial attendance at clinical hospitals. Mr. Stack's proposal is as follows:—"That the dental student be permitted to attend the surgical wards only of any of the Dublin Clinical Hospitals, and that he may be given a certificate of such attendance for the fee of 6*l.* 6*s.*, for each session of nine months, provided that proof of at least attendances during each such session is produced by him. That such certificate of partial attendance shall not be given by any hospital, except on the production by the dental student of a certificate that he has entered and paid his fees for the practice of a dental hospital, and for the special lectures in the dental school connected therewith, viz., Dental Anatomy, Dental Surgery, Metallurgy and Mechanical Dentistry, this certificate to be signed by three members of the staff of a dental hospital which courts the inspection of any of the licensing bodies in Dublin, which from time to time may, under the Dentist's Act, arrange to issue a dental diploma." A resolution was put to the meeting that Mr. Stack's proposition be acceded to, the following safeguards being adopted:—A special uniform

certificate of hospital practice to be issued to the dental students only, and a copy of the same to be forwarded to the various licensing bodies, such certificates to be available for the dental qualification only. After a very full discussion the resolution was rejected, *nemine contradicente*, chiefly on the ground that in the dental curriculum of the Royal College of Surgeons of Ireland it was provided that the two years of partial hospital attendance should count as full years should the dental student elect to complete his course for the letters testimonial of the College.

Fatal Epidemic in Virginia.—A New York telegram states that the outbreak of a fatal epidemic is reported from some remote counties of South-West Virginia, and some adjoining parts of Kentucky. Drought having dried up the ordinary wells, the inhabitants drank the water from some mineral wells, which produced a peculiar disease, as deadly as cholera. Several entire families perished, the effects of the disease being terribly sudden. The mortality is variously estimated from 400 to 800. Few of those attacked recovered, the proportion of fatal cases being from 60 to 80 per cent. A subsequent telegram states that the epidemic, which is considered by the medical authorities to be one of dysentery, has already abated owing to a heavy rainfall.

The Howard Medal.—At a meeting of the Statistical Society of London, held on the 18th instant, the Howard Medal and 20*l.* were presented by the President, Sir Rawson Rawson, K.C.G.M., C.B., to Clement Dukes, M.D., B.S., Lond., Physician to Rugby School, and Senior Physician to the Hospital of St. Cross, Rugby, for an essay on "The preservation of Health as influenced by personal habits, such as cleanliness, temperance, &c."

Prosecution under the Medical Act.—At Hammersmith police-court, on the 14th instant, Henry Trist, of Fulham, was fined the *maximum* penalty, 20*l.* and 1*l.* 3*s.* costs, for having falsely held himself out as a duly qualified medical practitioner. His solicitor wished to appeal, but it was found that the Act did not provide for it.

Count Lesseps on Quarantine.—M. de Lesseps, in reference to a visit which he is about to pay to Egypt, insisted at the Académie des Sciences on the uselessness of quarantine, which he considers as a vestige of the barbarism of former times. The ineffiecacy of this prophylactic measure, which has been so well demonstrated at the present time, gives reason to hope for its speedy and final suppression, with which will disappear one of the most troublesome obstacles to the freedom of circulation, which has become an imperious necessity for modern life.

Death after Tying External Piles.—It is a well known fact that ligature of external hæmorrhoids is always accompanied by excruciating pain, not to be relieved by narcotics, while that of internal piles is painless. This, probably, is also the reason why so frequently trismus and tetanus follow the tying of external hæmorrhoids. There are many such cases recorded, and Dr. Snamenski, in the *Moscow Zeit.*, No. 35, 1884, adds two more cases. In one of these trismus and death followed the operation on the sixth day, while in the other most violent pains occurred but eventual recovery took place. In thirty-nine cases of ligature of internal piles neither pain nor complication took place. Dr. Snamenski has made numerous experiments on dogs, stating that, as in man, the mucous membrane of the rectum 1½ centimetres above the anus is quite insensitive, while the last centimetre and the skin around the anus possess an extraordinary hyper-sensitiveness. This agrees with the anatomical researches of Fellner, who has discovered that the skin near the anus and the rectal mucous membrane for about one centimetre above the anus is provided with sensation by the sensory *nerv. pudend. comm.*, while the mucous membrane of the rectum about 1 centimetre above the anal orifice receives only fibres of the non-sensory middle hæmorrhoidal nerves.

The Microbe of Yellow Fever.—At the last meeting of the Paris Société de Biologie, M. Rebourgeon gave some additional information as to the researches of Professor Domingos Frére, of San Janeiro, on the microbe of yellow fever. He believes that a former communication to the Académie de Médecine has not met with the attention it deserves. M. Frére, he observes, is fully entitled to priority in this discovery, the reality of which is shown by the fatality which attends the inoculation of the microbe in animals, which is very easily brought about. A still more important result is the attenuation of the virus by means to be hereafter divulged; inoculation of this attenuated matter only produces temporary disturbance of the animal's health Informed of the experiments, the Emperor of Brazil ordered that 600 workmen, constantly occupied in the midst of highly infected centres, should be inoculated. While before this period 10 men out of every 30 had been attacked with the disease none of those inoculated have suffered, except four or five men, in whom the operation was performed by the lancet instead of by the Pravaz syringe. M. Bouley drew attention to the importance of giving the widest publicity to these statements, and stated that the attenuated virus was about to be taken to Senegal, where last year 23 out of 25 French physicians died of yellow fever.

Terpine.—Under this name M. Lépine gave an account at the Lyons Société des Sciences Médicales (*Lyon Médical*, November 16th), of a new therapeutical agent produced by a chemical combination of turpentine, alcohol, and nitric acid. In doses of from 29 to 40 centigrammes he has found it very useful in chronic, and even in sub-acute, bronchitis, greatly facilitating expectoration. Advantage has also been derived from it, in the same or smaller doses, in some cases of chronic nephritis. It is a diuretic acting directly on the renal epithelium, requiring to be used with circumspection.

APPOINTMENTS.

Allwright, Frederick William, L.K.Q.C.P. Ire., and L.R.C.S. Ire.—Medical Officer to the Eighth District, Wycombe Union, *vice* Mr. A. Warren, resigned.

Caiger, F. Foord, M.B., B.S., M.R.C.S., L.R.C.P.—House Physician to St. Thomas's Hospital.

Green, C. D., M.B., M.R.C.S., L.R.C.P.—Resident Accoucheur to St. Thomas's Hospital.

Hill, M., M.D.—Honorary Physician to the Bootle Borough Hospital, *vice* G. C. Walker, M.D., resigned.

Jones, R. Nelson, L.R.C.P., M.R.C.S.—House Surgeon to the Swansea Hospital, *vice* W. Carr Humphreys, M.R.C.S., &c., resigned.

Johnston, G. D., M.R.C.S., L.R.C.P.—House Physician to St. Thomas's Hospital.

Lankester, H. H., M.R.C.S., L.S.A.—Non-Resident House Physician to St. Thomas's Hospital.

Lawson, R., M.R.C.S., L.S.A.—Assistant House Surgeon to St. Thomas's Hospital.

Mackenzie, H. W. G., M.A., M.B.—Assistant House Physician to St. Thomas's Hospital.

Maclehose, N. M., M.B., C.M.—Resident Medical Officer to the Sick Children's Hospital, Glasgow, *vice* Mr. W. S. H. Walker.

Marriner, W. H. Lister, M.B., M.R.C.S., L.R.C.P.—Clinical Assistant in the Department for Diseases of the Throat to St. Thomas's Hospital.

Orford, J., M.R.C.S., L.R.C.P., L.S.A.—House Surgeon to St. Thomas's Hospital.

Plowman, S., M.R.C.S., L.S.A.—Clinical Assistant in the Department for Diseases of the Skin and Ear to St. Thomas's Hospital.

Reynolds, Lewis William, M.R.C.S., and L.S.A.—Medical Officer to the First District, Wycombe Union, *vice* Mr. W. Rose, resigned.

Robinson, H. B., M.R.C.S., L.R.C.P.—House Surgeon to St. Thomas's Hospital.

Robinson, H. S., M.R.C.S., L.R.C.P.—Honorary Surgeon to the Montwearmouth Dispensary and Accident Home.

Rose, J., M.R.C.S., &c.—Honorary Ophthalmic Surgeon to the Bootle Borough Hospital.

Russell, A. W., M.B., C.M.—Medical Superintendent to the Western Infirmary, Glasgow.

Smart, David, L.R.C.P. Lond., M.R.C.S., and L.S.A.—Medical Officer to the Bermondsey Workhouse, St. Olave's Union, *vice* Dr. Cuolahan, deceased.

Stirling, Charles, M.B., and M.Ch.—Medical Officer to the Second District, St. Olave's Union, *vice* Dr. Cuolahan, deceased.

Sutton, S. W., M.D., B.S., M.R.C.S., L.R.C.P.—Ophthalmic Clinical Assistant to St. Thomas's Hospital.

Walker, G. C., M.D., &c.—Honorary Consulting Physician to the Bootle Borough Hospital.

VACANCIES.

Addenbrooke's Hospital, Cambridge.—Resident House Physician. Salary, £65 per annum, with board, lodging and washing in the Hospital. Candidates must be duly registered. Applications with qualification and testimonials to be sent to the Secretary (from whom further particulars can be obtained), on or before Dec. 9th.

BECKETT HOSPITAL AND DISPENSARY, BARNSLEY.—House Surgeon. Salary, £130 per annum, with furnished rooms, gas, coal, and attendance. Candidates must possess full medical and surgical qualifications. Private practice prohibited. Applications, with testimonials, to be sent to the Honorary Secretary, before December 1st.

BIRKENHEAD UNION.—Medical Officer to the Fourth District, in succession to Dr. Richard Sylvester Daniel, deceased. Area, 3,621. Population, 20,033. Salary, £100 per annum.

BOROUGH OF NOTTINGHAM.—Medical Officer of Health. (*For particulars see Advertisement.*)

CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, PARK PLACE, MANCHESTER.—House Surgeon. Salary, £80 per annum, with apartments and board. Candidates must be duly qualified pretitioners. Applications, with testimonials, stating age, to be sent to Mr. Hubert Teague, Secretary, 38, Barton Arcade, Manchester, not later than December 4th.

DARLINGTON HOSPITAL AND DISPENSARY.—House Surgeon. Salary, £100 per annum, with board, lodging, and attendance. Candidates must possess double qualifications, and be duly registered practitioners. Applications, stating age and previous experience, and enclosing testimonials as to special qualifications, to be sent to Henry Fell Pease, Esq., Brinkburn, Darlington, on or before December 3rd.

HOLYWELL UNION.—Medical Officer to the Flint District, in succession to Mr. Richard Jones, deceased. Area, 11,700. Population, 11,116. Salary, £48 per annum.

KING'S COLLEGE, LONDON.—Chair of Materia Medica and Assistant Physicianship. (*For particulars see Advertisement.*)

MITFORD AND LAUNDITCH UNION.—Medical Officer to the North Elmham District, in succession to Mr. Peter Parlett Ranson, deceased. Area, 19,228. Population, 4,052. Salary, £60 per annum.

PEWSEY UNION.—Medical Officer to the Third District, in succession to Dr. Fulcher, resigned. Area, 14,145. Population, 2,440. Salary, £63 per annum.

RATCLIFFE INFIRMARY, OXFORD.—Honorary Physician. (*For particulars see Advertisement.*)

VICTORIA UNIVERSITY. — External Examiners in Physiology, Anatomy, Pathology, and Systematic Surgery. (*For particulars see Advertisement.*)

DEATHS.

BODDY, W. B., M.R.C.S., at 111, Camberwell Road, on November 20th, aged 89.

CLOTHIER, HENRY, M.R.C.S., at Haselmere, on November 25th, aged 76.

FLUDER, EISDELL, M.R.C.S., L.S.A., at Cromer, Suffolk, on November 15th, aged 40.

MAHOMED, F. AKBAR, M.B. Cantab., F.R.C.P., at 24, Manchester Sqnare, W., on November 22nd, in his 36th year.

MATURIN, LESLIE, M.K.Q.C.P., Resident Physician at Cork Street Fever Hospital, Dublin, on Novmber 19th, aged 35.

NOTES, QUERIES, AND REPLIES.

OUR APPEAL.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Three years ago a young surgeon practising in New Zealand died suddenly, nine months after losing his wife. Two little orphan sons aged 3 and 4 years respectively, were at once sent home to England to their grandmother, the widow of a clergyman, herself in delicate health, advanced in years and with scanty means of support. With praiseworthy energy this good old lady at once set about an active canvass to get one of the lads into the Wanstead Orphan Asylum and was happily successful. She is now most desirous, ere she dies, that the other little fellow should find a home in the same institution as his brother, so that the fatherless and motherless boys may at least see and know something of each other during their childhood and youth.

A sum of £180 will secure the fulfilment of this very natural wish and will provide a home and education for the child for the next nine years.

The British Medical Benevolent Fund, which has already on two occasions given assistance, has to-day promised £20 if the remainder of the sum required is forthcoming, and I venture to make an appeal through your columns for contributions for this purpose.

I shall be most happy to give fuller information either personally or by letter to any who may desire it.

I am, Sir, yours &c.,

STAMFORD FELCE.

Kenmure Lodge, Elgin Road,
St. Peter's Park, W.,
November 25th, 1884.

THE TREATMENT OF LEPERS IN CALIFORNIA.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Thinking that perhaps the Yankee mode of dealing with foreign lepers may not be generally known in Europe, I enclose a paragraph I cut from a New York paper, copied from a Californian colleague, railing against the actual Government because of the delay in depositing lepers of Chinese nationality existing in San Francisco, and stimulating the actual to imitate the energy of former Government in this matter. It would be better that the hyper-civilised Americans should enquire into the traditions of Mediæval Europe as to the treatment of those afflicted with this awful disease and learn therefrom lessons of charity.—"There is a leper colony struggling into life among us. It is small now, and, perhaps, scarcely noticeable. But it is striking its roots deep into the soil. If not excised it is bound to grow and expand. Leprosy is a disease of comparatively recent importation in the Sandwich Islands. But now 2 per cent. of the whole native population are afflicted with the horrible disease in various stages of development. We have had a notion that the white race need have no fears on the subject. But that is a wholly false and unreliable assumption. There are white lepers now. Former local administrations, fully impressed with the gravity of the matter, tore up, one after the other, two leper colonies and shipped them off. But now there seems to be a disposition to settle down and accept leprosy as a feature of San Francisco life. There is a hitch between the steamship companies and the authorities. There are some defects in the law. Upon the merits of the controversy we do not propose to pass now. All that we know is nothing is being done and that the leper colony grows. Against any further paltering with this great evil we protest with all the energy that can be thrown into language. The small interests that have grown up in favour of the continuance of the leper hospital should be trampled under foot. There should be no cessation of effort till the lepers are gone."

Last evening a total eclipse of the moon occurred here. During the period of complete eclipse there raged a violent storm which commenced and ceased suddenly.

I am, Sir, yours &c.,

RICHARD GUMBLETON DAUNT, M.D. Edin.

Campinas, S. Paulo, Brazil.

Royal College of Surgeons.—The half-yearly Primary, or Anatomical and Physiological, examiuation for the Fellowship of the College was held on the 21st instant, when twenty-one candidates pre sented themselves, as against forty-four at the corresponding period of last year, to whom the following questions on *Physiology* were submitted, when they were required to answer at least three of the four questions between 10 and 1 o'clock, viz.:—1. Describe the development of the Heart and Blood-vessels. 2. Describe the Nervous Mechanism by which Blood-pressure is regulated. Give the evidence on which your statements rest. 3. Give the Histology of the Macula lutea, and describe the Blood-supply of the Retina. 4. What are the average quantities of Carbon and Nitrogen eliminated by an adult in twenty-four hours? In what forms and by what channels are they excreted? What quantity of food would compensate this loss? Prove your statements by reference to the chemical composition of food, taking Albumin as the type of Proteids, Stearine of the Hydro-carbons, and Starch of the Carbo-hydrates.

The following were the questions on *Anatomy*, when three out of the four questions were required to be answered between 3 and 6 o'clock, viz.:—1. The Scalp and Calvaria having been taken away, describe in order the parts which must be removed to expose the upper surface of the Cerebellum. The portion of brain removed is to be described in detail. 2. Describe the Dissection necessary to expose the surfaces of Bone which enter into the formation of the Temporal Fossa. 3. Describe the Vascular Supply of the Thyroid Body, giving fully the course and relations of both arteries and veins. 4. Describe the Ligaments which connect the Vertebræ together. State what movements are permitted in each region of the Spine, and the mechanism by which these movements are permitted in certain regions, and prevented or lessened in others.

APPOINTMENTS FOR THE WEEK.

Friday, November 28 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY OF LONDON, 8.30 p.m.—Adjourned discussion on Mr. Morrant Baker's Paper, "On Cases of Charcot's Joint Disease." Living cases will be exhibited at 8 p.m., as well as some illustrative specimens sent by Professor Charcot. If time permit, a "Case of Tumour of the Frontal Lobe, with few symptoms," by Dr. Hale White, will also be read.

QUEKETT MICROSCOPICAL CLUB, UNIVERSITY COLLEGE, GOWER STREET, 8 p.m.—Ordinary Meeting. W. F. Bates, "On the supposed Sexual Threads in Zygnemacea.

Saturday, November 29.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, December 1.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Ceutral London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

MEDICAL SOCIETY OF LONDON.—Mr. Boyce Barrow, "A Case of Gastronomy" (with Specimen); Mr. John H. Morgan, "Cyst of the Neck."

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN, 8 p.m.—Casual Communications by Messrs. J. C. McAdam, Storer Bennett, W. Coffin, and Dr. St. George Elliott. Paper by Mr. J. Bland Sutton, F.R.C.S., "On Comparative Dental Pathology."

Tuesday, December 2.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 p.m.—Dr. Pye Smith, "Cystic Disease of Cerebellum, Kidney and Pancreas;" Dr. Lanchester, "Intussusception in an Adult Male;" Dr. Carrington, (1) "Simple Ulceration between Trachea and Œsophagus," (2) "Atrophy of the Liver" (Card); Mr. Treves, (1) "Two Specimens of Tumours of Soft Palate," (2) "Epithelioma of Bladder with Renal Calculus" (Card); Mr. Eve, "Lympho-sarcoma of the Bladder;" Mr. Poland, "Congenital Hydrocele of the Spermatic Cord;" Mr. Bowlby, (1) "Fistular Communication between Bladder and Rectum" (Card) (2) "Infiltrating Fibroma of Thyroid;" Dr. Paddison, "A Case of Charcot's Disease with Sections of the Spinal Cord" (Card). Mr. Hudson will show a new and simple "Ether Microtome."

Wednesday, December 3.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal Loudou Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central Londou Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

OBSTETRICAL SOCIETY OF LONDON, 8 p.m.—Adjourned discussion on Dr. Graily Hewitt's paper on "The Severe or so-called 'Uncontrollable' Vomiting of Pregnancy," to be opened by Dr. Robert Baines, and followed by Dr. Braxton Hicks; Dr. Potter on "A Case of Retained Product of Conception;" Dr. McKeown on "The Prevention of Ophthalmia Neonatorum and its ravages."—Specimens will be shown by Dr. Horrocks, Dr. Carter and others.

PARKES MUSEUM, 74A, MARGARET STREET, REGENT STREET.—Dr Norman Chevers, C.I.E., "On House Sanitation."

Thursday, December 4.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

ROYAL COLLEGE OF SURGEONS, 4 p.m.—Mr. W. S. Savory, F.R.S (Vice-President) will deliver "The Bradshaw Lecture" in the Theatre of the College.

CLINICAL LECTURES ON THE TREATMENT OF DISEASE.

Delivered in King's College Hospital,

By J. BURNEY YEO, M.D., F.R.C.P.,

Physician to the Hospital.

LECTURE V.

The Treatment of Phthisis.

GENTLEMEN,—Our ideas with regard to the treatment and management of pulmonary consumption will necessarily be greatly influenced by our beliefs with regard to its pathology.

If we believe that pulmonary consumption is an infective disease originating in the introduction into the body of a specific organism from without, the rooting, development, and spread of which depend on its encountering a suitable soil, or an inherited predisposition for its culture and growth; if we believe this doctrine of the origin and nature of pulmonary consumption, and with the evidence before us it seems to me that we are, logically, compelled so to believe, this belief must necessarily influence our views of treatment. Much of the phraseology that has been used in connection with this subject will then appear obsolete. Such expressions as "pretubercular phthisis," "the constitutional disorder which produced the tubercle,' "phthinoplasm," references to this disease having its origin in "exhausted or lowered vitality;" these and many other familiar expressions, vague and unintelligible as for the most part they are, and making the largest possible demands on our willingness to accept shadowy generalities and unsupported hypotheses as true indications for treatment, these we can no longer accept in the sense in which they were originally advanced.

We must regard the striking evidences of defective nutrition which we encounter in this disease, and which it will tax all our resources to arrest or check, not as the cause, but as the consequence of the pulmonary affection; as a consequence, mainly, of the infective fever which attends the development of tuberculous disease in the lungs, as well as in other organs.

What, then, are the true indications which may be laid down for the treatment of pulmonary consumption? They are these:—

(1) In the first place, to prevent or amend those faults of constitution, organisation and development which predispose to the acquirement of this disease.

(2) To prevent or cure those local pulmonary affections which may induce a tendency to this disease, even where no constitutional predisposition is found to exist.

(3) To prevent the possible spread of the disease by

the conveyance of its germs from the sick to those who are necessarily brought into close contact with them.

(4) To endeavour, so far as possible, to antagonise the influence of the infective organism *in situ*, and in its action on the constitution. To attempt to hinder the progress of its development and reproduction, and its extension to the sound parts of the affected lung, and also to the sound unaffected lung, and to prevent the infection of other organs. This is what is understood by antiseptic treatment.

(5) To lessen and remove the *fever* and other constitutional disturbances dependent on the infection of the constitution, as well as on the local inflammation.

(6) To lessen and arrest the local irritation and inflammatory and catarrhal changes when evidences of such make their appearance.

(7) To improve the disturbed and defective nutrition by all the means in our power, medicinal, regimenal, climactic, &c.

(8) To relieve the various distressing symptoms that occur during the course of the malady.

(9) To diminish as far as possible the evil consequences of the several grave complications incident to its course.

There is, then, no lack of indications for treatment in this disease; indeed, no other disease, perhaps, has so many. In the following lectures I shall consider, fully, all these indications.

And first with regard to

Prophylaxis.

The prevention of pulmonary consumption may be regarded from three principal points of view.

First, the prevention of the transmission of the phthisical disposition, or tendency, from parent to offspring.

Second, the prevention of the development of the disease when the predisposition exists; and

Third, the prevention of those unhealthy conditions and circumstances of life which are known to favour the acquirement of phthisis.

(1) The hereditariness of phthisis has been placed beyond a doubt, but from the point of view of prophylaxis it is important to remember, that by the hereditary nature of phthisis, we do not mean that phthisical parents convey to their offspring a constitution which must *necessarily*, at a given period of life, develop tuberculous disease, but rather that they transmit to their children an organisation which renders them more prone than others to be attacked by phthisis.

Difficult and delicate as the task may often be, it is undoubtedly the duty of the physician, and especially of the confidential medical adviser of families, to give timely warning of the danger and distress which are almost certain to follow in the train of marriages between persons who present well-marked hereditary tendencies to tuberculous disease. It will, we believe, be generally found that the public are more disposed than they formerly were to give a thoughtful attention to such warnings. The gradual spread of sanitary science, and the diffusion of a knowledge of the laws of health throughout society, and the existence of more intelligent and more truthful views of the nature of disease will account for this.

We should, then, on all suitable occasions insist on the perils that attend the union of couples when on either side, and more especially when on both sides, there exists an inherited predisposition to phthisis.

But if we would do all that lies in our power to prevent the origin and transmission of tendencies to tuberculous disease, we must carry our teaching and our warnings still further. We should let it be generally known also that considerable risk attends the union of persons closely allied by ties of consanguinity. The tendency which the offspring of such unions manifest to develop and propagate scrofulous maladies is well established, and although the scrofulous diathesis may be more or less distinct from tubercle, yet it is generally admitted that the existence of constitutional scrofula conveys a strong tendency to tuberculous disease. We should, then, be equally firm in opposing marriages of consanguinity, but chiefly and especially when there has already been manifested in the families concerned a tendency to scrofulous or lymphatic affections.

Marriage too early or too late in life, marriage between the constitutionally feeble, between persons weakened by dissipation or excesses of all kinds, or by poverty and privation, and between the subjects of constitutional syphilis, should all be prevented, so far as we can, by judicious and timely counsel and warning, prevent them, if we would do all that can be done to prevent the generation of offspring having a tendency to become phthisical.

But, as we have already said, there are unmistakable signs that the educated classes are becoming more and more alive to these dangers, and we hear now, much more frequently than we used to formerly, of objections to marriages wholly and rightly on account of hygienic considerations.

It is false sentiment, and a mistaken kindness to allow young people, ignorant of the consequences of their act, and inexperienced in all the cares and struggles of life, to enter upon a matrimonial union when the physical condition and prospects of the contracting parties are unsatisfactory.

The prospect of the anxiety, anguish, and misery attendant on constant illness and delicacy, and premature death, should outweigh all sentimental considerations.

(2) We have next to consider the best means of preventing the development of phthisis in those persons in whom a tendency to that malady is known to exist.

An infant born with an hereditary tendency to phthisis will require the most careful management. On no account should a mother with phthisical tendencies be allowed to suckle her offspring. There is danger in this to both mother and child. There is danger of injury to the nutrition of the mother by the tax which lactation imposes on a feeble organisation and there is danger to the infant that the mammary secretions, in such cases, may be vitiated and imperfect.

For such infants a vigorous and healthy wet-nurse should be selected, and if possible it should be brought up in the free, open air of the country, rather than in the confined atmosphere of crowded cities. Frequent exposure, carefully protected, however, from chill or from too rigorous weather, to pure air and sunshine, and residence in well-ventilated, but sufficiently warm, apartments by night and by day are of much importance to such infants. Their chest and limbs should not be cramped by any tightly-fitting garments, but allowed perfect freedom of movement. The nurse should be particularly cautioned against allowing awkward attitudes, and attitudes which tend to compress the chest and to hinder its free expansion. The reclining position is best for the weakly infant, so that the weight of the head and shoulders is not thrown on the front of the chest or on the spine, as is sometimes the case when the child is carried much in the nurse's arms.

Attempts should early be made to ward off that morbid sensitiveness and vulnerability of the cutaneous surface so common in those predisposed to phthisis, and which is, in a measure, the index of, and provocative to, bronchial sensitiveness and irritability; and without making any rash and risky attempts at

hardening such as some have advised, and which, when they do no harm, probably do much good, we may yet even in the early months of infant life adopt mildly bracing measures, which may afterwards give place to a more vigorous hardening system.

For this purpose it is a good plan, after the child's morning bath, to sponge over the surface of the body rapidly with cold sea-water, or water containing sea-salt, to which a tablespoonful or two of spirits of wine, or Eau de Cologne have been added. The infant should, of course, be quickly dried, and it will usually be found that this process has a bracing and invigorating effect, especially stimulating to the functions of respiration.

It should be remembered in this connection, that a certain amount of crying is not injurious to an infant, but is often a useful gymnastic exercise to the respiratory organs, leading to a more complete ventilation and expansion of the lungs than ordinary breathing ensures.

When it is impracticable to obtain a wet-nurse, the child should be given perfectly fresh cow's milk, boiled, slightly diluted with water, and to which a little sugar of milk may be added. At the period of teething, a little beef-tea may be added to the milk, and if dentition be tardy or difficult, some preparation of lime is useful.

When, as is the case with some delicate infants, the casein of the milk coagulates into a firm indigestible curdy mass in the stomach, and sets up vomiting and diarrhœa, an excellent food is made by mixing three parts of whey with one of beef tea, and thickening with a little arrow-root.

More than ordinary care is needed in watching these children through the common ailments of childhood, and, especially in measles and whooping cough as well as in scarlet fever. Measles and whooping-cough are especially dangerous to such children, for the catarrhal and congestive attacks of the respiratory organs, which so constantly accompany these affections, are prone to linger and degenerate into, or predispose to, incurable pulmonary mischief.

After weaning, which should not be too long delayed, milk should still form the chief part of the child's food, and the digestion of the food should be carefully watched. Any tendency which may manifest itself to acidity, flatulence, vomiting, or diarrhœa should lead to a careful revision of the diet. By degrees, a small amount of animal food, which, until the child has thoroughly learnt to masticate, should always be reduced to a finely divided or pulpy condition, may be introduced. All excess of saccharine substances, should be avoided as tending to set up acid fermentations.

As soon as the child begins to take bread-stuffs, it is highly advisable not to use the over refined wheaten bread, but the *decorticated whole wheat meal bread*[1] is much more suited to the nutrient needs of the growing child.

With respect to the administration of stimulants to such young and delicate children, much difference of opinion exists. It is desirable to have no prejudices or predilections on this head. There are many, probably the majority of such children, who positively dislike all stimulating drinks, and resist taking them, I would not press them upon these, but there are other, feeble, lymphatic, pale children, to whom a small quantity of wine or sound beer seems to serve as a remarkable aid to nutrition; and we must be cautious how we allow any theoretical or sentimental objections to alcoholic stimulants of all kinds to interfere with the chief duty which here lies before us, viz., to maintain nutritive activity whenever it shows any tendency to be lowered. I consider a small quantity of good sound beer more useful than wine, but of wines I prefer a little sound Burgundy with water, or one or other of the well selected red Hungarian wines. It is only in very exceptional cases that so stroug a wine as port is advisable. In these cases, the wine must be regarded as a medicine as well as a food. Hoff's malt extract may serve as a substitute for beer.

As the child advances in years, when it has reached 5 or 6 years of age, judicious and careful attempts to brace and harden the constitution should be systematically prosecuted.

For this purpose, free exercise in the open air, wisely devised gymnastic exercises, together with the use of cold sponging, cold affusion, or cold douches should be daily employed.

The gymnastic exercises should have for their object the complete development and expansion of the chest so as to lead to the thorough inflation and ventilation of all parts of the lung, the strengthening of the respiratory muscles and the development of the muscular system generally, and the correction thereby of faulty attitudes and positions. But these exercises must not be carried to the length of causing fatigue or exciting any feverish reaction. It should always be borne in mind that their object is to promote healthy nutrition; if they excite or fatigue, they must be modified or discontinued. We have already alluded to the value of cold affusion in lessening that sensitiveness of the surface, which proves often so serious a trouble in after life, while as a direct stimulant of the respiratory function it is also of great value. It is needless to insist that cold affusion and cold douches must be applied with great care and caution to delicate children. The process of accustoming them to this treatment must be a gentle and gradual one, and it must be particularly noted whether they re-act well to this stimulant or not; if it should cause chilliness or langour and drowsiness, it had better be discontinued.

The warm weather of summer is, of course, the best season for initiating this treatment, and when once it is established it may be continued throughout the year, but, in the cold season it should always be applied in a *warm* apartment.

It is also necessary to watch the education and school-life of such children closely. Close application to study in crowded school-rooms, must be positively forbidden; overtaxing the mental powers must be carefully provided against; sharing in athletic games which, while they tend to injuriously excite the circulation, expose also to the danger of chill after such excitement, must be strictly excluded; and all faulty attitudes and positions during school studies should be corrected. R. Liebreich has invented a chair for school purposes, intended to correct the faulty attitude so frequently assumed by pupils in schools, and also a couch for reading, which seems to me well calculated not only to support the back, but also to take the weight of the arms and shoulders off the upper part of the body[2]; for when these are allowed to hang forward, as in the stooping attitude which becomes habitual to many young people, they compress the upper part of the chest, and prevent due expansion of the apices of the lungs.

There are two periods of life which have been regarded as specially dangerous for those who inherit a predisposition to phthisis. One is the period of puberty, and the other is the period between the ages of 30 and 35.

At the period of puberty, we have to guard against the depressed nutrition so often associated with the

[1] The flour for making this bread can be obtained of Pimm & Co., Upper Mills, Wandsworth.

[2] These can be obtained of Callaghan, Optician, Bond-street.

exhaustive influence of rapid growth, and we have to be on the watch lest the strength and resisting power of the individual be not seriously compromised by the yielding to evil habits in connection with the development and prominence which the sexual functions now tend to assume. A life of wholesome activity in the open air, out-of-door exercises and occupations, a nutritious but unstimulating diet as well as the provision of healthy food for the mind, and the avoidance of romantic and erotic literature; these are wise and necessary precautionary measures at this period of life.

Especially ought the health of young women to be carefully looked to at this period, for in their case, besides the dangers already indicated, there are those of periodical and vicarious congestions of organs, and particularly of the lungs, which we should do all we can to avoid.

When the strength and nutritive power seem seriously impaired by rapid growth it will be advantageous for such cases to seek a sunny climate in winter, and tonic mountain or sea air in summer; in both cases in situations where an out-of-door life is possible.

Some physicians consider the period between thirty and thirty-five as one of especial danger to those who are hereditarily predisposed to phthisis, and one during which incessant precautions are needed. No doubt at this period the pressure of life, its duties, its trials, its wearinesses, and its disappointments are felt, perhaps, by many for the first time, and exercise a depressing effect on the constitution, physically as well as morally.

Excessive yielding to sexual appetite has been regarded by some as a danger especially active at this period.[3]

The severe ordeal of pregnancy and child-bearing, and the exhaustive effect on the general nutrition of the process of lactation when the mother undertakes to suckle her offspring, and this is more commonly the case than otherwise with persons of small means, have unquestionably much to say to the frequency with which phthisis occurs amongst the hereditarily predisposed at this epoch.

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.
President of the Health Department, Social Science Association, and of the Epidemiological Society.

(Continued from page 742.)

Scorbutus.

The chapter on Hospital Gangrene[72] should be read in connection with this chapter.

Very nearly first among the truths to be recognised by the young medical man commencing practice in India, is the fact, frequently insisted upon in these pages, that scorbutic and malarious cachexia most frequently exist combined in the constitutions of his European and native patients.

Early in the publication of these notes, when speaking of Food in India, I mentioned that scurvy is generally prevalent throughout extensive tracts of Hindustan, especially Scinde and Behar; and that, everywhere else in India, the influence of a scorbutic diathesis ought to be looked for in investigating the origin and nature even of those diseases which are not generally regarded as being allied to scurvy. I mentioned that, in India and elsewhere, the wealthy, who are well able to live generously, are by no means always exempt from scorbutic cachexia, easily recognisable by those intimate with the indicia of scurvy. At a meeting of the Epidemiological Society held in December last, Dr. Colan, R.N., observed that, on his return from Nares's expedition, he observed, in England, cases of scorbutus which, but for his experience of Arctic scurvy, he would have failed to recognise. I have written so fully elsewhere upon Indian scurvy[73] that I must trust that the reader who desires to investigate the subject at large will refer to those pages. I have shown that if, with the map before us, we draw an imaginary line from Aden upwards, principally within and near the stretch of the Indian Desert, through Scinde to Mooltan, we roughly define a tract in which apparently very trifling injuries, abrasions, scalds, contusions, are liable to degenerate into ulcers of the most intractable character, and even into sloughing phagedæna, or hospital gangrene. Along this line, land scurvy is rife; but, as it appears that the malignant ulcer of the fleet, prevalent at the end of the last century, which is so fully described in Trotter's "Medicina Nautica" and which was recognised at the time as resembling ulcers prevalent in the East Indies, committed its direst ravages subsequently to the almost entire disappearance of sea scurvy, pure and simple, under the influence of lime-juice, so it is probable that these forms of ulcerative disease are often merely con generic to scurvy, seeing that they by no means invariably yield to antiscorbutic treatment. Still I believe that it may be laid down as a certain law that the subjects of these ulcers invariably have a scorbutic taint and that, consequently, antiscorbutics must always be steadily employed throughout the treatment, however obstinately the local disease may appear to resist their power.

Among these forms of ulcerative disease the principal are known as the *Aden ulcer*, *Scindh boil*, perhaps *Delhi boil* (which Dr. Gavin Milroy and Dr. John Murray regard as a form of yaws) *Gwalior ulcer*. Such forms of ulcer were also very prevalent, in association with scurvy, among our native troops during the first Burmese War in 1825. Similar ulcers have been observed as occupying a prominent place among the endemic diseases of Malacca, Penang, Singapore, Batavia, Amboyna, and the Molucca Islands, Ceylon, the Andamans, and the Malabar Coast. It may be taken as a general rule that, wherever these obstinate forms of ulceration have prevailed, syphilis and dysentery have been markedly severe, the patients being scorbutic, the former being liable to run into sloughing phagedæna, the latter often terminating as gangrenous colitis.

I have already spoken of the fact that scorbutus is generally to be anticipated and guarded against as one of the most incapacitating and destructive attendants of sieges and protracted campaigns in India. I know officers who, having become scorbutic in the second Burmese War, in 1852–53, and throughout the siege of Lucknow, have never completely shaken off the sequelæ of this grave cachexia.

It is highly noteworthy that, while districts impested with the marsh poison afford a fitting habitat to scorbutus, malarious cachexia and scurvy are, if not allied conditions, states which most readily coalesce and run into one another—with double peril to their victims. Clearly, the fevers and dysentery of seafaring men, which formed the principal subjects of

those ships' surgeons who wrote upon the "Diseases of India" late in the last century, were greatly modified, as occurring chiefly in men whose constitutions were tainted with sea scurvy.

More than forty years ago, the late Dr. H. H. Goodeve made some excellent observations upon this point, which still well deserve the attention of practitioners.[74] "The melancholy accounts of the ravages committed by scurvy found in every narrative of a long sea voyage even up to a very late period are alone sufficient to account in a great measure for the frequent occurrence of "typhoid," [*i.e.*, typhus-like] or the putrid type of fever which the old surgeons, and especially the naval ones, so much dreaded during their residence in warm climates. The miserable condition to which the sufferers were reduced by scurvy, was precisely the most unfavourable state in which they could be placed to receive the attack of a severe febrile affection. The scorbutic diathesis required only the accession of a remittent to constitute the putrid synocha of our forefathers. We consequently find the most melancholy accounts of putrid fever in the East amongst the reports of our naval surgeons. This form of fever was not, however, confined to the sea or its shores; it existed occasionally upon land, and raged with great violence."

I had much experience of sea scurvy in the crews, principally of foreign ships, entering the Port of Calcutta, up to 1866. In that year, Dr. L. H. Lees published, in the *Indian Medical Gazette*, vol. i, p. 287, an account of this disease, numerous cases of the worst description of which, in his capacity as Superintendent of the Seamen's Hospital at Akyab, he saw in vessels arriving from Aden, whither they had carried cargoes of coal from England, for the P. & O. Co.'s depôt. No vessels entering the port, with the exception of those which had called at Aden, had cases. "One vessel, the crew of which was so reduced as to be unable to work the ship, had to put back to Madras, send all the men ashore, re-engage a fresh crew, and proceed on the voyage. Four others arrived at Akyab with only the cabin occupants fit for work. As may be conceived, they with the utmost difficulty made the port at all, and I do not hesitate to say that a few days' prolongation of the voyage would have been fatal to all concerned. The other vessels were all more or less crippled by the disease."

In 1839, Mr. W. A. Green published[75] a valuable paper in which he gave cases of sea scurvy, of putro adynamic fever, and of fever complicated with severe spleen disease, with remarks to point out severally a similarity in their probable causes, in their nature, and in some of their symptoms. Mr. Green wrote from his experience at Howrah, across the Hooghly, facing Calcutta. I was one of his successors in the medical charge of that station; it is a position in which the meeting and combination of cases of malarious splenic cachexia and of sea-scurvy could best be observed when the latter disease was prevalent, as there are extensive docks, and as many seafaring men, Europeans and natives, then frequented and resided in the place. Mr. Green analyses 43 cases of ordinary sea scurvy, and 9 cases of scorbutic febrile disease, showing that between these two cachexiæ, there appears a great similarity as to their essential nature, I would say rather in several of their characteristics than in their "essential nature." You cannot give a well fed man scorbutus by locating him in a marsh, any more than you can give another ague by giving him improper rations at sea.

Twenty years later, under improved arrangements for victualling and lodging the men of our merchant navy, cases of sea scurvy were far less common in the Port of Calcutta; but only too many (one of which was fatal) came under my notice while I was in charge of the Medical College Hospital from 1861 to 1876. Most of these were, as I have already mentioned, from foreign ships.

One of the most valid maxims which an old Indian physician can offer to a young one is: *never treat a case of any severe disease in India, whether the patient be European or native—landsman or sailor—without taking at least a glance at the question, is scorbutus possibly a factor in the causation of this malady?* This advice is not undeserving the attention of home practitioners.

Writing, in his "Pathologica Indica," in 1844, the late Dr. Allan Webb, an admirable observer, insisted that among the troops serving in Bengal, spleen disease and *consequent scorbutus* are a very frequent cause of invaliding and of death. So intimate, in his opinion, is the connection between certain morbid states of the spleen and the induction of general scurvy that he appeared to consider the latter as a necessary result of the former. He says:—"Now if the spleen be as intimately concerned in forming red blood, as I have with much labour endeavoured to prove that it is, we have only to stop its functions and we shall then produce scurvy. Thus scurvy is induced by disease of the formative organs of the blood-globules, as effectually as it can be, by withholding the material from which blood is formed, by feeding the animal man upon putrid meat and bad grain, and washing down such a *pabulum vitæ* with stinking, stagnant water. In either case, the blood is not renewed; the body therefore feeds upon itself." Without literally following this eminent man's line of argument or expecting that removal of the spleen will induce scurvy, every one who has practised in India must agree with Mr. Green and him that scorbutus and splenic cachexia have many leading features in common, and that the two cachexiæ, although they are perfectly distinct entities, often prevail together in the constitutions of Indian patients.

Study of the history of Indian scurvy clearly evolves this axiom. *Scorbutus often gives deadliness to Indian fever; and Indian scurvy never rages more obstinately than among the subjects of malarious cachexia.*

The literature of *Land Scurvy* in India, as occurring principally among troops in the field and in garrison and among native prisoners in gaols, is extensive.

In 1832 a markedly scorbutic condition prevailed among the European soldiers of H.M's. 48th Regiment, stationed at Cannanore, Madras Presidency, where good vegetables were scarce and high priced.[76] In the following year there was a disastrous prevalence of scurvy in H.M's. 62nd Regiment, stationed at Bangalore and Masulipatam. There were 57 admissions and 9 deaths.[77]

Mr. R. N. Burnard[78] describes cases, as occurring during the military operations in Arracan in 1825-26, of native soldiers suffering from dysentery and burning of the feet, in whom the application of blisters to the calves of the legs produced a livid, bruised, and ecchymosed appearance; and, in one patient, caused sores which led to rapid sphacelus. Dr. John Grant published[79] an analysis of the earlier reports on scurvy. He said that he believed cases of indubitable scurvy were then landed in Calcutta from Arracan and Rangoon. Many of these sank at once, being exhausted even by the exertion of disembarkation. Dr.

Waddell described[80] scurvy, as prevailing among our European and native troops in this Burmese war of 1825. The same general symptoms characterised the disease in Europeans and in natives "swollen, loose, and livid gums, with ulcerated or sloughing edges, fœtid breath, pain and hardness of the calves of the legs, contractions of the hams, and purplish discolouration of the skin, particularly of the lower extremities. In many instances of Europeans, diarrhœa and œdema of the feet, ascites in one case and universal anasarca in another." "A scorbutic diathesis was marked in almost every case of dysentery." In all the worst native cases "the feet became œdematous, and, however apparently mild the other symptoms, the œdema was an almost certain prognostic of anasarca, hydrothorax, and death." [Beriberi.] There is a valuable report by Superintending Surgeon Heward on the prevalence of scurvy among the European and native troops engaged in this war.[81] It was observed that "the disease which so generally afflicted the European soldiers, and with such fatal visitation, was dysentery combined with a scorbutic taint of constitution."

Ulcers became numerous, greatly more so among the natives than the Europeans. The smallest scratch or abrasion of skin degenerated into an ulcer, in a few cases among the Sepoys passing into the condition of "hospital ulcer." The duties of the men in the field were very trying and fatiguing. The diet of the Europeans consisted entirely of salt provisions, with biscuits or rice, "but without any admixture of vegetable food." "Little or no fruit was procurable at Rangoon, and the only vegetable available to the troops was wild spinach or country greens, and that even in a very limited quantity." *Provision of lime-juice for the campaign appears never to have been dreamt of.*

(*To be continued.*)

NOTES ON THE CAUSATION OF LABOUR.

By LAWSON TAIT, F.R.C.S.

I HAVE been greatly interested in the remarkably thoughtful paper of Dr. C. E. Shelly[1] on this subject, and I should be glad to be allowed to place before your readers, for the consideration of those who are interested in the subject, a few difficulties which have occurred to me concerning all the theories which have so far been advanced and which are admirably summarised by Dr. Shelly.

These difficulties have arisen from the consideration of the relation borne by the facts of the curious experiments performed by Nature herself in diseased conditions, which are now far more familiar to us than they were in the days when abdominal surgery had not achieved its recent advances.

My chief and initial difficulty is that the first step in the syllogism worked out in Dr. Shelly's conclusions is entirely unsupported by evidence which is before me in increasing quantities, some of which I have published already in your columns and much of which is under consideration for future display. In the paper on the "Ovular Theory of Menstruation," published in the *Medical Times and Gazette* early in the present year, I submitted a series of observations which, to say the least of it, raise a very great difficulty concerning the statements so often made, and repeated by Dr. Shelly, that "ovulation begets periodical congestion of the generative organs." The evidence on this question, constantly growing in my experience, to me conclusively establishes that the ripening and bursting of the Graafian follicles has nothing whatever to do with the periodical phenomena grouped under the term of menstruation. Whether I be right or not in my suspicion that the immediate agent in this exists in or about the Fallopian tube, it is perfectly certain it is not in the ovary; in fact, if I may here anticipate something which I believe I shall have to say when next I publish on this question, I think I may venture to prophesy that upon the subject of ovulation we shall have to abandon a great deal of what we have assumed concerning it, more particularly concerning the period of time occupied by the maturation of the follicles. I entirely agree with Dr. Shelly's conclusion that mere distension of the uterus can have no kind of influence in directing the period at which gestation is terminated. This requires no other proof than the pathological experiment of hydramnios. I have seen the abdomen distended by a collection of amniotic fluid within the uterus to an extent larger than I have ever seen it distended by an ovarian tumour, save perhaps in two cases, and yet at the time I saw these patients there was not the slightest indication of the approach of labour. That had to be brought about by artificial means, yet when induced, contraction in the uterine walls came on as rapidly and as vigorously as if the period of gestation had been the end of the ninth instead of the middle of the fifth and beginning of the seventh months respectively as was the actual fact.

A difficulty which I have already pointed out as being a very important argument against the ovular theory of menstruation is that removing one ovary does not distuab the periodicity and frequency either of menstruation or labour. Women who have had one ovary removed menstruate as regularly, have apparently as many children, and have the same periods of gestation as those who have been in no way interfered with. And I think it is not too much to assume that if the ovaries had anything to do with the periodicity of either or of both of these functions, the removal of one would show it in some way. More than this, operations for the removal of cystic ovaries performed in many instances during pregnancy rarely, if ever, interfere with the continuation of that pregnancy; not even as in one case in my own practice, where I removed both ovaries at the fourth month of pregnancy, the woman going on to her full time and being delivered in the ordinary way.

Dr. Shelly might of course account for this by the extremely interesting and valuable suggestion which he has made concerning the influences of an inherited tendency to produce the termination of labour at the beginning of the tenth month, and I am quite prepared to admit that something of this may be accepted. But against this explanation of Dr. Shelly's this question can be directed—how can we explain the acquisition of this inherited tendency? It must have had a determining cause, and for the purpose of the present discussion it is not essential to know or even to speculate upon the cause which brought about the tendency for the particular time at which gestation is terminated. It still leaves us entirely where we were in our endeavours to ascertain what is the particular mechanism by which this inherited tendency is put into action.

Let me just point out another difficulty concerning the ovular theory. Quoting Pflüger, Dr. Shelly says, "The slow continuous enlargement of the Graafian follicles causes the state of irritation in the terminations of the nerves embedded in the rigid stroma of the ovary; this irritation is at first too slight to beget an immediate reflex action; but at intervals—which

[80] "Transactions of Medical and Physical Society," vol. iii., p. 240.
[81] *Madras Quarterly Medical Journal*, vol. i., pp. 203–9.
[1] See *Medical Times*, Oct. 18, 1884.

are practically in consequence of the mode in which the producing causes act periodical—the sum of this irritation becomes so great as to cause a reflex nervous response which takes the form of a considerable arterial congestion of the genital organs. This suddenly increased afflux of blood produces a double effect."

After saying what is the fact, that this is merely raising a cloud of words to cover our ignorance, let me point out that the investigation of injected specimens of ovarian cystoma affords conclusive proof that the afflux of blood in them is, so far as increased size and number of blood vessels can demonstrate this, much greater than is seen in the ripening Graafian follicles and the mere fact of the continuous distension of the follicular cavity by pathological products, obliges us to assume that the intramural pressure is correspondingly greater than in the healthy follicles. I think, therefore, that I am justified in saying that the more we investigate the question the greater the difficulty becomes in accepting the assumption that ovular influences have any effect upon these periodical functions.

Of the other theories examined by Dr. Shelly it is hardly necessary to speak at length, because he shows the difficulty of accepting them, from their being as they are little more than crowds of words raised to cover ignorance and affording no kind of explanation of the phenomena. I desire, however, to say just one word as to the progress and partial separation which is alleged to occur between the decidua and the uterine walls during the later period of pregnancy, for it seems to me that a good deal of mistake has occurred here in the direction of putting cause for effect.

I have often felt, in thinking this matter over that a careful study of the phenomena of extra-uterine pregnancy would probably lead us into the right path of investigation, even if it did not completely solve the riddle. As far as the theory which attributes to the separating of the decidua the causation of labour, I have satisfied myself that the observations are erroneous. Some three years ago I had the opportunity of watching a case of extra-uterine pregnancy, of operating on it before the birth of the child, and, unfortunately, of seeing the *post-mortem* afterwards of the mother.

In various contributions to the clinical history of pathology on this curious condition, I have pointed out that a persistent feature in the history of the case is the occurrence of all the phenomena of labour just as if the fœtus was in the uterus. In the case of which I speak, I watched this false labour with very great care because I was anxious to save both mother and child, and I felt that it would be a very risky thing to operate during its existence. I felt strong contractions in the uterus going on exactly as if the real labour were proceeding, and the condition of the passages was entirely in harmony with this. So soon as the false labour was over, I removed the child, living, and he is now growing up. As I have said, the mother died, and I found when the uterus was removed that the decidual lining was absolutely undisturbed, and I could not discover on the most careful examination that it presented any appearance whatever of the so-called fatty degeneration. In fact this fatty degeneration of the decidua I believe to be quite as much a myth as the so-called fatty degeneration of the placenta, concerning which I said a good deal in a paper published in the "Transactions of the Obstetrical Society" in 1875. So far of course this is only an isolated observation, but it goes a long way to cast doubt upon a theory which has had a very wide acceptance chiefly because it fell in with, or rather grew out of, a view of pathology which was very fashionable some five and twenty years ago, but which now obtains but little acceptance.

This leads me to speak very briefly on a phenomena in which I believe will yet be found the explanation of the process of the termination of natural labour; though I am bound to say that at present I do not see my way any clearer to place a new theory before your readers for acceptance than I do to argue in favour of any one of the seven theories examined by Dr. Shelly. I allude to the curious rhythmical contraction of the pregnant uterus, first discovered by Dr. Braxton Hicks, and which occurs in the uterus throughout pregnancy from the very earliest time at which observations can be made with any accuracy upon the uterus, up to the very time when labour begins. I have satisfied myself of the occurrence of this contraction of the uterus when it was certainly not more than three months pregnant, and I have felt it within 30 minutes of the occurrence of the first labour pain.

It has ever been to me a matter of surprise that these rhythmical contractions have received the small amount of attention which has certainly been their share. They constitute the most certain sign of pregnancy with which I am acquainted, because they can always be felt; and sometimes even the most careful search fails to reveal to the practised ear the sounds of the fœtal heart. Again, on the other hand, I know of more than one case where competent observers have declared that they have heard the heart sounds of the child in cases where no child has existed. It is not difficult to imagine that with these strong rhythmical contractions persistently occurring, apparently throughout the whole period or nearly the whole period of gestation, that the secret of the immediate causes of labour will be discovered in connection with them. The uterine contractions which expel the child are nothing more than an exaggeration of these movements of the uterine walls, which have become increasingly frequent and increasingly powerful throughout the period of pregnancy.

Another matter of much less importance in the present discussion is one, however, to which I should like to draw attention, because I think Dr. Shelly has not perused the evidence, and line of argument based upon it, which I have advanced in the chapter on extra-uterine pregnancy in the recent edition of my book "Diseases of the Ovary," to the effect that we can no longer accept the statements that there is such a thing as an ovarian pregnancy, or that extra-uterine pregnancy ever occurs in any other way than from an adhesion of the fertilized ovum on the lining surface of the Fallopian tube.

In connection with the statement made by Dr. Shelly "that in cases of extra-uterine gestation the uterus itself does not usually undergo to any marked extent the development, anatomical and physiological, which attends a normal pregnancy, especially when the pregnancy is ovarian, abdominal or truly tubal, the increase in bulk of the uterus, and the formation of the decidua follow but in a slight degree, and the process usually soon subsides," let me say that I have now twice operated upon patients at the very end of gestation where the child has been extra-uterine, and in both the uterus had increased in size so markedly as to present in its bulk a very singular resemblance to the uterus immediately after labour. In every one of the seven other cases of extra uterine pregnancy upon which I have operated, the uterus has been markedly larger than normal. In many of them, if not in all, it had clearly undergone proportional evolution, as in some of the cases months had elapsed since the occurrence of the false labour. I think we may assume this involution, for the death of the child is always followed by the absorption of the liquor amnii, and contraction of the cyst round the fœtus.

From a study of the subject generally for now a

considerable number of years there are one or two other points upon which I have arrived at conclusions at variance with those advanced by Dr. Shelly. I cannot, for instance, in any way admit that abortion and miscarriage occur almost invariably at a period corresponding to the menstrual epoch; in fact, as an abortion or a miscarriage is a proceeding which generally occupies a somewhat protracted time, from its start to its finish, it is absolutely impossible to predicate that it has any such correspondence at all; and in a few instances which have come under my notice where it has occupied but a very short time, the evidence has been altogether against this view.

Again, in the case of the lower animals, or at least such of them as have no distinct œstrus dependent upon seasons, as is the case amongst the stags, there seems to be no kind of periodicity in the œstrus. This is certainly the case with the cat, an animal which does not allow its œstrus to pass without evidence. I have watched a large number of these animals for many years past, for the purpose of the investigation of this and one or two other points which are included in the paper in your own columns to which I have already alluded. Your readers will there find some arguments well worthy of attention, pointing to the conclusion that the œstrus and menstruation are wholly different and entirely independent functions, menstruation being limited absolutely, in so far as we know, to the human race.

In conclusion let me say that I think all who are interested in this subject are much indebted to Dr. Shelly for the paper he has published and for the recognition of the very important point, hitherto entirely overlooked, in the possibility of the periods of gestation in various animals being directed by an inherited tendency, produced certainly by circumstances governing their success in the struggle for existence, circumstances as yet quite unknown to us. But this does not seem to me to clear up in the least the riddle, the solution of which we are seeking—that of the immediate mechanism by which the termination of normal gestation is secured.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

(Under the care of Mr. RICKMAN GODLEE.)

(We are indebted for the notes of these cases to Mr. MONTAGUE WILLIAMS, Registrar.)

A CASE OF ACUTE TETANY—RECOVERY.

J. H., aged 9 years, was admitted into Barclay Ward with this history. A fortnight before admission, the mother told us, the boy complained of pain and stiffness in the back and afterwards of difficulty in opening the jaw. When he presented himself as an outpatient on Sept. 8th, the jaw was in a condition of trismus, the tip of the tongue could alone be protruded. When lying in a horizontal position the patient was unable to rise to the erect. The posterior spinal muscles were in a condition of tonic spasm. The spine was arched forwards and he walked with a bowed head. Purgatives were prescribed for him, with instructions to come up again if worse.

On the 11th he was again brought. He was now unable to stand at all. The jaw was in a firmer condition of trismus, and the abdominal muscles as well as the spinal muscles in a condition of tonic spasm. No history was given of any acute specific disease, injury, dog-bite, vermes, or discharge from nose or ear. Nothing of interest could be gathered from the family history.

On Admission.—Patient is a muscular, and fairly well-nourished, dark-haired boy. He is quite intelligent, talking and answering questions intelligibly. The pupils are dilated and act to light. The jaw is in a condition of trismus. The abdominal muscles, anterior and posterior cervical muscles with the spinal muscles are in a condition of tonic spasm. In consistency they are hard, knotted and cord-like. He is unable to walk, and when standing the spine is considerably arched anteriorly (kyphosis). When lying in bed there is considerable lordosis. Slight priaprism is also noted.

When the trunk-root of any given nerve is irritated by pressure or otherwise, the muscles directly supplied by it are thrown into violent spasm. When moved on to one or the other side, the side which does not touch the bed is spasmodically and tonically disturbed, whilst the muscles of the opposite side are generally flabby and have no spasm. He swallows small quantities of food administered with a spoon; drinking from a vessel produces an attack of choking almost immediately. Pulmonary percussion note unimpaired. Vesicular murmur normal. Cardiac physical signs healthy. Hepatic and splenic areas not exaggerated. The tongue is coated, and indented by the teeth. The bowels are obstinately constipated. The temperature is 99°, the pulse 90, regular, compressible and of equal volume. There is no evidence of any accidental wound. He was ordered to be dry-cupped this morning down the spine. A simple enema was administered; and he is fed frequently with egg and milk.

The evening note states that in his sleep he cries out lustily, complaining of cramps in one or more extremities, which said member is generally found rigid and in a condition of tonic spasm. Bowels open. He sleeps fairly well.

On the 14th.—Has had several marked fits of rigidity during the night, slight opisthotonos, well-marked priapism. Lies tranquil in intervals. When asleep the abdominal muscles are generally found in a condition of tonic spasm; and when carefully watching him one or more muscles spontaneously become rigid and hard. Bowels still constipated.

On the 17th.—The abdominal muscles and hamstrings with the jaw muscles are still in a condition of tonic spasm. Had one attack of rigidity during the night. Is taking nourishment well. Is much better.

On the 25th.—Is able to sit up in bed, cannot stand however without immediately falling. When attempts are made to remain in the erect posture the muscles generally of the trunk and extremities become rigid. The sterno-mastoids, platysma, and the abdominal recti muscles are still tense and prominent.

On the 30th.—Is able to walk in a shuffling manner, the spine being arched anteriorly and the head bowed. The jaw is trismic, and the abdominal muscles in a condition of tonic spasm. Can feed himself; sleeps quietly at night. Was sent home.

On October 14 he presented himself as an outpatient; he walked in with ease, the jaw was no longer in a condition of trismus, the abdominal muscles alone were a little rigid when touched. He expressed himself as feeling quite well. He is able to run and his sleep at night is undisturbed. Takes his usual nourishment and goes to school.

SHEFFIELD GENERAL INFIRMARY.

COMPOUND COMMINUTED FRACTURE OF FRONTAL BONE — COMPRESSION — TREPHINING — IMMEDIATE RELIEF — COMPLETE HEALING OF THE WOUND—SUBSEQUENT ABSCESS IN THE BRAIN — DEATH—AUTOPSY.

(Under the care of Mr. BARBER.)

(Reported by CHARLES ATKIN, F.R.C.S., House Surgeon.)

J. W., aged 60, was admitted on May 12th, 1884, at 6 p.m., in an insensible condition. He had been struck an hour and a half before on the forehead by a chain thrown from a joist. It was stated that he did not immediately fall but staggered, told a mate that he could not see, and walked with assistance to a druggist's 400 yards off. The wound being plastered, he then walked home, sat down, asked for something to drink, and in a quarter of an hour was found to be quite insensible, struggling with widely staring eyes, and moaning incoherently. His struggles were so violent that it took four men to hold him down. On admittance a contused wound 1½ inches long was found in the centre of the forehead, the bone was comminuted, two angular fragments below being driven forcibly in and under the upper projecting edge, there was some bleeding but the fragments were so tightly jammed in that it was doubtful whether any blood could have got from the outside into the cavity of the head.

The man was perfectly insensible, with stertorous breathing, flushed face, insensitive pupils midway between contraction and dilatation, pulse full and quick, twitchings of the mouth, face, eyelids and extremities, which he otherwise did not voluntarily move.

At 7.30, three hours after the accident, Mr. Barber removed a semicircular piece from the projecting edge of bone above and four or five loose pieces were removed; there was little hæmorrhage, and the dura mater was apparently uninjured.

Before he was removed from the table, the breathing became normal, and he was evidently sensitive to pain.

The following morning he was perfectly sensible, answered all questions correctly, and did what he was desired to. The wound was lightly dressed with carbolised oil lint. The temperature was under 100°.

The second day after the operation he became delirious, struggling and attempting to pull the dressings off his head and get out of bed. The temperature was 102°, the pulse being very full and strong. He was bled to the amount of 8 ozs., and a chloral draught given. He slept comfortably, and on the third morning was perfectly easy, and had no twitchings. He was sensible, with full use of his limbs and sphincters with only a slight purulent discharge from the wound, pulse 90.

He went on uninterruptedly well, the wound having completely healed till the 5th of June, 24 days after the accident, when he was found out of bed in the early morning, attempting to walk downstairs in his nightdress; he rambled and appeared quite stupid, but had no elevation of temperature or pulse, nor did he make any complaint. Gradually he became more incoherent, yet retaining his sight, hearing, and understanding till nearly the last.

Becoming quite comatose on the 11th of June, the wound was cautiously opened and explored, but no foreign body or pus was found. He died on the 12th, 31 days after the accident.

At the *post-mortem* a small abscess was found in the frontal lobe of the left hemisphere. It did not communicate with the ventricles or with the meninges; the former, however, were over full of fluid, whilst the latter were quite normal.

Remarks.—The symptoms coming on half an hour after the accident were not caused by the pressure of any effusion of blood or clot, but were no doubt due to the depressed bones, plus the hyperæmia; the removal of the pressure for a time cured the symptoms, only to recur, however, when the reactive congestion became excessive. The beneficial effect of the venesection was well marked. The abscess in the substance of the anterior lobe appears to have resulted more from bruising than from communication with the wound, or from infiltration through the dura mater, for there was no adhesive meningitis between the membrane and the subjacent brain. It suggests, however, the advisability of delaying the healing of a wound communicating with the cranial cavity until all secretions have had time to drain away.

Medical Times and Gazette.

SATURDAY, DECEMBER 6, 1884.

THE meeting of the Clinical Society on November 28th will long be memorable in the annals of the Society. The prospect of renewed discussion on the nature of the so-called Charcot's joint disease in locomotor ataxy, had brought together the *élite* of the profession to hear or take part in the debate; and members had sent for exhibition a collection of living specimens of the disease in all its varied forms, such as has, probably, never before been equalled or even approached. Besides these, a considerable number of pathological specimens were also on view, and M. Charcot had sent over a series of his own specimens and casts, which made together an unique collection. The whole suite of rooms was thrown open, and only just sufficed for the large concourse of members who assembled. Mr. Barwell opened the discussion with a survey of the chief pathological characteristics of the two diseases, as generally given in books. Sir James Paget followed with one of those delightful philosophical speeches for which he is so celebrated. He answered one of the most interesting of the points raised by Mr. Baker—Is the disease a new one? by proving that the disease is not an old one. As to its exact nature, Sir James regarded it not as a distinct entity, but as "a new compound of diseases, appearing only at a time when, we know not by what external conditions, all these constituents are met with in the same person." Because there are certain broad differences between typical rheumatic arthritis and "Charcot's disease" it would be unwise to assume that in locomotor ataxy there is no measure whatever of rheumatic arthritis; syphilis, too, is no doubt an element in many cases, and he could hardly doubt that it would modify the nerve disease, as well as the joint disease, and lead to a "mingled disease." Dr. Ord considered that there are strong evidences of a neurotic influence "direct or reflex," being the main, if not the sole agent. Professor Humphry thought this a disease of which "we, in the olden time" knew nothing. He agreed as

to its probable compound nature. Mr. Hutchinson, once a firm believer that Charcot had described a new disease, due to active interference of the nervous system, had lately changed his opinion, and now regarded the nerve influence as permissive, rather than causative. Mr. Hulke regarded the disease as a variety of chronic rheumatic arthritis associated with nerve disease, but not standing in any ætiological connection therewith. At this point the discussion was adjourned to the next meeting, which will take place on the 12th instant.

At the Medical Society on Monday last, Mr. Barrow related a case of malignant disease of the œsophagus, in which he performed the operation of gastrostomy; the patient living comfortably for four months after, and finally dying of acute blood-poisoning. The operation, performed with antiseptic precautions, was carried out as as follows:—The peritonæal cavity having been opened by an incision along the left margin of the thorax, the anterior wall of the stomach was drawn into the wound, a portion pinched up by the finger and thumb, and transfixed by two hare-lip pins, running parallel to each other, half an inch apart, at right angles to the skin wound. The projecting ends of the pins were left resting upon the abdominal wall and margin of the thorax, and were the only means adopted for securing the stomach in position. The edges of the abdominal wound were then closely and accurately brought together by catgut sutures around the protruding stomach. The advantages claimed were simplicity of detail, rapidity of operation, and the secure maintenance of the peritonæal surfaces in contact even during movements of vomiting. Mr. Morgan then read a paper on cysts of the neck. After alluding to the interest which belonged to the origin and development of cysts in this region, he classified them under two headings, viz., those which are the result of some change of condition in parts previously healthy, and those which may be said to arise from developmental errors. Under the first were classed bursal tumours and hydrocele of the neck, and under the second, congenital cystic hygroma and sebaceous cysts. Hydatids were alluded to as occurring in this as in other regions of the body, and the clinical and pathological characteristics of the other varieties were discussed, together with the several methods of treatment. Instances of each variety were detailed which had come under the author's experience. The paper concluded with an account of the sebaceous cysts which are found deeply placed, and which are supposed to be relics of the existence of the branchial arches of the fœtus, several cases of which had lately been operated upon by the writer.

The meeting of the Pathological Society last Tuesday was not so well attended as usual, though there was no lack of material. Dr. Pye-Smith recounted an interesting case of cyst in the cerebellum with multiple cysts in the pancreas and kidneys, and discussed at some length the mode of formation and pathological significance of these cysts. Dr. Lanchester showed a very rare specimen, an intus-susception of the rectum in an adult, the symptoms of which had been chiefly remarkable for their mildness. Dr. Carrington showed what he believed to be a case of simple ulceration of the trachea and œsophagus following exposure to the vapour of carbonate of ammonia. Several of the speakers suggested that there had been some new growth at the bottom of it, but of this there was no proof. Mr. Treves communicated two cases of primary tumour of the soft palate, one supposed to be sarcomatous, the other carcinomatous; they were referred to the Morbid Growths Committee. He also exhibited a most unique case in the way of congenital anomalies in a being who calls himself the elephant-man, who had in addition to an enormous hypertrophy of the right upper limb, several large exostoses on his apparently hydrocephalic skull, and a two-fold skin eruption, partly papillomatous and partly of an obscure nature scattered over his trunk and limbs. There were several card specimens.

The usual meeting of the Obstetrical Society was held on Wednesday evening. The business of the night was the adjourned discussion upon Dr. Graily Hewitt's paper on the uncontrollable vomiting of pregnancy. Dr. Hewitt thinks this condition due, like most other diseases peculiar to women, to flexion or version of the uterus. The debate on the subject was opened by Dr. Barnes, who spoke at great length, expounding theoretical views familiar to readers of his works. Dr. Hicks, who followed, called attention to the great utility of morphia in these cases, and aptly characterised Dr. Barnes' remarks as transcendental. The speeches of the evening were those of Dr. Matthews Duncan and Dr. Playfair. The former of these gentlemen called attention to the researches of Hecker and others into degeneration of liver and kidneys in association with pregnancy, and the association of severe and intractable vomiting with such changes. The cases of fatal vomiting he believed to be of this kind, and he drew a distinction between such cases of "pernicious" vomiting dependent upon degenerative changes in important organs, and the ordinary vomiting of healthy pregnancy, the latter, although often severe, never being fatal, and being so capricious in its onset and decline that every remedy used was sometimes followed by cessation of the vomiting. But no drug or any other treatment could be relied on to cure, and only very weak-minded persons could regard the occasional cessation of vomiting after treatment as proof that the treatment was the cause of the improvement. The drug that seemed to him to do most good was atropia, and he endorsed Dr. Hicks' praise of morphia. Dr. Playfair spoke in opposition to Dr. Hewitt's views, and humorously "chaffed" him (if we may be pardoned the expression) on the true British pluck with which he rode his hobby-horse (flexion of the uterus) at every obstacle. Dr. Hewitt replied ably and temperately to his various critics.

We wish to draw especial attention to the admirable and timely remarks of Professor Nothnagel, on the indiscriminate use of antipyretic drugs, which appear in our report of a recent meeting of the Vienna Society of Physicians. It will be paying no more than a just

compliment to many of our readers to predict that they will read these remarks with cordial appreciation and agreement. The meddlesome school of therapeutists is quite as rampant in England as it appears to be in Germany, and though it would be too much to hope that Prof. Nothnagel's remonstrance will induce the extreme wing of that school to lay aside, or to use with greater caution, the powerful and double-edged weapons which science has placed in their hands, it is quite probable that his remarks may have some influence on the large body of practitioners who are constantly hovering between credulity and scepticism. Bad as is the symptomatic treatment of the chemist or herbalist, who has one remedy for a cough, whether it be from larynx or lung, and one specific for an eruption, whether it be a symptom of great or small pox, far less excusable is the symptomatic treatment of the young physician, whose first thought and impulse when he sights a symptom is to hastily pick up a weapon wherewith to bring it down. Why, cookery or golf-playing is nearer to science than that kind of medicine! If we had our will we would send back these adventurous knights-errant of the hypodermic syringe to study the works of Thomas Sydenham, of which we have attempted, for their benefit, to give brief abstract and reverent praise in another column. From him, perhaps, they might learn to appreciate the truth sung by his great contemporary, "They also serve who only stand and wait."

At a special general meeting of the Liverpool Medical Institute on the 27th ult., it was resolved to raise a fund for the purpose of reimbursing Drs. Whittle and Hutchinson the expenses, amounting to 470*l.*, entailed upon them by the action of Good *v.* Whittle and others. It will be remembered that the action was brought against them last summer for conspiracy against, unlawful detention of, and want of care in certifying as a lunatic, a certain Mrs. Good. After a five days trial before a special jury, a verdict with costs was given for the defendants upon all counts of the indictment, but the plaintiff will not be able to meet the defendants' costs, and they will have to meet them themselves. The profession in Liverpool have decided that this ought not to be, and they have not only subscribed liberally themselves, but have appointed a strong and representative committee, with a view of seeking the support and sympathy of the profession generally, which we are sure will not be found wanting.

In Scotland the "overpressure" question appears to be entering a new phase. It is admitted, even by Dr. Crichton Browne, that there is very little overpressure in Scottish elementary schools; and Dr. Batty Tuke, who has recently been visiting the Edinburgh Board Schools, finds that "the disease newly invented in London, and called 'Board School headache,' is unknown." Dr. Tuke even goes further, and though admitting the existence of a certain amount of over pressure in England, characterises the complaint that the State is educating people into insanity as "one of those wild expressions which defeats its own aim and object." But if there is no overpressure in Scotland amongst children, there appears to be a deplorable amount of it among growing girls of the better class. Dr. Keiller recently devoted a whole address—the last of his course of Morison lectures—to the subject, and his strictures have been confirmed in several letters addressed to the *Scotsman*. Dr. Keiller spoke strongly because he feels strongly on the matter, "knowing that the highly-forced education of our time is often at the very root of the first breaking down of the health of young girls, by not only inducing various forms and degrees of early neurosis, but by stamping on their developing natures features of diminishing strength, and that at an age when health and strength, when physical building up and fresh nerve force and brain power, instead of being in any way exhausted, should be carefully tended as being of vital importance to their ultimate welfare." Dr. James Carmichael thoroughly endorses Dr. Keiller's views, and inculcates especial caution in imposing brain work on growing girls, as the evil effects are not immediate, but remote:—"A girl's general health does not appear to suffer when she is at school, but in after life when she attains to womanhood, and the strain of maternal duties are imposed upon her. It is then that she is so often found unequal to the task." Mr. Balsillie, again, writing from the educationalist's point of view, admits the existence of serious overpressure in secondary schools, especially among girls, as "a fact well enough known already," and not requiring further proof. It will be a curious commentary on our modern progress if it should turn out after all that the dogged conservatism of the upper classes has empirically, and without any help from science, found out the education which, both in the case of boys and girls, is most in harmony with the teachings of physiology. And yet it would appear that Eton and its feminine correlatives are almost the only places in which Giant Overpressure has not yet found any victims.

At the meeting of the Nenagh Board of Poor Law Guardians, held on Friday, November 28th, a letter was read from the Local Government Board for Ireland, sanctioning the payment of the Medical Officers of Health in the Union at the rate of *two shillings per house* for each house inspected and reported upon by them under the provisions of the Labourers' (Ireland) Act. The clerk also read a communication from the Dispensary Medical Officers (who are also Medical Officers of Health for their respective districts under the Public Health (Ireland) Act, 1878), expressive of their surprise at the offer of such miserable remuneration for responsible and onerous duties. The letter represented the conviction of the medical officers that the claim furnished by them—half a guinea a cottage—was reasonable in amount and well-earned. With this opinion we heartily concur, and we are sorry that the Irish Local Government Board should, by their action on this occasion, once more have succeeded in turning into ridicule the sanitary organisation of the sister island.

Mr. Victor Horsley, the recently appointed professor-superintendent of the Brown Institution, will

give his first course of lectures on December 12th, 15th, 17th, 19th, and 22nd, all but the last being delivered as usual in the theatre of the University of London, Burlington Gardens, at 5 p.m. The subject of the first two will be "The Thyroid Gland: its Relation to the Pathology of Myxœdema and Cretinism, to the Surgical Treatment of Goitre, and to the General Nutrition of the Body." The third lecture will be on "Simple Traumatic Fever, based on 160 Cases of Simple Fracture," and the subject of the fourth is "Urethral Fever." The fifth lecture will be a "Practical Exposition of the Work done at the Brown Institution," and will be delivered there at 3 p.m. We may mention, as a novelty, that Professor Horsley has produced myxœdema artificially, and will demonstrate the same during the lectures on the 12th and 15th of December.

With the examination for the Fellowship of the Royal College of Surgeons, which has just ended, we regret to say, Mr. Savory terminates his association with the College as an examiner. There is no disguising the fact that this is a great loss to the Court, and one which can with difficulty, if at all, be compensated. No doubt, however, the Council will do its best to fill the gap by the appointment of a Fellow of approved skill in the duties required of him. To be a good examiner it is not enough to be a sound practical surgeon or well-read in all the literature of the profession. A good examiner is, like a poet, born to the art. And as Spenser is the poet whose art poets themselves are supposed chiefly to study, so Mr. Savory's style as an examiner might well be studied by examiners. His questions were always straight to the point and uninvolved; cleanly put, they required a clean answer. We have never met with his equal in an examination-room. A student knowing his work had no need to fear being placed opposite to Mr. Savory, for he was as certain to recognise a good man as to turn inside out an empty one. It was a treat to hear him examining a candidate who was, so to speak, his match; he would get from him the utmost information obtainable. He knew a good man when he met one and never failed to appreciate him. Possibly Mr. Savory's standard was somewhat higher than that of others, though speaking as outsiders, and as only occasional visitors to the examinations, we must express ourselves with diffidence on that point. This much, however, is certain, that no examination with which he was associated would be allowed to suffer deterioration. Thus, after many years of work as an examiner in physiology, anatomy, zoology, and surgery, this particular path in Mr. Savory's illustrious career comes to an end. Thereby he gains a well-earned rest, and will be able, with less strain, to apply his energy to the affairs of the College, to private practice, and, we will venture to hope, to literary work in connection with the profession of surgery.

Our Paris correspondent writes:—The cholera seems to be dying out in Paris, and although the public authorities have ceased publishing official *bulletins* of the number of cases, and of the number of deaths which occur daily, some notion of the present state of things may be gathered from hospital statistics, since by far the greater number of patients have been removed to the special wards provided for their reception. From the 22nd to the 30th of November, only 66 cases were received in the hospitals of Paris; the number of deaths was 54, but most of these were occasioned by attacks of the disease which occurred at a previous date. From the beginning of the epidemic up to the present time (4th November to 1st December 1884), the whole number of cases treated in the Paris hospitals has amounted to 1,037. There have been 565 deaths, giving a proportion of 54·48 per cent. These figures, taken from a paper by M. Emile Rivière, seem rather unfavourable to the method of treatment carried out by Professor Hayem at St. Antoine. The injection of a solution according to the subjoined formula:—

Chloride of Sodium—5 grammes.
Sulphate of Sodium—10 grammes.
Distilled water—1,000 grammes.
The quantity injected amounts in general to 2,500 grammes (in adults).

has given him twenty cures out of 100 cases, according to his own statement. The mortality, therefore, amounted to 80 per cent., a much larger figure than that which results from ordinary methods of treatment.

Dr. Bergeron was elected Vice-President of the Paris Academy of Medicine, vice Fauvel deceased, on the 27th November last. At the same meeting, Dr. Charpentier was elected a member of the section of midwifery. The chair of children's diseases at the Faculty of Paris has just been declared vacant. It is universally believed that Dr. Graucher, well known to the public for his microscopical researches on tuberculosis, will be the successful candidate.

While M. Pasteur is absent in Brazil investigating yellow fever, he will, the *Union Médicale* observes, be spared the maledictions of the inhabitants of Villeneuf-l'Etange and other localities near Paris, for having turned out among them, as they allege, numbers of mad dogs. Of course, these are in reality dogs which have been rendered proof against rabies by inoculation with attenuated rabies virus. Moreover, these dogs are not turned loose, harmless as they are supposed to have been rendered, but are under effectual surveillance. However this may be, several communes in place of associating themselves with M. Pasteur's discoveries, and offering facilities for their pursuit, regard the arrival of the dogs as a calamity, and are opposing their installation as violently as they would the establishment of an industry prejudicial to the public health.

The iron will of Prince Bismarck has succeeded in forcing Dr. Schweninger, in gratitude for his having cured him and his son of a troublesome obesity, as an extemporised professor in the Berlin Faculty of Medicine. The Faculty protested in vain, both orally and in writing, and in spite of a deputation, composed of Professors Virchow, Dubois-Reymond, and Hirsch,

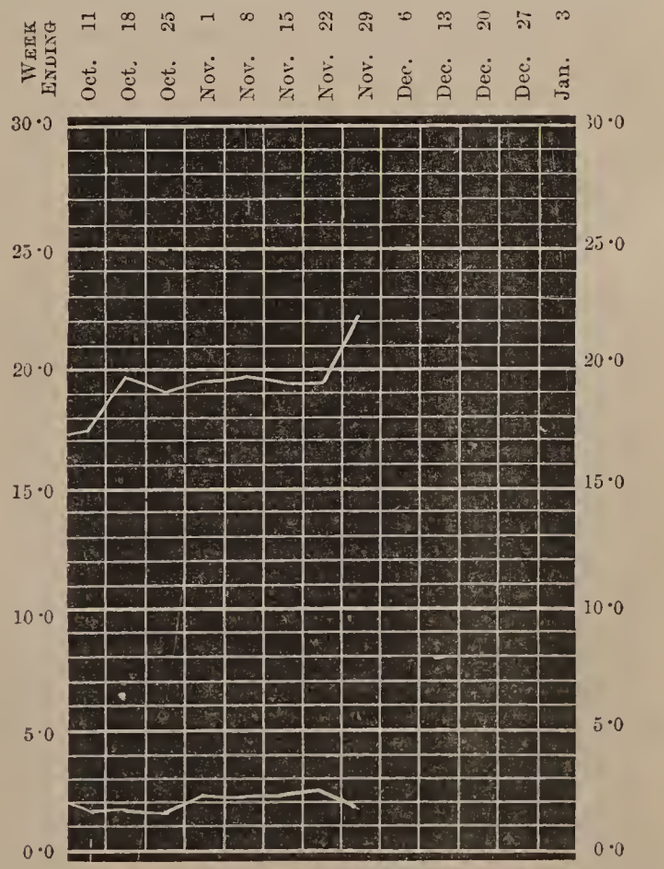
which waited on Prince Bismarck, Dr. Schweninger was inducted into the chair of dermatology, which had been held "provisionally" for twenty years by Dr. Lewin, a privat-docens. No student, it is said, has entered for his course, and most of the professors have declined calling upon him. Professor Dubois-Reymond having returned the card which had been left at his house, was challenged to a duel, with what result may easily be imagined. The Faculty, it is stated, has the intention of addressing the emperor himself, but every one knows what that means where Bismarck is concerned. Professor Leyden, the dean of the Faculty, has been to Munich for the papers relating to the process which was instituted against Schweninger there, and to his expulsion from the faculty of that university, and has communicated them to the Senate of the Berlin University. The Faculty has determined to continue its protests, and in the meantime to hold no intercourse with the new "professor."

We understand that the case of excision of a tumour from the brain, a brief record of which appeared in our last issue, is, according to the latest accounts, progressing favourably. The case, which is believed to be the first of the kind that has been thus treated, in this or any other country, is looked upon with much interest in medical circles. The chief symptoms which led Dr. Hughes Bennett to diagnose the extent and the locality of the tumour were paroxysmal twitchings of the left side of the face, alternating with twitchings of the arm on the same side, followed by slowly progressive paralysis of the hand, and later on by twitchings of the eyelids and leg without paralysis. These symptoms were accompanied by double optic neuritis and violent headache. The conclusion arrived at was that there was a tumour, probably not larger than a walnut, situated at the upper third of the fissure of Rolando. The skull was trephined by Mr. Godlee over the corresponding spot, under which the convolutions appeared to be healthy. An incision was then made in the ascending frontal convolution, and a quarter of an inch below the surface a tumour of the size suspected was discovered and removed. The operation, we need hardly add, was performed under strict antiseptic precautions.

The cases of dyspepsia amongst the Woolwich cadets are, we are told on official authority, more numerous than they ought to be, and their countenances generally look pale and jaded. The Board of visitors are therefore under the impression that some alteration in their mode of living might be advantageous. Having more acquaintance with candidates for cadetships than with full-blown cadets, we should be inclined to suspect that the fault lies in the mode of selection rather than in the mode of living when once chosen. It is true that a good digestion is one of the most important helps in passing an examination, and on the principle of natural selection, the Woolwich cadets ought to be able to digest anything; but those who have any knowledge of the amount of work demanded of the candidates before examination, will admit that it is calculated to ruin the strongest stomach that ever secreted. Twelve or fifteen hours a day over books, no time for exercise, meals hastily swallowed, and tea *ad libitum* in order to keep the over-pressed brain awake, are not conditions calculated to help the stomach in its daily work. If the visitors are wise, they will direct their attention to the cadets' mode of life before they go up for their examination, rather than to their mode of life after they have passed it. Is there not a saying that "a nation fights upon its stomach"? If so, it will be a poor look-out for England if we have to send our soldiers into the field under these dyspeptic subalterns. The visitors further report that the conduct and discipline of the cadets have been very good. Of course; dyspeptics may be irritable, but they are not likely to be uproarious. It is health and high spirits that kick over the traces. It takes a clean tongue to be unruly.

If it be true, as stated by a member of the London School Board in a letter to a contemporary, that the Board's enquiry on over-pressure is to be a private one, from which the representatives of the press are to be excluded, we shall have even more reason to distrust the report of the Committee. Its members are many of them anxious to prove that the accusers of the Educational system have no ease, and the only way of convincing the public that their enquiry is a *bonâ fide* one, is to conduct it openly and with judicial impartiality. Surely Mr. Mundella will not contend that the holding of a secret investigation, such as the London School Board appears to contemplate, is sufficient to absolve him from all responsibility in a matter which is admittedly of national importance.

A very considerable increase in the number of deaths in London last week is the natural result of the



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past eight weeks.

cold weather which then prevailed, and the general death-rate has risen, as will be seen by a reference to our chart, from 19·7 to 22·3 per 1,000. The zymotic diseases have had no share in the causation of this rise, for in only two weeks during the present quarter have the deaths under this head been lower than they were last week. There were 40 deaths from small-pox, 31 from measles, 27 from scarlet fever, and 16 from diphtheria. The rise in the total number of deaths is almost entirely accounted for by the large number included under the head of diseases of the respiratory system; the deaths in this column exceeded those of the previous week by 157. The cases of phthisis are tabulated separately from the diseases of the respiratory organs, so that when these are added to the others it appears that out of the total of 1,716 deaths more than 700 were from diseases connected with the respiratory apparatus. As usual, London compares favourably with the other great towns, three of them having a general death-rate of over 30 per 1,000. But Glasgow and Dublin have completely eclipsed all the above in their death-rates, the former giving 37·1 and the latter giving 35·4 per 1·000, in each instance the zymotic death-rate being high.

We are not surprised to hear that there is a movement amongst the more radical M.P.'s to secure the abolition of the representatives of universities in Parliament, Mr. Arnold proposing that the Universities of Oxford and Cambridge should each suffer partial disfranchisement. Such a movement is not likely to be successful with Mr. Gladstone at the head of the Government, but the force of the arguments in favour of it has been doubled by the foolish action of the Conservative graduates of Edinburgh and St. Andrew's in attempting to oust Sir Lyon Playfair from his seat on purely political grounds. Speaking as medical men, we shoud scarcely regret the abolition of the university seats, considering how little their occupants have done for the medical profession, to which in some cases so many of their constituents belong.

The American and other foreign journals are now filled with accounts of the trials being made of the therapeutical powers of cocaine. While they are going on, we may refer to the report made to the Sociéte de Biologie by M. Laborde on the results which he has observed from hypodermic or intravenous injections made on various animals. Experiments, he says, have been practised with solutions containing a centigramme of this alkaloid during the last two years. The general conclusions are—(1) Cocaine gives rise almost constantly to general analgesia; (2) It produces previous to all other phenomena a period of hyper-excitability or epileptiform convulsions; (3) Mydriasis is constant; (4) Corneal insensibility is far less important, and when it appears it is only an episode amidst the general phenomena which this substance gives rise to; (5) From all this we may easily deduce the important place which cocaine is destined to fulfil in the therapeutics of nervous diseases. We may remark that these results are very similar to those obtained by Dr. Hughes Bennett so long ago as 1873, and recorded in the *Edinburgh Medical Journal*. Dr. Bennett found that cocaine paralysed the sensory nerves throughout the body, and we regret having omitted to give him due credit for the discovery in our last week's article on the subject. Unfortunately his researches have remained for ten years without practical result.

It is proposed to hold a representative meeting at Guys' Hospital, on Wednesday afternoon, December 10th, at 4 p.m., with a view of concerting measures for giving substantial expression to the feeling of appreciation in which the memory of the late Dr. Mahomed is held by those who have been his colleagues, fellow-workers, and friends. It is earnestly hoped that as many as possible will attend.

A very practical illustration of the growth of the Cambridge School of Medicine, on which we have so often insisted lately, was given a few days since when the Museums and Lecture Rooms Syndicate applied for a vote of 700*l.* for the purchase of 100 extra microscopes, in consequence of the increase in the size of the school. Some of the Senate evidently thought it was rather a large order, and did not see why the students should not be required to provide their own microscopes; but when the representatives of the Syndicate pointed out that without these microscopes the University could not conduct its own examinations, opposition to the scheme died a natural death. Ten years ago the students used to take their own microscopes in to the examination rather than use the clumsy old-fashioned weapons with which chance and the University authorities supplied them. Professor Lankester has been urging on the University the claims of the newly formed Marine Biological Association, and seems to have met with a favourable reception. The university which possesses the first biological school in the kingdom, if not in the world, ought to lend a helping hand to further this most deserving project.

A correspondent writes—I am glad to see that in the last of his interesting Monthly Chronicles, Mr. Wynter Blyth has called attention to the recent growth of the fashion of having straw laid down in the streets for trifling illnesses. I can bear witness to the fact that in many, if not most, of the West-end cases, for which it is thought necessary to muffle the streets, the procedure is by no means warranted. I have myself, more than once, counted five or six straw-strewn streets within a radius of half a mile in one of our fashionable quarters, and have known for certain that in at least half the cases the straw was entirely a matter of supererogation. Ladies with highly strung nerves are often, no doubt, extremely sensitive to noise for a few days after their confinement, but even if the difficulty cannot be surmounted by a dose of bromide, and straw becomes a necessity, there is no reason why it should be left rotting in the streets, as it so often is, long after the occasion for it has disappeared. In many cases, however, there is even less excuse for this waste of good material. In the idle and emotional West-end a case of illness is apt to be

seized upon with avidity by the friends as a welcome excitement, and an excuse for zealous activity, of which the straw in the street is made at once a welcome outlet and a public testimony. A loving husband, father, or son is to be excused if, in despair when the doctors shake their heads and hint that they can do nothing for his loved one, he rushes off to order a few cart-loads of straw. It serves at once to relieve his feelings, and to bring it home both to himself and his friends that he at least is doing something. I have known other cases in which there was not even this excuse for the procedure. I remember one in which the husband of a wealthy wife, after living on unfriendly terms with her for many years, awoke one morning to realise that death was likely, ere long, to rob him at once of his partner and of the wealth she had brought him. With commendable activity he set himself at once to undo the neglect of years, and by an assiduous show of devotion to influence for his benefit the future disposal of his wife's wealth. Tins of beef essence and cart-loads of straw were the things that at once rushed into his mind as the best instruments whereby to manifest his changed spirit, and it is needless to say that there was at that moment not the smallest necessity for either. His wife saw through it all, and, sad to relate, left him not even money enough to discharge the straw bill. I would suggest, in conclusion, that it should be necessary always to obtain the sanction of the vestry before having straw laid down, for in some parts of town even this much is not required; and I would further recommend that the vestries should withhold this sanction unless the practitioner attending the case had certified that a noiseless street was a medical necessity of the case.

Those who braved the somewhat stormy weather last Thursday afternoon, and went to hear the Bradshawe lecture at the College of Surgeons, were amply repaid by the brilliant oration which Mr. Savory delivered. After a few opening sentences as to the meaning of the terms local and constitutional, and innocent and malignant, the lecturer approached the subject of cancer, the main topic of his discourse. Although undoubtedly in its later stages a constitutional affection, he pointed out that it might, like syphilis, in its very earliest stages be regarded as merely a local disease. Tumours had also been divided, he reminded his audience, into heterologous and homologous; the former word being true, however, only as regarded adult tissue. Innocent tumours were wont to be formed of fully developed adult tissue, cancers of embryonic tissue which never reached a higher state of development. The importance of this distinction was especially marked in the fact that the degree of growth and reproduction bore an inverse ratio to the degree of specialisation, a fact well illustrated in the difference in the repair exhibited by the fibrous and muscular tissues, as also in the vegetable kingdom. The cell theory must be admitted to have received its death-blow in the trenchant words with which Mr. Savory demonstrated its inconsistency with the facts revealed by modern researches, and the so-called cancer-cells must be regarded henceforth as mere fragments of protoplasm, resembling indeed in simplicity, and in their ability of living, the embryonic tissue from which they spring, but differing from it in their life history and vital attributes inasmuch as they have no power of higher development. As Mr. Savory with perfect truth pointed out, we do not really know what the cancer-cell or indeed the blood-cell is like during life, and it is quite possible that the nucleus which is so easily recognised in the well-prepared specimen may have no existence in the body. The large group of sarcomas Mr. Savory recognised as forming a useful and important connecting link between the cancers on the one hand and innocent tumours on the other. Finally, he pointed out the many close resemblances which exist between the most malignant cancers and the parasites, but a distinction must still be maintained between them until the transmission of cancer by inoculation, or by grafting, shall have been proved.

MRS. WELDON'S CAMPAIGN.

After a summing up by Justice Denman markedly favourable to the defendant, the jury have returned a verdict against Dr. Winslow, with 500*l.* damages. The charge upon which the damages were found was technically one of assault, the assault consisting in an attempt to take Mrs. Weldon from her home and confine her in an asylum. This attempt was made in due compliance with all the technical forms which are required by the law. Certificates had been previously given by duly qualified practitioners, and an order in due form by a person qualified to give it. It is provided by the statute that if a patient escapes from an asylum, the proprietor may send after and recapture him. It is not specially provided that the proprietor may send for and capture a patient who has not escaped, who has not at present come under his charge; but the judge did not appear to attach very much importance to the distinction. In spite of an exceedingly advantageous *primâ facie* case, the defendant is cast in 500*l.* damages; and the ground of the verdict is that "the defendent allowed himself to be unduly influenced by other motives than the interests of justice." This is as much as to say that the defendant had no business to take any part whatever in the consignment of a patient to the asylum of which his mother was proprietress, and he himself was superintendent. With this finding it is impossible not to agree. Dr. Winslow made a grievous mistake, and he has paid very heavily for it; but the matter does not end there. Mrs. Weldon has succeeded in making her case so notorious that there is probably no single matter now before the country about which so much feeling is aroused, and with regard to which there is such a universal consensus of opinion that "something must be done." While we are not of opinion that the danger of unduly incarcerating people in asylums is an urgent or a frequent one, it is impossible to say that it does not exist;

and even were we much more satisfied than we are of the rarity and minuteness of the danger, yet there is no doubt that in the minds of a large section of the public the fear that Mrs. Weldon's case is an example of many of which nothing is known, is a very real and a very strong feeling. The Government are verbally pledged to amend the law at the earliest opportunity, and, were it not so, there is no doubt that the pressure of public opinion would compel them to take steps in the matter.

As we have several times pointed out in these columns, there is no need, and there is little desire for new legislation or new safeguards in the case of pauper patients, and in the admission to public asylums. It is in the admission of paying patients to private asylums that reform is demanded; and there are several suggestions as to the nature of the reform. It is suggested that certificates should be signed only by experts in lunacy; but granting that a safeguard is demanded, the protection offered by this plan is practically *nil*, and it is certain that it would be attended by so much difficulty, delay, and expense as to be unworkable. The number of experts in lunacy is very limited. Such as they are, daily evidence shows us that they would be not less likely but more likely than other people to detect insanity in those in whom it did not exist, and to attach excessive importance to manifestations of harmless insanity. Seldom does a lunacy trial take place without some "expert" bringing himself and his profession into ridicule by the statement that "every one is insane upon some point." What would be thought of a physician who declared in court that "every one has tubercle in some organ"? Another suggestion is that within a week after a patient is consigned to a private lunatic asylum an independent expert—say a Commissioner in Lunacy—should be sent down to examine him, and upon his report the further detention of the patient should depend. There is much to recommend this plan, but it is open to very serious objections. In the first place it would entail a large staff and a great expense; in the second it might easily result in the liberation of dangerous lunatics, for there are many such who actually require to be lived with for days before evidence sufficiently tangible to be placed in a report can be collected about them; and in the third place it would shift responsibility both from the certifying medical men and from the superintendents of asylums, upon whom responsibility ought to rest. The only final and satisfactory solution of the question is the entire abolition of private asylums; and this we believe the public will demand. Doubtless to this course there are serious obstacles. It will be expensive. But, on the other hand, it will be final; and since the case of Mrs. Weldon, the proprietorship of a private asylum is no longer the lucrative business that it once was. Patients are being sent to them but slowly, and the quasi-public asylums—institutions like the St. Andrew's Hospital at Northampton, which are governed by a committee of public men and managed by a salaried superintendent—are crowded to overflowing. We have reason to believe that more than one proprietor of a private lunatic asylum would not be sorry to exchange his position for that of a salaried superintendent working under the supervision of a public committee.

ESSAYS ON MEDICAL CLASSICS.

No. II.—SYDENHAM.

The materials for the life of Thomas Sydenham are scanty. The best account of him is a short one by Dr. Johnson. He was born in 1624, at Winford Eagle, in Dorsetshire, and came of a good and ancient family. He became a commoner of Magdalen Hall, Oxford, in 1642, but left the University on the breaking out of the civil war, and joined the Army, probably on the Parliamentary side, but even this is doubtful. Accidentally, on the advice of Dr. Cox, he determined to enter the medical profession; he therefore returned to Oxford, and took the Degree of Bachelor of Physic, in 1648. He says that he applied himself in earnest and spent several years in the University before practising in London, and it seems that he visited Montpellier, then one of the most famous foreign schools. From his writings it is evident that he was familiar with the works of Hippocrates and many later authors, and he must have devoted some labour to master the complicated materia medica of those times. He took the degree of M.D. much later at Cambridge, became a licentiate of the Royal College of Physicians, and practised in Westminster, living in Pall Mall. He absented himself with his family from town while the plague raged, in 1665. Early in life (apparently in his 26th year) he was attacked by the gout which seized him more and more severely through his life and became complicated with stone in the kidneys; his health began to fail in his 52nd year, and he became further exhausted by pain and bleeding. He died at the age of 65, on December 29th, 1689.

Sydenham began writing after twelve years' practice and pursued it from time to time, often in the form of letters to his friends on special subjects. He was an accomplished scholar, and wrote in Latin. English translations have been made—first by Pechey (several editions), by Swan (1763), and by Latham for the Sydenham Society (1845). His works have also been translated into other languages, including Spanish. They repay reading to-day as much as when they first saw the light, not only because many of the facts and principles they enunciate are as accurate now as they were then, when they were really great discoveries; but because they train one in the habit of regarding disease in the plain and comprehensive way of this master of the art. To appreciate his writings fully one must read and re-read them carefully. On this the author himself insisted, else, he said, he would have written to no purpose. Boerhaave studied him constantly and keenly, and extolled him highly, placing him first among the moderns and on a par with the best of the ancients. Trousseau also was a close student and warm admirer of him. His fame was great in his life-time, and lived after him by tradition and through his works. So great were his genius and the results of his labours that he has well earned the title of the English Hippocrates. His peculiar excellence lay in the breadth, depth, and power of his intellect, united to an energetic spirit, an upright character, and a generous and loveable disposition. By the breadth of

his intellect he observed comprehensively and took in general features; by its depth he pierced to the root and core of disease; by its activity he was led to seize upon the right method of treatment, according to indications and on rational principles. From the first he resolved, of set purpose, to advance the knowledge of medicine; in his own words — "He would have always esteemed himself a useless member of society if he had not contributed his mite towards the improvement of physic," and he succeeded. He had a perfect perception of the proper province of medicine, aiming at and grasping the "middle propositions" of Baconian phraseology, which are of most value in an inexact and practical science. He says— "In all acute and most chronic diseases there is something *divine*, or some specific property, which is not discoverable by a search into the structure of the human body, and, therefore, accurate observation of symptoms is of more value than mere anatomy." In the same manner, he "censures those who hope for too much from chemistry, for the principal defect in medicine is not a knowledge of specific remedies, but a knowledge of the *indications* to be answered." Again, "the discovering and assigning of remote causes, which engross the thoughts and feed the vanity of many curious enquirers, is an impossible attempt, and only the immediate and conjunct causes fall within the compass of our knowledge: thus diseases may be cured though their remote causes are absolutely undiscoverable." He thinks "certainly the air sometimes abounds in particles injurious to man and brutes, and produces fever; but whether the air becomes infected by some alteration in the bowels of the earth (as he believes) or by some peculiar conjunction of the planets is a matter of indifference." Thus showing what is *not* the way to advance, he describes the right one, which is truly that of Hippocrates, and of which his works will ever stand as an example. "The improvement of Physic depends on (1) collecting as genuine and natural a description of all diseases as can be procured; (2) laying down a fixed and complete method of cure. All diseases, therefore, are to be reduced to certain and determinate kinds, as plants are, yet not in such a way as merely to support prepossessing hypotheses; and then the phenomena must be minutely investigated, and the accidents depending on age, constitution, or method of cure separated." "The absence of an accurate history of diseases is due to a general supposition that they are merely the confused and irregular operations of disordered and debilitated nature; cure is to be effected by a certain knowledge of the indications to follow, and should be established and verified by sufficient experiments." He cares only for "experience founded on the solid testimony of the senses." Thus his method is good and sound, and in the application of it he is bold and original; though well read and informed, not given to blind imitation of others, but carrying out the suggestions of his mind, without rashly experimenting, but merely observing, with his wonderful insight and sagacity, the "juvantia and lædentia" and whatever influenced the course of the disease; judiciously weighing the results of his procedure, and candid in narrating them, when, "after long deliberation and many years' close and faithful observation, he resolved to communicate his thoughts." Hence, amid all the "useless and trifling speculations,"—chiefly in anatomy and chemistry,—and the blind empiricism of his day, all which he earnestly shunned, he attained to clear and substantial notions. Though at once appreciated by the best men, nevertheless he "expects only censure and contumely from this degenerate age; but as long as he establishes the truth of his own observations, he does not care what other persons think." He is "sure that his method of treating fevers will prevail after his death, though at present opposed by ill-grounded prejudice." In fact he encountered great opposition from many of his contemporaries, and was looked on by them as a mere quack.

Sydenham always conceives as good a general idea of disease as possible; and while never overlooking the smallest symptoms, always pays more regard to general conditions than to irrelevant details; thus to the state of the health and animal spirits more than to outward appearance; to weakness, fainting and sickness rather than to the pulse and tongue. He used hypotheses freely in a legitimate way, but never became enslaved by them. His vivid though well controlled imagination is often displayed in his works, and expresses itself by apt metaphors; for, recognising as he did the large element of mystery in his subject, it was the natural way of conveying his thoughts. This adds much also to the literary charm of his writings. For instance, he compares the subtle fatal action of a grave acute disease to a needle penetrating a pillow. Again, hysteria is due to "irregular motions of the animal spirits (the finest particles of matter, bordering on immaterial or spiritual beings) from a weakness and laxity of their texture." This is simple and accurate, compared with the old theory of strange excursions of the womb over the body. And his description of the disease and its manifestations is lucid and correct. A large part of his works is occupied by treatises on acute diseases—continued, intermittent and "intercurrent" fevers, as well as small-pox, plague, &c. Among the first class he did not distinctly recognise our various species; but he regards the "comatous fever" (typhoid?) as requiring a special line of treatment. He lays much stress on the "epidemic constitution," or character depending on something in the year or season, which determined the particular degree of severity and the character of the symptoms. A disease is a "vigorous effort of nature to throw off morbific matter," and in acute diseases there is vigour enough to produce a crisis by means of fever; we must therefore learn the way adopted by nature in every case and do our best to assist her, though "as long as the patient gets no worse from day to day," no interference is called for. A fever being a "commotion of the blood" we should try to keep it within due bounds. Thus, experience taught him that a cooling and depleting regimen succeeded best; but he never carried this doctrine to extremes, and his guidance as to the cases time and amount in which to bleed, purge and cool is still safe to follow, though mostly neglected now. He introduced, chiefly in small-pox, the method of cooling by keeping the patient out of bed daily, while not too weak. Malignity, he found, was due to excessive

violence of the fever, was increased by heating medicines and relieved by the opposite. But he was so judicious and guided himself so loyally by experience that he learnt many exceptions, *e.g.*, that madness after an acute illness, unlike ordinary acute insanity, required restorative instead of lowering treatment; and that dropsy in exhausting diseases would not stand purging; also that cordials (mild ones) may be required in fevers, even at the outset, if the vitality is low.

Though his works abound in remarks worthy of consideration, only a few of the leading and incidental doctrines can be briefly referred to. The treatise on gout is the most luminous that has ever appeared before or since and is written in an excellent style, as might be expected from the personal interest the author had in the subject. He introduced some innovations in the treatment of fevers, besides those already mentioned: *e.g.*, bleeding in the plague, and during convalescence after fevers, and he made the customary rules more precise than they had previously been. He extended the use of opium and gave it with confidence, claiming for it in confluent small-pox a specific action equal to that of bark in ague. The use of bark in ague he was one of the first to extend, soon after it had been introduced. He strongly recommended horse-back riding in chronic diseases, especially consumption and dysentery. He warned against too early rising (at least before the tenth day) after confinement, and declaimed against the excessive and indiscriminate drinking of brandy. A few suggestions sound rather quaint; for instance, the old plan of applying the body of a young man to an old man to revive him (he asserts the benefit to be derived from it, but apologizes for mentioning it as sounding fanciful), the application of a live puppy to the abdomen in iliac passion; and of a cabbage leaf to the side in pneumonia; but he always chose the simplest remedies and declares a strong preference as a rule for vegetable drugs, and complex prescriptions.

The personal character of Sydenham was not less admirable than his scientific achievements; the more we see of his nature the more we esteem him. He "considered it a greater happiness to cure the slightest disease than to accumulate the largest fortune." He is always sensible and practical and eager to benefit mankind. He "does not desire to be called a philosopher, and recommends those who claim a right to the title to try and account for the various surrounding works of nature." He gained the esteem and admiration of all who knew him, for he was benevolent, candid, sincere and religious. His character, method and achievements render him the most perfect example to follow of any that can be found in the long array of our forerunners.

N. H.

Iodoform in Organic Diseases of the Heart.—Professor Testa, of Messina, has tried with success the treatment recommended by Molesehott for the relief of functional disturbances in incurable disease of the heart. This consists in giving seven centigrammes of iodoform in four pills daily, continuing it for some time, this lasting in one patient for nearly a month. It acts especially by diminishing the number of the beats of the heart and increasing arterial tension.—*Gazette des Hôp.*, Sept. 9th.

REVIEWS AND NOTICES OF BOOKS.

THE RABBLE OF DISEASE.[1]

In respect of the realm with which each deals, the physician of to-day stands in much the same relationship to the leech of the middle ages as an English statesman striving to govern according to the sound principles of political science does to the irresponsible ruler of an Eastern race. If the potentate, lapped in the birth-right of a selfish luxury, mostly has regard only for the effects, and not for the cause of satisfaction or discontent amongst his subjects; if their attitude of submission or of revolt is merely a source of careless satisfaction or an excuse for repressive violence; if there is complete personal ignorance of and indifference to the life of the people; and no attempt to master the cause of popular movements, or the elements of periodical revolutions; so too, the leech-astrologer looked on the symptoms that he recognised, as forming the entity of a disease, which he imagined was to be ejected by force of fire, of water, or of scourging; which might be cajoled by charms and incantations; or which was to be regarded as the just punishment meted out by an offended deity, against whose judgments it was impious for man to strive, heedless of the fact that while the wicked indeed suffered, they did so "in proportion as they were poor and miserable." On the other hand, just as the statesman seeks to know the people, and finds in the study of different classes of individuals the secrets which explain the unlooked-for results of their collective action; as he learns that what is irresistible as the *vox populi* can yet be guided, or stifled, so long as it exists only in the earliest stage represented by the scattered suggestions of a few individual minds; and as he recognises all the circumstances which must be properly combined in order to the success or the collapse of a popular movement; so, in the domain of medicine, scientific investigation has quite recently begun to lay bare what we may call the home-life of countless microscopic organisms, which, though only as yet convicted in a few instances of being the actual cause of disease, we are daily coming to associate more and more intimately with its existence and manifestations. While the ordinary machinery of treatment has been hitherto but little altered in consequence, *i.e.*, while the treatment of results still remains much as it was, the police and the detective forces of medicine are being gradually modified in accordance with these recent advances in knowledge. And, expressed more or less distinctly by different voices, it is the earnest hope of many minds, not wholly given over to a blind enthusiasm, that by perfecting our knowledge of the "dangerous classes" among micro-organisms, we may be enabled to do something better than attempt to resist the violence of their collective onslaught, or watch the repair of the ravages produced by their attack; that, in short, it may become possible to seek them out in their own

[1] Micro-Organisms and Disease. An Introduction to the Study of Specific Micro-organisms. By E. Klein, M.D., F.R.S., etc., with 108 engravings. Macmillan and Co.

haunts, there to isolate and to exterminate them ; so that a future generation of doctors may know nothing of the filth-diseases with which we are familiar, save the name, and, intelligently supervising the birth of healthy infants, may, at the other extreme of life, simply record the limit put to green old age by mere "effluxion of time."

Whether their hopes for the future soar as high as this or not, there are none who will not welcome the publication of Dr. Klein's recent papers on micro-organisms in book form. Within the covers of a modest little volume of less than two hundred closely printed pages, the author has treated his subject with a clearness and completeness which leave little or nothing to be wished. The first five chapters are concerned with such details as microscopic examination, the preparation of culture material and of culture media for inoculation, the vessels and instruments employed, and the methods of inoculation itself. These directions are concise, but clear and ample ; and, together with the short introduction, breathe a spirit of scientific caution and exactitude which is an especial requisite for workers in this field, and which is a noticeable characteristic of Dr. Klein's teaching throughout. The morphology of bacteria and a consideration of the forms included in Cohn's classification, with that of the yeast fungi, the mould fungi, and the actinomyces, occupy the next eleven chapters ; while five more are devoted to a study of the relations of septic to pathogenic organisms, to the vital phenomena of non-pathogenic and of pathogenic organisms respectively, to vaccination and immunity, and to the important subject of antiseptics. The value of practical manipulation is shown by the very small proportion of loss amongst inoculated tubes owing to accidental contamination with air-organisms during decantation. Dr. Klein says that to decant under the carbolic acid spray is not practicable and possesses many unpleasant drawbacks, and that in some instances in which it was used there was really a greater percentage of contaminated tubes than without it. This is interesting as giving some support to the theory of those heretics who regard the spray as an engine for blowing disease-germs about rather than one capable of destroying them.

The student of humanity knows not only that criminals may be developed, and that the vicious may be reclaimed in accordance with the treatment to which they are exposed ; but that the ultimate character of the individual, virtuous or vicious as the case may be, is practically dependent on the training to which he and his ancestors have been subjected. So it has been claimed not only that the virulence of a micro-organism may be attenuated by a succession of appropriate cultivations, until indeed a condition of absolute innocence is attained ; and that an innocuous microbe, of definite specific character, may become the ancestor of an equally specific pathogenic form ; but also that one of absolutely indifferent (and therefore in themselves harmless) proclivities, may develop descendants capable of evolving the phenomena of this, that, or the other "specific" malady, as played upon by the environment during the successive stages of their evolutional history. Dr. Klein writes of facts, and so far as careful observation of actual facts in this connection enables him to speak on these points, he does so in no uncertain voice. Thus, with regard to the alleged transmutation of the *bacillus anthracis* into the hay bacillus, he agrees with Koch in regarding this as a complete error and fully endorses Koch's criticism of Buchner's experiments and his explanation of their results. In respect of the supposed development of the hay bacillus into *bacillus anthracis*, Dr. Klein states :—"I have repeated Buchner's experiments on rabbits, guinea-pigs and white mice. I have grown the hay bacillus in various kinds of broth, in gelatine broth mixtures, in hydrocele fluid, in peptone fluid, in Agar-Agar and peptone, at temperatures varying between 30° and 38° C., and I have, to put it shortly, never seen that it shows the least tendency to change its morphological characters, or that it ever assumes any morphological or physiological character like the *bacillus anthracis*. I consider this a perfectly hopeless task, and I feel sure anyone might as soon attempt to transform the bulb of the common onion into the bulb of the poisonous colchicum." Again (p. 168), "I have made a series of experiments with the view to obtain pure cultivations of definite septic micro-organisms ; various species of micrococci, bacterium termo, and bacillus subtilis, of which the morphological characters could with precision be ascertained, and which at starting were tested to be barren of any power of inducing disease. I have cultivated these in pure cultivations for many generations, and under varying conditions, and then I have inoculated with them a large number of animals (mice, rabbits, and guinea-pigs) ; and to put it briefly, I have not found that hereby any of them acquired the least pathogenic power." Unlike their human prototypes, these organisms are, in Dr. Klein's opinion, either irreclaimably bad, or else incorruptibly good ; and the physiologist need not fear (so far as the existing evidence will warrant) the moral declension of his bacillar *protégés* any more than he may hope to educate them into an exercise of higher physical virtues. "There are micro-organisms which are pathogenic, while others are quite harmless ; the latter remain so, no matter under what conditions and for how long they grow."

In explanation of the immunity often conferred by one attack of many of the infectious diseases, the author adopts the "antidote theory" of Klebs, rejecting the "*exhaustion theory*," as unsatisfactory and at variance with facts, as well as that advanced by Grawitz and others who believe immunity to depend upon an alteration in the resisting power of the tissues. It is, however, difficult to imagine that the immunity resulting from a first attack is altogether dependent on the production of "a chemical substance in the blood and tissues which acts inimically to a new immigration of the same organism ;" because, when such immunity is life-long, for example, we must suppose this "chemical substance," originally formed by the action of long defunct micro-organisms to be persistent in kind, in amount, and in distribution, although the blood and tissues in which it abides are undergoing continual change and renewal. It seems more reasonable to suppose that the tissues themselves are so pro-

foundly affected in the course of the disease that they continue thereafter to perform their vito-chemical interactions in some slightly but sufficiently modified fashion; somewhat, for instance, as a twig of variegated holly, grafted into an ordinary holly tree, after a while infects the whole of the latter's foliage with its own peculiarities of assimilation and secretion. There are many other points, such as the theory of the bacillus of tubercle and of cholera, on which we are tempted to quote further; but the whole of the little book is interesting, and especially valuable for reference on account of the care and thoroughness which mark the details on every page. The illustrations are numerous and pertinent; and though not above the average of ordinary English wood-engraving in execution, they add materially to the usefulness of a work which is worthy of Dr. Klein's established reputation, and which also affords gratifying evidence of the valuable labours that are unostentatiously carried out by the Medical Department of the Local Government Board.

London Water Supply; by Colonel Sir Francis Bolton, C.E., International Health Exhibition Handbooks. London: Wm. Clowes & Sons, 1884.—We heartily welcome this book as supplying a long-felt want: a full description of the water supply of the metropolis, free from prejudice and bias. Colonel Bolton holds an unique position; himself committed to no particular system or theory, and responsible only to the Local Government Board, he enjoys in his official capacity unrivalled opportunities of making himself acquainted with every detail in the procedures and the administration of the Water Companies. The book opens with a general introduction on the sources of water supply, modes of purification and distribution, a table showing the consumption per head in a number of towns at home and abroad, and a short discussion of the relative advantages of constant and intermittent service, meters, and dual supply, while the method of filtration employed by the London Companies is more fully described in Chapter II. Next we find a statement of the sources whence each Company draws its supplies and the areas of distribution, with elaborate tables of the amount, storage, distribution and other engineering details, as well as a map no less instructive. In Chapter VI. we have Dr. Frankland's report to the Government, and that of Drs. Crookes, Odling, and Tidy to the Companies on the quality of the several waters. The second part of the work gives historical and descriptive notices of the operations of each Company in order, with financial statements, analyses, and maps. It is satisfactory to learn that since 1871 the Water Companies have of their own accord and in compliance with Col. Bolton's recommendation expended no less than 3,175,329*l.* in improvements in respect to source, storage, and methods of filtration. As regards the extension of constant service we observe that the New River, Kent, and Grand Junction take the lead, the Chelsea and Southwark having done the least; but at the end of the year 1883, no fewer than 258,205 houses received a constant service against 608,525 in which the supply was still intermittent. The consumption of water per head of the population is about 30 gallons daily for all purposes public as well as domestic, and the total amount supplied to the metropolis was during the year 1883 at the rate of 144,592,772 gallons daily. Of this 71,710,878 were taken from the Thames, the East London Company not availing themselves of this source, and the others keeping within the prescribed limits, 63,314,260 from the Lea, and 9,567,634 from deep wells in the chalk. This last figure refers only to the Kent Company, but we should have liked to know how much the East London draws from wells, for though from a hydrographer's point of view it is immaterial whether the water be taken directly from a river or from springs which feed it, the quality of the respective sources is very different. Thus we learn from other reports that of the 26,000,000 gallons supplied daily by the New River Company nearly 20,000,000 are taken direct from the Lea, so that the name of New River is, except historically, a misnomer. Their intake is, however, far higher up the river than are those of the East London, and therefore so much the better. They have indeed a station at Tottenham, but for twenty years it has not been used. The intakes of the East London at Old Ford, &c., are certainly open to grave objections. Two appendices are annexed, the first giving the Acts of Parliament relating to each Company and the regulations of the Water Companies Act of 1871, which are of great importance to the householder, and the second describing the pavilion at the Exhibition and therefore of merely temporary interest.

Report of the Sanitary Condition of Birkenhead for the year 1883; by Francis Vacher. Birkenhead: Willmer, & Co., 1884.—During the past year the total number of deaths in Birkenhead was 1,742, giving a death-rate which compares very favourably with that of other large towns similarly circumstanced. The proportion of deaths of infants, children, and young persons is less than the average of town districts. There were 226 deaths from zymotic diseases, giving a death-rate of 1·28 less than the mean rate for the preceding five years, a state which must be considered eminently satisfactory. Amongst the fatal zymotic diseases, small-pox finds no place, a source of congratulation to the medical officer of health and the sanitary authority generally. Typhus was said to be the cause of death in ten cases, and some particulars of each of these cases are given in the report. The number of uncertified deaths does not diminish, which is not only unsatisfactory from the point of view of the care of the sick, but also greatly diminishes the value of the mortality statistics by rendering them incomplete and unreliable. How a registrar should have accepted a statement that a baby's death had been due to hypertrophy we must confess ourselves unable to comprehend, and yet this intelligent diagnosis is set down as the cause of death in one instance. A map of the town showing the incidence of the cases of infectious disease is appended, as also a plan of the new fever hospital.

A Descriptive Catalogue of the Pathological Museum of the Middlesex Hospital; by J. K. Fowler, M.A., M.D. London: J. & A. Churchill.—The Middlesex Hospital museum was founded nearly fifty years ago, and up till now the catalogue has remained in manuscript. The school authorities have done well in calling public attention to their museum, which is already fairly well stocked with preparations, and we do not doubt that the publication of this catalogue will materially increase the usefulness of the museum, and be the means of bringing more specimens to it. The catalogue is made on the lines adopted by the Royal College of Surgeons and St. Bartholomew's Hospital, and contains a very full table of contents at the commencement. The book is well printed and admirably bound, and we hope that those hospitals that have not already published a catalogue of their museum will be stimulated into doing so by the very good example set by the Middlesex Hospital.

Medicinische Bibliographie und Anzeiger; compiled by Dr. Arthur Würzburg, Librarian to the Imperial Board of Health in Germany. Leipzig: Breitkopf and Härtel, 1883. Pr. 5 Marks.—The vast increase in the quantity of medical literature which is every year becoming greater, has created a demand for some system of registration and indexing which shall enable future readers and writers to refer to already published works without unnecessary confusion and delay. It is perhaps to be regretted that no common code of registration has ever been adopted by the four nations which chiefly contribute to the progress of medical knowledge. Each nation has its own form of Index Medicus, Bibliography, or Jahrbuch, but each comprises the works of other countries as well as its own, and hence arises a great deal of unnecessary repetition. The work before us, the first published volume of the Bibliography, which has for the last year made its weekly

appearance as the companion to the *Centralblatt für die gesammte Medicin*, is a very complete catalogue of its kind. It consists of a comprehensive list of all the original communications to periodical literature, of all the published works, and of very many clinical lectures, papers of especial interest read before any medical societies during the year 1883, and also of important critical newspaper articles. In every case a clear reference is given to the original paper, and in the case of published books and pamphlets the size of the work and also its price and publisher are duly noticed. Being prefaced by an index of authors' names and of the subjects dealt with, the book can be successfully referred to without much delay. An extension of the subject index, however, might be made with advantage by means of further subdivision under each heading. Thus, under the heading of syphilis, we have no less than fifty-four references without any indication as to the branch of the subject with which the several papers may deal. A subdivision into syphilis of the brain, skin, throat, &c., would greatly increase the facility of using the work. As a useful library work of reference, Dr. Würzburg's Bibliography deserves a cordial reception as one of the most comprehensive of its class.

A System of Human Anatomy; By HARRISON ALLEN, M.D. Section 6. London: Henry Kimpton & Co., 1883. —The sixth and concluding part of this important work is now on our table. The subjects contained in this section are the eye, the ear, the nose, the organs of digestion including the teeth, the organs of respiration, and the genito-urinary organs. To these are added chapters on superficial and topographical anatomy, and on embryology and the study of malformations. The concluding chapter is on the art of making *post-mortem* examinations. As we have in noticing the various parts of this work expressed our approval of it, we are glad to be able to find that the last section has been as carefully prepared as its predecessors, and that the plates are plentiful and well executed. The advanced student will, we doubt not, find this work of great assistance, but the beginner must not delude himself by supposing that in becoming the possessor of it he is on the high road to learn anatomy. He must have made some progress in the dissecting room before he can use such a work as this with advantage.

Notes on Physiology; by HENRY ASHBY, M.D. 4th Edition. London: Longmans, 1884.—A book which was originally published in 1878, and which is going through its 4th edition in 1884, does not require much commendation at our hands. It does not deal with debatable questions of transcendental physiology, but with certain now well-understood physiological facts, such as every medical man must keep at his finger ends. It is just the book that students require; in it they will find all that is essential for the ordinary and intelligent practice of medicine. These facts, however, should be committed to memory, and special points which are not sufficiently detailed can be supplemented from larger works as the want arises.

The Science and Practice of Midwifery; by W. S. PLAYFAIR, M.D., F.R.C.P., &c., &c. Fifth Edition, 1884: Smith, Elder and Co. We have pleasure in calling attention to the appearance of a new edition of this popular text-book. The work has been revised, so that it represents the author's most mature judgment on the subjects of which it treats, and we doubt not it will continue as great a favourite as heretofore with students and practitioners.

ABSTRACTS AND EXTRACTS.

OBSTETRICS.

ARREST OF TUBAL-PREGNANCY BY GALVANISM.—Dr. Paul Mundé, of New York, relates (*New York Medical Record*, September 27th) the following interesting case. "It is possible," he observes, "that at some future time the details of laparotomy may be so simplified that a fatal termination will be a rare exception; but at the present time, in spite of Tait's wonderful results, the fact remains undisputed, that every patient whose abdominal cavity is opened incurs the risk of losing her life. So long as this is the case, the majority of operators will hesitate before performing a dangerous operation, when the same result can be obtained, at least so far as the continuance of the gestation is concerned, by an entirely harmless and simple process. Whether this process, the passage of an electric current through the gestation-sac, is so entirely harmless; whether it can be relied upon always to arrest the growth of the ovum and its envelopes; and finally, whether the ovum so arrested is a safe thing to have in the abdominal cavity *ad infinitum*, these are points which only additional observation will decide. As a contribution to the settlement of these questions the following case is reported."—Consulted by a lady, 38 years of age, the mother of a child 8 years of age, and who had miscarried 6 years ago, Dr. Mundé found on examination that the uterus was empty and unenlarged, while a deeply fluctuating tumour, the size of a goose's egg, could be felt, slightly movable, at the right side of the pelvis, the uterus moving with it. Large vessels could also be felt pulsating through the right vaginal pouch. The diagnosis formed was that of a tubal pregnancy of two months' duration. This view was subsequently confirmed, after an examination by Professor Emmet. The patient had for some time past suffered a good deal of pain in the abdomen, and the two examinations caused her great suffering. Fearing that any delay might result in a rupture of the sac, Dr. Mundé at once proceeded to the application of galvanism, notwithstanding an extreme state of prostration into which the patient had fallen, "preferring to run the risk of producing that rupture by the electricity, rather than what seemed to me the greater risk of allowing the sac to grow even twenty-four hours longer. Placing a leather-covered button electrode in the rectum, and the other pole by a flat sponge on the abdomen over the mass, I passed the current of my newly filled galvanic battery through the sac, gradually increasing the current, a dozen times or more. The sitting lasted about ten minutes, and the shocks were quite painful. I did not think this current too strong, for I remembered that in one of the successful cases reported, Burney's thirty-six cells had been used. I left the patient fairly comfortable, no more prostrated than before the application." Next morning, on being sent for, Dr. Mundé found that the patient, after retching and vomiting during the night, had been seized with a violent pain in the abdomen, and had become pale, cold, and pulseless. He feared that rupture of the sac must have taken place, and was only prevented from concluding that this was the case by the fact that the patient could turn about in bed and answer questions. A state of collapse there was, but it did not seem exactly like prostration from hæmorrhage. A gently conducted examination showed that the outline of the mass remained as distinct as on the previous day. The treatment followed was the administration of stimulants for the purpose of rallying the patient sufficiently to allow of laparotomy being performed if rupture took place. As the stomach would retain nothing, hypodermic injections of brandy and ammonia were practised in different parts of the body every twenty minutes, and as she continued all day in this condition, about fifty of these injections were administered. Although advised by colleagues to operate, in spite of the collapse, Dr. Mundé forbore doing so under the hope that the collapse might be due to the shock produced by the painful vaginal examinations, and by passing the galvanic current through so sensitive an organ as an over distended tube. The next morning some return of pulsation took place in the wrist, and from this time the patient gradually rallied, and in a week was able to sit up in bed. The sac had become somewhat harder and fluctuation less distinct. Pulsation had disappeared, but the mass was not perceptibly smaller. To remove all reasonable doubt of the death of the fœtus "I thought it best to pass the faradic current through the sac a number of times, and beginning on the 16th day after the galvanic sitting, I made six faradic applications to the sac, one pole in the vagina, the other over the mass on the abdomen, using the full strength of a Kidder tip-battery, and frequently breaking the current. One sitting a day was

given, lasting about fifteen minutes. This treatment caused no pain or shock whatever." From this time the patient rapidly improved, and by the end of the fourth week was able to go out. The sac, however, diminished very slowly, so that when the patient was last seen, three months and a half after the galvanic shock, it was still two-thirds as large as at first, although perfectly solid. All pain had entirely ceased before she was allowed to go out. Menstruation reappeared, and the lady left for a tour in Europe. In the comments which Dr. Mundé makes upon his interesting case, he again expresses the conviction that the prolonged condition of collapse into which she fell was due to shock brought about by the pain caused by the examinations and by the galvanism, and naturally congratulates himself on having had the acumen to distinguish between this and the collapse that would result from intra-abdominal hæmorrhage, and thus saving his patient from a laparotomy which would probably have ended fatally. Still, he had remained for hours under the expectation that he should have to operate; and it was solely the persistence of voluntary muscular power during the collapse that gave him the courage to delay interference. The experience gained in this case induces him to give preference to the faradic over the galvanic current, for, although the former requires more frequent repetition at short intervals, it is much milder in its effect. He believes that this is the twelfth reported case of extra-uterine pregnancy being checked by electricity; the eleven other cases having been recorded by Dr. Garrigues in the seventh volume of the "Transactions of the American Gynæcological Society."

Extra-Uterine Pregnancy in a Tubo-Ovarian Cyst.—Dr. Vulliet, of Geneva, describes in the *Archiv für Gynäkologie* (Band xxii., Heft 3) a case which he believes to have been of the above kind. There was the history, common in such cases, of previous pelvic inflammation: of the symptoms of pregnancy, milk in the breasts, &c., and the discharge from the vagina of a decidual membrane. There was a tumour behind the uterus, pushing that organ forwards. An incision was made into the tumour per vaginam, but the wall found so thick (in consequence, as was afterwards found, of the implantation of the placenta in the lower part of the cyst) that nothing could be done by this method, and laparotomy was therefore performed, the fœtus removed, and drainage tubes inserted both into the abdominal and vaginal wounds. The fluid contained in the sac was scanty, greyish and fœtid. The patient died on the day after the operation from septic peritonitis. On autopsy the uterus was found enlarged. The left tube and ovary were found adherent to the parietal peritoneum, and a small abscess between the tube and the ligament of the ovary. The gestation cyst was bounded in front by the right broad ligament and the uterus, behind by the rectum and the pelvic wall. The right tube was adherent to the sac, tortuous, and when opened was found dilated, thickened and opening into the gestation sac. No trace of the right ovary could be found, and the most careful examination of the walls of the cyst failed to discover any ovarian structure in them. Nevertheless, from the fact that the ovary could not be found, and that the tube opened into the cyst, Dr. Vulliet endorses the view of Professor Zahn (by whom the cyst was examined) that it was originally a tubo-ovarian cyst; the ovarian tissue being, as is usual in such cysts, spread out over the wall of the cyst, but probably not recognisable in consequence of the secondary changes due to the pregnancy, death of fœtus, inflammation of cyst, &c. Dr. Vulliet has found, recorded by Cazeaux, an indubitable instance of pregnancy in a tubo-ovarian cyst. He points out, and shows from cases, that three forms of tubo-ovarian cysts are met with: (1) small and of recent formation with the ovary unaltered, (2) those in which the ovary is wholly or for the most part converted into a membrane, but retains its proper histological structure, (3) those in which, from tension or other changes, the ovigenous tissue is destroyed.

Oophorectomy.—Dr. Fehling, of Stuttgart, contributes to the *Archiv. für Gynäkologie* (Band xxii., Heft 3) an interesting article on the "Castration of Women." He relates ten cases, and then expresses opinions based upon other these and upon recorded cases. As to mortality, he thinks that with experience this will diminish. Hitherto it has been about ten per cent., but he thinks with our present experience it is not likely in the future to exceed at most five per cent. Next as to the effect upon menstruation. In 4 cases out of 9 he found the menopause immediately follow. The same happened in 4 cases out of 10 published by Tauffer, and in 31 out of 41 recorded by Hegar. Irregular hæmorrhages for a time followed by complete cessation, resulted in 3 of our author's 9, in 3 of Tauffer's 10, in 8 of Hegar's 41. Hæmorrhage continued to recur for a long period (two years or more) after operation in 2 of Fehling's cases, 3 of Tauffer's, and 1 of Hegar's. The result of other operators, says Dr. Fehling, give similar figures. He then considers the effect in different classes of cases. In cases of uterine fibroids the results are excellent. In 5 out of 6 cases of his own in which spaying was performed for fibroids, the menopause followed. In 21 similar cases of Hegar's, 3 died, the menopause followed immediately in 11, gradually in 6; in only one did hæmorrhage persist. Fehling removed the ovaries for ovarian neuralgia in one case only; relief was slow but complete. In nervous and mental diseases he finds the results are not good; even when benefited for a time, symptoms return. Goodell's wild assertion that all insane women ought to be spayed, Dr. Fehling rejects absolutely. He quotes Liebermeister to the effect that in hysteria, unaccompanied with local disease, castration ought not to be performed. He does not think it necessary, even if possible, to feel the ovaries before commencing the operation. He has not observed any loss of sexual feeling as a result of the operation.

On Errors in the Diagnosis of Pregnancy.—Professor Pajot, in a clinical lecture (*Presse Méd. Belge*, September 7), observed that he wished to refer to a case which would prove of great value to the pupils as putting them on their guard in relation to faults in the diagnosis of pregnancy. Such faults have been committed by men of the highest eminence, for if in 95 cases out of the 100 diagnosis is quite easy, in some others it is attended with extraordinary difficulty. In this case, of recent occurrence, such a fault had been committed by men in a high position, one of them enjoying great celebrity. In place of hesitating to communicate the case, Professor Pajot brings it prominently forward, as it exhibits the precise rule which should be observed on these difficult occasions, and may save the reputation of the practitioner and even the life of the patient. A lady, 35 years of age, had a child when she was 20, after a laborious labour, requiring the forceps, and followed by a vesico-vaginal fistula. Since then she had two labours, both quite easy. After the last of these, eight years ago, she suffered greatly from menorrhagia; but having five years since begun to introduce a large sponge into the vagina, for the purpose of sustaining the uterus, which had descended considerably and absorbing the urine from the vesico-vaginal fistula, the metrorhagia ceased and was succeeded by irregular and sparing menstruation. Having become a widow she re-married, and coition was always performed with the sponge at the bottom of the vagina. Last summer she consulted Professor Pajot because her abdomen had greatly enlarged and she wished to know whether she was pregnant. Having removed the sponge, he proceeded to examine her, and found the perineum very lax and easily depressed, a small vesico-vaginal fistula still existing. The cervix, in the erect posture, descended to within a few centimetres of the vulva, and was flattened, small, hard, atrophied and colourless. The orifice was but slightly developed. The uterus rose largely out of the pelvis and was very mobile, but its oscillations were not communicated to the cervix. Professor Pajot delayed giving his opinion on the case for a fortnight, when the patient declared that she felt the child move; but the fœtal heart could not be heard and the opinion was still withheld. Meanwhile an accoucheur and hospital surgeon was consulted, who, after an attentive examination, declared that an ovarian cyst existed. This alarming the patient, a celebrated laparotomist was consulted who stated that a large fibrous tumour of the uterus existed, and advised an operation. Three weeks after this last consultation, the patient, having taken some very violent

purgatives, gave birth to a child between seven and eight months old, all traces of the tumour disappearing. "Faults like these are committed only because old counsels which I long since delivered have been forgotten. In these difficult and obscure cases, I said there is a simple line of conduct to be followed which is both useful and prudent, and never compromises the health or life of the patient nor the reputation of the practitioner. This is *expectation*; we must know how to wait. If there is some pressing indication, of course we must fulfil it, for when life is menaced, what matter is it about the pregnancy? But, as a general rule, neither the health nor the life of the patient is in question. The woman desires to know whether she is or is not pregnant. And as long as the problem does not appear to be soluble with certainty we should make no resolutions. Let us wait and above all things wait without acting, if nothing creates an absolute necessity for action. Time is the best of all our means of diagnosis."

Abortion Induced by a Hair-pin: Death—The patient, aged 24, was the mother of one child and had had several miscarriages, presumably induced by herself. Having missed a menstrual period on March 5th or 6th, she introduced a hairpin into the uterus, the points downward. The pin slipped from her fingers and entered the womb, where she allowed it to remain until it should produce some symptoms. On March 27th Dr. Nesbit found the os closed, but the cervix enlarged and exceedingly sensitive; the body of the uterus was also very tender to the touch; there was no pyrexia. Up to this time the patient had been walking about as usual. A tupelo tent was introduced and on the next day two larger ones; in the evening several very offensive clots were passed, and during the night the patient flooded very freely. On the 29th there was evidently pelvic peritonitis; the temperature was 105° F., and the pulse 120. The cervix was pretty well dilated, and Dr. Partridge, who had been called in consultation, was able to touch the hairpin with the finger. The patient was anæsthetised, and after fifteen or twenty minutes' manipulation the foreign body which was lying across the right side of the cavity with its prongs embedded in the uterine wall, was disengaged and removed. The uterus also contained a mass which was evidently the greater part of an ovum which had lost its vitality some three weeks previously. Residual fragments of membrane were scraped out, and an inter-uterine douche of corrosive sublimate solution administered. The patient rallied well, and the temperature fell in the evening to 102·6°. Three days later the temperature was down to 99·8° and the pulse 102. That night the patient left her bed, in spite of the nurse's remonstrances, and walked about the room for twenty minutes. The next morning she presented signs of extensive peritonitis, and died six days later. The case is interesting because it is unusual, and verifies the fact that women do sometimes successfully resort to mechanical means for penetrating the uterine cavity in order to bring on abortion in their own person.—*New York Medical Journal*, Sept. 6th.

The Treatment of Pregnancy and Labour Complicated with Cancer of the Uterus.—In an article published in a recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* (Band X., Heft 1), Dr. Alfred Gönner relates six cases illustrating the above complication. In one case Cæsarean section, followed by removal of the entire uterus, after the method of Freund, was performed, with the result that the mother died in nine hours. In the second case the cancer was removed during labour with the galvano-caustic wire; and one month after the labour, and again four months after, bits of cancer were scraped away, with much temporary relief; but the patient died ten and a half months after labour. The third case was a most encouraging one. Premature labour was brought on in the thirty-fifth week, and a living child born. On the eighth day after delivery the cancer was removed by the galvano-caustic wire. Two years afterwards no trace of cancer could be found, and two and a half years afterwards the patient was naturally delivered of a healthy child. The fourth case was also very satisfactory in its result. The growth was cut away with scissors, and thus room gained for the passage of the child, which was delivered with forceps, but died from asphyxia. Two days after labour the cancer was thoroughly destroyed with the thermo-cautery. Two and a half years afterwards Dr. Gönner attended her for abortion with a vesicular mole, and found the cervix quite healthy. In the fifth case the growth was removed by cautery wire and cutting instruments during labour, and a living child born, but the mother only survived three months. The sixth case was treated in the same way, and a living child born; but the mother died four and a half months afterwards. These interesting cases, we think, tend to enforce the rule that in pregnancy complicated with cancer the first thing to be done is to remove as much of the cancer as possible; this proceeding being not attended with great risk, and often productive of much benefit.

The Remoter Dangers of Ovariotomy.—The patient, whose case is described in the *New York Medical Journal*, September 13th, had had an ovarian tumour removed some five or six years ago. The operation was a successful one and she made a speedy recovery, but the patient was subsequently much troubled by constipation and became subject to attacks of colic, in consequence of which she had become an inveterate pill-taker, remaining strong and robust notwithstanding. On August 5th, 1883, Mrs. M. took a dose of cathartic pills which operated freely; in the evening she partook of ice-cream and soon after was seized with violent colicky pains, which were temporarily relieved by morphia and hot fomentations to the abdomen. Pain and vomiting persisted; copious enemata of warm water failed to bring away any fæcal matter; there was an absence of tympanites and tenderness. On August 11th the vomiting was stercoraceous, and death occurred on the evening of the 12th. On exposing the abdomen *post-mortem*, a long white cicatrix, the line of the ovariotomy incision, could be traced from the pubes nearly to the ensiform cartilage; at its lower end, two inches above the pubes, a discoloured spot, half the size of the hand, was visible. Careful dissection showed that a portion of the ileum, about eighteen inches above the cæcum, was adherent to and incorporated with that part of the cicatrix corresponding to the lower angle of the original wound, and that around the short portion, between this point and the cæcum, a loop of small intestine was twice twisted, forming a kind of knot and a complete barrier to the passage of intestinal contents. The intestines and the cavity nearly everywhere afforded evidence of former inflammatory processes. The intestines were also extensively adherent to the sides and posterior wall of the abdomen, and being firmly bound down in this manner, the usual appearance of tympanitic distension of the abdomen was doubtless thus prevented.

Double Uterus and Vagina.—Dr. Dirner, of Buda Pesth, relates in the *Archiv für Gynäkologie* (Band xxii, Heft 3) a remarkable case of the above kind. The patient consulted a medical man because coitus was followed by involuntary escape of urine. He found that intercourse had taken place per urethram, and discovered and dilated a vaginal orifice. Connection henceforth took place through this canal, and pregnancy followed, which ended in abortion. After this she came under Dr. Dirner's observation at Professor Tauffer's clinic. It was found that vagina and uterus were double. Intercourse had taken place through the *left* vagina, and pregnancy in the *left* uterus. The right vagina was narrow and its orifice very small, the right uterus smaller than the left. Professor Tauffer treated the case by removal of the vaginal septum, as well as of a small urethral growth which was causing trouble. After this the patient became again pregnant, this time in the *right* uterus, and was delivered at term. It was noted that during labour the left uterus contracted at the same time as the right, and that after involution the right uterus was larger than the left.

Cystic Fibro-Adenoma of the Body and Neck of the Uterus.—Dr. F. Schatz describes a case of this rare form of disease, which will interest histologists (*Archiv für Gynäkologie*, Band xxii., Heft. 3). The uterus was enlarged, both by diffuse thickening of its lining membrane, and by polypoid growths, cervix and body being alike diseased. On microscopic examination the new growth was found adenomatous in structure; with cyst formation

towards its free surface, and at its deeper part muscular fibre. The muscular tissue of the uterus contained some small fibroids. Dr. Sehatz says that diffuse adenoma and polypoid adenoma have been described before; diseases limited to the mucous membrane. His case he believes to be the first on record in which the muscular tissue of the uterus was involved to a considerable extent.

A Caution to Laparotomists.—At the annual meeting of the American Gynæcological Society, Dr. Wilson, of Baltimore, read a paper on "Foreign bodies found in the abdomen after laparotomy," in which he stated that he had only succeeded in collecting 21 cases, of which only five had been published. Six occurred in America and fifteen in Europe. In five of the American cases, sponges were left behind, and in the other a forceps. In his own case ovariotomy had been performed on a woman five months advanced in pregnancy, and abortion took place eighteen days after the operation. A sponge remained in the abdomen for five months, and was discharged piecemeal through the walls of the abdomen, the woman recovering completely. Dr. Gaillard Thomas said that he was in the habit of attaching long pieces of tape to the sponges used to prevent their being lost. He had never left a sponge behind more than once out of his four or five hundred laparotomies. Dr. Jackson, of Chicago, stated that he had a list of the instruments and sponges used, which he examined after each operation. Dr. Dunlop made large incisions so as to allow of free inspection, and used large sponges. During the discussion seven other cases were mentioned, raising Dr. Wilson's number to 28. — *New York Medical Record*, October 4.

Changes in the Ovaries during Menstruation which can be Clinically Observed.—A recent number of the *Archiv für Gynäkologie* contains a short paper on this subject, by Dr. Meyer, of Dorpat. He has examined women in whom the physical conditions were such that the ovaries could be easily palpated, before, during, and after the menstrual period, and observed the following changes; In many cases he found an indubitable increase in size. He also found a difference in consistence, the gland feeling more elastic and tense. Only once did he find an ovary that seemed to get softer during menstruation. There were also changes in shape, the organs becoming more rounded, while in a few cases inequalities could be perceived on the surface. These changes generally affected both ovaries, often being more pronounced in one than in the other; but sometimes one ovary only appeared to be altered. The changes were perceptible between the third day preceding and the eighth day following menstruation. They were most marked between the second and fourth days of the menstrual flow. In one case Dr. Meyer thought he detected swelling of the tube. It will at once occur to our readers that in clinical observations of this kind many sources of error creep in; but we give Dr. Meyer's observations for what they are worth.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

Friday, November 28th, 1884.

Sir Andrew Clark, Bart., M.D., President, in the Chair.

Adjourned Discussion on Charcot's Joint Disease.

The discussion of Mr. Morrant Baker's paper, read at the last meeting of the Society, was resumed.

Mr. Barwell said there was now a feeling that many forms of multiple articular affection were due to a nerve lesion, and he thought there was especially strong evidence in favour of such a case for arthritis deformans. But was it therefore necessary to suppose that the nervous lesion was always identical, and always that called locomotor ataxy? He thought "Charcot's disease" a separate one. Both anatomically and clinically it differed from ordinary arthritis deformans; the one was an excess of hyperplasia, the other essentially an atrophy. The one was chronic in its onset, the other acute. Arthritis deformans selected the smaller joints, Charcot's disease the larger ones. Excess of normal and false movements predominated in all tabetic cases, while in chronic rheumatoid arthritis the opposite was true.

Sir James Paget was inclined to agree, almost completely, with Mr. Baker. In answering his question whether the disease was a new one, it would be necessary to prove that it was not an old one. Few could feel more deeply than he did what vast tracts of knowledge had in times past been overlooked. We could not study our own career, or observe, as science made progress, the number of things which had been constantly within our own sight or thoughts of which we had remained totally unconscious, without feeling that such a disease as this might have been overlooked in times past. Yet he did not believe that the older observers of cases of bone disease had overlooked it. It was said that these cases chiefly presented themselves in the out-patient rooms, and to surgeons at the workhouses. Well, he would remind the society that our teachers had studied their pathology in such places. John Hunter had collected hundreds of specimens from workhouses. George Langstaff, Cruveilhier, Stanley, had all been great collectors of bone cases, and yet, although these names covered a period of eighty years or more, they had never found such specimens as these, which were now well known in all museums. Had such cases as were exhibited this evening been present in any of the workhouses during the period referred to, their bodies would have been dissected and their bones preserved. Yet the fact was, that not one single specimen at all characteristic of Charcot's disease remained to tell the tale. Was the disease a neurosis, or was it rheumatic arthritis? It was neither one nor the other, but rather a disease made up of several different constituents, and appearing only at a time when, we knew not by what external conditions, all these constituents of disease were met with in one and the same person. The term "Charcot's disease" was itself an evidence of the obscure nature of the disease; it was the rule to give such obscure names to disease until their ultimate nature began to be made out, and then a more correct term was substituted. It would be wise, in attempting to define a disease, to proceed by way of analysing the various constituents of which it was composed; to see in what proportion each constituent was present. In rheumatic arthritis, for instance, in one case there was more gout, and in another more rheumatism. Then as to Charcot's disease, was it rheumatic arthritis altered from its ordinary fashion by the intervention of locomotor ataxy? Mr. Baker was doubtless right in saying that the characteristic of Charcot's disease was the atrophy without repair; in rheumatic arthritis there was atrophy also, but evidences of a reparative process were also present. Nevertheless if these two diseases could be broadly distinguished from one another, it was no argument that in locomotor ataxy there was no measure of rheumatic arthritis. It might possibly be that the spinal disease modified the rheumatic arthritis by interfering with the reparative processes. He could not quite accept the absolute distinctions drawn by Mr. Barwell, either clinical or pathological, and he thought there were not a few specimens which it would be difficult to classify at first sight. There was also in many cases yet another element, syphilis—not present in all cases, but a very common constituent. If we might assume the existence of three such diseases together, we might explain a very wide range of variation in individual cases. We could certainly say definitely that syphilis implanted in a person with gout was greatly modified in its later stages; so then we should have to analyse Charcot's disease, and endeavour to trace what diseases enter into its composition, and in what proportion each was found.

Dr. Ord had never had a case of Charcot's disease under his own care. He agreed with Mr. Baker in his general conclusions, yet he was compelled to recognise more than he had done in the matter of wasting. He agreed with Dr. Buzzard that there was actual wasting of bone substance quite independent of its wearing down. On the other hand, he could hardly admit the statement that there was scarcely

any attempt at repair. In all the cases he had carefully examined, he had found some outgrowths, and in a few he had seen something very like eburnation. He had thought much about this affection, and was inclined to include it under the head of chronic rheumatic arthritis, or as he would prefer to call it osteo-arthritis, which was a more neutral term. He then detailed some cases under his observation, in which the osteo-arthritis was greatly modified by a neurotic process; but he did not imply that this neurotic element was present in all cases.

Professor HUMPHRY agreed in the main with Sir James Paget, that this was a disease with which we were not familiar in olden time, for he went back to somewhat olden time. Until lately he had never seen such routings of joints, such deformations of articular surfaces taking place with such rapidity. He had worked much in museums without finding specimens. He agreed that it was probably a compound affection, between the old rheumatic arthritis and tabes dorsalis. The old affection was a wearing away proceeding from the articular surfaces, a resultant of a low inflammatory affection. In the new affection there was rapid decay, rapid wasting, or rapid removal of bone, well shown in the specimen he exhibited, which was taken from a woman, in whom it had only been going on for about three months. The whole head of the tibia was gone, the cartilaginous joint-surfaces remaining, showing that the process took place below the joint and not from it. He could not quite agree as to the entire absence of reparative power. It was curious what amount of reparative power existed in the bones of old people, side by side with extensive atrophy.

Mr. HUTCHINSON at one time was a believer in the special character of "Charcot's disease" and in the theory that it resulted from some active interference on the part of the nervous system. He had since changed his views, and now regarded these joint changes as made up in part of conditions which led to rheumatic gout, and associated with senile changes and with conditions of the nervous system which led to partial anæsthesia or inability to perceive pain. He thought the question might be much simplified by regarding the sensations of the ataxic patient as extremely dull. In this manner the painless retention of urine was explicable, and also the perforating ulcer of the foot, which resulted from pressure on a part devoid of common sensation. There were many conditions in which the nervous system was only passively engaged—permitting, but not actively causing. Between the pathological appearances in Charcot's disease and in chronic rheumatoid arthritis he admitted there was no abrupt line of demarcation; on the other hand, typical cases of the two differed widely, while the lesser degrees merged one into the other. He did not think that in many of the cases of Charcot's disease any history of gout would be got. On the other hand, many tabetic subjects did suffer from rheumatic arthritis, which got well and which never developed into the conditions now under discussion. The alteration in the cases was chiefly due to the fact that the patients continued to walk about. If a patient were placed in bed, and rested absolutely quiet, he never got eburnation. It was because he could bear rubbing of his joints for long periods that these peculiar changes resulted. This movement was hardly the whole cause, though a very important factor. Nerve function had failed in some peculiar way, and certain lesions of nutrition resulted, which permitted of these curious movements.

The PRESIDENT asked Sir James Paget as to his meaning of the expression "definite disease of the spinal cord" as associated with this joint affection; did he mean tabes, or some condition akin to it?

Sir JAMES PAGET explained that he was not disposed to accept Mr. Hutchinson's view that the nervous condition was merely a permissive one; he believed that the nervous system had the power of actually determining disease.

Mr. HULKE was quite unable to look upon Charcot's affection of joints as a distinct, a separate thing from the affections known for years past either as malum senile, rheumatoid arthritis or arthritis deformans. He used these expressions as labels to designate well known conditions without committing himself as to their exact nature. Taking a large number of cases, neither in their clinical nor pathological details did they show any essential differences; he exhibited a specimen in which the two diseases typically co-existed. Either we must imagine the coincidence of several diseases or their identity. As to Mr. Barwell's assertion that in Charcot's malady the lesser joints were not affected, curiously enough among the specimens sent from Paris by M. Charcot was a foot in which almost every joint was affected. As to the chronicity and sluggish nature of the disease, he would just say that he had recently had a case under care in the Middlesex Hospital which had commenced acutely. He felt, therefore, that this affection was really rheumatoid arthritis; it was sometimes associated with tabes, sometimes not so, just in the same way as tabes in many cases occurred without any joint affection. He was pleased to hear that Sir James Paget recognised syphilis as an important ætiological factor.

The discussion was then adjourned to the next meeting.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, DECEMBER 2ND, 1884.

J. W. HULKE, F.R.S., President, in the Chair.

Cyst of Cerebellum.

DR. PYE-SMITH showed this specimen taken from the body of a man, aged 27. The symptoms had existed for about three months; they were vomiting, severe occipital headache, vertigo, double optic neuritis, hæmorrhages into the right retina. There was no paralysis, spasm or convulsion. He died from asphyxia. A simple serous cyst was found in the left lobe of the cerebellum, about the size of a walnut; there was effusion into the ventricles, but no meningitis. Several small cysts were found in both kidneys, and in the pancreas. Dr. Pye-Smith referred to the other cases recorded in the Transactions.

Dr. NORMAN MOORE asked if the kidneys were examined microscopically. In congenital cases, when the tissue between the cysts was examined, it had been found to contain normal Malpighian bodies—this would suggest that they were developed in the connective tissue, and might therefore be found in different parts of the body.

Dr. HADDEN said that the case that had been referred to was that of a woman who died with cerebral symptoms, and had a cyst in the occipital lobe, and there was a history of violence.

Dr. CARRINGTON had examined the kidneys in this case, and found the structure between the cysts normal.

Dr. HALE WHITE referred to two cases of cysts in all the viscera mentioned in the last volume of the Society's Transactions.

Dr. PYE-SMITH said that the kidneys were practically healthy, and in his former case also there was plenty of normal structure. The cysts might be formed in the connective tissue, but he thought they were retention cysts.

Intus-susception in the Adult.

Dr. LANCHESTER exhibited this specimen. The patient had been taken ill with diarrhœa, some tenesmus, and passed a little blood. He came to the hospital on the eighth day, when the rectum was found to be occupied by a mass which could be freely handled, but was evidently firmly impacted. Left lumbar colotomy was performed the next day, it being felt to be unlikely that the intus-susception could be reduced. The patient died 48 hours after the operation, from peritonitis. The invaginated portion was three inches in length, and it was held firmly in place by the mesenteric attachment; it might possibly have been an old affair.

The PRESIDENT asked which portion of the bowel was intus-suscepted, when Dr. LANCHESTER replied that it was the rectum.

Mr. CROFT asked if all the coats were invaginated.

Dr. WILKS thought that all the coats were affected; it was a rare specimen. He had only seen two cases in adults.

Mr. Godlee had only seen intus-susception in the adult in connection with tumour. Colotomy would not be advisable in children at any rate, as the intus-susception was usually at the ileocæcal valve.

The President referred to a case of Dr. Coupland's in which nearly the whole of the small intestine was intus-suscepted.

Dr. Lanchester had no doubt that all the coats were intus-suscepted. He had been able to form an idea of the size during life, and felt confident he could get beyond the tumour, and therefore opened the left loin. The affected portion might have sloughed had the patient lived.

Ulceration of Trachea and Œsophagus.

Dr. Carrington showed this specimen, taken from the body of a man aged 20. On July 9th patient had opened a cask containing ammonium carbonate, and was nearly suffocated by the fumes. Some hours later he was seized with cough and spat up some blood. Swallowing was almost impossible from that date, and he was brought to the hospital on July 11th, a few days after which it was found that a catheter passed into œsophagus and entered trachea. Signs of broncho-pneumonia developed and increased, causing his death on July 23rd. A fistulous communication was discovered between the œsophagus and trachea, two inches below the cricoid cartilage; it was elongated and longer on œsophageal than tracheal side. There was no thickening of the edges, or trace of new growth. The trachea and bronchi were acutely inflamed, and there were patches of broncho-pneumonia. There was no evidence of syphilis. Dr. Carrington suggested that there might have been a diverticulum of the œsphagus in which there had been a lodgment of food leading to suppuration and perforation.

The President thought that the history ought to be taken into consideration, and referred to a case recorded at another society in which ammonia had caused ulceration of trachea.

Dr. Wilks referred to a case he had shown in the early years of the Society in which there was ulceration of the trachea. There had been much dispute as to the nature of the ulceration, the majority believing it to be lupoid.

Mr. Bowlby asked whether any examination had been made microscopically. He had lately seen a case where there had been no suspicion of malignant disease, but at the *post-mortem* secondary growth had been found in the viscera.

Mr. Butlin had looked up the case Dr. Wilks mentioned, and thought it was probably a case of epithelial carcinoma; the present might be of the same nature.

Dr. Money mentioned a case where an apparently simple ulceration of the trachea was found to be due to new growth.

Dr. Carrington had examined the ulcer microscopically, but no signs of new growth were found.

Tumour of the Soft Palate.

Mr. Treves exhibited two cases of primary tumour of the soft palate. The first patient was a man, aged 68; the tumour occupied the whole of the left side of the soft palate. It was first noticed eight months previously. A precisely similar growth had been removed from the same part of the palate thirty-seven years previously. He tied the left common carotid artery, and removed the growth with the left half of the palate. The tumour was an alveolar sarcoma; it was faintly encapsuled. The patient recovered. The second patient was aged 56, with a growth on the right side of the soft palate of two months' duration. The right common carotid artery was ligatured, and the growth removed, the patient making a good recovery. The growth was of an adenoid nature. Primary tumours of this region were very rare.

Mr. Godlee had seen two cases of recurrent fibroid, and two of papilloma.

The President had seen three cases.

Mr. Bowlby thought that both were carcinomata: the cells were of an epithelial type in each.

Mr. Treves admitted that there was a similarity to carcinoma in the one called sarcoma, but there were some doubtful points, and the history was against the idea of cancer. The specimens were referred to the Morbid Growths Committee.

Congenital Hydrocele of Spermatic Cord.

Mr. John Poland said that the specimen was taken from a child 3½ years old. The child died of peritonitis three days after the hydrocele had been tapped. At the autopsy it was found that the sac of the hydrocele communicated freely with the abdomen, its walls were much thickened and lining shaggy from purulent lymph, and it contained sero-pus like that in the abdomen. The tunica vaginalis at the lower end of the sac was intimately blended with it, the lining membrane being smooth and somewhat inflamed. The hydrocele sac was somewhat constricted at the upper end where it communicated with the abdomen; the cord lay on its posterior wall, and was closely connected with it. The specimen was of especial interest as showing a partial closure at the external abdominal ring.

Infiltrating fibroma of the Thyroid.

Mr. Bowlby said that the patient had noticed her neck big three years before her death. The thyroid was swollen, and after a time appeared to grasp the trachea, and was stony hard. It narrowed the trachea and paralysed the left vocal cord. Dyspnœa anddysphagia supervened. Tracheotomy was performed with temporary relief. The tumour was excessively hard, the isthmus broad, and the lobes reached to the level of the bifurcation of the trachea. All the surrounding tissues were involved in the growth, and could not be distinguished. The trachea was much compressed in both directions, but not ulcerated. The structure was fibrous throughout, no alveolar structure.

Mr. Butlin had been much puzzled by this case. During life he had supposed it to be a malignant tumour. He entirely agreed with Mr. Bowlby as to the microscopical characters, but he still regarded it as a malignant growth, though there were no secondary tumours, but its mode of invasion of surrounding structures was very suspicious. It appeared not to be a hard cancer. Tumours of the thyroid were apt to be very peculiar, and he referred to two cases shown by Mr. Morris and Mr. Haward.

Dr. Norman Moore quoted Matthew Baillie as to tumours of the thyroid and ulceration of the œsophagus.

Dr. Goodhart referred to infiltrating fibrous growths in peritonæum and ovary.

Mr. Bowlby said that the tumour clinically was malignant, and he supposed that it ought to be classed with the sarcoma.

Card Specimens.

Dr. Walter Edmunds—Hypertrophy of the tibia.

Mr. Treves—A Specimen of Charbon.

Dr. J. J. Pringle—Pseudo-membranous ulceration of the small intestine in a fatal relapse of enteric fever.

Mr. Treves—Epithelioma of bladder with calculus.

Mr. Bowlby—Fistulous communication between Bladder and Rectum.

Dr. Paddison—Charcot's disease.

Dr. Norman Dalton—(1) Tumour of Bladder and Surgical Kidneys. (2) Chronic orchitis. (3) Cylindrical epithelioma of the sigmoid flexure with tubercle.

Dr. Carrington—Atrophy of the liver.

Living Specimen.

Mr. Treves—Congenital Deformity.

SOCIETY OF PHYSICIANS OF VIENNA.[1]

Friday, October 31st, 1884.

Professor Nothnagel in the Chair.

False Meningocele.

Professor Weinlechner showed a girl, aged 16, with a tumour on the head, which he declared to be a false meningocele, and which was due to a depressed subcutaneous

[1] Reported by our Vienna Correspondent.

fracture of the skull. The tumour was of the size of a man's fist, oval in shape, and extended from the right parietal eminence to the ear. When the girl cried, the swelling extended in all directions; when she was quiet, it diminished, and a distinct pulsation of the cerebral vessels was to be felt in it. It was bounded above by the margin of a semilunar bone which belonged to the right parietal eminence, at the posterior and upper part of this margin a defect of substance of a triangular shape could be made out. Above the margin the parietal bone was lifted up, and had almost a horizontal position; the margin of the bone could be felt in all directions, and below it the needle of a Pravaz' syringe could be introduced for two and a half centimetres without coming on any hard substance. At the lower part of the tumour the bone was not depressed, but was smooth and bounded by a margin of bone. The puncture made with the syringe discharged a straw-coloured liquid, resembling the cerebro-spinal fluid.

Congenital Lymphangioma.

Professor Weinlechner also showed a boy with a congenital lymphangioma on the left leg. From the middle of the outer surface of the thigh an elastic and fluctuating tumour of the size of a man's head extended as far as the internal condyle, including the patella. It consisted of three portions, the largest of which corresponded to the thigh, while the two others were attached to the patella and the internal condyle. By means of a Pravaz' syringe, a yellowish fluid, containing lymphoid cells, was withdrawn from the portions attached to the thigh and the patella, but from the lower part of the swelling no fluid could be obtained. The tumour must be considered a lymphangioma, cavernous in its inferior part, cystic in its upper. Professor Weinlechner intends to extirpate the swelling as far as possible, and treat the rest with iodide.

The Use of Antipyretics in Fever.

Dr. Jaksch (assistant to Professor Nothnagel) read a communication on a new antipyretic remedy. He had made a series of physiological and therapeutic experiments with the "chinolin bases," which had first been synthetically produced by Skraup. In the course of these researches he met with a body which must be looked upon as a secondary chinolin base, namely, "Tetrahydroparachinanisol," which had marked antipyretic properties. All the salts of this base dissolved easily in water, had an acid reaction and were distinguished by forming green salts when treated with ferric chloride or with any oxidising agent. On account of this quality Skraup and Jakseh called this base Thallin, and the salts derived from it Thallin salts. Dr. Jakseh had tried the efficacy of three of these Thallin salts, namely, the chloride, the sulphate, and the acetate, as well as another Thallin-base, the chloride of aethylthallin, in 86 various cases of disease attended with fever, as *e.g.*, pneumonia, enteric fever, erysipelas, &c., and he found that these substances had a pronounced antipyretic action when administered in doses of a quarter, a half, and three-quarters of a gramme. The speaker remarked that experiments with new antipyretics, kairin, chinolin, &c., had shown that drugs which were only antipyretics were generally of very little use. He therefore suggested that further experiments with this drug should be tried on patients on account of its distinct antipyretic character, but he could not in the meanwhile answer the question whether it would obtain a permanent place in the materia medica. It should be remarked that in contrast with kairin, chinolin, and similar drugs, Thallin, when administered internally, caused no disagreeable sensations such as vomiting, cyanosis, collapse, &c., that it only now and then caused perspiration and very seldom gave rise to rigors. The antipyretic effect lasted much longer than that of kairin, and the subsequent increase of temperature developed gradually. Thallin was administered according to the following formula: ℞. Thallin sulph. 2·00, divide in doses quatuor, vel. octo. To be taken in wafer paper. Dr. Jaksch had also experimented with another drug, viz., "Parachinanisol" which, according to Skraup was about equivalent to the half molecule of quinine, but the antipyretic effects of this agent were so inconsiderable that he did not think it worthy of further trial. Another derivative of chinolin, viz., the "Tetrahydroparaoxychinolin" with which Jakseh had only experimented on rabbits, proved a strong poison, animals to which doses of from 0·6 to 0·2 grammes had been given dying in the course of two hours with strong tonic convulsions.

Professor Nothnagel said, "I cannot help protesting in this place against an abuse, I can call it by no other name—an abuse which has generally extended in practice, namely, the tendency to treat a fever *à tant prix*. When the practitioner is called to a patient who sickened yesterday, and who, to-day, has a temperature of over 101°, and it is not possible to make a positive diagnosis, as no local affection is as yet discoverable—treatment consists in administering quinine or some other antipyretic. In order to do no harm one prescribes a small dose, but one does give quinine, thereby suggesting that the fever must be in some way removed. I have received the impression during the last six years or so, that the employment of quinine has become a reflex phenomenon. We have begun to emancipate ourselves from the opinions which were general fifteen or twenty years ago. I would suggest that the fear of a temperature of 102·5° owes its origin to the scientific employment of the antipyretic method introduced by Liebermeister according to the method of Brandt, which in itself is an excellent procedure, and which has added much to our resources. As the treatment by cold baths is attended with some difficulty, and patients have some aversion to it, one began to employ quinine, and since then this drug has been given on a much larger scale than digitalis, nitre, and nitrate of soda were employed in earlier times. The two latter have now fallen into disuse and only digitalis is now used as an antipyretic. I cherish the hope and the conviction that this false and erroneous employment of quinine will also in time be discontinued. I need not remark that the way in which quinine is, in most cases, administered, is quite incapable of diminishing temperature. Two, three, or five grains have no effect, nor, indeed, have fifteen grains if taken at intervals of twenty-four hours. Dr. v. Jakseh has already remarked that the fever is not a symptom to be removed in every case; the fever, according to my conviction, which is also the conviction of many other investigators, is a most beneficial phenomenon, one of those processes of reaction which we must look upon as compensatory; we do not, however, know in what way these processes work. With respect to the infectious diseases it has been suggested that the growth of micro-organisms is diminished in high temperatures; to me, however, they seem quite on the contrary to find more favourable vital conditions in fever. But attention has been drawn to a new point of view. I refer to the interesting writings of Metschnikoff, who is of opinion that the "Fagocytes" destroy the micro-organisms and render them innocuous, and that these processes find more favourable conditions at a high temperature. I would only just mention it on this occasion, as our knowledge in this direction is not at all complete. Moreover, I maintain that we do not shorten the duration of the course of an acute fever, even by a single day when we have succeeded in diminishing the temperature; we even know that there are typhoid processes which run a non-febrile course without any therapeutic treatment, and in which, nevertheless, death occurs. We know of a great many accidents occurring in the course of a febrile disease which do not depend upon the high temperature, but which are due to other conditions. I do not mean to say, however, that we may be indifferent to very high temperatures. A temperature exceeding 104° must be energetically combated, but a temperature of 102·5° does not require such energetic treatment, and the less so in diseases which have a short course. This depends very much on the individual, on the constitutional conditions and so on, and I only mention it *en passant*. In general we may say that a temperature which does not exceed 104° does not injure the patient. Every one who has had the opportunity of observing a case of recurrent fever knows that it is so. The patient suffering from recurrent fever lies in his bed with a temperature of 104°, 105°, and even 106°, quite untroubled, his sensorium is quite unaffected; when the temperature diminishes, the patient is exhausted, but we do not find that the high fever has done him much harm. To return again to the point from

which I started, I maintain that it is an abuse to administer antipyretic agents, especially quinine, in temperatures of 102° and 103°, on the very first day of the treatment, when one has yet no definite idea of the development which the disease-process will take, letting alone the practical point of view, that quinine must rise in price if we employ it in all cases in which bicarbonate of soda, hydrochloric acid, or some similar drug would do as well.

Dr. TELEKY remarked that those practitioners of Vienna who were of the school of Skoda had been accustomed to treat patients on the expectant plan, that they, for the most part, still followed this rule and did not at once prescribe quinine where the temperature was 102° or 103°. He would remark this fact, as the words of Professor Nothnagel might be considered as a reproach directed against the physicians of Vienna.

Professor NOTHNAGEL replied that he scarcely need remark that he intended no reproach, but that he meant to make a general scientific observation; he expressly said that he had observed this fact during the last six to ten years, and it was known that he had lived in Vienna only for two years.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, NOVEMBER 3RD, 1884.

Mr. J. S. TURNER, M.R.C.S., L.D.S., President, in the Chair.

Treatment of Fractures of the Lower Jaw.

SEVERAL interesting casual communications having been brought forward, Mr. F. NEWLAND PEDLEY, M.R.C.S., read a paper on "Some Points in Connection with the Treatment of Fractures of the Inferior Maxilla." The most common site, he said, for fractures of the lower jaw was close to the canine tooth, for the bone narrowed somewhat at this point, and the depth of the socket of that tooth tended still further to weaken it. The next most common seats of fracture were through the angle, and through the neck of the condyle. Multiple fractures were very common, and the existence of a second or third fracture should only be negatived after careful search. It was chiefly in the treatment of the more complicated cases that the aid of the dental surgeon was sought. Three-fourths of the cases of fracture of the jaw would get well under any simple treatment. At Guy's Hospital Mr. Bryant used for such cases a splint made of several thicknesses of plaster of Paris bandage, accurately moulded to the outer surface of the chin and jaw, and fixed by means of a four-tailed bandage. This splint was light, efficient and easy of application, but he thought the modification of Hammond's splint, which he would describe, would be pleasanter for the patient, and give equally good results.

Mr. PEDLEY then described the ordinary Hammond's splint. This was required only where there were multiple fractures, or when there was obstinate displacement. The first step in the preparation of this splint was the taking of models of the upper and lower jaws, and this was in severe cases no easy matter, even to a dentist. Then casts had to be obtained from these models; that of the lower jaw might have to be sawn across at the point of fracture and the fragments adjusted to their proper position. A loop of wire is then framed on the corrected model of the lower jaw, passing behind the last tooth on each side, and accurately fitting the necks of the teeth at the margin of the gum. The wire collar thus prepared is slipped over the teeth of the fractured jaw by reducing the displacement, and is secured to the teeth by means of binding wire passed between each tooth. In the modification of this splint in use at Guy's the necessity for model-taking and soldering was dispensed with. It was especially applicable when the fracture was situated anteriorly, and the displacement was not very marked. Instead of the main wire passing behind the last tooth on each side, it was passed between the bicuspids or any teeth posterior to these. The point of the wire was passed between the teeth on one side, across the tongue, and between the corresponding teeth on the other side. The portion of the wire lying on the tongue was then bent against the necks of the teeth on their lingual aspect; binding wire was next passed between all the teeth opposite which the main wire lay, except those contiguous to the fracture, and the loops tightened up and secured in the usual way. The ends of the main wire were either twisted together, or passed through a short piece of closely fitting metal tubing, bent over in opposite directions and cut off short. This last was the better plan, as there was less chance of displacing the fragments. The patient could now open and close the jaws at will. The splint should be worn for six weeks, or longer if necessary. In cases where firmly implanted teeth do not exist in each fragment of the fractured bone, Hammond's splint was not applicable, and some other form, such as Gunning's, must be used; but for all cases in which it could be applied, it was as efficient as, and far less irksome to the patient than, any hitherto invented. In conclusion Mr. Pedley referred to the use of Hammond's splint in cases of surgical division of the jaw for the purpose of facilitating operations of the tongue or floor of the mouth. In such cases it was a good plan, instead of sawing the bone through vertically, to make two oblique cuts, meeting at an angle; in this way the ends of the bone would lock into one another, and maintain their position more readily.

A long discussion followed.

GENERAL CORRESPONDENCE.

OVER-PRESSURE IN ELEMENTARY SCHOOLS.

[To the Editor of the Medical Times.]

SIR,—As the question of over-pressure in elementary schools has been submitted to, or rather forced upon, the medical profession for solution, contributions like those of Dr. Donkin, Dr. Drewitt, and others, which you have published recently are very acceptable, as they contain facts as well as opinions from which we may draw our own conclusions. The question is a very complicated and difficult one, and cannot be settled by the every-day experience of medical men. To form a fair and dispassionate judgment it is necessary we should know the details of the Code, its fitness to the average intelligence of poor children, the mode of its application by the schoolmaster, and its supervision by the Government Inspector; and these are details which are not within the knowledge of probably one medical man in a thousand. Medical men have moreover taken little part in the maturation of our system of popular education, or in its practical administration, as they are rarely found acting as members of school boards or managing committees, and seldom put their heads inside a school-house. On the other hand, the scheme of education has been slowly developed during a period of more than 20 years by men of both political parties, who, to say the least, are not inferior to medical men in intelligence, benevolence, and interest in the welfare of children individually and collectively, and who have a practical knowledge of the subject of education however mistaken some may think them to be from a purely sanitary point of view. It is an arena into which we should walk with great circumspection, and not rush in as some have done, to interrupt, or turn back, labours, the nature and details of which we are so imperfectly acquainted with.

Dr. Donkin's letter (the main facts of which are quite in accordance with my own experience), while aiming at upsetting Mr. Fitch's position equally upsets that of the schoolmasters and Dr. Crichton Browne whose report is so largely based on their statements. I think most medical men will agree with Dr. Donkin that the clause in the Education Code providing for the exemption of children from the Inspector's examinations is sufficient for the purpose if properly carried out. As quoted by Mr. Fitch it runs thus:—"The following, amongst others, will be considered reasonable excuses for either withholding a scholar

or not presenting him in a higher standard; delicate health or prolonged illness; obvious dulness or defective intellect; temporary deprivation, by accident or otherwise, of the use of eye or hand. If a scholar has failed in two subjects, or twice in the same subject, he may generally be presented again in the same standard." Now Dr. Donkin falls into the error of attributing to the schoolmaster the duties of making the necessary exemptions, and of believing that Mr. Fitch has done the same in his memorandum. The exemptions are made by the managing committee with the aid of the schoolmaster, the school visitor (who is in constant communication with the parents and homes of the children), and the medical certificates for non-attendance which have been sent in. It is obvious that if the system breaks down it is due to the ignorance of their functions, or neglect to obtain better advice, of the school managers, and it is the duty of the School Boards, which are local institutions, and not the central government (as represented by the Education Department), to provide the necessary medical inspection, and secure the proper exemption of children deemed unfit for educational discipline. For this purpose no medical men are so well adapted or more competent to perform the duty as the parish medical officers under whose auspices many of the children, in the poorer districts at least, first saw the light, and to whom their subsequent medical histories are well known. It would not be for the advantage of either the medical profession or the taxpayer that a central system of medical inspection of schools should be instituted, nor could real benefit be expected from a Government Department which sent out two sets of officials to keep a guard on each other. There would be the further disadvantage of the propagation of fads by medical experts, and the creation of more panics and personal collisions like those we have witnessed lately.

But to return to the letter of Dr. Donkin. Although it is the duty of the managing committees to make the exemptions, it is very probable that they leave the work almost entirely to the schoolmasters, so that his contention, if not technically true, is in fact correct. He proved clearly enough that the schoolmaster is either not competent, or is not to be trusted to withhold the children who ought properly to be exempted from inspection, and that he picks out the dull ones who are impervious to educational pressure, and who will not do him credit, but retains the delicate ones who might be injured by it, but who are bright and quick at their work. This is the schoolmasters' view of over-pressure, and it is very largely on these views that Dr. Crichton Browne's report is framed. Speaking of the requirements of the Code from children of different mental calibres, Dr. Browne says: "The clever children must be practically kept back, much to their mental and moral detriment, and backward children must be stimulated to a rank, 'spongy brain growth, and a straining effect that wrenches the whole system, and may permanently damage health, in order, if it may without irreverence be said, that the great modern giant, Examination, may have a huge meal." Dr. Drewitt's notes on chorea show that, if over-pressure has anything to do with its causation, it is among the bright and intelligent children, and not the dull ones, that its effect is observed; and anyone who has watched the effect of school work on children under their immediate observation will agree, I think, that it is the clever children who require keeping back, and that pressing dull children—like throwing water on a duck's back—does them no harm. The over-pressure which no doubt exists among pupil teachers and in schools for the better classes is always associated with the brighter pupils, and not the dull ones, and comes rather from within than from without, and there is no reason why these conditions should be reversed in the elementary schools. We can all of us sympathise with the schoolmaster in the trouble his dull children give him, but we cannot go so far as to relieve him of his responsibilities by certifying that the additional labour required to sharpen their intelligence is likely to do his pupils harm. Such children may be exempt from inspection on the grounds of incompetence, but not on that of over-pressure.

One word more about keeping-in. It is obvious that if a large number of schoolmasters band themselves together to discredit a system of education they would not be over-scrupulous in the means they employ for the purpose, and as keeping-in is one of the most objectionable features of our present system they would make the most of it, and the poor children would be the sufferers. Now I quite agree with Dr. Drewitt that corporal punishment has been unwisely discredited, and for this change of opinion medical men are largely responsible from the readiness with which they have come forward to bear witness against it. For four years I was surgeon to one of the large county prisons in Yorkshire, and it was part of my duty to witness, and if necessary to put a stop to, the operation of flogging prisoners for breaches of prison discipline, and the birching of young boys for petty offences; and although I saw a large number of such punishments administered I never once saw any injury arise from them, and I believe that idle school boys, like vicious ones, would be found more amenable to the occasional application of the birch rod, and that it would be less injurious to their health than the present system of keeping-in; and it would, moreover, remove from the schoolmaster a temptation to use his children unfairly, as it would require considerably more courage and trouble on his part to flog a boy than to simply keep him away from his meals and games.

I am, Sir, yours, &c.,
CHARLES ROBERTS.

November 27th, 1884.

MEDICAL NEWS.

Royal College of Surgeons.—The following gentlemen having undergone the necessary examinations, were admitted Members of the College at a meeting of the Court of Examiners on the 1st instant, viz:—

Thomas U. Gray, L.R.C.P. Lond., Essex Road, N., student of St. Bartholomew's Hospital; George W. Mullis, L.S.A., Northampton, Guy's Hospital; and Joseph J. Dickinson, L.S.A., Bow Road, London Hospital.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, November 27th, 1884:—

Charles Plumley Childe, King's College; Upendra Krishna Dutt, St. Mary's Hospital; Albert Robert Jolliffe, Charing Cross Hospital; Mordaunt Percy Ladell, London Hospital; Selwyn Warner Quartley, Middlesex Hospital; Henry Albert Reed, Guy's Hospital; Adam William Thorburn Steer, St. Bartholomew's Hospital; Charles Henry Taylor, King's College.

The following gentleman also on the same day passed the Primary Professional Examination:—

Jno. Henry Garret, University College.

Dr. Paul Grawitz.—Dr. Paul Grawitz, of Berlin, Assistant of Professor Virchow at the Pathological Medical Institute, has just been appointed to the charge of the Carnegie Laboratory of Bellevue Hospital Medical College, New York.

The London Hospital.—Mr. Frederic S. Eve, F.R.C.S., was elected assistant surgeon to this institution at a Court of the Governors held on the 3rd instant. Mr. Eve holds the appointment of Pathological Curator of the Museum of the Royal College of Surgeons, and of Assistant Surgeon to the Royal Free Hospital.

Royal Institution of Great Britain.—The following lecture arrangements are announced:—Professor Tyndall, D.C.L., F.R.S.—Six lectures (adapted to a juvenile auditory) on "The Sources of Electricity," on Dec. 27 (Saturday), Dec. 30, 1884, Jan. 1, 3, 6, 8, 1885. Professor Henry N. Moseley, M.A., F.R.S.—Five lectures on "Corals and other Colonial Organisms," on Tuesdays, Jan. 13, 20, 27, Feb. 3, 10. Professor Arthur Gamgee, M.D., F.R.S.—Four lectures on "Digestion" (the subject to be continued after Easter), on Tuesdays, March 3, 10, 17, 24. Professor Dewar, M.A., F.R.S., M.R.I.—Eleven lectures on "The New Chemistry," on Thursdays, Jan. 15, 22, 29, Feb. 5, 12, 19, 26, March 5, 12, 19, 26.

Sanitary Assurance Association.—On Wednesday, December 3rd, Dr. Norman Chevers, C.I.E., delivered an address at the Parkes Museum, W., on the objects of the

Sanitary Assurance Association. Sir Joseph Fayrer, K.C.S.I., F.R.S., in the chair. Dr. Chevers urged that that the sanitary condition of London was such that no householder should be satisfied without the assurance of some competent authority that his dwelliug, whether a palace or a cottage, was free from drain contamination. He expressed an opinion that consumption was hereditary principally because successive generations ueglected to remedy the sanitary defects from which their forefathers suffered, and pointed out that unless dwellings were properly disconnected from the main sewers, such sewers might prove to be of the greatest possible danger to the whole community in case of any epidemic.

Death of Sir Alexander Grant, Bart.—Sir Alexander Grant, Vice-Chancellor and Principal of the University of Edinburgh, died on Sunday last of apoplexy, at the comparatively early age of 58. Sir Alexander was elected Principal in succession to Sir David Brewster in 1868, the election very nearly falling to the late Sir James Simpson. His tenure of office has been coincident with important events in the history of the University; five additional Chairs have been founded, new degrees instituted, and important additions made to the endowments of the Institution; while the attendance of students, more especially in the Faculty of Medicine, has so greatly increased as to render necessary the erection of an extensive and splendidly appointed medical school. Among the questions in the discussion of which he was led to take part was that of the medical education of women, with regard to which he stoutly defended the policy of the University in declining to allow mixed classes, though permitting the professors to give separate medical instruction to ladies. In consequence of Sir Alexander Grant's death, the classes at the University did not meet on December 1st, the day following his decease.

Twins and Triplets in the Austrian Empire.—How numerous these are may be judged of by the numbers which occurred in 1883. In that year there were 20,326 twins born, 19,269 living, and 1,057 dead. The triplets were 315 in number, 300 living, and 15 dead. The greatest number of twins (5,976) were born in Galicia, and then follow Bohemia with 5,012, and Lower Austria with 2,158. Of the triplets, 90 were born in Galicia, 63 in Bohemia, and 33 in Lower Austria.—*Allgemeine Wiener Medicinische Zeitung*, Nov. 11th.

The Mortality in the Russian Hospitals.—Professor Botkin, of St. Petersburgh, at the last meeting of the Commission on Public Health, explained, in reference to the frightful mortality which took place in the Russian hospitals, that the patients really died of hunger, the sum appropriated to supplying them with food being quite insufficient for this purpose. Moreover, the low wages which the nurses receive leads to their pillaging even the scanty supplies of the patients. — *Allgemeine Wiener Medicinische Zeitung*, Nov. 4th.

The Elevated Railroad and Injuries of the Eye.—This railroad, which is one of the features of New York, has proved quite prolific in injuries of the eye caused by the fine steel filings thrown into the air by the action of the brakes, and the sparks from the locomotives have occasionally caused injuries of the same sort. A case of the latter kind came before the City Court a short time since, and the jury awarded 250 dollars to the sufferer. The judgment was appealed from, but the General Term has affirmed it. Chief Justice M'c Adam in delivering the opinion said that the elevated railroads were bound to use the most approved method for preventing the escape of sparks.—*New York Medical Record*, Nov. 15.

Death of Professor Fonssagrives. — Professor Fonssagrives, the well-known author of several valuable works on hygiene, has just died of the cholera after 55 hours illness. He had been, however, the subject of an uncontrollable serous diarrhœa for ten days before, which he had acquired after a visit to L'Orient, where four cases of cholera had appeared. Educated as a naval surgeon at Rochefort, he filled several posts of distinction in distant regions, and obtained by *concours* the post of Professor in the School of Naval Medicine at Cherbourg, which, on the death of Professor Ribes, he exchanged for the chair of hygiene in the Montpellier Faculty of Medicine, to which was added the title of Médecin en Chef de la Marine. A facile and yet a practical writer, he produced several works on hygiene some of which have become classical, and others have attained great popularity. His contributions to the "Dictionnaire Encyclopédique des Sciences Médicales" are also numerous, many of them being of considerable value.

Professor Heinrich Neumann.—Dr. Heinrich Neumann, Professor of Psychiatry in Breslau University, has recently died at the age of 70. After the termination of his studies at Breslau, he was for a long time employed at the lunatic asylum at Leubus, and in 1852, he founded the asylum at Pöpelwitz, near Breslau, becoming at the same time a *privat-docent* in the University. Later on a Psychological Klinik having been established in Breslau, its direction was confided to him. Professor Neumann, besides his *Lehrbuch der Psychiatrie*, acquired a great name for his Shakespearian monographs, especially those relating to Lear and Ophelia.

The Embargo on Rags.—The effect of the embargo upon the importation of rags is likely to be badly felt by the consumers of white paper. The fact that rags are not arriving in this country has already decreased the supply of paper-stock, as the mills are not making so much as formerly, and one very prominent manufacturer says that 84,000 of the 260,000 tons of rags used in the manufacture of paper in this country are imported, and as the import has ceased, the effect on trade is to put up the price of paper, lessen the working-hours in mills, and cause unprecedented stagnation in trade.

Certificates of Insanity.—A case recently reported in the "Maine Law Reports" brings up the question whether a physician is responsible in a civil suit for damages for the incorrectness of the certificate given in an examination of a person alleged to be insane, and upon which a commitment had been issued. The Court held that in a case of this kind any defects in the form of the certificate should have been rectified by the committing magistrate, and that if the law had not been fully complied with, the order should not have been made. For any fault of this kind, which was more legal than medical in its character, the magistrate was liable rather than the physician. What the latter was liable for was an untruthful or malicious statement of facts, or the opinion as to insanity based upon them. If the physician should certify to an examination which in fact had not been made, such a breach of professional honour would, no doubt, make the offender liable in a suit for damages. A plain and honest statement of facts, as discovered by the physician, with a carefully prepared opinion based upon these facts, would never subject a physician to the danger of a verdict in case he should turn out to be mistaken.

The Berlin Dental Institute.—One of the great events of the past month at Berlin, has been the opening of the Dental Institute set on foot by von Gossler, the Minister of Public Instruction. Its necessity was shown by the fact that at the Surgical Clinic, the chief place of resort for diseases of the teeth, there have been annually, in round numbers, 180,000 teeth extracted. Moreover, there has been wanting a centre of instruction in practical dentistry, which has undergone such great development during recent years. It will be one of the objects of the new institution to supply such instruction and to render the country independent of foreigners in this respect. A distinguished surgeon, Professor F. v. Busch, has been appointed the director, and Herren Paetsch, Müller and Sauer are the teachers. The programme for the ensuing winter session has just been published by the university, and is of a very comprehensive character. Lectures are to be delivered on, (1) General Surgery; (2) The Diseases of the teeth and mouth; (3) The theory of the art of stopping (*Plombirungkunst*); (4) The normal and pathological histology of the teeth, with especial reference to the lower organisms, met with in the mouth; (5) Theoretical introduction to mechanical dentistry. Besides these theoretical lectures, practical instruction will be given at the

polyclinic on diseases of the teeth and mouth, and on extraction and stopping of teeth. Any applicant is to be treated free of expense, but for the material employed fixed charges will be made. For example, extraction of teeth without anæsthetics, will be without charge, while for stopping teeth, from 6*d.* to 1*s.* will be charged for the material employed. In cases of obvious necessity, the director may excuse these payments.

Anti-Vivisectionists in Trouble.—That violent anti-vivisectionist, Ernst Heinrich von Weber, has recently been sentenced to eight weeks' imprisonment. In the journal entitled *Der Thier- und Menschenfreund*, of which he is the editor, he published, under the heading "Vivisection of a Man," a statement that about eight years ago a Jewish physician of Osnabrück had made a *post-mortem* examination of a man while only apparently dead, and therefore had performed vivisection on him. Dr. Pelz, who had performed the *post-mortem* in question, summoned him before a court of justice with the above result. A clergyman, of Munster, also, who was the author of the article was sentenced to six' weeks imprisonment.

Infant Feeding and Summer Diseases.—In a paper read by Dr. Earle at the Chicago Medical Society (*Boston Medical Journal*, September 11), he came to the following conclusions:—(1) The most frequent infantile disease in Chicago during the summer is entero-colitis. (2) Excluding causes of infant mortality largely beyond our control, improper feeding is one of the chief causes of the great number of deaths. (3) Mothers should suckle their children, and in lieu of this a wet-nurse should be procured. If this is impossible a mixed diet is preferable, and, lastly, an artificial diet must be resorted to. (4) Artificial foods containing a considerable amount of casein are found to be a cause of indigestion and summer diseases. (5) In many cases cow's milk diluted with water does not seem to agree with children. Barley-water or rice-water, as the diluent, seems to make a more physiological food. (6) Condensed milk seems to agree with a considerable number of children, but in many cases a sufficient quantity is not used to nourish a child. Used in proper quantities, and diluted with rice or barley water, it is without doubt one of the best artificial foods. (7) Cream, mutton broth, and white of egg are valuable adjuncts to the dietary of children. (8) Whatever the artificial food a child is having, the physician should examine frequently for evidence that it is a proper food as regards quantity and quality. The normal elevation of the fontanelle and an increasing weight are among the conditions denoting a satisfactory nutrition.

Effects of a Pretended Oophorectomy.—A German girl entered St. Francis' Hospital, with a history of having been in nearly all the hospitals in the city for severe dysmenorrhœa, pelvic pains and epileptic seizures. She professed to live without eating, but it was discovered that she obtained bread in some surreptitious manner. Dr. Gillette found prolapse of the ovaries, and the patient was very anxious to have an operation performed. Thinking it a good case in which to try the influence of mind over matter, Dr. Gillette made all the necessary preparations for öophorectomy, placed the patient on the operating table, made an incision into the subcutaneous fat of the abdominal walls, and closed the wound. The patient improved greatly after the pretended operation. Lately, however, she is said to have had a return of the symptoms, and to have presented herself at several hospitals, desiring that something more than the ovaries should be removed.—*New York Medical Journal*, August 2.

Smallpox in New South Wales. — It is stated in a contemporary that smallpox has made its appearance again in Sydney. "Under our local laws we deal with it very trenchantly. Doctors and householders are bound under a penalty to report every suspicious case. Whenever the disease is pronounced to be smallpox, the patient is, if willing, removed to the quarantine ground, as well as all the persons who have been living in the house. The premises are then disinfected and quarantined for 21 days. In this way we have stamped out smallpox more than once, and hope to do it again; and the opinion here is that if in Europe and America the same vigorous policy were pursued, smallpox would be stamped out there too, and Asia alone would remain as the danger to the world. This time none of the patients have died, and there has been only one new case during the last week. All the cases but one have been developed in somewhat unsanitary abodes. An International Sanitary Conference has just commenced its sittings in Sydney, each colony contributing a medical officer. One of the objects aimed at is to secure uniformity in quarantine arrangements. The quarantine term for smallpox in Victoria is only 14 days, while in New South Wales it is 21. The medical authorities do not agree as to the term of the incubation of the disease, and on this point a bit of evidence has just turned up which will be of interest to the Faculty in England as well as in Australia. Last week the health officer in Melbourne pronounced the colony clean because 14 days had elapsed since the isolation of the last patient. But within 24 hours the husband of this patient was found to have contracted the disease, so that a 14 days' quarantine is proved not to be sufficient."

Cobra-Poisoning.—The following are the conclusions arrived at by Dr. Wolfenden, in a paper, published in the *Indian Medical Gazette* for September, entitled "Report of investigations into the Chemical Nature and Physiological Action of Cobra-Poison." "Summing up the results of these investigations, which are by no means yet to be regarded as complete, there are in cobra-poison two distinct venoms: globulin-venom and albumin-venom. They exist probably in different proportions in different secretions, but these two are always present. The globulin-venom is destroyed by high temperature, but the albumin-venom is not so affected. The globulin-venom poisons the respiratory centre, producing no paralysis of muscles; the albumin-venom does not affect the respiratory centre, but produces marked and progressive motor paralysis. I may here mention that, from the results of some investigations I have for some time been making upon the blood of many animals, I cannot consent to the generally received opinion that cobra-venom exerts no influence upon the blood. My investigations, which will shortly be published, have convinced me that it decolorizes, by driving out the hæmoglobin, a large proportion of the discs, and breaks up a large number of the white discs completely, filling the plasma with minute granules. The bacterial forms, which are present in such large numbers, I do not think have anything to do with the activity of the venom. When recovery takes place from poisoning with a dose insufficient to kill, it is not improbable that a condition of blood-poisoning may supervene secondarily, as in one of the cases I have quoted. The globulin-venom is slower in action than the serum-albumin, and a longer period often elapses after the injection before symptoms supervene or terminate life. The globulin is very deadly, and when once the symptoms have supervened, asphyxia rapidly ends the existence of the animal."

Mortality in Lying-in Hospitals.—Dr. Halliday Croom writing to the *Scotsman* in reference to the proposed Maternity Hospital in Edinburgh, calls attention to the fact that since the introduction of antiseptics and absolute care with regard to cleanliness, the mortality in the well-known lying-in hospitals has diminished to almost that of out-door practice. In support of this statement, he quotes, the following table showing the mortality during the last eight years in the Pavilion Tarnier of the Paris Maternité.

1876.....	88 accouchments	1	death.
1877.....	204 ,,	2	,,
1878.....	234 ,,	2	,,
1879.....	182 ,,	1	,,
1880.....	155 ,,	0	,,
1881.....	235 ,,	0	,,
1882.....	185 ,,	0	,,
1883.....	147 ,,	0	,,

It thus appears that since the year 1880 there has not been a single death in the Pavilion Tarnier, even though the deliveries extended to considerably over 700. The Maternity Hospital at Prague, he adds, shows even more strikingly the advances made in the reduction of maternal mortality. "This hospital, as is well known, is a large

teaching institution for better students and midwives under the charge of Breisky and Weber. Since 1878 the antiseptic method has been carried out with the greatest rigour, and a glance at the reports of the hospital will show that the mortality has fallen from 11 per cent. in 1869 to *nil* in 1882. To take one example more. In Copenhagen antiseptics have been carried out since 1870 by Stadtfelt, the result being that the mortality from puerperal fever has fallen to almost *nil*. Let me compare the mortality of the town of Copenhagen with that of the lying-in hospital, and statistics show that so long as the antiseptic method was *not* employed in the hospital, the mortality was five to seven times greater than in the town; but exactly in proportion as this method has been carefully carried out, so has the mortality of the hospital fallen, until in 1881 the mortality of hospital and private practice became almost the same. Again, in London, in Queen Charlotte's Lying-in Hospital, where puerperal fever used to be the scourge, the death-rate has fallen to 1 in 350."

Mr. Vanderbilt's Munificent Donation.—The American journals are naturally congratulating themselves on the noble gift of half a million of dollars to the College of Physicians and Surgeons, of New York, part of it being about to be expended in the acquisition of a piece of land of 350 feet in length, and 200 feet in width. This is much more than is wanted for the new buildings to be erected, which is, of course, one of the chief benefits derivable from the endowment. "He has had the project in his mind," it is said, "for more than a year, looking upon the medical profession as so largely entrusted with the lives, health, and comfort of the community. It is for the interest of all that its practitioners should receive the best possible education, and he wished to supplement the individual exertions of the doctors for that end by such material aid as would enable them to carry out the necessary improvements in medical teaching. Viewed in this light, his donation is of much wider importance than the benefit which it confers on this particular institution. It is an example and an admonition to the generous and public spirited everywhere, that wealth judiciously expended in the support and equipment of medical schools, is a public benefit, as much so as if it were devoted to the establishment of hospitals and dispensaries."

Child-Marriages among the Hindoos.—The native Press has lately been discussing a subject of immense practical importance. With reference to the death of the Hon. Rai Kristo Das Pal, at the comparatively early age of 45, the question arose—Why do all the leaders of native thought in India die young? The majority of the papers answered it by pointing to the unhealthy conditions under which an intelligent Hindoo is born and is obliged to work. His mother, probably his father also, was a mere child at his birth. He himself marries as a mere child, and at 21 or 22 has the cares of a large and increasing family upon him. He has no breathing-time, or happy independence in early manhood, like the youths of Europe. He is forced by necessity to be precociously old, and in what we should call early middle-life he finds himself prematurely worn out and exhausted. Thus the burden of the complaint is the custom of child-marriage. Certain educated Hindoo gentlemen are calling upon the Government to legislate against these enforced child-marriages, but these are matters in which it cannot interfere. Such social reform must be brought about within the society itself; and although its accomplishment is unlikely to be speedy, the educated part of the community should be encouraged to persevere in their crusade against ignorance and prejudice, in the hope of ultimate success.

Counter-opening and Drainage in Bullet-wound of Head.—The patient shot himself in the forehead, and the injury was followed by hemiplegia and coma. Dr. Fluhrer ascertained the direction of the ball by probing, removed it by a counter-opening at the back of the head, and maintained drainage by passing a rubber tube through the entire wound. The paralysis gradually cleared up, and the patient is now, three months after the shooting, in apparently excellent health.—*Boston Medical and Surgical Journal*, May 29th.

APPOINTMENTS.

Blackmore, Alfred, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the First District, Township of Manchester, *vice* Mr. R. M. Mann, deceased.

Brogden, R. W., M.R.C.S., L.R.C.P.—House Physician to Guy's Hospital.

Clarke, James Adams, L.K.Q.C.P. Ire., L.R.C.S.I.—Medical Officer to the Bushey District, Watford Union, *vice* Mr. G. A. Hicks, resigned.

Hall, Alfred, M.R.C.S.—Medical Officer to the Calton District, Ashbourne Union, *vice* Mr. J. B. Hall, deceased.

Jones, W. W., M.A., M.B. Oxon, B.Sc. Lond., M.R.C.S.—Resident Medical Officer of the Convalescent Hospital of the Manchester Royal Infirmary, Cheadle.

Lamb, William, M.D., and C.M.—Medical Officer to the Arnold District, Basford Union, *vice* Mr. R. S. Wallace, resigned.

Langford, Henry Edward, M.D. Edin., M.R.C.S. Eng.—Medical Officer to the Kidderminster No. 2 District, Kidderminster Union, *vice* Dr. Roden, deceased.

Murchison, F. F., M.B., M.A.—Medical Superintendent of Peckham House Asylum, Peckham, S.E., *vice* J. Ansell Brown, M.R.C.S., L.S.A., resigned.

Salvage, J. V., M.S., M.B. Durham, M.R.C.S., L.R.C.P.—House Surgeon to Guy's Hospital.

Shackleton, Edmund, L.K.Q.C.P., L.R.C.S.I., and L.M.—Medical Officer to the Ninth District, Croydon Union, *vice* Mr. W. Milligan, resigned.

Stowers, J. H., M.D.—Physician to the Department for Skin Diseases, North West London Hospital.

Symons, John George R., M.R.C.S. Lond., L.R.C.P. Edin.—Medical Officer to the Third District, Holsworthy Union, *vice* Mr. E. T. Pearce, deceased.

White, E. Wood, B.A., M.B., B.ch., Univ. Dub.—Honorary Surgeon to the Birmingham and Midland Eye Hospital, *vice* Edwin Cheshire, F.R.C.S., resigned.

VACANCIES.

Addenbrooke's Hospital, Cambridge.—Resident House Physician. Salary, £65 per annum, with board, lodging and washing in the Hospital. Candidates must be duly registered. Applications with qualification and testimonials to be sent to the Secretary (from whom further particulars can be obtained), on or before Dec. 9th.

Birmingham and Midland Eye Hospital.—House Surgeon. (*For particulars see Advertisement.*)

Depwade Union.—Medical Officer to the Fifth District in succession to Mr. F. R. Rose, resigned. Area, 13,571. Population, 6,784. Salary, £90 per annum.

East Suffolk Hospital.—House Surgeon. Salary £100 per annum, with board, lodging and washing. Candidates must be doubly qualified and registered, and be unmarried. Applications with testimonials to be sent to the Secretary, on or before Dec. 10th.

Edmonton Union.—Medical Officer to the Waltham Abbey District, in succession to Dr. Arthur Priest, resigned. Area, 11,870. Population, 5,368. Salary, £87 10*s.* per annum.

Herts County Asylum.—Medical Superintendent. Salary, £500 per annum, with good family residence, unfurnished, together with other allowances. Candidates must be duly qualified and registered under the Medical Act, and have not less than five years experience with the insane, and to be between 33 and 40 years of age. Applications, with copies of testimonials, to be sent to the Chairman of the Committee, on or before December 14th.

Ratcliffe Infirmary, Oxford.—Honorary Physician. (*For particulars see Advertisement.*)

Scarborough Union.—Medical Officer to the Workhouse, in succession to Dr. A. C. C. De Renzy, resigned. Salary, £70 per annum.

The Guest Hospital, Dudley.—Two Honorary Surgeons.—Candidates must be Fellows, Members, or Licentiates of the Royal College of Surgeons of England, Edinburgh, or Dublin, and possess a registered qualification in medicine. Testimonials and certificate of Registration to be sent to the Secretary, on or before December 15th.

The Middlesex Hospital, N.—Assistant Physician. (*For particulars see Advertisement.*)

The Victoria Hospital for Children, Queen's Road, Chelsea, S.W.—House Surgeon. Salary, £50 per annum, with board, lodging and laundry. Candidates must be Fellows or Members of the Royal College of Surgeons, England, and Licentiates of the Apothecaries, or of the Royal College of Physicians, or Graduates in Medicine of any University recognised by the Medical Council. Applications, with copies of testimonials, to be sent to the Secretary, at the hospital, on or before December 13th.

University of Edinburgh.—Examiner in Medicine. (*For particulars see Advertisement.*)

Victoria University. — External Examiners in Physiology, Anatomy, Pathology, and Systematic Surgery. (*For particulars see Advertisement.*)

DEATHS.

Dalgliesh, W. M., M.D., at Masham, Yorkshire, on November 25th, aged 79.

Dew, Edward, M.D., at Coleherne Road, South Kensington, on November 28th, in his 81st year.

Farley, G. C., M.D., late of Henwick Lodge, Maidenhead, on November 21st.

Seymour, Richard, M.D., at 3, Palace Square, Upper Norwood, on November 28th, aged 76.

STANWELL, WM., M.R.C.S., at Rochdale, on November 13th.
THOMAS, LLEWELYN, M.D., at 15, Weymouth Street, Portland Place, on November 26th, aged 36.
WADE, CHARLES, M.R.C.S., at Hatfield Broad Oak, Essex, on November 28th, aged 40.

NOTES, QUERIES, AND REPLIES.

WHITTLE AND HUTCHINSON FUND.

The following contributions have already been promised:—Dr. J. Cameron, £10; Dr. W. Carter, £5 5*s.*; Dr. R. Gee, £5 5*s.*; Dr. J. B. Nevins, £5 5*s.*; Mr. H. O. Thomas, £5 5*s.*; Dr. Macfie Campbell, £2 2*s.*; Dr. Crawford, £2 2*s.*; Mr. R. Hamilton, £2 2*s.*; Dr. D. M. Williams, £2 2*s.*; [Dr. W. Alexander, £1 1*s.*; Mr. R. Jones, £1 1*s.*; Dr. McClelland, £1 1*s.*; Dr. Rich, £1 1*s.*; Dr. Robertson, £1 1*s.*; Dr. J. H. Wilson, £1 1*s.*

Gentlemen wishing to contribute will please send their remittances to Dr. Nevins, 3, Abercromby Square, or to the Whittle and Hutchinson Fund, North and South Wales Bank, Hardman Street, Liverpool.

THE OUTBREAK OF ENTERIC FEVER AT ST. ALBANS.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—In your notice of Mr. Shirley Murphy's report on an outbreak of Enteric Fever at St. Albans, you say:—"Mr. Murphy after a long and laborious investigation succeeded in tracing the fever to the milk of a certain farmer Z." Permit me to say that this report has added nothing to the knowledge of the outbreak as it had been investigated and reported on by myself. There is, however, this difference, that while the same conclusions were arrived at by me in a fortnight, it has taken Mr. Murphy four months to report, notwithstanding that the facts were all cut and dried for him—the date of my preliminary report, of which I enclose you a copy, is June 4th; that of Mr. Murphy's, October 17th. Mr. Murphy has had the grace, as all who know him would expect, to make this "recognition" of my work in his report, and with his remarks before you, it was scarcely too much to expect you to do the same. As I am not actuated by personal motive, and still less by any wish to detract from the merit which may legitimately belong to Mr. Murphy, but only by the desire to shew that the whole intelligence of the country in matters relating to the investigation of disease is not centred either in the permanent or supernumerary staff of inspectors of the Local Government Board, I subscribe myself,

Sir, yours &c.,
M. O. H.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—In one of your notes in the *Medical Times* of November 29th, speaking of Mr. Murphy's report upon the outbreak of Typhoid in St. Albans, you say—"it is by no means improbable that the chamber slops, and the water in which the sheets and soiled linen of *the earlier cases* had been washed, may have been thrown on the ground in the vicinity of the well." In reading this remark, it seems to me that you are under the impression that typhoid cases occurred at the farm anterior to the epidemic throughout the town, which is not the case. The outbreak in Camden Town began on July 28th (1883), up to which time no illness had occurred in Mr. Z.'s household; on the 6th of August one member of the family was seen for a febrile attack, attended with diarrhœa, this lasted about ten days; five years previous to this he had had typhoid while living in Scotland, so that although the symptoms did not enable me to negative typhoid (in an abortive form), the history makes it highly improbable. But if it had been it cannot be regarded as the cause, occurring on the 6th of August, while the cases in Camden Town date from July 28th.

A visitor at the farm became ill on the same date (August 6th), returned to his home in London the same day, and went through a genuine attack of typhoid: here again we have a product, but not the source of the infection coming to the outbreak here in the early summer. There were no cases at the farm before the outbreak; a female servant left at Christmas, and some time after leaving had an attack of typhoid; her home was two miles from the farm, and there is nothing to show that she became a fresh source of infection although her case in connection with the outbreak in the early summer indicates that the infection, whatever its source, had abated, yet it had not been got rid of. About the end of May, a new female servant came to the farm. On the 10th of June she was taken ill, and went through a decided attack of typhoid. *This is the only case which has occurred at the farm*, but the date of attack is so late, and besides, when she became ill, all the milk not used by the family was given to the pigs, none of it was being sold.

From a consideration of the foregoing facts I think the alternative you suggest is entirely disposed of. With the hope that a wrong impression may be corrected may I ask your insertion of this in your next issue.

I am, Sir, yours &c.,
JOHN MURRAY, L.R.C.P.

St. Albans, 1st December, 1884.

Royal College of Surgeons.—The followiug were the questions on Pathology, Therapeutics, and Surgery, submitted to the thirty candidates at the half-yearly examination for the fellowship of the College on the 27th ultimo, when they were required to answer all four questions between 1·30 and 5.30 p.m., viz:—1. What do you understand by the term Phagedæna? Describe its clinical characters and treatment. 2. In the case of an Ulcer on any part of the face of some months' duration, state the chief facts to which you would direct your attention with a view to Diagnosis and Treatmeut. 3. Describe the Injuries to which the Epiphyses of the upper extremity are liable. Give the Diagnosis of each, and the results. 4. With what diseases is Hæmorrhage per Rectum associated? How is each to be recognised?

"*Sanitas.*"—Wilson's "Handbook of Hygiene" is certainly not sufficient alone for the examination, although a most useful book. Roscoe's "Lessons in Elementary Chemistry" and Balfour Stewart's "Lessons in Elementary Physics" contain sufficient chemistry and natural philosophy for the Cambridge Examination. The kinds of applications of the several sciences of which the candidates are expected to show a competent knowledge will be best understood of a perusal of Parkes's "Manual of Practical Hygiene." Candidates are expected to distinguish the several starches, entozoa, &c., &c., under the microscope. The requisite knowledge of this branch of the examination can best be obtained by attending the classes or the laboratory of those teachers who are in the habit of preparing students for sanitary science examinations.

H. C. F.—The lecture will be found at page 169, Vol. I., 1879. It is too valuable to be abstracted, even if our space would admit of it.

COMMUNICATIONS RECEIVED—

APPOINTMENTS FOR THE WEEK.

Friday, December 5 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

West London Medico-Chirurgical Society, 8 p.m.—Mr. Percy Dunn, Pathological Specimens; Mr. Keetley, Clinical Cases. Papers.—Mr. Spencer Watson, "A Case of Sympathetic Ophthalmia;" Mr. R. F. Benham, "The Uses of Sulphide of Calcium;" Dr. Thudichum, "On Inflammation, Abscess, and new growths of the Ethmoid Cells."

Saturday, December 6.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, December 8.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

The Parkes Museum, 74A, Margaret Street, Regent Street, 4.30 p.m.—Mr. Ernest Hart, on "National Precautions Against Cholera—Regulation of Travelling; Ships; Importation of Clothes, Rags, etc.; Uselessness of Quarantine."

Tuesday, December 9.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.

Anthropological Institute, 3, Hanover Square, W., 8 p.m.—By Sir John Lubbock, Bart, F.R.S., "Marriage Customs and Relationships among the Australians Aborigines;" by Mr. A. W. Howitt, "The Jeraeil, or Initiation Ceremonies of the Kurnai Tribe."

Royal Medical and Chirurgical Society.—Dr. Percy Kidd, on "The Distribution of the 'Tubercle Bacilli' in the Lesions of Phthisis;" Mr. W. B. Dalby, on "Cases in which Perforation of the Mastoid Cells is Necessary." Microscopical specimens, illustrating Dr. Kidd's paper, will be on view at 8 p.m.

Wednesday, December 10.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Epidemiological Society of London, 11, Chandos Street, Cavendish Square, 8 p.m.—Sir William R. E. Smart, K.C.B., M.D., "On Old London—its Insanitary Conditions and its Epidemic Diseases."

Hunterian Society, 7.30 p.m.—Mr. T. Mark Hovell will exhibit "An Appliance for removing False Membrane from the Trachea;" Dr. Alfred Carpenter, "Alcoholic Drinks as Medicine." Council at 8 p.m.

The Parkes Museum, 74A, Margaret Street, Regent Street, 4.30 p.m.—Mr. Shirley Murphy, on "Local Precautions Against Cholera—Duty of Sanitary Authorities in Town and Country, and of the Householder." 8 p.m.—Dr. William B. Beatson, of Bath, on "Sanitation at a Health Resort."

Thursday, December 11.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Ophthalmological Society of the United Kingdom, 8.30 p.m.—H. Eales, "Severe Retinitis Albuminurica affecting one Eye alone;" W. A. Brailey, "Hyphæma secondary to some deep-seated Intra-ocular change." Communications, &c.: E. Nettleship, "On the use of Cocain in Ophthalmic Practice;" A. H. Benson (1) "Further Observations regarding the value of Hydrochlorate of Cocain as a local Anæsthetic," (2) "Report of the Committee on the Influence of the Vapour of Bisulphide of Carbon and of Chloride of Sulphur on the Vision;" W. A. Brailey, "On the Condition of the Ciliary Nerves in Certain Diseases of the Eye;" J. Couper, "An Improved Ophthalmoscope;" Priestley Smith, "Ophthalmic Models used in Teaching." Living Specimens at 8 p.m.

Friday, December 12.

Clinical Society of London.—Adjourned Debate on Mr. Morrant Baker's Paper, "On Charcot's Joint Disease." Professor Charcot's specimens and others will be again on view.

The Parkes Museum, 74A, Margaret Street, Regent Street, 4.30 p.m.—Dr. Norman Chevers, C.I.E., on "Personal Precautions Against Cholera to be taken by each Individual; Panic; Food and Drink; Clothing."

University of London, Burlington Gardens, 5 p.m.—Mr. Victor Horsley's First Brown Lecture, subject—The Thyroid Gland, its relation to the Pathology of Myxœdema and Cretinism to the Surgical Treatment of Goitre, and to the general Nutrition of the Body.

CLINICAL LECTURE,

ON SCROFULOUS NECK.

By T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., F.R.S., F.R.C.P.

Consulting Physician to the Leeds General Infirmary.[1]

GENTLEMEN,—The malady which will occupy our attention to-day has arrested the attention of physicians from the earliest times of which we have any definite record to the present moment. So far as we may judge from the evidence before us, no age and no race of men in our own Continent have been beyond the reach of scrofula; all civilised men have striven with it, all kinds of remedies, rational or fantastic, have been set against it; kings and queens have willed the cure of princes and philosophers, as well as of humbler folk; images have been carried before patients in vain, lustral waters sprinkled in vain, and we doctors have to take up a task which is beyond the touch of kings or the conjurations of priests.

That the ugly finger of scrofula should be laid chiefly upon children, young men and maidens, has this pathos in it, that it disfigures them at the springtime of life—at that time when hope and promise make all life precious and all death seem the loss of untold treasure; when beauty and gaiety have their fleeting day, and for the loss of them the world is poorer.

Eagerly, then, do we desire to disperse this evil burden and to restore health and symmetry to the sufferers.

It is well known to most of you that scrofulous neck for the ancients made up the whole of "scrofula," a a name derived from the scrofous or sow-like fulness which it imparts to the neck and jaw of the patient.[2] The Greek word χοίρας, in like manner, signifies both the animal and the disease. Dr. Philemon Holland, in his translation of Pliny in the early 17th century, says that "A cataplasma of leaves and hog's grease incorporate together doth resolve the scrophules or swelling kernels called the 'King's evil'"—a medication derived from the doctrine of signatures, from the notion, that is, that natural objects often bear superficial similarities stamped thereon by an ingenious Providence as a means of indicating their therapeutical affinities. In later times, however, we have given a larger meaning to the word scrofula. We no longer mean by it solely the neck of scrofula but we include under that term a series—or supposed series—of morbid phenomena significant of a definite diathesis or supposed diathesis. It has been widely asserted, that

[1] This lecture is one of an extra academical course given to undergraduates and graduates alike by the Consulting Staff of the Leeds Infirmary.

[2] Littré says the term comes from the fact that swine are subject to a like disease.

scrofulous neck, as one of these phenomena, cannot possibly occur out of the diathesis; that, say, a gouty or dartrous person is incapable of scrofulous neck, and that scrofulous neck can be developed only in persons of a certain specific quality of body called scrofulous, and as a member of a series called "scrofula." Other members of the series are the impetiginous eczema of children, recurrent pituitous catarrhs on the mucous surfaces at all ages, certain glandular inflammations in youth and adolescence, certain diseases of bone likewise, and finally, certain quaternary or visceral degradations of a sub-inflammatory kind, all of which affections are marked by the issue of a more or less corrupt kind of pus, and a defect of healing impulse which Virchow has called a vulnerability of tissue. A certain primary conformation of body is also said to be the heritage of scrofulous persons; that in childhood they have a certain grossness of parts which vainly flatters the maternal eye; and in age, likewise, the same bigness without quality, of which the great lexicographer is the familiar instance.

It appears to me that these diatheses cannot be classified like dogs and cats, but that they rather represent aberrations from the normal, which in their minor obliquities can scarcely be regarded as beyond the latitude of sanity. The wider the obliquity, however, the more several become the diatheses both from each other and from the path of health, and their qualities and movements more proper for definition and prediction. The scrofulous diathesis is well marked when a patient in babyhood has scald head with associated cervical buboes; in youth, scrofulous neck; in adolescence, a white knee; and in adult life, catarrhal phthisis. If, however, we have a broken series, or still more if one of these phenomena occur alone in a life or even in a generation, the patient perhaps having no definite sign in scrofulous feature or proportion—and such cases often meet us in practice—then how are we always to agree with our learned colleagues who will not admit that scrofula can occur except in the originally scrofulous.

The argument would thus take this unprofitable form: Certain diseases can only occur in scrofulous persons, and because these diseases occur in them, therefore they are scrofulous. For my part I cannot regard scrofula as an *alterum quid*—a new quality of the body, as we regard syphilis—it seems, as I have said already, to be rather a deflection which may be induced by influences wholly external, and under these influences may manifest itself in an inferior healing power. That on the other hand, in the large majority of cases, a "vulnerability of tissue" is an inherited defect, and that an especial vulnerability of lymphatic glands runs in families is not to be denied, for such defects betray the original bad habit even under circumstances the most favourable. To deal then with scrofulous neck alone, as our subject for to-day, I believe that this disease may be produced in persons originally of healthy habit and of healthy stock if their external circumstances, or some of them, be sufficiently adverse, but that a disposition to such disease is more commonly inherited, and the greater the inborn frailty, the more readily will adverse circumstances produce it. In some persons, doubtless, the inborn frailty is such that the ordinary pressures and variations of normal conditions do not fail to initiate mischief in them.

Scrofulous neck is of course but one part of the glandular disease which may and often does invade the scrofulous subject. It is the most striking part, because in the neck and under the jaw it is evident, and destructive of beauty and symmetry. It is also an early site for such outbreaks, appearing usually there before it may appear in the axilla or in the groin. Until later times, when pathological dissections became more common, the frequency of like caseation in thoracic or mediastinal glands was scarcely realised, and still at the present day these inner changes are too obscure for popular discernment, and not uncommonly escape even that of the physician himself. It is a familiar doctrine that in all these cases the enlarged glands are buboes, by which I mean that they are secondary to irritation and absorption on and from their associated mucous surfaces.

Confining our attention, then, to scrofulous neck, we have learnt that chronic inflammatory enlargement of the glands of the neck is secondary to irritations in the associated mucous surfaces, and absorptions from them; the chief of these being the mouth and throat, and the next in order the nasal, aural and ocular surfaces. Irritations indeed upon the skin of the face and head are not without influence in the same direction, so that although the result be less common, yet glandular enlargements of the neck do occasionally owe their initiation to eczematous or other cutaneous disorders. We may feel tolerably sure that although in a given case we may be utterly unable to discover a peripheral cause for the enlargement of cervical glands yet they do not, under the influence of this diathesis at any rate, enlarge "of themselves," but only in obedience to some peripheral irritation which may belong wholly to the part. When the scrofulous diathesis is well marked the glandular expansion may be so enormously out of proportion to the initiating peripheral cause that this latter, if fugitive, may never be measured nor ever perceived. Now these considerations, although taught by every thoughtful clinician do not sink into the minds nor exercise the observation of the medical public so thoroughly as they ought to do. No competent observer would overlook such an obvious peripheral cause, for instance, as eczema capitis, scarlatinal sore throat, flux from the external meatus, and so forth; but I think the daily and hourly activity of the pharyngeal mucous membrane is not vividly realised in this matter. The mucous lining of the pharynx is a kind of screening machine which catches upon its moist surface and intercepts all that dust, organic and inorganic, which is drawn in with the air. Hence we know that these surfaces are constantly seeded with particles, many of them germinal, and not a few of them poisonous. Happily the membrane in its healthy state throws them off and allows no settlement to be made nor any germination to take place. All particles are promptly arrested and re-conveyed beyond the portals of the mouth, or consigned harmless to the stomach, and no local irritation arises on the surface nor any sympathetic change in the glands. But let us suppose for a moment that this mucous covering is something less than healthy. We know that in scrofulous persons the mucous membranes are not very sound nor resisting; the mucus they secrete is not very stable but is liable to slip down into chemically acrid principles, and into degenerative cell changes. Herein the fermenting or irritating particles find a food or a soil in which they work after their kind, and thus, even unperceived, the fluids of the throat become, when absorbed, the vehicle of poison to the lymphatic glands adjoining. It is, perhaps, not necessary that the mucous surface be absolutely broken. Certain variations of moisture or density may suffice to favour absorption, even through an unbroken surface. Let there be a trifling delay or languor of the epithelial function, and particles mechanically, chemically or vitally irritant will imbed themselves in the soft and absorbent vesture of the pharynx, and be themselves carried within or generate poisons upon the surface which are drawn inward. Again, by some vital mechanics a chill to the skin may disturb the nutrition of the membrane; if this occur in aseptic air, at sea, for instance, even the scrofulous subject may be quit for a cynanche; if it

occur in foul air, but in a vigorous person, the mucous membrane may overpower the evil as strong turnips outgrow the fly. Again, in the glands themselves a temporary irritation may subside if the conditions of life be favourable, or, on the other hand, may progress under adverse circumstances, or in vulnerable constitutions. But the surface may be broken, broken but lightly and transiently, so lightly and transiently that he who seeks for the breach may fail to find it, yet a breach deep enough and enduring enough to set up that prolification in the glands behind it, which, in the scrofulous person, has no tendency to heal. Given the "vulnerability" it will suffice to start the process, it will suffice to admit the match to the heap, and the fire will smoulder on thereafter of its own activity. If we think then of the rain of organic particles falling incessantly by way of nose and mouth upon the lining of the pharynx in those of us who live under the purest physical conditions, the wonder will be not that scrofulous neck is generated but that so many of us escape it. Given but a broken surface in the healthiest person and a sufficiently prolonged exposure to organic particles, and it seems certain that your scrofulous neck must at some point arise unless an originally high vitality be constantly favoured by healthful habits and surroundings otherwise healthful.

As among the fortunate of mankind there must always be multitudes whose vitality and general resisting power are, on the other hand, constantly depressed, and who are at the same time breathing constantly an air laden heavily with impurities, we do not wonder that scrofulous neck has been a common and mischievous result, nor that a pure air and wholesome dwelling-place have been regarded as chief means of cure. One source of impurity the scrofulous rich and poor enjoy in common—that is, the drain and the cesspool. Herein the rich have no advantage over the poor, indeed, herein, the richer classes fare perhaps worse than the poor, who often lack those gifts of civilisation, and are vulgarly content to cast forth their ordure to the sun and the winds. If I may make a guess on a matter of which I can know nothing definitely, I would guess that the emanations from foul drains are the unseen carriers of scrofulous neck to the greater part of its victims in the richer classes. It seems as if it must be so. No influence is so potent to lower general vitality, and no poison finds so readily its home in the pharynx. Drain throat has become a common term in the last few years, and every day we recognise such throats by their appearance alone. In these cases the superficial mischief is ample and patent; but in how many more is it, although slighter and milder, yet strong enough and baneful enough to set up unhealthy buboes in persons thereto disposed! The question thus, in my view, is reduced to one of the degree, duration and kind of local iritation acting upon subjects vulnerable in all degrees. When heredity is dominant local causation may take, no doubt, a lower place; where heredity is less, local causation is more, and where it is absent local causation rules alone. Next to that of the mouth, gums and throat the mucous lining of the ear seems to be most ready to propagate secondary mischief in the cervical glands. It seems probable that in all cases the irritation is first propagated from the mucous surface to the minute nodules of lymphatic tissue which lie immediately under the mucous membranes, and that from these the evil is forwarded to intermediate lymph centres, and thus to the principal lymph glands in the neck. These which in the normal state are barely palpable, gradually enlarge and succeed each other in chains, not larger at first than shot, but some of them ultimately increasing to the size of walnuts or even of a small orange. At first the glands, on section, show no cascation, but a pale transparent and uniform section. Neither at this stage, nor afterwards, is there any symmetry of disease between the two sides of the neck. In this stage the glands may return to the natural state, the hyperplastic material being re-absorbed.

If the malady progresses, however, caseation begins at multiple centres within each gland, which centres become fused until the whole gland becomes a cheesy mass. In the first stage it would be difficult, and without collateral evidence perhaps impossible, to distinguish scrofulous glands from those of lymph-adenoma. But as the infection becomes more distinctly inflammatory the diagnosis clears itself even to the explorer's finger. These bodies are no longer, as in lymph-adenoma, isolated, freely moveable, uniform and painless, but soon they form adhesions to the surrounding tissues and to each other; they become tender on pressure and slight nodulation of their surfaces is to be noticed. The same contrast helps us to distinguish these scrofulous glands from enlargements far more likely to embarrass our diagnosis, namely, from the albuminoid glands of rickets. The aspect of the scrofulous child, moreover, is rarely to be mistaken for that of the rickety, nor has it the peculiar chlorotic skin of the latter.

Once more: we have hitherto considered the mucous membrane as peripheral to the lymphatic system; let us now call to mind the like effect which would be produced by some one degenerate gland as peripheral to the rest. I have proved, or had proved for me by the revelations of the surgeon's scalpel that a forgotten surface irritation may have inflamed a few glands and have passed away; the glands themselves likewise passing away so far as the eye and hand could tell, but not altogether. One small, and perhaps deep-seated, enlargement may remain—a lump not larger than a pea—this may slowly caseate, and in the course of months, or possibly of years, become the focus of spreading poison to others; new activities then come on, successive glands in their turn enlarge and caseate, and scrofulous neck becomes established as a secondary event long after the primary affection of the mucous surface has disappeared and been forgotten. Such a state of things would be what lawyers call "consequential damage." Now here no purification of the mouth, throat or ear would avail to remove the trouble, for it comes from a source which is beyond our reach and even beyond our ken. Such cases of secondary bubonic development are, I believe, very common, and the knowledge of this possible sequence should put us on our guard against any careless dealing even with the smallest and most isolated bubo. In a scrofulous person it may ultimately be the source of most troublesome mischief.

Now, gentlemen, with your permission we will pursue the matter a step further.

A short time ago I referred to certain distinctions between the enlarged cervical glands of scrofula, lymph-adenoma, and of rickets, and some points of distinction then severally noted may be summed up in scrofula as features of chronic inflammation. Not only do they inflame with a slow destructive process within, but a capsular inflammation extends from gland to gland, matting them together; this in its turn propagates inflammation to the cellular tissues, and the skin; glands, subcutaneous tissues and cutaneous becoming involved in a general process of low inflammation. We have then chronic caseating adenitis, chronic suppurative cellulitis, and chronic suppurative dermatitis. These inflammations being, as I say, only partially adhesive in nature and largely necrobiotic, lead not only to the softening of the glands themselves but to the formation of cellular abscesses, more or less sinuous in distribution, between and around the glandular necrosis. As the glands soften and burst, then a

system of channels and pockets, of cells and passages, is formed, some pockets lying deep where glands lay under a muscle, such as the sterno-cleido-mastoid, others lying more superficially. From the lower to the upper source channels of communication may be established, or some of the deeper glands may be imprisoned in surrounding adhesions, and their products of degeneration have no outlet. Some glands are partially hyperplastic, with but nodules of caseation; others have softened in part, are caseated in part, and are only hyperplastic in part. Others have wholly softened and are represented by pockets of corrupt pus. As the skin is involved and becomes reddened and tender, the outward determination of the morbid products is hastened, the skin gives way, and cellular or glandular abscesses are emptied gradually as the establishment and the drainage of sinuses may permit. Nature thus works some kind of cure, sometimes a perfect cure, sometimes a very partial one, as from deeper glands or cellular abscesses no free issue to the light may ever be established. Some parts of the mass, and these probably the remoter and therefore the more dangerous, may remain unemptied, and abide in their breaches as means of offence in time to come. Nature's cure is thus seen to be of a haphazard and unsatisfactory kind. Still, a cure does commonly take place, after years of disease, at the cost of permanent scarring of the neck, and probably at a far greater cost than this. Nec causas solum sed exitus etiam rerum cognoscere oportet. We can not flatter ourselves that the patient is to be quit for his local embarrassment and his scars; his general health suffers, and soon is established the morbid see-saw, feeble tissue vitality admitting the incursions of local poison, and in its turn the local workings farther depressing the systemic health, each thus intensifying the other until the strands of life itself become strained. Septic matters are absorbed into the blood, recurrent and variable hectics dissipate the appetite, flesh and strength, so that the patient finds himself at the end of it all, if not unsound in his internal organs, at any rate a far worse man than he would have been had this trial been spared him. But even if it be but thus with him, he has still reason for congratulation. But too often two or three years of "ecrouelles" mean the implantation of the seeds of phthisis, of which disease he may die early. It must not be supposed that death by phthisis will usually spring up in him by virtue of inheritance alone. It supervenes at one time as the result of that general asthenia, that diminution of vital and nutritive values which long suppurations leave behind them, at another time as a consequence of the inoculation of the system with tubercular virus. Our knowledge of the tubercle bacillus is as yet too young to tell us whether scrofulous neck always depends upon the introduction of the tubercle bacillus by way of the mucous membrane of the throat or otherwise — too young, indeed, even to tell us whether the tubercle bacillus is an essential part of scrofulous neck at all. We know that it may be found there, and that scrofulous neck has of late years been regarded as morphologically tubercle, so that we are safe at least on the broad postulate that inoculation from sources of corrupt or caseating pus does very commonly set up a more or less generalised tuberculosis.

Our scrofulous patient, therefore, runs three risks in the continuance of his local malady over and above his faulty inheritance, namely, first, a tedious local disease, followed by a peculiarly unwelcome disfigurement; secondly, the fear of deterioration of his general health thereby, such that his best years of adolescence are spoiled, and his entrance into manhood thwarted and weakened; thirdly, an inoculation of the system with elements which favour the development of more general tuberculosis. Now, how are we to avoid these evils? In the first place, whenever we have reason to suspect the scrofulous diathesis in young persons, we should secure, as far as possible, under these circumstances, the favour of pure and invigorating air, of sunlight, and of good food. We should most jealously watch the sanitary conditions of the dwelling or schoolhouse, and prevent the possibility of the contact of infected air, water or milk. We should especially watch the lining of the throat, mouth, ears and so forth, and stop any tendency to unwholesomeness of the surfaces or secretions of these parts. If children inheriting such tendencies can be placed at the seaside, or in the fresh air of such health resorts as Harrogate, we shall help the growing body to rise above its original defects, and to mould itself on stronger lines. If in some early degree enlargement of the sub-maxillary and cervical glands have already taken place these precautions will be the more needful. If we find the glands smooth, and free from all nodulations, isolated and non-adhesive, we may almost promise a cure, if the constitution be fairly robust, by a residence at Margate together with other due cares. Such glands on the entire removal of baneful outer in uences, and the promotion of the general health will probably resolve. The dietary is to be dictated on principles already sufficiently familiar to you all, and cod liver oil will probably form a part of it. Medicines which favour the growth of red blood and stimulate appetite and digestion will be added. Of specifics there are few. I am satisfied, however, that the cautious use of mercury, say of the solution of the bichloride with tincture of iron, is desirable, unless the inborn frailty be very marked; and iodides with iron are likewise valuable.

External applications should be cautiously used; and in my own practice I have relied but little upon them. At any rate, it is certain that harm may be done by them if not most cautiously and judiciously managed. A well diluted ointment of iodide of mercury in proper cases is the most efficient means of this class.

So long as the glands remain free from adhesions and smooth on the surface, such remedies as the above may suffice to dissipate the malady; the removal to the sea-side being by very far the most potent of them.

So soon, however, as the glands become adherent, either to each other or to the surrounding tissues, so soon as they present small nodulations on their surfaces, caseation has begun, softening will succeed, and however great may be the benefits to be bestowed on the general health by climatic and medicinal remedies, yet we canuot at all rely upon the removal of the local mischief by these.

I say we cannot rely upon the removal of it. Not, infrequently, indeed, scrofulous necks of some inveteracy and severity have been and are cured by residence at Margate. But such means are not in the power of all people, and if they were, we still stand the risk of ultimate ill success, or the risk of shaking the constitution still farther by a continuance of the disease, and we give greater opportunities for the inoculation of the system with active or dormant tubercle.

These considerations, gentlemen, pressed so strongly upon my mind some years ago, that I found for myself a shorter way out of the difficulty, a way which puts an immediate term to the disease, and which abridges what I may call the septic or tubercular opportunities of the malady. These reasonings and some of their results were published by Mr. Teale and myself at the International Medical Congress in 1881. I called in the surgeon to my aid on the modern principle of *ubi pus ibi exitus*. Wherever septic material is contained in the system we rest not till it be expelled, and its burrows laid open and disinfected. The knife has been used hitherto freely enough in scrofulous neck, on the principle laid down by Sir James Paget, namely,

to wait till the skin warms, reddens and fluctuates: then to make a clean incision, permit simple evacuation of the present matter, but not to squeeze nor even press the surrounding parts. We are to wait until a new area of softening be obvious, then repeat the process, and so on. Now, gentleman, this is palliative surgery, but it is not curative surgery. It scarcely alleviates the cause of the disease, indeed, it does little more than substitute a fine and clean for a foul cicatrix. My proposal is a curative surgery, and it is now founded upon a wide basis of successful instances. It so happened that some of my earlier cases were referred by their friends to Mr. Teale, and consequently he and I so thoroughly discussed the matter together, that we found it convenient to work together in like cases, though I need scarcely say that others of my colleagues would have led me forward with a like ability: so it was, however, that we fell together on the matter and continued to co-operate.[3]

My purpose, and the purpose of the surgeon, whoever he may be who holds my views, is radically to extirpate every caseous gland or portion of gland, and so quench promptly the smouldering fire. At first, we naturally had for our patients only those sufferers whose endurance was exhausted, and who willingly accepted any way, however doubtful, out of their sufferings. Gaining courage, however, by our success even in the worst cases, we are advising the radical operation more and more, until, I may now mention it as one of our best means from the moment that caseation, however limited, is manifest. Recent instances lead me to hope that if such a practice become universal, scrofulous neck and all the hectic, asthenia, emaciation and phthisical risks which belong to it will become matters of history.

It is needless to say that the surgical procedure does not do away with the value of sea climates, good food and tonic medications, but it does put an end to those constitutional infections which make such means more necessary. Where in-born frailty is strongly marked, such means are still to be added, and in a few very vulnerable patients the surgeon may be compelled to call in the aid of Margate in support of his undertaking.[4] But such cases are the minority; many persons affected with cervical scrofula are not originally of bad physique, and these persons whom we meet daily, can be cured by the knife alone, always directly and sometimes rapidly. When after years of smouldering inflammation and caseation group after group of glands have become involved, it would be unwise perhaps, even were it possible, to enucleate the whole mass either in one sitting or in instantly successive sittings. It is not a part of my commission to-day, gentlemen, to describe to you the operative part of the radical cure; this chapter will be enlarged upon by Mr. Teale, on the 17th of December. But in general terms the aim which the surgeon must set before himself is to open all subcutaneous abscesses, to trace them to softening glands, to enucleate these, and to lay open all sinuses which lead to deep-lying glands, often concealed behind muscles or fasciæ, and to so completely eliminate all decaying tissue, and so cleanse the bed of disease that healing may be rapid and complete. In a severe case several operations, even six or eight, may be needed to secure a stable result; but it is surprising to see how quickly the general health rebounds after the two or three first sittings. Finally, we claim not only to cure but to beautify the patient, for if conveniently and neatly managed, the scars of the surgeon are so clean and fine as in a year or two to disappear altogether. To secure this desirable end, it is important, even at the risk of a repeated operation, to avoid the prolonged use of a drainage tube, for after such a procedure a denser and rougher scar remains behind.

Gentlemen, I thank you sincerely for your kind consideration.

[3] I do not for a moment pretend that eradication of scrofulous mischief in the neck by the knife and scoop is an original idea of my own. It occurred to me independently, as it doubtless occurred to many other physicians; I believe, however, that the idea has never been worked out so completely, nor in so many cases, as by Mr. Teale. Indeed, on hastily turning up the subject with the aid of "Neale's Digest," and "Virchow's Jahresbericht," I am surprised to find how little has been done by others on the same lines.

[4] I believe that by systematic enucleation and evacuation on the radical system, the stay of all scrofulous patients at Margate could be abridged and the benefits of it enlarged.

CLINICAL LECTURES ON THE TREATMENT OF DISEASE.

Delivered in King's College Hospital,

By J. BURNEY YEO, M.D., F.R.C.P.,
Physician to the Hospital.

Lecture V.

THE TREATMENT OF PHTHISIS.

(Continued from page 774.)

Prophylaxis—(continued).

The proneness to become phthisical which scrofulous persons display, renders it incumbent to watch with more than ordinary care all such as inherit a tendency to the manifestations of scrofula and to disorders of the lymphatic system; such as chronic enlargement and suppuration of superficial glands, chronic joint affections, chronic and recurrent cutaneous eruptions, chronic ophthalmia, and the well known series of phenomena generally regarded as scrofulous.

The extreme value of sea air and sea baths in combating the tendency to such affections has been established beyond doubt by long experience, and in all cases of delicate children and young people presenting the signs of the scrofulous diathesis, prolonged residence at the seaside and the regular use of sea baths, cold in the summer, and, if necessary, warmed in the winter, are of the greatest practical value. There are, however, some scrofulous children with feeble digestions who become ill at the seaside and suffer there from gastro-hepatic troubles, headache, and lassitude; and others who from nervousness can never be induced to bathe in the sea. The latter can of course be bathed in sea water at home, and for the former the treatment adopted at Kreuznach and other similar strong salt springs offers a valuable alternative. The method of adding the strong *mutter-lye* to the baths at these spas enables the physician thus to graduate their strength to individual needs.

It is important, in the case of individuals who inherit a predisposition to pulmonary consumption, to be watchful for any signs of defective nutrition which may render them more readily susceptible to atmospheric vicissitudes or to other injurious influences. It is on this account that so much stress has been laid by various authorities on the necessity of combating vigorously any tendency to progressive emaciation, although it may be unaccompanied by any other symptoms, when it is observed in those who have a phthisical tendency.

And no doubt the occurrence of loss of flesh is often one of the first evidences of the impending danger. But it would be incorrect to conclude on that account that all the subjects of progressive emaciation are on their way to become tuberculous. The numerous instances of the occurrence and long continuance of the most extreme and alarming emaciation in connection with hysterical anorexia and neurasthenia, which, under a suitable moral and physical *régime* completely

*

recover their former health and corpulence, absolutely negative any assumption that defective nutrition and emaciation can be regarded as of themselves causes of tuberculous disease.

The emaciation which is observed to be so frequently the precursor of pulmonary phthisis is, probably in most instances, but the first symptom of the actual presence of the disease, while, no doubt, in others it is simply the indication of an inherited vice of constitution which, if unremoved, will soon become associated with other manifestations of still more serious import. A vigilant prophylaxis then requires us to be on our guard lest we allow a tendency to progressive emaciation in the young and delicate to proceed unnoticed. The period of rapid growth and the approach of puberty must be especially protected against this tendency.

In such cases we should exercise a careful supervision over the diet, and see that it is sufficient in all respects and that it includes an adequate proportion of fat and flesh forming food. The introduction into the day's dietary of extra food in the shape of two or three glasses of new milk, of a certain quantity of cream or butter, of malt extract, or, in some cases, a glass or two of sound beer or stout ; and in scrofulous cases of a dessertspoonful or two of cod's liver oil twice a day ; these and various other dietetic expedients must be attempted and persevered in. A good deal of difficulty is often encountered in such cases, especially in young women, in overcoming a certain distaste for food, and in these and all such cases it is necessary to look to the digestive organs, and by the judicious use of bitter tonics, as well as of aperients, to overcome the frequently co-existing constipations, to improve the tone of the digestive functions and excite appetite.

Passive exercise in the open air is beneficial to such persons, such as horse, or carriage, or boat exercise, but much walking exercise is to be avoided as tending to further exhaust the ill-nourished muscles, but a well devised course of gymnastic exercises may be useful.

It is scarcely needful to insist that all such persons as we have been referring to should be protected in every way from the causes of catarrhal, congestive, or inflammatory attacks of all kinds ; from indiscreet exposure to changeable or inclement weather ; from the dangers of over excitement, and the draughts and rapid changes of temperature to which they may be exposed in social *réunions*, in places of amusement, in churches, and in all buildings where people assemble in numbers.

I have already alluded to the importance of suitable gymnastic exercises for the purpose of increasing the capacity of the thorax, generally small and narrow in such persons, of strengthening the respiratory muscles and those of the upper limbs, and so of promoting lung development and lung ventilation. These are as important in the adolescent as in the child, and at this age riding, swimming, boating offer additional inducements for systematic exercise in the open air ; but it is above all things essential that such exercise should be duly regulated and moderated, and all undue excitement of the circulation forbidden.

A few weeks during summer, or a longer period if any troublesome catarrhal attacks have occurred, spent in some mountain valley from 4,000 to 6,000 feet above the sea level is valuable, not only for its general bracing effect, but for the pulmonary gymnastics which a residence in the rarefied air of these regions necessitates, and the more complete pulmonary ventilation thereby secured.

The application of the pneumatic treatment, *i.e.*, of alterations of atmospheric pressure by means of pneumatic apparatus, to the treatment of the "phthisical habit," and to the modification thereby of the faulty form of the thorax so generally observed in those predisposed to phthisis is thus commended by Oertel in his "Respiratory Therapeutics" :—

"The build of the thorax and the expansion of the lungs correspond accurately with one another, and are mutually dependent. It is by the form, size, mobility, and expansibility of the thorax that the space is determined within the limits of which the expansion of the lungs is accomplished and the deepest inspiration can be attained. Any contraction of the space within the thorax limits in a corresponding degree the expansion of the lungs and the respiratory capacity, and lays the foundation for the development of pathological processes.

"Where the phthisical habit exists we must do all in our power to promote the re-modelling and widening of the thoracic space, as the form of the thorax is directly connected with the gradually developing respiratory insufficiency. In the long, narrow, shallow thorax, the sternal angle of which projects, while the epigastric angle becomes more pointed and the supra- and infra-clavicular fossæ are depressed, the lungs, especially at their apices, will not expand in a manner corresponding to their normal function. The respiration becomes weak and superficial, the inspiratory as well as the expiratory pressure falls below the normal, and disproportinate shortness of breath follows any increased physical exertion on the part of the patient.

"The application of altered atmospheric air pressure by the pneumatic apparatus is, in the first place, indicated in order to overcome the contraction of the thorax which has been produced by pathological conditions and to expand it as much as possible. As by inspirations of compressed air the intrapulmonary pressure of the pulmonary air is so far increased that it preponderates to a certain degree over the normal atmospheric pressure on the thorax, not only will an expansion of the lung tissue be thereby effected, but also—and that all the more the younger the individual we have to deal with—a widening of the thorax itself by elevation of the ribs and its expansible parts. The thoracic muscles are strengthened ; the lung capacity, as shown by the pneumatometer, is often considerably increased ; dyspnœa is removed ; with increased respiratory surface and functional activity of the lungs sanguification is improved ; there is increased appetite, a fresher appearance and subjective well-being, and under all circumstances, *even if the outbreak of phthisis itself cannot in every case be arrested, a power of resistance to predisposing diseases is created in the lungs.*

"Lastly, in the phthisical habit, not only the mechanical action of altered air pressure on the respiration, but also its mechanical effect on the circulation, gives it a definite value. By expiration into rarefied air, as in the rarer air of higher altitudes, the pulmonary blood channel is widened, the anæmic condition of the lung tissue removed, the nutrition stimulated, the change of matter accelerated, and thus the danger is averted that, owing to the anæmic condition of the lung tissue, such as often occurs in the phthisical habit, the remaining products of inflammatory processes, infiltrations, and exudations may result in thickening of the tissue and caseous degeneration.

"With the steady application of positive and negative pressure to the pulmonary surface, it soon becomes possible to demonstrate objectively the favourable effect of pneumatic treatment, and to express numerically the results obtained. Thus in faulty and insufficient apical respiration co-existing with hereditary predisposition, weakly constitution, and paralytic thorax the excursions of the chest, and especially of the upper parts of it, become visibly more extensive, the previously flat thorax becomes arched, its drawn and cramped position freer, and the apices of the lungs

which drew in air only sparingly, take in a fuller quantity with each inspiration (Geigel). But it is of special importance that the patient not only carries out this respiration, so different to what he has been accustomed to, for the first few months that he is subjected to the influence of altered pressure, but that he should also learn to breathe fully and deeply, and so to ventilate the apices of the lungs freely, by which means also the probability of dangerous bronchial irritations, excited by retained dust and secretions, is more and more reduced. We therefore observe as proximate and permanent results of the treatment, enlargement of the circumference of the chest, considerable, even double, elevation of the pneumatometric valves, increase of the vital capacity, improved nutrition, and a very remarkable increase of body weight. With these objective phenomena will be gradually combined the subjective ones of a feeling of well-being and increase of bodily strength."—(Pp. 556–558.)

And of treatment in the *Pneumatic Chamber* he speaks as follows :—

"The long, narrow, shallow thorax, more or less flattened in the infraclavicular region, with impaired mobility and expansibility in its upper part, under the mechanical influence of compressed air and improved nutrition of the inspiratory muscles acquires increased inspiratory expansion ; the feebly expanded, anæmic, and vulnerable lungs becomes more or less dilated ; the inspirations, previously superficial and frequent, become deeper and fewer ; the inspiratory and expiratory pressure are raised, and the vital capacity thereby increased, while, what is of special importance, the anæmic lung tissue itself is better nourished by enlargement of its blood channel and gains in elasticity and power of resistance.

"The general nutrition and sanguification, usually defective, are ameliorated, and the development of the individual is aided by improved muscular tone and vigour.

"Physical examination of the chest and the rise of the spirometric and pneumatometric figures, as well as the increase of body weight, are evidence of progressive improvement from this treatment."—(P. 696.)

It is desirable also that such persons should be guided in the selecting of an occupation or profession by a due consideration of the principles we have already referred to. Wherever it is possible an occupation should be chosen which allows of free exercise in good air without the necessity of undue exposure to the vicissitudes of weather or climate ; and all occupations should be avoided which entail confinement in close, ill-ventilated apartments or workshops, as well as those which necessitate cramped attitudes and positions which interfere with proper expansion of the chest. So also all employments which involve exposure to irritating vapours or dusts or other influences, such as sudden and great changes of temperature, which may excite or maintain catarrhal conditions of the air-passages are to be avoided.

There appears to be some difference of opinion amongst physicians who have investigated this subject as to the influence on the phthisically predisposed of professions which call for much exercise of the voice. Some consider them injurious[4] while others think them preservative.[5]

Exercise of the voice in moderation is probably advantageous as promoting pulmonary expansion and ventilation ; but it is also easy to understand how an excessive enforced exercise may become injurious.

With regard to singing Oertel observes :—

"The healthy influence of singing on the general health, and especially on the lungs, has long been acknowledged, and almost all singing masters of any celebrity can tell of one case or another of consumption cured by their method of singing. Even though their diagnosis may not be very accurate in these cases, yet there is no denying that the influence which may be exercised by singing upon imperfectly developed lungs, narrow chest, anæmia, disturbances of nutrition in the lungs, and catarrhal conditions is a very important one and generally attended with good result. The singing mistress, Marquise Ciccolini, mentions a phthisical girl, who, by means of judicious singing exercises, not only acquired a very good voice, but was perfectly restored to health.

"In consequence of the report sent in from various quarters on the healthy influence of singing on the respiration and circulation, and on the strengthening and nutrition of the lung, the practice of singing has been introduced even into prisons, in order to antagonise pulmonary consumption, which generally developes in a short time among the convicts." And P. Niemeyer mentions a phthisical subject who, probably having no capacity for singing, cultivated whistling as the most effectual form of respiratory exercises.[6]

The influence of marriage on persons with a predisposition to phthisis, apart from its effect on their offspring, is a question which admits of being regarded from two points of view. For the female it is altogether undesirable, the dangers to health which child-bearing and lactation bring in their train, and the worries and difficulties rarely wholly absent from the happiest unions tend to depress the general tone and so to lead to the development of the inherited disposition.

It may be different with the male, if, in his case, marriage be the only thing that can save him from a life of disorder and dissipation ; otherwise for both male and female, a quiet, well-ordered, single life is no doubt the most conducive to long life.

(3) We have long been thoroughly alive to the fact that certain conditions and circumstances of life, not only favour the development of phthisis in those who inherit the predisposition, but also tend to its production and acquirement in those who are apparently free from any such inheritance. Prophylaxis is then in the third place concerned with these conditions and with their removal.

It may be said that sedentary occupations in general favour the production of phthisis, and they do so still more when sedentariness of occupation is combined with faulty positions of body, which interfere with due expansion of the chest, as in the case of tailors, shoemakers, seamstresses &c., or with defective ventilation as when these occupations are conducted in close, hot workrooms or living apartments.

Occupations which expose the workers in them to the inhalation of particles of dust are dangerous, especially when the dust is of a hard metallic or mineral nature ; steel polishers, pin-makers, flint-polishers, mill-stone grinders, masons, plasterers, brush-makers, furriers, mattress-makers, all these occupations are found to favour the acquirement of phthisis.

Such persons would find a valuable protection in wearing, while at work, a light respirator containing a thin layer of cotton-wool between two pieces of stiff-net.

Occupations associated with the inhalation of irritating gases which tend to excite bronchial catarrh, are also to be avoided, as are those, too, which involve exposure to high temperatures and to sudden and

[4] Fonssagrives—"Thérapeutique de la Phthisie Palmonaire." Deuxième edition, p. 70.
[5] Lombard and Bouchardat.
[6] "Respiratory Therapeutics." Author's Translation, p. 532

great variations of temperature, as in the case of bakers and others.

Excessive study in a close and confined atmosphere and combined with faulty attitudes of the body must also be guarded against.

Finally something must be said on the subject of the prevention of the conveyance of the germs of phthisis from the sick to the sound.

Referring to the report published by the Collective Investigation Committee of the British Medical Association on the "Communicability of Phthisis,"[7] Professor Wm. Roberts, of Manchester, observes: "I think no candid person can read this report, and the detailed evidence on which it is based, without coming to this practically important conclusion, that no healthy person should be permitted to occupy the same bed with a sufferer from pulmonary consumption, and that no person with a hereditary predisposition to tuberculous disease should be allowed to have continued and intimate personal contact with a phthisical patient, and I cannot help adding that a grave responsibility would in my opinion be incurred by a medical man knowing this evidence, no matter what his theoretical opinions may be, who would permit such cohabitation and close personal contact." I cannot state the case in better words than these, and as I was myself the compiler of the report referred to I may add that I entirely agree with the deductions here drawn from it.

Oertel is very explicit on this subject:—

"The possibility," he says, "that individuals in whom there was no predisposition or hereditary tendency to pulmonary phthisis or tuberculosis should yet acquire it by means of contagion and succumb to it sooner or later, had been repeatedly put forward by the older physicians, who had opportunities of making many observations, and in our days the possibility of a direct communication of tuberculosis by inhalations of pulverised sputa and their extraordinary infectious properties have been experimentally ascertained.

"This being the case, the duty of the physician is to ward off in every way the well-known injurious influences by which this formidable disease is capable of diffusing itself wider and wider. The older physicians, who had large opportunities of observation, have repeatedly maintained, as Tappeiner has done recently, that quite healthy girls belonging to healthy families, by long attendance upon phthisical patients, have themselves become phthisical and died very soon, and they have then deduced the theory that the contagious infection of phthisis was possible. I myself have made a number of remarkable observations on the subject, and have received from physicians who practised for many decades in the same neighbourhood communications which could only be satisfactorily explained by the hypothesis of direct transmission of tuberculosis to healthy subjects.

"Tappeiner was the first to suggest the probability that phthisis might be transmitted by inhalation of the sputa of phthisical patients, scattered in fine particles through the air by coughing, and he made experiments on dogs with phthisical sputa in the Pathological Institute at Munich, which fully confirmed the accuracy of his theory. Comparatively small quantities of phthisical sputa sufficed to produce phthisis and tuberculosis in various forms in perfectly healthy dogs. Tappeiner's experiments were frequently repeated in the Munich Pathological Institute, with the same result, and the deleterious nature of the sputa was fully proved. We may safely assume that the same sputa which, inhaled in a pulverised condition, are capable of generating tuberculosis in the lungs of dogs, so little disposed to tuberculosis, will have the effect of producing this disease in the incomparably more sensitive human lungs. There is also no doubt that by the elevated respiratory pressure of coughing the tuberculous sputa are pulverised in the same manner as by the compressed air of a Bergson's hydroconion, and the difference only lies temporarily in the small quantity which is reduced to pulverisation by each fit of coughing, but which is more than balanced by the frequency of the paroxysms and the duration of the malady.

"In face of these facts the practical physician must put the question seriously to himself whether there are no means of preventing this transmission of tuberculosis to healthy persons by the respiratory air, and prophylactically resisting this disease as much as possible. I have myself been making experiments during the last two years for the solution of this question, and intend to carry them out systematically wherever there is reason to fear a direct transmission of such substances through inspiration.

"There are several methods at our command by which we may effect an elimination of the sputa scattered through the air by coughing, in the sick room and in the vicinity of phthisical patients generally—first, by passing a free current of air through the rooms inhabited by such patients, by thorough ventilation and general cleanliness; secondly, by direct disinfection of the air in the vicinity of the patients; and thirdly, by attempting by inhalations of disinfectant and anteputrefactive agents, to which we shall return later on, to render the infective substances in the bronchi and the cavities of the patient himself more or less innocuous. We have learned practically by the application of Lister's spray in operations how completely the air can be cleared of the bacteria or septic germs contained in it, and I would suggest that the same method should be adopted—the diffusion of the spray of carbolic, salicylic, or boracic acid in the immediate neighbourhood of the patient and in the sick room generally—for the purpose of precipitating from the air and destroying the sputa carried out by the expiratory current and scattered by the cough.

"When attending patients in advanced stages of phthisis, I have a three to five per cent. solution of carbolic acid or a four per cent. solution of boracic acid pulverised by means of a good inhalation apparatus every hour for a quarter of an hour or longer, close to the sick bed or even in the immediate vicinity of the patient, and administer the same solution to the patient himself in inhalations four to six times a day. But even in the early and the middle stages of phthisis, when the patients are still able to move about, I administer disinfecting solutions several times a day, especially when there is profuse expectoration, partly to paralyse the deleterious influence of the putrid and putrefying secretions of the bronchi and cavities upon the respiratory mucous membrane and the lungs, partly to reduce their infective property as much as possible even before their eventual suspension in the air and to protect other persons from infection. For the same reason I make such patients wear medicated respirators with strong disinfectants in the receiver, for their own benefit and for the protection of other people. I also recommend the male and female attendants, at times when no thorough ventilation and disinfection of the air of the room by carbolic spray can be carried on, and when the patient has laid aside his respirator, to wear in the nose Feldbausch's small inhalation tubes, which are impregnated with carbolic acid.

"I well know the difficulties that stand in the way of such a prophylactic treatment, as well as the objections that will always be raised against it. But necessity compels us, in dealing with a disease hitherto so inaccessible to prophylactic or therapeutic treatment, to

[7] Collective Investigation Record. July, 1883.

adopt extraordinary measures and to carry them out with determination."[8]

Care should be taken to disinfect the pocket-handkerchiefs used by phthisical patients, and their sputa should be received in spittoons or covered vessels containing a five to ten per cent. solution of carbolic acid.

Having now passed in review the chief points to be attended to in the Prophylaxis or Preventive Treatment of Phthisis, I shall pass on in the next lecture to the consideration of its remedial treatment.

A CASE OF DOUBLE POPLITEAL ANEURYSM — FAILURE OF PRESSURE — LIGATURE OF FEMORAL—RECOVERY.

By W. J. WALSHAM, F.R.C.S.,
Assistant Surgeon to St. Bartholomew's Hospital.

J. Y., a man 44 years old, but looking several years older, came under my care at St. Bartholomew's Hospital during the autumn of 1882. He had formerly been engaged as a potman and had "drunk a good deal." He ricked his right knee about two years ago, and has since had what he calls rheumatic pains in it occasionally; but he has only noticed a swelling in the right ham for one month, and was not aware that he had a similar swelling in the left ham. He denied ever having had syphilis or other venereal disorder. In the right popliteal space there was a pulsating swelling the size of an orange. The pulsation was of a distensile character and was stopped by pressure on the femoral artery in Scarpa's triangle; but not by flexion of the knee. There was a loud bruit in the swelling and throughout the whole length of the femoral artery. In the left popliteal space was a similar but smaller swelling. There was no œdema of either leg. The knee joints were natural and the tibial arteries were distinctly felt at the ankles. The heart's apex beat just outside the left nipple line, and over it an ill-defined systolic murmur was heard. There was a well-marked double aortic murmur at the base.

On August 21st, flexion and digital compression were begun on the right side at 4 p.m., and kept up during the night and greater part of the next day. Chloral grs. xv at 8 p.m. Morphia hypodermica gr. $\frac{1}{8}$ at 11 p.m., and at 2.30 a.m. Chloral grs. xx at 4 a.m., and pulv. opii gr. $\frac{1}{2}$ at 5.30 a.m. were administered, but he could get no sleep, complained of great pain, and begged that the compression might be discontinued. The tumour was not altered, or, if anything, slightly larger.

On August 24th I tied the right femoral artery in Scarpa's triangle. Two ligatures of kangaroo tail tendon were placed on the artery three-eighths of an inch apart, and the vessel was completely divided between them. The divided ends retracted on division fully a quarter of an inch. Pulsation in the tumour ceased on tightening the first ligature. The operation was done under the spray; a drainage tube was inserted into the lower part of the wound, which was dressed with antiseptic gauze, and the limb, which had been previous to the operation swathed in cotton wool was placed on a pillow and slightly raised. The patient had a fair night. The wound was dressed on the 26th, 29th, and September 1st, when it was found healed, except at the situation of the drainage tube. From this date the patient did well a small sinus remaining for some time where the tube had been. On September 18th, at 3.30 p.m., a shot bag was applied to the left femoral artery, but it caused so much pain that it was taken off again at 6 p.m. The patient absolutely refused to have it or any other form of pressure continued, and requested that the vessel might be tied. On September 22nd this was done, the artery being divided after two ligatures had been applied as on the right side. He progressed satisfactorily till the 25th, when his temperature suddenly ran up to 102·8°. The constitutional disturbance did not appear to be referable to the wound, which was looking well; and the next day, the 26th, a dusky red swelling about the size of the palm of the hand was noticed on the inner aspect of the middle third of the left thigh, the wound still looking well. On the 27th a large bleb formed over the inflamed spot. On the 28th the gangrenous patch was spreading, and a charcoal poultice applied. On the 29th the patch was still spreading; the operation wound was looking well; the gauze dressings were stopped and oil lint was substituted. On the 30th the slough was separating and was removed on October 4th, leaving an ulcer four and a half inches in diameter on the inner and posterior aspect of the thigh.

From this date the patient progressed satisfactorily, and on October 30th the note states "operation wound soundly healed, ulcer rapidly decreasing in size." After this time the ulcer healed but slowly, but the patient gradually improved in strength and was discharged on December 27th with the ulcer firmly cicatrised. The patient when last seen, a year afterwards, was, except from his heart mischief, in good health.

Simultaneous aneurysm of both popliteal arteries is, I think, sufficiently rare to make this case, did it possess no other features of interest, of value. The patient was the subject of double aortic and mitral disease; he confessed to having drunk a good deal; he was of an irritable and irascible temperament, and the aneurysms, especially the right one, appeared to be of recent formation and were rapidly increasing in size. He, therefore, appeared to be anything but a favourable case for treatment by pressure; but, as it was suggested at consultations that, probably, no harm could come by giving this a short trial, Mr. Willett had, previously to my taking charge of the wards during his autumn holiday, begun digital compression. The patient bore it so badly that it was discontinued after some hours, and the artery was ligatured at the apex of Scarpa's triangle. Digital pressure on the right side had given him so much pain and annoyance that he would not submit to its being tried on the left, and although, after much persuasion, he allowed a shot bag to be placed on the artery, he absolutely refused to have it kept on for more than three or four hours, and begged that the vessel might be tied. Both arteries were secured by applying two kangaroo-tail tendon ligatures about three-eighths of an inch apart and dividing the vessel between them. It is not here intended to further refer to the several advantages which this method presents over the ordinary way of tying the vessel. These were discussed and advocated in a paper in the *British Medical Journal* for last year. I would merely add that subsequent experience has not led me to change the opinion that was there expressed that this method is the safest at present known, and I have recently tied the external iliac artery in this way with the most satisfactory result. After the ligature of the right femoral the patient made a rapid recovery; but on the third day after the ligature of the left femoral the temperature suddenly rose, and a circumscribed gangrenous patch formed on the inner aspect of the middle third of the left thigh. When gangrene occurs after ligature of the femoral it generally begins in the toes and foot, and spreads upwards a variable distance towards the trunk, but I have hitherto had no experience of circumscribed patches of gangrene occurring,

[8] Respiratory Therapeutics. Author's Translation, p. 337 et seq.

as in this case, in the thigh. It was quite distinct from the operation wound, which was, moreover, healing satisfactorily, and it could, therefore, in no way be attributed to any abnormal process going on in the wound. The situation of the patch suggested the idea that it might be due to injury of the branch of the internal cutaneous nerve which crosses the artery at the place where it is usually tied. I do not think, however, that the nerve was injured; it was certainly not seen.

REPORTS OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

GUY'S HOSPITAL.

IRREDUCIBLE RIGHT FEMORAL HERNIA—OPERATION FOR RADICAL CURE BY EXCISION OF OMENTAL AND SEROUS SACS—PRIMARY UNION.

(Under the care of Mr. R. CLEMENT LUCAS.)

(The following case was reported by Mr. F. Pearce and Mr. Andrews, and dressed by Mr. Mugford.)

S. A., aged 25, was admitted into Martha Ward, Guy's Hospital, on July 14th, 1884.

Family History.—Patient is unmarried; her father was subject to rheumatism and died of consumption. The mother died from bronchitis some four years ago. There are two brothers, one of whom has suffered from rheumatism.

Previous Diseases.—Has had rheumatic fever three times, the last attack occurring about eight years ago. There is also a questionable account of an attack of inflammation of the lungs.

Present Disease.—The patient believes that the hernia existed some eight years ago, but it occasioned her no discomfort until four years ago. Since that time she has worn a truss, but irregularly and never for any very long period together. After any vigorous exercise the rupture gives her a good deal of trouble. The patient states that she has had for some time a similar swelling on the left side, but this has never troubled her much, and she gives no definite history of it.

She was a patient of Mr. F. M. Corner, and it had been found impossible to apply an efficient truss. On several occasions she had had symptoms of strangulation, necessitating the application of ice and taxis. The bowel had on each occasion been reduced, and the symptoms then subsided, but a tumour remained. It had been suggested by a surgeon who had seen her in consultation, that the abdomen should be opened, and the hernia pulled back from the inside.

Condition on Admission.—A strong healthy-looking woman with a right femoral omental hernia. On the left side, one of the femoral glands is enlarged to the size of a small haricot bean and is painful on pressure.

July 15.—Chloroform having been administered, Mr. Lucas operated in the following manner. A vertical incision was made over the tumour two inches in length, inside the line of the right femoral artery, and commencing a little above Poupart's ligament. The tissues having been carefully divided, the sac was reached, and upon being split open on a director, exposed a piece of omentum. This was also opened and another sac exposed, which, however, contained no bowel. The piece of exposed omentum, having been isolated by two catgut ligatures, was then excised. The excised omentum measured in its two longest diameters 1½ inches by ½ an inch. It was hollowed out in its interior into a cavity lined by thickened serous membrane, and it was evident that into this cavity the bowel was apt to descend and to become strangulated. After the omentum had been excised, the external peritonæal sac was dissected out and cut away at the neck, but no ligature was put round its base. The edges of the wound were brought into apposition by four wire sutures, and carbolic gauze dressings applied. No drainage tube was put in. In the evening patient complained of feeling chilly, but this was relieved by another blanket being put on, and hot bottles applied to her feet. Temperature 99°.

July 18.—The wound was dressed this afternoon for the first time, and seemed to be healing well, and without discharge. Temperature in the morning 99·2° F.; evening 97·8° F. Fish diet was ordered.

July 21.—The stitches were removed this afternoon (second dressing) and the wound was seen to be rapidly healing by first intention.

July 24.—The wound is now completely healed.

August 4.—Patient went out to-day, wearing a truss which fitted her comfortably.

Remarks.—The foregoing case ran the course of an uncomplicated antiseptic operation, healing without suppuration or rise of temperature, so that three weeks from the day of operation she was able to leave the hospital with the wound soundly healed, and bearing comfortably the pressure of a truss. The case illustrates well the value of an operation in such cases. The existence of a complete omental sac in which a loop of bowel was frequently entrapped accounted for the difficulty that had been experienced in fitting an efficient hollow truss over the tumour.

RIGHT INGUINAL HERNIA, CONTAINING OVARY AND FALLOPIAN TUBE—OPERATION FOR RADICAL CURE—REMOVAL OF OVARY AND TUBE, AND EXCISION OF SAC.

(Under the care of Mr. R. CLEMENT LUCAS.)

(The following case was reported by Mr. H. E. Crook, and dressed by Mr. W. L. Blight.)

J. D., aged 39, was admitted into Lydia Ward, Guy's Hospital, on August 7th, 1884.

Family History.—Father is alive and healthy; mother died of cholera about 30 years ago. Patient has one brother and three sisters, all of whom are alive and healthy.

Personal History.—The patient is a married woman, and has had eight children, all healthy. She has never had an illness that she can remember.

History of Present Disease.—Patient has had an inguinal hernia for the last 14 or 15 years. Until last Christmas she did not experience any inconvenience from it, and did not wear a truss. Last Christmas she had an attack of peritonitis which lasted about a month. A lump about the size of an ovary was then for the first time noticed blocking up the inguinal canal, so that the bowel did not descend. Other attacks of peritonitis ensued, the illness altogether lasting some six months. About four weeks ago the swelling increased and became very tender; the patient was again attacked by peritonitis and on recovery came up to the hospital. The rupture now comes down on the top of the lump.

Condition on Admission.—A healthy looking woman, of 39 years, with a lump the size of an ovary in the inguinal canal and above and internal to the pubic spine. It is soft and lobulated. and does not swell or

become tender at the menstrual period. The swelling in the inguinal region measures 2 by 1¼ inches. Urine normal.

August 8.—Chloroform having been administered, Mr. Lucas made an oblique incision 2 inches long, extending down to the inguinal canal. After some vessels had been twisted, the canal was opened on a director, and the sac exposed. This was opened and proved to contain the fimbriated extremity of the Fallopian tube to which was attached a small cyst (⅜ of an inch in diameter) filled with clear fluid. It was noted that the walls of the sac were very thick. The pedicle of the sac was then transfixed with an aneurysm needle, tied with a double ligature, and then divided. The edges of the wound were brought together by four wire sutures, and the usual green protective and carbolic gauze dressings applied. During the operation, patient was very sick, and on recovering from the effects of the chloroform, an opiate was given. (Pil. opii gr. j.)

In consequence of much sickness in the early part of the night Tr. Iodi m. ij, Aqua ad. ℥ij, was administered every half hour until the sickness ceased, when Mist. Ammon, effervescens ℥j were ordered.

August 11.—The external appearance of the wound is good, but there is much deep swelling due to blood extravasation. Temperature, morning 102° F., evening 101° F.

August 12.—The swelling has subsided. In consequence of pain, an ice bag was applied to the right side. Temperature, morning 101·2° F., evening 101·4° F. The wound was opened up and drainage obtained.

August 14.—Patient is progressing favourably. Temperature, morning 99·1° F., evening 100·3° F.

August 27.—Wound has been dressed daily, and is going on well. A tonic mixture containing iron was ordered.

September 1.—Patient has been up frequently. Wound still going on well.

September 10.—Patient discharged with wound healed.

Remarks.—Although the patient made a good recovery, in this case primary union was not obtained, and considerable fever with slight suppuration followed the operation. Mr. Lucas's rule is always to dress every case on the day following operation (1) if the temperature rises above a 100°, or (2) if blood has come through or by the side of the dressings. Bleeding from some unsecured veins took place in this case, forming a swelling beneath the skin and escaping by the side of the dressings, but the bleeding being venous in character and small in quantity was mistaken by the nurse for an onset of menstrual flux, and the case was left till the temperature had risen to 102° F. When free drainage was obtained, the temperature soon subsided, and the wound was healed at the end of a month. A great deal of pain extending into the loin followed the operation, apparently occasioned by the sympathetic around the Fallapion tube being included in the ligature. This may also account, in part, for the severe vomiting which followed the operation.

Prevention of Ophthalmia Neonatorum.—In the October number of the *American Journal of the Medical Sciences* Dr. Garrigues gives an account of the great success which has attended the adoption of Credé's preventive treatment of this affection in the New York Maternity Hospital, where it used to be very common. Immediately after tying the cord, the outer surface of the eyelids is washed with plain water. They are then separated slightly, and a single drop of a two per cent. solution of nitrate of silver is allowed to fall on the cornea from a solid glass rod, which is the best instrument for effecting the operation. Of 351 children so treated not a single one became affected.

Medical Times and Gazette.

SATURDAY, DECEMBER 13, 1884.

A meeting was held in the Governors' Court Room, at Guy's Hospital, on Wednesday, December 10th, to consider what steps should be taken to give substantial expression to the universal feeling of regret to which the death of Dr. Mahomed has given rise. A large attendance was gathered together under the presidency of Dr. Wilks, amongst whom were the treasurer of Guy's Hospital, and many prominent members of the medical profession with whom the late physician had been connected in the various undertakings with which his name has been associated. In a few eloquently simple sentences Dr. Wilks sketched the career of Dr. Mahomed, showing how, in spite of the ever-present drawbacks to which his slender means subjected him, he steadfastly fought his way onward until he had been able to enter upon practice in the West-end, not with any shadowy prospect of a sufficient income to maintain his position, but with the absolute certainty that with the maintenance of health his pecuniary resources would be amply satisfactory. Struck down at a moment when the necessary expenditure on house furnishing had temporarily drained his surplus capital, he had, by no act of folly or extravagance, left wife and children totally unprovided for. A resolution to open a general subscription on their behalf was proposed by Dr. Pavy and seconded by Mr. Field, and unanimously agreed to. A general Committee, consisting of representatives of the hospitals with which Dr. Mahomed was associated, and of the University of Cambridge, the British Medical Association, and the Collective Investigation Committee, and of personal friends, was nominated for the purpose. A smaller Committee, to whom the necessary work will be entrusted, was then formed, having Dr. Wilks as its Chairman, Mr. A. E. Durham as Treasurer, and Dr. Goodhart and Mr. Jacobson as Secretaries. The proceedings closed with a vote of thanks to the Treasurer of the Hospital for the use of the Court Room as the place of meeting. A subscription list was at once opened and found very many signatories, a list of whom will be found in another column. In accordance with the resolution of the meeting, a general appeal will be made without loss of time; but there are very many members of the profession who will not wait for it before communicating with the treasurer of the fund. The truth of the adage *bis dat qui cito dat* has never been more worthy of being borne in mind than in the present instance.

Dr. Isambard Owen, the Secretary of the International Investigation Committee, writes to us:—I think your readers will be interested to read some of the many expressions of regret and sympathy at the death of the late Dr. Mahomed, which I have received from the Members of the International Committee for Collective Investigation. Professor D'Espine, of Geneva, writes: "I hasten to express my sincere

sympathy for the sad loss that you have just sustained in the person of Dr. Mahomed, whose eminent qualities I had an opportunity of appreciating at the Congress of London." Professor Trier, of Copenhagen, writes: "With full and sincere sympathy I have received the information of the loss the profession of your country has sustained by the death of our excellent colleague. I beg you to receive the expression of my feelings on this occasion, and to communicate them to Sir William Gull and to Professor Humphry." Professor Lepine, of Lyons, says: "I learn with the most lively sorrow the death of our colleague, Dr. Mahomed. I shall devote a few lines to him in the forthcoming number of the *Revue de Médecine*. Personally, I am very grieved; for science it is a great loss, and for our Committee as well." Letters to similar effect I have received from Professors Ewald and Bernhardt, of Berlin; from Professor Bouchard, of Paris; and from Professor Lange, of Copenhagen.

At an extraordinary meeting at the Royal College of Physicians of London, held on Tuesday last, the president, after a brief reference to the grievous loss that the college and the profession has sustained through the death of Dr. Mahomed, announced that he had appointed Dr. Frederick Farre and Dr. Fincham vice-presidents of the College, and at his request Dr. Goodhart, the friend and colleague of the late Dr. Mahomed, had undertaken to deliver the Bradshawe Lecture next year. A communication was received from the General Medical Council, enclosing copies of its recommendations with regard to professional education and examination, and asking for the opinion and criticism of the College thereon. The Council purpose revising these recommendations during their next session, and desire to be aided in that work by the advice of the several licensing bodies. With this view the Council have proposed a series of questions on certain debateable subjects with regard to which it may be supposed that the opinions of the qualifying authorities will be especially valuable; such, for instance, as whether the present *minimum* period required by the corporations to be devoted to professional education is really sufficient; and whether the age of 21 years is practically the best that can be fixed upon as the earliest at which candidates shall be admitted to the final examination for a qualification to practice. This communication was referred to the Committee of Management for the Joint Examining Board. A report was received from that Board pointing out that the regulations of the Joint Examining Board will come into force on the 1st of January next, and recommending that, though these regulations are obligatory on those students only who commenced professional study on or after the 1st of October last, yet older students, should they desire it, shall be admitted to the examinations under the regulations of the Joint Examining Board, instead of as before by the separate Boards of the two Colleges. As under the new regulations a candidate may take the examinations in two or more parts at different times, and, should he be partially successful in any examination, will, on presenting himself for re-examination, be examined only in the subjects in which he formerly failed, it may be expected that senior students will be eager to go up under the new system of examination, instead of going before the old Boards. The recommendation of the Board of Management was adopted by the College. It was stated that synopses indicating the range of the subjects of the first and second examinations have been prepared; and can be obtained with the regulations of the Joint Board.

At the same meeting the Finance Committee presented a special report with a proposal to procure a site on which to build examination rooms. The number of candidates for the College licence has increased very rapidly in the last few years, and it has yearly become more and more difficult to conduct the required examinations within the College walls. In July last 281 candidates presented themselves at the first examination for the licence; and during October 340 candidates underwent examination there; and the whole College had to be given up to that one purpose, to the great discomfort and inconvenience of the Fellows, Members, Licentiates, and officials. In these circumstances new and larger examination rooms have become an absolute and urgent necessity; and as the College of Surgeons have for some time laboured under similar difficulties as regards their examinations, it has been decided that the two Colleges shall unite in erecting an examination hall which shall provide all the space, and all the appliances for conducting in the least uncomfortable way possible, all the examinations of the Joint Board. The proposals of the Finance Committee in this matter and the action already taken by them were approved by the College of Physicians; and it is understood that an excellent and very convenient site for the proposed building has been found, and that the two Colleges are in complete accord in the matter.

On Monday evening last, at the Medical Society, Mr. Trêves read a paper on Intussusception. It was a statistical rather than a clinical essay, but one of great value and interest nevertheless. His object was to show that spontaneous elimination of the intussuscepted gut occurs least frequently at the age when the most dangerous form of the disease is commonest, and in those cases in which ordinary treatment is least successful. Then he urged that laparotomy should be undertaken, and that the surgeon ought not to wait until the effects of the disease almost certainly preclude a successful issue to the operation. Dr. Day referred to a case which he had successfully treated by enemata and two minim (!) doses of tincture of belladonna. Dr. Routh also spoke of the value of this drug; but in such small doses that we should not expect any assistance from it. He appeared to forget that in order to obtain the physiological action larger doses comparatively must be given to children than to adults, as was pointed out by Dr. Crocker. Mr. Pitts advised careful manipulation, just as we apply taxis in hernia, with insufflation, under an anæsthetic. Mr. Barrow had seen good effects from ice. Mr. Pick thought there was no parallel between intussusception and hernia. Abdominal section was always a very grave and difficult operation;

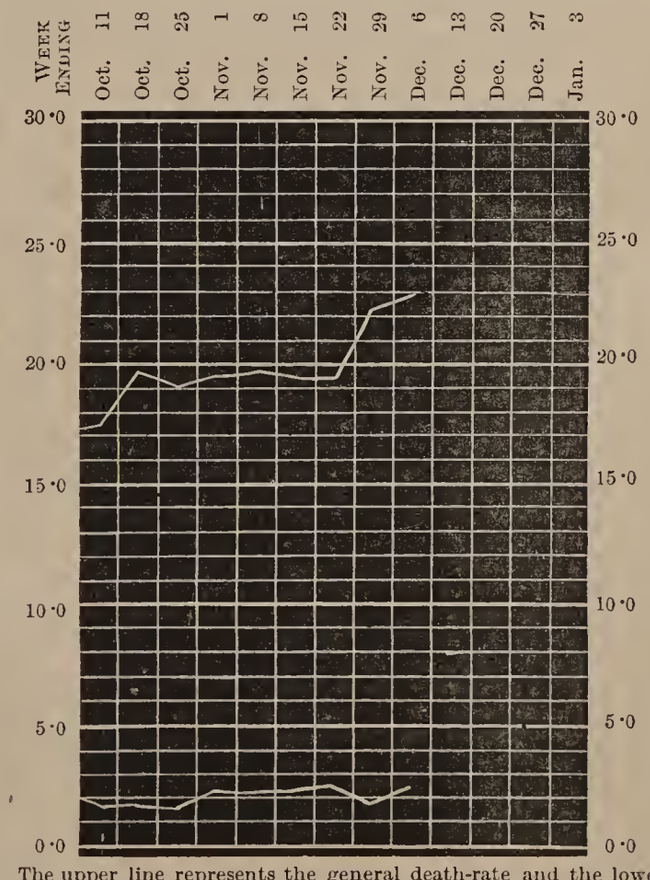
a statement with which Mr. Gould agreed. Mr. Royes Bell related two interesting cases. Mr. Rose thought the statistics both interesting and instructive. At the next meeting of the Society, on Monday next, Sir Andrew Clark will speak on a certain form of chronic pneumonia.

At the Royal Medical and Chirurgical Society on Tuesday last, Dr. Kidd read a paper on the distribution of the "tubercle bacilli" in consumption. He contended that the presence of these micro-organisms is too universal to be accidental. The discussion which followed was interesting from a two-fold point of view. Sir Andrew Clark, chiefly on clinical grounds, argued against the special significance of these bacilli: "For there are cases of destructive disease of the lung, giving symptoms indistinguishable from phthisis, in which no bacilli can be found." In a few cases also of general tuberculosis, after diligent search he had failed to find the bacilli; while in caseous pneumonia, which as far as its life history was concerned was *not* phthisis, the bacilli were found. By phthisis he meant, "that assemblage and progression of symptoms associated with or dependent upon the ulcerative or suppurative destruction of more or less circumscribed, non-malignant deposits in the lungs." The second point was Mr. J. B. Sutton's interesting explanation of the "histological puzzle, the giant-cell," as studied in the lower animals. In sections of the liver from birds dying of tuberculosis the giant cell is constantly found, and always filled with bacilli. Studied in still lower forms of life, as in the daphnia (the common water flea), it was shown to be an assemblage of white blood corpuscles, attacking, so to speak, a bacillus with a view to exterminate it, or hunt it out of the animal's organism. Dr. Creighton's remarks were quite wide of the mark, being a criticism on Koch's views and methods of cultivation, rather than on Dr. Kidd's paper; hence they did not meet with that attention from the meeting which they deserved. A motion to prolong the sitting was lost, but an amendment to adjourn the discussion until the next next meeting was carried *nem. con.* The great interest manifested in Sir Andrew Clark's views and the importance of thoroughly studying the question in the light of clinical facts, as well as from the more purely laboratory standpoint, fully warrants the adjournment. Many eminent authorities on lung disease have signified their intention of taking part in the adjourned discussion, which, however, will not take place until January 13th, 1885.

If it be true, as we hear it is, that Dr. Bristowe is to be the next President of the Pathological Society, the renewed lease of activity may be looked for. Dr. Bristowe has been a liberal and constant contributor to the Transactions of the Society, and will doubtless make an able and sympathetic President. Lately, it has appeared to us as if the object of the evening were to hurry through the list of specimens in the shortest possible time, while discussion on the card specimens, contrary to the original intention of the promoter of this plan of exhibiting, has been actually disallowed. We shall be glad to see the old and better plan revived of asking whether any member wishes to speak on them, as this is the only control to which they are subjected before being published in "The Transactions."

Oxford has during the past few years undergone a good deal of vilification in certain quarters for not providing a more complete medical education for her sons. It is a matter upon which there has been, and probably always will be, much difference of opinion, but the announcement which we have to make to-day cannot fail to meet with the approval of all. Hitherto the teaching of human anatomy, though not discouraged by the authorities, has not had the support it required, and it has, we believe, been entrusted mainly to some senior student in the shape of a prosector. It is officially announced, however, that a lecturer on human anatomy is to be appointed to lecture and give instruction as demonstrator in accordance with the requirements of the English Examining Boards. He will be appointed for five years, and will be eligible for re-election. The salary is to be 300*l.* a-year, and the lecturer is not to engage in private practice. Candidates, who must hold a diploma from a College of Surgeons in Great Britain or Ireland, must send in their applications, endorsed "Lectureship in Anatomy," to the secretary to the delegates of the Common University Fund, New College, Oxford, not later than February 1st, 1885.

The 1,764 deaths registered in London last week, though showing a considerable rise above the preceding record, are yet far short of the average. One tenth of all the deaths falls under the head of zymotic



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past nine weeks.

diseases, small-pox accounting for the lion's share with 37 deaths, to which must be added 24 deaths of Londoners which occurred outside the registration area. This is an unusually high figure, especially when it is known that no fatal case occurred in any of the other great towns of England. There were 263 fresh cases of small-pox admitted into the hospitals during the week. There were 28 deaths from measles and 23 from scarlet fever, showing a slight decline in each case. Diphtheria caused 29 deaths, 20 of them occurring in children under five years of age. There were 499 deaths from respiratory diseases, 11 less than the average. On five days out of the seven there was no sunshine, and the rain it rained every day, so much so that the rainfall exceeded that of the previous seven weeks taken together. There were only 45 deaths from violence, while Birmingham, with a population of less than half a million, had 16 deaths in this group. Oldham distinguished itself by a general death-rate of 38·7 per 1,000. There were 12 deaths from measles and 16 from scarlet fever in Liverpool, and 9 deaths from measles in Cardiff. The zymotic diseases are making very considerable havoc in some of the Scottish towns, as the following death-rates testify, viz., Glasgow, 6·2; Dundee, 6·9; Leith, 7·0; Paisley, 7·1; and Aberdeen, 7·9, per 1,000.

British Justice has found the survivors of the crew of the *Mignonette* guilty of murder, and few can object to the verdict. Some, out of pity for the terrible sufferings of the prisoners, and with serious doubts as to their own fortitude under similar temptation, may feel that the decision is a cruel one, even though the death-penalty has been remitted, but on ethical grounds it is unassailable. What has been the benefit of the centuries of murder and rapine which are supposed to have nourished in men the instincts of justice, helpfulness and loyalty to each other, if we are to pardon, and so to sanction, even under the stress of the greatest temptation, the dispossession of these higher instincts by the lower ones over which it is our boast that they have triumphed? It is not a question for the physiologist. He will tell us that human flesh is as truly nitrogenous food as is that of other animals; that human milk is the most perfect of all natural aliments; and human blood, when transferred into the veins of an exsanguined person, for instance, as truly a source of life and strength as is the butcher's meat provided for the healthy. The taste of human flesh, if it could be dissociated from its origin, might probably be found to differ but little from that of other mammals; indeed, if the stories told of Richard I., or of Sir Ewen Cameron, and the writings of Lindsay, of Pitscottie, are to be believed, as well as the generally received opinions of the Polynesian cannibals, its flavour is superior to that of other animals. St. Jerome records the existence of the practice; and so late as the end of the sixth century a certain king of Northumbria, Ethelfrith by name, is said to have encouraged its practice. On the other hand, when devoured in order to avert starvation, and under the ruthless tyranny of want, the flesh of man, like that of any animal worn out by toil and hunger, is a diseased and more or less innutritious food. These considerations, however, are little germane to the question, which, as we have said, is an ethical, and not a physiological one.

Meanwhile, if indignation is to be of any effective value, it should be reserved for those cases in which the occurrence of such lamentable tragedies as those of the Greely Expedition and the *Mignonette* might have been averted, or at least to some extent guarded against, by the adoption of reasonable practical precautions. And it is no unworthy use of the sensational interest excited by such narratives to endeavour to direct public attention to this end. Would it be impossible to make it incumbent upon the owners of all vessels, other than fishing boats and small coasting craft, to carry a supply of portable tinned provisions properly secured in each of the boats carried by their ships? The amount and character of these supplies and the efficiency of their storage might be inspected every six months or so, by the proper government officials, or whenever the vessel left a British or Colonial port. Twice a year these stores (which should be uninjured by the lapse of so short a time) should be replaced by fresh ones; and as the displaced provisions would be quite fit for immediate consumption, the adoption and working expenses of such a system would entail little beyond its first cost. Having regard to the great sustaining and recuperative value of *blood*, one or two tins of dessicated ox-blood might advantageously take their place in the equipment of each boat. One great difficulty, of course, is that of water; to a small extent this might be economically met by the storage of a certain amount in one or more properly enamelled or otherwise lined compartments in each boat, in the bows or stern; but until science has supplied us with some readier means than distillation, the problem of converting salt water into fresh will mar the perfection of such a scheme. Still, its adoption would go far to rob a shipwreck of much of its ultimate terrors; it would minimise the risks of sudden dangers, and give more time for attention to other important details; it would do much to lessen suffering, and would aid in the preservation of many a life, and lighten the load of many an un-seared conscience.

Mr. Ernest Hart's lecture on "National Precautions against Cholera," delivered at the Parkes Museum on Monday last, contained nothing of great novelty, but it was a forcible, lucid, and reasonable exposition of what ought to be the national policy with regard to a threatened onslaught of the "brutto morbo." Mr. Hart was, of course, severe on European quarantine by land or sea, and on the notorious report of the Vienna Convention, and hopeful as to the comparative immunity of this country in case of invasion. Rome with its pure water supply had escaped, and Paris would probably have been equally free but for a temporary supply of a highly polluted water; while Naples owed its lamentable losses to a soil impregnated with sewage, to its filthy habitations and foul water. In spite of his hopeful prediction, Mr. Hart admitted that the prevalence of typhoid was the true index of cholera

risk, and we could not consider ourselves proof against the latter disease until we had banished the former. He summed his lecture by urging—(1) That quarantine was useless ; (2) that medical inspection of ports was essential, and with this should go means of isolation, compulsory notification of infectious disease, and the active exertions of all local authorities to free the districts under their control from the conditions which rendered them liable to the extension of epidemic disease ; (3) that disinfection was of most doubtful value ; (4) that cleanliness in its fullest and widest sense was the prime element of safety. Votes of thanks were passed to Mr. Hart, and to Director-General Crawford, who presided.

On Thursday week Dr. C. S. Roy, the new Professor of Pathology, at Cambridge, was admitted to the degree of M.A., *honoris causâ*, having been presented by the public orator in the usual high-flown and laboured Latin periods. Dr. Roy's studies at Edinburgh and in Germany, the assistance he had formerly given to Dr. Michael Foster, and the lectures delivered by him at Cambridge at that period were in turn alluded to ; and then "ut ad remotiora transeamus" it was shown how "Ottomannorum inter milites arti medicae deditus, in ipsa Epiro, prope Pindi montes, prope Dodonae antiquae diu desertum oraculum, velut ἰατρόμαντις aliqui, consulentibus respondebat." The simile was pursued as follows :—"Ad eundem postea Respublica Argentina, morbo gravi et inexplicabili oppressa, velut ad oraculum aliquod misit, cujus responsis obsecuta peste illa dira sese protinus liberavit. Inter antiquos quidem victimarum in visceribus rerum futurarum praesagia quaerebantur ; hic autem, non vanus haruspex, ex ipsis morbis quos alii reformidant, ex ipsa Morte quae aliis tacet, veritatem ipsam audacter extorquet,—adeo ut Catonis verbis profiteri possit :

"'Me non oracula certum
sed mors certa facit.'"

Lucan, *Pharsalia* ix., 582.

Amidst all this Dr. Roy no doubt well kept up his new character of augur by laughing in his sleeve.

The profession in this town, writes our Belfast correspondent, has suffered a severe loss during the last few weeks. Dr. Martin, senior dispensary medical officer, died from acute pneumonia after three days' illness, at the early age of 45 years. He was the founder and originator of the Ulster Children's Hospital, which has recently been enlarged, and which has now incorporated with it a large maternity extern-department, and wards for the treatment of diseases of women. Up till the latter changes in the constitution of the hospital Dr. Martin maintained the most active interest in, and gave the most generous support to it. He took also the deepest interest in the Poor-Law Charities, with which he had been connected for many years. He commenced the practice of his profession at the early age of 18, after obtaining the diploma of the College of Surgeons. Dr. Charles Wadsworth, also medical officer of one of the dispensary districts of the town, and one of the obstetric physicians to the Ulster Hospital for Diseases of Women and Children, has succumbed to an attack of typhus upon the twelfth day of the disease. He had, a day or two before the invasion of the fever, been present at the funeral of Dr. Martin, and was one of those who assisted to carry the remains of his deceased friend to their last resting place. His manly figure, the very type and embodiment of health, strength, and vigour, was unusually conspicuous upon this sadly memorable occasion. Dr. Wadsworth was about 35 years of age, above six feet in height, and more than twenty stone in weight. He was champion athlete during his college years, and up till the time of his fatal illness had taken the most active interest in every local athletic undertaking. His remains were followed to the grave last Friday by nearly all the members of the profession in Belfast and surrounding districts. He was vice-president of the Ulster Medical Society, and was most successful in practice.

The bazaar which has just been held in aid of the funds of the Belfast Royal Hospital has been in every sense a solid success. The institution had found itself gradually drifting deeper and deeper into financial difficulties and last month a debt of more than 2,000*l.* existed against it. This was the more unfortunate and unsatisfactory as there had been no unusual expenditure or permanent buildings erected ; but the debt had simply grown from an accumulation of deficits in the income, which has not been meeting the working expenditure for a considerable time. The bazaar and fancy fair realized, as far as the returns show up to the present time, some 3,500*l.* The surplus 1,500*l.* can be well spent in rebuilding the present fever wards, and adding to the building, which is fast becoming unable or insufficient to meet the wants of a great mercantile and manufacturing district with a population of over a quarter of a million.

The Ulster Medical Society held its first ordinary meeting of the present session upon Tuesday evening last, when amongst other interesting matters submitted to the members was a goodly array of cases of *genu valgum*, exhibited by photograph, drawings, and in most instances by patients upon whom the operation of osteotomy had been successfully performed by Dr. St. George, Mr. Fagan (president of the society), and Dr. Browne (ex-president). Dr. Whitla exhibited some of the most interesting specimens which have been shown for a long time at any of the medical societies. They were some bones belonging to the extinct Irish elk—*megasarus hibernicus.* The bones exhibited in the plainest and most unmistakable manner all the pathological characters seen in a typical case of chronic rheumatic arthritis. Two of the huge vertebræ were examined and found to possess, when placed alongside some lumbar vertebræ from an advanced case of rheumatic arthritis in the human subjects, markings surprisingly identical. Professor Gordon, who has a most extensive collection of specimens of the disease in man, was satisfied with the identity of the pathological processes. Dr. Whitla gave a detailed account of the geological history of the Irish elk, and sketched

the position in which it is invariably found in the beds of clay under the peat bogs in the country. He endorsed Mr. Williams' views about the way in which the animal was trapped by its slender feet and legs in the waxy layer of fine boulder clay underlying always the stratum in which it was found. Reasoning from its position in these post-tertiary formations he believed it was clearly prior to man, and thought it was not improbable that the specimens were more than 10,000 years of age. The fact of one isolated discovery of human remains, however, rendered it just possible in the opinion of some geologists that it stretched into the period of early man. The discovery of unmistakable rheumatic arthritis in an animal like the elk, supposed to have been extinguished by a secondary minor glacial period, affords a new field for speculation upon the part played by the disease in its extermination, and opens up unexpected relations between modern pathology and palæontology just at a moment when the disease under question is receiving a very unusual amount of attention and investigation at the hands of scientific physicians. There were also exhibited a case of pseudo-hypertrophic paralysis presenting unusual features, and a series of vegetable, parasitic growths from favus, ring-worm, &c.

Attention was drawn not long since, both in and out of Parliament, to the question of the supposed ineligibility of dispensary medical officers in Ireland to hold Her Majesty's Commission of the Peace. The Irish Medical Association memoralised the Lord Lieutenant on the subject, and the memorial was by His Excellency laid before the Lord Chancellor of Ireland, with whom the appointments to the Commission of the Peace principally rest. After due consideration, the Lord Chancellor arrived at the conclusion that it would be better that no positive rule should exist making the holding of the office of "Dispensary Doctor" a disqualification for being placed in the Commission of the Peace, but that each case, as it came before him, should be dealt with upon its merits, subject, of course, to such safeguards as the interests of the public service might demand. We are very glad to be able to announce in this connection that Dr. George Plunkett O'Farrell, of Tangiers House, Boyle, co. Roscommon, has been appointed a Justice of the Peace on the nomination of the Lord Lieutenant of his county. Dr. O'Farrell is medical officer to the Boyle Workhouse and Fever Hospital, and to Boyle No. 2 Dispensary District. He is a Master of Arts and Doctor of Medicine of the University of Dublin, in which he carried off the highest honours.

Dr. Rogers, the medical officer of health for the Templemichael district of the Youghal Union, co. Cork, is certainly entitled to our sympathy. Having been requested to inspect and report upon certain labourer's dwellings in his district, he devoted six whole days to the task, inspecting no less than 87 cottages. Three more days were then consumed in assisting the guardians to select new sites. For these services he sent in a bill to the guardians of 19 guineas, and 8*l.* 2*s.* expenses. At the trial a verdict was returned in his favour, but this has just been reversed in the High Court of Judicature, though he had the Lord Chief Baron on his side. He was allowed his expenses only, the court deciding that the duties were performed by him in his official capacity. This is a most important decision affecting medical officers of health throughout Ireland.

The election of a successor to the late Professor von Jäger in the University of Vienna is giving rise to a series of heart-burnings and recriminations, such as are now becoming very familiar in the keen competition for the few good posts in the Academies of Medicine. Youth, activity, and the promise of a brilliant future have been for the nonce preferred, in the person of Professor Fuchs, of Liège, to long service and a record of good work in the past, as personified by Professor Mauthner, of Vienna. The choice, however, has yet to be ratified by the Minister for Public Education, and the medical papers in Vienna are making no secret of their respective views upon the merits of the case. So many of our own countrymen have been in the habit of late years of studying in the Viennese school of ophthalmology, that the name of Professor Fuchs, who until lately held the post of assistant to Professor von Arlt, is probably very familiar to our readers. His well-known sympathy with the English School and his remarkably perfect knowledge of the language will render his clinic, if he be ultimately appointed, more than ever the resort of English students of Ophthalmology.

A sad case of the suicide of a young surgeon is reported from Vienna. Having been accused of treating an inflamed finger unscientifically, he was fined and sentenced to repeat his examinations. This, to our ideas, novel and terrible sentence appears to have so affected him that he drowned himself in the Danube. Meanwhile the verdict was appealed against, and referred to the Doctoren-Collegium, who decided that the dead surgeon's treatment had not caused the loss of the finger in question, and so the High Court acquitted him.

The literature of nephrectomy, a subject which has lately been somewhat prominenty discussed, has recently been enriched by an account of a case to which its author rightly prefixes the term "puzzling." Abdominal section was performed on a woman, aged 52, for the removal of a large tumour due to calculous pyonephrosis of long standing. It is stated that the parts were much matted together, and that the pedicle of the tumour was transfixed and secured with a single ligature, being attached at the same time to the edge of the wound. The case did exceptionally well at first, but it was found, some hours after the operation, that no urine was being excreted, the bladder containing nothing but pus. On the second morning severe symptoms of uræmia set in, and a fatal termination rapidly ensued, no urine whatever having been passed into the bladder since the operation. On *post-mortem* examination the remaining kidney was found to be healthy in every respect, with the exception of extreme anæmia and a rather excessive surrounding of fat. Microscopically, no changes could be noted in it. Unfortunately, no record is published of the visible results of

the operation except the fact that no peritonitis had taken place. The complete disorganization of the diseased kidney proved beyond doubt that all the urine must have been secreted by its healthy fellow for many months before the operation. Why, then, did the latter cease to excrete from the moment that the operation was concluded? It is to be regretted that more information is not afforded by Dr. E. Sonnenburgh, who reports the case in the *Berliner Klinische Wochenschrift*, No. 47, 1884, as to the exact structures included in the comprehensive ligature which was placed around the matted pedicle. Even on the supposition that some of the renal vessels or nerves had been so included, it would be difficult to account, however, for the production of simple anæmia, unattended by microscopical changes.

In reference to our note last week on the health of the cadets at Woolwich, a correspondent writes :—I have just seen one of the cadets, and I think if you had seen him too you would not have thought that the hard work previous to admission or at any other time had disagreed with him ; he is the picture of health and robustness. He mentioned to me quite casually the unfavourable report which the visitors had made as to the health of the cadets, so I took the opportunity to ask him how much truth there was in it. He assured me that there was absolutely none. The visitors chose about the hottest day in the year for their inspection, and had been the means of keeping the cadets about six hours back from leave. Hence their pale and jaded appearance. He was positive that any one visiting them now and seeing them in the gymnasium would receive a very different impression. They are not at all flattered at the report which has been published, and consider themselves quite up to the standard of physique which ought to be expected of officers in the highest ranks of Her Majesty's army.

The dangers which are only too apt to attend the careless handling of firearms by persons who fail to appreciate the responsibilities entailed by the possession of such weapons have often served as a theme for the moralist. A case lately reported by Dr. Otis, to the *Boston Medical and Surgical Journal*, illustrates the way in which even the doctrine of chances is set at naught by the evil genius of this particular form of folly. The peculiarly luckless, and yet most fortunate, sufferer was a coachman who, while driving down a village street, was struck on the right side of the neck by a bullet which passed in front of the spine, wounding the lower part of the pharynx, and, avoiding all other important structures by means of a remarkable detour, was found lying just beneath the skin immediately over the great vessels of the left side of the neck. After more than a month of suffering, complicated with the formation of a large abscess originating about fragments of the coat and shirt collar that were carried through the neck by the wandering missile, the patient recovered with nothing more serious than aphonia, apparently due to congestion and thickening about the larynx and ventricular bands, some lack of power in the right arm, and a slight deflection of the head to the right side.

"Let us see how the accident occurred. A student left lying in his room a revolver of 32 calibre, known as the 'Excelsior' pattern, having five chambers. Two of these chambers, adjacent to each other, were loaded. A fellow student coming in, and seeing only the unloaded chambers, supposed they were all so, and so amused himself by snapping the revolver. The first time he pointed it towards his foot, and the hammer came down upon an empty chamber. The next time he aimlessly pointed it out of the window, and the hammer struck one of the two cartridges. The bullet went through a window pane only an inch inside of the sash. Directly in front of the window was an elm tree of moderate size, and perhaps five or six feet distant from the house. The bullet must have just grazed this tree, but it was impossible to discover any trace on the rough, broken bark. A vehicle passes any given point on that street on an average of once in ten minutes, I should think. Just at this time a vehicle did happen to be going by. From the head of the horse to the end of the wagon is quite a distance. Any part of this distance might have been in front of the bullet at the exact time of its discharge, and the chances were many to few against the man's neck being in front. It was in this case. Any part of the neck might have been in the bullet's track. The chances were infinitely few that just the point between the spinal cord behind and the great vessels in front should be the safest place to tap the pharynx from the side. Just that point did happen to confront the bullet. Let us sum up the immense preponderance of the chances against the bullet's causing the accident it did, or, indeed, any accident. First, it struck only one inch beyond the window-sash. Second, a tree was directly in front of the window. Third, a vehicle passes the window only about once in ten minutes. Fourth, the thickness of a man's neck is only a very small part of the line drawn from the head of the horse to the end of the wagon. Fifth, the time taken by the whole of a vehicle to pass a given point is very short; very much shorter is the time a man's neck is passing that point. Sixth, the safe track for a bullet through a man's neck and pharynx is extremely limited. Lastly, there were only two out of the five chambers of the revolver loaded ; the hammer had already descended upon one empty chamber, so that there remained two loaded and two empty chambers, making the chances for and against hitting a cartridge just equal. The bullet went out of the window at a vertical distance of about twelve feet from the ground, and the man's neck was about five or six feet from the ground." To this, as to all similar histories, there belong two morals, of primary and secondary rank respectively. Until the public learn and act upon the first, it will perhaps be safer for coachmen and pedestrians in quiet village streets to enlist in regiments on active service, where at least the majority of bullets wing a harmless flight.

A recent address on the Parasitic Doctrine of Epidemic Cholera, by Dr. Austin Flint, contains some reminiscences which are just now very much to the point, as showing how an incipient epidemic may be effectu-

**

ally strangled in its birth by the prompt and searching application of the principles of common sense sanitation. In 1866 New York was threatened with cholera. In anticipation of its prevalence a system of immediate and thorough disinfection, analagous to that of a fire department, was adopted by the Metropolitan Board of Health, which had lately been reorganised. Sanitary inspectors, of whom some were always on duty at the central office of the Board, were appointed to at once visit all cases as reported, and to decide upon the diagnosis. A "disinfecting corps," composed of soldiers who had recently been employed in the Civil War, was organised under the command of an officer of the army. Waggons loaded with materials for disinfection, and with their horses ready harnessed, awaited only a moment's notice to proceed to any infected spot. All these arrangements were placed under the supervision and direction of the sanitary superintendent, and their object was to disinfect the houses and the surroundings, wherever a case of cholera occurred, just as it is the object of a fire brigade to extinguish a conflagration as speedily as possible.

The results achieved by the thorough application of these measures afford the best proof of their efficiency. During the summer and autumn of 1866, cases of cholera occurred in 362 houses more or less widely separated from each other; and "in no case did the disease extend proximately beyond the house in which a case or cases occurred." In the course of the succeeding year twenty-seven deaths from cholera took place in New York City, five in Brooklyn, and eighteen at the military post in New York harbour. The measures used for stamping out the malady were the same as those employed in 1866, and the disease did not prevail as an epidemic. Dr. Flint maintains that in Marseilles, Toulon and Naples—cities which have been lately scourged by this disease—its progress might have been arrested, and thousands of lives might have been saved by measures such as those which proved so successful in New York in 1866-7; measures which may be cited throughout the world as evidence that cholera is a disease which can be stamped out by efficient sanitary measures efficiently employed. "I believe firmly that should the disease be again introduced into this country, to decide whether or not it shall prevail as an epidemic lies within the power of preventive medicine." These be brave words; but who shall say that they are not as true as they are full both of hope and warning?

Dr. Flint points out that the means which proved so effectual in dealing with the threatened epidemics in New York are quite in accordance with the parasitic doctrine of cholera. Assuming the truth of that theory, it is nevertheless impracticable to compass the destruction of the parasite within the intestinal canal by any of the parasiticides which are known to destroy it outside the body. Such anti-parasitic agents as we are acquainted with, if introduced into the digestive canal so as to prove toxic to the parasite, must also prove toxic to the patient. The parasitic doctrine, however, does not invalidate clinical experience; and Dr. Flint believes that there is no disease with greater certainty controlled at the outset than cholera. To such an end the remedy *par excellence* is opium. Opium, together with repose of the body and digestive organs, if judiciously employed before distinct choleraic dejections occur, will prevent the further development of the disease with almost absolute certainty. If this treatment be promptly resorted to as soon as choleraic discharges take place, the disease is arrested in a large proportion of cases. These assertions are based, he states, on a large personal experience as well as on the concurrent testimony of other observers.

Dr. Kelly's tenth annual report as medical officer of health for the combined sanitary district of West Sussex has recently been placed before us. As usual, it bears evidence on the face of it of much honest work, and it is so arranged as not to tax the minds of its readers unduly. The total number of deaths, 1,487, give a death-rate below that of any previous year, with the exception of the two immediately preceding. On the whole the district was fairly free from zymotic diseases, but in July and August there were some fatal cases of measles and diphtheria, and diphtheria and scarlet fever were rather prevalent in November. Lung disease, by which is meant bronchitis, pleurisy, and pneumonia, heads the list of causes of death, taking the place of consumption, which has heretofore stood first on the list, but which this year follows old age in point of frequency.

A GREAT OPPORTUNITY.

Our medical grandees in London have a great opportunity before them, which we very much fear they will have neither courage nor imagination enough to make use of. It is obvious, and needs no demonstrating, that one of the chief wants of the profession is a central home, beneath whose roof should be gathered the many different corporations and societies now scattered broadcast throughout the metropolis. Well, now is the opportunity to obtain it. The College of Surgeons are beginning a new wing, and seriously thinking, it is said, of founding a pathological institute; the College of Physicians, in conjunction with the College of Surgeons, have taken a site in Long Acre, and are about to erect thereon an examination hall, thereby adding one more to the many medical buildings in London; whilst a committee of the Medical Council are considering the advisability of procuring a more wholesome and convenient place of meeting, "whether by renting some more suitable building, or by the erection of a new structure." Here we have three different bodies forced into a policy of bricks and mortar, and yet no one has ventured to suggest that instead of sinking their money in scattered buildings, which they are sure sooner or later to want to enlarge, they should club together, and found a central building which would serve both their own immediate and contingent purposes and a dozen others besides. We should like to see the College of Surgeons taking the lead in this matter, and obtaining powers to build on either side of its present home a series of examination rooms, offices, and congress halls, sufficient to serve for all the examinations that medical students have to pass, and all the lectures and meetings

that medical practitioners are wont to attend. Under the same roof might be housed the Colleges of Physicians and Surgeons, the Medical Council, the British Medical Association, or at any rate its metropolitan branch, which has at present no worthy habitation, the Parkes Museum, and the offices of the various medical benevolent charities. In time, too, perhaps space might be found for that much-needed central polyclinic, where the wealth of material now distributed amongst a dozen special hospitals would be fully utilised for purposes of clinical teaching and research.

The scheme is a large and bold one, but it is amply supported by considerations of convenience, of economy, and of sentiment. First as to convenience. It never falls, perhaps, to the most active and enquiring practitioner to wish in the course of a single afternoon to look up a specimen in the Hunterian Museum in Lincoln's Inn Fields, to take out a book from the Physicians' Library in Pall Mall, to listen to a debate of the Medical Council, to pay a visit to the headquarters of the British Medical Association, and then, after a hasty dinner at his home or his club, to be present at a session of one of the societies in Berners or Chandos Streets. But it must often happen to many practitioners to have to undertake two or more of these duties in the intervals of their day's work, and as it is they cannot undertake them without an amount of locomotion which to the peripatetic portion of the profession will involve a measurable waste of energy and time. Then as to economy. At present the number of lecture and meeting rooms which have to be maintained are a serious tax on the revenues of the profession, and yet scarcely one of them is large enough for its requirements. The theatres of the Royal Colleges are cramped and comfortless; the meeting rooms of the Societies are utterly inadequate for the attendance attracted by a great debate; the well in which the Medical Council meets is admittedly unwholesome and inconvenient for the members of the Council itself, leaving out of account the representatives of the press, and the public; while the British Medical Association has no meeting room at all. For the sums expended on keeping up and periodically enlarging these various chambers, two large and comfortable lecture halls might be maintained, one of them capable of accommodating the largest medical assemblage ever likely to be drawn together. When the inevitable combination of the different medical societies comes about, something of this sort will have to be provided; and we are sure that if the College of Surgeons would use its best efforts to bring the combination about, at the same time undertaking to give house room to the new combined society, it would speedily recoup its initial outlay, and bind to itself by the strongest bonds of gratitude and allegiance the scattered members of the profession.

Lastly, as to considerations of sentiment which, to our mind, are by no means the least important. It is usual to throw ridicule on policies of bricks and mortar; but for keeping and binding men together, bricks and mortar have more lasting power than all the oratory and enthusiasm in the world—a view held from the building of the Tower of Babel to the building of the new Liberal Club. The medical profession has at present no visible symbol of its solidarity but a certain round table in Oxford Street and the *British Medical Journal*. If for these inadequate *eidola* it could substitute a palace in Lincoln's Inn Fields as visible to the public as to itself, it would gain a new consciousness of its own corporate unity, and would impress the laity with a new sense of its authority and importance. The scattered loyalties to different corporations and societies which now exhaust the sentiment of the profession would be gathered into one broad channel of allegiance to itself. Its members, no longer split up into coteries, would have opportunities of meeting, discussing, studying, perhaps dining together, and thereby dispelling the mists of suspicion and misapprehension which now so often separate them. For such results it seems worth risking some money on bricks and mortar.

THE LONDON UNIVERSITY.

So many hard things have been written of late about the University of London, that it is only doing it an act of justice to recall the circumstances under which it came into existence, the difficulties with which it has had to contend, and the influence it has exerted directly and indirectly on education, both general and professional. Sixty years ago, while every other country could boast of numerous seats of learning, where the members of all the liberal professions received their training, there was in England, outside the Universities of Oxford and Cambridge, actually no single institution for higher education, literary or professional. The two ancient Universities had indeed a noble history in the past, but they had failed to keep pace with the necessities of the age, and in several respects to realise the true idea of a university. Their doors were absolutely closed to all but members of the established church, the cost and conditions of college life excluded all but the comparatively wealthy, and attention was almost exclusively directed to classical and mathematical studies. Amongst their graduates, indeed, they counted nearly all the Clergy and a large proportion of the Bar, but not more than a hundred physicians, and, perhaps, half-a-dozen surgeons, and even these had received no part of their professional education within their walls. This they, like others, had to seek abroad or in the schools then growing up in connection with the London hospitals, where young men who, as boys, had served an apprenticeship with surgeons and apothecaries, "walked the hospitals" for a couple of years to study clinical medicine and surgery, and to attend occasional lectures given by the physicians and surgeons, often in their own houses.

Such was the state of professional instruction when a number of men representing every shade of religious opinion, but all equally in advance of their time, conceived the idea of establishing in London a real university on the Scotch or German plan, where arts, law, and medicine should be taught by the ablest professors that could be drawn together, and degrees should be granted by examination only and irrespective of

creed. The sum of 150,000*l.* was subscribed, and on October 1st, 1828, the first "University of London" was opened in Gower Street, but the attempt to obtain a charter empowering it to grant degrees provoked the most determined hostility, on the ground that it would be subversive of religion and morality, notwithstanding the unimpeachable orthodoxy of many of its promoters. Meanwhile, King's College, London, was founded with a view to counteract the influence of the "godless university" by offering like advantages, but strictly guarded by religious tests, and with the addition of a theological faculty. Shortly afterwards, Queen's College, Birmingham, was also established on the same lines. After eight years of fruitless effort at incorporation, the scheme for establishing a teaching university in London was reluctantly abandoned, and a compromise was effected. The original institution took the name of University College, and in 1836 the present University of London was founded on a plan without precedent, except in Republican France. From this time the history of the two institutions diverge, but each has had its influence on the education of the country. To the example of the former we owe the establishment not only of the rival colleges already mentioned, but of Owen's College, Manchester, since raised to the rank of a university, and of the numerous University and Queen's Colleges springing up in provincial towns; and we further owe to it much of the improvement in medical teaching during the last fifty years. But the influence of the University of London has been wider and deeper still, and is seen in the gradual abolition of tests which act as barriers only to the conscientious dissident, and in the recognition of the claims of natural science to an equal place with classics and mathematics in a university curriculum. Cambridge has closely assimilated her examinations for the M.B. to those of London, and it cannot be long before she will follow her younger and more progressive sister in the admission of women to degrees the examinations for which they are already allowed to pass.

The defect of onesidedness, as the Germans would say, of being a mere examining and degree-giving body is one for which the founders of the London University cannot be held accountable. It is a part of its constitution imposed upon it by its enemies in days long past, and fixed by successive Acts of Parliament. Convocation, that is the members of the University, is almost powerless; the Senate is composed of nominees of the Crown, few of whom have had any experience as teachers, or can have any real sympathy with a university to which they do not themselves belong. Recent changes in the examination for the B.A. and B.Sc., leave nothing to be desired; we cannot say the same of the LL.B.; but it is with the degrees in medicine, and the relation of the University to the Medical Schools, that we are chiefly concerned. We would deprecate any attempt to level down the standard to that of Aberdeen or Glasgow in order that every one who now passes "College and Hall" might add M.D. to his name, or to substitute for the present matriculation the smattering of schoolboy knowledge that satisfies the Medical Council. In view of the modern developments of physiology and pathology, we attach the highest value to the purely scientific training represented by the preliminary scientific examination, and that the present curriculum turns out highly educated and successful men is evident from the positions held by the majority of London graduates in the schools and the profession generally. But we must confess that setting aside those students who are excluded by neglecting to matriculate, a neglect for which they or their teachers are to blame, many who in all respects would do credit to the University are prevented from graduating by defects in the regulations of the Preliminary Scientific and Intermediate M.B. examinations. In the former it cannot be denied that the standard, in physics especially, is unreasonably high, and that the loss of an entire year, which failure in a single subject entails, debars the majority of men from further progress. So far as the University is concerned, the difficulty could be met by holding the examination twice a year, and so far separating the chemical and physical, and the biological parts that they might be taken together or separately, and that a man who failed in either might take it up at the next examination. The same remarks apply *mutatis mutandis* to the intermediate examination; the M.B itself calls for no change since the proportion of failures is but small, and a further year of study when a man's curriculum is finished can do no harm. It is only fair to point out, however, that most of the difficulty experienced by students in passing the preliminary scientific examination, is attributable to the defective teaching arrangements at the majority of medical schools, which are mere appanages of the hospitals, schools of medicine and surgery, not of science, and being unconscious of any connection with the University cannot be expected to provide for its demands. But no man can learn science from books alone: he will either find them broken reeds, or he will pass by mere cram, a kind of success which it is the special aim of these examinations to render as difficult as possible. Physics and biology must be learned in the laboratory, just as anatomy is in the dissecting-room; and laboratories with staffs of special teachers can only be supported by endowments, or by the fecs of a large number of students as at University and King's Colleges, where there are a numerous body of men studying science quite apart from medicine.

If by voluntary combination, or if necessary by legislative interference, the number of medical schools in London could be reduced from eleven to five or six by attaching the smaller to as many of the greater ones as centres, where alone the science schools with laboratorics, &c., would be located, much might be done towards raising the character of medical education, and with the changes we have proposed in the University regulations, towards bringing its degree within the reach of every student of abilities above the average. More than this we would not have, for as Professor Burrowes said, "degrees were not meant for idiots, idlers or invalids." Students would enjoy at once a better scientific training and wider fields for clinical observation. One word in conclusion as to the University itself. The Senate must be entirely re-cast and composed wholly of graduates of the University, and teachers in the metropolitan schools of arts, science, medicine and aw; and if the present

impossible standard for the LL.B. were lowered to a fairer pitch, there would be no excuse for the cry for the anomaly of another university for law alone. The existing Senate is an anachronism; for a university that can count among its graduates many of the most eminent names in medicine, law, science and literature need no longer be kept in leading strings and governed by strangers, however distinguished for their birth or their abilities.

CLINICAL PAPERS.

XVII.—The Diagnosis of Cavities in the Lung.

The physical signs produced by cavities in the apices of the lungs are, probably, the most easily learnt, and most clearly remembered by students, of all the phenomena due to disease in the chest. Certainly they present the most complete departure from the normal physical signs. But it is a remarkable fact that the more advanced in life, and hence in experience, the physician becomes, the more cautious is he in making a positive diagnosis of pulmonary cavities. Other conditions, such as pneumonic consolidation or pleuritic effusion, are not treated with a similar reserve. The reason is simple. In the case of the latter, the physician has been taught by experience that his means of diagnosis generally lead him to the right conclusion; but with respect to excavation of the lung, he, perhaps unconsciously, confesses to himself that, with all his diagnostic skill, his conclusions are sometimes wrong. Symptoms and physical signs which directly indicate a pulmonary cavity may sometimes be produced by other causes, and it is not, therefore, possible to fix upon any single sign or even any distinct combination of signs by which a cavity may be invariably recognised. In the vast majority of cases, however, no sort of uncertainty need exist, but the presence of the cavity is not unfrequently indicated to different physicians by signs to which a different relative importance is attached. It may, therefore, be of interest to pass in review the more frequent indications which are recognisable in these cases, and to attempt to assign to each its relative value. But before proceeding to the examination of physical signs we may enquire what may be gathered from the history and general statements of the patient.

In the antecedent progress of a case of phthisis, the occurrence of sudden and severe hæmorrhage is strongly indicative of the presence of a cavity, but such a cavity may be so small or so deeply situated as to baffle any attempts to discover its whereabouts by means of physical examination. Large and sudden hæmorrhages are produced by the rupture of a diseased blood-vessel in the lung, and pathological experience teaches that such lesions generally take place in or about excavated areas. Prolonged and excessive expectoration, especially when it is of a purulent, nummular, and adhesive character, is also of some diagnostic importance. The occurrence of wasting, dyspnœa, cough, slight hæmoptysis or sweating give no indication of the presence of cavity. They may or may not have been present in the history of a case.

Looking next to the present symptoms as described by the patient, can we fix upon any one point that will guide us to a correct diagnosis? Pain and tenderness may lead us to the seat of the lesion but will not indicate its nature. A dull aching pain referred to one shoulder or to the clavicular region on one side is at times misleading, even as to the locality of the mischief, the signs of disease being present on the side opposite to that in which the pain is felt. With tenderness, however, it will be generally noticed that its area corresponds to the seat and limit of the diseased pulmonary tissues beneath. In such cases it is probable that a more or less acute form of pleuritis is present, or that some violence has been done to pre-existent pleuritic adhesions by excessive coughing or retching. But we gain no information either from pain or tenderness that can be considered in any way diagnostic of a cavity. Are the patient's own sensations of any value whatever in the diagnosis of that condition? Very rarely. A patient is frequently able to point with approximate accuracy to the spot where a large hæmorrhage has taken place, or may sometimes be able to indicate correctly where his profuse purulent expectoration "comes from," but trustworthy subjective indications of a cavity are generally wanting.

From past history and present symptoms, therefore, we gain but little information. It is essentially by means of the familiar routine of physical examination of the chest that the diagnosis must be made. Inspection of the thorax during quiet and forced respiration will, in many cases of cavity, attract the attention towards the locality of the disease but, as in the case of pain, will not afford any real information as to its nature. Doubtless, in a very large number of apex cavities, a certain amount of flattening of the chest walls will be present, or there may even be a considerable degree of absolute concavity of the surface, but these changes may equally attend the conditions of atelectasis, or of fibroid disease of the lungs, or of empyema. The movements of the upper parts of the chest are not less open to misinterpretation. So many influences both from within and without may be combined to alter or modify these movements that in practical diagnosis their abnormality can only be said to give the rather vague indication that "there is something wrong somewhere." Cavities, moreover, are not unfrequently present in cases where the respiratory movements have given no indications of disease.

Palpation can only be made to yield positive evidence of increased or diminished vibration, both of which conditions may be observed over pulmonary cavities under varying circumstances. Turning now to the question of percussion we enter upon a more debatable ground. Few practical physicians will be found to deny that all degrees of note, from boxy resonance to absolute dulness, have been elicited by percussion over pulmonary cavities. It is thus evident that no positive law can be laid down as to the production of resonance or dulness in such cases in any degree akin to that which prevails in the diagnosis of pneumonic consolidation or pleuritic effusion. An attempt has been made, however, to show that the degree of resonance or dulness, whichever it be, that is present over any

pulmonary cavity, may be made to vary by opening and closing the apertures of the patient's mouth and nose during percussion. For the success of this experiment it is necessary that there should be free communication between the cavity in the lung and the upper air passages. To the importance of this condition we shall have occasion to refer again, since it forms the most essential point in the physical diagnosis of cavities. A tympanitic note obtained with the mouth open is said to be rendered deeper when the mouth is closed, and deeper still when the nasal openings are occluded.

To the time honoured but fallacious indications of the "cracked-pot" sound it is hardly necessary to refer. The sound is sometimes present in cases of excavation and at other times it is not. It is met with almost as frequently in cases where no excavation exists. The size and shape of cavities have been at times estimated with more or less precision by means of percussion, but for some undetermined reason it has been the custom in the English schools to keep clear of these refinements, which have been almost exclusively the property of the possibly more cultivated musical ears of our continental brethren.

So far, then, with the exception of the ingenious test above referred to, we do not obtain from the foregoing diagnostic processes any really distinctive indication of the presence of a cavern in the lung. It is to auscultation therefore that we must look to supply the deficiency and to decide the question left unsettled by the other means at our disposal. Here again, however, the diagnosis is beset with difficulty and cases are probably known to most practitioners in which the opinions of careful auscultators have been exactly opposed to one another after very close investigation on both sides. The clue to this divergence of opinion is generally to be found in the fact that the respective examinations have not been made at the same time.

The amount of fluid secretion which is present in a cavity at different times may give rise to great variety in physical signs. But more important even than its relative content is the relation in which the cavity stands to the larger or smaller tubes in the lung. The sounds heard over a cavity during respiration and during speech will be found to vary widely, according to the greater or lesser freedom of communication between the cavern and the bronchi.

The characteristic amphoric breathing is best heard when that communication is most widely open, and in like manner the vibrations of the voice, whether spoken or whispered, will then be most clearly distinguished. For this reason the rule has been established in every clinical text-book and clinical class, that in all cases of suspected cavity, the patients should be made to cough with some degree of force in order to expel, if possible, any plug that might be occluding these broncho-cavernous openings. Granted that typical amphoric breathing is present, have we any means of distinguishing whether the sound is produced at the spot where it is heard or whether, as in the case of solid lung, it is only conveyed hither from some other part? The simplest of all means, viz., direct comparison of the sound with that produced in the patient's own trachea. The habit of systematic auscultation of the trachea is not so widely practised as it might be. The fact is sometimes overlooked that every individual produces a "bronchial breathing," peculiar to himself within the recesses of his own air passages, and that no common standard of pitch or volume of that sound can be set up for universal application. In all cases, before estimating the quality, and hence the diagnostic value, of morbid breath sounds it is essentially necessary to compare them with the healthy sounds produced in the patient's own trachea. In the case of amphoric breathing heard for instance over a relatively dull patch of lung, this is of paramount importance. Experience shows that a most typically amphoric breathing is at times to be heard in the trachea, and may even be greatly modified by the shape or position of the mouth and nares. Such a sound conveyed by consolidated lung tissue may be, and frequently is, erroneously held to be indicative of a dry cavity.

Cavernous and tracheal breathing are both essentially *tubular* in character, but it is only when a marked difference exists between them that the former possess any real diagnostic value. Of the vocal resonance, the same rule holds good to some extent. The old idea that the conveyance of the whispered voice was diagnostic of a cavity has long since died out. It is well known that any laryngeal or labial sounds may be equally well conveyed by consolidated lung tissue. In some cavities, but by no means in all, a marked modification of the voice sounds may be noted on comparing them with those heard over the trachea. There is not, however, any distinctive alteration which is nearly so constant in its occurrence as the amphoric change in the respiratory sounds, and hence the degree and character of the vocal resonance is of far less importance in diagnosis.

Of the truly abnormal sounds which are to be heard in and about cavities in the chest, the most important are those to which the term "metallic" has been happily applied. Without being absolutely diagnostic of pulmonary excavation, they occur so frequently in association with it, that next to the amphoric modification of the tracheal breath sounds, they form the most valuable indication that we possess. It will generally be found that the peculiarly metallic twang which characterises them is to be noted at the same time in the cavernous alteration of the respiratory sounds and also in the augmented vocal resonance.

To sum up the views expressed in the foregoing, it may be said that while pulmonary cavities may at times give rise to alteration of every one of the normal physical signs, there are but very few of these alterations that are not capable of production by other means. Amphoric or cavernous breathing, that is to say, the normal tracheal sounds conveyed to a distance and altered in quality and tone, is the only sign that can be regarded as peculiar to the excavated condition of the lung. The greatest care, however, is necessary before accepting even this sign as absolutely conclusive, and as a general rule it will be found advisable to follow the prudent practice of those experienced auscultators who make no positive diagnosis of a cavity where there is any room for the shadow of a doubt of its existence. B.

REVIEWS AND NOTICES OF BOOKS.

DR. BRIEGER'S RESEARCHES ON PTOMAINES.[1]

In the monograph before us, the author gives the results of a series of observations undertaken by himself with the view of determining the true nature of the so-called group of ptomaines. The work is prefaced by a history of previous efforts in the same direction. To Professor Panum, of Copenhagen, belongs the credit of having first demonstrated the production of a poisonous substance, chemically obtained from decomposing animal tissues. Many experimenters have since succeeded in isolating various substances which have been proved to resemble the vegetable alkaloids in their physiological behaviour. None of these, however, had been obtained in a state of chemical purity, until Nencki extracted from the decomposition of gelatine a ptomaine, which he termed Collidin, in pure and crystalline form. An alkaloidal substance, almost identical with it, was obtained by Gautier and Etard from the decomposing tissues of fish. These two experiments are therefore the only instances that can be quoted with scientific accuracy, since they alone were conducted with scientific precision.

Dr. Brieger's own observations extended over a long period of time, and the success which attended his attempts to obtain the ptomaines is here set down. Following the well-recognised fact that the products of early decomposition of albuminous tissues, as peptone, are endowed with distinct toxic properties, he proceeded to search for ptomaines in the products of the artificial digestion of fibrin. He succeeded in extracting therefrom a poisonous substance in solution, which he was only able to crystallize in vacuo with extreme difficulty. For physiological experiments the solution was manifestly impure, but the results of injection gave evidence that it possessed violent toxic properties. After eight days decomposition this toxic material could not be obtained. By means of check experiments he proved that the poisonous material was not evolved from the gastric juice by which the artificial digestion was carried on. The next series of investigations were made upon decomposing flesh—equine, bovine and human. A crystalline substance was obtained to which the name of Neuridin was given. When in an absolutely pure state it was found to be very soluble in water, insoluble in absolute alcohol, ether, chloroform, amylic alcohol and benzine. It would appear, however, that neuridin is a body which is very widely distributed in all forms of animal tissues, and is therefore liable to a variety of combinations with organic substances, in which these chemical properties would not be present. It is probable that it plays an important part in the processes of tissue change.

The author gives a detailed account of the test reactions with various acids, and of the general chemical properties of the neuridin in its crystalline form, but he has not as yet been able to determine its exact composition. He has ascertained that, in the pure state, it is not poisonous, but when containing organic impurities it resembles peptotoxin in its effects. After complete extraction of this alkaloid, he found, however, that the remaining fluid still retained certain poisonous properties. By means of a process, of which he gives the particulars, he succeeded in isolating the hydrochlorate of a base possessing very marked toxic properties, as proved by experiments upon frogs and small mammals. Its action appeared closely to resemble that of muscarin, and seemed, like it, to be antagonistic to atropin. Both chemically and physiologically, however, he determined that the neuridin and this second base, to which he gives the name of Cholin, are quite distinct.

Investigating the products of the decomposition of fish, he succeeded further in isolating a new base in all respects identical with ethylendiamin, but not in sufficient quantity to enable him to carry out a thorough series of physiological experiments. He was able to establish the fact beyond any doubt that it possessed toxic properties. From the decomposition of cheese, a substance resembling neuridin was obtained. From glue Dr. Brieger succeeded in separating a minute quantity of a material having the properties of muscarin. Particulars are in every case given of the processes employed, and of the experiments made in arriving at the conclusions to which the author is led. The monograph is concluded by a chapter on the genesis of ptomaines, skilfully summing up the extent of modern knowledge upon the subject. As a whole the work must be accepted as a most valuable contribution to the literature of a branch of knowledge which seems destined, at no very distant time, to expand to proportions which may materially modify our present views of normal physiological processes.

[1] Ueber Ptomaine. By Professor Dr. L. Brieger, in Berlin. Hirschwald. 1885.

A NEW HANDBOOK OF GYNÆCOLOGY.[1]

This may be briefly, but we think justly, described as a fairly good book of a very bad kind. It is a book of a class for which we would much rather there were no demand; but there are only too many who think that such books meet their requirements, and are content with them accordingly. If, however, for a moment we may identify ourselves with the class of readers for whom we take it that the volume is intended, we must admit that the execution of the work—except for the evidences of haste which meet us on every page—is highly meritorious. It is a book intended to save students and practitioners the trouble of reading the larger treatises on the diseases of women, and to give them as it were a bird's-eye view of the theory and practice of the present day. It will familiarize students with the appearance of gynæcological instruments and acquaint them superficially with their uses; and enable them to give passable answers to the questions of examiners. It is not a book that throws new light on the subject; and if it supplies information to the student, it does not stimulate him to think. It does not appear to be its object to sift truth from error; nor to mark out the broad highway of proven fact along which scientific medicine advances, from the multitude of by-paths resting on hypothesis, and leading to practical results both bad for the patient and discreditable for the practitioner. But on the other hand it is clearly written and copiously illustrated, and it shows that the author is familiar with contemporary gynæcological literature. It also contains many useful practical hints; and in reading it we cannot but regret that the author should not have chosen, instead of giving us a patchwork representation of the different phases of opinion, to express his own deliberate and independent judgment on the many conflicting doctrines which here lie side by side for the reader to make his choice among them.

In the preface, and in many places throughout the book, Dr. Macnaughton Jones makes most judicious remarks on the evils of specialism, the necessity for a

[1] Practical Manual of Diseases of Women and Uterine Therapeutics, for Students and Practitioners, by H. Macnaughton Jones, M.D., &c., &c., Examiner in Obstetrics, Royal University of Ireland, formerly Professor of Obstetrics in the Queen's University, Ireland, &c., &c. London: Baillère, Tindall and Cox, 1884. Pp. 410.

knowledge of disease as it occurs in every part of the body before undertaking the treatment of those of one set of organs, and the injury done to patients by unnecessary local treatment. But the tendency of these excellent precepts will we fear be largely neutralized by the full descriptions which are given of methods of local treatment to which the general condemnation of the preface largely applies; methods, some of which are by common consent admitted to be useless, and others, if productive of good at all, yet much more limited in their application than the student would think from this and from the works from which Dr. Jones quotes. As an example of the way in which perplexity may well arise in the mind of an intelligent student, we may refer to p. 144, at which Dr. Matthews Duncan is quoted, that "thousands of blooming, happy, fertile women have displacements." This statement, says Dr. Jones, cannot be controverted. He says also that "in a very large percentage of cases any and every pessary fails to give relief and often only creates distress;" that "we are frequently creating an unhealthy state rather than relieving one." After this sweeping condemnation the student comes to 37 pages devoted to the consideration of flexions and versions. Anteflexion is styled "that most troublesome and frequent displacement," and ten different pessaries for its cure are figured. There is no hint that anteflexion may sometimes co-exist with symptoms without being their cause; and the student is left to reconcile for himself Dr. Duncan's views with the necessity for pessaries which appears to be inculcated in the pages which follow. Again, in the chapter on sterility, a list of causes of this condition is given, all but one of them being local. After this the author proceeds first to deprecate operations for the cure of sterility, and then to say that it is "far otherwise when some diseased or abnormal condition of the uterus is present which it is our duty to treat by operation." The student is not told which abnormal conditions (or when) it is his duty to treat by operation. This is an example of the main fault of the book. Sweeping condemnations of unnecessary local treatment go side by side with detailed descriptions of all kinds of interference, to many of which the best specialists would think the author's general denunciations most properly apply, and the student is given no clear guidance to teach him when he should do these things, and when he should not.

On Tumours of the Bladder: Their Nature, Symptoms and Surgical Treatment; by Sir Henry Thompson. London: J. and A. Churchill.—Although a considerable portion of this work has already appeared in the medical journals, still the lectures before us are the first adequate exposition of the author's views on this very important subject. Originally delivered before the College of Surgeons, Sir H. Thompson has added in the present work notes, histories and microscopic drawings and descriptions of the tumours such as could not possibly be given in his oral lectures. The result is an interesting volume which epitomizes the author's latest experience in a department of surgery in which he is *facile princeps*. We must congratulate Messrs. Churchill on the admirable manner in which the microscopical drawings have been reproduced.

Handbook of Midwifery for Midwives: From the Official Handbook of Midwifery for Prussian Midwives; by J. E. Burton, M.R.C.S., L.R.C.P., London, Surgeon to the Hospital for Women, Liverpool. Second edition. London: J. and A. Churchill. Pp. 308.

The Handbook for Midwives; by Henry Fly Smith, M.B. Oxon, M.R.C.S. Eng. Second edition, thoroughly revised. London: Longmans, Green and Co. 1884. Pp. 176.

We have pleasure in calling attention to the second edition of these two useful manuals. For those unacquainted with them we may say that Dr. Burton's volume is a translation of Litzmann's Handbook, and is fuller and more technical than any other work intended for the same purpose; while Dr. Fly Smith's is much less elaborate, is written in simpler language, but contains less information. We notice that both volumes recommend plugging the vagina for uterine hæmorrhage,—a makeshift which conceals hæmorrhage but does not stop it, and in our judgment therefore better omitted than practised. In this remark we think most practical accoucheurs will agree with us.

A Manual of Medical Jurisprudence, with special reference to Diseases and Injuries of the Nervous System; by Allan McLane Hamilton, M.D. London and New York: Bermingham & Co., 1883.—We feel somewhat disposed to quarrel with the author for his title, as the book ought to have been headed "The Medico-Legal Aspects of Injuries and Diseases of the Nervous System," such being the only subjects treated of. The first two chapters are devoted to insanity, then follows a chapter on hysteroid and feigned diseases, and then successively chapters on epilepsy, alcoholism, and suicide, the last two chapters being about cranial and spinal injuries. Although we do not like the style in which the book is written, still it is evident that Dr. Hamilton is speaking from a not inconsiderable experience of the topics with which he deals, and there is a good deal of interesting and useful information embedded in the book. If the redundant matter was removed, such, for instance, as the description of the anatomy of the brain, which is quite unnecessary in a work of this kind, and if not unnecessary would be quite useless in its present crude state, and what remained welded together a little, the value of the book would be immensely increased.

The Human Element in Sex: being a Medical Enquiry into the Relation of Sexual Physiology to Christian Morality; by Dr. Elizabeth Blackwell. Second edition, revised and enlarged: J. and A. Churchill, 1884.—The teaching of this little pamphlet is sound, and, if it can only be brought before those who need enlightenment, is calculated to do good. Hitherto, the great difficulty in dealing with an evil which demands plain speaking, if spoken of at all, has been the instruction of those—ignorant, careless, or even criminal, as the case may be—within whose cognisance the earliest habits of childhood are developed. The evil ignorance and vicious knowledge too common amongst the adolescents of both sexes is traceable, not to the corrupting communications of large schools, but in a great measure to the habits of mind and body acquired in the smaller preparatory schools, and even in the nursery; this is only possible because of the false shame and ignorance which leads parents to prefer that their children should find out for themselves the distinctions between good and evil, without help or warning from their natural protectors. Such a prejudice the book before us may serve to remove. In a revised edition "ova" should not appear (p. 24) as a singular noun. From a physiological anatomist of the present day we scarcely expect the positive statement that in the human male "there is no rudimentary part corresponding to the uterus."

ABSTRACTS AND EXTRACTS.

SURGERY.

The Electrolytic Treatment of Urethral Stricture.—Dr. Dukeman claims (*New York Medical Journal*) that this method excels all others; it is simple and requires no assistants and no anæsthetics; there is no hæmorrhage and no pain; it does not debar the patient from his daily avocations, and the cure is perfect and permanent. A good galvanic battery giving a steady smooth constant current of from ten to fifteen volts is necessary. The urethral instru-

ments used for absorption of the stricture are bougies made of metal and insulated with rubber, except at the point which is an olive-shaped silver bulb. The patient assumes the recumbent position. To the positive pole is attached a sponge electrode moistened with water, and placed in the patient's hand or on his thigh. To the negative pole the insulated electrode bougie is attached, and the instrument should always be inserted into the stricture before connection with the battery is made. It is advisable to begin the operation with a mild current and to increase it by one cell at a time. The bougie must be gently guided, no force should be used, and no pain should be inflicted. Care must be exercised to keep the bougie in line, so that the point will not deviate and make a false passage. An interval of four weeks should elapse between successive sittings; otherwise the slight subacute inflammation which sometimes follows the operation may become aggravated into such a swelling of the mucous membrane as almost to close the urethra, and thus discourage both patient and operator. The surgeon simply introduces the bougie to the seat of stricture and gently holds it there, with its point in the proper direction "while the electricity slowly dissolves the stricture." The time required varies, according to the bulk, kind, and extent of the stricture dealt with, from ten to forty minutes, usually; but in two cases, where a stricture from one-half to three-quarters of an inch in length had to be dealt with, it occupied nearly two hours. As the stricture is partially decomposed, and gradually washed away after each operation, an instrument of about two sizes larger than the calibre of the stricture should be used at each *séance*. Thus, if the stricture admits a number 11 French, a bougie number 13 would be the size of the instrument for electrolysis. In four weeks the decomposed portion of the stricture will be washed away, and it will then, in all probability, admit a number 15, when for the second electrolysis we should use a number 17 French scale, and so on until a cure is completed. Dr. Dukeman asserts that all kinds of urethral stricture can be cured by electrolysis, and after referring to his cases already reported in the medical journals, asks that the method may be given a fair, careful, and impartial trial.

Hot-water Injections in Gonorrhœa.—In the *New York Medical Journal*, Dr. S. C. Gordon relates several cases treated in this manner. Observing the benefit which follows the use of the hot vaginal douche when the mucous membrane and peri-uterine tissues are swollen and engorged with exudation from passive congestion, he was led to employ the same curative agency in cases in which the urethra and its mucous lining present similar conditions. About two quarts of water, as hot as the patient can possibly bear it, are injected at each sitting by a fountain-syringe. By getting the patient to strain a little, as though urinating, the bladder can be repeatedly filled and emptied with great relief to the dysuria. The douche is continued, twice a-day, for a few days as the symptoms indicate. Relief is experienced from the first; chordee is avoided, and the smarting sensation removed; no anodyne is given, and no medicine needed. Dr. Gordon concludes:—(1) Cases seen at the outset may be aborted in from three to five days, by the use of a two-quart douche three or four times daily. (2) In cases which have lasted ten to fourteen days (*i.e.*, when the acute inflammation has subsided), similar treatment will effectually relieve the distressing symptoms in the course of a very few days. (3) When two or three days have elapsed before the patient is seen, careful injections of simple water at about the body-temperature, or less, with the external use of very hot water, promotes cleanliness, acts as a sedative, and does much for the patient's comfort.

Danger of too Early Repetition of Iodine Injections in Hydrocele.—Professor Tillaux drew the attention of his class, at the Beaujon, to the danger of being in too great a hurry in repeating injections of iodine in hydrocele. It is only at the end of six weeks or two months that we can judge of the result of the first injection, and to interfere before this time is to expose oneself to induce the formation in the tunica vaginalis of those false membranes which are so vascular that they bleed on the slightest shock, and thus give rise to hæmatocele and the loss of the testicle.—*Revue de Thérapeutique*, August 14.

Extraction of a Bullet from the Urethra.—Dr. Wilder relates this remarkable case which occurred in the person of a coloured man, æt. 26, in the Cincinnati Hospital. About a year before he suddenly found himself unable to micturate, and since then he had always passed water drop by drop and in great pain. On sounding him a hard body of irregular shape, and supposed to be a stone, was struck, and as it resisted removal by the forceps, this had to be effected by means of an external incision. The body proved to be a leaden bullet about $\frac{42}{100}$ inch calibre, considerably flattened and indented, and nearly covered with urinary salts. It was so embedded in the urethra as to be removed with difficulty. In 1870, the man had received a pistol shot in the groin, and the ball was never found, a small circular scar about an inch below the middle of Poupart's ligament indicating its point of entrance. It would seem that the bladder was not perforated originally by the shot, for no vesical trouble appeared until about a year before the patient's admission. — *Philadelphia Medical News*, September 13.

Treatment of Hæmorrhoids by Forced Digital Dilatation.—In relation to Professor Verneuil's paper on this subject (*Medical Times*, July 19, p. 93), M. Charles Monod, *agrégé professeur*, writing to the *Gazette des Hopitaux*, in warm approval of the views expressed in that paper, observes that treatment by dilatation has now become the habitual practice of the younger surgeons. But he adds that he does not think that we should accept a qualification of the practice that is always observed, and is advocated by Professor Verneuil himself; and that is, in case of gangrene having occurred or being about to take place, the application of dilatation should be deferred, as after the slough has come away the relief of the strangulation of the hæmorrhoids which produced it will occur. The suffering of the patient is of too dreadful a character and a radical cure of such immediate importance, that M. Monod advises that, in spite of this complication, the dilatation should at once be proceeded with; and he relates an important case in which this condition existed in a very aggravated form, producing the most horrible suffering, that no anodynes relieved, and which was instantly remedied by dilatation, the disease being also completely cured at the same time.

Fat Embolism.—Dr. Park, Professor of Surgery, University of Buffalo, reports in the *New York Medical Journal*, August 16, two examples of this and takes an elaborate survey of the literature of the subject. He concludes as follows: "In the light of these and numerous other cases, and of careful experiments and pathological investigations, we are justified in formulating the following conclusions: (1) Fat embolism in varying degrees of severity is not an uncommon complication of surgical accidents and operations. (2) It may be so mild as to be lost sight of in the general condition of shock, or, perhaps, more properly speaking, it is one factor of a condition of prolonged shock. (3) Our knowledge of the subject will be greatly increased when we appreciate the possibilities of its occurrence and observe our cases more closely, watching for the appearance of fat in the urine of slight dyspnœa, &c. (4) When prostration and loss of blood have been great, a moderate amount of embolic disturbance of this kind may serve to turn the scale against a patient who would have otherwise recovered. (5) By a proper understanding of this subject, certain deaths may be explained which otherwise seem inexplicable. (6) Treatment can only be symptomatic, but may accomplish something. (7) Autopsies should be so conducted as to reveal this condition when present."

Plaster Supports.—Yet another mode of applying splints and supports of plaster of Paris is described in a recent number of the *Boston Medical and Surgical Journal*: — Three, four, or five pieces of gauze of the size required are taken, and on these is laid

another piece of the same length but three or four inches wider: these are all stitched together along the middle of their length, so that the seam shall extend up and down the middle of the completed support: cosmoline is rubbed into this seam in as narrow a line as possible; and the layers of gauze are then held up to the part and trimmed to shape if necessary. The plaster being mixed to the consistency of cream, and while an assistant holds the gauze up to the part, the first layer is brought down smoothly and filled with plaster, then the next, and so on until all have been laid and filled with plaster; the edges of the widest layer are then turned over the others, thus forming a binding and a smooth edge. Such a support is light and strong: and when it is necessary to remove it, it may be ripped open along the seam as easily as a piece of cloth.

Surgical Employment of Sub-Carbonate of Iron.—In an article in a recent number of the *Journal de Médecine* of Brussels, Dr. Timmermans calls attention to the great advantages possessed by the sub-carbonate of iron in the treatment of wounds and ulcers, and especially when these last are chronic, as it causes too much pain as long as any inflammation is present. He regards it as efficacious as iodoform, without its disagreeables and dangers. In recent wounds it arrests hæmorrhage and hastens cicatrisation, and recent ulcers due to excoriations or contusions are rapidly healed. After the ulcer has been washed and dried, its surface and edges are covered with a layer of the powder from one to three millimetres in thickness, over which is placed a pledget of charpie or lint, and a bandage. During the first days the dressing is renewed from two to three times a day, according to the amount of discharge. Care must be taken not to allow of accumulations of pus, it being necessary that the iron should be in direct contact with the ulcerated surface.

Surgical Treatment of Stricture of the Œsophagus.—Professor S. W. Gross, from a review of the cases which have been published, arrives (*American Journal of the Medical Sciences*) at the following conclusions:—(1) Two hundred and seven gastrostomies have afforded 61 deaths as the result of the procedure, being a mortality of 29·47 per cent., and had prolonged life for 82 days on an average, at the date of the last reports. (2) Thirty-two œsophagostomies have yielded nineteen deaths, a mortality of 59·39 per cent., with a mean life of 52 days. (3) Nineteen internal œsophagostomies indicate six deaths, or a mortality of 31·57 and an average life of 256 days. (4) Five combined œsophagotomies have resulted in two deaths, a mortality of 40 per cent., and a mean life of 168 days. (5) Five œsophagectomies have afforded three deaths, a mortality of 60 per cent., and an average life of 50 days. (6) Three retrograde divulsions, up to the date of the last reports, show a mean life of 22 days, all having been successful. (7) Hence, 271 examples of operative interference have yielded 91 deaths, or a mortality of 33·58 per cent., and an average prolongation of life of 90 days.

Traumatic Cephalhydrocele.—Dr. Conner read a paper at the American Surgical Association (*American Journal of the Medical Sciences*), founded on two cases of cerebro-spinal fluid after fracture of the skull, and on a consideration of the previously published cases. He terminates it as follows:—(1) Simple fracture of the vault of the skull may give rise to a collection under the scalp of the cerebro-spinal fluid, coming, it may be, only from an opened ventricular cavity. (2) Such traumatic cephalhydrocele may be developed quickly, or only after the lapse of a number of days or even weeks. (3) The condition is one that has been thus far only noticed in young subjects. (4) The accident is quite likely to prove fatal from lepto-meningitis or meningo-encephalitis. (5) Operative interference should be restricted to the removal by aspiration of a limited amount of fluid, and such aspiration should be made only when severe symptoms of pressure have manifested themselves. (6) A similar fluid accumulation may occur after the closure of the external wound of a compound fracture of the vault or of a trephining.

PHARMACOLOGY AND THERAPEUTICS.

Antipyrin.—Dr. Huchard terminates a lecture on the Therapeutics of the new antipyretic, Antipyrin, which he delivered at the Hôpital Bichat (*Union Médicale*, November 29 and December 6), with these conclusions:—(1) Antipyrin constitutes a powerful and certain means of lowering the temperature in almost all febrile diseases, as typhoid fever, pulmonary phthisis, pneumonia, pleurisy, acute articular rheumatism and cerebral rheumatism, angiocholitis, erysipelas, diphtheria, puerperal fever, scarlatina, phlegmon, abscess, &c. It mitigates the symptoms which are due to the pyrexia, acceleration of the pulse and respiration, dryness of the mouth, &c., but it does not seem to possess any *direct* action on the respiration and circulation. (2) It is an antipyretic, but not an antiperiodic, whence its inefficacy in intermittent fevers as a *preventive* of the paroxysms. (3) Its administration only gives rise to slight and occasional complications, such as moderate sweating, pharyngeal constriction, slight nausea or vomiting, and in some relatively rare cases to a rubeoliform or scarlatiniform eruption. No tendency to collapse is produced, nor any intoxication such as is caused by preparations of cinchona and salicylic acid. (4) Numerous observations have demonstrated that it constitutes a powerful, and up to the present time the sole, means of efficaciously lowering the temperature in tuberculous subjects. After a dose of two grammes, administered especially in the evening at the time of the recurrence of fever, the temperature falls half a degree centigrade, by the end of half an hour and sometimes after a quarter of an hour. It then diminishes progressively, until the normal temperature is attained in an hour-and-a-half or two hours. It is, however, sometimes necessary to prescribe an hour or two later another dose of one or two grammes; but in phthisical subjects it, in consequence of the very certainty of its actions, and with the aim of avoiding accidents that may be induced by hypothermia, should only be administered in small and increasing doses, as from two to four grains. (5) The antithermic effect is ordinarily maintained in these patients for from six to nine hours, and is sometimes perceptible on the following day, during which the temperature does not regain its previous height. The subsequent rise of temperature takes place progressively, resembling in that the course of the defervescence. It is never sudden, as with kairin, and is never accompanied, like the latter substance, with more or less prolonged shivering. (6) It is eliminated in the urine, in which its presence is recognised two to four hours after its administration during a period of from 30 to 48 hours. Some drops of perchloride of iron poured into urine of patients taking this medicine immediately produces a highly characteristic red colour. (7) Dr. Huchard cannot speak from his own experience as to its effects in typhoid fever; but he is disposed to regard the doses of from six to eight grammes per diem, recommended by various observers, as excessive, as in several of the cases in which they had been employed a condition of hypothermia has been induced, the temperature falling to 35° or 36° C. In typhoid fever, also, the temperature, after having been lowered, will about the fifth or sixth day rise again a degree centigrade for about an hour, after which time it resumes its regularly descending progress. Dr. Huchard has also noted the same temporary ascent of the temperature during the apyrexia, due to action of antipyrin on the fever of phthisis.

Apocynum Cannabinum.—Canadian or American-Indian hemp bark has a very persistent bitter taste, and contains tannin and gallic acid. It is sometimes emetic and causes diaphoresis, and is cathartic, like jalap. It promotes expectoration, also drowsiness, increases urinary secretion and diminishes the force and frequency of the pulse, like aconite or digitalis. It is most used in dropsy, and as a tonic and alterative in dyspepsia. Dose of powdered root 5 grains as an anti-periodic, 20 grains as an emetic. Decoction of ʒ j to O j ss water and boiled down to a pint—a wine-glassful three times a day as a diuretic, or ʒ j of the bark of the root in ʒ viii of water, half an ounce every six or eight hours. This is one of those remedies that should

always be thought of in obstinate cases of cardiac or hepatic dropsy. Its diuretic action is frequently prompt and even extraordinary. It is, however, so disagreeable in taste to some persons that they cannot be induced to take it. A large addition of chinaphila or winter green, aids its diuretic powers and improves its taste.—*New York Medical Record.*

Hypodermic Medication.—Dr. Moriee, at the meeting of the French Association, read a paper, recommending hypodermic injections as the best mode of administering various remedies when we wish to produce a rapid general action, or limit the action of the substance employed to a given point. He cites some cases of obstinate intermittent, in which the patients had taken ineffectually large doses of quinine, but were relieved by small injections (10 centigrammes) of sulphate, sulpho-vinate or bromhydrate of quinine. He also recommends injections of ergotine, peptonates of iron, and mercury, these substances being thus absorbed more easily than when swallowed. For the treatment of neuralgias, and sciatica among others, Dr. Morice has found injections of salt and water (one or two per cent.) useful; or in severe cases injections of alcohol, ether, or nitrate of silver (one-fifth to one-tenth) should be employed. These irritant injections act as minute blisters or moxas, and may induce small abscesses, which are of no consequence. The injection should be stronger in proportion as it is made nearer to nervous centres. For injections intended for rapid and general action the solution should be perfectly neutral.—*Gazette Hebd.*, September 12.

The Chloride of Gold and Sodium.—Dr. Roberts Bartholow has lately been vaunting the use of the double chloride of gold and sodium (*New York Medical News*, August 2). He has studied its alterant effects, its actions on the nervous system, and on the genito-urinary system. He advises the use of one-twentieth of a grain twice or three times a day, and he states that under its use considerable improvement may be seen in cases of posterior spinal sclerosis and chronic interstitial nephritis. Hypochondriasis, coincident with the onset of degenerative changes in the cerebral vessels, and certain affections characterised by spasm, as asthma, laryngismus stridulus, and singultus, are also benefited by its employment. He also speaks highly of its efficacy in cases of sexual debility, accompanied by hypochondriasis, in dysmenorrhœa with scanty menstruation, and in chronic metritis.

Decisive Employment of Important Remedies.—In describing a case of purpura hæmorrhagica, occurring in a little girl, which was combated successfully by large doses of quinine administered in enemata, Professor Thiry, of the St. Pierre, Brussels, took occasion to repeat a proposition of which he had frequently had occasion to point out the extreme importance in relation to the employment of active remedies in severe diseases. "Whenever," he said, "you have been able to establish your diagnosis with certainty, and that the indications demand the employment of quinine or any other heroic remedy, act promptly and without hesitation, and if the disease resist oppose to it persistence in the remedy. It is in this way alone that you will carry off victories, unknown to those who, not possessing any convictions, invoke the intervention of a whole crowd of various remedies, to which, in most cases, they do not give sufficient time to produce their salutary effects, even when they are able to produce such."—*Presse Méd. Belge.*

Chloral Hydrate as a Vesicant.—Powdered chloral sprinkled on adhesive plaster, and melted by a gentle heat (not more than enough to cause the plaster to adhere) is applied while warm to the part. Within a few minutes a gentle warmth is felt, increasing for a short time and then gradually easing off, so that at the end of ten minutes all pain has ceased. As soon as it has ceased the plaster is removed, and a surface is disclosed as effectually blistered as by cantharides after six hours. Thus in about ten minutes the work of an ordinary blister is accomplished with the advantages over this of rapidity of action, ease of application, and the non-occurrence of strangury. The plaster may also be left on without dressing until it comes off of itself.—Dr. Fauntleroy in *Southern Clinic.*

Datura Stramonium in Painful Affections of the Joints.—Dr. Wyman, Professor of Physiology at the Michigan College of Medicine, states that for several years past he has been in the habit of applying green leaves of the datura stramonium to joints suffering from pain from various causes, and that the results have been most satisfactory. The joint is wrapped in the leaves during a period of 24 hours, when fresh leaves are applied. All that seems necessary is to invest the inflamed joint with a layer of leaves thick enough to shut out the air and prevent surface evaporation. Profuse perspiration from the skin of the part follows, and pain and swelling usually vanish. When the leaves could not be got, stramonium ointment proved no substitute.—*New York Medical Journal*, September 20th.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, December 9, 1884.

Dr. Overend Priestley, Vice-President, in the Chair.

On the Distribution of the Tubercle Bacilli in the Lesions of Phthisis.

Dr. Percy Kidd communicated a paper on this subject based upon an examination of 80 cases. These included two cases of malignant disease of the lung, two cases of sacculated bronchiectasis, and one case of dysenteric ulceration of the intestine. With these exceptions all the cases were described as "tuberculous." In more than half the cases the lung was examined, in twelve cases the larynx or trachea, in thirteen the intestine, and in thirteen lymphatic glands. Various other parts were examined in a few instances. With regard to the lung, the object kept in view was to examine the various lesions comprised in the phthisical process, and to ascertain their connections with the development of the tubercle bacilli. These bacilli were invariably found in pulmonary cavities, and in nearly all cases in softening caseous material, provided that the morbid process was associated with a tuberculous affection. On the other hand, the fœtid-cavity contents in two cases of sacculated bronchiectasis contained numerous micrococci, but no tubercle bacilli. In most instances these bacilli were detected in the nodular lesions of phthisis, though their number was almost always small, whereas in the three cases of acute miliary tuberculosis examined they were in many nodules very abundant. He thought it probable that in all cases, whether of acute miliary tuberculosis or phthisis, some stage of the growth of the nodules was associated with the presence of these micro-organisms. The distribution of the bacilli in the so-called caseous pneumonia appeared to be very irregular. Generally speaking, where the caseation was uniform and firm no bacilli could be found. But where the caseous process was commencing, or where softening was going on and microscopical cavities were present, bacilli were often seen in great numbers. Where the caseation was recent, bacilli were usually scattered among the caseating epithelioid cells, whereas in the later stages they were more often collected in groups, and their distribution was very circumscribed. In this as well as in the nodular form the bacilli were usually situated in the caseating alveoli, more rarely in the alveolar walls. Both in the nodular and caseous pneumonic forms bacilli were often found in the infiltrated walls of the small bronchi. Where fibroid induration was pronounced no bacilli were found. Their presence or absence in caseous material seemed to depend mainly on its age. The older the caseation the less chance that bacilli would be present, unless softening took place, when their appearance was certain sooner or later. It seemed probable, as Koch suggested, that the spores of the bacilli might lie dormant for a very long time, and when suitable conditions were provided

the spores developed into mature bacilli. In the larynx, intestine, and lymphatic glands the presence of the bacilli seemed to depend on similar conditions. The fact that the same micro-organisms were found in tuberculous disease of such remote parts as the pia mater, peritonæum, lung, intestinal and genito-urinary tracts, showed that their association with tuberculosis could be no accident.

Dr. CREIGHTON considered the paper a very good one; any paper which recorded a careful microscopical examination of 80 cases involved a great amount of labour, yet it neither added to, nor took away from, Koch's own arguments and the conclusions at which he had arrived. The bacilli were most numerous in the walls of the cavities, and in the moist secretions; while in glands which were undergoing dry necrobiotic changes, these bacilli were least numerous. Rod-shaped organisms were present, he said, in all the granulomata. He criticised some of Koch's methods of separate culture.

Dr. THEODORE WILLIAMS thought that Koch had not arrived at quite the same conclusions as Dr. Kidd with regard to the giant cells, and he enquired whether Dr. Kidd had observed how these giant cells were destroyed by the bacilli?

Mr. J. B. SUTTON remarked that the "giant cell" was a well-known histological puzzle; its connection with tubercle bacilli added a further interest to its significance. In sections of tubercle, this cell, when present, frequently contained bacilli; and in the lesions found in the liver of birds affected with the so-called "avian tuberculosis," the giant cell was a very frequent constituent, and always crammed with bacilli. A little inhabitant of our ponds and ditches, known as the "water flea" or daphnia, was covered with a thin transparent shell through which it was possible to watch all the movements of the heart, intestines, &c. When living in stagnant water this shell often became coated with a fungus, which was evidently an annoyance, for the daphnia rid itself of the enemy by casting its shell. Dr. Elias Metschnikoff, of Odessa, had made some interesting observations on a singular spore-disease which attacked some daphnia kept in his aquarium. The blood corpuscles of this insect, like those of other invertebrates, were colourless and moved about in lacunar spaces. When these spores gained entrance into the tissues of the daphnia, the corpuscles attacked them and digested the spores; but if a spore was too much for one cell, two, three, or more assisted and *fused to form a giant cell* and repel the invaders. It thus became a combat between the blood cells and spores. If the cells conquered the spores, the daphnia lived; but if the invaders conquered, then the daphnia, over-run with spores, died. This question was interesting, he said, for it seemed to afford evidence in support of the notion that the giant cell, in its relation to bacilli, was an attempt on the part of the organism to rid the tissues of a parasite inimical to the animal whose body they infested.

Sir ANDREW CLARK congratulated the author on his honest and cautious work. He could not quite accept the idea that the presence of the bacilli accounted for the entire phenomena of phthisis: even the anatomical side was not perfect; while as to the clinical, the phenomena were quite inexplicable when we tried to account for them by the bacillus. He asked what was meant by phthisis, and then gave his own definition: that assemblage and progress of symptoms associated with or dependent upon the ulcerative or suppurative destruction of more or less circumscribed, non-malignant deposits in the lungs. There was a condition of chronic ulcerative interstitial—or fibroid—lung which ulcerated and gave symptoms not distinguishable from phthisis, but in which, nevertheless, there were no bacilli. Again, in a few cases of general tuberculosis, bacilli, according to his experience, could not be found. On the other hand, in a certain number of cases of caseous pneumonia, with a life history quite unlike that of phthisis bacilli might be found. He contended that the criteria of a disease were found in the life history, and not in the anatomical characters; the disease was a series of conditions alternating, influencing, surrounding each other, hence he was unable to admit a causal connection between them and the bacilli.

The discussion was adjourned until the next meeting of the Society.

SOCIETY OF MEDICAL OFFICERS OF HEALTH

FRIDAY, NOV. 21ST, 1884.

Dr. T. O. DUDFIELD, President, in the Chair.

The Supervision of Offensive Trades.

MR. ALFRED SPENCER read a paper on the Supervision of Offensive Trades, the number of which had, he said, greatly increased of late through the introduction of processes for the utilisation of materials formerly looked on as refuse or waste; and he could see no reason why legislation which had, in the case of some, proved of the greatest benefit to the public, while inflicting no injury on the industries themselves, should not be extended to others no less offensive but as yet exempted from all interference. The first legislative restrictions, so far as London was concerned, were contained in the Metropolitan Building Act of 1844, of which the 55th section provided, with regard to the trades of a blood-boiler, tribe-boiler, bone-boiler, fellmonger, tallow-melter, soap-boiler, slaughterer of cattle, sheep, or horses, and "*any other like business offensive or noxious*," that it should be unlawful *hereafter* to erect any dwelling within fifty feet of a building used for such purpose, or to carry on such business within the same distance from a dwelling, or forty feet from a public way. And as to existing buildings, it should become unlawful to carry on these trades within the prescribed distances "after the expiration of thirty years from the passing of the act "*except as hereafter provided.*" During the thirty years 1844–74 these provisions were rarely if ever enforced, and had they not been repealed they would have remained a dead letter from the complexity of the saving clauses and the amount of litigation that any attempt to carry out proceedings would have involved. But as the expiration of the thirty years of grace drew near the manufacturers sought and obtained the appointment of a committee of the House of Commons to "consider the operation of Clauses 55 and 56 of Act 7 and 8 Vict., cap. 84, and the best means of making provision concerning the offensive and noxious trades therein specified." The Committee recommended the repeal of these clauses, and the substitution of stringent rules and frequent inspection. The Government of the day took no action in the matter, but in 1874 a Bill introduced by a private member, and embodying the recommendations of the Committee, became law, as the "Slaughterhouses, &c. (Metropolis) Act, 1874." It repealed the clauses in question only so far as concerned the business of a soap-boiler, tallow-melter, knacker, fellmonger, tripe-boiler, and slaughterer of cattle; absolutely prohibiting the establishment in the future of those of a blood-boiler, bone-boiler, manure manufacturer, soap-boiler, tallow-melter, or knacker within the metropolis, but permitting those of a fellmonger, tripe boiler, or cattle slaughterer, "or any other business which the local authority may declare, by order confirmed by the Local Government Board, to be an offensive business," provided the sanction of the local authority had been formally obtained. It also provided for the enactment by the local authority of regulations for the conduct of these trades. There were at that time 1,429 licensed slaughterhouses, and about 200 other premises in which other offensive trades were carried on. By the exercise of extreme caution in granting new licences and the refusal to renew existing ones when the surroundings were unsatisfactory, the number of slaughterhouses had been reduced to about 800; but the bringing of new industries under the bye-laws had increased that of other offensive trades. To do so, however, the business must be *ejusdem generis* with those named in the Act, all of which, with one exception, were concerned with the utilisation of the skins, bones, fat, blood, or offal of slaughtered animals, the single exception being that of manure manufacturers, who *may* employ other materials exclusively or in part. Very few complaints had been made of late in respect of slaughterhouses, though neither they nor the bye-laws regulating them were all that might be desired. The next group of trades included those of leather tanning, fellmongering, glue and size making, which were chiefly carried on in Bermondsey, Southwark, and at Belle Isle in Islington, and

it was highly desirable that these should be aggregated as were the leather works in Bermondsey, where the neighbouring population were so identified with these industries that so long as the public health was unaffected they could not be felt as nuisances. A third group comprised blood-boiling, bone-boiling, manure manufacture, soap-boiling, and tallow-melting. The bye-laws in respect of these did not attempt to deal with the conduct of the business in detail, but only provided in general terms for the storage of offensive matters, and the carrying out of offensive processes in such a manner that no effluvia should escape into the surrounding air. Blood-boiling was, in London at any rate, practically obsolete, being superseded by better processes, but bone-boiling was an important industry often carried on in connection with soap-boiling, &c. It consisted in the collection of bones fresh and stale from butchers, knackers, marine store dealers, &c., which, after the shafts of the long bones that were available for turnery had been trimmed by a steam saw and set aside, were crushed in a mill and boiled to extract the fat. The crushed bones, until taken away by manure manufacturers and others, were usually stored in pits called bone holes. The boiling of more or less putrid bones was frequently productive of sickening odours, but the effluvia from the bone holes were especially offensive and pungent. Too often the buildings were ill-arranged and unsuitable, but there was no doubt that the nuisance could be minimised by the processes being conducted in a set of closed chambers, with a single door, and an exhausting shaft at the opposite end of the series. The effluvia might then be condensed, washed, and finally passed through a furnace. (Mr. Spencer here described somewhat fuller the arrangements he would suggest.) The manufacture of manure included a variety of processes from the mere mixing of fish offal with absorbents to the treatment of the same together with coprolites and other mineral matters with strong sulphuric acid. The latter, commonly known as the manufacture of superphosphates, was a most offensive process, but the work was mostly carried on outside of the metropolitan area, on the banks of the Thames. On account of the technical character and complexity of these processes the Board issued a number of suggestions illustrated with drawings of apparatus for the better regulation of the manufacture. These suggestions having been adopted and circulated by the Association of Artificial Manure Manufacturers had been productive of good elsewhere than in the metropolis. The manufacture of soap had of late undergone such improvement that it could scarcely be looked on any longer as an offensive trade. This, however, could not be said of tallow melting and gut-scraping, in which the guts were purposely kept until putrid, that the mucous membrane might be the more easily separated, and though some improvements had been made, gut scraping was without exception the most abominable of all. It was of the highest importance that the inspector should be able to acquire an insight into the practical working of all the manufactures with which he was brought in contact, that his suggestions might be listened to with attention and respect, and it was the practice of the inspectors under the Board to meet periodically for interchange of ideas, and to acquaint themselves with the latest improvements as well as to ensure uniformity of procedure. If they could thus speak with the authority that comes from knowledge, and at the same time exercise judgment and tact, they would find that they were generally received as friends and advisers, and their visits looked forward to with pleasure. It was highly important to convince the manufacturers that the improvements by which the nuisances were abated would nearly always prove sources of additional profit, in short, would pay; and, not less, to gain the goodwill and confidence of the workmen. But the inspections to be of use must be made at all and often unexpected times, Sundays and nights not excepted. Judicious enquiries must be made of the neighbouring householders, and is was often very difficult to trace a nuisance to its true source, or to hit on the moment of its occurrence. In 1876–7 a Royal Commission was appointed to consider the case of manufactures giving off noxious vapours other than those they had been considering. Evidence was taken respecting a large number, but the only result was the Alkali, &c., Works Act of 1881, which regulated also sulphuric acid, gas liquor, nitric acid, and sulphate and chloride of ammonia works. It was, however, administered by the inspectors of the Local Government Board, so that the Board of Works had no jurisdiction here. A very general nuisance, and one from which nearly every suburban district suffered, was that of ballast burning and brick-making, the offensive odours being given off in the combustion of the dustbin refuse used as fuel, which contained much organic matter. It was not at present under any legal supervision, and the nuisance in question was inseparable from the process of burning in clumps, employed in the manufacture of cheap stock bricks. The kiln process used for making hard red bricks was more costly, requiring coal, but was free from all objection, carbonic acid and water vapour alone being given off.

A long and lively discussion, in which Drs. Dudfield, Corfield, Kelly, Iliff, Bate, Gwyn, and Saunders, Messrs. Murphy, Lovett, and Rogers took part, followed the reading of the paper, and Mr. Spencer replied at some length. Dr. Iliff's account of the utilisation of manure and street refuse by the Vestry of Newington was considered of such interest that he was requested to furnish the Society with a more detailed account of the methods adopted.

OBITUARY.

DANIEL JOHN DUIGAN, C.B., M.D.

DEPUTY INSPECTOR GENERAL OF HOSPITALS AND FLEETS.

AN old friend and comrade of this well-known Crimean medical hero has sent us the following notice of him :—Dr. Daniel John Duigan, C.B., Deputy Inspector General of Hospitals and Fleets, on the retired list, died on the 2nd of December at 63 years of age. He belonged to an old and much respected family in Kilkenny, was educated in Dublin and became F.R.C.S.I., M.D. of Aberdeen, and M.R.C.P.L. He entered the naval service in 1844, was employed for a year at Haslar Hospital, after which he served for seven years in the Mediterranean, in the *Hibernia* and *Queen*, flagships of Admiral Sir William Parker, G.C.B. In December 1853 he was appointed to the *Royal George*, whence he was transferred in April 1854 to the *Duke of Wellington*, and was engaged in the Baltic, in the operations at Bomarsund during the Russian War, being in all the most important boat operations by night and day, as well as in the assaults on batteries, in which his conduct gained the approval of Sir H. Jones, the Commanding Engineer. On returning to England he was ordered to join the Naval Brigade before Sebastopol and to take passage in the *Prince*; he escaped the dreadful fate of his fellow passengers by his alacrity in proceeding asbore to his appointment immediately the *Prince* arrived at Balaclava, on the eve of the total wreck and disappearance of the ship. Through the terrible winter, 1854-55, he served in the camp of the Royal Naval Brigade as surgeon-in-charge of its 2nd division hospital. On the return of spring, with the re-opening of the bombardment, he volunteered for service in the batteries and trenches, being the only officer of his rank, on leaving England, who was in that position ; from that time until the fall of Sebastopol, on the 8th of September, he was present in the batteries on the opening day of every one of the three great bombardments. On that of the fatal 10th of June, being confined to his tent by a severe attack of camp fever, he rose from his bed and proceeded at dawn to his proper post in the Diamond battery, under Sir William Peel's command, whose admiration he excited for his steady attention to the many sufferers during that eventful day, so far that his valuable services being recorded by that most distinguished officer, were approved of by the Commander of the Naval Brigade, Sir Stephen Lushington. His valour was equally conspicuous on the closing day of the siege—in fact, it may be said he was ever on the alert to be present at the point of danger, and was never behind time there. For these services he obtained the Sebastopol medal with

clasp, the fifth class of the Order of the Medjidie, the Sardinian and Turkish medals, and lastly, the decoration of Companion of the Order of the Bath, He subsequently served for two years in the *Vulture* in the Mediterranean from 1858 to 1860; in the *Mersey* on the North American and West Indian Station from 1860 to 1862; at Jamaica Naval Hospital for five years, 1862 to 1867; he was employed with the Royal Marines at Deal from May 1867 to July 1870, and in the *Agincourt* from August 1872 to February 1874, when he was appointed to Devonport dockyard, which appointment he held until he was placed on the retired list, with the honorary rank of Deputy Inspector General, in April 1876. Always exemplary for his kind, gentle, courteous demeanour to all around him, for his unswerving zeal and attention to his duties, and for his oft-repeated acts of self-denial, he was esteemed by his nearest friends and companions in arms as a gentleman and officer in a classical sense truly—*factus ad unguem.*

GENERAL CORRESPONDENCE.

OVER-PRESSURE IN ELEMENTARY SCHOOLS.

[To the Editor of the Medical Times.]

Sir,—Allow me to make a correction and a comment with reference to the letter of Mr. Roberts on this subject in your last issue.

(1) Mr. Roberts says that I "fall into the error of attributing to the schoolmaster the duties of making the necessary exemptions, and of believing that Mr. Fitch has done the same in his memorandum." This is in no wise the case. I simply took the facts as I found them; and *quoting* Mr. Fitch, who said that on a visit to schools containing 40,000 children the exceptions desired by the managers and teachers had been almost always freely sanctioned, I proceeded to show that the principle on which these exceptions are generally made is *no safety valve* against over-pressure in the medical sense; but is based generally on the *teacher's* views of the improbability of the children passing the examinations. It will not be denied that though the managers may have to sanction the exceptions, the schoolmaster practically suggests them. For this purpose the managers might just as well be non-existent.

(2) Mr. Roberts considers that my contention that the schoolmaster's exceptions do not remove the danger of over-pressure, upsets Dr. Crichton Browne's position as well as that of Mr. Fitch. This is an erroneous inference. Dr. Browne's report does not rest for its main support on what the teachers think or say, but on independent observations; and though Dr. Browne may be of opinion that some dull children are injured by the code, and some clever ones even kept back by it, he nowhere implies that the teachers' view of over-pressure is coterminous with his own, or that no clever children can be overpressed. There is no real *contradiction* between my statements of what I have observed, and Dr. Browne's general views.

It is somewhat difficult to understand Mr. Roberts' position from his rather pointless and hair-splitting letter on this matter; but he practically concedes that the present system in no way provides for any adequate carrying out of the exemption clause of the Education Code. This is exactly what I have endeavoured to show. And, as to Mr. Roberts' warning that the question of over-pressure is a complicated and difficult one, all your readers will remember that this point has been prominently and repeatedly emphasized by yourself and by some of your correspondents, no less than the necessity of some kind of medical inspection should an earnest and impartial and not wholly medical inquiry prove that the *primâ facie* case of over-pressure made out by Dr. Crichton Browne is a real evil that can be practically dealt with by such means.

I am, Sir, Yours, &c.
H. B. DONKIN.

HINTS AS TO PROFESSIONAL CONDUCT.

[To the Editor of the Medical Times.]

Sir,—I hope you have read with as much appreciation as I have the article in last week's *Lancet* on doctors and their female patients. To my mind the writer—and we ought to be grateful for enjoying the services of so faithful and outspoken a mentor—only commits one fault, and that is a fault of omission. He is too vague, and fails to give advice on many little points of professional conduct on which, I am sure, advice is much needed by our junior practitioners. There are many young doctors now entering upon practice who, never having passed through an apprenticeship like their predecessors, have no idea, and no one to advise them, how to comport themselves when they visit a well-to-do patient, for as the *Lancet* justly observes, there is (or ought to be) all the difference in the world between a professional visit and an afternoon call. May I, therefore, trespass on your space a little, while from the experience of a long and varied life, against which never an aspersion has been breathed, I supplement the incomplete counsel of your contemporary. If all practitioners would bear my advice and that of the *Lancet* in mind, the profession, I am sure, would never have to sigh over those unfortunate cases which have been of late so frequent. Without further parley, then, let me state that danger begins on the doorstep. How shall the young practitioner announce himself? In a good neighbourhood he sees before him two bells, marked "visitors" and "servants," and a knocker. He has thus, I calculate, according to the theory of combinations, seven ways of announcing himself; which is it proper for him to choose? My own practice has been to ring the visitors' bell gently, though even that, when calling to see one of the servants, has seemed to me to savour of impropriety. But whatever course the young doctor may choose, let him, above all things, beware of using the knocker. That would imply a familiarity with the family, the very suspicion of which it behoves the circumspect practitioner to avoid. So long as he confines his manipulations to the bell handle he is safe. The next problem that confronts him is, what to do with his hat. Following the custom of other men who have business in the house, he should by rights leave it in the hall, not on the floor, but on the hall table. This course, however, may involve him in serious danger. If there are children about the house, they may be counted upon to play with it, perhaps to march into the drawing room with it on their heads—a complication which, I need hardly say, as being evidence of undue familiarity, would be of the gravest import. My own plan has always been to take my hat with me, and only to relinquish it when the clinical investigation of a case rendered such a course absolutely necessary. Familiarity is impossible so long as the hand keeps touch of the beaver. It is an almost impregnable rampart, and would take the sting out of anything that tale-bearing domestics might say hereafter. The ethics and etiquette of hand-shaking form a most difficult subject. As a rule, I agree with the *Lancet* that it is best to avoid it. If a lady of title offers two jewelled fingers, the young practitioner would be at once foolish and rude to decline to take them, but the touch should be cold and momentary. With the wives of commoners it will be best, if it can be done without obvious rudeness, to bow formally, instead of offering to shake hands, both on entering and leaving. It is in the nursery that the greatest circumspection is required. It is a very common occurrence for young infants, not yet skilled in the differentiation of the members of a sex of which they see but little, to greet the young doctor by a title to which he can have no claim. What is the poor unprotected practitioner to do? In my opinion, he should at once assume a dignified deportment, and gravely expostulate with the young offender; otherwise his silence may be misconstrued, possibly to his serious disadvantage. There are many more hints I should like to give, but I fear that I have already trespassed too far upon your space.

I am, Sir, yours, &c.,
A PRACTITIONER
Of Fifty-one Years' Standing.

MEDICAL CONSULTATIONS.

No. V.—REFLEX THERAPEUTICS.

SCENE—*A library in South Kensington.*

DRAMATIS PERSONÆ.

M.D., OXON.—*A physician of the old school.*
M.R.C.P.—*A physician of a new school.*
L.R.C.P.—*A general practitioner of no school in particular.*[1]

M.D., OXON. And what have you been doing for the poor girl?

L.R.C.P. What is there to do? We have fed her, kept her warm, and done our best to relieve individual symptoms. She implored us to stop her night sweats, and by M.R.C.P.'s advice I gave her atropine. It acted like a charm, but the cough got worse and diarrhœa set in. So we were driven to opium. Then the sweats came back worse than ever, and we again resorted to atropine, then back to opium, and so on; the one drug always bringing back the night sweats, and the other the diarrhœa.

M.R.C.P. I admit the sequence, but not the consequence. Our friend is too ready to jump from the *post* to the *propter*.

M.D., OXON. Strange! Usually we doctors are more prone to make the jump when the sequence of events is favourable. We leave the converse to our patients.

M.R.C.P. We should be most cautious in avoiding either. Here, no doubt, the opium increased the perspiration, but I want clearer evidence to prove that the atropine brought on the diarrhœa or the cough. My explanation of the facts is this. You stop her night sweats, and she wakes feeling much better, or, as she herself aptly puts it, much less washed out; she eats more heartily in consequence, and with her vulnerable mucous membrane of course gets diarrhœa. The atropine again gives her a comfortable night, and her increased cough simply means that she has to make up for lost time in getting rid of her secretion. I have given atropine in hundreds of these cases, and never knew it increased the other troubles.

M.D., OXON. I regret to say that my experience is different, in respect not only to atropine, but to most other drugs given to relieve a special symptom. We are on ticklish ground, remember, when we lose sight of the general indications, and are driven to treat particular phenomena. How can you or I tell what is the meaning of this or that symptom, or what amount of harm our gratuitous tampering with one wheel in the delicate clockwork of a human body may do to the remainder? See what the poor untutored layman does! He feels overwrought, sick, miserable, and instead of asking himself what has caused it—has he worked, has he eaten, has he slept too much?—flies at once to the remedy which he knows will remove his trouble—alcohol; till, with repetition, his act becomes an almost unconscious habit, a secondary automatic, in one word, a reflex phenomenon. I am disposed to believe that there is a good deal of this reflex prescribing amongst the new school of therapeutists.

M.R.C.P. You are somewhat hard on us. Yes, I am proud to admit that I am of the new school. We may fall into errors, we may ride our hobby now and then too far, but when you consider that the treatment of disease remained absolutely stationary for centuries, and only began to advance when the new school came in—that within the few short years that it has been at work it has discovered and forced into general use nitrite of amyl, nitro-glycerine, salicin, pilocarpine, apomorphia, kairin,—and, greatest triumph of all, cocaine—you must admit that it has some claim to your consideration.

M.D., OXON. Stay, you mistake me. I have the greatest respect for those who are studying drugs scientifically. I am afraid I am too old myself to be likely to see the practical result of their work. But they are finding out *facts*, and facts are always worthy of reverence. It may never be of much practical service to know that this drug lowers the blood-pressure, and that one sets the sweat glands to work; but each is after all a scientific fact, and as such I bow to it. What I protest against is the hasty and inconsiderate use of such facts on the patients who are committed to our care. It is not sufficiently borne in mind, I think, that the knowledge and power of disposing of these potencies doubles the responsibility of the practitioner.

M.R.C.P. Granted; but is it right to shuffle off responsibility, as the expectant physician does, by believing in nothing and doing nothing? From my standpoint that would be assuming responsibility—a terrible responsibility—not getting rid of it.

M.D., OXON. I repudiate the title of "expectant" physician, unless by it you mean that I expect more of nature than you perhaps do. I am quite prepared to treat urgent symptoms—pain especially—when there is clear need of it. Practically, I doubt if there is much difference between your prescriptions and mine, and I should be sorry if you were to think that my strictures were aimed at you. You, of course, who have worked at the subject, do not prescribe thoughtlessly; with full knowledge you weigh the case, you consider the indications, the *juvantia* and *lædentia*, you seek out and try to remove the cause, you act in a word in every way as a philosophical physician should do, and if you see that symptoms must be treated, you treat them with one of the many agents that the researches of yourself and others have placed in your hands; but never, I take it, do you forget that in treating a symptom you are not treating the disease. No, my remarks were aimed at the credulous, indolent and ignorant followers of your school. Here lies the danger. Every case that comes before you, properly advised, means thought, an active expenditure of nerve force, a going-out of virtue from you. As human nature is constituted it must often happen that such an effort will be unpleasant—an effort to be avoided. Now, your new school has provided us with a number of short cuts, royal roads whereby we may satisfy our consciences that we are reaching our goal, that goal being not seldom the satisfaction of the patient, the alleviation of his symptoms, the capturing his confidence by storm, leaving his permanent welfare to take care of itself. As regards the physician himself, the evil of symptom-treating is that it is too easy. He has done something, he has written a prescription, he has given relief, and that makes him forget all else that is to be expected of him.

M.R.C.P. Pardon me if I suggest that these are mere generalities, that you have given us no instances to prove them.

M.D., OXON. I can supply you with any amount. A young girl is sent to me by a general practitioner with headache. She pulls out a bundle of prescriptions. I know exactly what I shall find—Bromide, Bromide, Bromide; and I say to myself, reflex doctoring. The practitioner did not go to the trouble of a long investigation of the

[1] But by no means as Herr v. Goethe would have classed him—a fool on his own account (*Ein Narr auf eigner Hand*).

circumstance which caused that particular symptom. No, he took the short cut from the headache cell to the bromide cell, pluming himself no doubt on his faith and skill in medicinal therapeutics.

M.R.C.P. O, that is merely a gross case of symptom-treating—a practice which the youngest clinical clerk knows how to avoid.

M.D., OXON. Well, what say you to this? A young man comes to me with slight albuminuria, and shows me a prescription from one of the most rising men of your school. What do I find? Nitroglycerine. Reflex doctoring again! A little more scientific than that of the general practitioner, but reflex for all that. The vascular tension is increased in Bright's disease, nitroglycerine will lower it, and so now and then relieve uncomfortable symptoms. Therefore, albuminuria and nitroglycerine are ticketed together, connected by a short cut in the brain, and the appearance of the one means the prescribing of the other. Shoulder, present, fire!

M.R.C.P. I am not concerned to defend every unthinking practitioner who misreads and misapplies our teaching. I simply contend that the alleviation of symptoms is as important a function of the physician as the removal of causes: indeed, in many of his cases, is all that is left to him to do. The expectant physician, because he cannot remove the cause, stands by inactive, and refuses to prescribe for symptoms, on the ground that it is unscientific. We, on the other hand, are not idiots enough to treat a symptom medicinally if we can cut the ground from beneath it in other ways, but we have discovered a list of remedies which are potent in relieving symptoms, and which, let me say, would never have been discovered, if all of us had belonged to the inactive and sceptical school. These drugs we do not hesitate to employ. Take the case you quote. A patient with chronic kidney disease comes before the expectant physician. Quite rightly he does his best to get the skin to work, to depurate the blood, to lighten the labour of the incompetent kidney. But meanwhile the patient is suffering, perhaps, agonies from headache and from dyspnœa. Your remedies give no relief. Then we step in and show that these troubles are bound up with increased blood pressure, and that one of the drugs discovered by us will remove that phenomenon, and with it relieve the symptoms. Then you turn round on us and call it reflex doctoring. I should be glad to know of any therapeutic expedient which has a better claim to be recognised as the outcome of a reasoned out process than that.

M.D., OXON. In the first instance I grant. But what I contend is, that the line once laid down with so much thought and care is afterwards used as a short cut. You, I take it, do not prescribe nitro-glycerine in more than perhaps 10 per cent. of your cases of albuminuria; but I know of men who, on your teaching, prescribe it in 100 per cent., and think that thereby they have done the utmost that science can demand of them. It never, of course, occurs to them to ask whether they are doing harm. Really, I fear that many wicked things are done in the name of your school. A short time ago I was asked to see a patient with typhoid fever, and how do you think his medical attendant was treating him? Why, with a scruple of quinine every morning, and with one night a hypodermic injection of atropine to check the perspiration, and the next night an injection of pilocarpine to bring it back. That is the sort of thing your school is responsible for. You have simply gone mad over fever. Your cry now is all for a safe and efficient reducer of temperature, which I could almost find it in me to wish that you may never discover. For what do we find now? Why, doctors all over the country, literally in awe of their clinical thermometers, intent on watching the excursions of a thread of quicksilver, in order to be down on it and duly chastise it with quinine or kairin or the cold bath, if it venture beyond the bounds which their preconceptions have fixed for it. Happily, perhaps, their efforts to restrain it are of little use; but have these go-ahead practitioners ever asked themselves what the pyrexia they have declared war against means? Has the possibility ever entered into their heads that their patients may be made worse by their meddlings? I will undertake to say that in every town in the country you shall find at this present time some doctor giving five, ten, twenty grains of quinine at varying intervals to some unlucky patient, simply because he or she has a temperature of over 102° or 103°, and perhaps a disease which they have not yet diagnosed. Now that is the distorted result of a perfectly rational teaching of your school, that if fever as such threatens to kill a patient, it can and must be brought down. You agree with me?

M.R.C.P. Perfectly on this last point, because we are both equally in the dark as to the indications in minor degrees of fever. You have no more ground for saying that quinine does harm in such cases than I have for saying that it does good. But our action is not so irrational as you seem to think. The aim of our researches is not to counteract the fever *quoad* symptom, but to nullify the cause on which it depends. Quinine does this in malarial fever, and I see no reason why we should not yet discover a drug which will do the same in continued fever. If it is ever discovered, it will be by the new school, and not, I will venture to say, by the expectants.

M.D., OXON. No; but let us hope that before you have discovered your antidote, we shall have succeeded in stopping all occasion for its exhibition. The rational treatment of fevers is prevention. And pray, what do you say to all this, Mr. L.?

L.R.C.P. I have no theories. We general practitioners are here to cure our patients, or to relieve them, for our own sake, if not for theirs. We must cure them, or else call you in to help us; and I must say that much as I enjoy the pleasure of meeting you, I am heartily grateful for any means whereby the necessity for it can be avoided. You see, we have to please our patients as well as to treat them. We cannot look down on them from your serene height, and so I fear we fall occasionally into reflex doctoring, which I may perhaps observe would never have become reflex if it had not been successful. By the way, I think they will be expecting us upstairs.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.

AT the ordinary meeting of the Council of the College held on Thursday, the 11th instant, the following elections were made:—To the Court of Examiners: Mr. Hulke (re-elected), Mr. Langton, and Mr. Pick. The following Examiners were appointed by this College to conduct examinations under the combined scheme:—*Elementary Anatomy*—Messrs. Davies, Colley, Gould, Mansell, Moullin, Black, and Reid. *Elementary Physiology*—Mr. Golding-Bird. *Anatomy*—Messrs. Howse, Owen, Godlee, and Bennett. *Physiology*—Messrs. Power, Baker, and Yeo. *Midwifery*—Drs. Galabin, Champneys, Herman, and W. A. Duncan. As Board of Examiners for the Fellowship

the following were elected:—*Anatomy*—Messrs. Howse, Anderson, Owen, Godlee, and Morris. *Physiology*—Messrs. Power, Baker, Golding-Bird, and Yeo. Sir James Paget, Sir Spencer Wells, Mr. Erichsen, and Mr. Marshall, together with the President and Vice-Presidents were appointed Delegates of the College to confer with an equal number of Delegates from the College of Physicians with a view to acquire, as conjoint tenants, a site in Long Acre for the erection of buildings for examination and other purposes. Mr. Marshall's motion to reduce the fee for the College Diploma (when granted under the combined Colleges) from 20 to 15 guineas was postponed in Mr. Marshall's unavoidable absence through indisposition.

THE MAHOMED FUND.

The following subscriptions, amounting to over £600, have been already promised or received:—

Professor Humphry, £50; Mr. Field (in instalments), £100; Mr. Burdett makes himself responsible for £100; Dr. Wilks, £26 5*s.*; Mr. Durham, £50; M.D., £25; F. D., £25; Dr. Chadwick (within six months), £50; Dr. D. Hood (in four instalments), £50; Dr. C. Grigg, £20; Dr. Cayley, £21; Dr. C. T. Williams, £10; Dr. Markham Skerritt, £10; Mr. Bryant, £10; Dr. Dyce Duckworth, £10 10*s.*; C. Bader, Esq., £10 10*s.*; C. A. Aikin, Esq., £10 10*s.*; Dr. E. Clifford Beale, £10 10*s.*; Dr. Goodhart, £15 15*s.*; Mr. Jacobson (in instalments), £15 15*s.*; Dr. Bright, Forest Hill, £5 5*s.*; Dr. W. Moore, Brighton, £5 5*s.*; G. Lawson, Esq., £5 5*s.*; Dr. Coupland, £5 5*s.*; C. Woolridge, M.B., £5 5*s.*; C. Macnamara, Esq., £15 15*s.*; H. W. Page, Esq., £10 10*s.*; the President of Guy's Hospital, £5 5*s.*; the Treasurer of Guy's Hospital, £5 5*s.*; Dr. Isambard Owen, £5 5*s.*; Dr. Douglas Powell, £3 3*s.*; Dr. Pitt, £3 3*s.*; G. Eastes, M.D., £1 1*s.*; Dr. Sharkey, £2; Dr. Shingleton Smith, Clifton, £1 1*s.*; A. B. R. Myers, Esq., Scots Guards, £1 1*s.*; T. Easter, M.D., £2 2*s.*; J. Wickham Barnes, Esq., £1 1*s.*; A. Jackson, Sheffield, £1 1*s.*

We are asked to state that subscriptions should be sent to Mr. Durham, Treasurer, 82, Brook Street, W.; or to the Secretaries, Dr. Goodhart, 25, Weymouth Street, W.; Mr. Jacobson, 41, Finsbury Square, E.C.

UNIVERSITY OF CAMBRIDGE.—On December 4th, the following degrees were conferred: M.D., John Maekern, Caius; M.B., Harold B. Shaw, Sidney.

ROYAL COLLEGE OF SURGEONS.—The following members of the College having undergone the necessary examinations for the Fellowship, at meetings of the Court of Examiners, on the 27th, 28th, and 29th ultimo, and on the 1st instant, were reported to have acquitted themselves to the satisfaction of the Court, and, at a meeting of the Council on the 11th instant, were duly admitted Fellows of the College, viz.:—

Messrs. Edward S. Bishop, L.R.C.P. Ed., Manchester; Alexander R. Anderson, L.S.A., Bond Street, Holford Square; Walter H. H. Jessop, B.A. and M.B. Cantab, Harley Street, W.; George L. Johnson, M.B. Cantab., Highfield Hill, Upper Norwood; Henry B. Tait, L.R.C.P. Lond., Highbury Park; Ernest G. Colville, Eastbourne; Joseph L. Hewer, M.B. Lond., Highbury New Park; Edwin F. White, L.S.A., Putney; Thomas H. Pounds, L.S.A., Snodland, near Rochester; John Cahill, L.R.C.P. Lond., Albert Gate; Walter C. Dendy, L.R.C.P. Lond., Forest Hill; Archibald Watson, M.D. Paris, Queensland; Thomas H. Morse, L.R.C.P. Ed., Norwich; William Bull, Bromborough, Cheshire; Robert B. Howard, L.R.C.P., Lond., Montreal, Canada; and James Wilson, M.D., Queen's University, Ireland, Maneymore, Derry.

Two other gentlemen passed, but their diplomas are retained until reaching the required age of 25 years, and twelve candidates having failed to acquit themselves to the satisfaction of the Court of Examiners were referred to their professional studies for twelve months. Thirty candidates were examined against seventeen the corresponding period last year. With this meeting the examinations for the present year were brought to a close.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, December 4th, 1884:—

William Amherst Henry Barrett, St. Thomas's Hospital; Isaac Rising Cory, St. Thomas's Hospital; Jno. Alfred Gray, St. Bartholomew's Hospital; Francis George Clifton Martin, London Hospital; Montague Williams Oldham, Guy's Hospital; Bernard Relton, St. Thomas's Hospital; George Francis Sydenham, St. Bartholomew's Hospital; Charles Henry Wade, London Hospital; Charles Yeoman, St. Thomas's Hospital.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Samuel Constable, Dublin and St. George's Hospital; Edward Soy, King's College.

UNIVERSITY OF DURHAM.—The following gentlemen satisfied the Examiners in the various examinations, viz.:—

Degree of Doctor in Medicine for Practitioners of fifteen years' standing—

Rowland Hill Coombs, L.R.C.P., M.R.C.S., L.S.A.; William Young Martin, F.R.C.S.

Degree of Doctor in Medicine (Thesis.)—

William Robinson, M.B., M.S., M.R.C.S.; William John Sheppard M.B.; Thomas Coke Squance, M.B., M.S.

Second Examination for the Degree of Bachelor in Medicine—

Frederick Martindale Blackwood, M.R.C.S., College of Medicine, Newcastle-upon-Tyne; Charles Robert Davidson, Westminster Hospital; Solomon Abraham Erulkar, Grant Medical College, Bombay, and College of Medicine, Newcastle-upon-Tyne; Alexander Harper, M.R.C.S., St. Bartholomew's Hospital; Frank James Malden, St. Bartholomew's and College of Medicine, Newcastle-upon-Tyne; Frederick Charles Mears, M.R.C.S., L.S.A., London Hospital; George Palmerston Newbolt, St. Bartholomew's Hospital; Reginald Pollard, St. Bartholomew's Hospital; George William Richards, London Hospital; William Slater, College of Medicine, Newcastle-upon-Tyne; Charles Edward Tanner, M.R.C.S., St. Bartholomew's Hospital; Mark Joseph Wakefield, College of Medicine, Newcastle-upon-Tyne; James Russell Watson, M.R.C.S., Charing Cross Hospital; William Harper Wigham, College of Medicine, Newcastle-upon-Tyne.

Degree of Master in Surgery—

Robert J. Irvine, M.B.

For the last-named examination there were four candidates.

ROYAL COLLEGE OF SURGEONS.—The following synopsis indicating the range of subjects in the examination for the diploma of membership of the Royal College of Surgeons will, no doubt, be read with great interest by Metropolitan and Provincial Teachers, viz.:—

SYNOPSIS indicating the Range of Subjects in the Examination on *Chemistry* and *Chemical Physics*.—I. *Chemical Physics*: Heat—Definition of Heat and Temperature; Thermometers; Latent and Specific Heat; Conduction, Conviction and Radiation; Expansion of Liquids and Gases; Tension of Vapours; Hygrometers. Light—Laws of its Propagation, Refraction and Reflection; Refraction through Lenses and Prisms; Formation of Images. Electricity—(Frictional Electricity) The two Electrical States; Conduction; Insulation; Induction; Electrical Discharge; (Voltaic Electricity) Simple forms of Batteries; Currents, their Heating and Chemical Effects. II. *Chemistry:* Mechanical Mixture and Chemical Combination; Elements and Compounds; Laws of Chemical Combination and Decomposition; Atoms and Molcules; Calculation of Quantities by Weight and by Volume; Specific Gravities; Diffusion; Acids, Bases and Salts; the more Imortant Elements and their Chief Compounds. Carbon Compounds—The Cyanogen Group; Alcohols; Ethers; Aldehyd; Acetic Acid; Glycerine, Fats and Saponification; Amylaceous and Saccharine Substances; Fermentation; the Principal Vegetable Acids and Chief Natural Organic Bases; the Chemical Constituents of the Animal Organism. Qualitative Analysis, including the Detection of Poisons.

SYNOPSIS indicating the Range of Subjects in the Examination on *Materia Medica, Medical Botany, and Pharmacy.—Materia Medica:* The Candidate shall be required to possess such knowledge of the drugs of the British Pharmacopœia as shall enable him (*a*) to recognise them, to refer to them their officinal source, and to state their general effects on the system; (*b*) to describe the physical and chemical characters of drugs derived from the Inorganic Kingdom; (*c*) to mention the active principles of drugs derived from the Organic Kingdom, and to give an account of the physical and chemical characters of such principals; (*d*) to state the impurities or adulterations to which the principal drugs in the Pharmacopœia are liable. *Medical Botany:* The Candidate shall be required (*a*) to recognise the officinal indigenous plants, and to exhibit a knowledge of the botanical and general characters of their Natural Orders; (*b*) to possess a general knowledge of the chief exotic products contained in the Pharmacopœia. *Pharmacy:* The Candidate shall be required to possess a knowledge (*a*) of the several Pharmaceutical Groups, such as Extracts, Tinctures, Infusions, &c.; (*b*) of the officinal preparations of the more important drugs; (*c*) of the essential ingredients in the more important preparations of the Pharmacopœia and the proportions of these ingredients in such preparations; (*d*) of the ordinary doses of the principal drugs and their preparations.

SYNOPSIS indicating the Range of Subjects in the Examination on *Elementary Anatomy.*—1. The Bones. 2. The Attachments of the Muscles to the Bones of the Upper and Lower Extremities.

SYNOPSIS indicating the Range of Subjects in the Examination on

Elementary Physiology.—1. The recognition, under the microscope, of the Elementary Tissues, namely:—(*a*) Fibrous (including Elastic) Tissues; (*b*) Adipose Tissue; (*c*) Epithelium; (*d*) Bone. (*e*) Cartilage; (*f*) Muscle; (*g*) Nerve-Fibres and Cells; (*h*) Blood. N.B. No Histology will be required beyond that which is included in the recognition of the above Tissues. 2. The phenomena of the Coagulation of the Blood. 3. The Course of the Circulation of the Blood, including the plan of construction and the action of the Heart. 4. The principal changes produced in the Blood and Air by Respiration. The plan of coustruction of the Respiratory apparatus. The movements of Respiration, and the means by which they are accomplished. 5. A general classification of Food, and the principles on which such classification is founded. Diet and Dietaries. 6. The principal changes which Food undergoes in the Mouth, Stomach, and Intestines. 7. An Enumeration of the chief constituents of the principal Secretions and Excretions. 8. The Temperature of the Body. The means by which it is produced and maintained. 9. The phenomena of Contraction in Striped and Unstriped Muscle. 10. The general plan of construction of the Nervous System.

The Library of the Royal College of Surgeons will be closed on the 26th and 27th of December.

Royal College of Surgeons in Ireland.—At a meeting of the Council, held on December 4th, the following were elected examiners in dental surgery for the ensuing year, viz.:—Edward Stamer O'Grady, M.A.; Henry Gray Croly, Henry G. Sherlock, J. Daniel Corbett, Robert Hazelton, and Richard Theodore Stack, M.D., Esqrs.

The Mater Misericordiæ Hospital, Dublin.—It is proposed to complete the very extensive buildings constituting this hospital by the erection of a large western wing. The hospital, constructed on the corridor system, was in part opened in 1861, and ten years later the eastern wing was finished, just in time to afford accommodation to 680 patients suffering from small-pox in the epidemic of 1871–72. It is now intended to collect a sum of 19,000*l.* to defray the cost of the completion of the buildings. When finished, the hospital will be the largest in Dublin. There was a meeting of sympathisers with the movement on Sunday last, and Cardinal MacCabe, the Roman Catholic Archbishop of Dublin, presided. A collection amounting to about 1,000*l.* was made before the meeting separated.

Charitable Bequests to Dublin Hospitals.—Mr. Robert Billing has left to the Hospital for Incurables, Donnybrook Road, 3,000*l.*; to the Meath Hospital, Heytesbury Street, 3,000*l.*; to the City of Dublin Hospital, Upper Baggot Street, 3,000*l.*; to the Cork Street Fever Hospital, 2,000*l.*; to the Rotunda Hospital, Great Britain Street, 2,000*l.*; and to the Adelaide Hospital, Peter Street, 2,000*l.*

Army Medical Staff.—A monumental brass to the memory of the officers of the Army Medical Department and non-commissioned officers and men of the Army Hospital Corps, who lost their lives in Egypt in the years 1882–3, has just been erected in the Chapel of the Royal Victoria Hospital, Netley. The memorial was raised by subscription among those officers of the Department and Corps who served in Egypt during that period.

The Surgical Aid Society.—On December 5th, the Lord Mayor presided at the 22nd annual meeting of the friends and subscribers of this society. He was sorry to hear that unless an additional 1,000*l.* per annum was forthcoming the society would be compelled to curtail its sphere of usefulness, but he would advise the governing body to appeal to the various city companies, who would, he was convinced, be only too pleased to support such an institution. The annual report, which was then read, mentioned that during the year 5,357 patients had been relieved, including 1,946 men, 2,585 women, 826 children. There was a total increase of 725 patients over the number relieved during the previous year, and this made an average of 103 per week. No less than 46,385 persons had been relieved since the foundation of the society, and the number of surgical appliances supplied during the same period was 61,644, of which number no less than 8,101 had been supplied during the past 12 twelve months. Special grants had also been made in 487 cases. The total income during the year was 6,380*l.* 4*s.*, and the expenditure amounted to 6,310*l.* 11*s.* 11*d.*

University Seats in Parliament.—Mr. Bryce proposes to move in Committee on the Redistribution Bill that the representation in Parliament of the English Universities shall cease, on the ground that such representation, while it has not benefited the country generally, has been found in practice injurious to the Universities themselves.

The Parkes Museum.—At the annual general meeting of the members held on Thursday week, the council reported with much regret that the museum was very greatly in want of funds, and urged upon the members to bring forward its claims for support, and to endeavour to obtain new members and donations from those interested in its work. Since the first establishment of the museum those who had been most interested in its progress had always hoped that it might grow into a health institution, established on a wide and truly national basis, and it was with great satisfaction that they had heard a rumour to the effect that such an institution might possibly be established as a result of the International Health Exhibition. The Council were confident that members would co-operate with them in furthering by every means in their power the realisation of so beneficent a scheme.

Aberdeen University.—At a largely-attended meeting of students of Aberdeen University held on the 5th instant, it was unanimously resolved to form a Students' Representative Council, to watch over the interests of the students. Representatives to the Council from the various classes of the Arts and Medical Faculties were then elected, and it was agreed to send intimation to the Divinity and Law Faculties, requesting them also to elect representatives to the Council.

The Paris Obstetrical and Gynæcological Society.—This Society has just been formed at Paris, and consists of 30 titular members, and of 70 national and foreign associates and correspondents. As the foundation members at present exceed in number the 30 titular members determined upon, there will be no new election until these have become fewer than 30. The officers of the Society are: Professor Pajot, president; MM. Alphonse Guérin and Gallard, vice-presidents; and M. Charpentier, secretary.

Cholera in France.—The Minister for Foreign Affairs has just issued a circular addressed to all French plenipotentiaries, ambassadors and consuls, instructing them to announce to the foreign powers to whom they are accredited that the epidemic cholera which has prevailed in France has now entirely disappeared, and requesting the removal of all quarantine regulations that have been applied to French commerce.

The Cholera Epidemic.—Dr. Collingridge, the Medical Officer of Health for the port of London, has been engaged in Paris in an investigation into the nature and characteristics of the cholera epidemic, the conditions under which it existed, and the special arrangements made for combating the disease, both as regards hospital and sanitary administration.

The English Cholera Commission.—Doctors Klein and Gibbes have completed their inquiries and submitted a short preliminary report. They state that Dr. Koch's comma-shaped bacilli are not peculiar to cholera, but occur also in other diseases of the intestines: that these bacilli do not behave in any way differently from other putrefactive organisms, and that inoculations of animals with recent and old cultivations of comma-shaped bacilli, as well as with cholera excreta, produced no effect.

The Hospitals Association.—There was a large gathering of members and friends of this association on Saturday evening at a *conversazione* given in the rooms of the Medical Society. The guests included several eminent members of the medical profession, together with the secretaries of the principal London hospitals.

Charitable Bequest.—Mr. E. Ralli has bequeathed £500 to St. Mary's Hospital, Paddington.

Errata.—Page 740, 2nd column, 4th paragraph, for "Between London and the Snowy-Range," *read* "Landour."

University of Edinburgh New Buildings.—The Earl of Home has just intimated a subscription of 1,000*l.* to the fund for completing these buildings. This and other similar donations that have been received since Mr. M'Ewan's munificent offer of 5,000*l.*, on condition of the balance of 10,000*l.* being raised before May, gives every promise that the requisite amount will be forthcoming. The Committee feel, however, that in order to contribute to this result further subscriptions of substantial amount will require to be announced, and they earnestly hope that this will be done.

Volunteer Medical Staff Corps.—This corps held its first general parade on Saturday evening in Westminster Hall, when nearly 300 officers and men out of about 500 on the books appeared in uniform before Surgeon-General Hunter, and went through stretcher drill. It is anticipated that the formation of this corps will be the means of furnishing a large trained reserve capable of affording efficient aid to the country in time of foreign war.

Recrudescence of Cholera in Italy.—There has been a serious outbreak of cholera at Tegiano, in the province of Salerno, where fifteen cases and five deaths are reported. This will somewhat delay the total abolition of quarantine between the Italian continent and the Islands of Sicily and Sardinia. The disease in the above-named Commune is, however, already on the decline.

APPOINTMENTS.

Brierley, Thomas Booth, M.R.C.S. Eng., L.S.A.—Medical Officer to the Tattenhall District, Tarvin Union, *vice* Mr. T. J. Proudlove, deceased.

Cresswell, Thomas H., M.R.C.S., and L.S.A. Lond.—Medical Officer to the Grassington and Kettlewell Districts, Skipton Union, *vice* Mr. J. Anthony, resigned.

Dodds, Dr.—Assistant Medical Superintendent of the Montrose Asylum.

Dunn, Thomas, M.B.—Assistant Medical Officer to Woodilee Asylum, Lenzie, *vice* William Gibb, resigned.

Emmerson, William, L., M.D.—Re-appointed Analyst for the Borough of Stamford.

Fitzmaurice, Richard, L.R.C.P., and L.R.C.S. Edin.—Medical Officer to the Third District, Cuckfield Union, *vice* Mr. W. E. Porter, resigned.

Francis, Lloyd, B.A., M.B. Oxon, M.R.C.S.—Assistant Medical Officer to Saint Andrew's Hospital for Mental Diseases, Northampton, *vice* E. V. Cooper, L.R.C.P.L., M.R.C.S.L., resigned.

Givan, Joseph.—Medical Officer to the Ballygawley Dispensary, Clogher Union.

Handfield-Jones, M.B., M.R.C.P.—Assistant Physician to the Chelsea Hospital for Women, *vice* Lendon, resigned.

Hardie, Robert, M.B., M.R.C.S.—Resident House Surgeon to the Gateshead Dispensary, *vice* Robert Purdie, M.B., C.M., resigned.

Harper, Gerald, M.D.—Additional Assistant Physician to the Chelsea Hospital for Women.

Holyoake, Ralph, M.R.C.S. Eng., L.R.C.P. Edin.—Medical Officer to the Hanbury District, Droitwich Union, *vice* Dr. S. S. Roden, resigned.

Peskett, A. F., M.R.C.S., L.S.A.—Assistant Resident Medical Officer at Stockwell Fever Hospital.

Stephens, L. E. W., M.R.C.S., L.S.A.—House Surgeon to the Bristol General Hospital.

Stonham, C., F.R.C.S.—Assistant Surgeon to the Cancer Hospital, Brompton.

Welch, Robert, M.R.C.S. Eng., L.R.C.P. Edin.—Medical Officer to the Workhouse, Southampton Incorporation, *vice* Mr. H. Bencraft, deceased.

VACANCIES.

Altrincham Union.—Medical Officer to the Lymm District, in succession to Dr. W. P. Brabazon, resigned. Area, 12,216 acres. Population, 6,583. Salary, £60 per annum.

Birmingham and Midland Eye Hospital.—House Surgeon. *For particulars see Advertisement.*

Depwade Union, Norfolk.—District Medical Officer. *For particulars see Advertisement.*

Durham Union.—Medical Officer to the Eastern District, in succession to Mr. E. S. Robson, resigned. Area, 11,282 acres. Population, 13,843. Salary, £45 per annum.

East Riding Asylum, Beverley, Yorks.—Assistant Medical Officer. Salary £100 per annum, with board, furnished apartments, &c. Candidates must be qualified, unmarried, and not above 30 years of age. Applications, stating age and qualifications, with not more than four recent testimonials, to be sent to M. D. Macleod, Medical Superintendent, before December 20th.

Portland Town Dispensary, Henry Street, St. John's Wood.—House Surgeon. Salary £80 per annum, with apartments, &c., and attendance. Candidates must be duly qualified, and will be required to dispense. Applications and testimonials to be sent to the hon. Secretary, 10, Ormond Terrace, Regent's Park, not later than December 13.

Ratcliffe Infirmary, Oxford.—Honorary Physician. *For particulars see Advertisement.*

Southmolton Union.—Medical Officer to the Seventh District, in succession to Mr. Timothy Daly, resigned. Area, 9,770 acres. Population, 1,455. Salary, £31 10*s.* per annum.

St. Mary's Hospital, Paddington, W.—Two Physicians. Candidates must be Fellows or Members of one of the Royal Colleges of of Physicians in the United Kingdom. Applications, with three recent testimonials, to be sent to the Secretary (from whom further particulars can be obtained), on or before December 13th.

The Guest Hospital, Dudley.—Two Honorary Surgeons.—Candidates must be Fellows, Members, or Licentiates of the Royal College of Surgeons of England, Edinburgh, or Dublin, and possess a registered qualification in medicine. Testimonials and certificate of Registration to be sent to the Secretary, on or before December 15th.

The Middlesex Hospital, N.—Assistant Physician. (*For particulars see Advertisement.*)

The Victoria Hospital for Children, Queen's Road, Chelsea, S.W.—House Surgeon. Salary, £50 per annum, with board, lodging and laundry. Candidates must be Fellows or Members of the Royal College of Surgeons, England, and Licentiates of the Apothecaries, or of the Royal College of Physicians, or Graduates in Medicine of any University recognised by the Medical Council. Applications, with copies of testimonials, to be sent to the Secretary, at the hospital, on or before December 13th.

Truro Union.—Medical Officer to the St. Agnes District, in succession to Mr. F. G. H. Whitley, resigned. Area, 14,600 acres. Population, 6,202. Salary, £45 per annum.

Watford Union.—Medical Officer to the Sarratt District, in succession to J. H. Bartlett, resigned. Area, 1,550 acres. Population, 690. Salary, £50 per annum.

DEATHS.

Banister, George, late Surgeon-General, Indian Army, at Eastbourne, on December 6th, aged 64.

Duigan, Daniel John, C.B., M.D., Deputy Inspector-General of Hospitals and Fleets, R.N., at 29, Edith Road, West Kensington, on December 2nd, in his 63rd year.

Gibson, J.B., M.R.C.S., at 9, River Street, Myddleton Square, E.C., on December 5th, aged 73.

Lay, J. J., M.D., M.R.C.S., L.S.A., at Peasenhall, Suffolk, on December 4th, aged 70.

Muscroft, Henry, M.D., at Pontefract, on December 5th, in his 55th year.

Robertson, J., M.D., M.R.C.S., F.C.S., &c., formerly of Rochester, at Bath, on December 2nd, aged 45.

NOTES, QUERIES, AND REPLIES.

MALOJA.

[TO THE EDITOR OF THE MEDICAL TIMES.]

Sir,—Will you allow me to state that the rumour of the closure of Hotel Kursaal de la Maloja, which has been so diligently circulated privately and by a portion of the Swiss press, is quite incorrect. The Kursaal (constructed especially for Alpine winter residence) will remain open the whole season.

I am, Sir, yours &c.,

Maloja, Upper Engadine. A. Tucker Wise, M.D.

APPOINTMENTS FOR THE WEEK.

Friday, December 12 (*this day*).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

The Parkes Museum, 74A, Margaret Street, Regent Street, 4.30 p.m.—Dr. Norman Chevers, C.I.E., on "Personal Precautions Against Cholera to be taken by each Individual; Panic; Food and Drink; Clothing."

University of London, Burlington Gardens, 5 p.m.—Mr. Victor Horsley's First Brown Lecture, subject—The Thyroid Gland, its relation to the Pathology of Myxœdema and Cretinism, to the Surgical Treatment of Goitre, and to the general Nutrition of the Body.

Clinical Society of London.—Adjourned Debate on Mr. Morrant Baker's Paper, "On Charcot's Joint Disease." Professor Charcot's specimens and others will be again on view.

Saturday, December 13.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, December 15.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

University of London, 5 p.m. Mr. Victor Horsley's Second Brown Lecture, subject—"The Thyroid Gland: its Relation to the Pathology of Myxœdema and Cretinism, to the Surgical Treatment of Goitre, and to the General Nutrition of the Body."

Medical Society of London.—Sir Andrew Clark, Bart., will read a Paper on "A Case of Relapsing Pneumonia in an aged man, with some observations on the nature of the Disease."

Tuesday, December 16.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2¼ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.

Pathological Society of London.—Dr. Wilks, "Intestinal Obstruction produced by Gall-stones;" Dr. Carrington, "Thyroid from a Case of Exophthalmic Goitre;" Mr. Rose and Dr. Sainsbury, "Gunshot Injury of the Brain;" Dr. Hale White, "The Sympathetic System, from four Fatal Cases of Diabetes;" "Patent Ductus Arteriosus" (card); "Abnormality of Lung" (card); Mr. Godlee, "Fracture of Skull in an Infant, followed by the Effusion of Serous Fluid;" Mr. Lane, "Fracture of First Rib;" Dr. Norman Moore, "Hæmorrhage into Substance of Liver;" Mr. Pepper, "A Case of Malignant Disease of the Spermatic Cord;" Mr. D'Arcy Power (for Dr. Mackinder), "A Pinched or Duplicate Bladder" (card); Mr. G. R. Turner, "A Drawing of Congenital Deformity of the Perinæum" (card).

University of London, 5 p.m. Mr. Victor Horsley's Third Brown Lecture, subject—"Simple Traumatic Fever, based on 160 Cases of Simple Fracture."

Wednesday, December 17.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

The Hospitals Association, 1, Adam Street, Adelphi.—Mr. John Marshall, F.R.S., "On Hospital Circular Wards;" Mr. Keith Young, "The Miller Memorial Hospital at Greenwich."

Thursday, December 18.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Friday, December 19.

University of London, 5 p.m. Mr. Victor Horsley's Fourth Brown Lecture, subject—"Urethral Fever."

Society of Medical Officers of Health, 1, Adam Street, Adelphi, 7.30 p.m.—Mr. H. E. Armstrong, "The Statistics of the Medical Officer of Health as a Criterion of Sanitary Progress."

SUMMARY OF CONTENTS, DECEMBER 6.

MEDICAL TIMES

AND GAZETTE.

No. 1799. LONDON, SATURDAY, DECEMBER 20, 1884.

Contents.

ON A CASE OF RELAPSING OR INTERMITTENT PNEUMONIA OCCURING IN AN AGED MAN.[1]

By SIR ANDREW CLARK, Bart., M.D.

Physician to the London Hospital.

On the twenty-fifth of March, 1884, I was summoned to see a gentleman who, for five days, had been complaining of disordered digestion, general malaise, aching of the limbs and feverishness.

The patient was 82 years of age, tall, spare, light-eyed, and, when in health, vivacious, temperate almost to abstinence, actively occupied with private and public business, going out in all weathers, and never sparing himself when summoned to work.

In 1877 the patient had an attack of pneumonia, which, except for the greater length of its prodomal stage, closely resembled the attack which is now to be described.

On that occasion the patient was attended by Mr. Potts, and was seen from time to time by Sir William Gull and myself.

The patient made light of the illness for which I was summoned to see him, and referred it to a chill, which he had caught by sitting in the park, without an overcoat, when overheated by a long ride.

At the time of examination the patient looked pinched and ill; the eyes were dull, the face was yellowish; the tongue loaded, the appetite gone; there was some thirst; the bowels were inadequately relieved; the abdomen was full; and the high-coloured urine, free from albumen, was loaded with lithates. Beyond feeble breathing at the posterior base of right lung nothing was discovered in the chest. The heart, fairly strong, was beating with clear sounds and without murmur 86 times in the minute, and a sufficient amount of blood reached the smaller arteries which were exceptionally soft and otherwise sound. The temperature in the mouth was 102°. The skin was hot, pungent, dry. Nothing definite was discovered in the nervous system; but the patient complained of a dull headache and of difficulty of mental exertion.

A double inguinal hernia had existed for some years.

The patient was ordered immediately to bed; placed upon fluid food every two hours; and had his usual alcoholic supplies, which were very moderate, temporarily suspended. There were furthermore prescribed for him a simple saline at short intervals, and a mild dose of colocynth and blue pill to be taken at 10 o'clock the same night.

On the 26th the patient was in much the same

[1] Paper read before the Medical Society of London, on Monday, December 15th, 1884.

general condition as on the previous day; but there had been a severe rigor late in the afternoon; the temperature had risen to 103°; the pulse was 94; the breath sounds at right posterior base were very feeble with slightly heightened resonance; and the patient felt weak.

The chest was surrounded by a hot poultice. The saline was continued with two grains of quinine added to each dose and given every two hours. The colocynth and blue pill was repeated at night; and an enema was ordered to be administered the next morning on waking.

From this time to the conclusion of the illness the patient was attended twice or thrice daily by Mr. James Newham. To his care and skill was in great measure due the happy issue of the case, and to his ready kindness I am indebted for many of the facts recorded in this narrative. For the reflections which follow I am myself alone responsible.

On the 27th, the patient had another severe rigor: the general condition was otherwise unaltered; the enema had brought away copious fœtid fæculent discharges from the bowels; the breath sounds at posterior base of right lung were still very feeble, but a faint hollow bronchial breathing had become just audible, and the vocal resonance was slightly increased. The left lung remained free. Treatment continued.

On the 28th there was another rigor, and the patient felt ill and weak. The mouth and tongue were dry; thirst was becoming urgent; the bowels were again freely relieved; the urine was passed freely, had a density of 1014, was free from albumen and deposited purple lithates. The pulse was 104, of moderate fulness and strength, and the ventricular sounds were regular and good; the temperature at 4 p.m. was 104°. There was dulness over the posterior base of left lung; the breath sounds were harsh, granular, loud; there was faint distant bronchial breathing, and the vocal resonance was increased. The respirations were 24 per minute, but there was neither cough nor expectoration. The diet was continued. Half an ounce of brandy was ordered twice or thrice daily, according to circumstances. A fresh saline with a little citrate of potash was prescribed, and five grains of quinine were directed to be given in water twice or thrice in the twenty-four hours.

The report of the 29th was that the patient had passed a very restless night, but that there had been no fresh rigor. In the morning the temperature was 100°, the pulse was 80, and the respirations were 28 per minute. At my visit in the afternoon the patient expressed himself much better. The tongue was cleaning; food had been taken in sufficient quantities; thirst had abated; the bowels had been satisfactorily relieved; the urine was copious and clear, and the pulse, temperature, and respiration were the same as in the morning. A great change, however, had come over the condition of the base of the right lung. There were now complete dulness to percussion, increased tactile vocal fremitus, tubular breathing, and loud bronchophonic voice. There was no pain; no distress of breathing, which had risen to 30 in the minute; no cough; no expectoration.

The treatment was continued as before.

On the 30th the patient improved in all ways, and began to talk of getting up. Temperature 99°. Respiration 28. Pulse 84. Treatment continued.

Early on the morning of the 31st, the patient had a rigor and became rapidly worse. At 11 a.m. the temperature was 103°; the pulse was 110; the respirations were 32. The tongue was loaded and dry; the abdomen was full and tympanitic, the urine was scanty and dark.

In the evening the patient, although still very ill, was somewhat better than in the morning. Since the previous day a fresh consolidation of about three fingers' breadth had occurred in the middle of the right back from the axillary line to the spine. Treatment continued; an aperient was prescribed in addition.

On the 1st of April patient was again much better. The tongue was cleaning; food was again relished; the abdomen had become soft; the bowels had been abundantly relieved; the urine was clear, copious, and free from albumen; the condition of the right lung remained much the same without discernible sign of reparative resolution. The respirations were 36; the pulse was 90, and the temperature 101°.

The treatment was not materially altered. It consisted of food every two hours; an alkaline saline every four hours; half an ounce of brandy diluted with water twice or thrice in the day; quinine twice or thrice in the 24 hours in doses of five or more grains; occasional aperients, and hot poultices.

In the early morning of the 2nd April, patient spoke of himself as well. He had passed a good night, felt no discomfort, and desired food. The tongue was again cleaning; thirst had ceased; the bowels had been comfortably relieved; the urine was abundant and natural; the heart was acting well; the pulse had fallen to 84; the respirations were 34; the temperature was 98·2°, and the skin had become moist. Large moist crepitation was heard at base of right lung, and repair was obviously in progress.

In every respect locally and constitutionally the condition of the patient appeared to be exceptionally satisfactory. Nevertheless within four hours of the time when this state was seen the patient had a very severe and prolonged rigor; and when I saw him late in the evening he was extremely exhausted and distressed; the pulse and temperature had risen; the breathing had become more frequent; for the first time there was a little cough; the tongue had become dry, the face bluish, and the extremities cold. On examining the chest it was found that a fresh strip of consolidation had arisen in the upper and back part of the right lung. Repair at the base of the lung had not advanced.

The quantity of alcohol was increased to three ounces of brandy in the twenty-four hours and was given in hot water; free ammonia and quinine were added to the saline; five grains of quinine were given separately every six or eight hours in the course of the day and hot bottles were placed around the patient's extremities. On the morning of the 3rd of April it was reported that the patient had passed a comfortable night and was better. The tongue was less dry, food had been taken regularly, although the stimulant had been once or twice refused; the bowels had been relieved; the urine was high-coloured, loaded with lithates, and free from albumen; there was neither cough nor expectoration; the breathing, although frequent, was not distressing; the temperature was 96·3° and the pulse 80, but weak and small.

In the evening of the same day the temperature had risen to 103°; the pulse was 100; and the respirations were 34. The consolidation in the upper part of the right lung was extending. Nevertheless the patient was comfortable; food was regularly taken; repair at the base of the lung was advancing; there was neither cough nor expectoration.

From the morning of the 4th to the evening of the 5th April, patient again improved rapidly. Then the patient became suddenly chilly, the temperature rose to 104° and the pulse to 106. The mouth became dry, and there was thirst; the patient grew restless and uneasy, and although by nature good tempered and of gracious manners, he rebelled against all treatment. Except as respects the administration of food and stimulants, often refused, all treatment was suspended.

On the morning of the 6th the patient was again looking and feeling much better. The pulse was about 88, the temperature 97·2°; food was being taken, and repair was making rapid progress at the base of the right lung. About noon, however, the patient had a sudden severe and prolonged rigor, during which he became cold, livid, and almost pulseless and insensible. From this state the patient was recovered by frequent supplies of hot strong soup, and by the use of half an ounce of spirit in two ounces of hot water every two hours.

In the evening there was slight dulness to percussion at the base of the left lung, and the respiratory sounds were extremely feeble. The patient had recovered from his collapse, and the skin, although everywhere very dry, was cold only at the extremities. The pulse was 116, the respirations were 40, and the temperature was 104·5°. The treatment was confined to food and stimulants.

On the 7th there was another rigor, and the patient became so much exhausted and so cold that he was revived only with difficulty. Consolidation to the extent of a hand's breath had taken place at the base of the left lung.

In the evening the patient was worse than he had yet been; slightly delirious, and difficult to manage. Twice or thrice when almost pulseless he managed to leave his bed, and to stand up in the effort to relieve his bladder. On one of those occasions he fainted, and was restored with difficulty. The temperature which in the morning was under 96° was now 105°.

The patient was surrounded with hot bottles; greater firmness was employed in the administration of food and stimulants; and the use of quinine and ammonia in diaphoretic form was successfully resumed.

During the 8th, the patient had another rigor, but held his ground. Right lung rapidly improving; left lung unaltered. Temperature in the morning 97°, in the evening 105°; pulse 120; respiration 48.

During the 9th and 10th, patient continued in much the same condition. Each day about 12.20 there was a rigor. On the evening of the 10th it was found that a second consolidation had taken place in the middle of the back of the left lung. Food and stimulants were now taken with fair regularity, and from ten to twenty grains of quinine were given in the twenty-four hours.

On the 11th and 12th there were no rigors, and the patient began to improve in every way and in the same manner as he had done on several occasions before. Suddenly, however, about mid-day on the 13th, the patient had another rigor and was again much exhausted. In the evening the temperature rose to 104·5° and the pulse to 114. The respirations were 44. The right lung was still rapidly improving. Large crepitations were heard at the base of the left lung; the consolidation at the middle of the lung was unaltered, except that tubular breathing had been replaced by hollow bronchial breathing; and over the upper fourth the respiratory sounds were either very feeble or very harsh; the resonances were not distinctly altered. Treatment continued.

On the morning of the 14th the patient was reported to have passed a fair night, to have taken sufficient food and stimulants, and, although extremely weak, to have felt more comfortable and more himself than for some days. The temperature was 96° and the pulse 108; the respirations were 40. The tongue was moistening at the edges; there was no thirst; the abdomen was soft and small; the bowels had been comfortably and naturally relieved, and the urine was copious. The skin, although still dry, was softer. The intellect was quite clear. There was no distress of breathing, and only occasional cough with a little frothy mucoid expectoration of a viscid sort. About the usual time, however, that is between twelve and one, the patient, without having a distinct rigor, and feeling only "strangely chilly," began quickly to fail. The mouth dried, the extremities became cold, the skin turned dusky, dry and hard; the breathing was hurried and difficult and the pulse small, weak and irregular; the face grew livid, pinched and anxious, and he looked like a patient who was suffering from cholera and about to die. Nevertheless, supported by pillows, the patient sat up in bed, and apparently much distressed clutched a vessel, into which he desired but was unable to expectorate. In this state the patient remained for over four hours, refusing food, and taking only once or twice a spoonful of brandy and water.

About five, the patient began to recover, and at my evening visit with Mr. Newham, was able to be examined. It was then found that the upper and remaining portion of the left lung had become consolidated. The tongue was loaded and dry, distaste for food and stimulant continued; the urine contained a little albumen, and the bladder acted with difficulty. There was no cough or expectoration, and although the respirations were 48, there was no distress in breathing. The heart sounds were rough, and the arteries small; the pulse was 116, compressible and irregular. Air was everywhere entering the back of the right and the base of the left lungs. Coarse moist crepitations were heard over the middle consolidation, and bronchial breathing had disappeared.

The treatment pursued was the same as before, except that in addition to it, the patient, at the suggestion of Dr. Andrew, who saw him several times in my absence, took five drops of liquor strychniæ thrice daily.

On the 15th, the patient's condition was greatly improved; but in the evening the temperature was 103°, the pulse 110, and the breathing hurried. Nevertheless, the patient felt no discomfort and declared that he was getting rapidly better. On the faith of this belief, the patient insisted on having his bed made, and was none the worse for it.

On the 16th, the patient was again greatly better: the tongue was cleaning; the appetite had returned; the bowels were with a little help acting satisfactorily; and the urine passed without difficulty, was clear, copious and free from albumen. The back of the right lung was still somewhat dull to percussion, but everywhere the air was heard entering the alveolar passages, and there were no râles. Over the upper half of the posterior part of the left lung there were still dulness to percussion, moist subcrepitant râles, and increased vocal resonance. The heart was regular in action; the pulse had fallen to 86; and the evening temperature was 98·5°. Patient had slept a good deal during the day, but awoke always refreshed. The patient was now directed to have food of a semi-fluid sort every four hours; to have from two to three ounces of claret at 11, at 2, and at 8; and to take an effervescent solution of citrate of potash with quinine, iodide of potassium and iron.

On the 17th, the left lung was almost clear, and the patient was in every other way so much better that he insisted successfully in passing an hour on the sofa during the evening.

It is unnecessary, and it would be tedious to continue in detail the remaining part of the narrative of this case. Let it suffice to say that the patient, notwithstanding sundry indiscretions, continued to improve daily, and that on the 6th of May, after having passed through nine or ten severe rigors, six small successive attacks of pneumonic exudation and seven weeks' illness, was declared to be quite well.

I saw the subject of this narrative a fortnight ago. Since the termination of his illness he had continued

to enjoy good health, and was actively engaged in the business of public as well as private life.

It will be seen in the early part of this narrative that the patient ascribed his illness to a chill; but, dissatisfied with the insufficiency of his explanation, we endeavoured to find, in the patient's antecedents, surroundings, or present personal condition, some other cause or concurrence of causes adequate to account for the exceptional characters of this case. We thought of filth poisoning and malaria, of phlebitis, hæmorrhoids, prostatitis, and phlegmon; of autogenetic poisoning, thrombosis, and gout. But of all these possible modes of causation, only two had reasonable grounds for consideration, and neither of the two was satisfactory. Was the origin of the attacks to be found in gout, which sometimes manifests itself in anomalous visceral seizures of the kind suffered by our patient? But he had never had gout; he had never lived the life which leads to it; he was too old for the first manifestations of the gouty inheritance, and he had no signs of the gouty habit beyond those which may be found in every aged man.

It is true that the country home of the patient was alleged to be malarious, and that several ponds stood near the house. On the other hand no evidence of malarial disease was to be found, either in the family of the patient or among the people dwelling in neighbouring parts. In these circumstances we prefer confessing our ignorance to advancing an inconclusive hypothesis.

I have ventured to bring this case before the Society, because in the character, assemblage and progression of the symptoms, in the frequency of the relapses or recurrences, in the severity of the rigors preceding them, in the age of the patient, and in the happy issue of his illness, the case, in the annals of medicine, is rare, if not unique; because in the records of exceptional cases are sometimes to be found not only unexpected helps to the advancement of our knowledge, but also criteria whereby the accuracy of our generalisations may be tried, and especially because the history of the case is one which raises anew those problems concerning the nature of pneumonia now so widely and warmly discussed throughout the profession. In pneumonia, is the local lesion the sole cause of the accompanying fever? or is pneumonia a fever which has inflammatory consolidation of the lungs as one of its local manifestations? And if pneumonia be primarily a fever is it due to a poisoning or a parasite?

As, however, these questions have been recently discussed with as much breadth and as much minuteness as the present state of knowledge would permit, it is not my intention to deal with them on this occasion. But among all the questions raised concerning the nature of pneumonia there is still one, and a very important one, which has been almost wholly overlooked. Every one appears to have asked if pneumonia is not a fever, but scarcely any one has asked if pneumonia is really an inflammation. In the admirable work of Dr. Sturges, who regards pneumonia as a fever begetting inflammation, it is said that in pneumonia the phenomena of inflammation are conspicuously exhibited; that in it both the clinical and anatomical requirements are satisfied; and that there are present all the classical results of the inflammatory process—pyrexia, exudation, migration of leucocytes; cell proliferation and excess of tissue change. Pneumonia, he says, is not only an inflammation, but it is the pattern and model of all inflammations.

Now, I propose to say a few words upon this question which has long occupied my thoughts, and which I dealt with at some length in a lecture delivered at the College of Physicians in 1866.

If we proceed to examine critically a bit of hepatised lung, three chief points demand attention: the solid exudation, its relation to the alveolus, and the condition of the alveolar walls.

When recent the pneumonic exudation consists essentially of leucocytes, red blood discs, hyaline globules, granule cells, and desquamated epithelium, all interpenetrated and held together by a delicate network of the finest threads of fibrine. For our present purpose the epithelial cells may be dismissed from consideration. Now, collectively these elements resemble a capillary blood clot, and not an ordinary fibrinous exudation. Everywhere you can see signs of regressive involution, and nowhere signs of true advancing development. However "healthy" the exudation, and however early you may examine it, the number of red discs present in it often equals and sometimes much exceeds the number of the leucocytes, whilst many of the leucocytes may be proved to be nothing more than red discs undergoing histolytic changes. Furthermore, the fibrinous network differing in many respects from that of an ordinary inflammation resembles closely that which is formed in small blood clots.

When we examine the relation of the exudation to the alveolar wall, we discover no evidence of any organic connection between them; and from each pneumonic alveolus a practised hand, furnished with a needle, can turn out the little lump of exudation without apparent injury to the alveolar walls.

Nor does a critical study of the alveolar wall in a hepatized lung furnish us with any conclusive evidence of the inflammatory nature of a pneumonia. With two exceptions no manifest structural change can be found therein. Instead of being swollen and very red, as one would expect them to be after being the seat of an inflammatory exudation, the alveolar walls are pale, thin, blanched as if from loss of blood, and devoid of any sign of active textural change. Furthermore, many of the alveolar blood vessels are occluded, a fact which distinguishes the pneumonic from every other acute parenchymatous inflammation. In nephritis, for example, Johnson has shown us not only that the blood vessels of the acutely inflamed kidney are not occluded, but that they are enlarged. The resemblance of a pneumonic exudation to croupous exudation of mucous membranes, and of the pleura, and even peritonæum has been admirably set forth by Hamilton; but in my opinion the conditions are far from being identical, and in croupous inflammations of the mucous membranes and the pleuræ structural changes may be found which do not exist in the pneumonic lung. Nevertheless, Hamilton himself says, what I too have said before, that croupous inflammation is not to be reckoned as a true inflammation.

Here then in pneumonia is a sometimes enormous consolidation, and yet, as I believe, no conclusive signs of a prolonged inflammatory process: there are signs of slight exudation and of great extravasation of all the elements of the blood; but no signs of active cell proliferation in the exudation, no signs of interstitial structural change in the alveolar walls, and no signs of an organised bond between them.

How is all this to be explained? Is it sufficient to say that the alveolar tissues are of such a sort and supplied with blood of such a kind that they cannot undergo any other manifestation of the inflammatory process? But this cannot be the explanation. For when the alveolar tissues are cut by an instrument, or ploughed up by a bullet, or irritated by bits of stone or steel, or pressed upon by indurated tubercles or invaded by inflammatory processes from the pleuræ, air tubes, or interlobular tissues, they behave like any ordinary part, and produce an exudation which soon becomes rich in migrated leucocytes, proliferating cells, and developmental tissue change.

Once again, then, what is the explanation of the pneumonic consolidation? At present, for my own part, I can say only that the facts admit of the most complete explanation on the assumption that the consolidation is the result of an active congestion (or aborted inflammation) of tissues in which the blood vessels, almost unsupported and naked, give way to sudden pressure sufficiently prolonged, and permit, with a slight exudation, the extravasation of all the elements of the blood before the inflammatory process, if begun, can be carried to its classical completion in cell proliferations and textural development.

If you still say that the pneumonic consolidation is an inflammatory exudation, I will still reply that the rapidity with which hepatization occurs, the rarity with which it remains, and the rate at which it disappears, are incompatible with the history of the products of any other recognised inflammation.

But in a communication of this kind, I must not weary you with further histological details. Returning, therefore, for a concluding moment or two to the case which has led me into this long digression, I will anticipate and answer a question, which, in a practical society, such as this is, will surely be put to me when I conclude.

What were the general principles which guided us in the treatment of our patient? It might very justly be replied that there are no general principles in medicine—that it is one of the most unprincipled of arts; that every case is a law to itself; and that only in the patient himself, in the assemblage of conditions constituting his disease, in the character of his surroundings, and in the special ways in which death is threatened are the rules of treatment to be found. Well, as the result of our study of all these things, we gave our first attention to the man and the next to his malady. In the first place, we endeavoured to support life by relays of nourishing food, freshly prepared, not too liberally given lest we should overcharge the pulmonary vessels and dangerously increase exudation, and not too frequently given lest we should outrun the digestive powers and increase the patient's peril by filling his bowels with decomposing stuffs.

In the second place we endeavoured to promote the vigour of the circulation by the administration of alcohol in such forms and doses, and at such intervals as seemed best calculated to strengthen and steady the ventricular contractions without interfering with the chemical changes of digestion, or dulling too deeply the nervous sensibilities.

In the third place, we endeavoured by hot spongings of the skin, by gentle but regular evacuations of the bowels, by light, air and moderate warmth, by the avoidance of noise and fussiness, and by all quiet, cheerful and encouraging ways, to keep the man and his mind in the general conditions most favourable for physiological resistance, endurance and repair.

In the fourth place, we tried by alkaline diaphoretic salines to promote secretion and to keep the mucous and cutaneous surfaces at work, and by quinine in full and frequent doses to lower the temperature, restrain the rigors and control septic involution.

And lastly, when in the course of the malady, unexpected and inexplicable symptoms arose, we treated them as best our physiological or empirical knowledge would permit, regarding carefully on the one hand the general condition of the patient, and on the other hand the inroads made upon his breathing capacity.

Not high scientific treatment this, you will say. Perhaps not. But for any adverse criticisms upon this point Mr. Newham and I will console ourselves with the reflection that the patient recovered and is well.

The library and museum of the Royal College of Surgeons will be closed on and after Thursday the 25th instant (Christmas-day), until Monday the 29th instant.

CLINICAL LECTURES ON THE DISEASES OF WOMEN.

By J. MATTHEWS DUNCAN, M.D., F.R.S.
Physician Accoucheur to St. Bartholomew's Hospital.

III.—*On Polypus Uteri.*

This is the simplest subject to describe in this whole course, and in some respects the most pleasant; for it is easy to diagnose a polypus, and easy to remove it and cure all the evils it may have entailed. Like a fibroid, a polypus is almost always a healthy (!) not a malign disease. No doubt you do occasionally have malignant polypi, adenomatous in structure, but they are rare, and generally form only a small part of more extensive malignant disease. Polypoid masses of malignant structure are sometimes separated and discharged from the interior of the uterus, and give you valuable diagnostic information, derived from histological examination. There is another polypus which I dislike extremely to meet with, for it is of bad omen; a small, sessile, or nearly sessile, simple, mucous polypus of the cervix, in a case where the body of the uterus is enlarged with suspicious characters, and generally in elderly women.

There are many false polypi. A bit of adherent chorion, or of adherent placenta, cannot be called a polypus; but a bit of placenta, partially adherent, hanging by a stalk, is called a placental polypus. It is enveloped in old clot, and consequently smooth on the surface, and has to be examined after removal to be recognised. A fibrinous polypus is a false polypus. It occurs after delivery or abortion, is of considerable size, as of an egg, is generally lying in the cervix, and broadly attached to the placental site by a thick neck, scarcely a stalk. At its attachment chorionic structures in small quantity are generally found, and the mass of the polypus is formed of blood. This polypus is firm enough to maintain its shape when removed by avulsion. On examination, its outer surface is formed of a thick yellow fibrinous layer, and inside is a dark firm blood-clot. It behaves and is treated as a polypus, and is not very rare.

A fibroid in process of enucleation is a kind of false polypus, often taken for a true one. Here the fibrous tumour is bare, having no mucous or muscular envelope, or only a partial envelope. It behaves quite as a true polypus does, and is treated in the same way. When you seize it by volsella and pull, it often comes off, having no real stalk, but only incomplete attachment. This false fibrous polypus is not to be confused with a fibrous polypus whose lowest part has sloughed off or is sloughing off, the mucous and muscular coverings being so removed, and the subjacent fibroid laid bare. Yet another kind of false polypus is a fungous mass of so-called endometritis hanging through a dilated cervix.

The great polypus of the uterus is the fibrous polypus growing from any part of the uterus (or even of the vagina, or of the Fallopian tube), but most frequently from some part of the body of the organ; never found in the proper uterine cavity, not rarely in the cervix,

most frequently in the vagina; its pedicle or stalk passing from its site to its insertion. A fibroid has been often observed in all stages of enucleation; but a fibroid has not been so, nor its history well traced, from being an embedded tumour to the state of a sessile tumour and then of a polypus. This process has, nevertheless, been often described, but I doubt the truthfulness of the description. Sometimes a fibrous polypus has only a mucous envelope; generally it has also a muscular envelope, which is thicker near the stalk than far from it. These envelopes are sometimes greatly thickened by œdema. The enveloped tumour has almost always all the characters of a fibroid, and the bleeding from it also owns an identical pathology. You may, in the same uterus, have one or more embedded fibroids, and another one polypoid. A fibrous polypus may be of any size that can get accommodation in the pelvis, and size may increase the difficulty of removal but has little influence over the amount of blood lost.

Sometimes the polypus is not a distinct mass with envelopes, but a direct outgrowth of muscular and mucous structure continuous with the uterine wall, from which it takes its origin.

Besides fibrous you have the much more numerous mucous polypi; and there may be several of these in the same uterus. They are of various kinds, simple mucous polypi, never large; or fibro-cellular, that is, with a rounded mass of connective tissue having no definite arrangement of fibres, often with some muscular tissue, inside the mucous membrane enveloping, and sometimes as big as an egg, but rarely so large; or glandular, attached to the cervix, or body, oftenest to the cervix, and constituted of open or closed hypertrophied and distended Nabothian or other glands of the part, one or more; or channelled, a variety of glandular cervical, composed of large open glandular channels or cavities, sometimes quite empty. These mucous polypi are all of less importance than the fibrous; less in bulk, bleed less.

A polypus has no symptoms constantly attending it, being frequently found accidentally on examination. In this way you often meet with mucous polypi of the cervix in elderly or old women. Sometimes you find one when investigating a case of vaginal discharge. But, generally, it is some degree or form of bleeding which, leading to suspicion of it, leads also to the examination which results in its discovery. It is not rare for a mucous polypus to be so soft, glabrous, and mobile, as for a time to elude detection, even by an experienced finger.

Most polypi are vaginal and easily discovered, but bloody, or purulent, or serous uterine discharge may so excite your suspicion of a polypus or other disease higher up as to impel you to further investigation. This is effected by dilating the external os of the cervix; and fortunately further dilatation is rarely required, for a polypus imprisoned above the cervix is extremely rare, and always mucous.

Dilatation is effected by tangle tent kept *in situ* by a vaginal plug, all in the usual way, and easily.

You may have a small mucous polypus above the cervix, perhaps by the side of a projecting sub-mucous fibrous tumour; or you may have an intra-uterine fibroid nearly polypoid. The dilatation and further digital examination of the interior of the uterus proper is, as I have in another lecture told you, neither an easy nor quite a safe operation. You must not proceed to do it without good and sufficient reason.

You can scarcely make any mistake about a polypus, except when it is of the size of a rather small egg and has its pedicle passing through the cervix. Then you must make sure that you have not an inverted uterus —chronic inversion. A probe passed by the side of the supposed pedicle is quickly arrested if the case is one of inversion, passes easily into the uterine cavity if it is not so. If, after this, you still feel insecure in your diagnosis, you can easily complete it by a finger in the rectum feeling the absence of the uterine body from its proper place, or by bimanual examination.

For the treatment of polypus you need only two instruments, a volsella to seize and perhaps pull down and a curved scissors to divide the pedicle. Some small mucous polypi you simply seize by a uterine forceps and tear or twist off; but most are treated by volsella and scissors. You should wash out the vagina with antiseptic lotion as you begin and after you have done. By the volsella you seize and fix the polypus. If it is a mucous polypus you cannot drag by it, for it will tear out; but if it is a fibroid, and of large size, you may find it advantageous to pull it down even to the vulva, thus getting easy access to the stalk. If it is very large, as big as a fœtal head, you must pull it out to get access to the stalk. To get it out you may have to slit the perinæum, as you are recommended to do in some cases when the head is passing over it in labour. Or, you may cut out wedges of the tumour to reduce its size; or get it out gradually by what is called the spiral cut, that is, cutting on and on without detaching; in this way getting a longer and longer flap of the tumour away. If the tumour is truly intra-uterine, having an imperfect pedicle, or being sessile, your best plan is to enucleate by avulsion. After the operative removal no further treatment or interference is required—no plugging, no cauterising.

As bleeding is the evil to be cured and the woman is already often very anæmic, it is natural to fear loss of blood as an immediate result of the removal of the polypus; and up till twenty or thirty years ago the method of operating was planned with a view to obviate this risk.

It is now known that bleeding after the operation very rarely occurs. I have never seen it after the removal of a fibroid, and the number that has passed through my hands is great. I have seen it after the removal of a glandular polypus, and after the removal of a fibro-cellular polypus, but in neither case was it very alarming, and it was arrested by a simple vaginal plug. In the second case it was secondary, that is, it did not begin till many hours after the operation. I have seen dangerous hæmorrhage after the removal of a sessile mass of the size of the last phalanx of a finger projecting into the cervix This was arrested by a firm plug and you observe that this was not a case of polypus. You may, therefore, without hesitation proceed uninfluenced by dread of hæmorrhage; preferring, of course, the simple volsella and scissors to

the complicated and slow proceedings of thirty years ago.

The absence of hæmorrhage in the removal of fibrous polypi is explained by the powerful retraction of the pedicle. You have a pedicle of some length, say an inch, and you cut it through the middle, and after the operation you cannot feel the half inch left, it is destroyed by retraction. The half inch cut away is also not to be found for the same reason, and in its place you find, not a projecting half inch of pedicle, but a cup-like depression.

All fibrous polypi are not distinct tumours; sometimes they are muscular outgrowths continuous with the uterine wall, and the stump of the pedicle of one of these may bleed. I have removed several without any hæmorrhage, unless the case I have just spoken of, the phalanx-like tumour, be an example.

But hæmorrhage is not the only danger attending this operation. You may have septicæmia and death. The new and simpler mode of operation is recommended by its involving much less risk of this dangerous affection than the slower old methods. I have had in all my practice, including a very large number of operations, I am sorry I cannot say how many, only one surgical calamity—one death—and it occurred in "Martha," a most lamentable and most lamented death. The case was a simple one—a common fibrous polypus of the size of an apple and a stalk as thick as your little finger. It was removed easily by volsella and scissors. In a few days the patient was dead. A *post-mortem* examination was made and nothing peculiar was found. The little wound near the internal os uteri seemed quite healthy. In no other case have I had even alarm.

THE THYROID GLAND, ITS RELATION TO THE PATHOLOGY OF MYXŒDEMA AND CRETINISM, TO THE QUESTION OF THE SURGICAL TREATMENT OF GOÎTRE AND TO THE GENERAL NUTRITION OF THE BODY.[1]

By VICTOR HORSLEY, B.S., M.B., F.R.C.S.
Professor-Superintendent of the Brown Institution.

Lecture I.

[Abstract].

The object of the first lecture is to review the structure of the Thyroid Gland, to narrate the methods of experiment, and to detail the clinical phenomena resulting after its ablation. It is further shown that myxœdema, cachexia strumapriva and cretinism are closely related to this gland and the question of its removal. Mr. Horsley proposed to support the view, which was first clearly formulated by Dr. Felix Semon, that cretinism, congenital or acquired, myxœdema and cachexia strumapriva, are one and the same condition. Further, it is urged that this condition arises from arrest of the function of the thyroid gland. It is pointed out that although the thyroid gland had formed the theme for much surmise, especially in relation with cachexia strumapriva, only 18 months since did it first become invested with a definite physiological importance. This advance was due to the labours of the Reverdins père et fils and Kocher, who published cases of persons from whom they had removed the thyroid gland, and who subsequently lapsed into the state called cachexia strumapriva. The discussion which followed as to the justifiability of removing goîtres helped on our knowledge, bringing several important facts to the surface.

The anatomical structure and position of the thyroid gland is first described. The thyroid gland, then, is bi-lobed, encapsuled, having its substance divided by trabeculæ of connective tissue which, starting from the capsule, run into and divide up the gland tissue. Thus is formed a stroma with large alveolar spaces. Running in the course of these trabeculæ are very numerous and large blood vessels and lymphatics. These last have been shown by Frey, Boéchat and Baber to form large lacunar spaces immediately outside the margins of the alveoli. The nerves have at present been associated in function with the vaso-motor system. Mr. Horsley believes that the thyroid body must be considered to be a gland. He urges that this view has support lent to it by the history of the thyroid's development, which is quite similar to that of a racemose gland.

Although an anatomical proof is yet wanting of the intercommunication of the acini, yet, as is pointed out, Virchow and Boéchat cling to their belief that such intercommunication exists. Nor is the theory that it is a gland of modern acceptance only: Theophile de Bordeu taught that there existed minute ducts leading from the thyroid into the trachea, and Ricou held that a similar duct existed between it and the larynx. Further support of the view that the acini of the thyroid form part of a large ductless gland is found in their structure and relation. In an early stage they are composed of columnar epithelium, which later becomes cubical. Their walls are surrounded by a rich capillary network, while their lumina contain a glairy fluid. This fluid Kühne and Eichwald aver contains mucin, while Gorup-Besanez believes it differs from that body in being soluble in acetic acid. These facts would, then, seem to support the views advanced by Baber and others, that the mucinoid contents of the acini are excreted from the blood by the epithelium cells, and again thrown into the circulation through the channels of the large lymphatics.

Other views of the function of the thyroid have been brought forward. One, really advanced by Mr. Simon, although usually attributed to Liebermeister and Guyon, that it regulates the cerebral circulation; and another that it secretes something which is necessary to the nutrition of the brain.

Mr. Simon found that in many vertebrates the thyroid is in close relation to the cerebral arteries; and Guyon, drawing attention to the fact, capable of easy verification Mr. Horsley says, that after prolonged effort, pulsation in the carotid branches ceases, states that this is beneficial to the cerebral circulation by lessening the blood supply to parts from which blood return is by the conditions of the experiments impeded. Guyon thinks the pressure of the thyroid upon the common carotid can effect this result. Mr. Horsley does not consider the arguments which support the view above enunciated of much value. Luschka's view is, that the thyroid acts simply in a mechanical way, and protects the carotid from the pressure of the contracting neck muscles. The second theory, due also to Mr. Simon, is too limited in range, since although profound changes are promoted in the nervous system by altered conditions in the thyroid, yet such changes are present all over the body. It would seem that all the views held up to 1883 were incomplete and too narrow in scope.

[1] Being two of the Brown Lectures delivered at the University of London, December, 1884.

Mr. Horsley next considers the results following thyroidectomy. Kocher has shown that the subject of the ablation becomes cretinous. Schiff, Wagner, Sanguirico and Canalis demonstrated that dogs in which thyroidectomy is done become idiotic and die comatose. Mr. Horsley, working with monkeys, has found that when the thyroid is removed they assume the condition called by Dr. Miller Ord myxœdema. This condition is, Mr. Horsley believes, one stage in a general and profound change occurring in the nutritive processes of the human frame, consequent upon removal of the thyroid.

The details of the operations may briefly be noticed. The anæsthetic employed was ether, strict antiseptic precautions were used. Dividing superficial structures in the middle line, the fascia between the sterno-hyoid muscles was cut through, while the isthmus was isolated by a blunt instrument, and a cat-gut loop placed around to produce traction if needful. The lobes were separated from the false capsule by means of a blunt instrument and enucleated, save where the arteries entered, and these were seized with forceps and torn out of the gland, thus obviating bleeding and the necessity for applying ligatures. The dressing used after uniting the wound-edges with horsehair sutures was dry gauze and collodion. Healing was complete in three days.

The *post-mortems* made upon these cases showed that in no case were the recurrent laryngeals or the sympathetic trunks injured, a fact which goes far to disprove the theory that myxœdema is a primary disease in, or injury to, a sympathetic nerve.

Schiff's first experiments, we are told, were in the first series performed under septic conditions, and so are out of court; his second series, performed antiseptically, agree with those of Wagner, Canalis, and Sanguirico, and these Mr. Horsley quotes in the sequel.

Following thyroidectomy in monkeys, the phenomena which supervene are :—in about five days anorexia, constant slight fibrillary twitching appears in the face, hand and foot muscles, which disappear upon muscular effort. In a day or so appetite returns, but the animal grows pale and thin. The fibrillary tremors increase and affect the whole body, the animal becomes completely imbecile, while his movements are languid and paretic. Then puffiness about the eyelids and swelling of the abdomen appear with increased hebetude. In the last stages the temperature falls to subnormal, the tremors disappear in the same order as they came, while extreme pallor of skin supervenes, leucocytosis taking place, to be followed by oligaemia. Death occurs in coma, usually in five to seven weeks after the thyroidectomy.

Examining the symptoms more in detail, those related to the *motor apparatus* come first.

In the dog, and in the cat although more rapidly, fibrillation, which is usually paroxysmal, comes first, and according to Wagner, this is succeeded by clonic spasm, tetanus next appears, and finally rigidity.

In monkeys, on fifth day, a slight fibrillation of the intrinsic muscles of the (1st) hands, (2nd) feet, and (3rd) jaws appears. This gives way to a steady constant tremor, which resembles the tremor elicited in ankle clonus. The grouping of the fibrillation into paroxysms occurs on the second or third day. The paroxysms assume so violent a character as to simulate convulsion; but Mr. Horsley has never seen true tetanus in a monkey. Tracings taken in various stages elucidate those points. Thus in dogs death often occurs when the paroxysmal stage is at its highest; in monkeys it supervenes ten days or so after all paroxysm has passed away, leaving only fibrillation.

The rate and character of these twitchings are then briefly compared with similar twitchings or tremors all occurring in paralysis agitans and allied conditions.

The origin of the tremors is then considered. Schiff showed by dividing the motor nerves that these tremors were probably central. This experiment, however, does not altogether preclude the possibility of the tremors being idio-muscular.

Mr. Horsley ablated the upper arm centre in the cortex, producing total brachioplegia, but without stopping the tremor. The evidence in favour of the tremor being due to the bulb or cord is, first, they are lessened by voluntary movements, second, increased by inhalation of ether; and, third, reflex irritation causes it to disappear. The rate per second also corresponds to what Lovèn finds it to be in frogs, and what Mr. Horsley believes it to be in man.

Paresis and rigidity co-exist with the tremors in all the muscles affected. The former comes on gradually, but the rigidity varies directly as the force of the tremors. The paresis never becomes a complete paralysis, but wrist drop and the "paralytic posture" are well shown. In two cases well-marked hemiplegia was present, appearing suddenly and obviating the tremors in the limbs, but not affecting those in the jaw muscles.

In one case, the attack, one of functional hemiplegia, as was shown by the *post-mortem*, lasted an hour, and then the tremors reappeared.

Sensation seems little affected; in severe paroxysmal stages some delay of sensation may occur and slight anæsthesia.

Reflexes. The superficial are diminished; the deep knee-jerk was found, unless rigidity had set in; ankle clonus was never found.

The centres in the lumbar cord perform their functions normally. Bulbar symptoms have rarely been found, nor does evidence exist pointing to a vaso-motor disturbance.

The affections of the higher functions of the cortex cerebri are a slow onset of hebetude, which ends in partial or complete imbecility. In this state they present quite a similar appearance to that of severe cretinous and myxœdematous conditions.

The emotions vary but little; these monkeys were easily enraged, just as are idiots. A rarer symptom was occasional attacks of dyspnœa. Peripheral nervous system. The pupils always reacted normally.

The blood pressure steadily falls. The blood suffered a steady decrease of its red corpuscles for about 14 days, at which time oligæmia persisted until death. A steady increase of white corpuscles occurred reaching its height when the red corpuscles were fewest. The tendency to clot is lessened, the "buffy coat" becoming well marked. Mucin, absent from the blood of healthy monkeys, is present in considerable quantities after thyroidectomy. The amount present varied directly as the duration of the monkey's life. The proteids of the blood remained normal in total amount, but there was an increase of the serum globulin. Dr. Halliburton, who conducted the chemical examination of the blood and tissues, also found that the serum albumin was not differentiable into the three forms usual in the normal monkey.

The affection of the *respiratory system* was the dyspnœa noted above. Mr. Horsley regards it as of bulbar origin, from the suddenness of its onset and its subsequent speedy disappearance, and the absence of other physical signs. No laryngeal stenosis or paralysis of the vocal cords existed, nor were the recurrent laryngeal nerves ever found to be abnormal.

The Alimentary System.—A point of extreme interest occurs in the huge hypertrophy of the salivary glands which appeared in the monkeys. This hypertrophy presents the appearance of mumps, and is due, as analysis shows, to the muciparous swelling of the cells. The parotid gland further takes on in these monkeys a muciparous function, while it normally

secretes only a serous saliva. To the consideration of this point Mr. Horsley returns later, giving ample proof of his assertion that, in monkeys deprived of their thyroids, the parotid becomes a mucin-forming gland. The condition of the appetite undergoes curious changes. Shortly after operation it fails, then it soon regains its former state, and becomes greatly increased until the animal becomes ravenously hungry. The appetite again fails just before death. Mr. Horsley confirms the statement of Credé and others, who assign a correlation between the spleen and the thyroid. In his experiments he found, during life, a sensible increase of the splenic dulness after removal of the thyroid, and *post-mortem* examination showed a considerable increase in the size of the spleen. The marked swelling of the abdomen, which forms so striking a symptom, was, Mr. Horsley found, to be due to hypertrophy of the great omentum and some distension of the intestines. There was some, but not much, peritonæal fluid. The fluid, however, contained mucin.

Renal System.—The urine examined qualitatively appeared normal; occasionally glycosuria was present for a day or two. Throughout the life of each animal a trace of mucin was present in the urine, but this, Mr. Horsley says, was not pathological.

Cutaneous System.—The skin showed marked pallor; it was, Mr. Horsley believes, of normal moistness. The hypertrophy and swelling such as occur in myxœdema were reproduced in these monkeys. The swelling of the eyelids and face gave them that facial expression so striking and pathognomic in the myxœdematous human subject. There was atrophy of hair in the amimal which lived longest. The baldness appeared first on the right side at the root of the tail, then on the left side. The situation suggested to Mr. Horsley a similarity to bed-sores in man. In some monkeys whose hair was cut, little or no growth of hair occurred in the above situations. The constitutional change is best estimated by careful thermometric observations. From such Mr. Horsley finds that, after thyroidectomy, at first there is a slight rise, followed by a fall, which in a few days brings it to the normal level—the temperature, in fine, of traumatic fever. With the onset of the tremors an exaggerated morning fall and evening rise occurs. Schiff's observation that high fever supervenes in dogs during the tremor stage has, Mr. Horsley finds, no counterpart in monkeys. After the most severe stage of tremor the temperature gradually falls, so that at death it has become subnormal. This lowering of temperature shows itself by cold extremities and cold skin, but shivering when cold air blows against the skin has never been observed by Mr. Horsley. The symptoms will, when taken together, present a picture which may well be described as pathognomonic of myxœdema. The pathological appearances presented after death are detailed in the second lecture.

Lecture II.

[Abstract].

In this lecture the *post-mortem* appearances are described which are found in monkeys from which the thyroid gland has been removed. The subcutaneous tissue was swollen, jelly-like, bright or shining and very sticky. This latter quality Mr. Horsley has never met with, save in these experiments. The increase of connective tissue is most marked in the triangles of the neck and hypochondria. In one case this tissue was continued into the muscle, and in this case mucin was found in the muscle. Similar tissue was found in the body-cavities, the omentum and mediastinal tissue were loaded, and a like condition obtained in the auriculo-ventricular groove. Accompanying this change was a remarkable atrophy of the body fat, such as is found in children after a long wasting disease. In fine, the connective tissue of the whole body showed hypertrophy of the fibrous tissue with mucoid transformation of the ground substance, together with atrophy of the fat. In the bursæ no changes were seen; in some cases congestion of the sygnovial membranes of the larger joints was seen, although no effusion was present. The bones and cartilages were but little altered. In the muscles only an increase of connective tissue was detected. The heart is only affected in a manner the same as the other tissues. No changes existed in the respiratory system save in one case in which œdema of one lobe of the lung was present.

In the alimentary tract profound changes are met with. The salivary glands are found greatly hypertrophied, each lobule being several times its natural size. A glairy translucent fluid transudes on section of the gland. The parotid, normally a secreter of serous saliva, seems pressed into the service for the secretion of mucin. This alteration of function is shown both by the macroscopic and microscopic appearances. Chemical analysis shows that while the normal parotid contains no mucin, in the parotid of these monkeys as much as 1·21 per thousand was found. Likewise in the submaxillary gland in the healthy state the mucin proportion is ·01 per thousand, but becomes 4·6 per thousand in the diseased.

The mucous membrane throughout the whole alimentary tract is swollen, and an increased quantity of mucus is found in the dejecta.

The tongue, Mr. Horsley thinks, was enlarged, but he does not state this certainly.

The spleen was hypertrophied, but presented a normal appearance.

The other viscera showed simply increased pallor.

The Nervous System.—The naked eye appearances of the brain and cord are simply those of anæmia and atrophy. The meshes of the pia mater were distended with fluid. (The microscopic appearances are deferred.)

The peripheral nervous tissues present in these cases no departure from health; careful microscopic preparations of the sympathetic and musculo-spiral nerves failed to detect disease.

Mr. Horsley then passes in review the various theories promulgated with respect to cretinism and goître, and having contrasted the symptoms evinced in myxœdema (Dr. Ord's account), in cachexia strumapriva (Dr. Kocher), and cretinism (Dr. Hilton Fagge and others), he states that he has no doubt that these conditions are really the same. He refers them to some profound changes which are called forth by injury to, or ablation of, the thyroid, although he does not deny that some other agencies at work may produce such results, although he contends they will do so *quâ* the thyroid.

Dr. Kocher taught that the myxœdematous symptoms which followed his removal of the thyroid for disease were due to chronic asphyxia, arising through atrophy and softening of the trachea. This atrophy followed, he assumed, the ligation of the thyroid arteries which supply that structure. But, as Mr. Horsley points out, many cases of narrowing of the trachea exist, but in none have myxœdematous symptoms arisen. And further, in Mr. Horsley's experiments, the trachea and gullet remained healthy while myxœdema arose.

Dr. Hadden's view that myxœdema is due to capillary spasm, from sympathetic irritation, is negatived by the experiments of Schiff, who irritated the sympathetics without causing myxœdema, as well as by the fact that in all the cases examined by Mr. Horsley he failed to find any abnormality about the sympathetics. He points out that a mere increase of con-

nective tissue cannot be regarded as more than a by-phenomenon of the general tissue hypertrophy found in myxœdema.

Mr. Horsley then formulates his facts to guide as accurately as possible to the ultimate elaboration o a theory as to the true pathology of myxœdema.

I. Anatomical.

(A.) The thyroid appears to consist of two portions : (1) a glandular, consisting of highly vascular acini, which excrete a mucoid substance—a mucin-excreting portion ? and (2) highly vascular lymphoid nodules —hæmatogenous function ?

(B.) Excision of the gland is followed by a great increase in the quantity of mucin found in the tissues, an increased activity of the mucin-producing glands, and a change in function of other non-muciparous glands whereby they become mucin formers.

(C.) Profound changes also ensue in the blood. The red corpuscles are decreased with leucocytosis, the coagulability is lessened, and its albumins are altered in character.

(D.) Nerve symptoms also appear, changes taking place in the lowest motor centres causing rigidity, tremors, and paresis. Changes occur in the higher psychological centres, whereby imbecility and cretinism occur, followed by death, which usually occurs in a condition of coma.

Reviewing these facts, Mr. Horsley points out that it is clearly shown that removal or alteration of the function of the thyroid is the cause of the general bodily condition. Whether such changes may be due to the intermediate action of the vaso-motor, or a trophic centre, it is impossible to say. When it is remembered that the thyroid body contains a mucinoid material, and that after removal mucin appears largely in all the tissues, it becomes a question whether the thyroid may not be an excreting gland, the removal of which, as is usual in analogous cases, induces death. In support of this, it is urged that removal of one lobe causes hypertrophy of the other. If subsequently the second lobe be removed, myxœdematous symptoms arise.

Mr. Horsley next addresses himself to the surgical treatment proper to goître.

The conditions demanding treatment are (1) Hypertrophy, or adenoma, with or without some amount of cystic degeneration, or fibroid overgrowth ; (2) cystic disease ; (3) malignant new-growth. In this last case only removal of the gland can be of any avail. Adenoma occurs as exophthalmic and simple goître. The former has been relieved, it is said, by total or complete removal, and this treatment seems to hold out most chance of benefit.

Injection and removal are the two modes of treating simple goître.

Injection with laceration of tissue, as formerly practised by Billroth, is very dangerous, as secondary inflammation may arise. Simple injection has caused sudden death. This has been attributed to the injection of air into a wounded vein, but Mr. Horsley believes this is a mistake, and alleges that it is due to the injection of the iodine into a vein, and the iodine travelling to the heart and causing thrombosis. Experimentally, Mr. Horsley has found this actually to happen. To avoid this danger, Demme's plan is advised. He waits before injecting, to see by the flow of blood whether a vein has been wounded.

Excision of the thyroid as a whole, it is said, is absolutely unjustifiable, especially as excision of a part causes the goître to shrink. Mr. Sydney Jones removes the isthmus between silk ligatures, and obtains good results.

Royal Medical and Chirurgical Society.—The Library will be closed on December 25th, 26th, and 27th.

REPORT OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

GENERAL HOSPITAL FOR SICK CHILDREN, PENDLEBURY, MANCHESTER.

A CASE OF VILLOUS CARCINOMA OF THE PLEXUS CHOROIDES IN A BOY OF THREE YEARS OF AGE.

By HENRY ASHBY, M.D., M.R.C.P.

(Notes by H. Chester Nance, M.R.C.S.)

John D., aged 3¼ years, was admitted to hospital March 10, 1884, with the following history :—His father died, aged 35 years, in the Royal Infirmary, of a "tumour of the spine" (tumour compressing cord). Six weeks before admission, his mother noticed his right arm was weak and shook when he attempted to use it, his face was drawn to the left when he smiled, and he dragged his foot in walking. His speech also was affected, being slow and difficult. On admission it was noted that while he could stand alone, his gait was uncertain, the right leg shaking when he attempted to use it, his grasp with the right arm was feeble, and it performed rhythmical movements when he attempted to grasp anything. Patellar reflex is diminished on the right, normal on the left ; the muscles of the right thigh and leg are very irritable. There is no marked facial paralysis. There is no loss of sensation ; he is fairly bright and intelligent. Discharged April 20th, much in same condition. Re-admitted May 1st. Mother states he is much weaker, complains of headache, and his arm and leg "work like a clock." He cannot stand alone. He lies quietly in bed, hardly taking any notice of anything ; the right elbow is flexed to a right angle, the wrist extended, the fingers clenched, the right leg is drawn up, the knee bent, the ankle extended. There is apparently no loss of sensation, the pupils are equal and act to light, there is double optic neuritis. May 5.—Vomited this morning, answers "yes" and "no" to questions, and sometimes shakes his head ; some facial paralysis of right side, left arm and leg shake when he attempts to use them. May 9.—Convulsions to-day, left arm and leg worked most ; there is ptosis of left eye-lid. May 24.—Is much emaciated, lies quite unconscious, both legs flexed and rigid, knees touching chest, feet extended, both elbows flexed, hands clenched, is frequently convulsed. Remained in such state till June 13th, when he died.

Post-mortem Examination. — Body extremely emaciated. No important lesions except in brain. Skull thin. Veins on surface injected. Much serum in lateral ventricles. On making vertical sections through the brain, it is noted that the left lateral ventricle is occupied by a soft lobulated tumour, which has grown more especially outwards compressing the optic thalamus and neighbouring parts ; it has also bulged the roof of the ventricles. It has extended towards the right side, but does not appear to have exercised much pressure on the right thalamus, at least there is no evidence of it *post-mortem*. The tumour is soft and vascular, and is apparently connected with the choroid plexuses, probably having commenced in the left choroid plexus of the third ventricle. It has not extended much forwards, but has spent its force in growing outwards, compressing and almost obliterating the left optic thalamus, internal capsule, and in a lesser degree the lenticular nucleus ; it has also grown posteriorly, occupying and distending the posterior and descending cornua. The microscopic

structure of the tumour is peculiar, resembling in some respects the tumour of the choroid plexus, figured by Ziegler in his "Lehrbuch der Pathologischen Anatomie" as a "Papillöses Carcinom," though in the present case there is no colloid degeneration, and no cell-nests were detected. Sections of the tumour show numerous dilated capillaries, some arranged in loops, freely branching and anastomosing with one another; they are distended with red corpuscles, and their walls resemble those of ordinary capillaries. The vessels are supported by a delicate stroma only present in some places, and extending very sparsely through the growth. The spaces between the strands of the stroma are occupied by irregularly shaped, large, nucleated granular cells, some being elongated or columnar in shape, and forming a layer, lining the spaces formed by the stroma. Some of the cells are larger than the rest and contain many nuclei. No inter-cellular stroma can be detected. The tumour is very soft, and frozen sections when thawed at once become diffluent. It is evident the tumour was of rapid growth. It did not infiltrate, but displaced and softened the brain substance. There were no secondary deposits.

Remarks.—The tumour seems to have originated in the choroid plexus of the third ventricle, to have grown outwards and to the left, compressing the optic thalamus and internal capsule, giving rise to a paresis of the right arm, leg, and face, and rhythmical movements when they were attempted to be used, without loss of sensation. Later on, as still greater compression took place, the arm and leg became fixed and rigid in a position of flexion. One of the difficulties met with in trying to connect the symptoms during life with the lesion found after death is the impossibility of determining the exact progress of the tumour, and what symptoms its advance corresponded to. In this case the boy lived some 5 to 7 weeks in a semi-comatose condition, and during this period examination as to sensations were unsatisfactory, but 7 weeks before his death it was quite certain there was no loss of sensation on the paralysed side. It must also be remembered that the tumour pressed rather upon the posterior part of the thalamus than the anterior end, which at the *post-mortem* could still be traced, while the rest had completely disappeared. It is difficult to explain the paresis and final rigidity of the left arm and leg except by supposing that the right side was compressed similarly to the left. But at *post mortem* there was no evidence, though as the right half being apparently healthy was separated from the opposite half before vertical sections were made, it is possible that evidence of pressure was over-looked. Very probably during life pressure was exerted on the sound side by the fluid present in the lateral ventricles.

Medical Times and Gazette.

SATURDAY, DECEMBER 20, 1884.

The adjourned debate upon Charcot's joint disease attracted an audience to the meeting of the Clinical Society on Friday, 12th instant, which once more overtaxed the normal capacity of the auditorium. Some hopes had been expressed that Professor Charcot himself would be able to be present, but these were doomed to disappointment. Two letters, however, which had been received from him by Dr. Duckworth were read to the Society, and on the suggestion of the president a cordial vote of thanks was passed to Professor Charcot for the interest that he had shown in the debate, and for the material contribution to its success which he had made in submitting his specimens for examination. The task of proposing this well deserved compliment fell to the lot of Dr. Moxon, who, while acknowledging the great services which the French physician had rendered to medical science, took occasion, in a speech of considerable length, enlivened by numerous passages of pungent humour and brilliant suggestion, to point out the tendency that exists to appeal to the mystic influence of the nervous system as an explanation of all the most difficult problems of pathology. He showed with much force how the occurrence of bed sores in paralysed persons could be as well explained on anatomical grounds as by any assumption of a "trophic" lesion, and how the production of Charcot's joints could be accounted for by ordinary influences without assuming any nerve disorder whatever. With somewhat unsparing satire he ridiculed the fallacies which used formerly to exalt hæmatoma auris into a system of mania, and the absurdities which were practised some years ago under the pseudo-scientific title of metallo-therapy.

Records of valuable clinical cases bearing upon the subject under discussion were contributed by Mr. Henry Morris and Mr. Page, the latter of whom expressed an opinion which was probably shared by the majority of members present, that the ultimate result of the debate would be to leave individual opinions unshaken. Dr. Pye-Smith wound up the debate for the evening in a useful and argumentative speech, showing in turn the relations between the supposed new disease and the various conditions with which these joint affections might be associated. Several members having intimated their intention of speaking, it was decided that a special meeting of the Society should be held for the purpose. Tuesday, December 23rd, has been finally fixed as the date for the conclusion of the debate.

At the Medical Society on Monday last, Sir Andrew Clark related the history of a peculiar form of pneumonia which he had lately observed in a gentleman 82 years of age. The paper will be found in full in another column. The consolidation occurred in large patches, first in the lower, then in the central, and next in the upper parts of one lung, then spread over to the opposite side and affected the other lung in a precisely similar manner. The patient was extremely ill, having characteristic symptoms as each patch of pneumonia developed. Sir Andrew Clark described it as "relapsing pneumonia;" although no one part was twice affected. It might perhaps have been more properly described as "migrating pneumonia," or "multiple pneumonia." In the discussion which followed, probably for want of similar cases to record, the speakers referred more especially to the probable ætiology of the case, and the general feeling appeared to be that it was of a septic nature, although Sir Andrew stated that no source of contagion could

be discovered even after a careful search ; he was inclined to think it might be due to gout.

Dr. Wilks brought forward at the meeting of the Pathological Society on Tuesday the account of a case in which intestinal obstruction had been caused by gall stones. This raised two points of importance : the first as to how the gall stones reach the intestine, and what part of the intestine they pass into ; the second as to how they cause obstruction. No discussion was necessary to show that in these cases, or in the very great majority of them at any rate, the stone has not passed along the duct, and we are surprised hat so many members found it necessary to unburden themselves on this point. As to the exact way in which the obstruction is caused there is more room for doubt. After the narration of Mr. Hulke's case no one can doubt that the obstruction may take place in the rectum, but we should be inclined to think with Mr. Treves, that in the vast majority its seat is in the small intestine, probably by a spasmodic grasping of the stone by the intestine such as he described. Mr. Rose and Dr. Sainsbury recounted a case of gunshot wound of the brain, in which both the clinical and the *post-mortem* features had been carefully studied. The case was quite in harmony with the modern teachings of cerebral localisation. There were no motor sym toms during life, and the injury nowhere touched the motor tract.

At the Ophthalmological Society's meeting on the 11th, Mr. Priestley Smith exhibited a series of exceedingly simple but nevertheless very efficient models, which he had constructed for the purpose of demonstrating to students the elementary principles of refraction, and the mode of correction of the various errors thereof. They seemed to be admirably adapted for their purpose, and nothing could have exceeded their simplicity. As usual there were several cases of interest in the adjoining room, amongst which we may mention especially a somewhat unusual case of conjugate deviation of the eyes in a young woman, which was probably hysterical, whatever that may mean. Mr. Eales contributed a short paper, in which he suggested that lesion of one kidney might be followed by albuminuric retinitis of one eye only, but the few facts that are at present to hand on this point do not support his view, and indeed there was not universal agreement that in the patient on whom his paper was based the retinitis was of a type that could fairly be classed as albuminuric. Three papers were read on cocaine ; this of course was to be expected. Mr. Nettleship's was a communication of considerable physiological as well as clinical interest.

Dr. Richelot, a hospital surgeon, and the able editor of the *Union Médicale*, seems to be what is called "too old a bird to be caught by chaff." Commenting on the circular issued to the medical staffs of hospitals by Dr. Peyron, the new director of the Assistance Médicale, which, in complimentary phrases expresses the anxious desire of the writer to be guided by the advice and to receive the concurrence of those whom he is addressing. Dr. Richelot observes that he has heard something very like this before. Former directors have often abounded in kind words, some of them having even declared that they felt quite a *penchant* for the medical bodies, but almost always there they have stopped, so embarrassing has their situation proved to be. Now, that the administration has been placed in the hands of a *confrère*, while thanking Dr. Peyron for his liberal sentiments expressed in his circular, Dr. Richelot can only express the wish that circumstances will not reduce them to mere pious opinions. Taking the new director at his word, however, he at once indicates to him a pressing reform upon which he can try his hand forthwith. It seems that the hospitals of Paris are very insufficiently supplied with medical officers, so that the just claims of neither the patients nor the students can be attended to. The officers are greatly overworked, and are unable to perform their duties effectually, while at the same time there are numerous surgeons at the Bureau Central, who have gained their posts by concours, in a state of inactivity, many of these having reached their fortieth year without a service being allotted to them. M. Richelot especially mentions the Lariboisière and the St. Louis and states that he may add the Hôpital des Enfants, and the Tenon Hospital, where one man has the charge of 120 beds.

At a recent meeting of the Society of Physicians of Vienna, Professor Kaposi showed a patient, an army surgeon, who suffered from a very rare disease on the foot, the so-called "Aleppo boil." It was, he said, a disease which was endemic in several parts of the East, especially in Mesopotamia ; it was found amongst the natives as early as the second year, none escaping. The method of development was as follows :—a red patch, resembling that of urticaria, appeared without any assignable cause on some part of the skin, on the face, the nose, the cheek, the forehead, and especially on the extremities ; it next became a nodule of the size of a bean or a nut, developing very slowly without inflammation, and without affecting the functions of the organism. After three or four months had elapsed, a most indolent crateriform ulcer burst out at the top of this nodule, which did not heal for ten months or a year. The disease was on this account called by the Arabians "Habbet-es-Seneh" (year-boil). After the disappearance of the ulcer, there remained a cicatrix of the same form and size. Foreigners living in those regions in which the Aleppo-boil was endemic also became affected by it after a certain time. Professor Kaposi further remarked that many diseases which occurred as endemic affections in the East, and which had been looked upon in former times as specific pathological processes, had ceased to exist, since we had learnt to diagnose them correctly, and to reduce them to their real nature, as was the case with syphilis, lupus, lepra, and caries. As to Aleppo-boil, he was inclined to consider it as an affection *sui generis*. Professor Geber, of Klausenburg, who had made a special journey to the East for scientific purposes, had asserted that many affections had been looked upon as Aleppo-boil which were in reality syphilis, lupus, &c.

But the descriptions which Geber had published favoured the conviction that in many cases neither syphilis, lupus, nor lepra had been present, but a morbid process which he regarded as a skin-disease *sui generis*. The appearance of invariably a single nodule, the course of the disease, and the absence of any recurrence, were a proof of the specificity of the affection. The ætiology of the process was somewhat doubtful; the mode of living, and climatic or telluric conditions played no part in it. The present patient's experience was that Aleppo-boil occurred only in the plains; at a distance of ten miles from great towns it was no longer observed. The patient had served as an army surgeon for two years and a half in a region in which the affection was endemic, and he, his wife, and his children—a boy, aged 6 years, and a child, aged 6 months—were attacked by the disease. As soon as Professor Kaposi saw the patients he was convinced that the affection was Aleppo-boil. Syphilis, lupus, sarcoma, and lepra could be excluded. It might perhaps be suggested that a micro-organism of an animal or vegetable character penetrated into the skin, and led to the growth of a tumour, consisting of connective tissue. Professor Kaposi was of opinion that by the removing of the nodule, the whole process might be shortened. When the nodules have been removed, they will be examined under the microscope.

The special committee appointed by the London School Board to enquire into the over-pressure question have evidently a better idea of the difficulties of the investigation, and less confidence in their own abilities to cope with them, than the members of the Board generally. The sub-committee wished to engage three medical practitioners, nominated by the presidents of the Royal Colleges of Physicians and Surgeons, to enquire into the truth of Dr. Crichton Browne's allegations. Such an investigation would not have been wholly satisfactory. In fact, no enquiry will be efficient which does not allow of the taking of sworn evidence in public under qualified medical guidance. But the suggestion of the committee at least evidences their desire to deal with a scientific problem through more or less efficient instruments. The Board, however, would have none of it, and though even Sir E. H. Currie admitted that Dr. Browne's charges could not be answered without skilled medical aid, they rejected it by 22 votes to 13. Possibly the expense of the suggested enquiry, estimated at 150*l*., may have had some influence on the decision; but a body with such a princely revenue as the London School Board ought not to shrink from spending a few score pounds on a subject admitted by all to be one of the greatest moment.

The result of the Harrison and Page case cannot be regarded as satisfactory to any of the persons concerned in it, and still less so to the medical profession at large. It might, however, have been much worse. It was quite possible that the jury, disregarding the evidence as to Dr. Page's character, and attaching an undue importance to the statements of the servants, might have found the co-respondent guilty of a charge as to which all his friends and intimates strongly attest his innocence. He still, however, is under the stigma attaching to a verdict of "not proven," and under these circumstances he may count on the sympathy of his fellow practitioners throughout the country. The charge of the judge was not a happy one, though we are grateful, of course, for his kind expressions with regard to the medical profession, which, by the way, the *Lancet* in its ill-advised article of the 6th inst. has done its best to nullify. To say that a woman is addicted to habits of intoxication because she takes chlorodyne, is a confusion of terms as commonly accepted, and could not fail to disturb the minds of the jury.

With due ceremony and splendour, the new out-patient rooms at the Middlesex Hospital were opened on Tuesday by the Princess Christian. The new buildings replace some houses in Cleveland Street, and one at the corner in Mortimer Street, so that an entrance for out-patients has been obtained from Cleveland Street, no small advantage in the interests of the hospital authorities. From the somewhat cursory glimpse we were able to obtain of the waiting rooms, and physicians' and surgeons' rooms, we were much impressed with the convenience of the arrangements, and the heating apparatus seemed to be doing its work well—almost too well, in fact, at the time of our visit.

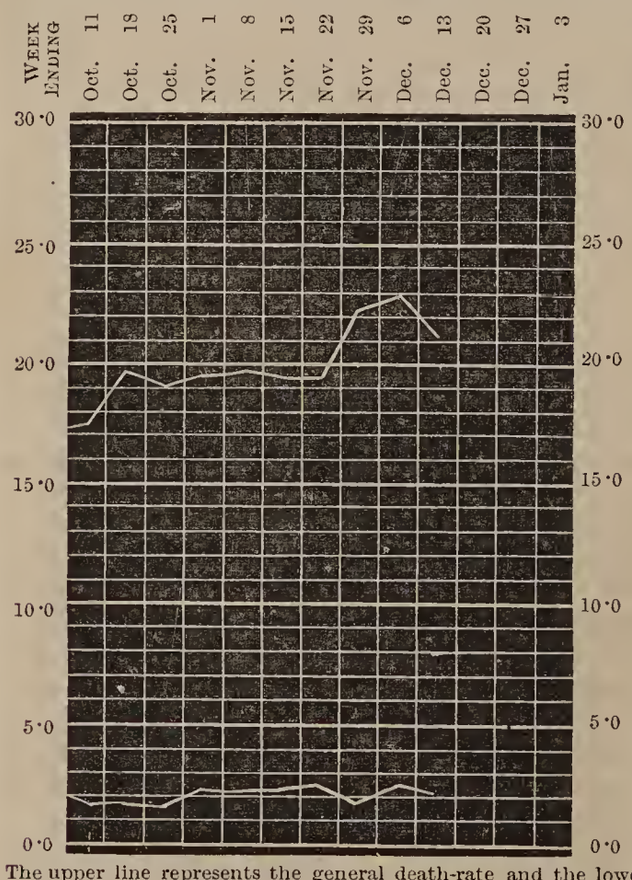
It is stated in a petition to Parliament by certain delegates of Boards of Guardians, that the annual expenditure for wines and spirits at the Homerton Hospitals was 6,425*l*. for 150 patients, or an average cost per patient of 43*l*. The fact is, that during the year ending 30th September, 1884, the account for wines and spirits amounted to 2,012*l*. 19*s*., and the number of patients was 3,331, giving a cost per patient of 12*s*. 1*d*., instead of 43*l*. To this has to be added a daily resident staff of about 180 persons, including medical officers, nurses, assistant nurses, scrubbers, porters, ambulance nurses and ambulance porters, certain of whom, by reason of the infectious nature of the diseases with which they come into contact, are constantly sick.

The meteorological conditions of theMetropolis were on the whole more favourable to the living exhibits at the cattle show last week than has been the case in some previous years. Yet we are told that on one day, at all events, the crowd, the heat, and the oppressive atmosphere produced a marked effect upon the animals, that after the gas had been lighted several of them showed symptoms of asphyxia, and that removal from the building failed in many instances to avert a fatal issue. It is probable that the practical lesson thus preached was generally unheeded, and that its effect evaporated in a few expressions of pity for the sufferings of the "poor beasts." The wonderfully elastic power of adaptation to our environment which we possess is apt to make us oblivious both of the privilege and of its risks. "Heat, overcrowding, impure air, and gas," wreak their evil on ordinary specimens of mankind not less surely than on over-fattened prize-

winners amongst the lower animals; and if the effect of such agencies upon human beings is not so prompt, it is not less real for being insidious. We must regret the occurrence of these examples of involuntary experients in vivisection; but if Fate decrees that a crowded gathering of pleasure-seeking sightseers must have its victims, there is some comfort in the provision of a *corpus vile*, and we hope that the practical demonstration of great physiological truths may not have been utterly in vain.

In the beginning of the present year a scheme of amalgamation was agreed to between the representatives of a proposed Central Hospital for North London and the Governors of the Great Northern Hospital with a view to the erection of a new hospital building in the densely populated districts of North London. In hardly any part of the Metropolitan area is there so urgent a need for hospital accommodation, and constant efforts have been made by the united committee to obtain a suitable site for their purpose. A piece of land, an acre and a half in extent, has now been obtained, having a good frontage to the Holloway Road, and situated a little to the north of the Camden Road, and within reach of Holloway Station. It is proposed to commence building operations directly that possession is obtained, on March 25th, 1885. The present building of the Great Northern Central Hospital in the Caledonian Road has long been found inadequate either to meet the demands for admission or to fulfil the increasing requirements of the out-patient department.

In London last week the deaths numbered 259 below the average, which more than suffices to counteract



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past ten weeks.

the lack of increase in the population shown by the number of births being 112 below the average. The week appears to have been a particularly favourable one for infants, as the number of deaths recorded is, with a single exception, the lowest of the present quarter. Though the small-pox epidemic exhibits some signs of declining, the total number of cases last Saturday being 1,011 as compared with 1,027 on the previous Saturday, yet there have been 69 deaths, a larger number than has been reached for many weeks past. There were 23 fatal cases of measles, and 22 of scarlet fever during the week. Whooping cough had 31 victims or 22 less than the average. Diphtheria alone, with its 27 deaths, exceeded the average, and this too without taking any account of the 17 deaths of children under 5 from croup, though it is morally certain that the majority could not have been cases of simple laryngitis. The deaths from diseases of the respiratory organs numbered 457, showing a further decline on previous weeks. There was sunshine last week of a duration in all reaching one hour and twenty minutes, only ten minutes of which were registered from Monday to Friday inclusive.

We are glad to see that Mr. H. R. O. Cross, late Instructor of the Army Medical Staff Corps, who served with the Mounted Infantry through the Zulu and Boer Campaign, and gained considerable *kudos* from his management of the electric light ambulance drill, at Aldershot, last summer, has been appointed Surgeon to the Grenadier Guards.

Dr. Buchanan's annual statement which has just been issued as a supplement to the thirteenth Annual Report of the Local Government Board, touches, as usual, on most important problems, while the appendix gives an account of researches of the deepest interest. This week we can only briefly summarise the Report. The first subject dealt with is vaccination, with regard to which Dr. Buchanan records "a fairly steady advance in obedience to the law." The fatal incidence of small-pox amongst unvaccinated and vaccinated infants he shows to have been in the ratio of 200 to 1. The animal vaccine station supplied during the year 9,311 points and 2,151 tubes of animal lymph in reply to 1,666 applications, the applicants for humanised lymph being nearly five times as numerous. Various important enquiries were made by the medical inspectors during the year as to milk-diphtheria, epidemics in relation to schools, and the distribution of enteric fever. The report next deals with cholera. As to the origin of the outbreak in Egypt in 1883, Dr. Buchanan thinks that the discussions amongst English, Egyptian, and foreign physicians led to no conclusive result—a statement in which we thoroughly concur. He thinks that "the application to Damietta at the first appearance of the epidemic of those inductive methods of investigation which are familiar to the practised sanitary enquirer in England," would probably have resulted in the discovery of some introduction of the disease into that town from outside.

The report next summarises the scientific investigations undertaken under the auspices of the Board. In laying down the lines for an investigation into the disinfectant power of the products of putrefaction—*i.e.*, into the poisons which micro-organisms brew for their own destruction, Dr. Burden Sanderson has opened an entirely new country. He shows that the most interesting of these products from his point of view belong to the chemical group of "aromatic" compounds, the best known example being carbolic acid. Others of the group, however, are probably even more effectual, and it has been Dr. Sanderson's object to ferret out those which are most likely to be of practical value. The substances chosen for investigation were phenylpropionic and phenylacetic acid, and Dr. Klein was commissioned to prove their disinfectant power. The method he employed was based on the principle that the first question to be answered is not whether the disinfectant in question can restrain the growth of a specific microphyte, but whether it can destroy its infective activity. Dr. Klein's researches were very similar to those of Mr. Wynter Blyth, described by him in these columns a few weeks ago. He first experimented with anthrax, and found, like Mr. Blyth, that it is easy enough by means of either of the above disinfectants to kill the microphyte in the form of bacilli, but extremely difficult to kill it when in the form of spores. Experiments made with swine plague gave similar results, while on coming to tuberculous matter, it was found that it resisted the disinfectants in question as strongly as the anthrax spores. There are several other interesting papers by Dr. Klein in which he records the results of his further study of pathogenic organisms, but we have only space to quote his estimate of the part played by tubercle bacilli in the production of local disease in inoculated animals. His researches, in which he was assisted by Dr. Heneage Gibbes have led him to the conclusion that the bacilli are not necessary precursors of each separate local deposit. He is, in fact, rather disposed to regard caseation as being essential to the multiplication of the bacilli, than to think of the localization of bacilli as an antecedent to the first formation of the nodule. This view seems to us to fit in with clinical experience with remarkable neatness.

Very little intelligence is allowed to leak out about the progress of the Nile Expedition, but we are informed, on excellent authority, that the sick, who are more numerous than is generally admitted, are well supplied with comforts and medicine all along the line, and there are not likely to be any of the complaints and recriminations which followed the Tel-el-Kebir campaign. The medical requirements are now being sent up Nile by the post-boat, so as to reach their destination at the earliest possible moment. A flying camel field-hospital has been organised by Surgeon-Major Marky to accompany the camel corps; and a camel bearer company, consisting of 84 men from the Medical Staff Corps, 70 natives, and 200 camels, has been formed under the charge of three medical officers. Meanwhile, considering the admirable water supply enjoyed by the troops, we are sorry and surprised to hear that there is a good deal of sickness. Diarrhœa and dysentery are very prevalent, and there have been several deaths from typhoid at a comparatively early stage of the disease.

BELOW THE CATARACTS.

No one can rejoice more heartily than we do that the proposal to establish a real university in London has at length passed out of the hands of leader writers and "visionary educational reformers" into those of practical and persuasive men of affairs, who alone can carry it into effect. The journalist cannot help being grateful when he sees himself able to exchange the uphill and thankless task of advocacy for the less exhausting duty of criticism, and his only ground for complaint in the present case is that this welcome relief has been deferred so long. The recommendations of the sub-committee appointed to draw up a plan for a teaching university in London have been so fully detailed in the daily press that it is unnecessary for us to go over the ground again. We may say at once that their report strikes us as excessively immature, and the members of the Committee acted most wisely in refusing to adopt it. The sub-committee have drawn up a plan for the government of the new university, with a cunningly devised system of checks and counterchecks, before they have even ascertained what will be the attitude of the present University of London, of the Inns of Court and of the Medical Corporations; in other words, they have sketched out a full plan of their campaign before they have surveyed the cataracts before them, and ascertained whether they are passable. Under these circumstances it may be perhaps futile to criticize the constitution which, falling victims to a common human frailty, they have framed for their non-existent University. We may perhaps point out, however, that this constitution is absurdly complex and oligarchical. The faculties are to send representatives to the Boards of Studies, and the Boards of Studies are to send representatives to the Council; but it is recommended that the Council should also appoint additional members to both the faculties and the Boards of Studies—an entirely gratuitous proviso. Again, it might have been expected that the promoters of a new university in this year of grace 1884, would have thought it advisable to give at least as much power to the general body of graduates as the present London University does. But the sub-committee only propose that the graduates *might* be honorary members of their respective faculties, having the right to attend and vote at a general meeting summoned on requisition when necessary, and give them no voice whatever in the election of the Boards of Studies and of the Council. There is no provision at all for a general meeting or convocation of all the graduates, and in a question of policy affecting the whole University, the voice of its members would not according to the present scheme be able to make itself heard at all. We are quite aware that many professors and teachers maintain that the affairs of a university ought to be left entirely in the hands of the teaching body. Frankly we do not agree with

them. The teachers may know how to teach but they often do not know so well what to teach, as those who are engaged in the active exercise of a profession. In medicine the tendency now-a-days is ever towards widening the gap between the teacher and the practitioner, and we believe it will be generally admitted that a board composed of pure physiologists, pure pathologists, and pure chemists would be the last body to decide wisely as to the exact range and degree of knowledge required for the effective practice of the medical art. The College of Surgeons has been for years an irresponsible examining body composed almost exclusively of teachers, and we venture to say that there is no body whose examinations have been conducted on such glaringly absurd lines. Again, a university is not solely a teaching or examining body; it is a corporation disposing of large funds, and deciding on large issues of national importance—witness the vivisection question at the Oxford, and the female graduate question at the London University. In such matters experience tells us that we are more likely to find sound sense in a large body of cultivated men than in a limited coterie of educational specialists. In short, if the new university is to be a success it must be founded on the most liberal basis possible, and must start at least abreast with modern ideas. It is ridiculous to go to bureaucratic Germany for a model.

When we first noticed the present scheme we asserted that no new university in London would be worth raising a finger for which could not promise (1) a fairly easy medical degree, and (2) centralisation of primary medical education. As to the second point the report of the sub-committee promises little. "The Council is to negotiate with associated institutions for the increase of facilities for common attendance at lectures and laboratory work, and for the concentration of teaching within one or more of such institutions, or within the University itself, in such studies as may appear desirable." *Voila tout!* It may no doubt have been politic in the sub-committee not to appear to threaten the teachers at the smaller medical schools until the scheme is on its feet; but it should be remembered that these schools must be swept away, except as clinical centres, if the interests of medical education in London are to fare any better under the new scheme than they are faring now. The need for an attainable degree, however, is still more pressing than the amalgamation of medical schools; with it, the medical teachers of London could snap their fingers at Edinburgh, Cambridge and Manchester; without it the amalgamation of schools might make the medical teaching of London more efficient, but it would never make it more popular. What prospects, then, do the sub-committee hold out of being able to grant the sort of degree that every medical teacher in London is crying out for? Wisely enough, they hold out none whatever until they have passed their first cataract—the present University of London. The task of the sub-committee would have been comparatively easy if the founders of that admirable institution had acted more wisely, or had forborne to act altogether. At present it is the London University that blocks the way, and it is an open secret that the Senate of that body are not very favourably disposed to the schemes of Lord Reay's committee. It would indeed tax the ingenuity of the cleverest of mortals to devise a plan whereby two bodies with such different ideals as the present and the proposed University can exist side by side even in this monstrous metropolis of ours. There is no doubt, however, that a *modus vivendi* must be found if the new university is to get beyond the stage of plans and reports. For our own part we attach such importance to the existence of sterling degrees like those of the present University, that we should witness with regret any concession which involved their depreciation. We would rather see the University left alone, to continue its present useful function, and a new degree established side by side with it.

The first cataract having been forced or turned, there remain the cataracts of Pall Mall and Lincoln's Inn Fields to be surmounted before the medical wing of the expedition reaches navigable waters. The members of the sub-committee do not appear to have quite made up their minds how to deal with these twin obstacles. In one part of their report they recommend that the University's degrees in medicine and surgery should be "recognized as qualifying *pro tanto* for licence to practise, the power of conferring such licence being reserved to the existing authorities." That appears to mean that the corporations should practically cease to examine, and support themselves by trading on their licensing privileges. We are certain that two such influential bodies as the Royal Colleges will never willingly accept a position of that sort. In another paragraph, however, the sub-committee hints that it may be found possible to blend the examinations of the teaching university with those of the existing corporations, and herein they foreshadow a plan of overcoming the opposition of the colleges which we hope they will in the end boldly adopt. If the new university is to be a success, it must allow each of its faculties perfect liberty to work out its own conditions of union with the university. It would be absurd to organize a new faculty of medicine when we have one ready to hand. It is obvious that in the probable event of the present London University refusing to take part in the new movement, the two Royal Colleges, which comprise amongst their fellows nearly all the medical teachers of London, should be pressed to combine and constitute themselves the faculty of medicine in the teaching university. The fellows of the colleges might elect the larger proportion of the medical "Board of Studies," the remainder being elected as representatives of the various medical schools. The colleges would then be able to give, instead of their present cumbrous titles, degrees which every English student would be anxious to hold, the M.B., B.S., corresponding to the present L.R.C.P., M.R.C.S., and the M.D., and M.S. to the M.R.C.P. and F.R.C.S. respectively. The obstacles are difficult enough to surmount even in this way. Under any other plan they appear to us absolutely insurmountable. Indeed, we cannot help feeling that the advantages of a teaching university, undeniable as they may be, would be dearly purchased at the cost of extinguishing the colleges or relegating them to the obscure positions occupied by the corresponding institutions in Edinburgh.

THE PATHOLOGICAL RELATIONS OF THE THYROID GLAND.

THERE are few subjects which present more points of interest than the group of diseases usually, although somewhat vaguely, held to be associated with the sympathetic system. Exophthalmic goitre, or more familiarly Graves' disease, myxœdema, and simple goitre present at first sight few features in common. With myxœdema and cretinism has been associated the so-called cachexia strumapriva, and the symptoms do tally more or less closely in all the three conditions. As to myxœdema, although a fairly large number of cases have at present been collected, many of them have helped but little to elucidate either the pathogenesis, or even the clinical features of the disease. That the forthcoming report of the Clinical Society will shed some light upon the subject we may expect, since of no observations can it be said more truly than of clinical records, that a few thorough reports are worth tons of ill-digested and imperfectly arranged records. But while the clinical aspect of myxœdema remains much as it rested when Dr. Ord first so incisively sketched the history of the disease, yet experiment and surgery have both been busy during the past few years, and have done much to thresh out the solution of at least some of the questions at issue. The papers published by the Reverdins showed that they had noticed that the thyroid body has something to do with the group symptoms which we nowadays call myxœdema. Dr. Kocher's work, on the other hand, was rather misleading, for although he clearly enough demonstrated that ablation of the thyroid caused myxœdematous symptoms, yet he attributed them to an erroneous cause, namely, chronic asphyxia. In his recently delivered Brown Lectures, two of which we publish in abstract in another column, Mr. Horsley has attempted to show that he has succeeded in producing in monkeys a condition which he believes to be identical with myxœdema. The animals, after ablation of their thyroid, soon sank into the state so familiar in patients who are the victims of myxœdema. There was the swollen expressionless face, the loss of hair, and the obliteration of wrinkles. The œdema was solid and resilient. The gait grew weak and uncertain, listless and impassive, and the monkey gradually passed into a condition of coma, and so died. That this was myxœdema no one can doubt who has seen the specimens. The imbecile stage of these monkeys must recall only too readily the mental condition of the cretin. Again, the so-called cachexia strumapriva which Kocher found following his operations upon diseased thyroids differs in no way from the results following ablation of the normal thyroid in monkeys. It is remarkable that within so brief a period as that over which Mr. Horsley's experiments extended, we should have unfolded before us so exact and speaking a picture of myxœdema.

The upshot of the researches in question clinch one fact, and that is the immense importance to the organism of the thyroid body, or as we think we must now term it, the thyroid gland. What is the exact *rôle* taken by it is less certain. We may say without fear of overstating the case, that there is strong evidence to show that it is largely concerned in the nutrition of the whole body. The extraordinary mucoid degeneration, if we may so phrase a pathological change which combines vast hypertrophy with the formation of inconceivably large quantities of mucin, is clearly a result of thyroid influence, or rather of absence of that influence. We do not deny that many cases of myxœdema exist in which the thyroid gland is to all appearances but little changed; even here, however, there is no proof that the gland has not taken on a perverted function. There is one feature of uncommon interest attached to these experiments, and that is the development of the nervous symptoms. There have been several cases of myxœdema in which "fits" so called have been observed, but the clinical side of the question has not been at all fully elaborated in this direction, observers not having attached enough importance to it. The physical changes in the brain and cord tissues at present cannot be said to show any sufficient correlation with the symptoms, a discrepancy which will we hope ere long be got rid of, and the whole physical basis established for clinical characters so extraordinary.

There are so many points of interest in Mr. Horsley's statements that it would be impossible at present to do more than pass some few of them under review. Thus his experiments, which, although unsupported, were too carefully performed to allow of their being gainsaid, have exposed the fallacy of at least two theories as to the pathogenesis of myxœdema. Dr. Kocher's view that the symptoms followed softening and stenosis of the trachea—in short, were the sequel of a chronic asphyxia—is met by the fact that in the monkeys no such stenosis occurs. And, again, we are fully aware of the fact that Dr. Kocher's views have not been substantiated by the now numerous *post-mortem* examinations which have been made upon myxœdematous patients. It has further been sought to show that sympathetic irritation, or disease of the sympathetic trunk, may affect the individual in such a way as to cause myxœdematous symptoms. However plausible the theory, we fail to see what grounds in fact there are which support it. It is certain, as all must admit who saw Mr. Horsley's specimens, that the nerve tissue in his cases was absolutely normal; and, further, he points out that in Schiff's experiments, in which the sympathetics were subjected to irritation, no symptoms suggestive of the disease in question appeared. Upon the whole we think we may congratulate ourselves upon the fact that a distinct advance has been made through these researches, and what is perhaps quite as important, that the whole subject has been systematised and prepared for even further extension. There is, we need hardly say, room for much further work. The functions of the so-called ductless glands are likely to prove a fruitful field, and the further elucidation of the influence of the sympathetic system, the thyroid and spleen upon nutrition, must be held to be a subject urgently demanding the attention of physiological enquirers.

MEDICAL SOCIETY OF LONDON. — We are asked to announce that no meeting will be held on Monday next, the 22nd instant.

REVIEWS AND NOTICES OF BOOKS.

THE LOG-BOOKS OF THE SOCIETIES.*

We apologise for the triteness of our metaphor. It has been said that for a simile to be a good one, the likeness between the two things compared should be difficult to the first discoverer of it, but obvious to every one when once discovered. Ours, we fear, can lay claim to neither of these distinctions. Except that each has a captain and a crew there is little resemblance between our increasing array of societies and a fleet of argosies, and still less between the bulky and interesting reports of the former, and the bare records of facts which mostly form the log-books of the latter. Our societies are happily nearly always in smooth water, the worst weather they meet with being a mere ripple of discussion or a passing difficulty of finance. For them "the roaring forties" are but inadequately represented by the most strenuous debate on antiseptics; the Sargasso sea finds a poor counterpart in a few stagnant and frothy debates which it would be impolite and perhaps impolitic to particularise. Societies do get into troubled water sometimes and suffer shipwreck, but the history of the past year has been one of successful and remunerative voyages, aided by the trade-wind of professional favour, and brought to a happy close by the united efforts of skilful captains and hard-working crews.

The thirty-fifth publication of the Pathological Society is by far the bulkiest log on our list, and is, we believe, the largest volume ever issued by the Society. One reason for the increase in size would appear to be that the "card-specimens" have not been printed in smaller type than the other communications, as has been the practice heretofore. As a result, the volume no doubt presents a more uniform appearance, but it also makes serious demands upon our already over-crowded shelves. It would be difficult, if not impossible, to over-estimate the value of the work that is being done by this Society year by year, and as time rolls on that value increases rather than diminishes, in proportion to the steady growth in the number of papers attacking the great problems of disease. As we have commented editorially on the most important communications after each meeting, there is little necessity for us to add much now to what we have already said. With the exception, perhaps, of the series of cases of tubercular disease of the tongue, the best communications are to be found in the miscellaneous group towards the close of the volume. We would especially instance Mr. Watson Cheyne's paper on the presence of micro-organisms in two cases of purpura hæmorrhagica, Messrs. Shattock and Parker's monograph on the pathology and ætiology of congenital clubfoot, Mr. Bowlby's paper on four cases of sporadic cretinism, and Dr. Barlow's case of so-called fœtal rickets. The volume is profusely and well illustrated, there being no less than 36 lithographic plates.

The current volume of the Transactions of the Royal Medical and Chirurgical Society is decidedly smaller than many of its predecessors. This is due in part to the rigid, and sometimes inexplicable, exclusion of papers which fail to please the referees, and in part to the growing tendency there is to take interesting cases to the Clinical Society, where the authors are always sure of a good attendance of members to discuss them, and of a place in the Transactions at the close of the session. The exclusion of papers from the Transactions, which have been considered suitable for discussion, is a practice we do not approve of, though we think some control is very desirable. This control, however, should be exercised when the papers are sent in; if, on examination, they are found unworthy of a place in the Transactions, they should be returned to their authors with a formal letter to that effect. It is probable that there would be many unoccupied evenings during the session; this, however, would be better than wasting time in useless and profitless discussion. Among the most noteworthy papers may be mentioned Dr. Ferrier's "review and forecast" of cerebral localisation, being his Marshall Hall prize oration. Mr. Sutton's paper on the "Systematic Examination of Stillborn Children" contained interesting details more than sufficient to warrant his contention "that much good light may be shed concerning hereditary diseases if the bodies of stillborn children be *systematically* examined." A case of a very rare skin disease, xeroderma pigmentosum (Kaposi), is recorded by Dr. Crocker. Dr. Cayley, and Mr. Gould jointly contribute a paper on the operative treatment of gangrenous patches in the lungs, on which an instructive debate took place. The papers are mostly illustrated.

The new volume of the Clinical Society's Transactions may safely challenge comparison with any of its predecessors. In addition to the usual contents, a list has been inserted for the first time this year of the living specimens shown at the Society's meetings, by card. A short account of each is given, and coloured plates are appended to two of the cases. Among the miscellaneous collection of subjects dealt with in the various papers, the purely medical are about equally represented with those dealing only with surgical subjects. Many papers of interest relating to cerebral disease are included, among which we may refer to a well-reported case of disseminated cerebro-spinal sclerosis, by Dr. Bastian, and two instances of severe intraventricular hæmorrhage, by the same author. An important case of old hydrocephalus, leading to insanity and death, is reported by Dr. Whipham. Some noteworthy cases of pneumothorax are recorded by Drs. Cayley and S. West, recovery having been complete in both instances, and in the latter without effusion of fluid. But few examples of cardiac disease are to be found in the volume, the most remarkable being a case of pulmonary regurgitation, by Dr. J. K

Fowler, and an instance of pericarditis closely following angina pectoris, by Dr. Donald Hood. Of affections of blood vessels there are some very interesting cases. Mr. Pearce Gould and Dr. Hadden respectively contribute papers on spreading obliterative arteritis; Mr. Mansell-Moullin gives an account of a case of thrombosis of the vena cava, and Mr. Arbuthnot Lane describes an instance of extensive thrombosis following fracture of both bones of the forearm. The subject of peritonæal abscess in children is discussed in a paper by Dr. Goodhart. He is inclined in such cases to advocate an early evacuation of the pus. Similar treatment of multiple abscesses in the liver was employed in a case related by Dr. S. West. Among the surgical achievements recorded in the volume are three successful excisions of the rectum, by Mr. Harrison Cripps, undertaken for the relief of cancerous disease. The subject of the operative treatment of fractured patella is dealt with by Mr. G. R. Turner, and a case in illustration of the immediate plaster of Paris treatment is put on record by Mr. C. Heath. A remarkably successful case of abdominal section for the relief of internal strangulation is related by Mr. Clutton, and forms an apt illustration of the advantage of early and decisive action in such cases, lately advocated by Mr. Bryant in his Harveian Lectures. Impaction of a set of false teeth in the œsophagus and of a wedge of bone in the larynx led to the performance of an operation for their removal by Mr. Butlin and Mr. Golding Bird respectively. The records of œsophagotomy are not numerous in the annals of surgery, and Mr. Butlin's case will probably take a prominent position in the history of the operation. Among general diseases may be noted an interesting case of pyrexial syphilis by Dr. Burney Yeo, and several uncommon varieties of skin affections. Myxœdema and Charcot's joint disease are represented by single cases only. From this brief summary it will be seen that the Clinical Society has been occupied with the discussion of many difficult and important subjects during the past year, and, it may be added, that most of the debates have been conducted with a vigour well worthy of the occasion. After a careful study of the balance sheet of the Society, we have arrived at the opinion that the additional expense of having the pages of their Transactions cut might be incurred without much risk that the operation would reduce the Society to a state of insolvency.

The Medical Society of London now publishes its proceedings—"irrespective of their having appeared in print elsewhere"—every year instead of as heretofore in biennial volumes. The fellows of the society will doubtless be pleased with the change. The new volume contains many excellent papers, but the discussions thereon are so meagre, and so badly reported, as to be quite worthless. We would recommend better reporting, or else that the discussions be left out.

The volume issued this year by the Ophthalmological Society will compare most favourably with any of those we have referred to above, both as to matter and appearance. It contains several papers of first-rate excellence, so much so that it is difficult, without being invidious, to pick out any for special mention. Mr. Nettleship certainly has a claim to the first place, by reason of the number and general excellence of his communications; his papers on retro-ocular neuritis, and on amaurosis in infants, will be of permanent value. Dr. Sharkey's paper on homonymous hemianopia, and Dr. Brailey's paper on sympathetic ophthalmitis are both contributions of an order not always to be met with in the transactions of our societies. Mr. Snell's paper on miner's nystagmus will, we should think, practically settle the question as to the cause of this disease, though it is still open to doubt whether the affection is of central or peripheral origin, a point well handled in the interesting discussion which follows the paper. Mr. Snell's other paper, too, on congenital anomalies, deserves a passing word of praise. Mr. Streatfeild and Mr. McHardy each supply a practical suggestion of great value, the former in regard to occluding the lacrimal sac before performing extraction of cataract in cases where there has been any lacrimal catarrh, the latter in advocating a large iridectomy in cases of primary glaucoma. The President contributes a most interesting case of proptosis, and Drs. Edmunds and Lawford give a further and valuable statistical contribution to the relationship between optic neuritis and cerebral tumour. A great many isolated cases of interest are recorded, which we are compelled to pass without notice, in order that we may express our satisfaction at the plates, which are admirably executed.

The second volume of Transactions of the lately formed Academy of Medicine in Ireland contains many important and interesting papers. In the medical section, diseases of the nervous system receive a very large share of attention, Dr. Nixon contributing no less than three, viz.: on a case of brachial monoplegia with anæsthesia, on a case of lateral sclerosis, and a paper headed "Does reflex paralysis occur?" Dr. Finny and Mr. J. B. Story also contribute papers of interest to the neurologist, whilst amongst the other papers we may notice Surgeon-Major Gore's paper on the climatic fevers in Bengal, Dr. Beatty's note on a rare form of skin disease, and Mr. Kendal Franks cases of intestinal obstruction. In the surgical section the place of honour as regards importance must be awarded to the three papers on the radical cure of hernia by Messrs. Stokes, Barton, and Franks. Sir George Porter contributes a paper on foreign bodies in the knee-joint, and Dr. E. H. Bennett one on excision of the knee followed by a false joint; Mr. W. Thomson records a case of pistol shot wound of the cerebellum, Mr. Tobin a case of successful treatment of an ununited fracture of the femur, and Mr. Cahill has a long paper on the carbolic treatment. The obstetrical section, as might be expected, contains papers of great interest; we refer especially to Dr. Macan's report from the Rotunda Hospital, and a paper by Dr. W. C. Neville on the graver fevers of child-bed. In the pathological section a great variety of specimens are described, the most remarkable being that of an ossifying sarcoma of the skull, of which photographs are given. The volume is admirably printed and nicely bound, so that both internally and externally it worthily represents the contributions to the great science of medicine during the past year from the sister isle.

The next report on our list, viz.: the third volume

of the Edinburgh Medico-Chirurgical Society's Transactions, like the Irish volume, shows a slight increase in size as compared with its predecessor last year. It contains, amongst other things, the address of the retiring president, Dr. G. W. Balfour, a large portion of which deals with the too obsolete custom of bleeding, a subject which is also treated of further on in the volume by a Brazilian practitioner, Dr. Gunning. The paper on Catheter Fever by Sir Andrew Clark is given in full, with a verbatim report of the discussion upon it, from which we gather that the subject was better received than when he introduced it to the critical audience at the Medical Society. Dr. Craig, the editor of these Transactions, communicates an interesting note respecting the contents of the little known three volumes which constitute the first series of the publications of this society, and though it is exactly 60 years ago since the first volume appeared, the names of two members in the list then published are still to be found on the roll, so that longevity is not a peculiar feature of our own Medico-Chirurgical Society. We have not space to notice the many excellent communications here given, but one on a case of patent ductus arteriosus with aneurysm of the pulmonary artery, deserves a word of praise as a most learned disquisition on the subject. In one respect this volume is superior to all those that are included in this notice, and that is in the admirable way in which the discussions are reported, the value of the papers being much increased thereby. The book is well got up, the pages are cut, and the leaves gilt at the top, another point of similarity with our own Medico-Chirurgical Society.

The twentieth volume of Transactions of the Medical Society of Paris differs in many respects from our own, and the society is somewhat differently constituted. The Frenchmen consider the debates as of more importance than the papers, and accordingly they print all the discussions, but only a few of the papers in full. One of those thus honoured is a most important monograph by M. Troisier, on subcutaneous rheumatic nodules. Of the discussions, that relating to the cold bath treatment of typhoid fever is perhaps the most interesting. The society has been unusually unfortunate in the number of its distinguished members that have died during the year; amongst them we notice the names of Lasègue, Parrot, G. Homolle, and Archambault.

The Hip and its Diseases; by V. P. Gibney, M.D., "Bermingham's Medical Library." Bermingham and Co.: New York and London, 1884, pp. 412.—The work before us is by an author who for "nearly thirteen years" resided in the hospital for the ruptured and crippled, and during whose term of office no less than 2,048 cases of hip disease were treated. It will be conceded therefore that he is not without a large experience of the subject on which he writes. Over and above this statement, however, the book bears internal evidence of being the work of one who is thoroughly familiar with the diseases which are generically classed under the rather loose term "hip disease." Besides the chapters on the anatomy of the hip-joint, and on sprains and contusions, there are others on neuroses, on rheumatism of the hip, and on chronic rheumatic arthritis, before we get to the subject of hip disease in its more conventional sense; and in order that nothing be left out the author discusses coxo-femoral peri-arthritis in its causal relation to disease of the joint proper. We cannot do justice to the eighteen chapters into which the book is divided in the space at our disposal; we therefore determine to point out such views and statements as we cannot accept, in preference to those with which we agree. In the first place we think the author would have done well to have studied the disease as it occurs in children, apart from its more adult manifestations: this would have led to better chapters on neuroses and on rheumatic arthritis; conditions which are exceedingly rare in childhood. As regards rheumatism of the hip, we are inclined to agree with the general practitioner, in thinking many cases of hip disease are really rheumatism, though both he and consultants also occasionally mistake one for the other. We do not, however, quite agree with the author in thinking these cases to be *muscular* rheumatism in the vicinity of the hip; they are much more probably affections of the joint proper. Many such cases have come under our own observation; points which appear to distinguish them are the rapid onset and the tendency to recur. Chapter VI. deals with coxo-femoral peri-arthritis, which we find means inflammation of the "abundance of cellular tissue about the hip." We confess not to have become familiar with hip disease from this source; on the contrary, when infiltration occurs about the joint, we have usually regarded it as a secondary result. Chapter VII. treats of bursitis of the hip. The author has not made as much out of this variety as its frequency would justify, for bursitis is undoubtedly a frequent cause of hip disease. The number and extent of the bursæ about the hip is very considerable, and when we remember how many of them communicate with the joint itself, how they are, in point of fact, only extensions of the synovial membrane of the joint, it is not surprising that they should increase the risk which this joint runs of becoming diseased. The importance of careful treatment, of thorough Listerism when opening such bursal swellings will be at once apparent. Acute epiphysitis of the hip is dealt with at some length; but no very clear pathological anatomy of the disease is given to support the author's views. To our mind it is very rare, although disease and even separation of the epiphysis consequent on caries in the neck of the bone, that is secondary epiphysitis, is a condition which is found on the operating table as well as in the *post-mortem* room in cases where an operation has not been practised. Chronic articular ostitis, that is to say, hip disease proper, is gone into as thoroughly as its importance demands The book is illustrated, but with illustrations which will do a great deal to prejudice readers against it. We do not remember ever to have seen anything so bad for a very long time. There are numerous errors, both in grammar and spelling, besides peculiarities of diction, which not infrequently obscure the author's meaning. Should a second edition be required—which is not improbable, for the book contains a great deal of useful information—we should recommend a careful overhauling and re-editing, and a new series of wood-cuts.

Regional Surgery, including Surgical Diagnosis. Part, II.—The Upper Extremity and Thorax; by F. A. Southam, M.B., F.R.C.S. London: J. and A. Churchill, 1884, pp. 582.—The present volume forms the second part of a work on regional surgery. About two years ago we briefly drew attention to Part I., and expressed a qualified approval of the author's scheme, and the mode in which its fulfilments had been commenced. We have much pleasure in having again to notice a further instalment of this work, which we think improves as it gradually unfolds. Such a work naturally loses by being published at intervals and in parts, for cross references cannot be so freely inserted as they should be, and thus analogies and contrasts on the diseases of distant parts cannot be so fully brought out as is desirable. We notice too, in describing certain affections, that the parts most frequently affected are not selected, but rather those which happen to come first in order of description, an arrangement which savours of anatomy more than of surgery. Thus epiphysitis, acute as well as syphilitic, is described under "shoulder joints," which for some unaccountable reason suffers but rarely from these affections, while at "elbow joints," at which epiphysitis is

common, the reader is referred back to the shoulder. The account of syphilitic epiphysitis, however, is faulty in more important points than the foregoing. Thus, "if the upper extremity of the humerus is involved, the arm of the child will be observed to hang motionless by the side, as though it had been fractured or paralysed." This is doubtless correct, but it is not a special feature of epiphyseal disease at this point. The same obtains when the disease is situated at the elbow joint, while it is most obvious when situated in the legs. Then again, contrary to our author's experience, the temperature of the part *is* increased, and pain and tenderness *are* present. The affection "is very liable to be mistaken for *infantile paralysis*." Yes, doubtless by one not accustomed to treat children's diseases; but the presence of pain on handling, together with the peculiar cry, and often of increased temperature, are points which will better guide to a differential diagnosis than those given by the author on p. 260, under this heading. It is especially in affections as syphilis, rickets, rheumatism, and other general diseases, that the disadvantages of such a classification of disease, anatomical rather than pathological, as the one before us shows itself defective. We will not be hypercritical, but rather hope that in future editions the few shortcomings which are inherent to a work of this kind will be amended. Some paragraphs might be left out (*e.g.*, clubhand), many may be enlarged and bettered (*e.g.*, empyema). The index can also be improved. The book is well printed in clear readable type, and the size well suited for convenient reference.

ABSTRACTS AND EXTRACTS.

NEUROLOGY.

Thomsen's Disease.—Under the head of "A new neurosis," Dr. W. H. Spencer describes, in the *Bristol Medico-Chirurgical Journal*, for September, a case probably of this rare and very obscure affection. His patient was a labourer, aged 36, who was subject to attacks, or fits as he called them, in which the following phenomena were observed. First the man's appearance became altered, his face became flushed, passing into a state of extreme vascular turgidity, there was slight tremor in the muscles of his arms and legs followed by gradual rapidly succeeding muscular rigidity and spasm, the teeth were ground together, the jaws tightly clenched, the facial muscles set, the arms pressed against the sides, and the legs extended. His voice at this time was muffled and indistinct, there was no loss of consciousness. Muscular relaxation then supervened and the fit was over. Each attack would last about two minutes, and he usually had several attacks in succession, rarely only a single one at a time. The attacks varied greatly in severity. Conium seemed to be beneficial at first but lost its effect after a time. The patient stated that he had been subject to these fits for about fifteen years, and that twelve years previously he had had an attack of mania and been in an asylum for rather more than two years. Five years before he came under observation he had had an accident, an iron bar falling on to his foot, and eighteen months after this he had an attack of lock-jaw lasting for ten days. Since then his fits had been more severe and more frequent. Nothing was to be made out by physical examination, the reflexes were fairly normal and the electrical reactions natural. Dr. Spencer does not indulge in any hypothesis as to the nature of this affection. Previous writers have speculated on this subject, some assigning it to the nervous system, others, such as Ballet and Marie, whose paper we analysed in 1883, believing the muscular system to be at fault. More recently, in the *Archives de Neurologie*, for November, Dr. Romain Vigouroux has recorded the case of a young man, aged 19, in whom the system of Thomsen's disease were well marked, and coincided with a typical pseudo-hypertrophic paralysis, the two diseases appearing not to modify each other in any way. Two points were observed in this case worthy of being especially mentioned—one is the exaggeration of the reflexes, and the other certain peculiarities in the electrical reactions. Every contraction provoked by the current, whether faradic or galvanic, became tetanic and lasted longer than the current. This was observed both when the electrode was placed on the muscle or on the nerve.

Numbness of the Upper Extremities.—Dr. Sinkler says (*New York Medical Journal*, July 26th) that the symptoms are regular and constant in their general characters; the patients are usually women, and at the change of life. The numbness generally began in one or both hands, and gradually extended up the arms; it was usually most marked in the morning before getting up. There was but little loss of feeling to touch, or pain; the numb member was weak, but there was no paralysis, and the weakness was transient; the patients sometimes thought the hands were swollen when the numbness was most marked. The condition was only occasionally associated with rheumatic affections; it seemed sometimes due to over-use of the limb first affected; its duration varied from a few months to several years. The ulnar and median distributions were most frequently affected, and tenderness over the ulnar or median nerve was frequently observed. Many patients were in good general health, but some were anæmic or over-worked. Dr. Weir Mitchell, referring to cases in which numbness came on during sleep, remarks that in such cases the numbness was frequently hemiplegic in character, and alludes to the fact that some persons who have got pretty well of a hemiplegia of organic origin, are liable to wake out of sleep with numbness and lessened power of the side once paralysed. Dr. J. J. Putnam has published a paper, based on the notes of thirty-one cases. His treatment comprised galvanism, phosphorus, strychnine, potassium, bromide, &c.; and he seems to have found phosphorus of more value than any other single means used. Dr. Putnam states that he has lately found lead in the urine of one of these patients, and advises that it should be sought for in all such cases. Dr. Ormerod ascribes the affection to vascular spasm, and observed that bromide of potassium afforded marked relief in several of his cases. Dr. Sinkler inclines to the belief that in these cases there is either hyperæmia of the nerve-trunk, or (as when the numbness is bilateral in its distribution) that there is a congestion of the cervical enlargement of the spinal cord. This view is strengthened by the occurrence of the numbness at night, for the supine posture favours a hypostatic congestion of the cord; and he has seen patients in whom the numbness came on if they lay down and fell asleep even for a short time in the day. Women, at the climacteric, are more prone to hyperæmias and congestion, and they are the more frequent subjects of this form of numbness. Further, improvement usually followed the administration of remedies which are believed to diminish the blood supply of the nervous centres. The prognosis in middle-aged women is not good as regards permanent relief, though the numbness can generally be much benefited or stopped for a time. When the trouble has been induced by over-work of the part, permanent cure is almost certain, if the cause can be removed. In Dr. Sinkler's hands, ergot has proved the most useful drug. Massage and spinal galvanism are useful adjuvants, as are all means which improve the general health. Bromide of potash sometimes does good, and one of his patients was much benefited by sinapisms over the spine. In most cases it was found advantageous to give strychnine for some time after the disappearance of the numbness.

Electrical Neurosis.—Under this head M. Féré records in the *Progrès Médical* a sufficiently unusual case. A woman, aged 29, who had exhibited various nervous symptoms, including well-marked ovarian hyperæsthesia, had for two years presented the remarkable phenomena about to be mentioned. She noticed that her fingers attracted bodies, such as pieces of paper, ribbons, &c., and her hair not only gave sparks when in contact with the comb, but had become very unruly in the matter of lying smooth. When her linen came near her body, a flash of light was produced, and her clothing adhered closely to her body, so much so sometimes as to interfere with the freedom of her movements. These phenomena

were more marked under the influence of strong emotions, and were lessened in damp weather, so that she was able to foretell what the weather was going to be like from the increase or diminution in her state of electric tension. The patient was thin and anæmic, and subject, especially in damp weather, to œdema of the legs. With a view to prevent this loss of electricity, she was recommended to wear silk next to her skin, which was further powdered all over with lycopodium, but without much benefit. Subsequently the daily application of static electricity by means of an electric bath for about ten minutes, was followed by good results. This fact confirmed M. Féré in his idea that this was a case not of exaggerated production of electricity, but rather of an abnormal loss of it, probably owing to the dryness of the skin.

Multiple Neuritis.—At a recent meeting of the American Neurological Association, Dr. S. G. Webber read a paper on this subject, detailing several cases that had come under his own observation. Disturbance of sensation in one or more nerve districts was one of the most constant symptoms, the pain sometimes exactly followed the course of a nerve; it might be boring, shooting or burning; hyperæsthesia of the skin, and tenderness of the muscles usually accompanied it. The special senses had not often been attacked. Motor paralysis was often preceded by stiffness and followed by contraction. Electrical reaction of the nerves and muscles showed changes, but we are not told what those changes were. The superficial and deep reflexes were absent. The pulse and temperature were usually raised in the earlier stages, and in fatal cases throughout. In fatal cases the respiratory muscles became paralysed, the voice was altered, and swallowing rendered difficult. As to diagnosis, it was to be distinguished from acute poliomyelitis by its gradual onset, by the pain, hyperæsthesia, and tenderness over nerve trunks. From progressive muscular atrophy it was to be distinguished by the electrical reactions; from lead paralysis by the sensory disturbances; from spinal meningitis by the relatively insignificant pain in the back.—*Philadelphia Medical Times.*

Acute Painful Paraplegia.—Some years ago an epidemic occurred at Azannon, in Spain, in which paraplegia was the most prominent symptom. A somewhat similar outbreak in a French village named Vizille, is described in the *Revue de Médecine* for July, by M. Dumolard. The disease commenced with pain in the back and a sense of stiffness in the legs; in a short time there also appeared pain in the thighs and legs, not following the course of any nerve or confined to the neighbourhood of any joint, but invading the whole limb. The difficulty of walking increased, and in a few days the patient was obliged to take to his bed. The pain in the loins and legs was sometimes excessive. The reflex excitability of the cord was exaggerated, sometimes to such a degree that the patient could hardly bear to be touched. In some cases there was difficulty in micturition. The patient generally lay in bed with his legs drawn up and thighs flexed on his abdomen. At the end of a fortnight the acute symptoms used to commence to disappear, and in about a month the patient was well. All the cases terminated in recovery. From transverse myelitis, the only disease about which there might be some confusion, the disease is to be distinguished by the incomplete character of the paralysis, and the absence of any nutritive disturbances. Of the seven cases, six occurred in February or March. The author surmises that there was some irritative lesion of the spinal cord, but is quite in the dark as to its exact nature.

Locomotor Ataxy.—Clitoridean crises as a sign of locomotor ataxy, though described nearly twenty years ago by Charcot, have not met with that general recognition that their frequency would justify. Like the other crises they come on spontaneously at intervals of one or a few months. In the *Progrès Medical*, No. 37, M. Pitres has recorded three cases of well marked advanced progressive locomotor ataxy, in all of which this symptom had been prominent in the early stages of the disease, appearing even before the lightning pains. In one of his patients the crises had persisted for four years before any symptoms of tabes showed themselves. He regards them as analogous to the sexual perturbations that occur in the early stages of the disease in men. He concludes with the following propositions. (1) When we find clitoridean crises, we ought to suspect tabes in the absence of any other manifestation of spinal lesion. (2) When clitoridean crises co-exist with any of the ordinary symptoms of ataxy (abolition of the knee jerk, visceral or lightning crises, ocular disturbances, &c.), we ought to diagnose tabes even in the absence of any sign of ineo-ordination of movement. At the annual meeting of the American Neurological Association, Dr. Graeme Hammond read a paper (*Boston Medical Journal*, July 3rd), entitled, "Can Locomotor Ataxia be Cured," which he terminated with the following conclusions:—(1) The absence of the patella tendon reflex is not always caused by sclerosis of the posterior columns. (2) Sclerosis of the posterior columns may exist without being accompanied by the ordinary prominent symptoms of ataxia. (3) Congestion of the posterior half of the spinal cord may give rise to most, if not all, the symptoms of ataxia. (4) It is impossible during life to make a differential diagnosis between posterior spinal sclerosis and posterior spinal congestion. (5) Posterior spinal congestion is curable. (6) There is no evidence that sclerosis, once existing in the spinal cord, has ever been removed. (7) Those cases of so-called locomotor ataxia which have been cured are simply cases of spinal congestion, more profound in the posterior half of the cord.

Cortical Lesions of the Brain.—At page 609 of our last volume, we noticed a communication in the *American Journal of Medical Sciences* on this subject by Dr. Allen Starr. In the July number of that periodical we have a further contribution from his pen. The last paper dealt with the American cases of disease of the non-motor region, this one examines the cases in which the motor region was affected. This area, which he terms the central region, includes the anterior and posterior ascending convolutions, the Island of Reil and the paracentral lobule. The cases of spasm confirm the conclusions arrived at by the study of the cases of paralysis, viz.: that the upper part of the central region corresponds to the leg, the middle part to the arm and the lowest part to the face. One result of this study is the opinion that disturbance of sensation must be regarded as one of the direct local symptoms of lesion in the central region. The same distribution for sensory areas was found to obtain as for motor, viz., that the upper part corresponded to the leg and so on. In three-fourths of the cases of sensory disturbance the lesion was behind the fissure of Rolando, and in more than half of these the parietal lobules were also affected. It would appear therefore that to some extent the motor and sensory areas coincide. Aphasia was referred to lesion in the left Sylvian region, but not restricted to the third frontal convolution. The paper is based on an analysis of 70 cases.

Ankle Clonus.—In a recent number of the *Revue de Médecine* is a short note by M. de Fleury on the relation between epileptoid tremor of the foot and exaggeration of the patellar tendon reflex. From the habitual co-existence of these phenomena, there has arisen an idea that they both own the same cause, viz., sclerosis of the lateral columns of the cord. This idea he believes to be erroneous, and he records a series of cases in which the ankle clonus or "foot phenomenon," as he calls it, was present, the knee jerk being normal. In a second series of cases he shows that ankle clonus may be present when the knee-jerk is weak or even absent altogether. In a third series of cases he shows that when these two phenomena are co-existent, the artificial production of anæmia in the limb, by means of an Esmarch's bandage, will cause the ankle clonus to disappear, the knee-jerk being unaffected. It is probable therefore, he concludes, that the two phenomena are not of the same nature. They may be usually contemporaneous, but there is no common bond of causation between them.

Death of Professor v. Wittich.—Dr. von Wittich, who on account of illness was obliged to resign his professorship of physiology at Königsberg, and was succeeded by Professor Hermann, has recently died in the 64th year of his age.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, DECEMBER 12TH, 1884.

Sir ANDREW CLARK, Bart., M.D., President, in the Chair.

ADJOURNED DISCUSSION.—CHARCOT'S JOINT DISEASE.

AT the request of the President, Dr. DUCKWORTH read some abstracts from letters that he had received on the subject from Professor Charcot.

The PRESIDENT observed that Professor Charcot had contributed in a very large degree to the interest and success of the debate. He hoped that a vote of thanks to him would be duly proposed and carried, and at the same time that the Society would not forget its indebtedness to Dr. Duckworth, who had induced Professor Charcot to send his specimens and the interesting communications which had been read.

Dr. MOXON expressed his gratification at the opportunity thus afforded him of proposing a vote of thanks to Professor Charcot. He was able to do so with much admiration of that illustrious physician. He believed that no clinician had ever brought so grand an imagination to the service of his science, and that no scientific imagination had ever had a better power of observation sub-ordinated to it. He thought that it might be accepted as certain that there had been a fact put before the Society, and one which he must regard as a very suggestive fact, looking to the great interest that was manifested by the large attendance of members. What it was that this fact suggested, however, appeared somewhat indefinite. He could quite sympathise with the spirit in which the President had put a question to Sir James Paget at the previous meeting, asking that he would make more clear to the Society what it was that he meant. He fully agreed in the implied suggestion that there was no one fitter to give an answer upon a subject requiring range of thought and accuracy of utterance. The answer which Sir James Paget gave was somewhat disappointing, in that he dragged in herpes zoster. To him herpes zoster was a narrow clinical puzzle, and he heartily wished there were no such thing in the catalogue of diseases. He would be very thankful to any member of the Society who would explain to him in what possible way herpes zoster threw any light on this so-called Charcot's disease. He related a case of herpes zoster illustrating clearly its inflammatory nature and its tendency to run a definite course, ending perhaps in some painful after effects, but always healing and never coming again. What had a disorder so characterised to do with the so-called Charcot's disease? The latter commenced in a condition extremely like common chronic rheumatic inflammation of the joint affected, only that there was no pain in the joint, nor were there any nervous symptoms. Very little that was definite had been put before the Society about this supposed new disease. Mr. Hulke had, however, definitely shown that in the initial stages of this so-called peculiar disease of the joint there is nothing peculiar at all. It was only after an at first simple rheumatism has domiciled itself for approximate ages in the particular joint, that it began to show those peculiarities which make up Charcot's disease. This lateness of character was remarkable, and so also was the absence of pain. What parallel could there be between herpes zoster, which was definite in its origin, exact in its course, and complete in its termination; and this other disorder, which at first showed no definiteness at all, which was absolutely, hopelessly indefinite in its course, and which was peculiar amongst rheumatisms in having no nervous phenomena at all? In one line only did they touch each other, that was the line of indefiniteness, the line in which we knew nothing about them. Seven or eight years ago Professor Westphal had shown that in what was called general paralysis of the insane the conditions of locomotor ataxia to a large extent were present. Being much interested by that statement, he (Dr. Moxon) had made a careful examination of the general paralytics in St. Luke's, and had come to the conclusion that about one-third of all those unhappy sufferers had the physical conditions objectively characteristic of locomotor ataxia. He quoted Dr. Savage to the effect that in his experience about one-third of all general paralytics in Bethlem showed locomotor ataxia, but that he had never met with a single example of Charcot's disease in that hospital. If in truth the conditions of ataxia were present in a paralysing disorder, and if this peculiar joint disease supposed to belong to ataxia did not appear in the ataxia that went with paralysis, then, he thought, we must look for some traceable effect of paralysis to explain the absence of the joint affection, and possibly some light would thus be cast back upon the causation of the whole mystery. If an ataxic person were paralysed, and therefore could not go about upon his ataxic joint, he was thereby saved from the effects of continual irritation. Possibly this might be the reason why he did not make an originally chronic simple rheumatism into an aggravated, unrepairing, irritative, severe, therefore strange and peculiar disease of the joint. He exhibited a specimen from Guy's Museum consisting of the shoulder joint of an ex-cabman who was thrown from his cab and hurt his shoulder a year before his death, but in order to support his wife and family had continued driving his cab. The constant jarring involved in a year's cab-driving with an injured shoulder joint would not be so very far different from a year's unsteady stumbling about on an ataxic knee joint. In the specimen one-half the head of the humerus was entirely gone, and yet there was no production of new bone about it. Those, he considered, were the most striking characters of the so-called Charcot's disease as defined and summarised by Sir James Paget at the last meeting. A half-Charcot's joint could thus be made by the irritation connected with the unguarded and continued use of a joint suffering rheumatically or from any injury. When demonstrating anatomy at Guy's Hospital, it had always been his pride and pleasure to make the subject interesting to his class by trying to show some reason why that which was evident should be expected to exist. And amongst the most interesting general facts of anatomy first observed, and to the larger extent by Mr. Hilton, but also carried a little further by himself, was this in particular. Mr. Hilton said that wherever a nerve supplied a muscle it supplied the skin over that muscle. From his own observation, he would say that wherever a nerve supplied a muscle it supplied the skin of the part moved on the side towards which motion was effected, and it likewise supplied the joint which that muscle moved, and generally on the side towards which motion took place. There must be some meaning in such an arrangement. The meaning must be that there was some underlying necessity that the part moved should be sensitive to the effect of motion; and they might understand the necessity, for, given that anything harmful is occurring through a movement, the moving agency ought to be immediately and duly checked. If that was a requisite of joint life, what ill results might not ensue if the sensibility of a joint were taken away and the muscles rendered spasmodic in their action. These ill-results must be first measured and stated before it was asserted that when a joint deprived of its sensibility and subjected to spasm showed serious signs of chronic inflammation, that there must be something mystical and marvellous in the nervous system to explain it. He pointed out that Mr. Hulke had shown that this so-called Charcot's disease began as a common rheumatism, and ended in extensive disorganisation, only after long experience of spasmodic irregularity of action in the presence of a wholly broken down condition of that protective system to which he referred. He thought that it was no new thing in the history of the medical profession for a mysterious origin to be claimed for a local manifestation. The supposed association of mania with hæmatoma auris was an example of this. In the absence of proven or direct causes there was a tendency in the profession to appeal to the nervous system, as if it were a kind of special providence, something like the sort of influence which before the days of Sir Charles Lyell was thought to enter into geological periods, the special providence of geology. There used to be some degree of moderation in that invocation, until what was called the trophic nervous system was invented. This trophic

or nourishing system seemed indeed to be a special branch of providence which had charge of the supplies of the several textures, such as the bones, and gave daily bread to the joints, having its seat in the *medulla oblongata*, and being, in fact, a sort of Secretary of State for the Joint Department in that over-occupied kind of Downing Street of the Physiological Economy. Why, however, should one knee-joint out of the whole system of articulations be singled out for destruction when all were under this same central control? Those who believed that the knee-joint in Charcot's disease was affected by the nerves should show that the nerves themselves were affected, as Danielssen and Boeck had done in the case of anæsthetic leprosy. He considered that there was a very large opening in this direction for further contributions, and that they ought to be extremely exacting and not easily diverted from the severity with which they would pursue and force that question home. Not only must a diseased condition be demonstrated, but a diseased condition in itself proven and obvious. The French professor had brought forward, as evidence of some very mysterious influence of the trophic nerves, the very strikingly significant occurrence of unilateral bed sore on persons paralysed on one side only. He (Dr. Moxon) was not ready at all to admit that they must here suppose any vague providence of trophic nerves to explain such an occurrence; they must rather look straight into the particulars of such a case and see if they could not understand it. A hemiplegic patient always lay toward the buttock that was paralysed. In certain arteries, such as the perforating arteries of the thigh, the vessel passed through a tunnel of tendinous fibre to which many of the muscular fibres of the part were attached in such a way that the contraction of the muscle held the tunnel open, and so kept free the course of the artery from pressure by the mass of contracting muscle. In the inanimate clay-like mass to which a paralysed buttock was reduced, this pressure was no longer counteracted, and the vessel was closed. If, then, the buttock was fed by arteries coming through the gluteus maximus, and with the whole weight of the body, through the roll of the patient, resting on the gluteal mass of the one buttock unprotected by the tone of the muscle, it was not surprising if the muscle and the textures over it should perish exactly in proportion to the pressure, a proportion which the destruction always closely observed. In proposing a vote of thanks to Professor Charcot, he did so with the highest admiration of the great services which he had rendered to medicine. But it must not be forgotten that this was not the first occasion on which the profession had had a somewhat mystic light thrown by Professor Charcot on an obscure subject. The function of genius was to bring the marvellous to play round the ordinary—it was the very charm of genius so to do. The vagaries of hysterical females in response to the application of metals, &c., attracted some attention a few years ago and there could be no doubt that on that occasion the marvellous was brought to bear upon the ordinary in a very suggestive manner. He would conclude by thanking Professor Charcot profoundly, and asking the society to pass him a vote of thanks.

Mr. Morrant Baker seconded the vote of thanks to Professor Charcot, which was carried by acclamation.

Mr. Henry Morris thought that the contribution of the complete histories of two cases might lend some usefulness to this discussion, because he considered that the way to arrive at any definite conclusions upon this or any similar subject would be rather by inductions drawn largely from individual cases, than from any general reasoning. The first case was that of a man who, in 1877, was sent to the Middlesex Hospital with a knee for which it was supposed he would require amputation. The knee was described in the report at the time as chronic rheumatic arthritis of a most aggravated and special character, but it had all the well-marked conditions of those knees which had been exhibited during the last few meetings. This man had come also with a malignant tumour of the face, which he had had five times removed. After the removal of this malignant growth of the face, which turned out to be a rodent ulcer, he was fitted up with Thomas's knee splint, and returned to his home in Staffordshire, where he continued working with this splint a little over six years as a miner. The history of the case with regard to the knee was briefly that of chronic rheumatic arthritis. But throughout its whole course there had been no ataxic symptoms, and at one time, under the rest furnished by the splint, there had been distinct improvement. This fact supported the views of Mr. Jonathan Hutchinson and those who thought with him, that if these joints were submitted to a condition of rest, the changes would cease and improvement would take place. The second case was that of a man who had a leg in a condition of elephantiasis. He was admitted into hospital with an intestinal obstruction, for which he was operated upon. He died after the operation, and an opportunity was afforded of obtaining his limb. This man had complained throughout the greater portion of his life of severe sudden pain in his abdomen, lasting only for a short time, and then passing off. These pains were fully explained by the condition which was found in his abdomen after death—an enormous volvulus, in a huge sac-like omentum, which must have existed for a very long time. The leg had been getting bad for ten years, the ankle becoming quite slough-like, and movable in any direction. It had lost all shape; it was rotated outwards, the bearing point was almost brought upon the inner border of the foot. There was a perforated ulcer on the great toe of one foot, and a similar condition on the corresponding spot on the other. These conditions had been gradually progressing for 21 years. On closer examination of the limb it was found that the bones of the foot had worked down in a saucer-like cavity with considerable thickening of the bone around, the external malleolus was more like the condyle of the femur, the tibia and fibula were firmly united at the lower ends, and the shape of the bones was altered by an irregular bony growth along their shafts. Very marked changes were found in the posterior tibial nerves, but they were precisely those which had been described by Mr. Savory and Mr. Butlin and others in a recent volume of the Medico-Chirurgical Society's "Transactions," as occurring in perforating ulcer of the foot. There was enormous thickening of the epineurium, and scarcely any change in the perineurium. The nerve fibres were scattered very sparsely; only the large nerve fibres were visible, the smaller, which were considered to be the sensory and trophic fibres, were almost entirely absent. Throughout the case there was a complete absence of any ataxic symptom. Whether these remarkable changes in bones, joints and skin were brought about originally by some change in nerve or not, there was here, at any rate, a condition of marked change in the nerve, and an undoubted association between a perforating ulcer and a condition of a neighbouring joint, exactly similar to those described by Charcot, and further there was associated with these conditions the peculiar elephantoid condition of the whole of the tissues from the knee to the foot.

Mr. Page referred to a case brought before the Society early in the previous year, of a man who for some years had been the subject of gastric crises, attacks of vomiting to an extreme degree, and who also had pain of great severity. The man came under observation for an affection of the tarsal bones of one foot, which apparently was associated with, if not caused by, a lesion of the nature of tabes dorsalis. The tarsal bones of both feet gradually underwent a very considerable change, consisting in extensive destruction of the tarsal bones. Under the influence of rest, however, ankylosis eventually took place. So far, the history of the case was that of rheumatoid arthritis attacking the bones of the feet, possibly promoted by certain nerve changes. The man remained at work in what was to him perfect health, till about the end of August in the present year, when he again came into the hospital with a recurrence of the attack in one foot. Most extensive changes had lately taken place in one ankle and one series of tarsal bones, but the other foot had been wholly unaffected. This fact seemed to point to some other cause than that of such a general condition as rheumatoid arthritis. He thought that the debate had hitherto been more or less pathological. Speaker after speaker had referred to the pathological changes which were met with, but very little indeed had been said about the clinical features of the affection, whereas it was upon these that Charcot himself

desired to establish the existence of a wholly distinctive disease. Various speakers had referred to the gradual wearing away of the ends of the bones which was met with in this condition. But in the clinical history of these cases of Charcot's disease, the wearing away was not gradual: it was rapid, and took place in a very short space of time, and it seemed that there must be some other cause than the rheumatoid change or the friction of the bones one against another to account for the condition. Charcot himself had pointed out numbers of cases which had been brought forward of recent years, in which a rapid wearing away had taken place in association with exacerbation and other symptoms of the disease, increased pain, gastric crises, and other things of the same kind, and in his own cases attacks of hæmaturia which probably had a nervous origin. There was no reason to believe that in a case such as his the friction of the bone could have given rise to the condition, because in the later stage only one joint had been affected, both having been subjected to precisely the same influences. It might be allowed that certain irritative lesions of nerve trunks did give rise to certain different effects, in a nerve which had been divided, and in which the distal end of the divided nerve was irritated by inflammation; or by being bound down in cicatricial tissue, the changes were somewhat different. When the distal end of the nerve had been released from the cicatrix by operation, the changes which were due thereto ceased, but the passive condition of nerve activity remains for some time till the nerve function has been restored by the union of the nerve. Those might or might not be trophic changes, but they were essentially due to some effect upon the nerve trunk at the part where the division had taken place. If such effects might take place in that way he did not see why it was not possible that the same sort of change might not be due to lesions in more central parts of the nervous system. But recent observation had shown that nerve trunks themselves underwent very extensive and serious changes in this disease, and also in the case of acute bedsores. He believed that in some of the cases described by Professor Charcot, where paralysis was induced accidently, not only was bedsore met with on the opposite side to where there was anæsthesia, but actual changes were met with in the joints on the same side as the lesion where there was motor paralysis. So that possibly if the condition of paresis on one side were due to changes in the nerve, the same thing might be on the other side also, so that possibly these changes were really due to some alteration of the nerve trunks themselves, though determined by the condition of the nervous system itself. He thought that the result of the debate would be to leave the minds of members in a state of individual belief, in reference to this disease. For himself he confessed his belief, without desiring to pin himself to one particular faith, very strongly indeed that they had to do with a distinctive disease of joints induced by some change in the nervous system, and that Professor Charcot himself was not far wrong when he originally, in his description, decided that this was a distinctive disease having special clinical characteristics of its own.

Dr. Moxon asked Mr. Page, with reference to the case that he had brought forward, whether the person with this tarsal disease, as he described it, had or had not locomotive ataxy definitely; and, secondly, whether he would tell the Society in what way locomotor ataxy was a less general disease of both feet than was rheumatoid arthritis?

Mr. Page replied that his patient had certainly no ataxia in the ordinary sense of the word. With respect to the disease being limited to one side, he could hardly conceive a rheumatoid arthritis being absolutely quiescent in one limb previously affected to so extreme a degree, and yet voluntarily active in the other.

Dr. Pye-Smith remarked that the first point which was brought before the Society, in the admirable speech by Sir James Paget, was whether this Charcot's disease was a new disease. With regard to that he would venture to express his opinion that they had no evidence of any actual new disease, certainly not of this. Cholera, diphtheria, and that curious affection known as cerebro-spinal, insular sclerosis, which again they owed to the acumen of Professor Charcot, had all been only recently recognised, but no one believe that these diseases did not exist previously. They were new to them but not new in nature. The second point was the relation of so-called Charcot's disease to osteo-arthritis; and, on the whole, it seemed to him that the weight of evidence was somewhat in favour of connecting the two, and that at any rate there was no adequate evidence for separating them. If somewhat extreme or well-marked cases of the two affections were compared there was, no doubt, sometimes a great excess of fresh bone, a great hypertrophy in osteo-arthritis, and there was a great diminution, a great waste, in Charcot's joints. In most cases of Charcot's disease, where there were several joints to look at, an attempt more or less at the production of new bone could be discerned in some of them. If the disease were admitted as belonging to the somewhat large group of osteo-arthritis, it was evident also that even in this well-recognised group of affections certain varieties could be distinguished. There was, if they were put side by side, apparently but little similarity between the early stages of osteo-arthritis as it affected the girl, where it attacked very symmetrically the small joints in the fingers, with considerable pain, and a little febrile re-action perhaps, and a very little distortion, and a disease affecting one hip-joint of an old man with perhaps hardly another joint in the body affected, very slow, very local, very, so to speak, traumatic, very little, so to speak, constitutional. There was all the difference between the early affection of the young woman and the late and obstinate affection of the old man. With such a contrast they might be inclined to say "Here are two diseases." The mere fact of a well-marked typical case of Charcot's disease differing from an ordinary case of osteo-arthritis should not lead them entirely to separate them. He had seen a gouty joint with all the clinical features of gout, in which the pathological changes had left the joint very much in the condition of an osteo-arthritis; but no one would say that gout and osteo-arthritis were the same disease. So with acute rheumatism, true rheumatism, rheumatic fever, he for one believed most thoroughly in that being an absolutely distinct, definite disease, entirely separate from everything known as chronic rheumatism, osteo-arthritis, or rheumatic gout, or any of those rather vague terms. At the same time there was no doubt that occasionally deformity and other changes might result from acute rheumatism, which were far more frequently seen in osteo-arthritis. He related two cases in illustration of this fact. Had this osteo-arthritis or Charcot's disease, taking the two together, any definite relation to rheumatism, to gout, to trophic disease, nervous diseases, or to tabes? With regard to trophic nerves, he could not agree with Dr. Moxon in regarding them altogether with scorn. The early experiments upon the trophic nerves of the cornea, confirmed as they had been by a series of modern physiologists, placed their existence beyond all possibility of reasonable doubt; and when once that had been done, the many clinical and physiological facts which before they had endeavoured to explain, and rightly so, upon other hypotheses, without calling in these obscure trophic nerves, had become not only clear, but added much weight to what they knew before—such cases as Mr. Hilton's of the ulcer on the hand, which waxed and waned on pressure on the ulnar nerve from exostosis—such cases as those remarkable ones of bed sores of rapid, severe, violent description, very different from the bedsores of pressure—compelled them to admit the existence of trophic nerves; but he could not admit that they had any evidence that they have much to do with Charcot's disease. There was no reason to suppose that a trophic nerve had any connection with the posterior columns of the cord, and there was reason to believe that the trophic nerves passed out through the anterior roots, which, so far as they knew, were quite unaffected in tabes. Then, with respect to gout, was there the slightest connection with gout of any sort? The whole pathology of gout and osteo-arthritis was so different that he rather wondered that there should be any resemblance seen between them. There was an entire absence of urate of soda from the true cases. The extreme rarity of gout in certain parts of the world, and the extremely common diffusion of this disease was surely enough to show that there was no connection between them. The same disease was common among animals, and he exhibited a specimen of

the fetlock of a horse, showing a good example of osteo-arthritis. Many other specimens of this had been shown by Professor Flower and others. But no one had traced gout in any one of these instances. He pointed out at some length that equally little connection could be traced between this joint disease and syphilis. Having seen a great many cases of tabes dorsalis or locomotor ataxy, he had never seen a case of joint affection supervening in the course of this disease. As regards the connection between tabes and Charcot's disease, he thought that tabes itself was not such an absolutely fixed and definite entity that they could afford to hang a still more doubtful disease on it. Without absolutely denying its existence, he thought that it had suffered very much from want of accurate definition; under the wide category of tabes a number of cases had been included which were wanting in many of its essential features, and if they were to arrive at better knowledge they wanted not philosophical views as to its origin and connection with other forms of pathology, but more carefully observed cases of joint affection in persons with locomotor ataxy, and better prepared sections of spinal cords. It was not by generalisations or theories, or by referring to occult causes, or by invoking dyscrasiæ, diatheses, blood diseases, and neuroses, and all those somewhat vague and undetermined causes, that they would arrive at any further knowledge of them. He thought that of further contributions which the Society would receive, and which would help in the solution of this very interesting question, those would be of the least value which smelt most of the lamp, and those would be the most useful which smelt most of the dead house.

The discussion was then adjourned to Tuesday, the 23rd instant.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, DEC. 11TH, 1884.

JONATHAN HUTCHINSON, F.R.S., President, in the Chair.

Living Specimens.

Mr. R. M. GUNN showed a little girl with unilateral choroiditis in the right eye. There was a history that two years previously she had been taken ill with convulsions and unconsciousness, probably due to an attack of meningitis. From that date she had been blind with the right eye and deaf with the right ear. Posterior synechiæ were found, and at the outer part of the disc there was some choroidal atrophy. Some connective tissue growth could be seen stretching into the vitreous and partly obscuring the disc. There were two small detachments of the retina. There was a most distinct history of syphilis in the mother, and some of the earlier children had exhibited symptoms of hereditary syphilis, but this child had none. He nevertheless attributed the affection to inherited syphilus.

Messrs. CRITCHETT and JULER exhibited a man who for five months had been subject to a recurring vesicle on one cornea. There was much photophobia and lacrimation when the vesicle was present; each one only lasted a few days. In other respects the eye appeared sound.

The PRESIDENT observed that a vesicle was often seen on an eye that was nearly lost, but he did not remember to have seen one on a perfectly sound eye.

Dr. W. A. BRAILEY showed a case of hyphæma supervening on some deep-seated intra-ocular change. There was irido-cyclitis, and hæmorrhage into the vitreous. There was no history of gout.

The PRESIDENT said that this was just the sort of case in which he would have expected that gout had been present.

Mr. NETTLESHIP thought that this was a case which formerly would have been described as idiopathic phthisis bulbi.

Dr. BRAILEY in reply pointed out that it differed from cases of phthisis bulbi in every respect except one, and that was the variation in temperature.

Mr. ADAMS FROST showed a young woman with conjugate deviation of the eyes to the right, probably hysterical.

Retinitis Albuminurica in the left eye only.

Mr. HENRY EALES (Birmingham), communicated this case.—F. B., aged 25 years, single, came to the Birmingham Eye Hospital on August 25th last, complaining of loss of sight in his left eye of three weeks standing, when the house-surgeon made a note that his right eye was normal while his left eye presented all the typical appearances of retinitis albuminurica, that the urine contained albumen in a small quantity, and that he had been a heavy beer drinker for seven years. On enquiry it was ascertained that on Saturday, August 2nd, being very drunk, he had a fall on some steps in which he twisted his left side. This pained him for a fortnight after so severely that he was unable to stand upright. His urine remained normal in appearance as far as he could tell, but on the following morning he noticed his sight dim, there being "a cloud over the upper part of his sight." He has never had scarlet fever, syphilis, or, in fact, any illness till the present. Having been treated as an in-patient, by frequent purgatives (mostly of elaterium), hot baths, and with liq. ferri. perclor and digitalis as the principal medicines, his albuminuria and retinitis rapidly subsided—indeed, for a time, it was thought the albuminuria had quite disappeared, but careful investigation still showed albumen in the urine about two hours after breakfast in slight traces. No casts had been found, possibly on account of not being looked for in the more acute stage of the affection. The retinitis was typical, the retina being covered by large milky opaque effusions, with a few hæmorrhages, the yellow spot and disc being especially affected. The right eye had never shown a sign of retinitis, even of the slightest kind. The appearances in the left eye at the present time were —disc, white and atrophied, and margin blurred; retinal arteries reduced to threads, several glistening dots in retina all round the macula as seen after typical retinitis albuminurica. Urine showed trace of albumen after breakfast, but at no other time.

Mr. MCHARDY exhibited a drawing of the right eye of a woman who had had albuminuria which exhibited changes analogous to those seen in albuminuria, though not characteristic. The other eye was normal. The case had been brought forward at the International Congress in London. He also referred to a case of uniocular changes which had been recorded, in which *post-mortem* it had been discovered that there was only one kidney.

Dr. STEPHEN MACKENZIE narrated a case which he thought of interest as bearing upon the difficulties in diagnosis. A young girl with albuminuria had changes in the retina of a marked character, and there was neuritis like that seen in cases of cerebral tumour. After death, tubercular meningitis was found, and there was only one kidney which appeared to be healthy, so that the cause of the albuminuria remained uncertain. It was, he thought, often impossible to decide with the ophthalmoscope alone between Bright's disease and cerebral tumour. Uniocular neuritis was occasionally seen in cerebral disease.

Mr. NETTLESHIP, referring to the nature of the choroidal patches, observed that they were abrupt, very white, and rather large, unlike those due to severe retinitis. The patches in the choroid were not most marked in that part of the fundus where the retina was most liable to changes. He thought that they were of much older date, possibly the result of the blow ten years before. The disc suggested to his mind a rather slow arterial thrombosis.

Mr. EALES, in reply, said that at first he had been inclined to regard the choroidal changes as the result of the blow, but the severity of the disease had been greater at the lower part, and over the atrophic patches in the choroid, which had been for some time concealed. He had no doubt that vascular obstruction had played an important part in the production of the changes.

On the Use of Cocaine in Ophthalmic Practice.

Mr. SIMEON SNELL (Sheffield) communicated a short paper on this subject. He had tried it in most of the eye operations. In tenotomy some pain was felt when the

tendon was hooked up and cut. In iridectomy only the pulling out and cutting of the iris was felt. In lacrimal operations he had not found it of any use. The mydriatic effects were somewhat uncertain.

Mr. NETTLESHIP had operated on about seventy eyes under the influence of cocaine since October 10th, on which day six eyes were so dealt with. The operations were the following:—

	Eyes.
Extraction of cataract, with iridectomy	12
,, ,, after preliminary iridectomy	4
,, soft cataract through small incision without iridectomy	4
Iridectomies for various purposes	16
Conical cornea (apex excised)	1
Discission	8
Iridotomy	2
Scraping corneal ulcers	2
Tenotomy	17

It was used in several other operations (chiefly tenotomies), but without the fact being recorded, and it had been used almost daily for several weeks in cases of foreign body on the cornea. The preparations used were a two per cent. watery solution, a 2·5 per cent. solution in vaseline and in castor oil, occasionally a four per cent. watery solution, and of late usually gelatine discs, each dise containing $\frac{1}{200}$th of a grain of cocaine hydro-chlorate. These had always caused complete anæsthesia of the cornea and conjunctiva of healthy (*i.e.*, non-inflamed) eyes; but the iris had never been completely anæsthetic in any of the operations involving iridectomy, even after frequently repeated applications; indeed, it was doubtful whether the sensibility of the iris was lowered at all in any of the cases. In one preliminary iridectomy the patient became so unruly when the iris was grasped that the operation had to be completed under chloroform, and with the other patients some difficulty was experienced at the iridectomy stage, although the operations were satisfactorily finished without general anæsthesia. In tenotomy there was sometimes slight pain, when the parts were put on the stretch by the hook and scissors. But with the exception of the above mentioned iridectomy the operations had almost invariably been completed without a hitch, with next to no discomfort to the patient, and with no bad after effects. Had cocaine not been in use, the writer would have given ether or chloroform to about one-half of the patients referred to. Cocaine was used prior to application of actual cautery to granular lids on several occasions with partial success. In a case of cauliflower warts about the inner canthus, and in a case of lupus on the skin of the lower lid, with little or no success. Cocaine greatly relieved the photophobia in several cases of corneal ulcer. When the ciliary region was much congested, it had remained sensitive to deep pressure, though the conjunctiva had seemed anæsthetic to light pressure, and the cornea completely so. The mydriatic effect was often less marked in inflamed than in healthy eyes, and repeated applications to congested eyes had not produced any decided blanching. A single application to the healthy eye caused complete anæsthesia in two to three minutes, which began to diminish in about four minutes, and had entirely passed off in about twenty minutes. Retraction of the upper lid began in four or five minutes, and lasted about half-an-hour; during the same time well-marked blanching of the surface of the globe occurred. Mydriasis began in three to ten minutes, was at its maximum ten to fifteen minutes later, and lasted in all at least twelve hours. The reflex and associated actions of the pupil were present throughout. Accommodation, though scarcely affected by one application, was almost completely paralysed, but for a very short time, by repeated applications. A single drop of eserine solution acted as fully and quickly as if no cocaine had been used. Probably the retraction of upper lid, whitening of eyeball, and mydriasis were caused by spasm of muscular fibres innervated by the sympathetic. The very fleeting cycloplegia caused by the repeated use of the drug might be due to ischæmia of the ciliary muscle from spasm of its nutrient arteries.

Mr. ARTHUR BENSON (Dublin), made a further communication on the same subject. He had found that the specimen of cocaine with which his previous experiments had been conducted was contaminated, probably with eserine. Hence the subsequent contraction of the pupil, &c. This result did not occur when the pure drug was used, but the pupil remained dilated for several hours. The most minute trace of eserine counteracted the dilatation. He found in experimenting on himself, that the anæsthesia produced reached its maximum in two or three minutes, and was extremely local; he could, by applying a small quantity, produce anæsthesia of one half of his cornea and conjunctiva, whilst the other half retained perfect sensation. The degree of anæsthesia depended, within limits, upon the amount of the drug employed: repeated applications of a 2 per cent. solution produced almost total anæsthesia of cornea and conjunctiva, so that the removal of foreign bodies and other operations could be performed painlessly. The sensibility of the iris seemed to be only slightly, if at all, diminished. He had applied it on the tongue and lips without marked results, a slight dulness of sensation alone being produced. In cases of photophobia, he had used it with marked benefit (keratitis and conjunctivitis), and considered it of great value in facilitating the examination of such cases, as well as from a therapeutic point of view. In normal eyes it usually produced an increase of tension amounting to + 1 within from a half to one hour, the tension falling before the dilatation ceased. He had not tested its effect upon the tension of diseased eyes. He had removed an aural polypus, having applied cocaine to the ear, with apparently good results. He was certain that the drug when used pure and in abundance would prove one of the most valuable ever discovered. Its action being so local, and the duration of the anæsthesia so limited, it should be used abundantly, and a very short time before the operation.

Ophthalmic Models.

Mr. PRIESTLEY SMITH demonstrated his models illustrating the following points:—(1.) Hypermetropia and myopia, a diagrammatic section in two parts, the one sliding upon the other. (2.) The condition of the retinal picture in emmetropia, hypermetropia, and myopia, with and without accommodation, and with and without glasses; a spherical wooden model, capable of elongation and with a movable lens. (3.) The same conditions by a different arrangement to demonstrate the fundus image-test. (4.) Astigmatism; a "cornea" of india-rubber cut from the side of a large ball. (5.) The mechanism of accommodation; a thin elastic steel band curved to the proper shape to represent the lens in section. The suspensory ligament was represented by spiral steel springs; the ciliary muscle by ribbons, which could be pulled upon when it was desired to illustrate its action. (6.) The causation of diplopia, and its correction by prisms; two cardboard cylinders mounted on a vertical axis, with a convex lens in front, and an aperture covered with thin paper behind. At the yellow spot region, the paper was made more transparent by a drop of paraffin; at the fixation point was a lighted candle. The relation between deviation of the cornea and the apparent deviation of the image in paralysis of the sixth nerve, and in other deviations of the eye, could be demonstrated, as well as the effect of prisms. Mr. Priestley Smith also exhibited a simple artificial eye, and an apparatus for demonstrating operations on pigs' eyes, which consisted of two short cylindrical pillars with cupped extremities, over which tubular caps were arranged to slide and to keep up a proper amount of tension in the eyes, which otherwise would be too flabby.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, DECEMBER 16TH, 1884.

J. W. HULKE, F.R.S., President, in the Chair.

Report of the Morbid Growths Committee.

DR. PAYNE read the report on Drs. Lanchester and Hobson's case of caseous pneumonia. The reporters agreed with the description as to the naked eye appearances given by the authors. They found tubercles in the left pleura. The alveoli of the left lung were filled with amorphous granular material. Cells when present were chiefly seen in the walls of

the alveoli. The septa were not thickened. Miliary tubercles were not found in the lung, and there were no giant cells. The change was very uniform. The right lung and other organs showed miliary tubercles. The pneumonic process was originally acute; there had been a fibrinous lobar process, followed by caseation. Very little mention was made of the subject in the books, but Corneil and Ranvier had alluded to it. Their report concluded by accounting for the bulging during life by actual increase in the size of the lung.

Intestinal Obstruction Caused by Gall Stones.

Dr. WILKS described this case for Mr. Wilks, of Salisbury. The patient was a lady who had obstruction of the bowels for seventeen days, when one stone came away in an enema, and two days later a second likewise came away. The large weighed 250 grains, and had one facet; the smaller weighed 150 grains. Dr. Fagge had recorded several similar cases. In most there was no history of pain or jaundice. The stones probably passed directly into the intestine. Nearly all the causes of complete obstruction were to be found outside the intestine; obstruction did not occur from any impediment from within. The case was quite exceptional in this respect.

Mr. JOHN WOOD had operated in a case of painful tumour in the region of the gall bladder. After careful dissection he reached an abscess with two gall stones in it. This was adherent to the hepatic flexure of the colon.

The PRESIDENT asked where the obstruction was supposed to have been. He referred to a case of obstruction he had seen in which the stone was close to the anus, and was easily removed by the finger.

Mr. LUCAS had felt the same difficulty as the President, but thought that possibly a local peritonitis where the ulceration had taken place might have caused it.

Mr. TREVES thought that stones must reach the intestine by ulceration. He had collected forty-eight cases, and there was only one of these in which the stone had presumably passed along the duct. He thought that the obstruction was in the lower part of the ileum in this case. Active treatment was to be avoided, especially that by aperients.

Mr. BARKER had already recorded a case in the Society's "Transactions" of a large stone which had passed by means of an abscess into the second portion of the duodenum. The patient had died of obstruction.

Dr. WILKS thought the stone had probably been in the rectum, but enemata had been given without difficulty.

Dr. GEORGE HARLEY said that if the stone had passed along the duct there must have been jaundice and pipeclay schools. It might ulcerate into the duodenum, jejunum, or colon. If it became impacted in the rectum it had probably ulcerated into the colon.

Dr. GOODHART mentioned a case where a patient died from peritonitis after the stone had ulcerated its way into the duodenum. It was blocked in the ileum. The obstruction was due to the bowel hugging the stone so that there was a spasm causing the blocking.

Dr. CARRINGTON mentioned the case of a lady who died after five days' symptoms. There was a stone firmly impacted in the ileum. The patient died of peritonitis.

Gunshot of Injury of the Brain.

Mr. ROSE gave the clinical details of this case. The patient, a man aged 45, had shot himself through the roof of the mouth. Brain matter had come through the nose. There was tumefaction of the scalp, but no aperture of exit could be made out. The patient was conscious and rational. Later he became noisy. Next day he was weaker, and had involuntary discharge of urine and fæces. Next day (fourth day) a fracture of the skull could be made out, and an operation was performed, some pieces of bone and the bullet being removed. He died fourteen hours later.

Dr. SAINSBURY said that the bullet had passed through the ethmoid bone and right orbital plate. It came out near the coronal suture, one inch in front of the sagittal suture. There was laceration of the orbital convolutions on both sides, but most on the right side. The left hemisphere was intact; on the right side the marginal convolution was completely destroyed in front. The first frontal convolution was slightly damaged. There had been no sensory trouble at first. The case agreed with the results of Horsley and Schäfer as to the functions of the marginal convolutions. Dr. Sainsbury referred to the universal intercommunication of nerve centres, and the possibility of a lower centre cut off from its higher centre of its own side receiving stimuli from the opposite cerebral hemisphere through the opening up of side paths.

Mr. LUCAS asked whether any cerebro-spinal fluid had been noticed to escape from the ear or nose.

Dr. RICHARDS mentioned the case of a boy who had had a piece of lead driven by an explosion into the parietal region of his skull, there being no symptoms for two days, and then sudden death occurred.

Mr. VICTOR HORSLEY noticed that the lesion in this case was in front of the sulcus which contained the centres for the muscles of the trunk and leg in the marginal convolutions. In regard to recovery of motor power in hemiplegia by absorption of blood clot, he thought that the arm was singly represented in the cerebral hemispheres, and the legs were doubly represented, and this would explain why recovery was so rarely obtained in the arm as compared with the leg.

Mr. PAGE referred to a case of extensive gunshot wounds in the front part of the brain. There were no symptoms for four days, and then aphasia set in.

The PRESIDENT referred to a case published by Mr. Lawson, of suicidal wound in the frontal region in which the man was able to give an account of himself, and recovered after removal of the bullet.

Mr. ROSE said that there had been no escape of cerebro-spinal fluid.

Dr. SAINSBURY said that the inter-communication in the case of the arm might be so fine that recovery was impossible.

Sympathetic System in Diabetes.

Dr. HALE WHITE had examined this microscopically in four cases. In all he found chronic inflammatory changes. In one case he noted in the thoracic portion great increase of small cells, with great engorgement of the vessel and new growth of fibrous tissue in their wall; the splanchnics and semilunar ganglia showed similar changes. In a second the changes were very similar. In a third the changes were similar, but less pronounced. In the fourth the vessels were much dilated, the surrounding structures being much degenerated and containing many leucocytes. These changes he looked upon as pathological. It could not be expected that lesion of the vasomotor nerves should always produce glycosuria, as the area of vascular dilatation might be too extensive or the lesion might be irritative and not paralytic. Diabetes, he said, might be due (1) to an affection of the vasomotor nerves or some part of their course between the vasomotor centre and the liver as in his four cases. (2) To an affection of the vasomotor centre itself, as where glycosuria was due to cerebral lesion. (3) To an affection of the vasomotor centre by reflex irritation, as in the cases of neuralgia, sciatica, &c., in the glycosuria recorded by Frerichs.

Mr. LOCKWOOD asked whether both semi-lunar ganglia had been examined, or if only one, which, as there was a considerable anatomical difference between them. In cranial injuries of the frontal region he had often found glycosuria.

Dr. HADDEN had recently examined the sympathetic system in a case of diabetes, but found no lesion. He was not satisfied that all Dr. White's specimens were abnormal.

Dr. PYE SMITH thought that no one could consider the specimens shown as normal.

Dr. WHITE, in reply, said that he had examined both ganglia in one case and both were diseased. The existence of diabetes in cranial injury was by no means uncommon, and easily explained.

Card Specimens.

Dr. HALE WHITE—(1) Abnormality of lung. (2) Patent ductus arteriosus.

Mr. D'ARCY POWER (for Dr. Mackinder)—A pouched or duplicate bladder.

Mr. RIVINGTON—Osteitis of upper part of tibia with disease of knee-joint.

Mr. G. R. TURNER—Congenital tumour of perinæum.

CORRESPONDENCE.

THE DURHAM DEGREE.

By a Correspondent.

"Go to Brussels" is a piece of advice too often given to the qualified or unqualified man of our London schools who, having neglected to obtain or prepare himself for obtaining a medical degree, finds that it will be greatly to his advantage to possess such a distinction emanating from a respectable University. Probably, however, even the most ardent advocates of the Belgian Degree will admit that it falls somewhat short of the object required, and if this be so, what is the better course for our aspirant? There can be but one answer in the majority of cases, so far as this country is concerned, and that is, "Go to Durham!" and in order to demonstrate this, I propose to give a short account of the Durham Degree and the facilities for obtaining it, together with some particulars relating to the Medical School which, by the by, is at Newcastle-on-Tyne, some 17 miles from Durham, the University town.

Nothing points more conclusively to the value of the Degree than its rapidly increasing popularity, and that too with a very good class of men. I am referring here, in the first place, only to the "one year residence degree"—that obtainable by practitioners over 40 years of age and of 15 years' standing being of an entirely different order. The number of men now on the books at Durham is about 220, the entries for this year showing an increase of 50 per cent. upon those for 1880-81; and this increase is most apparent in the ranks of the "Foreigners"—as those coming from London and elsewhere are sometimes called—who constitute about 25 per cent. of the whole. Of these foreigners a large proportion (sometimes I believe a hundred per cent.) are qualified men, and many have held resident hospital and other temporary appointments. The remaining number are mostly men in their third or fourth year, who have come to finish their medical and surgical subjects at the Newcastle School before going up for their "College," &c. Some have passed the London matriculation examination, and some the preliminary scientific, but these latter are few. The London men, and they form the great majority of the "foreigners," are very evenly drawn from the different Metropolitan schools, but it is said that St. Thomas' and King's College sometimes send a slight relative majority (*on their respective entries*), and this may be accounted for by the fact that members of the staff at both of these schools are on the First M.B. Examination Board, viz., Drs. Curnow and Harley.

The examinations proper consist of the Extra Arts examination (a species of matriculation), fee 2*l.*; the First M.B., fee 5*l.*; Final M.B., fee 6*l.*, with the M.S., also 6*l.* For the first (Extra Arts) are required—Greek (1 Book of Xenophon) and Euclid (books iii. and iv.), with two only of the following, viz., Latin, French, German, Mechanics, and History. This examination is required in addition to the ordinary Arts Preliminary, and is by no means easy; but it should be observed that the corresponding examination of other Universities, such as Edinburgh and London, are accepted at Durham. This extra examination, or its equivalent, must be passed before the Final, but not necessarily before the First M.B. It is held in March and September of each year.

The First M.B. is generally held to be the *pons asinorum* at Durham. It takes place twice yearly, in September and April, and lasts five days. Its subjects are anatomy, physiology, botany, and chemistry; theoretical, and practical, and *vivâ voce* in all. A man must have a very fair general knowledge of the subjects for this examination to ensure success; about 50 per cent. are referred.

The final examination, held in June and December, comprises medicine, surgery, midwifery, diseases of women and children, pathology, medical jurisprudence, materia medica, therapeutics, and public health. About 25 per cent. are referred from this examination, and the somewhat large per-centage of passes is said to be due to the longer time and greater care taken by candidates—frequently qualified men engaged in practice—in preparing for it. The M.S. examination after the M.B. includes operations upon the cadaver, and may, considering the status of the University, be said to be somewhat unduly severe; on one or two recent occasions all the candidates have been referred.

Of the relative values of the Durham and other British Degrees I purposely say nothing; but a glance at the papers of the first M.B., with its well known minimum standard of 50 per cent. of full marks in anatomy and physiology, will be sufficient to suggest that the short term of compulsory residence is the chief attraction in point of facilities. I should mention that the First M.B. may be passed at any time before the Final, either before or after the one year's (resident) attendance at the Newcastle school.

The degree for practitioners of over 40 years of age and of 15 years' standing consists practically of the same subjects as those for the ordinary final examination with the addition of a simple and easy arts' preliminary if such has not already been passed. The examination is essentially practical in character, and about 60 per cent. of the candidates are referred.

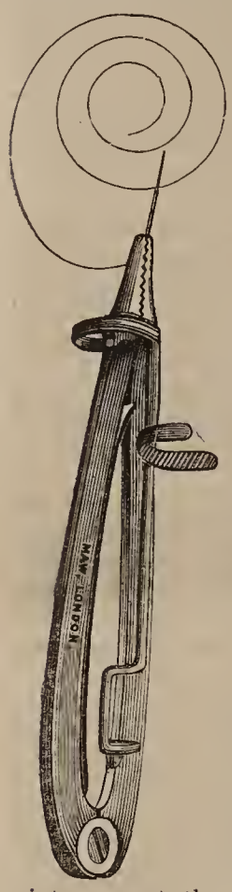
As to the opportunities for study at Newcastle, any industrious man will find plenty of facilities for work, and of material to work with, in almost all subjects. I may mention anatomy, chemistry, clinical medicine, theoretic surgery, and, latterly, pathology, as those most thoroughly and effectively taught; and clinical and operative surgery, with perhaps one redeeming exception, as unmistakably weak points in the practical teaching. This latter fact is indeed notorious, but no one has as yet had the courage to "bell the cat." Another matter of urgency which is having very tardy attention paid to it, is the appointment of a professor of physiology, but it is said that this will not now be long delayed. Clerkships and dresserships are for the most part readily obtained, and there is never any lack of good cases in the Infirmary. For each sessional course a fee of 5 guineas is paid; and four such courses only, *i.e.*, two for each session of the one year of residence, are required for qualified men. This is exclusive of hospital attendance, for a full annual course of which 12 guineas are paid. Thus the total amount necessarily paid in fees during the one year is £33 12*s.* I may remark here that students, unless holding office as clerks or dressers, are not allowed in the wards except at the period of the surgeon's or physician's visit, but I believe that this is a rule of the lay committee for which the staff is not responsible. The medical school is about 400 yards from the hospital, and they are situated on either side of the "central," or main railway station; but a new block of buildings is now about to be constructed for the medical school, and I am glad to hear also that a wing of 100 beds is to be added to the general hospital.

Lastly, as to the residence of "foreign" students: by far the best plan is to live out of Newcastle, either in the country or at the sea-side, and if at the sea-side by preference in Tynemouth, Cullercoates, or Whitby. In proof of this, a large number of the sojourners do so live—at the sea—and go to and fro daily by train, a distance of ten miles, taking about half an hour. The fare is one shilling third class, return. The lodgings at the sea-side are clean, plentiful, and for the most part cheap, and season tickets on the railway are very moderate in price.

INVENTIONS AND IMPROVEMENTS.

NEW NEEDLE HOLDER.

The special feature of this instrument consists in the novel device by which the opening, shutting, and fixing movements are accomplished. The blades are surrounded by a triangular collar, with rounded angles, fixed just below their points, and under the control of the thumb by means of a lever. When the holder is grasped by the hand this collar can be easily rotated. In its long axis the blades are released by a recoil spring, but by a slight movement they are securely fixed, and the points are brought into close contact with each other. The holder is represented in the engraving carrying a surgical needle and thread. It is adapted for the introduction of every kind of needle, and it is not liable to get out of order. The pressure at the points can be accurately regulated by the hand of the surgeon, and thus the risk of breaking needles is greatly diminished. The long lever attached to the thumb-plate is intended to facilitate the insertion of deep stitches in plastic operations. The rotatory action of the instrument is the chief element of novelty, and this marks the difference between it and the holders now in general use. By slight movement of the thumb on the lever complete control is obtained over the needle. Sir Spencer Wells' short scissor-shaped holder is suitable only for the introduction of large needles, and the ordinary spring instrument gives no variation of pressure at the points, except the slender accommodation obtained by covering them with soft metal. The new holder is made by Messrs. Maw, Son and Thompson.



J. Ward Cousins.

MOVABLE CROSS BAR FOR PREVENTING DISPLACEMENT IN THE APPLICATION OF LISTON'S LONG SPLINT.

In the treatment of fractured femur, hip-joint disease and other complaints, necessitating the use of Liston's long splint, the surgeon often has considerable difficulty in keeping the splint in position. No matter how carefully it may have been applied, if the patient is young or a restless adult some degree of displacement is sure to take place, and complete rest of the affected part, one of the principal objects for which it is applied, is as a consequence not attained. Sand bags are often very useful in controlling the movements of the limb, but in my experience are far from efficient. Hamilton's splint certainly answers the purpose for which it is applied admirably, but it necessitates the fixing of both limbs, and is, in addition, very cumbersome. In preventing displacement I have found the following simple contrivance very effectual. It is made of wood, and consists of an upright, varying in length according to the size of the patient, fixed at right angles into a base the same length as the upright, and of sufficient width to form a good support and prevent tilting. The upright has two vertical slits, one near each extremity, into which the projecting end of the long splint is to be inserted. When two splints are necessary both slits are in use, and a very efficient Hamilton's splint is the result. About 1½ inches to the inner side of each slit the upright is pierced by a round hole through which the cord attached to the foot piece may pass when extension by weight and pulley is used. Besides preventing displacement and rendering the use of sand bags unnecessary, pressure upon the heel is avoided, the long splint with the attached limb being raised when it is inserted into the slit. If the upright is made high enough, the toes are protected from the bed clothes and a cradle is not required. It is very portable, and can easily be removed from one bed to another, or packed away when not in use.

Wm. J. Spence.

NEW MEDICAL BATTERY-CELL.

The well-known electrician, M. Chardin, of Paris, has lately imagined a simple but effectual arrangement, by which the sulphate of mercury cell may be used as a convenient element in medical batteries. The new form of cell consists of a large test tube, at the bottom of which is placed a small quantity of the salt. Water is poured in so as to fill about half the tube, and a couple of ordinary corks floated on the top. The electrodes consist of small rods of carbon and zinc, the size of an ordinary pencil. They are fixed in pairs to the under surface of the element board. By a lifting arrangement the tubes can be raised; the pair of electrodes force the corks downwards, and so displace the exciting liquid which rises and puts the battery into action. The advantages of this battery are the high electromotive force of the elements; their small size and light weight; the security against accidental spilling; and last, not least, the facility with which anybody can re-charge the cells when exhausted. We speak from personal experience, and can fully recommend M. Chardin's heat element to the attention of medical men. For electrolytic, as well as for ordinary therapeutic, purposes it will be found to answer all the requirements of practice. M. Bernard (47, Jewin Street, E.C.) has always a number of the batteries in commission, and will show them to those interested in the subject. He also has in stock other kinds of medico-electrical apparatus made by M. Chardin, among which we may mention an ingenious battery for galvanocaustic purposes.

SOUTHALL'S SANITARY TOWEL.

The sanitary towel introduced for the use of ladies by Messrs. Southall, Bros. and Barclay, of Birmingham, some four years ago, has commended itself so thoroughly to the common sense of practitioners, nurses, and laywomen, if we may use the expression, that the issue of a cheaper sanitary towel, which, being retailed at the price of one shilling a dozen, is brought within the reach of even the poorer classes of the community, will be regarded by many as a great boon. The newly issued appliance, which is distinguished as "Sanitary Towel No. 2," is well adapted for the purposes it is intended to serve; it is soft, elastic and firmly made, and its absorbent capacity is considerable. The cotton wool together with the other constituents of the towels, professes to be antiseptic; and thus, though it is advisable to burn them as soon as possible after use, they may be kept with less danger of becoming offensive from the products of decomposition than the ordinary diaper.

BARNES' IMPERMEABLE CARRAGEEN POULTICE.

Appliances such as Barnes' Carrageen Poultice (J. B. Barnes, Trevor Terrace, Knightsbridge), have one great advantage, viz., that they render it easy for the medical practitioner to follow the time honoured rule, "If you want a thing done well do it yourself." Once great importance was attached by doctors to the preparation and application of poultices; at the present time all this is left to the friends of the patient or his nurse, with the frequent result that on his next visit the doctor finds his poultice put on in the wrong place, or a large one applied when he intended a small one, and *vice versâ*. With the neat roll of prepared poultice supplied by Mr. Barnes, such misadventures would be avoidable, the practitioner being able to cut off the exact size required, and to apply it himself *secundum artem*. Apart from this advantage, the carrageen poultice is im-

permeable to moisture and retains heat well; it is light and pliable, adapting itself accurately to the contours of a part. The ordinary carrageen poultice is composed of Irish moss, glycerine, and thymol, spread on a light impermeable material; but a poultice is also obtainable which contains in addition 10 per cent. of carbolic acid.

CRAPE OF HEALTH UNDERCLOTHING.

This cunningly woven material, manufactured by Strähl-Siebenmann, in Switzerland (agent in London, Howell, 60, Watling Street, E.C.), is well suited to its purpose. It makes a warm, light and unirritating vesture, and might be substituted with advantage for some of the thick and skin-tormenting under-garments which are so widely used in England by persons who are nervously afraid of cold. It is difficult, however, to convince such valetudinarians that the thicket vest is not necessarily the warmest.

MEDICAL NEWS.

THE PRESS ON THE PROPOSED TEACHING UNIVERSITY FOR LONDON.

The *Times* trusts that the scheme will receive all the attention it deserves, and before long become a reality. London is far worse organised in the matter of the higher education than any other great European capital, and, as regards university teaching, the total that is accomplished is ludicrously small if we judge it by the standard not only of Paris and Berlin, but of Edinburgh and Glasgow. It is eminently desirable that this state of things should be set on a better footing. King's and University College would be all the more animated if they felt themselves part of a great teaching university, while the medical schools might surely be brought into greater harmony, excellent as many of them are in their way.

The *Standard* admits that the ideal of the reformers is certainly an imposing one. A great academic centre, including the educational departments of the Inns of Court, the Colleges of Physicians and Surgeons, the hospital schools, and in time, perhaps, the Royal Academy, the British Museum, and the Society of Civil Engineers, is a fascinating vision. A great city like London, indeed, ought to have something of the sort. But should the idea ever be realized, how the elder institution, with its limited functions and capacities, can continue to exist at all it is not easy to continue to conjecture.

The *Daily News* says that to give London a teaching university, and to find a legitimate place for the teachers of London in the operations of the University of London, are not only desirable, but most important objects. The deficiency which Lord Brougham and his friends felt sixty years ago has even yet been only partly met. The capital ought to have the largest and fullest possible provision for university teaching, and the only question is how it can best be supplied.

The *Morning Post* remarks that many will echo Dr. Matthew Duncan's doubts as to the possibility of forming an alliance between existing institutions and the new university. However, all educational movements have difficulties to encounter at the outset, and those visible in the path of the present enterprise ought not to prove insurmountable. As Lord Justice Fry pointed out, the enormous increase of late in the number of purely examining bodies in this country, as distinguished from bodies connected with teaching, does unquestionably "tend towards that hideous simulacrum of learning, 'cram.'" A new departure, therefore, seems called for; and that suggested certainly promises well.

The *Pall Mall Gazette*, criticizing the meeting, says that where so many professional men were gathered together, the goddess of jealousy was of course in the midst of them. But the mere fact that these jealousies did not prevent substantial agreement in the main point involved is the best possible augury for the future University. The so-called University, which is already in possession, is no doubt the chief rock ahead. To ignore it altogether and to expect it to entirely abrogate its present functions would be alike impossible. Between these two extremes, however, a middle way ought not to be impossible.

The *St. James' Gazette* thinks that it would be a good thing to have a real London University; but it does not follow that it would be a good thing to have two of them. To have one University of London which examines only and another which examines and teaches as well, while both grant degrees, would add considerably to the complexities of our educational system. Surely a means might be devised by which the present Burlington House examinations and degrees might be worked in with a regular system of faculties and professional teaching.

The *Globe* points out that one grave objection to the scheme is the danger of bringing the entire body of professional education under one fixed and inelastic system. The whole idea as at present before the world distinctly confuses the ideal of professional and academic training. So vague and costly a scheme has first of all to prove its necessity, and this unquestionably still remains to be done.

THE MAHOMED MEMORIAL FUND.

In addition to the subscriptions which we announced last week, the following have been received:—

W. Adams, Esq., F.R.C.S., £5 5*s.*; Anonymous, per C. A. Aikin, Esq., £1 1*s.*; E. Edmund Aikin, Esq., £3 3*s.*; E. Garrett Anderson, M.D., M.P., £10 10*s.*; Anonymous, £2 2*s.*; Dr. Andrew, £10 10*s.*; Mrs. Wemyss Anderson, £1 1*s.*; R. Stow Armstrong, Esq., £1 1*s.*; F. Argles, Esq., and Mrs. Argles, £15 15*s.*; Tom Bird, Esq., £1 1*s.*; W. E. Buch, M.D., £10 10*s.*; Dr. Robert Barnes, £1 1*s.*; Dr. Fancourt Barnes, £1 1*s.*; Dr. Burnet, £2 2*s.*; Harrison Cripps, Esq., £2 2*s.*; G. Anderson Critchett, Esq., £5 5*s.*; Dr. Cavafy, £5 5*s.*; Dr. Cleveland, £1 1*s.*; Dr. H. Donkin, £3; J. N. C. Davies-Colley, Esq., £50; Dr. Langdon Down, £5 5*s.*; Dr. Duffey, £2 2*s.*; Dr. Duffin, £2 2*s.*; W. Dendy, Esq., F.R.C.S., £2 2*s.*; Dr. Finlay, £2 2*l.*; J. Cooper Forster, Esq., £10 10*s.*; Dr. Wilson Fox, £10 10*s.*; Sir William Gull, Bart., £50; W. Grieve, Esq. (per Harrison Cripps, Esq.), £10 10*s.*; W. A. Garrard, Esq., £1 1*s.*; E. C. Greenwood, Esq., £1 1*s.*; Dr. Herringham, £10; Dr. Wharton Hood, £5 5*s.*; Richard Hickman, Esq., £1 1*s.*; J. R. Jessop, Esq., F.R.C.S., £2 2*s.*; Dr. Hughlings Jackson, £26 5*s.*; Mrs. Jacobson (Chester), £1 1*s.*; Victor A. Jacques, Esq., £2 2*s.*; Dr. Robert Liveing, £5 5*s.*; T. G. Lithgow, Esq., F.R.C.S., £2 2*s.*; Dr. Stephen Mackenzie, £10 10*s.*; Cardinal Manning, £5; H. Manley, Esq., M.B., £1 1*s.*; A. Kinsey Morgan, Esq., £1 1*s.*; Dr. Moxon, £50; Edmund Owen, Esq., £2 2*s.*; Malcolm Morris, Esq. (in instalments), £10 10*s.*; Sir James Paget, Bart., £10 10*s.*; Dr. Pye-Smith, £25; The President of the Royal College of Physicians, £100; Dr. Playne, £1 1*s.*; Dr. Pavy, £26 5*s.*; Dr. J. A. Parry Price, £2 2*s.*; Sir Edwin Saunders, £10 10*s.*; Dr. Stevenson, £26 5*s.*; Dr. Sturges, £5 5*s.*; Henry Sewell, Esq., £10 10*s.*; Thomas Smith, Esq., £10 10*s.*; Dr. Felix Semon, £2 2*s.*; Anonymous (per Dr. Felix Semon), £2 2*s.*; Dr. Shepherd, £5 5*s.*; Henry Willson, Esq., £1 1*s.*; J. Cooper Wilkinson, Esq., £2 2*s.*; Dr. Hale White, £3 3*s.*

Subscriptions will be received by the Treasurer, A. E. Durham, Esq., of 82, Brook Street, Grosvenor Square, W.; or by the Secretaries, Dr. Goodhart, 25, Weymouth Street, Portland Place, W.; and W. H. A. Jacobson, Esq., 41, Finsbury Square, E.C. The Fund will remain open in case any contributors may wish to spread their subscription over a term of years.

University of London.—The following pass and honours' lists have been published:—

M.D. Examination—John Metcalfe Beverley, John Thomas Rogerson, B.S., Malcolm Webb, Manchester Royal Infirmary; Hugh Walter Boddy, Manchester Royal School of Medicine; John Howard Champ (Obtained the number of marks qualifying for the Medal), Wheelton Hind, B.S., Guy's Hospital; John Clinenson Day, London Hospital; William Dobinson Halliburton, B.S. (Obtained the number of marks qualifying for the Medal), Sidney Harris Cox Martin, B.S., Hubert Montague Murray, William Pasteur, Reginald Pratt, William Camac Wilkinson, B.A., Sydney, University College; Henry Hoole, Charing Cross Hospital; Edmund Wilkinson Roughton (Gold Medal), St. Bartholomew's Hospital; John Frederick William Silk, King's College.

Logic and Psychology only—Robert Henry Scanes Spicer, B.Sc., St. Mary's Hospital; Sidney Worthington, Guy's Hospital.

M.B. Examination—Examination for Honours (Medicine) William Thorburn, B.Sc., (Scholarship and Gold Medal); John Hervey Jones, Owens College; Alfred Jefferis Turner (Gold Medal), University College; Charles Edwin Purslow, Birmingham School of Medicine; Frank Rushworth, St. Bartholomew's Hospital; Francis Helen Prideaux, London School of Medicine for Women, (First Class).

William Ayton Gostling, B.Sc., John Joseph Powell, University College; Frederick William Bennett, Owens College; Edmund Percival Cockey, St. Mary's Hospital (Second Class).

Herbert Ritchie Spencer, University College; John Philip Glover, St. Thomas's Hospital (Third Class).

Obstetric Medicine—A. H. Nicholson Lewers (Scholarship and Gold Medal), John Joseph Powell, University College; William Thorburn (Gold Medal), Owens College; Francis Helen Prideaux, London School of Medicine for Women; Frank Rushworth, St. Bartholomew's Hospital (First Class).
William Ayton Gostling, University College; Edgar March Crookshank, Harry Lord Richards Dent, King's College; George Elliott Caldwell Anderson, Guy's Hospital (Second Class).
John Raglan Thomas, St. Bartholomew's Hospital (Third Class).

Forensic Medicine—Edmund Percival Cockey (Scholarship and Gold Medal) St. Mary's Hospital; Alfred Jefferis Turner (Gold Medal), University College (First Class).
Ernest Septimus Reynolds, William Thorburn, Owens College; George Elliott Caldwell Anderson, Guy's Hospital; Francis Helen Prideaux, London School of Medicine (Second Class).
Arthur Hamilton Nicholson Lewers, John Roberson Day, John Joseph Powell, University College (Third Class).

B.S. Examination—William Henry Bowes, Charles Gross, Guy's Hospital; Joseph Collier, William Thorburn, B.Sc., Owens College and Manchester Royal Infirmary; Charles Reginald Elgood, William Ayton Gostling, B.Sc., Herbert Ritchie Spencer, University College; Joseph Langton Hewer, St. Bartholomew's Hospital; Francis Helen Prideaux, London School of Medicine and Royal Free Hospital (First Division).
George Elliott Caldwell Anderson, William Thomas Frederick Davies, Maurice Parry-Jones, Guy's Hospital; George Frederick Cooper, St. Thomas's Hospital; Robert Nightingale Hartley, Leeds School of Medicine; Eugène Arthur Laurent, University College (Second Division).

B.S. Examination for Honours—Surgery—Joseph Collier (Scholar and Gold Medal), William Thorburn, B.Sc. (Gold Medal), Owens College (First Class).
William Ayton Gostling, B.Sc., Herbert Ritchie Spencer, University College (Second Class).
Frances Helen Prideaux, London School of Medicine; Joseph Langton Hewer, St. Bartholomew's Hospital (Third Class).

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, December 11th, 1884:—

Charles Edmund Adams, St. Bartholomew's Hospital; George Henry Baker, Charing Cross Hospital; Leonard Bramah Diplock, St. George's Hospital; George Thomas Hartley, Leeds School of Medicine; Percy George Lewis, King's College; Jno. Henry Spreat, St. Bartholomew's Hospital; Robert Wrigley, St. Bartholomew's Hospital.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Charles Albert Adams, Charing Cross Hospital; James Young, St. Bartholomew's Hospital.

Small-pox at Trieste.—Small-pox has been raging in this town for some time, and there are on the average about 25 cases a day, without counting milder cases.

The Albany Memorial Hospital.—It was decided at a large and influential meeting at Brighton, on Saturday last, to promote a local fund for the purpose of maintaining a certain number of beds in the National Hospital for the Paralysed and Epileptic for the reception of patients from Brighton and the surrounding neighbourhood.

Paisley Home for Incurables.—At a meeting held in Paisley on the 15th instant, under the presidency of the Lord Provost, it was resolved, on the motion of Mr. Stewart Clark, M.P., to form a committee for the purpose of providing a home for patients suffering from incurable diseases. It was intimated that a house for the purpose had been obtained by Mr. Archibald Coats, who would transfer it to the committee, and donations of 500*l.* each were announced from Mrs. Archibald Coats and Mr. James Coats.

The Association for Providing Trained Nurses for the West of Scotland, which is under the patronage of Her Royal Highness Princess Louise, is at present making urgent appeals to the public for funds, in order to prevent its total collapse. Nurses are sent out to attend the sick poor, and there can be no doubt that they do a great amount of good, providing attendance, medicine and nursing in all its different forms. The funds, however, have become all but exhausted, 500*l.* being required for meeting expenses. The ninth annual meeting took place on Wednesday, the 17th instant.

St. Mary's Hospital.—The two vacancies upon the junior medical staff of this hospital have been filled up by the appointment of Dr. Sidney Phillips and Dr. Robert Maguire. Dr. Phillips, who has for some years been Senior Demonstrator of Anatomy in the Medical School, and an assistant in the out-patient department, was elected to the senior vacancy. Dr. Maguire, who took the gold medal at the M.D. degree of the London University in 1882, is migrating from Manchester, where he has already made for himself a great reputation as a teacher; of the eight candidates whom he recently sent up for the M.B. degree of the London University, six passed, one of them taking the first place in honours in medicine. For the two vacancies there were eleven applicants, and St. Mary's Medical School may be congratulated on these strong additions to the permanent staff.

South London School of Pharmacy, 325, Kennington Road.—The following prizes were presented to the successful competitors at the school examinations held from the 3rd until 6th December, on Saturday the 13th, 1884:—Senior Chemistry: R. Atkinson, Medal; Thos. J. Clark, Certificate. Junior Chemistry: F. W. Taylor, Medal; F. B. Bennett, Certificate. Senior Botany: Thos. J. Clark, Medal. Junior Botany: G. D. Cooper, Medal. Materia Medica: J. B. Bennett, Medal; F. W. Taylor, Certificate. Pharmacy and Practical Dispensing: F. W. Taylor, Medal; F. E. Brown, Certificate. Extra Certificates of Merit: Messrs. Gooch, Marshall, Brown, Davies and Daintree.

Responsibility in Sanitary Matters.—Dr. Sieveking presided on Wednesday, December 17th, at the last of the lectures which the Sanitary Assurance Association have arranged this year at the Parkes Museum of Hygiene. The lecturer was Mr. Mark H. Judge, A.R.I.B.A., who delivered an address on "Public and Private Responsibility in Sanitary Matters." Mr. Judge began his remarks by asking his audience to consider whether there was any real cause for serious attention to the conditions under which we live — whether sanitary reformers from Moses and Mahomed to Edmund Parkes and Florence Nightingale had been right in the importance they had attached to man's environment? The answer to this must come from the physician, from whom the architect must be content to learn what conditions are essential to health, that he might be able to design dwellings so as to secure such conditions. The authority of Professor de Chaumont and Mr. Eric Erichsen was given to show that good sanitary conditions were not only essential to the maintenance of health, but often to the existence of life itself. Reference was made to the defects common to houses in all parts of the country. Speaking of main sewers Mr. Judge said that they were specially within the province of the engineer, and that the best constructed and ventilated main sewer was a piece of engineering with which the sanitary architect desired to have no direct connection. Across the outfall drain he constructs a sanitary moat with iron draw-bridge for easy access in case of invasion from without or mutiny from within. Mr. Judge criticised the powers conferred on Local Boards and their surveyors, and said that they did not possess the qualifications which would warrant the legislature in handing over to them the right to regulate the internal sanitary arrangements of our houses. He would strengthen the law by minimising its demands to essentials, and by insisting on its absolute enforcement. The responsibility of the individual owner or occupier should be increased, but in so far as the public authority pretended to interfere he would make it a real interference, and in every case where the law was not complied with, there should be some punishment meted out to those responsible for the breach. Mr. Judge concluded by suggesting light points, which, if embodied in the law, would define the duties of the public authority and the householder in such a way as to improve the health of the public and preserve the liberty of the individual. Of these suggestions the one to which most importance was attached was the second, viz.: "Every house drain to have between the house and the public sewer or common drain an air-chamber and disconnecting syphon trap or an air inlet-disconnecting syphon trap, in a position where it can be readily inspected by the officer of the sanitary authority." Dr. Sieveking, in opening the discussion, expressed his concurrence in the remarks of Mr. Judge, except with regard to the suggestion that medical men should be included among those entitled to certify the sanitary condition of houses. It was not the function of medical men to know of the whereabouts of pipes and drains, and

it would be misleading the public if medical men should pretend to certify about such things. Mr. Cave Thomas, F.S.S., Mr. Andrew Sterling, Mr. R. E. Farrant, and others having spoken, votes of thanks were given to the lecturer and to the chairman, and the meeting terminated.

THE JUBILEE OF THE BRUSSELS UNIVERSITY.—The whole of the number of the *Presse Médicale Belge* for November 30th is occupied with a description of the celebration of the fiftieth anniversary of the Free University of Brussels. The epithet of "free" was attached to it at its foundation, which took place in antagonism to the Catholic University, which was at that time the only one in existence; and it indicated its purport of affording an advanced education quite untrammelled by religious dogmas of any kind, the beliefs of professors and students forming no subjects of enquiry or direction. The anniversary of an institution like this, which after much up-hill work at first, and in spite of the calumnious opposition it was subjected to, has proved highly successful, would be a matter of great interest at any time, but is especially so now, when so critical a condition as to political and religious parties prevails in Belgium. The municipal authorities have always taken great interest in the prospects of the new University, and on this occasion took a leading part in conjunction with those of the University; and all was conducted with much enthusiasm and good temper. Professor Roubaix, the Dean of the University, in his address, protested against the dispirited views entertained by many in consequence of the recent successes of the enemies of free education, and maintained that the scientific spirit which had so often been stated as wanting to the Belgians has of late years established itself, as is shown by the intimate conviction now prevailing of the vast importance of instruction. Progress can no longer be arrested whoever is in power. Professor Rousseau, the Rector, pointed with satisfaction to the immense progress the "Free University" had made, and prophesied that what is now but a domestic festivity to celebrate this will in another half century have become an international one, to which many nations, then having also their free universities, will send their representatives. The Brussels University, he added, was no opponent to religious beliefs, but attached itself to none, leaving them to stand or fall according to the results of free enquiry. Next day about 2,000 present or former students from all parts of Belgium and other countries assembled, and formed themselves into a congress, at which the position of medical education was freely canvassed, all passing off without any violation of order, as might have been feared during the present excited state of the country. Banquets, theatrical representations and balls terminated what is evidently regarded as a most successful demonstration. The Medical Faculty of the University, now very prosperous, was a long time before it made much way, so that in 1844 it did not number more than 34 students; vigorous measures were then taken for its improvement, which have proved highly successful. One great defect in the regulations of this faculty, however, was brought about by the Catholic party in 1876, in which students of medicine were exempted from the necessity of examination in arts, and were allowed to enter the University when only 14 or 15 years of age. The repeal of the law is justly considered a matter of great urgency.

APPOINTMENTS.

BEATTIE, HENRY, L.R.C.P. Lond., M.R.C.S Eng.—Medical Officer to the South District, St. George-in-the-East Parish, *vice* Dr. Pritchard, deceased.

BELLAMY, EDWARD, F.R.C.S.—Examiner in Surgery to the Victoria University, Manchester.

COSGRAVE, E. MACDOWEL, M.D., Ch.M., L.K.Q.C.P., L.R.C.S.I.—Chair of Botany and Zoology in the Carmichael College of Medicine, Dublin.

FOX, W. P., L.R.C.P., L.R.C.S.—Resident Medical Officer to the Rochdale Infirmary, *vice* Herbert M. Gay, M.B., resigned.

GOULD, A. P., M.S. Lond., F.R.C.S. Eng.—Surgeon to the Hospital for Epilepsy and Paralysis, Regent's Park, *vice* Prof. Godlee, resigned.

HAYDEN, WILLIAM G., L.R.C.P. Lond., M.R.C.S. Lond., and L.S.A. Lond.—Medical Officer to the Bishopstone District, Wilton Union, *vice* Dr. D. M. Jones, resigned.

MASKEW, JOHN SHEPPARD, M.R.C.S. Eng., L.R.C.P. Edin.—Medical Officer to part of the Third District, New Forest Union, *vice* Dr. Jenkins, deceased.

MASTERTON, JOHN, M.B. Edin., L.R.C.S. Edin., and L.R.C.P. Edin. —Medical Officer to the Second District, Alston-with-Garrigill Parish, *vice* Dr. W. R. S. Jefferiss, resigned.

PRAGER, I. F., L.D.S., L.R.C.S.I.—House Surgeon to the National Dental Hospital.

RICHARDSON, FRANK LEWIS CHARLES, L.R.C.P. Edin., and M.R.C.S. Eng.—Medical Officer to the Rhayader District and Workhouse, Rhayader Union, *vice* Mr. R. Richardson, deceased.

SALMON, ARTHUR GUY, M.B., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Fifth District, Bodmin Union, *vice* Mr. T. Q. Couch, deceased.

SUFFERN, A. C., M.D., M.Ch.—Assistant Medical Officer to the Borough Asylum, Winson Green, Birmingham, *vice* Dr. Dodds, resigned.

TUXFORD, HAROLD ARTHUR, L.R.C.P. Edin., L.R.C.S. Edin.—Medical Officer to the Second District, Eastbourne Union, *vice* Mr. J. P. Billing.

WILLIAMS, P. W., L.R.C.P.—Clinical Assistant to the Birmingham Borough Asylum, *vice* J. D. Bush, resigned.

VACANCIES.

DEVONSHIRE HOSPITAL, BUXTON, DERBYSHIRE.—Assistant House Surgeon. (*For Particulars see Advertisement.*)

NEWCASTLE-UPON-TYNE INFIRMARY.—House Surgeon. Salary, £50 per annum, with board, lodging and washing. Candidates must be registered in surgery, unmarried, and free from the care of a family. Applications and testimonials must be in the hands of the Chairman of the House Committee on or before December 29th.

SCARBOROUGH HOSPITAL AND DISPENSARY.—House Surgeon and Secretary. Salary, £80 per annum with board and lodging. Candidates must be registered practitioners. Applications, with testimonials, stating age, to be sent to the medical staff on or before December 27th.

THE QUEEN'S HOSPITAL, BIRMINGHAM.—Honorary Obstetric Officer. Candidates must be either Doctors in Medicine of a British University or Fellows or Members of the Royal College of Surgeons of England, Edinburgh, or Dublin. Applications, testimonials, and evidence of degree or diploma to be sent to the Secretary of the Hospital, from whom all further information may be obtained, on or before December 27th.

THE ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, BRIGHTON. —House Surgeon. Salary, £80 per annum, with board, lodging, and washing. Candidates must be qualified both in medicine and surgery, and registered under the Medical Act. Applications, with recent testimonials, to be sent to the Chairman of the Medical Committee, before January 2nd, 1885.

TIVERTON UNION.—Medical Officer to the Bampton East and West Districts, *vice* Mr. Edward Nason, resigned. Bampton East District—Area, 7,851. Population, 1,362. Salary, £27 per annum. Bampton West District—Area, 14,062. Population, 1,888. Salary, £35 15*s.* per annum.

WOLVERHAMPTON UNION.—Medical Officer for the Second District, *vice* Mr. W. Hayward, resigned. Area, 1,331. Population, 26,352. Salary, £95 per annum.

DEATHS.

BAYLIS, C. O., M.D., M.R.C.S., at 62, Windsor Road, Southport, Lancashire, on December 12th.

SNAPE, GEORGE HENRY, M.R.C.S., at 73, Rodney Street, Liverpool, on December 13th, aged 40.

WASHBOURN, T. B., M.D., at Ashmeade House, Gloucester, on December 11th, aged 55.

WILLS, J. S., M.R.C.S., at Thorncombe, Dorset, on December 8th, in his 59th year.

NOTES, QUERIES, AND REPLIES.

Royal College of Surgeons.—The following are the subjects required at the second examination in Physiology for the membership of the College, viz :—1. HISTOLOGICAL.—The Structure of the Tissues of the body; the Structure of the Organs of the body; recognition of microscopical preparations of the Tissues and Organs. 2. CHEMICAL.—The composition of Food, and of the Tissues, Secretions, Excretions, and other Fluids of the body. 3.—PHYSIOLOGICAL.—The Physiology of Digestion, Absorption, Circulation, Respiration, Secretion, Nutrition, Animal Heat, and Animal Motion. The Functions of the Nervous System and Sense Organs. Reproduction. A practical acquaintance with the methods of microscopical and chemical examination will be required under heads 1 and 2.

Royal College of Surgeons.—Members of the Royal College of Surgeons competing for the Jacksonian Prize of the College, are reminded that their essays for the same must be sent in to the Secretary on or before Wednesday the 31st instant. The subject for this prize is "The Surgical Treatment of Uterine Tumours, both Innocent and Malignant." For the ensuing year, the subject is "The Diagnosis and Treatment of such affections of the Kidney as are Amenable to Direct Surgical Interference." The collegiate triennial prize will not be awarded until early in 1886. The subject for it is "The Nature of Inhibitory Action in the Animal Body to be elucidated by Original Research." The competition is limited to Members of the College only.

Lock Hospital.—It is obvious that students ought not to be altogether excluded. It is not desirable, however, that any but senior students should attend, and in restricted numbers.

COMMUNICATIONS RECEIVED—

Sir ANDREW CLARK, London; Dr. CHAMPNEYS, London; Dr. ASHBY, Manchester; Dr. HERMAN, London; Dr. R. A. APPOINTMENTS FOR THE WEEK.

Friday, December 19 *(this day).*

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CHARING CROSS HOSPITAL MEDICAL SCHOOL, 12 noon.—Distribution of Prizes, by H. B. Martin, Esq., Treasurer of the Hospital.

UNIVERSITY OF LONDON, 5 p.m. Mr. Victor Horsley's Fourth Brown Lecture, subject—"Urethral Fever."

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, ADAM STREET, ADELPHI, 7.30 p.m.—Mr. H. E. Armstrong, "The Statistics of the Medical Officer of Health as a Criterion of Sanitary Progress."

Saturday, December 20.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, December 22.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, December 23.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.

CLINICAL SOCIETY OF LONDON.—Adjourned Debate on "Charcot's Joint Disease."

MANSION HOUSE, 2.30 p.m.—Meeting of Constituents of Metropolitan Hospital Sunday Fund.

Wednesday, December 24.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

A CLINICAL LECTURE.

ON ANEURYSM OF THE AORTA.

By GEORGE JOHNSON, M.D., F.R.S.,

Professor of Clinical Medicine, Senior Physician to King's College Hospital.

GENTLEMEN,—A case of aneurysm of the aorta, now in Craven Ward, presents some interesting features, with reference especially to diagnosis, to which I desire now to direct your attention.

W. D., aged 51, admitted October 29th, 1884. For seven years he was a guard on the Great Western Railway. Since then he has been for years an inspector on the same line. His life has been on the whole a laborious one; he has been in the habit of lifting heavy weights; he has been much exposed to cold, and has been a rather liberal consumer of beer, spirits, and tobacco, but until lately he has had very little illness.

About a month before his admission he began to complain of pain in the back of the chest, with palpitation and dyspnœa on slight exertion.

These symptoms have continued, and rather increased.

The pain is of a gnawing character, and is most severe about the angles of the scapulæ. It is made worse by the recumbent posture, and for ease he has to be propped up in bed at night.

The sounds of the heart are normal. On auscultation over the manubrium sterni a loud impulse is heard, followed by an accentuated second sound. There is no blowing sound. In the first left intercostal space a pulsation is felt by the end of the finger, and on pressing the chest-end of the stethoscope firmly over the top of the sternum, the ear-end of the instrument is seen to move freely with each arterial pulsation. On auscultation over the spinous processes of the second and third upper dorsal vertebræ loud tracheal breathing and voice are heard.

The left side of the chest appears somewhat flattened, and is, in fact, three-quarters of an inch smaller than the right.

It is somewhat, though not much, less resonant on percussion, but the respiratory murmur is much feebler on the left side, and especially over the upper lobe. The vocal resonance and the vocal fremitus are much lessened on the left side.

He coughs occasionally, but there is nothing remarkable about the cough. The radial arteries are hard and tortuous, the pulses on the two sides being equal. The pupils are equal. The voice is natural and there is no dysphagia. The urine is normal.

The physical signs amply suffice for the diagnosis of an aneurysm of the transverse aorta, which pulsates against the sternum in front, and presses the bifur-

cation of the trachea back against the bodies of the upper dorsal vertebræ, and by its pressure on the left bronchus lessens the supply of air to that lung.

He has been kept absolutely at rest with permission to sit up occasionally in a chair near the bed. He has a nutritious but unstimulating diet, and small doses of morphia to quiet the cough; and as a result, mainly, I believe, of the rest which is the chief remedy in these cases, he has less pain and general discomfort than when he came in. It is evident, however, that he is in daily and hourly peril of his life. With the cough there is an occasional tracheal wheeze which probably results from irritation and congestion of the mucous membrane of the windpipe, excited by the pressure of the aneurysm, and if, as often happens in such cases, the wall of the trachea becomes inflamed and ulcerated, there will be a sudden burst of bleeding and speedy death, either from suffocation by hæmorrhage into the bronchi, or from exhaustion by mere loss of blood.

In the case which we have now under observation, the direct physical signs of aneurysm are so obvious that the disease could not well be overlooked, but cases of aneurysm of the aorta are not seldom met with in which these direct physical signs are obscure or even entirely absent, and in some of these cases we derive invaluable assistance from the use of the laryngoscope.

Here is a specimen of an aneurysm of the arch of the aorta compressing the left pneumogastric and recurrent nerves. The case is published in the 15th volume of the "Pathological Transactions" (p. 72). The patient, a hawker of intemperate habits, was admitted under my care in July, 1863, with symptoms which were at first supposed to indicate laryngitis. The main symptoms were cough, dyspnœa, laryngeal stridor, hoarseness, and dysphagia.

At my visit the stridor had ceased, and I saw with the mirror only a slightly congested larynx without swelling, the arytænoid cartilages and the vocal cords being freely movable, and the glottis opening fully in inspiration.

I suspected aneurysm, but a careful examination failed to discover any physical sign of the disease; there was no abnormal dulness on percussion, no pulsation or bruit, no inequality of pulses or pupils. Two days after his admission he spat up a few mouthfuls of florid blood, and again two days later, at 1.15 p.m., he suddenly became faint, and vomited three quarters of a pint of florid blood. No more blood came up, but he rapidly became weaker, while dulness on percussion over the stomach indicated a probable accumulation of blood into that viscus. He died at 5 p.m. The stomach was full of blood which had escaped from an aneurysm the size of a small orange, which projected from the posterior wall of the transverse aorta. By an oval opening it communicated with the œsophagus. The trunk of the left pneumogastric and its recurrent branch were both compressed by the aneurysm.

In this case the laryngoscope, by showing the absence of disease of the larynx, rendered the presence of an aneurysm much more probable than it would have been without such aid. The laryngeal symptoms were no doubt the result of spasm of the glottis, excited by pressure on the trunk of the vagus.

When an aneurysm or other tumour presses on one recurrent nerve, the result is generally unilateral palsy of the laryngeal muscles, indicated by immobility more or less complete of one vocal cord; and when, as usually happens, the *abductor* muscles are chiefly affected, the cord remains nearly motionless in the median line of the larynx, even during a deep inspiration. I have met with a considerable number of cases in which the discovery of the laryngeal palsy by the aid of the mirror has led to the further discovery, in some cases, of an aneurysm, and in others of a cancerous or other tumour pressing on one recurrent nerve.

When an aneurysm presses on the *trunk of the vagus*, as well as on its recurrent laryngeal branch, *both* sides of the larynx may be affected either by spasm or by palsy.

In the 23rd volume of the "Pathological Transactions" (p. 66), Dr. Baümler has published a case of bilateral palsy of the larynx caused by an aneurysm of the innominate artery pressing on the right vagus and recurrent nerve; and in the 24th volume of the same "Transactions" I have published a case of bilateral laryngeal palsy from an aneurysm of the aorta pressing on the left vagus, and recurrent.

I have discussed these cases, and given what is now generally accepted as true, my theory of the production of bilateral palsy of the larynx from pressure on the trunk of one vagus in the "Medico-Chirurgical Transactions" (vol. lviii., p. 29). My patient, a man 45 years of age, had suffered for nearly a year from dyspnœa, with stridor, and a feeble but tolerably clear voice. The vocal cords were of their natural colour, nearly touching each other in the middle line, and nearly motionless.

During inspiration the glottis did not open as in the normal state, but on the contrary the cords were pressed nearer together by the inspired current of air; while in expiration they were slightly pushed apart by the outgoing stream of air. This condition of larynx led to a careful examination of the chest, and the discovery of dulness on percussion over the manubrium sterni, and a palpable and audible impulse in the same position; hence the diagnosis of aneurysm.

For some months the dyspnœa had been so urgent that he had been unable to lie down, and he was much exhausted from want of rest. The day after his admission Sir William Fergusson, at my request, performed tracheotomy. This afforded great relief, and enabled him to sleep for several hours continuously.

Two days afterwards, however, symptoms of pleuropneumonia set in, and on the fourth day after the operation he died. An aneurysm the size of an orange projected backwards from the transverse aorta. The left vagus and its recurrent branch were compressed by the tumour, while the right vagus and recurrent were free and normal. The preparation is on the table.

For a full explanation of the phenomena of bilateral spasm and palsy of the larynx from pressure on the trunk of one vagus, I must refer you to my paper before mentioned. The main points are that while pressure on one recurrent, which is a purely motor nerve, may cause spasm or palsy of the muscles on the same side, pressure on the vagus, which contains both afferent and efferent fibres, may affect both sides of the larynx through those commissural fibres in the nervous centre by which the nerves on the two sides are intimately connected. The laryngeal muscles are pre-eminently bilateral in their normal physiological action. This is explained, as the late Dr. Lockhart Clarke demonstrated, by the decussation of their fibres of origin in the medulla oblongata.[1]

Then, as irritation of one vagus may through its efferent fibres excite a reflex bilateral spasm, a prolonged irritation, by the pressure of an aneurysm, may cause a structural change in the closely connected nerve nuclei, with resulting bilateral palsy of the laryngeal muscles. Such structural change in the nervous centre as a result of peripheral irritation, is analogous to the anatomical changes which Dr. Lockhart Clarke demonstrated in the spinal cord as a result of traumatic tetanus. Facts and arguments in support of this view are given in the paper before referred to.

---

1 "Philosophical Transactions," 1868, pp. 272, 273.

Aneurysm of the aorta may cause stridulous breathing and dyspnœa, not only by pressure on the pneumogastric and recurrent nerves, but also by direct pressure on the trachea. Of this I have seen several examples; but the most interesting case I saw in consultation with my friend and former pupil, Dr. Richards, of Winchester. A gentleman, 33 years of age, had suffered from shortness of breath, with noise in the throat, on any unusual exertion, for nearly a year. When I saw him on October 30th, 1871, there was loud stridor on a deep inspiration; but with this the voice was clear and distinct, indicating, as I at once said, that the obstruction which caused the stridor was below the larynx. The laryngoscope showed nothing more than slight redness of the mucous membrane, without swelling. The vocal cords moved freely; and, during a deep inspiration with a widely open glottis, there was loud stridor, evidently originating below the larynx. Suspecting aneurysm, I carefully examined the chest. There was no abnormal impulse or dulness on percussion. On auscultation behind, over the upper dorsal spinous processes, there were loud tracheal stridor and vocal resonance. The respiratory murmur was decidedly more feeble over the lower lobe of the right lung than over the corresponding part of the left side. There had been occasional difficulty in swallowing. The pulse was equal at the two wrists. The right pupil was smaller than the left—a result, probably, of iritis some years before. The diagnosis was, aneurysm of the transverse aorta pressing on the trachea. I did not see the patient again; but I learnt from Dr. Richards that the symptoms became steadily worse, until he died from apnœa on November 20th, three weeks after his visit to me. An aneurysm of the size of a walnut projected from the posterior wall of the transverse aorta, and bulged into the trachea just above its bifurcation.

I show you a photograph of the parts, for which I am indebted to Dr. Richards.

The Trachea opened from behind, showing an Aneurism bulging through its Anterior Wall (from a photograph).

The opening of the right bronchus was somewhat more obstructed than that of the left, thus explaining the comparative feebleness of the respiratory murmur on the right side of the chest. One advantage of an exact diagnosis of this case was, that the patient was not subjected to the operation of tracheotomy, which, on a superficial view of the symptoms, might seem to have been indicated. The operation was not resorted to, because it was known that the obstruction in the trachea was below the point at which an artificial opening could be made, and therefore no relief could have been given by an operation.

With reference to the question of tracheotomy in such cases, it is of primary importance to distinguish between tracheal obstruction by direct pressure of an aneurysm, and laryngeal obstruction, the result of primary disease in the larynx or of spasm and paralysis of the laryngeal muscles, which may be caused by the pressure of an aneurysm or other tumour on the pneumogastric nerve and its branches. In most cases the diagnosis by the aid of the laryngoscope is not difficult. If you see on laryngoscopic examination a perfectly healthy larynx and a widely open glottis during inspiration, you may be sure that the stridor and dyspnœa are the result of obstruction below the larynx. But, if unfortunately you have not learnt to use the laryngoscope, auscultation will help you to distinguish between laryngeal and tracheal stridor. Laryngeal stridor is louder over the larynx than over the trachea just above the sternum.

Auscultation over the spinous processes of the vertebræ is often of great assistance. In the case of laryngeal obstruction, you hear the stridor most distinctly over the spinous processes of the middle cervical region. If, on the other hand, the stridor is the result of obstruction of the trachea just above its bifurcation you will hear it much more distinctly over the upper dorsal spinous processes than over the middle cervical region. When an aneurysm of the transverse aorta presses directly on the trachea, it very frequently causes a peculiar loud ringing cough, to which I wish now to direct your particular attention; for the recognition of this loud barking cough has more than once led me to the diagnosis of an aneurysm which might otherwise have escaped notice.

A few years since, I travelled from Ostend to Strasburg in the same railway carriage with a physician and a surgeon who were on their way to Switzerland. In the course of the journey I could not fail to notice that the physician had a very loud ringing cough, and I privately expressed to his travelling companion my belief that an aneurysm of the aorta pressing on the trachea was the cause of the cough. In consequence of my remark, the surgeon did his utmost to prevent his friend from exerting himself during the Swiss tour.

After leaving the train at Strasburg, I did not see the patient again, but I heard that after his return from Switzerland, he called to consult me, and hearing that I was not expected home for some days, he sought other advice, and in about six weeks he died suffocated, after the operation of tracheotomy for a supposed affection of the larynx had failed to relieve him.

I heard from a friend who was present at the *post-mortem* examination, that a large aneurysm of the aorta was found pressing against the sternum in front, and on the trachea behind.

When my friend and former pupil, Dr. Hebb, was house physician here in 1876, he heard amongst a crowd of out-patients a man coughing in this peculiar loud manner, and calling him forward discovered the physical signs of aneurysm of the aorta, and at once took him into the hospital.

About the same time one of the sisters told the house-physician that a man just admitted had such a loud, harsh cough, that she thought he must have an aneurysm, and her surmise proved to be correct. A case of aneurysm pressing on the trachea and causing the loud cough had shortly before been under my care in the hospital, and the lady had remembered and profited by my bed-side comments on the cough.

You see, then, that this loud ringing cough, occurring in a man who is not likely to be hysterical (the cough is somewhat like the loud bark of some hysterical women), is a valuable diagnostic symptom. The question then arises, what is the explanation of its peculiar resonant character? I believe that the

cough is tracheal, not laryngeal. I mean that the cough originates in the trachea and not, like most coughs, in the larynx. In ordinary coughing the patient takes a deep inspiration by which he fills the chest, then he forcibly drives the air through the partially closed glottis, and so the sound of the cough originates in the larynx.

But the cough which results from the pressure of an aneurysm on the front of the trachea is mainly caused by the forcible driving of the current of air through a constricted and mis-shaped trachea, as a consequence of which the walls of the trachea are thrown into loudly resonant vibrations.

With a forced inspiration, if not in ordinary breathing, there is usually in these cases tracheal respiratory stridor, the inspired current of air is interrupted by the narrowing of the canal, and that causes stridulous breathing, which originates at the constricted portion of the trachea. The stridor and the cough are both of tracheal origin.

CYSTS OF THE NECK.[1]

By JOHN H. MORGAN, F.R.C.S.,

Assistant Surgeon to Charing Cross Hospital and to the Hospital for Sick Children, Great Ormond Street.

The interest attaching to this subject centres not only in the diagnosis and treatment, but even more specially in the development and origin of the various forms of cysts which are found to occur in the region of the neck. They may be divided generally into those which are the result of some change of condition in parts previously healthy, and those which may be said to arise from developmental error. Naming them more specially, we find in the first category (1) Bursal tumours, (2) Hydrocele of the neck; and under the second (3) Cystic hygroma, (4) Congenital sebaceous cysts.

Bursal cysts are necessarily rare from the fact that few bursæ are normally found to be developed in this region, and their enlargement is therefore exceptional. The situation in which they are usually found is in front of the pomum Adami and between the posterior surface of the hyoid bone and the upper surface of the thyroid cartilage. In these situations they may sometimes become enlarged, and appear as round, smooth, single collections of fluid moving with the larynx, increasing slowly, if increasing at all, and causing little inconvenience or distress.

The second variety of acquired cyst, which goes by the name, not particularly well-suited, of hydrocele of the neck, has been described in this country by Cæsar Hawkins and others, is found in adults, and may occur even at advanced age, one of Mr. Hawkins' patients having been a man upwards of seventy years old.

The clinical characteristics are too well known to need further description here, but their origin and causation are still in doubt, and the main point of obscurity in their diagnosis is the difficulty of distinguishing them from solid tumours. In a case which I saw some time ago, in consultation with Mr. Holmes, and which occurred in an elderly woman who was very thin and emaciated, the difficulty of ascertaining the nature of the tumour was so great that it was with the most serious doubts that we ventured to insert a fine trocar. The swelling was about the size of an orange, moved with the trachea, was not attached to the skin, was loose, smooth, hard, and slowly increasing. It lay to the left of the trachea, and was quite painless, nor had it interfered with respiration or deglutition. Still, so great was the tenseness of the fascia overlaying it, and so solid the general feeling of the tumour, that we felt grave suspicion that it was of a malignant character. A puncture was, however, made, and a quantity of dark fluid was evacuated, and the patient, after several puncturings, got perfectly well.

In contrast with this case, on the contrary, there is now under my care in Charing Cross Hospital a woman, aged 47, in whom a swelling, bearing great resemblance to the cyst just mentioned, had been punctured by a surgeon in the country some time before she came to London, and is now a mass of malignant disease, too far advanced for removal, with a large ulcerated surface around the spot where the puncture was made, from which there is frequent hæmorrhage. The size of these cysts may vary from that of a walnut to that of a cavity capable of holding nearly a pint of fluid, and upon their size as well as upon their situation depend the effects which they produce upon the functions of the trachea and œsophagus. Although not invariably, these cysts are single, a fact of some importance, and one which distinguishes them from the variety which is next to be described.

Again, although the analogy of the name would lead to the impression that the contents are of an aqueous character, in all that I have seen, and in most that have been recorded, the fluid has been more or less dark coloured, as if it consisted of blood in some altered condition. When this is the case, it is possible that the effusion may have, in the first place, arisen from the rupture of a vein, which in the loose connective tissue of the neck might occur as the result of violent coughing, or severe exertion; but the cause of their origin is otherwise difficult of explanation, seeing that they have no analogies in other parts of the body, except perhaps the cysts of the arachnoid or hæmatoma of the scalp, both of which are the residual effects of effused blood.

Turning to the cysts of congenital origin, the disease which has been termed congenital cystic hygroma finds its most frequent situation in the neck, although it occurs in other parts where the areolar tissue is lax, as, for example, the back, the axilla, around the kidney, and in one case which I exhibited at the Clinical Society, in the forearm and hand.

In the neck the growth lies beneath the deep fascia, and dips between the muscular interspaces. This form is always polycystic, and the spaces which divide the sections of the tumour can usually be detected beneath the skin. They are generally situated in the posterior triangle of the neck, and do not often pass across the median line. In size and in the number of component parts they show very great variety, but, as a rule, one or two large collections of fluid seem to keep the smaller in check, as they are found to enlarge when the others are emptied. Otherwise their growth is capricious. There is also a great variety in the thickness of the surrounding walls, the larger ones being covered by a smooth, glistening, finely fibrous texture, whilst the smaller are confined by tissue much denser, though identical in structure. So, too, the contents may exhibit every variety of colour and consistence, so as in some instances to consist of dark grumous fluid in which float patches of lymph coagulum, in others of clear serous fluid, the nature of which has been investigated, but the composition throws no light upon its origin.

Not infrequently the walls contain solid masses, which are merely exaggerations of cellular tissue, and are always of an innocent nature. I shall not dwell here upon the diagnosis of these tumours, which, as a rule, is sufficiently obvious; but the two points on which

[1] Read before the Medical Society of London on December 1st, 1884.

I especially seek for information are the origin and the treatment of these cysts.

As regards the first point, the suggestion has been thrown out by Sir James Paget, in a paper in the Medico-Chirurgical Society's Transactions, 1878, "that there is a probability that some congenital and infantile cysts, and even some ranulæ, may be derived from branchial canals closed at both ends and distended with fluid, as hydrocele in the inguinal canal may be formed by the filling of part of a canalis vaginalis."

The suggestion is followed by Mr. Treves, who has described, in the Transactions of the Pathological Society, 1881, a case of cystic hygroma of the neck, where beside one very large cyst there were several smaller, one of which lay in the line of the second branchial cleft. For my own part, I cannot but regard this as a coincidence, seeing that the larger number of these tumours are placed in situations where there can be no possible connection between them and the branchial clefts. Nor do their structure or contents seem to bear out the analogy between them and a hydrocele of the tunica vaginalis, which is formed by hypersecretion of a section of serous membrane. A closer resemblance would seem to commend itself between these tumours and those hypertrophies of the connective tissue which are not infrequently found in the limbs, and which are mainly due to an excessive growth of the fatty tissue, as in the case of an hypertrophied foot depicted in Holmes' work on "Diseases of Children," which after amputation was found to be due only to an unusual deposition of fat and cellular tissue, the muscles as well as the bones being normal. Not long ago I removed a large congenital tumour from the palm of a child's hand which on examination proved to be nothing but a mass of hypertrophied fat and cellular tissue. In another case I removed a very enlarged toe from a child, in which an increase of fat and cellular tissue was all that could be seen to cause the hypertrophy. So I believe these tumours to consist of an exaggeration or hypertrophy of the cellular tissue of this region, which is naturally so extensive, and from the anatomical nature of the parts is of a somewhat looser character than in other regions of the body, except those where a similar development sometimes, though more rarely, is met with.

In reference to treatment, the circumstances of the case may make various expedients desirable. Tapping with a fine trocar may effect a permanent diminution, and should be tried before more active measures.

A short time since a child of eight weeks was brought to me at Great Ormond Street Hospital with a very large hygroma, occupying the right side of the neck. One large cyst stood out prominently, and this I tapped, withdrawing about 2½ ounces of dark brown viscid fluid. When seen the following week the cyst seemed to be nearly as full as ever, but there was no sign of inflammation, and the child was not seen again for ten days, when it was found that the swelling had very nearly disappeared, and the skin, which had been tense, now hung in loose flaps over the region of the swelling. In another case a boy of 9 years old was brought to me with a large oval swelling over the thyro-hyoid region. On putting in a fine trocar, some clear gelatinous fluid issued, but as it was too thick to pass freely I placed the patient under chloroform, and proceeded to dissect out the cyst, which extended itself rather deeply, and was connected with several smaller ones which lay behind and dipped down between the trachea, the muscles, and large vessels, and required a long and careful dissection. The whole mass was taken away, and though the cavity was deep, healing proceeded satisfactorily, and the boy was soon able to leave the hospital. Mr. Smith, who has described several cases of this affection, recommends the use of setons, preferring for the purpose carbolised catgut, and suggests the use of Morton's iodoglycerine.

But the great danger to this and to all other treatment lies—(1) In the very extensive connections which may exist, and be prolonged into parts where pressure may cause serious danger. (2) In the readiness with which these structures become inflamed.

The serious nature of the inflammation which so readily occurs in this tissue even from a blow, or from the introduction of setons in parts where danger cannot arise from impeded respiration, such, for instance, as the outer part of the neck or the axilla, was pointed out by Mr. Smith in two cases which he showed at the Clinical Society. This would suggest the desirability, when possible, of taking a somewhat bolder course, and of opening as many of the sacs as possible, and by free drainage and antiseptic dressing avoiding any septic complications, and trusting to a limited inflammation producing cohesion of the remaining tissue. But the feasibility of such a course must depend upon the size and position of the cysts, as well as upon the nature of their deeper connections. The first of these may prohibit all interference, as in the case of a very young child which was brought to me on account of a hygroma on both sides of the trachea, but which did not seem to have exerted any baneful effects from pressure. The child caught a slight cold and died suddenly. I made an examination with the assistance of Dr. Angel Money, and found that the tumour was composed of many cysts containing dark brownish fluid in which were some floating clots of decolourised fibrin. It extended downwards on each side of the trachea into the thorax and behind the pleura on each side. The trachea was compressed and narrowed, and bronchitis supervening, death had occurred in consequence of the obstruction to respiration. The knowledge obtained from this case has made me refrain from interfering in a similar one which is now under my observation.

In the previous class of cases, viz., the hydroceles of the neck, where the cyst, however large, is single, such treatment is much more easy of application, and there would now be no hesitation in opening the cavity, and after evacuation of its contents, in washing it out freely with antiseptic lotion, draining and keeping aseptic after the usual method.

The remaining class of cysts to which I will refer have no doubtful origin. The sebaceous cysts which occur congenitally in the neck are doubtless the relics of some aberrant portion of epiblast which has become misplaced in the course of development of the body. They are often deeply situated, and have a further interest from the fact that they are in most cases found to lie in the position of one of the branchial arches or of the clefts between them, which are found to exist in an early stage of embryonic development. Thus, they are found beneath the tongue, probably in connection with the first branchial arch which forms the lower jaw, and they occur in the line of the sternomastoid, particularly about its insertion into the sternum and clavicle, where, in fact, the fourth and fifth arches unite to form the anterior wall of the neck. Other relics of these arches and of the clefts between them are found in these situations, such as branchial fistulæ and supernumerary auricles, several examples of which I have come across during the last few years. I have met with a large number also of these congenital cysts, and during the last year at the Children's Hospital have operated in four cases for their removal. Beyond the ordinary altered sebaceous material and a few rudimentary hairs, I have not found any of those other structures which are occasionally met with in tumours of a similar character, such as bone, teeth, &c. In the case of a woman who came to me at Charing Cross, I evacuated

from a large swelling below the jaw, which raised the floor of the mouth, a quantity of material, having the consistency of putty, of a greyish pink colour and with a very foul odour, which evidently belonged to a cyst of this nature. The patient had been under treatment on several occasions at other hospitals, and when seen by myself was in too weak a state of health to submit to the prolonged and dangerous dissection which would have been necessary for the removal of the sac. It became much reduced in size by means of draining and frequent washing.

I have not alluded to hydatids, which may be found here as in other parts of the body, but have brought forward some points of interest in connection with this group of tumours in the hope of eliciting suggestions and information from the experience of members of the Society.

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.
President of the Health Department, Social Science Association, and of the Epidemiological Society.

(Continued from page 776.)

Scorbutus—(continued).

Dr. Burt described the annual occurrence of Land Scurvy in the native lunatic asylum, Moorshedebad.[82] In 1822 his attention was drawn to the disease in consequence of the occurrence of severe ptyalism caused by a small dose of calomel given to a patient with slight fever. The disease was "very insidious in its progress, and Dr. Burt was inclined to think that it might have occurred in previous seasons, and have been reported as fever or dysentery, these being the first symptoms of which the patient complains, *although his gums may have been in an ulcerated state for months before.*" In 1825 Mr. J. Hutchinson[83] saw cases of scurvy in Cachar. He described a fatal case as occurring there in a Sepoy of the 7th N.I.

In 1834 Mr. D. Macnab published[84] an account of scurvy as it occurred in that and the preceding year among the native troops at Nusserabad. No similar visitation had attacked the troops there during the previous 14 years; but it seems to have prevailed there extensively in a cavalry corps about the year 1820. The people of the bazaars escaped, very few of the camp followers suffered.

Generally the disease was very intractable, nearly every mode of treatment which the surgeon's imagination could suggest (with the exception of antiscorbutics, the idea of lime-juice never having apparently occurred), including large bleedings, having been tried. In describing the disease as it then occurred in the 4th Regiment of Light Cavalry, at Nusserabad, Mr. T. Ross[85] says that he found medicine almost unavailing, although "mineral and vegetable acids were liberally employed." It was then usual to give nitrated vinegar in scurvy, but the report does not mention lime-juice. Most of the fatal cases sank from diarrhœa. In July, 1837, Mr. Macnab laid another communication on scurvy before the Medical and Physical Society,[86] strongly recommending, as an antiscorbutic, the fruit of the Anola, Phyllanthus Emblica, Emblic Myrobalons. Dr. Waring, "Pharmacopœia of India," describes this fruit as acidulous, purgative, and astringent, being employed in tanning. This authority cites Dr. Irvine ("Medical Topography of Ajmeer," p. 118) as being of opinion that it does not possess any peculiar antiscorbutic virtues, and that, in this respect, it is not superior to any other acid vegetable astringent.

Dr. R. H. Irvine says that, when the disease described by Mr. Macnab (which occurred as a severe epidemic in the district of Ajmeer) appeared, bad grain was considered to be the cause, but he considered that facts did not seem to warrant this opinion. "The disease subsided as the season became milder."

In 1837-38, a great deal of scorbutic cachexia existed among the native troops at Agra.[87] Dr. W. L. Macgregor showed[88] that, in 1841-42, at Kurnaul, sloughing followed the application of blisters and leeches in the hospital of H.M.'s 3rd Buffs. This place appears to have been over-crowded, to have had a low verandah and an insufficient area, pent in by lofty buildings. The reporter adds, however, that scurvy appeared in other hospitals at Kurnaul during the same season. One of the most severe cases he ever witnessed occurred in a havildar of the 3rd Cavalry, on whom a blister had been applied to the nape of the neck, and the whole of the integuments and adipose substance were destroyed by the sloughing, laying the muscles completely bare. We may infer from the context that the soldiers had an abundance of excellent food. We thus see that—say between 1820 and 1842—scorbutus prevailed at Nusserabad in the W. and Cachar in the E.; at Kurnaul and Agra in the N.W.; in Assam in the N.E.,[89] and Arracan and Burmah in the S.E. Are we to consider that this widely ranging disease was a true epidemic? It apparently depended much upon the prevalence of dry seasons, causing augmentation of the price of grain, a valid source of disease among parsimonious Hindu Sepoys, who were the principal sufferers, serving in the field, or stationed in places distant from their homes, but a circumstance which could only have affected the European soldiers by diminishing their supply of fresh vegetables and fruits. The question of the epidemicity of scurvy will be continued presently.

An account[90] of the presumed remarkable efficacy of *free blood letting* in sea and land scurvy, by Deputy Inspector General Murray, Surgeon Bailey, R.N., and Assistant Surgeon Armstrong, of the 29th Regiment, deserves to be consulted as a curious document, illustrating the "good in everything" in therapeutics. A considerable amount of information regarding scurvy as it formerly prevailed in Indian gaols will be found in my chapter on Hospital Gangrene.

In his admirable *Medical Topography of Scindh*, the late Mr. Kinloch Kirk showed that the great characteristic of the Desert Tract, especially of Scindh, is its impregnation with saline matter, similar to what is obtained by the evaporation of sea water. Everywhere that a well is dug, the water is brackish and bitter. Throughout the Desert Tract, true scurvy is constantly endemic among the poorer natives, and there European troops have always been liable to scurvy, both in its masked and in its developed forms. There also scorbutic dysentery is a leading disease. Here it is noteworthy that, throughout the true Delta of the Ganges, the well water is brackish and undrinkable. Undoubtedly there is a considerable amount of scurvy in that immense tract, but there the disease is far less generally prevalent than it is in Scindh or Behar. The natives of the Delta use either river water or rain

water, collected in more or less well puddled tanks. One of the most important accounts of land scurvy in our Indian literature has been given by my friend Mr. Alexander Grant, in his excellent *Medical Sketches of the Expedition to China*, in 1840 (Finch's "Indian Journal of Medical and Physical Science," 1845). While stationed on the north side of Hong Kong, the 37th Madras N. I. suffered much from fever, dysentery, and malignant ulcers on the lower extremities. These unfortunate troops, ill-fed, being debarred by cast prejudice from eating much of such limited supplies of food as were available, and ill-lodged in tents and mat huts, which a hurricane finally levelled to the ground, became, Mr. Grant informed me, thoroughly scorbutic, and then sloughing of the cornea was rife amongst them. At the same time the Bengal European troops, similarly exposed and rationed scantily on weevilly biscuits and salt meat, were attacked with scurvy, bloated countenances, spongy gums, and legs swollen and covered with petechiæ, and often died suddenly from effusion into the cavities [Beriberi ?]. Ulcer was not developed in the European force, but cases of scorbutus occurred among the seamen in the ships.

In 1851 there appeared, in Mr. Woodcock's Prison Report, Appendix E., p. 150, a report by Mr. S. Clarke on scurvy in the Humeerpore Gaol, and at about the same time[91] Dr. A. H. Leith reported the frequence of scurvy among the prisoners confined in the Bombay House of Correction, evidently in consequence of the absence of an antiscorbutic ingredient in their food. The sickness was arrested by issuing a supply of *kokum*, the dried fleshy part of the *garcinca purpurea*, a tree which is cultivated in the Konkan. Having seen a notice, I think in Dr. Mouat's Gaol Reports, of the prevalence of scorbutus in Behar, I, on inspecting the principal gaols of that district in 1865, examined every prisoner, and found a purple line edging the gums (quite like the lead line, except in its colour) in the great majority of the prisoners.

I often, but by no means so generally, found this indubitable sign of scurvy in poor Bengalis, as I have mentioned in the chapter on Hospital Gangrene.

Scurvy was, in old times, one of the direst scourges of Indian native gaols. It was considered that, although probably more regularly fed, and at a greater cost than their brethren outside (when their food was not stolen by gaol servants), the prison dietaries fell short of the requirements of health in not being sufficiently varied, and especially in not containing a great number of spices and of antiscorbutic vegetables, such as *sag* (wild spinach), *mohwa* flowers, and cresses found in native gardens, and picked up in waste places, and by brooks and tanks. The wise measure of establishing a garden for each Bengal gaol, carried out by Dr. Mouat, having been for many years in operation, the danger of scurvy among the prisoners ought, by this time, to be greatly diminished; but now, as always, scurvy is an evil which appears to be ever ready to show itself in India. In December, 1868, we in Calcutta were surprised to see it reported[92] that an outbreak of scurvy had occurred in a fine Sikh regiment in Fort William. More than fifty were admitted to hospital, of whom five or six died, independent of twenty or more sent to their homes on medical certificate. The appearance of this disease was attributed to want of milk and butcher's meat, confined barracks, and protracted residence in an uncongenial climate.

The Sanitary Commissioners' returns give the following statistics of scorbutus in India. In 1880, 41 European soldiers were admitted, 1 died. Cases did not occur among the women and children. There were 1,149 cases, with 32 deaths, in the native army. The prisoners had 467 admissions, and 8 deaths. In 1881, the admissions of European soldiers were 33, without any deaths. One soldier's wife and 3 children were admitted. There were 903 Sepoys admitted, with 27 deaths. The number of prisoners treated was 411, of whom 9 died. In 1882, the admissions of European soldiers were 26. The women and children were free from the disease. Of the Sepoys, 471 were admitted, and 18 died. Among the prisoners, 362 were treated, with 6 deaths.

Carefully read, these statistics are full of invaluable suggestions. Thus the occurrence, annually, of from 30 to 40 cases of scurvy in our force of some 60,000 European troops proves that the men are never quite exempt from the tendency to scurvy which prevails in certain Indian localities, and that this spark of disease, which now smoulders, will burst into flame at any moment in the field, on foreign service, in sieges, or whenever the troops may be deprived of their due supply of fruit and fresh vegetables. It will be borne in mind that from 30 to 40 *admissions* per annum in such a body of men evidences a very considerable prevalence of scorbutic cachexia among those whose condition of disease is not so pronounced as to compel them to seek relief in hospital. The annual occurrence of from 400 to upwards of 1,000 cases of scurvy among the 115,000 men of the native army in time of peace shows that, although it does not rest with us to diet these Sepoys, it is a matter of great importance everywhere, whether in cantonments, in stations remote from their own districts, or in the field, and most especially in times of scarcity, that we should provide that abundance of good food, at moderate rates, shall be obtainable in their bazaars. The occurrence of a considerable amount of scurvy among prisoners is evidence that the gaol garden system needs extension. It is probable that very little of the scorbutus which occurs among prisoners originates in the gaols. The fact that, in the three years 1880-82, only five fatal cases of scurvy occurred in the gaols of the Bengal Presidency, which in the last of those years contained 59,489 prisoners, a large number of whom came from districts where scorbutus is constantly endemic, is evidence that the gaol garden system is working efficiently in that Presidency.

It appears to me that, carefully weighed, the whole of our facts regarding scorbutus and hospital gangrene in India may be viewed as more or less directly substantiating the truth of Kenneth Mackinnon's opinion that *land scurvy assumes an epidemic character in that country*. In one of his last writings,[93] that excellent observer remarked, "As far as my knowledge goes, in no other country has it been observed that land scurvy shows itself in an epidemic form, but it does so here, and particularly in Rajpootanah, and, as I think also, in Scinde. It was a knowledge of this which induced me, when a member of a committee directed by Government to report upon the probable causes of scurvy among the troops which came from England in the end of 1853, to give it as my opinion that the appearance of the disease on board so many ships, many of which vessels had, on previous voyages, brought troops in perfect health to Bengal, that the prevalence of scurvy depended upon an epidemic constitution of the atmosphere in that particular season. The presence of scurvy on board of ships is usually assigned to the continued use of salt provisions; there was evidence before us that the voyages had not been of inordinate length, and that the men had been freely supplied with fresh hermetically sealed meat and with potatoes prepared in the same manner. In fact, the salt meat theory, as entirely true, must be abandoned,

for the Rajpootanah epidemic was among regiments of Native Infantry where no animal food is consumed, and I am inclined to believe that epidemic scurvy may be independent of every kind of diet, for these Sepoys in Rajpootanah used the same grain with the neighbouring villagers, who had no scurvy among them. In Scinde, and even at Lahore, a great prevalence of scurvy has been seen, with no changes in diet to account for it; and this is true also of the hills, as pointed out by Dr. Grant in his paper on Hill Diarrhœa.[94] The disease is also endemic in the gaols of the Sangor and Nerbudda territories. The whole question is very mysterious, for while in the hills and on the voyage round the Cape in the year I have spoken of, unusual damp might be held to influence the presence of disease, in Rajpootanah, on the other hand, when the epidemic prevailed in 1835, the season had been very unusually dry; and, strange to say, in Rajpootanah the disease was confined to Sepoys."

The above appeared in 1857. In like manner I have shown, *ante*, p. 790, vol. i., for 1884, that in the years 1830–33, 1837–38 hospital gangrene, the congener if not the offspring of scorbutus, affected alike the inhabitants of the village of Chittoor (South Division of Arcot, Madras Presidency), and the prisoners in the gaol, and both classes were attacked precisely at the same period. In like manner I have cited (at p. 792) Dr. Beaumont's report to the effect that, Indore having scarcely known this form of disease, sloughing phagedæna became so very prevalent during the rainy season and up to the end of 1872 that it was feared it was about to become established as an endemic disease. In five months there were 315 cases, with 51 deaths. It is particularly noticed that "there was nothing exceptional in the season or food supply."

The opinion that scorbutus has, from time to time, appeared as an epidemic, rests upon a considerable mass of evidence. We read in Hecker that it did so, more especially in Germany, in the year 1846, and with such severe and unusual symptoms that people were inclined to regard it as an entirely new malady. Hecker cites various authorities in evidence that, on several occasions in the 15th and 16th centuries, scurvy occurred as an epidemic in Europe.

The subject of land scurvy in India deserves a volume to itself. I have treated it concisely, but I think that I have given those who may desire to study the subject fully data which will enable them to refer to all the best authorities.

Note on Bronchocele in India.

Since the appearance of my chapter on Indian Bronchocele, I have received from Dr. L. A. Waddell, resident physician Medical College Hospital, Calcutta, an interesting contribution to our knowledge of the pathology and therapeutics of this disease.[95]

Dr. Waddell, having examined the blood microscopically in four cases of goitre, found that anæmia was not present in either. In two of the cases there was decided plethora of blood corpuscles, and the hœmoglobin was also above the average.

In 1881, Dr. E. Woaker, who for several years had been using hydrofluoric acid in the treatment of goitre, published in the *Lancet*[96] a report giving the results of twenty cases treated by this method: he placed the recoveries at eighty-five per cent., concluding that the acid may justly be considered an anti-goitrous remedy which, although not a specific, deserves to be regarded as a basis of constitutional treatment. Reviewing Dr. Woaker's cases (which remained under treatment from 3 to 13 months, with an average of $7\frac{3}{4}$ months), Dr. Waddell infers that Dr. Woaker's percentage of recoveries requires to be considerably modified; but then, even with this qualification, a large margin of undoubted success must still be allowed to the hydrofluoric acid treatment. In two cases treated by Dr. Waddell, the sodium fluoride was taken with great disgust.

He considers that, in simple soft enlargements of the entire gland, by persisting with the fluorides, one may reasonably hope to effect ultimately a substantial reduction of the tumour, if not complete cure. It is clear that the agent is of but little avail in hard fibrous enlargements.

It is not probable that this plan of treatment will become established in India, considering the slowness of its action when small doses are given, and the intolerable nausea produced by large doses. It is held that "considerable anæmia," a condition to which all in India are sadly liable, "must attend the prolonged use of the drug, even in small doses."

As, however, it appears that hydrofluoric acid and the alkaline fluorides exert a decided therapeutic influence upon goitre, and as it is to be conceded that their use in combination with other agents may not improbably be found advantageous, these papers merit the full attention of Indian practitioners.

REPORTS OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

NORTH EASTERN HOSPITAL FOR CHILDREN.

CASES OF ACUTE TETANUS FROM UMBILICAL WOUNDS.

(Under the care of Mr. R. J. GODLEE.)

(For notes of this case we are indebted to Mr. M. Williams.)

Case I.

E. G., aged one week, was brought to the out-patient department on the 28th of October, 1884. The grandmother who brought it told us that the child was well nourished when born; lactation was continued regularly and with the normal periods of remission until the morning of the 28th, when the baby refused the breast. This refusal was attributed, according to the mother, "to a stiff jaw from cold." The mother was confined by a midwife.

When seen at 1.30 p.m. the jaw was found in a condition of trismus; the act of examining the child produced a well marked tetanic fit. The spasm was violent. The abdominal and thoracic muscles, with the muscles of the upper and lower extremities, were thrown into violent clonic spasm. The belly was tense and hard, and the walls of the chest expanded imperfectly in the effort of breathing; in fact, inspiration momentarily ceased, as was evinced by the intense cyanosis. The spasms were of a few seconds' duration. The pulses were imperceptible during the spasm. The muscles of the arms and legs were extremely rigid, and convulsed in a most violent manner. The attacks of clonic spasm were very frequent, re-

turning about every ten minutes ; touching, or otherwise exciting the child, was always followed by an attack.

Upon examining the umbilicus, a portion was still semi-attached ; the part looked neglected and far from clean, it was discharging a sanguineous pus and bled readily when touched. The relatives strongly objected to allow the patient to come into the hospital.

The baby was ordered a mustard bath hourly and a mixture containing bromide every second hour.

The grandmother returned with the child again at 8 p.m. The fits were now more frequent and more lasting. Cyanosis was intense. Complete trismus. The patient's body is now bent like a bow—opisthotonos. It can be readily lifted by placing two fingers beneath the occiput and two beneath its heels. The interval between the paroxysms of spasms is considerably less. The child is unable to utter any articulate sound. The surface of the skin is moist and the pulse rises and falls with the intensity of the spasms. It has taken no nourishment. Still refuses admission.

Word was sent the following morning that the child died in the night. The duration of the attack, from the onset to its death, was eighteen hours. An autopsy was not permitted.

Case II.

G. S., aged three weeks, was admitted into Barclay Ward on February 11th, 1884, with the following history :—For the past seven days has refused the breast, being apparently unable to swallow, owing—according to the mother—to the fixity of the jaw, due to "internal convulsions" ; occasionally the attacks are accompanied by stiffness and arching of the back backwards. Is wasting. The spasms latterly have been more severe, lasting and frequent. No previous illnesses. Parents enjoy good health. No history of tubercle or syphilis.

The child is thin and emaciated, has a brownish-yellow pigmentation of the skin. Temperature 98°, pulse, 100. The face is wrinkled and prematurely old-looking. Is very fretful. When watched for a few moments, or suddenly touched, rigidity of the muscles of the neck, trunk, and extremities results. The spasms, which are tonic, are persistent, intense, and prolonged, beginning in the face. The countenance assumes the "risus sardonicus." The rigidity extends to the muscles of the trunk, and finally all the voluntary muscles appear to become implicated. The muscles feel hard, tense, knotted, and rigid, and stand out cord-like. During the spasms the spine is curved posteriorly—opisthotonos, and the posterior cervical muscles forcibly extend the head. The jaw is fixed—trismus—and cannot be opened. During the interim the jaw is lax, and the mere introduction of food suffices to re-excite a fresh spasm. Respiration ceases during the paroxysms, for the child rapidly becomes cyanotic. The extremities are cold and blue. No congenital heart murmur. Breathing puerile and normal. No abnormalities of liver or spleen. There is a red, irregular, sloughy-looking wound over umbilicus, which has existed since its birth.

Was ordered a mustard bath every hour, with gr. j$\frac{1}{4}$ of bromide of potassium every second hour. Milk and peptonized emulsions as enemata frequently.

The same evening the spasms were still continual and more lasting. Cannot retain enemata. Attempts were made to feed it by passing a soft No. 12 catheter down the œsophagus, but this only excited fresh spasms, and was therefore given up. Sleep is entirely absent.

Next morning the temperature was 106·4°. Pulse almost imperceptible. The spasms continued every few seconds. Died asphyxiated shortly afterwards.

Necropsy twenty-six hours after death.—Body much emaciated. Subcutaneous fat almost absent. Muscular development deficient. Rigor mortis passing off. Hypostatic congestion over back, arms, and legs. The umbilicus projects about half an inch, centrally there is an irregular, sloughy-looking wound, not in any way connected with the abdominal cavity. The obliterated hypo-gastrics are visible on its posterior aspect. Abdominal cavity opened. The liver fills the whole of the epigastric region. The intestines are contracted and partly covered by omentum. On raising liver, stomach is seen to be pale and closely contracted. Both pleuræ are empty, their surfaces are smooth. Pericardium contains about half a teaspoonful of a dark brownish-yellow but clear fluid. Internal surface pale and smooth. Right side of heart distended with dark clotted blood. All the valves are regular in form and of a slightly reddish tinge. Foramen ovale imperfectly closed. The muscular tissue is pale. The thymus gland is medullary looking in colour and of a similar appearance on section. The lungs float in water, everywhere normally crepitating ; externally they are of a dark red colour with intermixed blue marbling ; on section the tissues are much engorged, especially at both bases ; dark fluid blood is readily squeezed out. Spleen, dark brownish red in colour, of flabby consistence ; on section the pulp is fragile and abundant. The capsule of kidneys is easily separable. Medullary and cortical substance normal. The substance of the liver is flabby. Lobules clearly recognisable. Uniformly red throughout. Small intestines contain flocculent pultaceous matter. Ileum contracted. Fæcal matter in large gut. Brain very soft ; longitudinal and lateral sinuses contain fluid blood. The dura-mater is healthy. Brain regularly formed. The pia-mater is delicate, containing numerous venous net-works ; the membrane is hyperæmic. The substance of the brain is pale and soft, lateral ventricles contain a small quantity of fluid, punctiform hæmorrhages visible, but not in great quantities. No further evidence of any abnormalities. The dura-mater of the cord was slit up, inner surface smooth, consistence firm. The cavity of the arachnoid was next opened. This was found to contain a small quantity of thick clear fluid. The pia-mater was much congested, little leashes of swollen vessels were visible coursing up the cord, the membrane itself was somewhat adherent to the cord-substance. The cord was hyperæmic and very soft, but no particular abnormalities could with the naked eye be detected.

Medical Times and Gazette.

SATURDAY, DECEMBER 27, 1884.

On Friday last, Charing Cross Hospital Medical School celebrated the fiftieth anniversary of its foundation. The proceedings commenced at noon with the distribution of prizes by Mr. Martin, one of the treasurers of the hospital. In the course of an admirable speech, Mr. Martin showed that although he had only recently become connected with the school, he had already made himself acquainted with its history, and that he took the deepest interest not only in its welfare, but in the rapid advances that are being made on all sides in every department of medicine. In the afternoon a dramatic entertainment was provided at Toole's Theatre by the Students' Club, one of the pieces played having been written especially for the occasion by the wife

of a member of the staff. A very considerable amount of histrionic talent was displayed, and it is needless to add that the house was well filled. In the interval between the pieces, Mr. James Cantlie recited an epilogue of his own composition recounting the various successes of past students in this country and abroad. In the evening the staff celebrated the event by holding their annual dinner at the Grand Hotel, on which occasion there were but two absentees. Mr. Francis Hird was in the chair, and gave a most interesting account of the early days of the school; his own connection with it dating from the year 1838, only four years after the school had been started. In that year he and the late Mr. Hancock were attracted from the Westminster School to teach anatomy and physiology respectively, and in their first year at Charing Cross, they had only one new entry. After referring to the numerous difficulties the infant school had to contend with, difficulties both from within and from without, Mr. Hird alluded to the satisfactory position which the school had now attained amongst the metropolitan teaching bodies, and to the palatial accommodation now provided for it compared with the subterranean establishment that formerly did duty, and he prophesied a great future for the institution.

The increase of the small-pox epidemic in London has not been so great, it appears, as was at one time thought probable. On Saturday last there were only 36 more cases under treatment in hospital than a fortnight previous. This result must be in great measure attributed to the admirable organisation of the Metropolitan Asylums Board, which we are glad to see is being constantly improved. Meanwhile, as a result of the friction which is inseparable from such work amongst uneducated persons, there is a tendency to find fault with the Board, which has shown itself in two regrettable incidents during the past week. In both cases, in the West Ham and Darenth complaints, Sir E. H. Currie has been able to show most conclusively that the complaints had not a shadow of foundation. Another point which has recently attracted attention, and which ought not to be lost sight of, has reference to the want of experience of small-pox amongst our students. A casual case or two in the hospital out-patient room, which are driven away as soon as discovered, form almost all the practical experience that a young practitioner has of the disease when he passes his examinations. It is no wonder, then, that many mild cases of small-pox go through their illness undiagnosed, until they have worked irreparable mischief. There is no doubt that senior students ought to be allowed and encouraged, if not enforced, to study the disease for a month in a small-pox hospital. And their teachers ought to impress upon them that, in addition to typhoid and syphilis, there is another disease which every young practitioner ought to be always suspecting, viz., variola.

It has been so much the fashion of late, and especially in a particular class of cases, to decry the value of opinions given by medical experts, that it is a relief to find that this opprobrium, perhaps not wholly undeserved, is not universal. That the conviction of Elizabeth Gibbons for the murder of her husband rested entirely on the medical evidence there cannot be the shadow of a doubt. Putting aside for the moment the position and number of the bullet wounds, there is absolutely nothing in the case which points to murder more than suicide. If there was no good motive for suicide, it is equally true that there was no motive for murder. The discrepancies in the different statements made by the accused would have had no weight if the medical evidence had been to the effect that the wounds were as consistent with suicide as with murder. Medico-legally the case presented no difficulty. The wound in the back, it may safely be said, could not have been intentionally self-inflicted; nor is it easy to understand how it could be possible to fall on a pistol so that it should go off, the bullet entering the left shoulder and passing straight through the chest from behind forwards; so that the hypothesis of accident may be as safely dismissed on the strength of this wound. Could it, then, have been received during a struggle in which the wife was endeavouring to wrest the pistol from a determined suicide? We must confess ourselves unable to believe it possible that such a wound should have been so received. There were several points in regard to the three other wounds which ill accorded with the theory of suicide, to say nothing of the extreme improbability of a man missing himself altogether. Without entertaining the exalted views of expert testimony that the Lord Chief Justice holds, we consider that in matters of life and death expert testimony is always entitled to something more than mere respect. And when, as in the present instance, experts explain their meaning by a cast showing the exact position of each wound, the decision becomes less a matter of scientific infcrence than of mere fact.

Another "miscarriage" of justice is the sole result of the eight days trial of Lotinga *v.* the Commercial Assurance Company. Indications of a difference of opinion between the jurymen might have been observed as early as the third day of the trial, differences which apparently were not removed by the subsequent evidence. Of the two points on which payment of the policy was disputed, viz., suicide and incorrect statements as to temperance in the proposals, the second was that on which the Company mainly relied. In regard to this there was a great deal of conflicting evidence. Much of that on the plaintiff's side, however, reminded us of the Irishman who, when charged with breaking a window by stone-throwing, offered to bring into Court fifty witnesses who did not see him throw the stone. It has been suggested by a daily contemporary that the fact that Lotinga had been passed as a good life by their own medical man was a strong argument against the contention of the Company. But there is a well known leading case in which a company successfully resisted a claim on the ground of intemperate habits, the insured having been accepted as a good life by their own medical man a fortnight after he had passed through an attack of delirium tremens. The medical evidence in the present case was of but little moment, and it is much to be regretted that there was no *post-*

mortem investigation, though it is quite possible that the evidence thus obtained would not have sufficed to enable the case to be settled out of Court. Insurance companies will perhaps, as a result of this action, be led to take a deeper interest in the financial condition of intending clients before turning a willing ear to their proposals.

Much excuse is to be made for every display of jealous susceptibility amongst the French, but we should have expected at least to find the French students of medicine free from the present besetting sin of their fellow countrymen. The French school of medicine has deservedly won a foremost place in the scientific world, and it still holds it, in spite of the preponderance of Germany in the political world. With this record of success on the part of their predecessors and present teachers, the French students ought not to have shown so much self-distrust as is implied in their foolish agitation for protection from foreign rivalry. There is no doubt that the proportion of foreign to native students inscribed at the Paris Faculty of Medicine is very considerable, being nearly 1 in 8. M. Béclard, the dean, in his report to the Conseil Académique, states that at the commencement of the school year (October 15th) the number of students inscribed at the Faculty was 3,994, or 550 more than last year, and out of this total there were 538 foreigners—127 Americans, 96 Russians, 61 Roumanians, 52 Spaniards, 45 Turks, 30 Brazilians, 26 Swiss, 25 Greeks, and 22 English. There is, however, we believe, no ground whatever for the assertion that foreign students are admitted to French degrees more easily than native students. If it were so, there would be some excuse for the cry for a fair field and no favour ; but when this misconception is removed, we may be sure that the cry will cease, and that the students will desist from their efforts to injure that reputation for friendliness and hospitality which their nation has earned so well. No doubt many Frenchmen are looking with a longing eye to practise amongst the rich English sojourners at the southern health resorts ; and if they could exclude English practitioners from French degrees, the whole of this lucrative business would fall into French hands. That, however, would be not only a serious injustice to the visitors, but it would no doubt drive some of them to pass their winters amongst less jealous nations. A course which led to such a result would, we are sure, commend itself neither to the selfish interests nor the generous instincts of the French nation.

It is generally admitted within the profession, we believe, that F.R.S.'s letter to the *Times*, on the case of excision of a brain tumour, was ill-advised, though well meant. Whatever happens to the individual patient, and we hear that his prospects of recovery are not satisfactory, the case is a striking instance of the application of facts learned, and only to be learned from vivisection, to the treatment of an otherwise incurable disease. The issue of the case, even if unsuccessful, will not detract from the force of F.R.S.'s logic ; but it will cause it to be impressed less cogently upon the lay mind, and for that reason we regret the premature publication of his letter. People outside the profession do not sufficiently realise the risks of capital operations ; they are apt to generalise too hastily, and from a single unsuccessful case to condemn an operation *in toto*. Within the profession, however, the dangers of interfering with the brain are so well known that many of us have hardly yet realised that there is such a thing as brain-surgery, except where accident or injury has been before us. Dr. Ferrier, we believe, lost something like 25 per cent. of his monkeys from meningeal inflammation, even when strict antiseptic precautions were employed, and it is not likely that the proportion of unsuccessful cases in human subjects will be very different. In operations for saving life, however, a mortality of 25 per cent. ought not to paralyse the surgeon, especially where there is every prospect of his being able to reduce the mortality as the conditions of success become more clearly formulated. We repeat that in the present case the physician's success in localising is entirely a different matter from the surgeon's success in removing, and the issue of the case does not detract one whit from the former. And, in spite of all that has been said, we maintain that neither would have been possible but for vivisection.

In the ablest article we have yet seen on the Teaching University, *Nature* has given such forcible support to the views repeatedly advanced in these columns —the necessity for amalgamating the London medical schools, and the advisability of appointing University lecturers on the higher branches of medical science—that we make no apology for giving the passages in full. On the first point, *Nature* is perhaps more hopeful than the difficulties of the case justify. "The altered character of medical education," it believes, "has made the continued isolation of the smaller medical schools a practical impossibility. Not merely has technical instruction gone beyond the capacity of the junior members of the medical staff who are usually told off for it, but the appliances required are too costly for all but the wealthier schools to provide efficiently, and the teachers are themselves wanted for the more minute and careful clinical instruction which is now everywhere demanded. The Medical Schools will therefore combine, perhaps, into some four great groups, for purposes of education and the organisation of laboratories. Once federation has begun, the foundation of a medical faculty for London is only a question of time. This will come about, probably, whatever the fate of the more general movement. But such a faculty would undoubtedly be found to be politically a body to whose just claims to direct medical education the University of London would find it impossible to lend a deaf ear." The second point is thus dealt with : "What is absolutely essential to add lustre and distinction to the work of a Metropolitan University is a body of University Professors who would take charge of the higher studies, which never can be properly cared for by bodies sedulously occupied with the very serious business of the higher education. What we hope, then, some day to see is the University of London equipped with a proper staff of regius professors, who themselves would be, at the least, an invaluable bond of union

between its own too abstract isolation and the living reality of the actual teaching bodies." Such higher teaching is no doubt needed. The only question is, who will be the first to provide it: the Royal Colleges who seem tending that way, or the examining Board in Burlington Gardens.

According to the Calcutta correspondent of the *Times*, the *Indian Gazette* of Saturday last contains a further addition to the literature of the cholera in the shape of a short paper by Dr. Klein, throwing fresh discredit on Dr. Koch's comma-bacillus theory. Dr. Klein examined three houses in Calcutta wherein a severe outbreak of cholera had occurred in November. He found that all three were supplied with good water. At some distance from these houses, and never used by their inhabitants, were three tanks full of dirty water, containing the comma-bacilli in large numbers. Various families lived in the huts round these tanks, and used their water for washing and drinking purposes; yet only one case of cholera had occurred among them in November. In the present state of the question, of course, every piece of fresh evidence is of importance; but in justice to Dr. Koch, we must say that the new discovery has little more weight than the fact that Dr. Klein is still alive after swallowing "a microbe." Dr. Koch's position, which we think has yet to be proved, is "no cholera without a comma-bacillus;" but we have never understood him to claim the converse, "no comma-bacillus without cholera." Even Dr. Koch does not deny—in fact, he makes much of—the predisposing causes of cholera.

We learn with pleasure that the Fellows of the Royal College of Physicians are about to demonstrate their appreciation of the long services of Sir Henry Pitman to the College. At a preliminary meeting last week it was resolved to invite the Fellows to co-operate for the purpose of presenting his portrait to the College. We are sure that all who know anything of Sir Henry Pitman and the value of his work will agree with us that the compliment is richly deserved.

We have not yet heard what has been done about the appointment of a medical officer of health for Calcutta, but from what the *Times* correspondent states, his services are very much required. The Calcutta municipality have shown a most short-sighted niggardliness in respect to their sanitary expenditure, with the result that, according to an able memorandum by Mr. Justice Cunningham, from seven to eight thousand persons die yearly in Calcutta and its suburbs from preventible causes. It would be an experiment of historical importance to try whether cholera, for instance, could not be banished from Calcutta by a strict system of sanitation. For the success of such an experiment no doubt the people themselves must be educated into habits of cleanliness, but the first step is to educate their representatives, if necessary by force.

At the meeting of the Pathological section of the Academy of Medicine in Ireland on the 5th inst., a long and varied programme was placed before the fellows. One of the most remarkable specimens exhibited during the evening was a calculus removed from an enlarged tonsil. Mr. Nixon who brought the case forward, did not state the chemical composition of the calculus, nor did he commit himself to any expression of opinion as to its causation. The patient appeared to be suffering simply from enlarged tonsils. He was a great smoker, and there was some tartar on his teeth. Another specimen in which much interest was exhibited consisted of the lungs of a lion who had been bred and born in the Zoological Gardens in Dublin, and died at the age of 12 years with symptoms of pneumonia. Both lungs showed extensive phthisical lesions, including a large cavity in the base of one. Microscopically, Dr. Abraham, who brought the specimen forward, had not been able to find any tubercles, but we did not gather whether any examination for bacilli had been made. The lion had not shown any symptoms of illness until a short time before its death, and had not suffered from cough. The father of this lion was stated to have died in a similar way.

For those who would make the title of "Dr." the common property of the profession, and for all who hunger for the cheapening of the M.D. degree—which is not necessarily the same thing as its greater accessibility—there is food for thought in the consideration of some proposals which have been soberly put forward in a country where the first of these conditions may be said to have been practically realised. The American student is reminded from time to time in a letter or report on the medical curriculum of this country, that "but few Englishmen proceed to the degree of M.D.;" but so general a condition of professional incompleteness is an idea which he fails to grasp. In America every medical man, with the rarest exceptions, is an "M.D.," and it takes him only two years to attain the right to that distinction. Only three colleges in that country now demand the qualifications which were held requisite to the study of medicine a hundred years ago. A necessary result is that the stamp has lost much of its original significance; it has become assimilated, as it were, to that of a token-coin, and although exceedingly common and everywhere of the same nominal value, it is felt to bear little or no evidence of its intrinsic worth, which may vary in different cases to almost any amount from an alloy of the minimum of true metal with a maximum of brass.

Starting with this universal basis of M.D., many strive to equip themselves for the requirements of actual practice by further courses of study in special branches of their profession. But the possession of deep and varied knowledge thus gained can only be inferred by the public by the results achieved by the practitioner in actual practice, and although this may be very solid and satisfactory ground to go upon, it is contended that such results are not immediate or generally self-evident; and that, until the patient has actually undergone a sort of trial by ordeal at the hands of his doctor, he is unable to derive any information as to the latter's acquirements in any particular

branch of his profession; at all events no such indication is now afforded by the generic title of M.D. Various means have been proposed in order to overcome this difficulty: the *Journal of the American Medical Association* has even gone so far as to declare it allowable for a physician to announce on his card, "practice limited to such and such diseases." It is satisfactory to learn that "this view has not been generally accepted," for its general recognition would probably result in the establishment of co-operative medical firms in which "our Dr. So-and-So" would undertake the gastric department, while Professor Some-one-else would attend solely to the pulmonary customers, and the sub-division of labour, running riot, would score the grooves of specialism so deeply that the practitioners of the various divisions of their art would, in the prosecution of their isolated labours, ere long sink out of each other's sight and consciousness.

Dentistry, however, is the thin end of the wedge which is to split this too huge and homogeneous mass of doctors of medicine into more useful and more recognisable groups. And the lines of cleavage are to be determined by the particular study or studies that the practitioner has undertaken, these being vouched for by an appanage of appropriate symbols. Those who object to specialism are reminded that the degree of M.D. is (in this case, was?) "in itself a special degree, and limits the service of those who bear it." No one objects to the degree of D.D.S,, or can deny that the value of dentistry has been vastly improved by the establishment of colleges, and the creation of the degree. "Why, then," it is argued, "should we not multiply these degrees, and so arrange the college courses that each might be conferred on those who prepare for it? Doctors of Ophthalmology, Otology, and Dermatology may seem strange to our ears, but they are as reasonable as the titles Bachelor of Science, of Mining, or of Music, now conferred by the universities." In other words, if "John Smith, M.D., D.D.S." is a legitimate method of showing that an individual has pursued a course of study in general medicine, as well as then in a special department, what is the objection to "John Smith, M.D.O." as indicating the same with regard to ophthalmology?

The prospect thus opened up is almost dazzling. The lavish creation of separate professional chairs, each engaged in teaching the requirements for its own degree; the time necessary for conferring the several distinctions upon the average "good man;" the niceties of distinguishing hoods and robes, and the rearrangement of orders of precedence; the sensation experienced while "taking out" degree after degree until one assumes the proportions of an alphabetical Crœsus, complete a picture which fairly takes away the breath. The proposition is one on which the publishers of medical directories and the makers of door-plates are certainly entitled to express an opinion. What the thickness of the one and the area of the other might amount to in different cases it is difficult to conjecture. In time, no doubt, every evil works its cure. The more ambitious Browns, Joneses, and Robinsons of the profession might not find nine square feet of brass plate, or a corresponding expanse of pasteboard too large a surface on which to display the abbreviated symbols of their professional acquirements; while the few choice spirits who had fathomed all depths of medical knowledge — as indicated by the total of degree-conferring chairs established—might be content more modestly to announce the fact somewhat thus, "James Bragge, M.D. (A—Ω.)" —"Words, words, words. Bring me my tablets!" Truly, another Hamlet, if he dipped into a medical directory, or found himself in the Harley Street of the future, might be pardoned for his madness.

The close of the year brings with it the somewhat depressing duty of surveying our ranks to see who have fallen out in the last twelve months. The missing ones of course must always reach a considerable number, but this year we are pleased to notice how few young faces we have lost, though amongst the elders several good men and true have passed away. Cæsar Hawkins, who resigned his surgeoncy at St. George's Hospital nearly a quarter of a century ago, after a long and useful career in its service, is quite out of the recollection of those of us who have any claim to have not yet passed middle life. Springing from a great surgical stock, he worthily maintained the good name made by his ancestors, and was deservedly respected by all who knew him. Though no longer following the active practice of his profession, he continued to maintain the deepest interest in it until within a short time of his death. Dr. Barclay, another St. George's man, had only lately retired, to enjoy it was hoped for many years the rest which his long public career as physician to his hospital and medical officer of health for Chelsea seemed to have entitled him. Like Mr. Hawkins, he did not write much, but there must be hundreds of men throughout the country who will not readily forget his kindness of heart and courteous manner. Within a few days of each other in the early part of the year there died two of the original members of the General Medical Council, viz., Dr. Alexander Wood and Dr. Allen Thomson. The former will be remembered in Edinburgh for his zeal in the service of the College of Physicians and the University. The latter, for a long time professor of anatomy in Glasgow, is known to every student as one of the editors of "Quain's Anatomy." Up to the day of his death he quietly exercised a considerable influence amongst the leaders of the profession. Two others more intimately associated with the Northern Athens have joined the great majority during the year, Dr. J. H. Balfour who, for the space of 40 years taught botany first in Glasgow, and afterwards for a much longer period in Edinburgh, and Sir Alexander Grant, the President and Vice-Chancellor. The latter had held office for about ten years, and had taken a most active part in the many changes which have been brought about in that time.

Two men almost at opposite extremes of life have passed away whose names are closely associated with

the subject of fever and the London Fever Hospital. Alexander Tweedie died in the spring in his 90th year, and Frederick Mahomed the other day at the age of 35. The death of the latter is so recent that his work will be in the memory of all; whilst of Dr. Tweedie it may fairly be said that he had outlived almost all who had any recollection of his active career. He was first appointed to the London Fever Hospital in 1822, and after holding office for 40 years, resigned 23 years ago. He will be remembered chiefly as the projector of the "Cyclopædia of Practical Medicine," and the editor of the "Library of Medicine." In Mr. Netten Radcliffe we have lost another man who had made his name in connection with epidemic disease, and who was one of the first to show us how successfully a strict process of inductive enquiry can be applied to the causation of outbreaks of infectious disease. We have kept the name of Sir Erasmus Wilson to the last, as that of one who, by his perhaps unparalleled munificence, has laid the medical profession under a debt of gratitude, which can never be wiped out except by making the best use of the vast sums with which he from time to time endeavoured to encourage good work in our midst.

Passing from our own losses to contemplate those of other nations, we find several world-renowned names on our list. In France, last spring, within a few weeks of each other, there died two of the most eminent chemists that that country has produced, Jean Baptiste Dumas and his quondam pupil Adolphe Wurtz. Both had been honoured by our Royal Society, and both had earned, and earned well, the Copley medal of that Society. It will be long before Wurtz's name is forgotten in connection with organic chemistry. Within the last few weeks the death of M. Fauvel has once more created a gap in the ranks of the French school. Though advanced in years, and in somewhat failing health, the Inspector of Public Health of Paris did not fail to appear at the Academy of Sciences at the time of the outbreak of cholera in Toulon, to defend with his wonted vigour his view as to the local nature of the epidemic. He died just too soon to realise the complete disproof of all his theories. Not Germany only, but the whole world, is the loser by the death of Julius Cohnheim, which occurred at the time of the International Congress. He has left his mark on pathology so firmly impressed, that so long as disease is studied his name must ever maintain a prominent and honourable place. In the death of Jäger, Vienna has lost one more of the eminent men who have helped to secure for its school the well-deserved reputation which it enjoys; Jäger's test-types have become a household word in every ophthalmic out-patient room. In Zeissl, too, Vienna has lost another specialist of the highest repute in his own line, and no one can consider his knowledge of syphilis thorough until he has made himself acquainted with his writings. Samuel D. Gross, the Nestor, as he has often been called, of American surgery, though last on our list, is second to none as regards the value or number of his contributions to the healing art. For nearly sixty years as pupil or teacher, he was engaged in the study of his profession. At the commencement of his career he made a great reputation for himself by his lectures on pathology, at Cincinnati, the first ever delivered on this subject in America, and subsequently for 42 years he taught surgery in Philadelphia. The profession in America are justly proud of having given birth to a man whom all Europe delighted to honour.

It is announced by the *Liverpool Press* that Mr. Henry Tate has determined to spend ten thousand pounds in building a hospital for that city where the poor may be treated homœopathically, *and in accordance with the most advanced principles of medical science.* Mr. Tate thinks that, by means of this hospital, a fair comparison may be made between the treatment there and the treatment in hospitals where the allopathic system is *still* adopted. The hospital is not to be endowed, as its founder believes each generation should support its own charities.

THE FRENCH BIRTH-RATE.

The thrift and prudent habits of the middle class and of the skilled artizans in France are generally acknowledged, and the extreme sub-division of landed property brought about by a law which not only precludes entails, but necessitates the equal division of a man's estate, whether real or personal, among his children has constantly been held up by a certain class of political economists as an almost ideal state of society, contrasting favourably with ours where the land is in the hands of a few wealthy owners, let on annual tenure or on lease to tenant farmers, and cultivated by day labourers. It is not for us to discuss the relative productiveness of the land under the systems of large or small holdings, but in France, at any rate, the whole question of the sub-division of property is inseparably connected with doctrines and practices the moral and physiological effects of which neither statesman, economist, nor physician can ignore. Happily for us, Malthus was a prophet without honour in his own country; but his teachings have permeated every stratum of society in France, and the national birth-rate has steadily declined during the last 75 years from 31 to 25, and the average number of children in a family is three, or just sufficient to maintain a stationary population. The Malthusian doctrine is that the food-producing power of the soil being limited, unrestricted propagation tends, after a certain point has been reached, to the increase of poverty. It is generally admitted, however, that Mr. Henry George, whatever may be thought of his general conclusions, has effectually disposed of this doctrine. Theoretically, the doctrine would be true of a purely agricultural community; but the soil is not the only source of wealth, and in these days food may generally be obtained from abroad at less than the cost of its production at home. There is, practically, no limit to manufacturing industries so long as foreign markets can be found, except those created by fiscal imposi-

tions based on erroneous theories of economy. So long as the manufactures of one country can be freely exchanged for food products of another, the densest industrious populations may be mutually self-supporting; and the evils commonly attributed to over-population are in great part due to the fact that in every community there will be a number of the idle, ignorant, improvident, and vicious, whose progeny tend to sink lower and lower in the social scale.

In France, however, it is not so much the actual state of the law that is responsible for the low birth-rate, but rather the limitation of families, by means of what is euphemistically termed "moral constraint," though it would be more correctly described as "mechanical restraint," a practice which thirty years ago was tacitly admitted to exist there as elsewhere, but which is now unblushingly recognised among all classes. After the war between France and Germany, Dr. Decaisne raised his protest against a practice repugnant to the best instincts of human nature, urging the different periods within which each nation would make good its losses and their probable relative strengths in the future, but the question has recently been taken up in real earnest by statists and physicians alike. M. Cheyssus shows that the difference between the present birth-rate and that at the commencement of the century represents an annual deficit of 250,000 infants, and in 20 years of 80,000 or 90,000 men capable of bearing arms; while, if the fecundity of the French equalled that of the Germans, it would furnish annually 150,000 conscripts more than now answer to the call. Well may M. Rochard denounce it as "a ruinous and fatal economy that squanders future for present profit, prefers fixed to human capital, and sacrifices the harvest to spare the sowing." M. Cheyssus shows that the population of France, which in the year 1700 equalled four-fifths of that of the great Powers, is now only one-tenth, and that at the present rate of increase from all causes the foreign element would in 50 years amount to one-fifth of the whole. The extremes of the birth-rate are seen in Brittany and Normandy, viz., 18 to 29 per 1,000 inhabitants in the latter, and 31 to 34 in the former. Between the years 1856 and 1881 the population of the former province increased by 230,000, and that of the latter decreased by 157,000, yet it was chiefly from Normandy that the French population of Canada sprang, a vigorous race which, numbering only 60,000 in 1763, now amounts to a million and a half, besides half a million who have crossed over into the States. The social and moral condition of the capital he depicts in the darkest colours. Its population is like that of too many large cities—maintained by immigration. The statistics of births and deaths appear at first sight satisfactory, but they are illusive. For every 1,000 married women in Paris there are but 129 children against 181 in the provinces; the infant death-rate is falsified by the exportation of nurse children to die in the country, so that in reality the deaths exceed the births. Illegitimate births amount to 28 per cent. of the total against 7·8 in the country as a whole, and their higher mortality is answerable for 10,000 deaths of children every year.

The annual increase of the population of France at the beginning of this century was, according to M. Rochard, 6·02 per 1,000; it is now 2·42, while that of Germany is 10 and of England 13. It is not the death-rate that is to blame, for that has fallen from 27·82 to 22·34, nor the marriage-rate, which in spite of social and legal hindrances equals that of this country; but the smallness of families, the numbers of which are everywhere, not only in entire provinces, but in the different quarters of the large towns, inversely as the material prosperity of the people. The explanation is to be found, according to the authorities we have quoted, so far as regards the peasant-proprietors and tradesmen, in the laws governing the succession to property. The anxious father sees in the prospect of any addition to his family the cutting up of the little farm, or the collapse of the business which he has struggled to acquire, but which in freer countries he would leave intact to one or two of his sons, bringing up the others to make their way in the world. Among the higher and wealthier classes who could easily provide for a normal family of five or six, other and less excusable motives come into play: the fears of selfish mothers that the care of children will debar them from indulgence in the pleasures of fashionable society, and that their figures will be spoilt by successive pregnancies. But the number of cases of involuntary sterility among the higher classes is rapidly increasing, a consequence, according to M. Rochard, of the unhealthy and unnatural conditions under which girls are brought up, leading to general feebleness of constitution, exalted nervous irritability, disturbance of the menstrual function before marriage, and abortion, metritis, and confirmed sterility after. Not less detrimental to the manhood of the nation is the education of boys, who grow up into precocious libertines, incapable of begetting a progeny healthy in mind or body.

CANNED FOODS.

Cases of illness and of death stated to be due to the consumption of canned food find their way into the papers from time to time, and elicit the usual series of more or less contradictory comments. Sometimes it is the viand itself, at others the method of preserving it; now the solder, now the composition used in lining the tins, and now mere carelessness and neglect of the contents after the receptacle has been opened which is declared to be the real cause of the mischief. In this country it is difficult to find data of the needfully accurate and exclusive character on which to found a satisfactory opinion. Amongst the cheaper brands in the market there is, no doubt, a proportion of absolutely unsound—that is putrescent—food offered to purchasers. But the total amount thus consumed in the course of a year is probably less than that of a similar kind which is made to assume the form of the seductive sausage in a month. The class, too, by whom these cheaper canned meats are mostly purchased are fairly shrewd in the matter of selection. It may be that two solder holes do not indicate that the manufacturer, having allowed the gases to escape from "blown" tins through a puncture made for that purpose, has checked further putrefactive changes by a process of reheating, and has then soldered the second hole up again. But a tin holding actually unsound contents

is generally bulged, whereas, when properly prepared, the head and bottom should be distinctly concave as seen from without; moreover, when indented by the pressure of the thumb, the depression will remain—unless the covering is again forced outwards by the imprisoned gases of decomposition. The very fact that the purchaser is unable to judge beforehand by the test of sight or taste or smell puts him more keenly on the alert against deception, and once bitten he is twice shy of being taken in again in the same manner; and finally, if the contents of a tin when opened are found to be undoubtedly "bad," it is very rarely indeed that they are used for food. The better class of provision dealers have a fairly regular demand for the goods which they supply; they know that it is to their interest to sell only brands of recognised reputation, and to keep on hand a stock as fresh as possible. They will exchange a tin the contents of which, when opened, are clearly below the recognised standard of quality, and they readily open the tin in the presence of the purchaser, or before sending it home to him. Under such circumstances a case of complaint is rarely met with. The conditions are obviously less favourable when canned provisions are obtained from the small general dealer, who seldom buys direct from the best manufacturers or importers, but recruits his shelves from such cheaper sources as the bankrupt or surplus stock of other houses, and stores his already aged purchases for an indefinite period amongst an olla podrida of paint, oil, soap, colours, and patent medicines, to meet a somewhat precarious and haphazard demand. And yet instances of mischief directly traceable to the consumption of such preserved meats are relatively so few and far between, as almost to preclude the idea of their being dependent upon the canning of decayed food, imperfect removal of air, or chemical defects in the soldering or in the lining of the receptacles employed, since all these are causes which, if operative at all, would necessarily affect a very large proportion of the particular batch or brand of tins, and would consequently entail similar results upon a correspondingly large number of consumers. As has been already hinted, when canned provisions form, as in this country, but a small and varying proportion of the total amount of food eaten by the individual, it becomes extremely difficult to eliminate all sources of error and uncertainty from any case in which harm is alleged to have accrued, and it is almost impossible to be able to appeal to anything in the nature of a satisfactory and unimpeachable "control experiment." Peculiar interest therefore attaches to evidence on this head derived from observations on a large population entirely supported for long periods together upon canned provisions only. Such experience is occasionally supplied by ships' companies and expeditionary forces placed under special circumstances; but it is then so complicated with exceptional conditions of climate, exposure, fatigue and privation, as to make the results not fairly comparable with those obtaining in the course of ordinary civilised life. A report lately published by a general officer of the United States Army deals very conclusively with this subject. It is stated that the army posts throughout the United States have now for nearly twenty years been supplied with canned articles—fruits, meats, vegetables, and preserves—and that during this period not a single case of poisoning from this source has been known or heard of. In many instances these posts are located in situations where climatic conditions render the cultivation of even garden produce an impossibility, so that for very many officers and soldiers and their families, canned foods form the only means of subsistence. These foods are not of any special brand, nor supplied by any particular firm. "A good article is bought from any packer who will furnish a proper quality," and considerable competition is thus excited amongst the various manufacturers. Nor are they obtained from any particular section of the country, but the purchasing area extends from Maine to Texas, and from the Atlantic to the Gulf. Hence the army provisions are drawn from the same sources that supply the community at large, and "civilians and the army consume the same canned articles and under the same circumstances." It is pointed out that soldiers often report themselves as sick to the surgeon on account of very trifling ailments, and that, as a body, they are under more watchful medical scrutiny than any other class of people; so that, were a case of poisoning fairly attributable to tinned foods ever to occur amongst them, even though not fatal or serious, it would almost inevitably come to the knowledge of the surgeon in charge of the post. Further, if any medical officer entertained the suspicion that canned food of any sort was the cause of a case, or of an epidemic of a sickness, there is every probability of his making a formal report to that effect to his superior, and through him to the entire medical profession in the army. On these two heads the medical director speaks most positively. He says, in answer to a direct question on the subject, that he has never in the course of a long experience met with a case of poisoning referable to the eating of canned goods, nor has any such case ever been reported to him by or through his military subordinates.

The only conclusions deducible from this array of apparent trustworthy evidence are that canned foods such as those supplied to the United States Army, and eaten as they are eaten by it, are not only harmless but good food; and that complaints as to the unwholesomeness of canned provisions, in so far as they are true, depend upon some oversight on the part of the consumer—a carelessness either in the purchase or in the subsequent treatment of the article. Amongst the civil population of America, where the production is stated to average five hundred million tins a year, the occurrence of illness alleged to be dependent on this cause is at least as common as in this country; we may, therefore, regard the two nations as on all fours in respect of the real reason, whatever this may be. But in comparing the relative positions of the United States Army posts and the general body of civilians on this question, there are one or two important points to be noticed. In the first place, the soldiers and their families are direct buyers and experienced consumers, familiar with good articles of the kind, keen to detect and uncompromising in rejecting those of inferior or doubtful quality.

Secondly, the character of the market, the regularity and certainty of the demand, the sharp competition, and the ruinous results which must certainly attend the exposure of inferior goods, ensure a supply of good and even quality. On the other hand, amongst civilians there is some sort of market for second-rate, and consequently less expensive, articles. Probably but little food in an actually unwholesome state is canned; but of this the major portion is "preserved" by the aid of condiments, &c., which may serve to suspend putrefactive changes, and to disguise an otherwise nauseous flavour, but which do not obviate the disastrous effects of its ingestion. At all events, the highly spiced articles—*e.g.*, the various "pastes" and potted meats—more commonly produce derangements of digestion than do the simpler roast and boiled. Lastly, and probably this is the most important point of all, a population living exclusively on canned meats, or nearly so, will consume the contents of each individual tin quickly, often at a single meal; so that it will be quite exceptional for the contents of a tin to remain exposed to the air for more than a very short time before being eaten. Whereas, when preserved food is used only occasionally in addition perhaps to other dishes, and is partaken of by but a few of those present at the table, the contents of a tin are likely to appear again and again at successive meals; and when at length some suspicion of taint attaches to them, the remains will still be deemed a useful addition to the soup kettle. Under such circumstances it is not remarkable if unpleasant results now and then ensue. Possibly the greater amount of illness connected with potted meats and pastes, as noted above, may be partly due to the fact that, owing to their being used in smaller quantities at a time, they remain for a longer period exposed to the action of the atmosphere before being entirely consumed. Most of the meat preserved in tins is in the course of that process exposed to a higher temperature, or is so exposed for a longer period than is usual with fresh meat cooked in the ordinary way. The result is an "over-cooked" condition of the viand shown by the peculiar disintegrated and sodden state of its tissue—points which are practically realised, by the way, in the preparation of animal infusions intended for the artificial cultivation of micro-organisms in the laboratory; and when exposed to the air it thus presents a soil specially favourable for the implantation of putrefactive germs, and for their rapid extension throughout its mass. In common parlance it "goes bad" more readily and more quickly than is the case with ordinary cooked butcher's meat subjected to similar exposure; and a slight degree of taint apparent in such canned food is a more serious matter than the same thing occurring in a recently cooked joint. This is a distinction probably not always insisted on by those members of the poorer classes of the community who are accustomed to eating scraps of meat bought cheaply late on Saturday night in the state described as being a little "off." Nor can it be imagined that prolonged storage is entirely without its effect. Although perfectly sound when canned, and hermetically sealed, the lapse of time is almost certainly attended with gradual molecular changes; and though, under the conditions supposed, these cannot be of a putrefactive nature, they are of a kind which favour the rapid onset and extension of decomposition when once the necessary exposure to the air has taken place.

If we may draw a lesson from these considerations, it would be one of mingled warning and congratulation. Even in those cases in which deleterious compounds, traceable to the solder or the lining of the tins, have been discovered on analysis, their quantity has been so minute as to acquit them of producing anything like a really serious effect. The evidence derived from communities almost or entirely dependent upon tinned foods is overwhelming in favour of their wholesomeness. And, putting the fashionable ptomaine aside for the present as at least unproven in this connection, we may conclude that when mischief does occur, it is the fault rather of the eater than of his meat. We believe that the public is itself mainly responsible for its scare, if scare there be, in this matter of tinned foods; and that, so far as is possible in human affairs, the evil results we hear of every now and again may always be avoided by exercising in the case of tinned articles of diet just so much care as should always be bestowed upon the purchase and the after treatment of ordinary butcher's meat.

REVIEWS AND NOTICES OF BOOKS.

ZIEGLER'S PATHOLOGICAL ANATOMY.[1]

Two volumes have been lying on our table for some time past which deserve to be spoken of in the highest terms. We refer to Dr. Donald Macalister's translation of Professor Ziegler's "Text-Book of Pathological Anatomy and Pathogenesis." Part I., dealing with general pathology, was published in 1883, and the volume containing Sections I. to VIII. of the second part appeared during the present year. The remaining sections of the work, dealing with the kidney, the lungs, and the nervous system, are already in hand, and will be issued as a third volume. In reality, however, the first part constitutes a complete work in itself, as it more or less completely covers the whole range of pathology. Malformations are dealt with in the first three chapters, and in these the student will find a more satisfactory account of them, short as it is, than is to be found in any work on pathology with which we are acquainted. It is mentioned that a malformation may originate in one of two ways: either the owner may have inherited a tendency to abnormal growth, or the normal embryo may in the course of development be affected by external disturbing influences; and, as regards the latter, it is said that "the earlier the injury the greater is usually its effect. The loss of a few cells in the earlier stages of growth may involve the absence of an entire organ or limb, while later on, after the general form is nearly complete, the same loss may not be noticeable at all."

Anomalies in the distribution of the blood and lymph are then dealt with—hyperæmia, œdema, dropsy, and hæmorrhage—these phenomena being, for the most part, explained in accordance with Cohnheim's classical

[1] "A Text-Book of Pathological Anatomy and Pathogenesis," by Ernest Ziegler, Professor of Pathological Anatomy in the University of Tübingen. Translated and Edited by Donald Macalister, M.A., M.B. London: Macmillan & Co.

researches. In the chapters on (*a*) the retrogressive and (*b*) progressive (or formative) disturbances of nutrition the reader is introduced to necrosis and degenerations of various kinds under the former heading, and to hypertrophy, hyperplasia and regeneration under the latter. The account given of amyloid degeneration is a particularly valuable one, though as the view adopted as to the kind of tissue primarily affected differs from that, perhaps, most generally maintained, it may be more open to criticism than other parts of the work. Ziegler holds that it is in the connective tissue of glandular organs that the disease at first appears, whereas other writers maintain that it is in the glandular cells themselves. Rindfleisch, for example, even in his lately published new work, "Die Elemente der Pathologie," which is now before us, speaks of such an infiltration of the cells; and, while Ziegler points to the fibrous textures of the blood vessels as being the first affected, Cornil and Ranvier state that it is the muscular element of their walls which undergoes the change. As regards the most suitable chemical test for the amyloid (or albuminoid, as some prefer) substance, we should have liked greater prominence given to the value of methylviolet (or some other of the aniline dyes), as in our hands it has proved to be far superior to iodine when the tissues are examined under the microscope. We should be inclined to say that a solution of iodine was the best for macroscopic and methylviolet for microscopic examination.

The description given of cell growth and cell multiplication is very clear, and the summary furnished of recent views as to the changes undergone by the nucleus is particularly deserving of commendation. The formation of giant cells is, in this connection, incidentally referred to as being the result of subdivision of the nucleus without a corresponding subdivision of the cell. We do not, however, see any reference to the possibility of giant cells being also produced by the amalgamation of two or more amæboid corpuscles; nor, by the way, is the caution thrown out that it occasionally happens that transverse sections of the altered walls of blood vessels are mistaken for giant cells.

The very difficult task of giving an intelligent account of the inflammatory process in a concise form is achieved with considerable success in this volume, and the view adopted, as regards its salient features, may be summed up in the author's own words as follows:—"The slowing of the blood current, the dilatation of the vessels, the peripheral disposition of white cells, the migration of these from capillaries and veins, and the migration of the red cells from the capillaries, are all of them referable to a molecular alteration in the vessel walls;" and that the causes of the alteration in the vessels—thermal and, especially, chemical—are the causes of inflammation. The discussion of inflammatory growths naturally follows, and these are described as "infective granulomata"—a definition which appears to us to be more open to objection than the term "specific inflammations" applied to them by Rindfleisch. These growths are tubercle, syphilis, leprosy, lupus, glanders, and actinomycosis. "All these affections," it is stated, "are due to the invasion of the body by a virus or poison derived from the outer world, or from the body of another individual." The space at our disposal does not admit of our closely examining the data on which this classification is based, nor to refer to the excellent description given of the microscopical characters of the several lesions, but we cannot turn over the pages without drawing attention to the excellence of the woodcuts illustrative of these granulomata. Indeed, the engravings, of which there are nearly two hundred in the portion of the work already published, are throughout unusually well executed, and add very materially to the value of the text.

Section VI. of the first volume is devoted to the elucidation of tumours, which are treated under two principal headings, tumours of connective tissue origin and tumours which are characterised also by increase of epithelial elements. A particularly lucid description is given of cutaneous cancer, or epithelioma. This is referred to as consisting essentially of cellular prolongations of the inter-papillary promontories of the Malpighian layer, penetrating and ramifying in the fibrous tissue of the corium. On the other hand, it is very properly pointed out that mere thickening of the subepidermic epithelial layer, or mere increase of the epithelial elements of glandular tissue, is not to be looked upon as a carcinoma; in the latter the new epithelial formation is not limited to the surfaces where its constituent elements are normally found, but actively invades the contiguous connective tissues.

A very carefully prepared summary of what is known of the animal and vegetable parasites which affect man brings the first volume to a close, and the chapters devoted to this subject will probably be very generally looked upon as forming one of the chief attractions of the entire work. The pages devoted to the schizomycetes present a very complete, and at the same time a condensed, account of all the organisms of this group of fungi which can be said to have even a remote claim to be considered as disease-causes. The rapid strides which have recently been made in this direction, and the publication of Zopf's excellent little work on cleft-fungi ("Die Spaltpilze") will, however, doubtless suggest some additions, omissions, and modifications, even though references to mycological literature are given in the text which were published as late as 1882. Still, taken altogether, the summary given in this volume of the parasites of man is, if not unequalled, certainly not surpassed in any text-book which we have seen, English or foreign. Indeed, the whole volume is remarkably free from any drawbacks due to carelessness of expression or of compilation, and we only note one trifling error which is not pointed out in the corrigenda prefaced to the second volume, viz., that the *Filaria sanguinis hominis* is called *F. Sanguinolenta* in its mature form, whereas, in reality, Lewis applied to the parental form also the designation which he had applied to the embryos. The *F. Sanguinolenta* is another parasite whose anatomy he investigated, and which he found was developed in the arterial walls of dogs.

We have devoted so much space to the first volume that we can barely do more than call attention in a general way to the contents of the second. It opens with an account of the pathological changes which the heart, the blood, and its vessels may undergo, the paragraphs devoted to endocarditis and arteritis being particularly worthy of careful study. This is followed by a description of the morbid changes in the lymphatics, the spleen, and the lymphatic glands which, however, do not call for special remark here, nor do the succeeding chapters dealing with the serous membranes except to say that, like the rest of the work, they are well written. Those of our readers who are specially interested in the study of skin diseases will find an exceptionally valuable account given in this book of the minute changes which disease gives rise to in the epidermis, the corium, and the subcutaneous tissue, the researches of Kaposi in particular being largely drawn upon. The remainder of the volume is devoted to the pathology of mucous membranes, the liver, and the pancreas, and it is with much regret that we are compelled by want of space not to be able to give an analysis of the contents of these chapters. Enough, however, has been said to show how highly we appreciate the author's labours. The work not only testifies to his ability as a teacher, but also gives evidence that he is an accomplished practical patholo-

gist. Dr. Ziegler is, moreover, particularly fortunate in having had his work brought out in its English dress by one so well qualified for the duty as Dr. Macalister, and the remark which the latter makes in his preface as translator and editor that the portions of the text in small print had had his special care is but a very modest claim on our recognition for what must have been a very onerous portion of his labours, as it is very evident that the English edition bristles with information from beginning to end which is not to be found in the original.

Lectures on Mental Disease; by W. H. O. SANKEY, M.D., F.R.C.P., &c. Second edition, pp. 454. London: H. K. Lewis, 1884.—Nothing is more characteristic of the prevailing tenour of thought in modern medicine, and especially in English medicine, than fear and dislike of hypothesis. We must have facts, and we must not go beyond facts. It is a little strange that the nation to which the world owes its greatest, its most comprehensive, its most daring theories should be the one which, in medicine at least, is most timorous of leaving the firm shore of fact and embarking on even the smallest stretch of hypothesis. When we do find an author who dares to promulgate opinions not only opposed to prevailing opinions but of a somewhat comprehensive nature and of a character not admitting of direct support from fact, they come upon us like a fresh sea breeze to a dweller in a town, and such is the impression derived from Dr. Sankey's book. It is a departure from the recognised and received modes of treating the subject, it is conducted on different lines, and leads to different conclusions, and the several positions are sustained, with no great dialectical skill it is true, but with a directness and an ability which should induce every alienist who looks beyond the barren routine of his daily duty to study them with care, and which will compel future writers on the subject to give them serious attention. The book must arouse opposition, it ought to provoke controversy, and to say this is to say much in its favour. Dr. Sankey devotes the first part of his book to an exposition of mental science—of the science of the normal mind, a topic strangely disregarded in most treatises on insanity. It is in this department of medicine only that it is commonly considered proper to study the morbid, without a preliminary study of the normal, and the result has hitherto not been particularly successful. Dr. Sankey not only recognises the necessity of giving some account of the normal mind before entering on the consideration of insanity, which, as times go, is an unusually enlightened view, but he makes a singularly happy division of the former subject into mental products and mental processes. The principle of evolution is accepted as the basis of the doctrines taught, and Herbert Spencer and even Hughlings-Jackson are quoted in support, but we cannot say that Dr. Sankey always correctly apprehends these authors, or that he is very successful in avoiding the obscurity with which the subject is so much beset. The framework of the book—the main principles upon which its design is laid down—appear to us excellent, but the working out of the design in detail is often faulty and inefficient. Although Dr. Sankey quotes verbatim the explicit terms in which the current doctrine of the absolute diversity of mental states and nervous processes is laid down by Dr. Hughlings-Jackson, yet he falls repeatedly into the common error of confounding the two, and speaks of sensation producing motion. Explaining, as he apprehends it, Herbert Spencer's doctrine of the nature of the nerve current, Dr. Sankey states that "the main objection to Mr. Spencer's theory is, that it is a simple chemical change, *and chemical changes are electrical*, and the phenomena of the neural current do not accord with the electrical theory according to general consent of authorities." It is rather hard on Mr. Spencer to father on him, through the remarkable assumption contained in the passage that we have italicised, a doctrine which he not only does not hold, which he not only disowns and repudiates, but against which he brings forward a whole battery of arguments. We shall expect to hear next, that Mr. Spencer is the chief opponent of the doctrine of evolution. Other doctrines of Mr. Spencer's which have for years become commonplaces of neurology are attributed to Dr. Wiglesworth, who argued ably from them in a paper read last year. Nowhere does Dr. Sankey more thoroughly and on the whole more justifiably and successfully break away from the traditions of his subject than in his classification of insanity. The classification of mental disorders has been a quagmire into which nearly every writer on the subject has sunk and struggled and struggled and sunk. Dr. Sankey leaps over it with one bound. His system, if not quite perfect, is at least simple, intelligible and fairly consistent, which is more than can be said of any other as yet proposed, and his advocacy of it is vigorous, and against all previous classifications convincing. The division of all cases of idiopathic insanity into the two species of ordinary insanity and general paralysis is at first sight, it is true, somewhat like that of the amateur of music, who divided all music into two tunes, one of which was "God save the Queen" and the other was not; but upon consideration it becomes manifest that there is no logical halting place between the collection of all cases of idiopathic insanity, minus general paralysis, into one group, and a division which makes of every individual case a separate species. Dr. Sankey is logical; he rejects the latter alternative. Compromise he regards as impracticable, and thus his own division is the only one which is to him possible. Throughout the work, we find that so long as the author is arguing a question of principle he always compels attention and often carries conviction, but on points of detail his remarks appear hurried, and sometimes erroneous, and the literary style is slovenly and often obscure. Thus, his discussions of the pathology of "ordinary insanity" and general paresis, are bold, well argued and able. His remarks on masturbation are excellent. The subject of periodicity and the similarity existing between drunkenness and general paralysis are very well treated, but the remarks on prognosis are not in our opinion trustworthy. The subject of moral insanity merits a more detailed discussion. To say, as on p. 138, that the urine is abnormal, does not convey much information; and the following extract appears to contain a vicious circle—*a circulus in probando*:—"A thing is remembered only when a previous impression is resuscitated by a new or present impression. The tendency of a present impression to recall an old impression depends upon what is called the *association of ideas*. . . . The *association of ideas* depends of course on the faculty of memory." (p. 14). A similar passage occurs on p. 139, where we are told that patients "have the propensity, which is the symptom, and the bodily symptoms may perhaps be greatly accounted for by the propensity." The remarks as to treatment present nothing novel, but they are sound and sensible. It is interesting to note that Dr. Sankey is among the increasing number of those who regard opium and morphia as useless in melancholia. Upon the whole, the book is an honest and useful one. It is not the book that would be recommended to one entering on the study of the subject, but to those who are well grounded in current notions on insanity it should be invaluable; for it should compel them to take up their old beliefs one by one and examine thoroughly the grounds upon which they rest, and few will emerge from the process in quite the same condition as that in which they entered on it.

ABSTRACTS AND EXTRACTS.

OBSTETRICS.

THE INFLUENCE OF AGE UPON CHILDBEARING.—A recent number (Band x. Heft 1) of the *Zeitschrift für Geburtshülfe und Gynäkologie* contains an interesting article on the above subject by Dr. Ludwig Kleinwächter. The author's immediate object in undertaking the investigation of which he here gives the results, was to ascertain whether the common belief, that first labours occurring late in life are attended with special danger, is well founded. This belief, although general, is not universal; it has been

by some maintained that labour is easier in primiparæ who are elderly than in those who are young. Hence, the greater necessity for thorough investigation of the point. There is one general reason why a slightly greater proportion of difficult cases should occur in those who have their first children late, viz., that women who are dwarfed, deformed, weakly, or suffering from chronic disease, may be expected to be less attractive to the opposite sex, therefore to marry later and bear children later, than their better-shaped and healthier sisters. But the assertion of even such greater mortality as can be thus accounted for has to be proved. Dr. Kleinwächter has set himself to fill this hiatus in our knowledge, and his researches have brought out some facts of much interest. They are based upon 920 women pregnant for the first time, 878 of whom were also observed during labour. The ages of these patients ranged from 16 to 41. Arranging them for the purpose of his enquiry, our author divides them into three groups, viz.: (1) those aged from 16 to 19, of whom he has details of 111 with 108 labours; (2) those from 20 to 29, comprising 694 patients with 662 labours; and lastly (3) those from 30 to 41, numbering 115 with 108 labours. Dr. Kleinwächter compares the different sets of facts relating to each of these groups. He gives the particulars relating to each different year of age, but for the sake of brevity we shall only here quote the generalizations referring to the larger groups. The first point on which information is given is the age of first menstruation. These facts appear. In those pregnant first between 16 to 19, the average age of first menstruation was 13·73 years; in those commencing fertility between 20 and 19, it was 15·41 years; and in those in whom pregnancy did not occur till between 30 and 41, it was 15·81 years. The conclusion follows that the slowness of development which causes menstruation to be late in its appearance causes also delay in the more important function of pregnancy. That lateness of childbearing is often dependent upon imperfect development, preventing the due performance of the menstrual function, is supported by another set of figures, viz., those showing the frequency of menstrual irregularities in the different groups. Of those pregnant first at from 16 to 19 years of age, in 22·36 menstruation was irregular; this irregularity was present in 24·56 of those beginning to bear children at from 20 to 29; and in 30·76 per cent. of those in whom parity did not occur till the age of 30 to 41. Dr. Kleinwächter brings more facts pointing in the same direction. Of those bearing children before 20, only 1 per cent., but of those in whom pregnancy did not occur till after 29, 5·20 per cent., had suffered from diseases which commonly delay the establishment of menstruation, viz., epilepsy, imbecility, infantile paralysis, cardiac disease, uterus bicornis, deaf muteness, "psychosis" and "psychopathy," uterine fibroids. Beside these disorders, there are others which, although not specially affecting the genital functions in the female, yet may do so indirectly, by rendering proper coition less likely. Among these, our author mentions dislocation of the thigh, tumour of labium, sarcoma of tibia, tumour of upper part of thigh, chronic eczema of leg, and ulcer of foot, anchylosis of knee, prolapsus of vagina, ascites. These occurred with a frequency of ·90 per cent. in those of 16 to 19, 1·00 per cent. in those of 20 to 29, and 2·60 per cent. in those aged 39 to 41. Putting both classes of ailments together, we have ·92 per cent. in the young (16 to 19), 2·01 in the intermediate ages (20 to 29), and 7·82 in the old (30 to 41). The conclusion follows that lateness of conception is sometimes the result of congenital or acquired disease. Figures which support this conclusion have also been published by Schwing and by Cohnstein. Turning now from the causes of late primiparity, Dr. Kleinwächter considers the influence of age upon the course of pregnancy. First, taking disease broadly. In those under 20, pregnancy was complicated by morbid conditions in 13·81 per cent., in those of intermediate age in 18·15 per cent., and in those over 29 in 39·13 per cent. Late pregnancy is therefore attended with especial risk; next in point of danger is too early pregnancy; while the safest age is the middle period. The figures do not hold good equally when we consider diseases specially dependent upon pregnancy, and when we look at those accidentally coincident with it. The liability to the latter steadily increases with age, as shown in the following figures: 4·50 per cent. in the young, 5·61 per cent. in the middle period, 13·91 per cent. in the older. Taking the maladies special to pregnancy, we find the law mentioned above more clearly illustrated. In the young primiparæ we have 15·31 per cent. of such diseases; in those of intermediate age only 12·53 per cent.; in the elderly 26·95 per cent. Our author gives figures showing the frequency of ante-partum hœmorrhage, and of excess of liquor amnii; but with regard to both these conditions, the numbers seem to us too small to warrant any confident deduction from them. We now come to the course of labour. The duration of labour is greatest in the elderly primipara; next in length comes that of the young; and the shortest is that of those aged from 20 to 29. Dr. Kleinwächter takes 18¼ hours as the average duration of normal labour. This was exceeded among those under 20 in 41·5 per cent.; among those aged 20 to 29 in 15·38 per cent; and among those over 29 in 50 per cent. Weak labour is least often met with in those aged 20 to 29, most often in the elderly. It occurred in 6·03 per cent. of those under 20, in 4·80 per cent. of those from 20 to 29, in 8·92 per cent. of those over 29. As might be expected from the foregoing, the forceps was found least often required in those bearing their first child at the most favourable age, viz., 20 to 29 (these operations among them numbering 3·66 per cent.), more often in those under 20 (4·76 per cent.), and most often in those over the age of 29 (5·36 per cent.). The foregoing figures indicate the frequency with which anomalies in the parturient process were met with. Taking all labours together, it appears that the duration of labour increases with age. In those under 20 it averaged 16 hours 35 minutes; between 20 and 29, 17 hours 4 minutes; over 29, 20 hours 26 minutes. This increase with age in the duration of labour seems due to prolongation of the first stage of labour in the elderly. The second stage shows scarcely any difference at different ages, and the third stage none at all. The figures supporting this proposition are too lengthy for us to quote. Dr. Kleinwächter thinks that the greater length of the first stage of labour in the elderly depends upon the soft parts of such patients yielding and dilating less readily. The mortality after forceps delivery, according to our author, steadily rises with age. The figures upon this point are based only on 36 cases, a rather narrow foundation for so broad a generalisation. The older the primipara, the more likely is rupture of the perinæum to occur. Dr. Kleinwächter in this statement is able to adduce figures given by Liebmann, Fasbender, and Steinmann, which all confirm this conclusion. The older the patient, the greater the liability of post partum hœmorrhage. With increase of age, increases also the number of cases of renal disease, and of œdema without evidence of renal disease. This is very marked. Under 20, our author found 1·85 per cent. of œdema with renal disease, 6·30 per cent. of œdema without. Between 20 and 29, 2·26 per cent. of œdema with renal disease, 7·06 per cent. without; over 29, 10·18 per cent. with, and 10·43 per cent. without. Inflammation of the mamma, on the contrary, is more apt to occur in the young. Of those under 20, 2·77 per cent, were thus affected, of those aged from 20 to 23, 1·81 per cent.; and of those over 29, ·92 per cent. Deficiency in the supply of milk, preventing suckling, was observed in an inverse ratio of frequency; in 5·55 of those under 20, 11·47 per cent. of those between 19 and 31, and in 25 per cent. of those over 30. The law with regard to age which applied to puerperal fever holds good also of puerperal mania, of the percentage of puerperal deaths and diseases taken together, and of premature labour. We group the figures together so that they can be seen at a glance:—

Age.	Puerperal Fever.	Puerperal Mania.	Puerperal Mortality.*	Puerperal Morbidity.	Premature Delivery.
16—19	13·88	·92	3·70	20·37	28·71
20—29	10·87	·48	3·60	17·97	27·50
30—41	16·66	1·85	6·48	23·14	34·26

* The high mortality will strike our readers; but to comment on this would be foreign to the present subject.

It will be seen that in all these different ways the risk of the elderly primipara is greater than that of the young, and that of the very young primipara greater than that of the woman who begins to bear children at the most suitable age, viz., the third decade of life. Abnormal presentations in the cases used by Dr. Kleinwächter increased in frequency with age. Here, however, the figures are too small to be in our judgment conclusive. He found no connection between age and pelvic contraction. He gives the singular generalisation as to the sex of the child: that in those of mothers between 20 and 21 females are in excess, males at other ages. This does not seem to us supported by enough evidence. He gives also the curious fact, that the umbilical cord falls off sooner in the children of the older mothers than in those of the younger. In some other points the author has been anticipated by Heeker and by Matthews Duncan. He finds that the production of twins and of monsters, and the mortality among the infants, rises with the advancing age of primiparity.

Rapid Dilatation of the Uterine Canal.—In a paper read at the Obstetrical Society of Philadelphia (*Philadelphia Medical News*, October 18), Dr. Goodell observed that for many years he had been in the habit of enlarging or straightening the uterine canal, according to the requirements of the case, either by tents or by Sims's operation. "Having had several serious warnings in the shape of inflammations following these operations, I began to perform them with fear and trembling. Yet nothing very untoward happened until 1878, when two grievous mishaps befel me." These arose in the cases of two young ladies. One of these suffered from bad dysmenorrhœa with such marked stenosis and angularity of the canal, that Sims's operation was performed without hesitation, but with the effect of killing the patient through septicæmia. In the other case, the canal was dilated by means of tents for exhaustive menorrhagia, many vegetations also being removed from the endometrium by means of the curette. Violent peritonitis followed which proved fatal. Alarmed at these results, Dr. Goodell substituted rapid dilatation, which Ellinger and others had proposed, and so gratified has he been with his success that he has abandoned Sims's operation, and has employed tents very seldom. Referring to the article itself for a minute description of the dilators employed and the mode of using them, we may observe that the utility of the procedure is not confined to dysmenorrhœa, as it may also be resorted to for the safe performance of irrigation of the uterus or making applications within its cavity, as also in exploration of the womb with the finger, when polypus or other growth may be suspected as the cause of the menorrhagia. Not counting cases in which dilatation was practised without ether, or for mere digital examination or the removal of growths, Dr. Goodell believes that of cases of dilatation under ether he must have had over 300, the employment of an anæsthetic implying full dilatation—cases in which serious injury, if ever, would be most likely to be sustained. Yet not a death, nor a case of severe inflammation has occurred, while the results have been far more satisfactory than from the cutting operation. Of 168 cases of dysmenorrhœa, 80 occurred in unmarried, and 88 (almost always accompanied by sterility) in the married. Of the 80 unmarried, 18 were unheard of after the operation, leaving 62 from which any data could be obtained. Of these 38 were cured, 17 more or less improved (most of these greatly so), and 7 were not improved at all, the ovaries being so diseased as to render the dysmenorrhœa incurable except by their removal. Of the 88 married women, 53 were heard from, 39 having been cured, 10 improved and 4 unimproved. "When compared with the cutting operation this one looks like rough usage, yet the woman rarely needs more than two or three suppositories, and complains merely of soreness for one or two days. To forestall any tendency to metritis, she is kept in bed until all tenderness has disappeared. Pain is met by rectal suppositories of opium, and by large poultices laid over the abdomen; but it has always been readily controlled, and has not given any alarm."

Spondylolisthesis.—In the *Archiv für Gynäkologie* (Band xxii., Heft 3), Dr. Franz Ludwig Neugebauer, of Warsaw, brings forward additional evidence in favour of his views on the subject of spondylolisthesis, in the shape of three cases observed at Freiburg, two at Strasburg, and two at Berlin. He examines also a case diagnosed by the late Professor Depaul as one of deformity due to congenital dislocation of both hips; and gives reasons for regarding it as a case of spondylolisthesis. He gives some very clear and instructive diagrams of the contour of the body in spondylolisthesis, and in congenital dislocation of the hips, as compared with that of health. He formulates his views on the origin of spondylolisthesis as follows. It may result (1) from a congenital, unilateral or bilateral, defect of ossification in the fifth lumbar vertebra, especially in its inter-articular portion; (2) primarily from a fracture (*a*) of the sacral articular processes, when the posterior arch of the fifth lumbar vertebra is displaced forwards, and its inferior articulations shew a corresponding degree of elongation by traction in the sagittal direction; (*b*) of the arch of the fifth lumbar vertebra in its inter-articular portion, when the posterior part of the arch of that vertebra is not displaced forwards, but remains in its normal position, whether synostosis of the lumbo-sacral articulations has taken place or not.

Uncontrollable Vomiting of Pregnancy.—Dr. Fifield related a case which he had met with to the Obstetrical Society of Boston (*Boston Medical Journal*, October 23). The patient was about three months pregnant, and for two weeks her attendants had tried in vain to relieve an obstinate vomiting, which was rapidly reducing her strength. As all the usual remedies had been tried in vain, and rectal enemata were not well borne, and the patient was rapidly sinking, it was determined to induce labour. Dr. Fifield therefore introduced a bougie within the uterus and waited twenty-four hours, but neither this nor another, passed in to the depth of several inches, produced any effect. A sound was now passed in, and moved freely about, no pain being caused by it, nor any blood following its removal. Next day, however, the fœtus with unbroken membranes was discharged. The change induced in the patient was immediate and marvellous, and by the end of the week she was up and dressed. In passing the sound, Dr. Fifield observed that the uterus was much anteverted, and he alluded to the fact that in fœtuses and young infants the uterus is anteflexed, and bent to the left. Dr. Blake regretted that there ever should be need to resort to the premature induction of labour for the relief of vomiting, and he had always found some other treatment suffice. He thought that counter-irritation was often efficient, with regulation of diet or rectal alimentation. If patients with gastric ulcer or intestinal obstruction can be tided over with rectal alimentation, why not pregnant women?

Pain as a Symptom of Salpyngitis.—In the *New York Medical Journal* for July 12th, a case of ovarian disease is described, in which the patient gave a history of pelvic discomfort, with pain constantly referred to the left ovarian region. On examination a tumour as large as an orange was found in the region of the right broad ligament, and displacing the uterus, while nothing abnormal was detected on the left, or painful, side. Laparotomy was performed, mainly on account of the excessive and constant pain, when the tumour was found to be a dermoid cyst, free, and consequently easily removable; the Fallopian tube on that side was entirely free from disease, and its fimbriæ were normally distended. The left Fallopian tube, however, was found to be dilated; its fimbriated extremity was firmly adherent to the posterior surface of the ovary, which was in a condition of cirrhosis. Both ovaries and both tubes were therefore removed, although the pain which had been suffered was doubtless due to the (unsuspected) diseased condition of the left tube only.

Suicide of a Liverpool Surgeon.—Dr. Graham, a well-known Liverpool medical man, and one of the most successful surgical operators in the North of England, committed suicide on Saturday morning at his residence by cutting his throat in a terrible manner. Some time ago he had to give up practice for a time in consequence of his mind becoming affected, but he had apparently quite recovered, and had resumed practice.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, DECEMBER 3RD, 1884.

H. GERVIS, M.D., F.R.C.P., President, in the Chair.

The following specimens were shown:—

1. Fibrous tumour of uterus removed by operation—Dr. WALTER, Manchester.
2. Two-headed fœtus—Dr. HORROCKS.
3. Fibrous polypus—Dr. GODSON.
4. Ruptured uterus—Dr. CHAMPNEYS.

Uncontrollable Vomiting in Pregnancy.

The DISCUSSION on Dr. Graily Hewitt's paper on Uncontrollable Vomiting in Pregnancy, adjourned from the November meeting, was resumed. Drs. Champneys and Galabin spoke at the November meeting, but the whole discussion is given below.

Dr. CHAMPNEYS observed that many of Dr. Hewitt's anticipations of probable objections amounted to a declaration that in spite of them all he believed his own theory. Anteflexion or anteversion is found in 80 per cent. of all cases of early pregnancy. No attempt has been made to show the difference as regards vomiting between those whose uteri are "displaced," and the small minority in which they are not displaced. In the puerperal state anteversion and anteflexion are at least as common. Here is a large uterus full of blood, anteflexed. But where is the vomiting? Again, it has been assumed that anteflexion is a position of constraint. Here are these women lying on their backs and yet the uterus persistently anteflexed. It has never been proved that flexion as flexion ever disturbs the circulation in the uterus. If, however, we look for a typical condition of flexion with pressure, we find it in the case of the retroverted gravid uterus. Here we have acute flexion with incarceration, either of which on Dr. Hewitt's theory is sufficient to cause vomiting. But where is the vomiting? Flexions have been proved to be very common in women whether well or ill, and association without severe sifting proves nothing. The sudden cessation of vomiting recorded in some of the cases is a well-known character of this vomiting, and is a precarious foundation for theories. The cases themselves require more details as to other possible causes of vomiting, such as albuminuria, jaundice, constipation, &c.

Dr. GALABIN said that anteflexion was so common in early pregnancy that it was one of its best diagnostic signs. If it were the cause of vomiting, a pessary should cure the vomiting; not one of the cases related was cured by this means. In backward displacement relief followed reposition oftener in Dr. Hewitt's cases. Excessive vomiting was plainly only an extreme degree of the common vomiting of pregnancy. Tension must be an important element, witness the cessation of vomiting if the ovum dies, and the excessive vomiting associated with hydatid mole. When the nervous system is hyperæsthetic, some morbid condition of the uterus, such as inflammation, induration, and grave displacement such as retroversion, especially with incarceration, might produce excessive vomiting. Dr. Hewitt's theory did not explain the relief which he had several times seen follow dilatation of the cervix. The *modus operandi* of this procedure was hard to explain, but it might be connected with overstretching the nerves or rupturing some of the fibres about the os interum, which is a special seat of reflex action in labour. Incarceration of an anteverted or anteflexed uterus in early pregnancy was to him inconceivable apart from adhesions.

Dr. BARNES said that excessive vomiting in pregnancy was an instance of a physiological process passing the healthy boundary. The physiological basis is vascular and nervous tension peculiar to pregnancy. Vomiting is a safety valve for nervous energy, and a safeguard against nervous seizures such as eclampsia. Vomiting is a sort of physiological convulsion, and so is labour itself. After delivery the tension ceases and the liability to vomiting also. The exciting cause of the vomiting of pregnancy is usually in the uterus itself. The fact of the vomiting occurring as soon as the patient gets up, may be partly explained by increased flexion, partly also by Bretonneau's theory of rapid distension of the uterine fibres under increased hydraulic pressure of the blood from the erect position, when the nervous centres are most excitable after rest, and the inhibitory force weakest from fasting. Since flexion remains for the rest of the day, however, flexion is not sufficient. Vomiting later in pregnancy, which is the severer from, is kept up by starvation when once started, degraded blood increases the nervous irritability, and a vicious circle is formed. Albuminuria is a further evidence of toxæmia, and hiccough is a form of convulsion. The vomiting seen in obstructive dysmenorrhœa is analogous. The solution is not to be sought in any one factor, but nervous and vascular tension underlies the whole question.

Dr. BRAXTON HICKS said the term "severe" was too vague, and he had never seen uncontrollable vomiting. The vomiting of pregnancy was so variable that severe vomiting could not be considered apart from the vomiting which might be called natural. When the pulse rose, emaciation commenced, and the tongue became red and the epigastrium tender, the case became urgent. He had never seen a case which had not yielded to remedies. With regard to the cause of vomiting he agreed in many points with the previous speaker. Since Dr. Graily Hewitt's first paper he had examined all cases carefully, and he had never found any displacement or other local disturbance requiring mechanical treatment, nor had he ever failed to carry his patient safely to full time by the persistent use of remedies, especially opiates, given perseveringly until some portion was retained by the stomach, and the system was calmed. The nerves of the mucous membrane of the stomach became irritated, and after a time formed a centre of disturbance, after the manner seen in other parts. By the administration of opiates by the mouth, these nerve ends were soothed and consequent benefit ensued.

Dr. MATTHEWS DUNCAN knew no controllable vomiting of pregnancy. Medicines might do some good, and perhaps in some cases stop it. This he did not deny; but every one in practice knew that the vomiting was practically uncontrollable. He placed most reliance on atropia in the common variety of vomiting when excessive. The vomiting of pregnancy was of course stopped by emptying the uterus —that was not to control it, nor really to stop it: that was to stop the pregnancy. He recognised, meantime, only two kinds of vomiting of pregnancy—the ordinary, natural, physiological; and the pernicious uncontrollable, very dangerous. The former generally ceased about mid-pregnancy, but it might go on longer, be excessive, and induce emaciation. He was not quite certain that it ever ended fatally. The pernicious kind had been the subject of several recent memoirs, and was often fatal, rapidly fatal; it might begin at any period of pregnancy, and run its course slowly or more quickly; and till our new knowledge of this kind was used in the investigation of all cases, he would not admit that a fatal result came from the ordinary or physiological kind, even though very severe. The pernicious kind was no doubt induced by pregnancy, and in it we had degeneration of organs, granular, fatty, or inflammatory. Cases often presented all the characters of icterus gravis, but they varied much from the apparently simple cases of fatty degeneration of Heeker, Grainger Stewart and others, to cases with symptoms more or less like those of Bright's disease or of yellow atrophy of the liver. They presented great prostration, often bleedings, often albuminuria more or less considerable, also often bile in the urine; sugar even had been observed. Such cases were not always fatal. He was disposed to regard this pernicious vomiting as certainly sometimes passing off after delivery, or perhaps even before it. It often led to the death of the fœtus. He knew of no remedy but emptying the uterus.

Dr. PLAYFAIR said that we are all apt to ride our hobbies too hard, but, in this respect, Dr. Hewitt carried off

the palm with ease. Indeed, with perfect good faith he fitted his facts to suit his theory. In many of Horwitz's cases there were conditions which might quite account for the vomiting, such as perimetric adhesion, tumour, parenchymatous metritis and other inflammatory conditions. All these Dr. Hewitt calmly puts aside as beside the question, and points to a slight deviation as the cause of the vomiting. The plainest of all facts about the vomiting of pregnancy is that it is a neurosis of an intense degree, and only one of many neuroses accompanying pregnancy, and also associated with many forms of pelvic disease, such as inflammation and dysmenorrhœa. All these differ only in degree from the vomiting of pregnancy. It was observed long ago by Dr. Bedford, of New York, that when there was no vomiting in pregnancy, some other and often more distressing form of neurosis, such as fainting and palpitation, was apt to be present. He therefore used actually to prescribe ipecacuanha as an emetic, and Dr. Playfair thought with much justice. In every case of intractable vomiting we should endeavour to find out the special form of irritation. There is much to be said about the risk of the indiscriminate use of pessaries for cervical dilatation during pregnancy, but above all things it is necessary to take a broad, scientific view of the whole question, and not to adhere to any exclusive theory such as that advocated by Dr. Hewitt, to the overlooking of the concomitant conditions of which he makes so light.

Dr. Cleveland believed that the opinion of the Society was, on the whole, that the relation of the ascertainable condition of the uterus with, at all events, the less severe forms of vomiting could not be regarded in the light of cause and effect. Pregnancy disturbs the nervous equilibrium, and some women suffer from toothache, in others from a grave neurosis (may be) of the pneumogastric nerve (vomiting). His special object was to point out the danger to life from prolonged and excessive vomiting in pregnancy, and to enquire what is the probable mode of death. Is it not failure of the heart's action? and if so, as one of the means of averting the tendency to death ought we not to lay stress on the necessity of rest in the recumbent position? He related a case of violent vomiting in which death ensued on the patient's getting out of bed contrary to strict injunctions. *Post-mortem* the heart was found somewhat dilated, the liver large and congested. The uterus was pregnant about ten weeks.

Dr. Murray was not inclined to believe that in pernicious vomiting other organs are implicated, for, if so, why does the vomiting sometimes cease when the cervix is dilated? He had recently seen a case where this treatment stopped the treatment for some days, but the patient died exhausted after expelling the uterine contents. There was no displacement of any kind. He thought that after a fair trial of remedies, early interference with the pregnancy was best for the patient.

Dr. Wynn Williams did not find that flexion of the uterus, apart from adhesions, was associated with severe vomiting in pregnancy. Neurosis would account for great sickness. The only two deaths he had seen had been in alcoholic patients with liver disease. In a case of severe vomiting he had advised the passage of a sound just within and around the os uteri, and the vomiting had ceased.

Dr. Bantock had never met with a case of uncontrollable vomiting. He thought Dr. Hewitt's theory too one-sided. The apparent state of anteflexion in early pregnancy is not properly flexion at all, but a condition produced by change in the size of the organ as it grows and expands, the apparent flexion increasing as pregnancy advances. Therefore the ordinary teaching that anteflexion is usual in early pregnancy is utterly wrong. He thought the cause of the vomiting was irritability of the uterine body, especially about the os internum. This is illustrated by the vomiting which accompanies artificial dilatation of the os internum (though not of the os externum), and also the normal dilatation of the os internum during labour. He could understand the possibility of increased tension of the fibres about the os internum in retrovertion and retroflexion, but not in anteflexion, and still less in anteversion.

Dr. Heywood Smith said that the uterus of early pregnancy was best described as antecurved. He had a case in which vomiting had persisted to within seven days of confinement, but there was probably a small fibroid as well as ovaritis, and another was probably due to cervicitis. He thought that the fact that vomiting often began on waking and before getting up, spoke against Dr. Barnes' explanation, and in favour of the waking up of the uterus and its renewed energy acting on an empty stomach.

Dr. Graily Hewitt said that the paper stated that there were two factors in the vomiting—(1) altered position of incarceration, (2) induration of tissue near the os internum. Dr. Galabin said that the therapeutic test, viz., by the elevation of the uterus, spoke against the theory, but in 5 out of 27 typical cases the sickness was cured by elevating and replacing the uterus, and in two others it was at once relieved for a time, the uterus not being maintained in position. Five other cases of severe sickness were cured by postural treatment, rest, and measures calculated to prevent impaction. Uterine sickness, apart from pregnancy, might even lead to vomiting of blood. He did not consider the frequent occurrence of degeneration of organs in pregnancy proved. Dr. Playfair had made similar remarks to those made to-night as to "riding a hobby" some few years ago at a discussion of a former paper of Dr. Hewitt's, but a year or two later he stated that he had changed his mind since reading Dr. Hewitt's book. He hoped for a similar revulsion of feeling in the present instance. With regard to the criticisms on his cases, he had collected all the illustrative cases he could find, whatever their import. Vomiting after the middle of pregnancy was probably due to continued distension and growth of the uterus acting on the indurated tissues near the os internum.

ACADEMY OF MEDICINE IN IRELAND.

Medical Section.

F. R. Cruise, M.D., President, in the Chair.

Friday, November 21st, 1884.

The President's Address.

The President, having congratulated the Academy on its highly satisfactory position, entered upon the discussion of some of the relations existing between medicine and law, pointing out their frequently unsatisfactory nature. In passing, he touched upon the position of medical men as experts, as witnesses, and as defendants. He proceeded to discuss their relations with the Court of Chancery, both as regards their attendance on minors and lunatics and as claimants for settlement of accounts paid through the court. He illustrated by cases arising within his own experience the difficulties met—first, from the non-payment of these accounts through the fault of officers of the court; and, secondly, by the arbitrary reduction of fees.

Lupus and its Treatment.

Dr. Walter G. Smith read a communication on the various forms of lupus, which he illustrated by plates. The discussion on this paper was postponed to the next meeting.

Case of Anuria.

Dr. Walter Bernard, of Londonderry, related the clinical history and exhibited the morbid specimens of a case of prolonged anuria occurring in a man, aged 75 years. In December, 1883, micturition became unusually frequent. In February, 1884, epistaxis and hæmaturia occurred, accompanied by diarrhœa and febrile symptoms. In May the hæmaturia recurred, and between the 6th and 17th of June complete suppression of urine existed, curiously without any inconvenience to the patient. When the flow of urine was re-established, the amount passed averaged 125 to 140 ounces. Suppression of urine set in again on July 4th and 5th, and on the third day he passed bloody urine. In August a tumour was detected behind the pubes. He rapidly wasted, and died on September 13th. The *post-mortem* examination was held eleven hours after death. The urino-genital organs were removed. Mr

Shattock reported having found soft carcinoma of the prostate, bladder, and liver; both ureters were dilated. No carcinoma existed in the substance of the kidneys.

The PRESIDENT said this was the first time he had heard of total suppression of urine lasting eleven days. It was difficult to understand how it could have taken place for such a length of time without uræmic poisoning.

Dr. ABRAHAM observed that the microscopical specimens were the most beautiful he had seen for some time of morbid growths in the bladder and prostate. As regarded the origin of the growths he would scarcely venture an opinion. There were several cells and nests of cells which were extremely similar to the cells of the epithelium of the bladder. He agreed with the remark as to the extreme rarity of carcinoma of the prostate. Indeed, having seen a large number of tumours, he had only come across a single case, which had occurred in the practice of Mr. Martin.

Dr. FINNY expressed his satisfaction with Dr. Bernard's remarkable paper. The pathological conditions to which he had alluded were of great rarity. The clinical aspect of the case was also unique—that suppression of urine could exist for so many days without symptoms. The explanation that it must have been from some nerve cause was likely to be the true one. Where complete suppression of urine took place, head symptoms were extremely rare, but urinary fever and uræmic poisoning were not uncommon. In the absence of pathological change to account for the suppression of urine so many days, they must look to a nerve origin.

Dr. HENRY KENNEDY, referring to the duration of the anuria, said he had, in cases of cholera, frequently seen patients recover after four days, and once after five days, and the recovery was apparently due to the vomiting. Even when the primary symptoms of cholera had subsided the vomiting went on, and the patients recovered; so that vomiting seemed to be a vicarious effort on the part of the system to keep life going. He did not know that there was any connection between the malignant disease and the anuria. Any cases he had seen were not connected with malignant disease, and the case under consideration was in that respect uncommonly remarkable.

Dr. BERNARD briefly replied.

DIARY OF THE YEAR.

JANUARY.

4th.—Annual Meeting of the Pathological Society—Mr. Hulke's Presidential Address.

7th.—Publication of Dr. Koch's Fifth Report on Cholera.
Mr. Brudenell Carter's First Lettsomian Lecture on Cataract at the Medical Society.

9th.—Surgeon-General Hunter's Paper On the Origin of the Cholera Epidemic of 1883 read at the Epidemiological Society.
Death of Mr. Wheatley, Resident Librarian to the Royal Medical and Chirurgical Society.

10th.—Discussion on Sympathetic Ophthalmia at the Ophthalmological Society.

11th.—Annual Meeting of the Clinical Society.

15th.—Presentation of Testimonial to Messrs. Bower and Keates.

19th.—The Great Northern Hospital amalgamated with the Central Hospital for North London under the title of Great Northern Central Hospital.

21st.—Complimentary Dinner to Sir Richard Owen, K.C.B., by the Employés at the British Museum.

22nd.—Professor Roy's Paper on the Arterial Blood Pressure read at the Royal Medical and Chirurgical Society.

FEBRUARY.

1st.—Inaugural Meeting of the Hospitals Association at the Mansion House.

4th.—Death of Armand Leslie in the Soudan.

5th.—Defeat of the Antivivisectionists at Oxford in Convocation.

9th.—Death of Dr. J. H. Balfour, Professor of Botany in the University of Edinburgh.

11th.—Banquet given by the President of the Royal College of Surgeons of Ireland.

12th.—Dr. Straus' Communication on Cholera to the Royal Medical and Chirurgical Society.

13th.—Deputation of the Volunteer Medical Organisation to the Marquis of Hartington.
Adjourned Discussion at the Epidemiological Society on Surgeon-General Hunter's Paper.

16th.—Mr. Mundella invited Dr. Crichton Browne to visit some of the Elementary Schools.

18th.—Discussion on the Cold Bath Treatment of Enteric Fever at the Medical Society.

26th.—M. Pasteur announced to the Academy of Science in Paris his Protective Inoculation against Rabies.
Death of Dr. Alexander Wood at Edinburgh.

29th.—*Conversazione* given by the Cambridge Graduates Medical Club.

MARCH.

1st.—Annual Meeting of the Royal Medical and Chirurgical Society—Dr. George Johnson, F.R.S., elected President.

3rd.—Annual Meeting of the Medical Society—Mr. A. E. Durham elected President.

6th.—Medical Act Amendment Bill read a second time in the House of Lords.

7th.—Dr. Clifford Allbutt's First Gulstonian Lecture on Visceral Neuroses.

8th.—Annual Dinner of the Medical Society.

12th.—Formation of Oxford Graduates Medical Club.
Mr. R. T. Reid's Bill to Absolutely Prohibit Vivisection read a first time in the House of Commons.

14th.—Publication of Dr. Koch's Sixth Report, announcing the Comma-Shaped Bacillus to be the Micro-Organism of Cholera.

17th.—Mr. F. S. Eve's First Erasmus Wilson Lecture on Pathology at the College of Surgeons.
First Trial of Weldon *v.* Winslow concluded.

19th.—Dr. Hughlings Jackson's First Croonian Lecture on Evolution and Dissolution of the Nervous System.
Death of Dr. Hall Davis.

20th.—Medical Act Amendment Bill passed through Committee in the House of Lords.

21st.—Death of Dr. Allen Thomson, F.R.S.

22nd.—Meeting of the Fellows and Members of the Royal College of Surgeons.

25th.—Meeting of the General Medical Council.

26th.—First Meeting of the Hospitals Association.

27th.—Mr. Watson Cheyne's Demonstration of Pathogenic Organisms at the Parkes Museum.
Discussion on Pneumonia at the Liverpool Medical Institution.

28th.—Dr. Andrew's First Lumleian Lecture on the Ætiology of Phthisis.

31st.—Scottish Corporations' Conjoint Scheme received the Sanction of the General Medical Council.

APRIL.

2nd.—End of the Session of the General Medical Council.

6th.—Publication of Dr. Koch's Seventh Report on Cholera.

7th.—Meeting at the Royal College of Physicians—Re-election of Sir William Jenner as President.

9th.—Jacksonian Prize of the Royal College of Surgeons awarded to Mr. Treves.

11th.—Death of J. B. Dumas.
Decision in the Gilbert-Scott Case.

16th.—First Meeting of the Association of Medical Officers of Schools.

17th.—Opening of the Edinburgh Tercentenary Festival.

28th.—Death of Dr. A. W. Barclay.

30th.—Formation of the Association of Members of the Royal College of Surgeons.

MAY.

1st.—*Conversazione* at the Charing Cross Hospital Medical School.

5th.—Debate on the Lunacy Laws in the House of Lords.
Conversazione at the Medical Society—Annual Oration delivered by Dr. C. T. Williams.
6th.—Death of Dr. Samuel Gross.
Meeting of the Society of Apothecaries to Protest against their Exclusion by the Medical Bill.
8th.—Opening of the International Health Exhibition.
12th.—Death of Adolphe Wurtz.
13th.—Guy's Hospital Biennial Festival.
14th.—Consecration of the University of London Lodge of Freemasons.
22nd.—First Meeting of Oxford Medical Graduates Club.
24th.—Dr. C. S. Roy elected first Professor of Pathology at Cambridge.
27th.—Discussion on the Drainage of Basic Cavities of the Lung at the Royal Medical and Chirurgical Society.
29th.—Meeting at the College of Physicians—List of Fellows proposed by the Council referred back.
30th.—Death of Dr. Alexander Tweedie, F.R.S.

JUNE.

9th.—Conference on Public Health at the Health Exhibition.
11th.—Sir Henry Thompson's First Lecture at the Royal College of Surgeons, on some points in connection with the Surgery of the Urinary Organs.
12th.—Formation of the Association of Fellows of the Royal College of Surgeons—Mr. Pollock elected President.
15th.—Hospital Sunday in London.
16th.—Public Meeting at the Mansion House in support of the Funds of University College Hospital.
18th.—Official Declaration of the Outbreak of Cholera at Toulon.
19th.—Mr. Stewart elected Conservator of the Hunterian Museum at the Royal College of Surgeons.
24th.—Debate on the Medical Act Amendment Bill in the House of Commons.
26th.—Bill read a second time in the House of Commons.

JULY.

3rd.—Annual Election of Council at the Royal College of Surgeons.
4th.—Annual Meeting of the Ophthalmological Society.
10th.—Mr. Cooper Forster elected President of the Royal College of Surgeons.
11th.—First Cavendish Lecture delivered by Mr. Holmes at the West London Medico-Chirurgical Society.
Death of Professor Jäger.
14th.—Opening of Miss Mary Wardell's Convalescent Home for Scarlet Fever.
18th.—Debate on the Indian Medical Service in the House of Commons.
20th.—Death of Mr. Cæsar Hawkins.
23rd.—Mr. Victor Horsley elected Professor-Superintendent of the Brown Institution.
24th.—Ambulance Drill at Aldershot conducted, for the first time, by means of the Electric Light.
25th.—Medical Bill abandoned in the House of Commons.
29th.—Meeting of the British Medical Association at Belfast—Dr. Cuming's Presidential Address.
Discussion on Over-pressure in Schools at the International Health Exhibition.
30th.—Dr. Ord's Address in Medicine at the Belfast meeting.
Sir W. MacCormac's Address in Surgery at Belfast.
31st.—Professor Redfern's Address in Physiology at Belfast.
Weldon *v.* Semple—Verdict for Plaintiff.

AUGUST.

2nd.—Conclusion of the Belfast Meeting.
5th.—Gold Medal of the Royal College of Surgeons awarded to Sir Erasmus Wilson.
Report of Dr. Straus to the Academy of Science of Paris on the Outbreak of Cholera at Toulon.
8th.—Death of Sir Erasmus Wilson.
10th.—Opening of the International Congress at Copenhagen—Inaugural Address by Professor Panum.
11th.—Pasteur's Address on Rabies at the Congress.
Good *v.* Whittle concluded at Liverpool—Verdict for the Defendants.
14th.—Sir W. Gull's Address on International Collective Investigation at the Congress.
15th.—Virchow's Address on Metaplasia at the Congress.
Death of Professor Cohnheim.
16th.—Termination of the Congress.
18th.—Dr. Phillipson's Bradshawe Lecture at the Royal College of Physicians.
21st.—Meeting of the International Congress of Hygiene at the Hague.
23rd.—Hospital *Fête* at the International Health Exhibition.

SEPTEMBER.

1st.—Meeting of the International Otological Congress at Basle.
Red Cross Conference at Geneva.
Outbreak of Cholera at Naples.
6th.—Hospital Saturday.
11th.—Death of Mr. Netten Radcliffe.
15th.—Publication of Dr. Crichton Browne's Report on Over-pressure in Elementary Schools.
17th.—Publication of Professor T. R. Lewis's Memorandum on the "Comma" bacillus.
Meeting of Social Science Congress at Birmingham.
30th.—Meeting of the Sanitary Congress at Dublin.

OCTOBER.

1st.—Opening of the Medical Session in London and the Provinces—Introductory Addresses at St. Mary's, St. George's, Middlesex, King's College, St. Thomas's, University College and the Westminster Hospitals—*Conversazione* at Guy's and the London Hospitals—Dinner of Past Students at St. Bartholomew's Hospital.
2nd.—*Conversazione* at St. Mary's Hospital.
7th.—Meeting of the General Medical Council—Re-election of Sir Henry Acland as President for a third term of five years.
9th.—Conjoint Scheme of the College of Surgeons and College of Physicians sanctioned by the General Medical Council.
11th.—Opening of the New University Buildings in Vienna.
The General Medical Council determined to re-consider the Subject of Preliminary Education.
Dr. Koller communicated his researches on Cocaine as a local anæsthetic to the Vienna Society of Physicians.
18th.—St. Luke's Day—Dr. Russell Reynolds delivered the Harveian Oration at the College of Physicians.
20th.—Sir Joseph Lister read a Paper on Corrosive Sublimate as an Antiseptic Dressing at the Medical Society.
Death of Dr. Samuel Rabbeth.
23rd.—Discussion on Intestinal Obstruction at the Liverpool Medical Institution.
27th.—Opening of the Irish Medical Schools.
28th.—Opening of the Medical Schools in Glasgow.

NOVEMBER.

3rd.—Outbreak of Cholera in Paris.
5th.—Discussion at the Obstetrical Society on the Uncontrollable Vomiting of Pregnancy.
Sir Spencer Wells gave an Address at Birmingham on the Revival of Ovariotomy.
Death of M. Fauvel.
6th.—Mr. Cross made a statement in the House of Commons relative to the Alterations in the Indian Medical Services.
8th.—General Meeting of the Association of Fellows of the Royal College of Surgeons.
Publication of Dr. Koch's reply to his Critics in the *Deutsche Medicinische Wochenschrift.*
10th.—Private Meeting in reference to establishing a Teaching University in London.
13th.—Mr. Jonathan Hutchinson delivered the First Bowman Lecture at the Ophthalmological Society.
14th.—Mr. Morrant Baker's paper on Charcot's Joint Disease at the Clinical Society.
22nd.—Death of Dr. Frederick Mahomed.
25th.—Removal of a Tumour of the Brain by Operation—First case on record.
Weldon *v.* Winslow—Appeal—Verdict for Plaintiff.

28th.—Adjourned debate on Charcot's Joint Disease at the Clinical Society.
30th.—Death of Sir Alexander Grant, Vice-Chancellor and President of the University of Edinburgh.

DECEMBER.

12th.—Mr. Victor Horsley delivered the First of his Lectures as Professor-Superintendent of the Brown Institution.
Adjourned debate on Charcot's Joint Disease at the Clinical Society.
15th.—Meeting of the Committee to take steps to establish a Teaching University in London.
16th.—Opening of New Out-patient Rooms at the Middlesex Hospital.
19th—Jubilee Meeting at the Charing Cross Hospital Medical School.
23rd.—Close of debate on Charcot's Joint Disease at the Clinical Society.

MEDICAL CONSULTATIONS.

NO. VI.—THE MEDICAL YEAR.

SCENE—*The staff-room of the "Stethoscope."*

DRAMATIS PERSONÆ.

NONPARELL.—*Editor.*
BREVIER.—*Sub-editor.*
DIAMOND.—*A Medical Journalist.*

NONPARELL. Pleased to make your acquaintance Mr. Diamond. Pray find a chair. My Chief-of-the-Staff, Dr. Brevier. I am glad you can come to our help in this little matter. If you ever find time to read us, you will know that it has not been our practice to pass judgment on current medical events. We regard the *Stethoscope* simply as a medium for the propagation of facts, which must be neither magnified nor distorted in passing through it.

DIAMOND. A plane mirror, in other words.

N. Exactly. Well, this December we have decided to break through our custom for once, and to give a brief running criticism of the more noteworthy occurrences of the year. By this means we hope to fulfil our duty to our readers, without laying ourselves open to the charge of passing crude and hasty judgments, such as the writers of weekly journals must inevitably incur. In medicine, I take it, nothing is gained by slap-dash criticism. Well, the preparation of the article which I have in contemplation is a little out of the line of our ordinary staff, most of whom are cultivators, so to speak, and not excisemen.

D. You want a specialialist, then, an expert at the scales?

N. Just so, and we hope to find him in you. But it will be worth while, I think, to have a little talk over matters as a preliminary, and then we will leave you to shape our rough-hewn criticisms. I have jotted a few notes down here to guide us. Let me see, they begin with Koch on cholera.

BREVIER. And end, perhaps, with Koller on coca.

N. Steady, Brevier. No, my last entry is F.R.S.'s letter to the *Times* on brain surgery.

B. We set off, then, with a "comma," and end up with a note of admiration.

N. And, jesting apart, both a trifle premature.

D. Stay, let me make a note. I thoroughly agree with you. (*Writes.*) "Premature disclosures, impatience for results, science getting fussy, evil influences of popularity—*moral*, keep clear of daily papers." We can make a good point of that. As for Koch, I doubt if he ever meant his reports to be published in the *German Gazette*. It has put him in quite a false position. The same cannot be said for F.R.S. To my thinking, science ought to keep out of the crush. There is no need for hurry. We might say she should be "like Patience on a monument."

B. "Smiling at grief."

N. No, no. We don't want to put a motto in Miss Cobbe's mouth. Well, then, we defer comment on Herr Koch, refuse to accept the "comma" as proved, but incline to regard it as provable. We must say something more about cholera generally. What do you propose, Mr. Diamond?

D. That during the past year neither the discussions on cholera nor its invasion have taught us anything new.

N. Except that, while like other low creatures it loves warmth and dirt, unlike them it loves water.

D. That remains to be proved. I think Koch was wrong. Not in his premisses, possibly, but in deciding that the time was ripe to work upon them. To banish water-carts from a cholera-stricken town, on the strength of a laboratory experiment, is, to say the least, a large order.

N. Immense. My next note is "Typhoid and the cold bath."

D. Good, the transition is easy. One moment. (*Writes.*) "Cold water, cholera, and typhoid."

B. Someone said the other day that the prevalence of typhoid was an index of susceptibility to cholera.

D. I will note that too. Well, what attitude will you take as regards the cold bath treatment?

N. That it is excellent when used with discrimination, but, like all fashions, it is apt to carry unreason off his feet. It is not adapted for routine use.

B. What treatment is?

N. The thermometer, in short, is a good ally, but a bad master. I should like you to take up a strong position on the whole question of antipyretics. Quote Nothnagel, and say that all antipyretic treatment as such implies a one-sided view of the fever process. We know little or nothing of its intimate pathology, and the consciousness of ignorance ought to enforce caution. The same remark applies all round. Nothing has come out more clearly during the year than our ignorance of pathology. At present it is like the old maps of Africa. We have not yet succeeded in scratching out the hypothetical elephants and camels that our grandfathers drew; and if we had, there is nothing to put in their place. Take the pathology of myxœdema, for instance, and Charcot's joint disease, two subjects which have this year drawn all eyes upon them. What accurate knowledge have we of the physiology of the thyroid gland, let alone its pathology, or of the relations of the nerves to joint integrity. Charcot has claimed the discovery of one hitherto unsuspected pathological link, and Mr. Horsley has demonstrated another; but can we doubt that there must exist many more behind, which no one has yet so much as dreamt of? If every practitioner would but always remember to hold these unimagined possibilities before him *in terrorem*, there would be less of the prescribing with a light heart of which we hear and see so much. Have you followed me? Well, then, let us pass to the next subject. O! "Visceral neuroses."

B. Another unsuspected link.

N. More or less so. Dr. Allbutt has certainly lightened our darkness on one point, or, at any rate, made us realize it better. There is the same danger here, however, that undiscriminating practitioners will fall into a habit of putting all visceral trouble down to nerves.

B. And give up treating them, which might be an advantage.

N. Well, yes, it might be an advantage to have one category of disease which paralysed the active therapeutist. But it would be a disadvantage if diet and regimen were neglected in these cases, under the idea that they are nervous. Dr. Allbutt showed that they are eminently treatable, and it is only those who misread his teaching who will neglect them.

D. What will you say of the other lectures at the College of Physicians?

N. Both excellent! But both again remarkable rather for indicating our ignorance of pathology, than for diminishing it. Dr. Hughlings Jackson's were, I think, *caviare* to the general, a glimpse into the pathology of the future, when men shall live in a Spencerian atmosphere; Dr. Andrew's, a dignified, logical, and effective protest against the prevalent bacillus worship—a reminder to give the bacillus his due, but not to be hasty in revolutionizing our modes of treatment. Looking more to the active than to the predisposing cause, it might be logical to treat phthisical patients like lepers, as they are said to be doing in Austria. But it is illogical on any view to attempt to disinfect within the body an organism which, according to Dr. Klein, fights disinfectants as stubbornly as anthrax spores do. In fact, we are wofully ignorant on the whole subject of disinfection. Dr. Klein and Mr. Wynter Blyth have been doing something towards giving us sounder knowledge, but it is difficult to convince people that half the disinfection they practise with such circumstance is little better than fetish-worship. You must say something of the new field that Dr. Burdon Sanderson has opened in the researches on the disinfectants of the "aromatic" group, which bacteria themselves elaborate. It is a paradoxical chapter in biology.

D. Paradoxical only at first sight, I think. We, too, excrete poisons which would kill us, and do kill us, if they are not removed. Plants are the only things that flourish on the products of their own decay.

B. I would suggest that all the scattered points that have been mentioned should be grouped together in illustration of this salient fact—that we now are in the very thick of a struggle against lower organisms, which will some day hold a prominent place in the history of medicine. It has all the incidents of a military campaign. Here a rapid attack of the enemy's forces on our flank in the form of a cholera outbreak; met by belated attempts to cut off their supplies, by Chinese expedients to bar their march, and by efforts more successful to surround stragglers and exterminate them. In another part of the immense field endeavours to turn our enemies against themselves, to drill and culture them into our mercenaries, a task to which M. Pasteur has devoted himself with such success. Elsewhere we are learning from the enemy the secret of manufacturing Greek fire for their annihilation. And all the while the foe is lurking in our midst, striking out, never blindly, but with unerring instinct choosing only one's weak spots.

N. Magnificent, my dear Brevier, but not criticism; or if so, criticism that would rather astonish the readers of the *Stethoscope*. Don't waste it on them; reserve it for an epic. We must say something about Pasteur and hydrophobia, however, and that brings us to the International Congress.

D. We can hardly give any useful criticism on that until we have the Transactions before us. Sir W. Gull's paper and the organisation of international collective investigation deserve a sympathetic mention, the more so on account of poor Mahomed's death. Who would have thought a twelvemonth ago, when Mahomed was working hard at the Bower and Keates Fund, that before another January came round we should be subscribing with equal enthusiasm to a Mahomed Fund. Happily in both cases the profession has shown that it has an open hand when its sympathies are touched.

N. Yes; it is only medical politicians who find it unresponsive. I doubt, for instance, whether the failure of the Medical Bill disappointed anyone but the journalists. The profession at large did not appear to care a snap of the fingers about it.

D. Well, speaking as a journalist, I do not greatly mourn its failure. What we wanted was finality, something to dissipate the idea that all our arrangements were only provisional, and dependent on the goodwill of Parliament. The failure of the Bill has secured this almost as efficiently as its success would have done. How different is the outlook now from what it was last December! Then all the licensing bodies were paralysed by the prospect of impending legislation. Now the incubus has been removed, and they are all setting steadily to work to make the best of things, with the view of showing that by the time a new ministry has got up steam enough for a new Medical Bill, the necessity for it will have become a thing of the past. In England as well as in Scotland the corporations have combined, and even the Apothecaries Society is anxious to give a complete diploma. Then there is a faint possibility that this new Teaching University may revolutionise medical education in London. And all this recent activity, which is born out of the feeling that the State will not interfere, will serve as an additional excuse for its non-interference. The only body which has shown no signs of mending its ways is the General Medical Council, which at its last sitting, when so many matters of the greatest importance were waiting for discussion, wasted days on debating whether boys should learn geography.

N. Well, we will leave the Medical Council to your tender mercies.

D. You may trust me. It is bad form to abuse it too much. To return to the English corporations, there is no question about their waking up. The democratic spirit is spreading among the Fellows, and during the year both Councils have been sharply reminded that they are not entirely irresponsible. They are entering upon a period of transition, and I think we might fairly express a hope that they will emerge from it combined into a College of Physic, or if the New University scheme succeeds, into a full-blown Faculty of Medicine.

N. Yes, I approve the idea; but pray do not let your article be too dreamy, Mr. Diamond. Sound common sense is what the medical reader likes; "eloquence and showy-literary qualities," we have it on the best authority, are not to be encouraged. Of course you will say something nice about the Health Exhibition.

D. Yes, it will be easy to do that. And what shall I call the article.

B. Why not "Progress and Poverty"—which would express your main thesis—the minuteness of our advance compared with the desert of ignorance before us?

N. I don't like catch-titles. Give me good common-sense English. If you write rubbish, a telling title won't make it more readable.

D. Pardon me, it is not my intention to write rubbish.

N. No, no, of course not. I was only speaking generally. Well, then, we shall expect a straightforward, common-sense article on the lines we have laid down, and a common-sense title to match it. Good-bye!

MEDICAL NEWS.

University of Edinburgh.—At a recent meeting of the Senatus Academicus, the following gentlemen received the degrees of M.B., C.M., viz. :—

R. M. Brown, A. H. Croucher, J. C. Mackenzie, Y. S. Sanitwongse, and G. H. H. Symonds.

University of Dublin, Trinity College.—At the Michaelmas Term Examination for the Degree of Bachelor of Medicine (M.B.), held on Monday, December 1, and following days, the successful candidates were placed in the following order of merit, viz :—

Francis J. G. King; Walter Kiddle; Richard W. Gilmore; William Hallaran; Francis I. Harpur, William R. Rice, equal; Rowland H. Scovell; George Raymond; James I. O'Donnell; Orlando P. Beater; John B. Buchanan; Alexander I. Boyd; Thomas N. Flood; Samuel H. Halahan; John I. C. Watson

At the Michaelmas Term Examination for the Degree of Bachelor of Surgery (B.Ch.), held on Monday, December 8, and following days, the successful candidates passed in order of merit as follows—

Walter Kiddle; William Hallaran; Francis I. G. King; Baptist G. Frith; Smith Telford; Francis I. Harpur.

The examination for the Diploma on State Medicine took place on Thursday, December 11, and following days. The undermentioned candidates were successful—

John S. Fenton; Glascott H. Symes; Nicholas C. Ferguson.

King and Queen's College of Physicians in Ireland. — At the usual monthly examinations for the Licenses of the College held on Monday, Tuesday, Wednesday, and Thursday, December 8, 9, 10 and 11, the following candidates were successful, viz. :—

For the Licence to practise Medicine—

Patrick Duff, Ballaghaderrin, County Mayo; Martin Fennelly, County Kilkenny; Charles Jackson, Southsea; Cornelius Ignatius Kelly, Birr, County Tipperary; Graham Kennedy, Kilcool, County Wicklow; Charles Edmond Lister, Liverpool; John Joseph McDonnell, Dublin; Thomas George Millerick, Limerick; Andrew Murphy, Balbriggan, County Dublin; Llewellyn Thomas Manly Nash, Dublin; Jane Harriett Walker, London.

For the Licence to practise Midwifery—

Martin Fennelly; Charles Jackson; Cornelius Ignatius Kelly; Graham Kennedy; Charles Edmond Lister; John Joseph McDonnell; Llewellyn Thomas Manly Nash; Francis Howard Sinclair, Bray, County Wicklow; Jane Harriett Walker.

The following Licentiate in Medicine of the College, having complied with the by-laws relating to Membership pursuant to the provisions of the Supplemental Charter of December 12, 1878, was duly admitted a Member of the College—

Joseph John Lamprey, Lic., Med., 1874, Surgeon, Medical Staff.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, December 18th, 1884 :—

Leonard Henry Armstrong, Newcastle-upon-Tyne College of Medicine; Lawrence Barnett, University College; Harvey Bradbury, London Hospital; Harry Percival Gaston, Charing Cross Hospital; Joseph Andrew Going, London Hospital; John Good, Charing Cross Hospital; Robert William Hazell, London Hospital; Jno. Frail Harries, King's College; Charles Booth Meller, St. Bartholomew's Hospital; Colin Dwight Morris, London Hospital; William Edward Picton Phillips, Guy's Hospital; Rick James Reece, St. Bartholomew's Hospital; Robert Briggs Wild, Owen's College, Manchester; Bernard Volckman, London Hospital.

Cocaine as an Anæsthetic for the Genital Mucous Membrane.—Dr. Ernst Fränkel, of Breslau, contributes to the *Centralblatt für Gynäkologie* (December 6th, 1884) a paper on this subject. The usefulness of this newly introduced drug as an anæsthetic to the mucous membrane of the eye and the larynx has been attested by many observers. Dr. Fränkel found that the 5 per cent. solution, which is effectual in the case of the just named mucous membranes, is not enough to anæsthetize the vagina. He therefore employed a 20 per cent. alcoholic solution. (Cocain mur. 1, aq. dest. 3, spt. vin. rect. 2—not to be filtered. This solution, if kept, becomes thick and turbid, but can be restored to its proper condition by putting to it a few drops of alcohol.) By painting the valvo-vaginal mucous membrane with this solution, he finds the following results can be obtained: (1) The sensitiveness to pain is considerably diminished—proceedings which ordinarily produce painful sensations are felt superficially on the mucous membrane hardly at all, and in the deeper parts much less than without cocaine. (2) Inflamed mucous membrane is made free from pain by cocaine, and the pallor which follows its application shows its effect in producing ischæmia. (3) The reflex excitability of the vaginal orifice is diminished. Hence cocaine is of great value in vaginismus. It is useful in fissure of the anus, and as a preliminary to the introduction of the rectal speculum; also as a preliminary to cauterization of the vulva, the removal of warts of a urethral carunele, and other measures which cause local pain.

Enucleation of the Eyeball under Cocaine.—Dr. Turnbull, oculist to the German hospital, Philadelphia, states (*Philadelphia Medical Reporter*, Nov. 29) that on the 12th November he successfully extirpated the eyeball of a healthy German, 30 years of age, for traumatic (cicatricial) irido-cyclitis, "using no other than the new local anæsthetic and hæmostatic, the hydrochlorate of cocaine. Of a freshly made 4 per cent solution 1 drop was instilled every 3 minutes until the 8 drops had been used, the patient lying on his back on the table. The conjunctiva was seen to pale gradually. During the successive stages of the operation one or two drops were let fall in from time to time, less than half a dram of the solution having been employed altogether. The amount of hæmorrhage attending the operation was much below the average, and the patient declared that he felt no pain. Dr. Carl Seyler, who dropped the solution into the eye, and other medical men present confirm his statement. Dr. Turnbull would not propose cocaine as a general substitute for ether or chloroform, but thinks it a matter of great satisfaction to be possessed of such an agent when any circumstances counter-indicate their employment.

The Causes and Prevention of Blindness.—The International Society for the Prevention of Blindness and Amelioration of the Condition of the Blind has adjudged to Dr. Mules, surgeon of the Manchester Royal Eye Hospital, one of two prizes offered by the Society for an essay on the "Causes and Prevention of Blindness." The jury, 12 in number, were selected from the leading ophthalmic surgeons of Europe. The decision of the jury on the merits of the respective essays was given at the Hague in June last, but the names of the successful candidates for the international prizes have only now been published.

Female Medical Students at Paris.—The number of female students inscribed at the Paris Faculty of Medicine shows a considerable increase, there being at the present time 78 upon the register, as against 45 last year, while 12 more are awaiting admission. Only 13 of the whole number are French, there being 47 Russians, 11 English, and 3 Americans. M. Béclard expressed his regret that most of the female students of foreign origin had been admitted without producing their degree or the equivalent of it, and urged the Council to make this compulsory in the future. No decision was arrived at as to the admission of women as in and out students at the hospitals; but the preponderance of opinion seemed to be in favour of admitting them as the latter, but not as the former.

Wound of the Internal Mammary Artery, with Recovery.—Dr. Tilling, of the Alexander Hospital, St. Petersburg, relates (*St. Petersburger Medicinische Wochenschrift*, November 15) the case of a man 19 years of age, who had received a wound from a knife in the fourth intercostal space. Considerable bleeding into the cavity of the thorax having taken place, it was resolved to tie the internal mammary which could scarcely have escaped the knife. The vessel was cut down upon and tied, and the man recovered. Dr. Tilling says that of 38 cases of this injury 26 proved fatal. Dr. Vosz in his dissertation on this accident, states that primary ligature had been applied once by himself and twice by Dr. Bergmann, of Dorpat, his own case alone recovering.

Salicylic Acid for Corns.—M. Pierre Vigier (*Gazette Hebd.*, October 31) observes that there have been for some time past sold in the shops, various applications for corns under the most fantastic names, but of undoubted utility. Their authors have profited by the remarkable properties of salicylic acid, fixing it by means of collodion, and which applied to the skin produces a solid varnish, and causes neither pain nor other inconvenience. He has examined all these secret preparations, and believes that the following formula is a correct representation of their composition:—Salicylic Acid, 1 gramme; Alcoholic Extract of Cannabis, Sativæ, ½ a gramme; Alcohol, at 90°, 1 gramme; Ether at 62°, 2½ grammes, and Elastic Collodoin, 5 grammes; mix *secundum artem* and keep in a stoppered bottle. This is applied by passing over the corn several times a little brush, or the end of a match, which has been dipped in the liquid. This is repeated every other day for a week, and some days later the corn may be easily removed under pressure of the finger, or after a foot-bath.

Ovariotomy.—Reporting to the Paris Société de Chirurgie on 35 cases of ovariotomy and laparotomy which have occurred in his practice, Professor Terrillon concludes (*Bulletin de Thérapeutique*, October 30) as follows: (1) it seems that the contra-indications of ovariotomy become more and more rare in proportion as the operation furnishes more recoveries; (2) I have operated, without making any choice, upon all the cases that have presented themselves to me, at least when there has been no absolute contra-indication derived from disease of an important organ; (3) I have thus acquired the assurance that old and resisting adhesions, whatever may be their extent, no longer prove an obstacle either to the operation or to recovery; (4) in four incomplete operations which I have practised there were infiltrated cysts in the broad ligament, of which two were para-ovarian, and two multilocular; (5) although nothing can be more mortifying for the surgeon than to leave an operation unfinished, yet as it is almost impossible to foresee the obstacles which may present themselves; this consideration ought not to arrest us, for we always have the hope of terminating difficult operations. Moreover, incompleted operations, whatever may be their primary gravity or the chances of relapse, where multilocular cysts are concerned, may still allow of a cure or a prolongation of existence.

Chloral Hydrate as an Antiseptic.—Dr. Warner, of Worcester, Mass., in a communication to the *Boston Medical Journal* (August 21), states that during the last ten years he has used a solution of chloral (three to five grains to the ounce) as almost his only dressing, and has found it acts admirably, as, while it is inodorous itself, it removes the fœtor of purulent discharges effectually. It is cheap, and simple in its application, and causing no stain can be sprinkled freely about. It seems also to act as a local sedative, often relieving pain of a recent injury or operation as to render resort to an opiate unnecessary. During the treatment of large suppurating wounds, it keeps the air of a ward or room pure, while there is no danger from its absorption, and the comfort from a light compress, moistened in the solution, is very great. Somewhat frequent changes are required to prevent the compress from becoming dry and sticky, and secure perfect cleanliness. It acts as a perfect germicide, rendering spraying quite unnecessary. In a solution in warm water, the hands of the operator, instruments, sponges, &c., are cleansed. Dr. Warner speaks of his experience of its employment in ovariotomy and other operations producing large surfaces, and greatly prefers it to carbolic acid and other antiseptics. Chloral may also be used with vaseline or glycerine, in the same proportions, if there is any reason to prefer this form of preparation.

Fees to Medical Witnesses.—At the Munster Winter Assizes, held at Cork, before Chief Justice Morris, on Friday, December 12th, Mr. Mahony, B.L. (instructed by Mr. Moran, solicitor, Rathkeale), applied, on behalf of the medical gentlemen attending the assizes, for an increase of the fees paid to them for attendance. It appeared that the limit had been struck at two guineas a-day, and 10*s.* for hotel expenses; and Mr. Mahony pointed out that 10*s.* was altogether inadequate for hotel. Mr. Atkinson, Q.C., said the order regulating expenses limited the Crown Solicitor. Mr. Mahony cited a decision made by Judge Lawson at Carrick-on-Shannon, where they allowed three guineas a-day, and 15*s.* for expenses to a medical man. Some of the witnesses attending at the assizes had come as far as from Scariff, in the county Clare, and others from Glin and New Pallas, in the county Limerick. His Lordship said, without making any abstract rule on the point, he would allow three guineas a-day, and 15*s.* hotel expenses to medical witnesses who came from long distances.

Morphiomania.—M. Notta, terminating an article on this subject in the *Archives Générales* for October and November, observes that the victims of this affection may be divided into two classes:—Those who employ morphia for the relief of incurable and painful maladies, as cancer, ataxia, &c., and who may well be excused for acquiring a habit which relieves them from dreadful suffering—in such persons morphomania may be regarded as incurable. But other persons, in whom it is curable, although often with great difficulty, the addiction to morphia, whether derived originally from using it in painful disease or as a means of satisfying pleasure, are less excusable than are the victims of alcoholism, surrounded as these are by so many temptations, and such facilities for obtaining the article which acts so mischievously on them. However this may be, morphomania has become a rapidly-spreading evil, and is by no means confined to the well-to-do classes; and M. Notta agrees with Dr. Huchard in proposing that pharmaciens should be prohibited from supplying morphia except upon the presentation of a recently dated prescription; and that practitioners should use every endeavour to prevent patients practising the injections themselves; while the late Professor Fonssugives would prohibit instrument makers from selling the Pravaz syringes except on the order of a physician. In hospitals also, M. Notta observes, the syringes are left about most carelessly.

Action of Convallaria on the Heart.—From a number of experiments on terrapins and frogs, Dr. Beyer, of the Navy (*Proceedings of Naval Medical Society*, 1884, No. 1.), concludes—(1) That convallaria increases the rate of the heart's action; (2) The work which the organ has to do is slightly increased; (3) It raises the intra-cardiac pressure; (4) Both auricles and ventricles are arrested in systole when medium doses are used: (5) Large doses arrest the heart at once; (6) The results are most probably due to the direct action on the muscular substance of the heart; (7) The drug has a decidedly cumulative action, acts much more slowly than digitalis, and is much more persistent after the heart is once under its influence. Dr. Beyer adds that the whitish, shrunken, and puckered appearance which the heart presents when very much under the influence of convallaria, the slow appearance of this phenomenon, and its persistence, all speak in favour of the view that the muscular substance of the heart is much interfered with. So far as his experiments go, he thinks that they warrant the conclusion that convallaria is contra-indicated in advanced cases of cardiac disease, in which the muscular structure has undergone degeneration. Convallamarin should be used in preference to any other preparation of the drug, and, on account of its cumulative action, not more than one full medicinal dose should be given in a day.—*New York Medical Journal*, August 23.

APPOINTMENTS.

Jones, T. W. C., M.A. Camb., F.R.C.S. Edin.—Surgeon to the Western Ophthalmic Hospital, *vice* Percy S. Jakins, M.R.C.S. Eng., resigned.

Key, A. C., M.R.C.P., L.M. Edin., L.S.A. Lond.—Physician to the Home of the Good Shepherd, Kinnerton Street, Belgrave Square.

Nicholson, G., M.R.C.S., L.R.C.P. Ed.—House Surgeon to the Royal Cornwall Infirmary, *vice* E. Roberts, M.R.C.S., resigned.

Paterson, W. B., M.R.C.S., L.D.S.—Dental Surgeon to St. Bartholomew's Hospital.

ROBINSON, L., M.R.C.S., L.S.A. Lond.—Senior House Surgeon to the Darlington Hospital, *vice* Dr. Hern, resigned.

SKIPTON, ALEXANDER, L.R.C.S.I. and L.R.C.P. Edin.—Resident Medical Officer of the Holloway and North Islington Dispensary.

VACANCIES.

BRISTOL GENERAL HOSPITAL.—Assistant House Surgeon. Salary, £50 per annum. Board, lodging, and washing, provided in the house. Candidates must send a certificate of registration, and also satisfactory testimonials of ability and good moral character. Applications to be addressed to the Secretary at the hospital, on or before January 10th.

DEVONSHIRE HOSPITAL, BUXTON, DERBYSHIRE.—Assistant House Surgeon. (*For Particulars see Advertisement.*)

LONDON FEVER HOSPITAL, LIVERPOOL ROAD, ISLINGTON.—Physician and Assistant Physician. Candidates must be Members or Fellows of the Royal College of Physicians. Applications to be sent in on or before January 2nd, 1885.

NEWCASTLE-UPON-TYNE INFIRMARY.—House Surgeon. Salary, £50 per annum, with board, lodging and washing. Candidates must be registered in surgery, unmarried, and free from the care of a family. Applications and testimonials must be in the hands of the Chairman of the House Committee on or before December 29th.

SCARBOROUGH HOSPITAL AND DISPENSARY.—House Surgeon and Secretary. Salary, £80 per annum with board and lodging. Candidates must be registered practitioners. Applications, with testimonials, stating age, to be sent to the medical staff on or before December 27th.

THE QUEEN'S HOSPITAL, BIRMINGHAM.—Honorary Obstetric Officer. Candidates must be either Doctors in Medicine of a British University or Fellows or Members of the Royal College of Surgeons of England, Edinburgh, or Dublin. Applications, testimonials, and evidence of degree or diploma to be sent to the Secretary of the Hospital, from whom all further information may be obtained, on or before December 27th.

THE ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, BRIGHTON.—House Surgeon. Salary, £80 per annum, with board, lodging, and washing. Candidates must be qualified both in medicine and surgery, and registered under the Medical Act. Applications, with recent testimonials, to be sent to the Chairman of the Medical Committee, before January 2nd, 1885.

WEST OPHTHALMIC HOSPITAL, 153 and 155, MARYLEBONE ROAD, W.—Assistant Surgeon. Applications, with testimonials, to be sent to the Secretary, by January 17th, 1885.

DEATHS.

AYLING, W. H., L.R.C.P., at 94A, Great Portland Street, Portland Place, W., on December 19th, aged 67.

BARROW, JOHN, M.R.C.S., L.S.A., at 219, Tufnell Park Road, on December 14th, aged 33.

DALBY, W. B., M.D., F.R.C.S., at Belvedere House, Torquay, on December 17th, aged 60.

LACY, THOMAS SAUMAREZ, Deputy Inspector-General of Hospitals, H.M. Indian Army (retired), at Sanmarez Lodge, Guernsey, on December 18th, aged 66.

TEBAY, GEORGE, M.D., of 37, Belgrave Road, S.W., on December 20th, aged 69.

NOTES, QUERIES, AND REPLIES.

Dr. Edwd. Dapples, Genoa.—Letter and enclosure received with thanks.

COMMUNICATIONS RECEIVED—

Dr. HERMAN, London; Dr. MULES, Manchester; Mr. NOBLE SMITH, London; Dr. FORBES, Philadelphia; Mrs. WRIGHT, Lostwithiel; Capt. A. P. HOBSON, London; OUR LIVERPOOL CORRESPONDENT; Messrs. R. HOWELL & Co., London; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; Mr. HENRY MORRIS, London.

BOOKS RECEIVED—

Membrana Virginatatis, by E. S. McKee, M.D.—The Story of a Great Delusion, by William White—Annual Report on the Health of Salford—Natures Hygiene, by C. T. Kingzett, F.I.C., F.C.S.—Helps to Health, by Henry C. Burdett—The New Chemistry, by J. P. Cooke, LL.D.—Report on the London Water Supply.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Révue Médicale—Gazette Hebdomadaire—Nature—Boston Medical and Surgical Journal—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medicin—Philadelphia Medical News—New York Medical Journal—Louisville Medical News—Weekblad—Maryland Medical Journal—The Philadelphia Medical Times—Le Progrès Medical—The Students' Journal and Hospital Gazette—Berliner Klinische Wochenschrift—Société Médicale—The Western Medical Reporter—The Builder—Revue de Médecine—Revue de Chirurgie—North Western Lancet—Centralblatt für die Medicinischen Wissenschaften—Caslon's Circular—Manchester Weekly Post.

APPOINTMENTS FOR THE WEEK.

Saturday, December 27.

ROYAL INSTITUTION, 3 p.m.—Professor Tyndall, "The Sources of Electricity."

Tuesday, December 30.

ROYAL INSTITUTION, 3 p.m.—Professor Tyndall, "The Sources of Electricity."

1885.

Thursday, January 1.

ROYAL INSTITUTION, 3 p.m.—Professor Tyndall, "The Sources of Electricity."
